Alphabetical List of Functions

2

Functions By Category

The MATLAB Function Reference contains descriptions of all MATLAB commands and functions.

If you know the name of a function, use the "Alphabetical List of Functions" to find the reference page.

If you do not know the name of a function, select a category from the following table to see a list of related functions. You can also browse these tables to see what functionality MATLAB provides.

Category	Description
Development Environment	Startup, Command Window, help, editing and debugging, other general functions
Mathematics	Arrays and matrices, linear algebra, data analysis, other areas of mathematics
Programming and Data Types	Function/expression evaluation, program control, function handles, object oriented programming, error handling, operators, data types
File I/O	General and low-level file I/O, plus specific file formats, like audio, spreadsheet, HDF, images
Graphics	Line plots, annotating graphs, specialized plots, images, printing, Handle Graphics
3-D Visualization	Surface and mesh plots, view control, lighting and transparency, volume visualization.
Creating Graphical User Interface	GUIDE, programming graphical user interfaces.
External Interfaces	Java, ActiveX, Serial Port functions.

See Simulink, Stateflow, Real-Time Workshop, and the individual toolboxes for lists of their functions

Development Environment

General functions for working in MATLAB, including functions for startup, Command Window, help, and editing and debugging.

Category	Description
"Starting and Quitting"	Startup and shutdown options
"Command Window"	Controlling Command Window
"Getting Help"	Methods for finding information
"Workspace, File, and Search Path"	File, search path, variable management
"Programming Tools"	Editing and debugging, source control, profiling
"System"	Identifying current computer, license, or product version
"Performance Improvement Tools and Techniques"	Improving and assessing performance, e.g., memory use

Starting and Quitting

exi t Terminate MATLAB (same as qui t)
fi ni sh MATLAB termination M-file
matlab Start MATLAB (UNIX systems only)

matlabrc MATLAB startup M-file for single user systems or administrators

qui t Terminate MATLAB

startup MATLAB startup M-file for user-defined options

Command Window

cl c Clear Command Window di ary Save session to file

dos Execute DOS command and return result

format Control display format for output

home Move cursor to upper left corner of Command Window

more Control paged output for Command Window

notebook Open M-book in Microsoft Word (Windows only)

uni x Execute UNIX command and return result

Getting Help

doc Display online documentation in MATLAB Help browser docopt Location of help file directory for UNIX platforms

hel p
hel pbrowser
hel pwin
Display help for MATLAB functions in Command Window
Display Help browser for access to extensive online help
Display M-file help, with access to M-file help for all functions

info Display information about The MathWorks or products lookfor Search for specified keyword in all help entries

support Search for specified keyword in all help entries

Open MathWorks Technical Support Web page

Web Point Help browser or Web browser to file or Web site

what snew Display information about MATLAB and toolbox releases

Workspace, File, and Search Path

· "Workspace"

• "File"

"Search Path"

Workspace

assi gni n Assign value to workspace variable

cl ear Remove items from workspace, freeing up system memory eval in Execute string containing MATLAB expression in a workspace

exi st Check if variable or file exists

openvar Open workspace variable in Array Editor for graphical editing

pack Consolidate workspace memory which Locate functions and files who, whos List variables in the workspace

workspace Display Workspace browser, a tool for managing the workspace

File

cd Change working directory

copyfile Copy file

del et e Delete files or graphics objects di r Display directory listing exi st Check if a variable or file exists

filebrowser Display Current Directory browser, a tool for viewing files

lookfor Search for specified keyword in all help entries

1s List directory on UNIX

matlabroot Return root directory of MATLAB installation

mkdi r Make new directory pwd Display current directory

rehash Refresh function and file system caches

type List file

what List MATLAB specific files in current directory

whi ch Locate functions and files

See also "File I/O" functions.

Search Path

addpath Add directories to MATLAB search path

genpath Generate path string partial path Partial pathname

path View or change the MATLAB directory search path

pathtool Open **Set Path** dialog box to view and change MATLAB path

rmpath Remove directories from MATLAB search path

Programming Tools

· "Editing and Debugging"

"Source Control"

• "Profiling"

Editing and Debugging

dbcl ear Clear breakpoints dbcont Resume execution

dbdown Change local workspace context

dbqui t Quit debug mode

dbstack Display function call stack

dbstatus List all breakpoints

dbstep Execute one or more lines from current breakpoint

dbst op Set breakpoints in M-file function dbtype List M-file with line numbers dbup Change local workspace context

edi t Edit or create M-file

keyboard Invoke the keyboard in an M-file

Source Control

checki n Check file into source control system checkout Check file out of source control system cmopts Get name of source control system customverctrl Allow custom source control system

undocheckout Undo previous checkout from source control system

Profiling

profile Optimize performance of M-file code

profreport Generate profile report

System

computer Identify information about computer on which MATLAB is running

j avachk Generate error message based on Java feature support

license Show license number for MATLAB

usej ava Determine if a Java feature is supported in MATLAB ver Display version information for MathWorks products

versi on Get MATLAB version number

Performance Improvement Tools and Techniques

memory Help for memory limitations
pack Consolidate workspace memory
profile Optimize performance of M-file code

profreport Generate profile report

rehash Refresh function and file system caches

sparse Create sparse matrix zeros Create array of all zeros

Mathematics

Functions for working with arrays and matrices, linear algebra, data analysis, and other areas of mathematics.

Category	Description
"Arrays and Matrices"	Basic array operators and operations, creation of elementary and specialized arrays and matrices
"Linear Algebra"	Matrix analysis, linear equations, eigenvalues, singular values, logarithms, exponentials, factorization
"Elementary Math"	Trigonometry, exponentials and logarithms, complex values, rounding, remainders, discrete math
"Data Analysis and Fourier Transforms"	Descriptive statistics, finite differences, correlation, filtering and convolution, fourier transforms
"Polynomials"	Multiplication, division, evaluation, roots, derivatives, integration, eigenvalue problem, curve fitting, partial fraction expansion
"Interpolation and Computational Geometry"	Interpolation, Delaunay triangulation and tessellation, convex hulls, Voronoi diagrams, domain generation
"Coordinate System Conversion"	Conversions between Cartesian and polar or spherical coordinates
"Nonlinear Numerical Methods"	Differential equations, optimization, integration
"Specialized Math"	Airy, Bessel, Jacobi, Legendre, beta, elliptic, error, exponential integral, gamma functions

Category	Description
"Sparse Matrices"	Elementary sparse matrices, operations, reordering algorithms, linear algebra, iterative methods, tree operations
"Math Constants"	Pi, imaginary unit, infinity, Not-a-Number, largest and smallest positive floating point numbers, floating point relative accuracy

Arrays and Matrices

- "Basic Information"
- "Operators"
- "Operations and Manipulation"
- "Elementary Matrices and Arrays"
- "Specialized Matrices"

Basic Information

di sp	Display array
di spl ay	Display array
isempty	True for empty matrix
i sequal	True if arrays are identical
i sl ogi cal	True for logical array
isnumeric	True for numeric arrays
i ssparse	True for sparse matrix
length	Length of vector
ndi ms	Number of dimensions
numel	Number of elements
si ze	Size of matrix

Operators

+	Addition
+	Unary plus
-	Subtraction
-	Unary minus
*	Matrix multiplication
^	Matrix power
\	Backslash or left matrix divide

/ Slash or right matrix divide

' Transpose

. ' Nonconjugated transpose

.* Array multiplication (element-wise)
.^ Array power (element-wise)
.\ Left array divide (element-wise)

Right array divide (element-wise)

Operations and Manipulation

: (colon) Index into array, rearrange array bl kdi ag Block diagonal concatenation

cat Concatenate arrays
cross Vector cross product
cumprod Cumulative product
cumsum Cumulative sum

di ag Diagonal matrices and diagonals of matrix

dot Vector dot product

end Last index

find Find indices of nonzero elements

fliplr Flip matrices left-right flipud Flip matrices up-down

fli pdi m Flip matrix along specified dimension

horzcat Horizontal concatenation

i nd2sub Multiple subscripts from linear index

i permute Inverse permute dimensions of multidimensional array

kron Kronecker tensor product
max Maximum elements of array
min Minimum elements of array

permute Rearrange dimensions of multidimensional array

prod Product of array elements repmat Replicate and tile array

reshape Reshape array

rot 90 Rotate matrix 90 degrees
sort Sort elements in ascending order
sortrows Sort rows in ascending order
sum Sum of array elements
sqrtm Matrix square root

sub2i ndLinear index from multiple subscriptstri lLower triangular part of matrixtri uUpper triangular part of matrix

vertcat Vertical concatenation

See also "Linear Algebra" for other matrix operations. See also "Elementary Math" for other array operations.

Elementary Matrices and Arrays

: (colon) Regularly spaced vector

bl kdi ag Construct block diagonal matrix from input arguments

di ag Diagonal matrices and diagonals of matrix

eye Identity matrix

freqspace Frequency spacing for frequency response

linspace Generate linearly spaced vectors

l ogspace Generate logarithmically spaced vectors

meshgri d Generate X and Y matrices for three-dimensional plots ndgri d Arrays for multidimensional functions and interpolation

ones Create array of all ones

rand Uniformly distributed random numbers and arrays randn Normally distributed random numbers and arrays

repmat Replicate and tile array zeros Create array of all zeros

Specialized Matrices

compan Companion matrix
gallery Test matrices
hadamard Hadamard matrix
hankel Hankel matrix
hilb Hilbert matrix

i nvhi l b Inverse of Hilbert matrix

magi c Magic square pascal Pascal matrix

rosser Classic symmetric eigenvalue test problem

toeplitz Toeplitz matrix vander Vandermonde matrix

wi l ki nson Wilkinson's eigenvalue test matrix

Linear Algebra

- "Matrix Analysis"
- "Linear Equations"
- "Eigenvalues and Singular Values"
- "Matrix Logarithms and Exponentials"
- "Factorization"

Matrix Analysis

cond Condition number with respect to inversion condeig Condition number with respect to eigenvalues

det Determinant

norm Matrix or vector norm normest Estimate matrix 2-norm

nul l Null space orth Orthogonalization

rank Matrix rank

rcond Matrix reciprocal condition number estimate

rref Reduced row echelon form subspace Angle between two subspaces trace Sum of diagonal elements

Linear Equations

\ and \ Linear equation solution chol Cholesky factorization

chol i nc Incomplete Cholesky factorization

cond Condition number with respect to inversion

condest 1-norm condition number estimate funm Evaluate general matrix function

i nv Matrix inverse

1 scov Least squares solution in presence of known covariance

l squonneg
l u
LU matrix factorization
l ui nc
Nonnegative least squares
LU matrix factorization

pi nv Moore-Penrose pseudoinverse of matrix qr Orthogonal-triangular decomposition

rcond Matrix reciprocal condition number estimate

Eigenvalues and Singular Values

bal ance Improve accuracy of computed eigenvalues

cdf2rdf Convert complex diagonal form to real block diagonal form

condei g Condition number with respect to eigenvalues

ei g Eigenvalues and eigenvectors

ei gs Eigenvalues and eigenvectors of sparse matrix gsvd Generalized singular value decomposition

hess Hessenberg form of matrix
pol y
pol yei g
Polynomial with specified roots
Polynomial eigenvalue problem

qz QZ factorization for generalized eigenvalues rsf2csf Convert real Schur form to complex Schur form

schur Schur decomposition

svd Singular value decomposition

svds Singular values and vectors of sparse matrix

Matrix Logarithms and Exponentials

expm Matrix exponential logm Matrix logarithm sqrtm Matrix square root

Factorization

bal ance Diagonal scaling to improve eigenvalue accuracy cdf2rdf Complex diagonal form to real block diagonal form

chol Cholesky factorization

chol i nc chol update Incomplete Cholesky factorization
Rank 1 update to Cholesky factorization

l u LU matrix factorization l ui nc Incomplete LU factorization

pl anerot Givens plane rotation

qrOrthogonal-triangular decompositionqrdel eteDelete column from QR factorizationqri nsertInsert column in QR factorizationqrupdateRank 1 update to QR factorization

qz QZ factorization for generalized eigenvalues

rsf2csf Real block diagonal form to complex diagonal form

Elementary Math

- "Trigonometric"
- "Exponential"
- "Complex"
- "Rounding and Remainder"
- "Discrete Math (e.g., Prime Factors)"

Trigonometric

acos, acosh Inverse cosine and inverse hyperbolic cosine	
acot, acoth Inverse cotangent and inverse hyperbolic cotang	ent
acsc, acsch Inverse cosecant and inverse hyperbolic cosecan	ıt
asec, asech Inverse secant and inverse hyperbolic secant	
asi n, asi nh Inverse sine and inverse hyperbolic sine	

at an, at anh Inverse tangent and inverse hyperbolic tangent

at an 2 Four-quadrant inverse tangent cos, cosh Cosine and hyperbolic cosine Cotangent and hyperbolic cotangent csc, csch Sec, sech Secant and hyperbolic secant si n, si nh Sine and hyperbolic sine Tangent and hyperbolic tangent

Exponential

exp Exponential log Natural logarithm

log2 Base 2 logarithm and dissect floating-point numbers into exponent and

mantissa

l og10 Common (base 10) logarithm next pow2 Next higher power of 2

pow2 Base 2 power and scale floating-point number

sqrt Square root

Complex

abs Absolute value angle Phase angle

compl ex Construct complex data from real and imaginary parts

conj Complex conjugate

cpl xpai r Sort numbers into complex conjugate pairs

i Imaginary unit

i mag Complex imaginary part i sreal True for real array j Imaginary unit real Complex real part unwrap Unwrap phase angle

Rounding and Remainder

fix Round towards zero

floor Round towards minus infinity ceil Round towards plus infinity round Round towards nearest integer

mod Modulus (signed remainder after division)

rem Remainder after division

si gn Signum

Discrete Math (e.g., Prime Factors)

factor Prime factors
factorial Factorial function
gcd Greatest common divisor
True for prime numbers

i spri me True for prime numbers l cm Least common multiple

nchoosek All combinations of N elements taken K at a time

perms All possible permutations
primes Generate list of prime numbers
rat, rats Rational fraction approximation

Data Analysis and Fourier Transforms

• "Basic Operations"

• "Finite Differences"

"Correlation"

· "Filtering and Convolution"

• "Fourier Transforms"

Basic Operations

cumprod Cumulative product cumsum Cumulative sum

cumt rapz Cumulative trapezoidal numerical integration

max Maximum elements of array mean Average or mean value of arrays

medi an Median value of arrays
mi n Minimum elements of array
prod Product of array elements
sort Sort elements in ascending order

sort Sort elements in ascending ord sortrows Sort rows in ascending order

std Standard deviation sum Sum of array elements

trapz Trapezoidal numerical integration

var Variance

Finite Differences

del 2 Discrete Laplacian

diff Differences and approximate derivatives

gradi ent Numerical gradient

Correlation

corrcoef Correlation coefficients cov Covariance matrix

subspace Angle between two subspaces

Filtering and Convolution

conv Convolution and polynomial multiplication

conv2 Two-dimensional convolution convn N-dimensional convolution

deconv Deconvolution and polynomial division

det rend Linear trend removal

filter Filter data with infinite impulse response (IIR) or finite impulse response

(FIR) filter

filter2 Two-dimensional digital filtering

Fourier Transforms

abs Absolute value and complex magnitude

angle Phase angle

fft One-dimensional fast Fourier transform fft2 Two-dimensional fast Fourier transform fftn N-dimensional discrete Fourier Transform

fftshift Shift DC component of fast Fourier transform to center of spectrum

ifft Inverse one-dimensional fast Fourier transform
 ifft2 Inverse two-dimensional fast Fourier transform
 ifftn Inverse multidimensional fast Fourier transform

ifftshift Inverse fast Fourier transform shift

next pow2 Next power of two unwrap Correct phase angles

Polynomials

conv Convolution and polynomial multiplication deconv Deconvolution and polynomial division

pol y Polynomial with specified roots

pol yder Polynomial derivative

pol yei g Polynomial eigenvalue problem

pol yfit Polynomial curve fitting

pol yi nt Analytic polynomial integration

pol yval Polynomial evaluation pol yval m Matrix polynomial evaluation

resi due Convert between partial fraction expansion and polynomial coefficients

roots Polynomial roots

Interpolation and Computational Geometry

- "Interpolation"
- "Delaunay Triangulation and Tessellation"

Search for nearest point

- "Convex Hull"
- "Voronoi Diagrams"
- "Domain Generation"

Interpolation

dsearch

pchi p

dsearchn	Multidimensional closest point search
gri ddata	Data gridding
gri ddata3	Data gridding and hypersurface fitting for three-dimensional data
gri ddatan	Data gridding and hypersurface fitting (dimension >= 2)
interp1	One-dimensional data interpolation (table lookup)
interp2	Two-dimensional data interpolation (table lookup)
interp3	Three-dimensional data interpolation (table lookup)
interpft	One-dimensional interpolation using fast Fourier transform method
interpn	Multidimensional data interpolation (table lookup)
meshgri d	Generate X and Y matrices for three-dimensional plots
mkpp	Make piecewise polynomial
ndgri d	Generate arrays for multidimensional functions and interpolation

Piecewise Cubic Hermite Interpolating Polynomial (PCHIP)

ppval Piecewise polynomial evaluation spl i ne Cubic spline data interpolation

tsearchn Multidimensional closest simplex search

unmkpp Piecewise polynomial details

Delaunay Triangulation and Tessellation

del aunay Delaunay triangulation del aunay3 Three-dimensional Delaunay tessellation del aunayn Multidimensional Delaunay tessellation dsearch Search for nearest point dsearchn Multidimensional closest point search tetramesh Tetrahedron mesh plot trimesh Triangular mesh plot tri pl ot Two-dimensional triangular plot tri surf Triangular surface plot

tsearch Search for enclosing Delaunay triangle tsearchn Multidimensional closest simplex search

Convex Hull

convhul l Convex hull

convhulln
patch
plot
Create patch graphics object
Linear two-dimensional plot
tri surf
Multidimensional convex hull
Create patch graphics object
Linear two-dimensional plot
Triangular surface plot

Voronoi Diagrams

dsearch Search for nearest point
patch Create patch graphics object
pl ot Linear two-dimensional plot

voronoi Voronoi diagram

voronoi n Multidimensional Voronoi diagrams

Domain Generation

meshgrid Generate X and Y matrices for three-dimensional plots

ndgri d Generate arrays for multidimensional functions and interpolation

Coordinate System Conversion

Cartesian

cart2sph Transform Cartesian to spherical coordinates
cart2pol Transform Cartesian to polar coordinates
pol 2cart Transform polar to Cartesian coordinates
sph2cart Transform spherical to Cartesian coordinates

Nonlinear Numerical Methods

- "Ordinary Differential Equations (IVP)"
- "Boundary Value Problems"
- "Partial Differential Equations"
- "Optimization"
- "Numerical Integration (Quadrature)"

Ordinary Differential Equations (IVP)

deval Evaluate solution of differential equation problem

ode113 Solve non-stiff differential equations, variable order method ode15s Solve stiff ODEs and DAEs Index 1, variable order method

ode23 Solve non-stiff differential equations, low order method ode23s Solve stiff differential equations, low order method

ode23t Solve moderately stiff ODEs and DAEs Index 1, trapezoidal rule

ode23tb Solve stiff differential equations, low order method

ode45 Solve non-stiff differential equations, medium order method

odeget Get ODE options parameters odeset Create/alter ODE options structure

Boundary Value Problems

bvp4c Solve two-point boundary value problems for ODEs by collocation

bypset Create/alter BVP opti ons structure bypget Get BVP opti ons parameters

deval Evaluate solution of differential equation problem

Partial Differential Equations

pdepe Solve initial-boundary value problems for parabolic-elliptic PDEs

pdeval Evaluates by interpolation solution computed by pdepe

Optimization

f mi nbnd Scalar bounded nonlinear function minimization

fmi nsearch Multidimensional unconstrained nonlinear minimization, by

Nelder-Mead direct search method

fzero Scalar nonlinear zero finding

l sqnonneg

Optimset

Optimset

Create or alter optimization options structure

Optimget

Create or alter optimization options structure

Get optimization parameters from options structure

Numerical Integration (Quadrature)

quad Numerically evaluate integral, adaptive Simpson quadrature (low order) quadl Numerically evaluate integral, adaptive Lobatto quadrature (high order)

dbl quad Numerically evaluate double integral

Specialized Math

ai ry Airy functions

bessel h Bessel functions of third kind (Hankel functions)

bessel i Modified Bessel function of first kind

bessel j Bessel function of first kind

bessel k Modified Bessel function of second kind

bessel y Bessel function of second kind

beta Beta function

betainc Incomplete beta function
betaln Logarithm of beta function
ellipj Jacobi elliptic functions

ellipke Complete elliptic integrals of first and second kind

erf Error function

erf c Complementary error function erf ci nv Inverse complementary error function erf cx Scaled complementary error function

erfinv Inverse error function expint Exponential integral gamma Gamma function

gammai nc
gammal n
Logarithm of gamma function
Logarithm of gamma function
Associated Legendre functions

Sparse Matrices

- "Elementary Sparse Matrices"
- "Full to Sparse Conversion"
- "Working with Sparse Matrices"
- "Reordering Algorithms"
- "Linear Algebra"
- "Linear Equations (Iterative Methods)"
- "Tree Operations"

Elementary Sparse Matrices

spdi ags Sparse matrix formed from diagonals

speye Sparse identity matrix

sprand Sparse uniformly distributed random matrix sprandn Sparse normally distributed random matrix

sprandsym Sparse random symmetric matrix

Full to Sparse Conversion

find Find indices of nonzero elements full Convert sparse matrix to full matrix

sparse Create sparse matrix

spconvert Import from sparse matrix external format

Working with Sparse Matrices

i ssparse True for sparse matrix

nnz Number of nonzero matrix elements

nonzeros Nonzero matrix elements

nzmax Amount of storage allocated for nonzero matrix elements

spall oc Allocate space for sparse matrix

spfun Apply function to nonzero matrix elements

spones Replace nonzero sparse matrix elements with ones

spparms Set parameters for sparse matrix routines

spy Visualize sparsity pattern

Reordering Algorithms

col amd Column approximate minimum degree permutation

col mmd Column minimum degree permutation

col perm Column permutation

dmperm Dulmage-Mendelsohn permutation

randperm Random permutation

symamd Symmetric approximate minimum degree permutation

symmetric minimum degree permutation symmetric reverse Cuthill-McKee permutation

Linear Algebra

chol i nc Incomplete Cholesky factorization condest 1-norm condition number estimate

ei gs Eigenvalues and eigenvectors of sparse matrix

l ui nc Incomplete LU factorization normest Estimate matrix 2-norm

sprank Structural rank

svds Singular values and vectors of sparse matrix

Linear Equations (Iterative Methods)

bi cg BiConjugate Gradients method

bi cgstab BiConjugate Gradients Stabilized method cgs Conjugate Gradients Squared method gmres Generalized Minimum Residual method

1 sqr LSQR implementation of Conjugate Gradients on Normal Equations

mi nres Minimum Residual method

pcg Preconditioned Conjugate Gradients method

qmr Quasi-Minimal Residual method spaugment Form least squares augmented system

symml q Symmetric LQ method

Tree Operations

etree Elimination tree etreepl ot Plot elimination tree

gpl ot Plot graph, as in "graph theory" symbolic factorization analysis

treel ayout Lay out tree or forest treepl ot Plot picture of tree

Math Constants

eps Floating-point relative accuracy

i Imaginary unit I nf Infinity, ∞ j Imaginary unit NaN Not-a-Number

pi Ratio of a circle's circumference to its diameter, π

real max Largest positive floating-point number real min Smallest positive floating-point number

Programming and Data Types

Functions to store and operate on data at either the MATLAB command line or in programs and scripts. Functions to write, manage, and execute MATLAB programs.

Category	Description
"Data Types"	Numeric, character, structures, cell arrays, and data type conversion
"Arrays"	Basic array operations and manipulation
"Operators and Operations"	Special characters and arithmetic, bit-wise, relational, logical, set, date and time operations
"Programming in MATLAB"	M-files, function/expression evaluation, program control, function handles, object oriented programming, error handling

Data Types

- "Numeric"
- "Characters and Strings"
- "Structures"
- "Cell Arrays"
- "Data Type Conversion"

Numeric

[]	Array constructor
cat	Concatenate arrays
cl ass	Return object's class name (e.g., numeric)
fi nd	Find indices and values of nonzero array elements
i permute	Inverse permute dimensions of multidimensional array
i sa	Detect object of given class (e.g., numeric)
i segual	Determine if arrays are numerically equal
isnumeric	Determine if item is numeric array
i sreal	Determine if all array elements are real numbers

permute Rearrange dimensions of multidimensional array

reshape Reshape array

squeeze Remove singleton dimensions from array

zeros Create array of all zeros

Characters and Strings

Description of Strings in MATLAB

strings Describes MATLAB string handling

Creating and Manipulating Strings

cellstr Create cell array of strings from character array

datestr Convert to date string format

debl ank Strip trailing blanks from the end of string

l ower Convert string to lower case sprint f Write formatted data to string sscanf Read string under format control

strcat String concatenation strjust Justify character array

strread Read formatted data from string

strrep String search and replace

strvcat Vertical concatenation of strings upper Convert string to upper case

Comparing and Searching Strings

cl ass
fi ndstr
findstr
isa
Detect object of given class (e.g., char)
Determine if item is cell array of strings
Determine if item is character array

isletter Detect array elements that are letters of the alphabet

i sspace Detect elements that are ASCII white spaces

strcmp Compare strings

strcmpi Compare strings, ignoring case
strfind Find one string within another
strmatch Find possible matches for string
strncmp Compare first n characters of strings

strncmpi Compare first n characters of strings, ignoring case

strtok First token in string

Evaluating String Expressions

eval Execute string containing MATLAB expression eval c Evaluate MATLAB expression with capture

eval i n Execute string containing MATLAB expression in workspace

Structures

cell 2struct Cell array to structure array conversion Return object's class name (e.g., struct)

deal Deal inputs to outputs fi el dnames Field names of structure get fi el d Get field of structure array

i sa Detect object of given class (e.g., struct)
i sequal Determine if arrays are numerically equal
i sfield Determine if item is structure array field
Determine if item is structure array

rmfield Remove structure fields setfield Set field of structure array struct Create structure array

struct2cell Structure to cell array conversion

Cell Arrays

{ } Construct cell array cell Construct cell array

cellfun Apply function to each element in cell array cellstr Create cell array of strings from character array

cell2struct Cell array to structure array conversion

cel l di sp Display cell array contents

cel l pl ot Graphically display structure of cell arrays cl ass Return object's class name (e.g., cell)

deal Deal inputs to outputs

i sa Detect object of given class (e.g., cell)

i scel l Determine if item is cell array

i scellstr
i sequal
num2cell
struct2cell
Determine if item is cell array of strings
Determine if arrays are numerically equal
Convert numeric array into cell array
Structure to cell array conversion

Data Type Conversion

Numeric

doubl e Convert to double-precision

int8	Convert to signed 8-bit integer
i nt 16	Convert to signed 16-bit integer
int32	Convert to signed 32-bit integer
si ngl e	Convert to single-precision
ui nt 8	Convert to unsigned 8-bit integer
ui nt 16	Convert to unsigned 16-bit integer
ui nt 32	Convert to unsigned 32-bit integer

String to Numeric

base2dec Convert base N number string to decimal number
bi n2dec Convert binary number string to decimal number
hex2dec Convert hexadecimal number string to decimal number
Convert hexadecimal number string to double number

str2double Convert string to double-precision number

str2num Convert string to number

Numeric to String

char Convert to character array (string)

dec2base Convert decimal to base N number in string
dec2bin Convert decimal to binary number in string
dec2hex Convert decimal to hexadecimal number in string

int2str Convert integer to string
mat2str Convert a matrix to string
num2str Convert number to string

Other Conversions

cell 2 struct Convert cell array to structure array datestr Convert serial date number to string

Arrays

- "Array Operations"
- "Basic Array Information"
- "Array Manipulation"
- "Elementary Arrays"

Array Operations

[] Array constructor
, Array row element separator
; Array column element separator
: Specify range of array elements
end Indicate last index of array
+ Addition or unary plus
- Subtraction or unary minus
. * Array multiplication
. \ Array right division
. \ Array left division
. \ Array power
. \ Array (nonconjugated) transpose

Basic Array Information

di sp Display text or array di spl ay Overloaded method to display text or array isempty Determine if array is empty i sequal Determine if arrays are numerically equal isnumeric Determine if item is numeric array i sl ogi cal Determine if item is logical array Length of vector length ndi ms Number of array dimensions

numel Number of elements in matrix or cell array

si ze Array dimensions

Array Manipulation

: Specify range of array elements

bl kdi ag Construct block diagonal matrix from input arguments

cat Concatenate arrays

find Find indices and values of nonzero elements

fliplr Flip matrices left-right flipud Flip matrices up-down

fli pdi m Flip array along specified dimension

horzcat Horizontal concatenation i nd2sub Subscripts from linear index

i permute Inverse permute dimensions of multidimensional array permute Rearrange dimensions of multidimensional array

repmat Replicate and tile array

reshape Reshape array

rot 90 Rotate matrix 90 degrees

shi ftdi m Shift dimensions

sort Sort elements in ascending order sortrows Sort rows in ascending order squeeze Remove singleton dimensions sub2i nd Single index from subscripts Vertcat Horizontal concatenation

Elementary Arrays

: Regularly spaced vector

bl kdi ag Construct block diagonal matrix from input arguments

eye Identity matrix

linspace Generate linearly spaced vectors

l ogspace Generate logarithmically spaced vectors

meshgrid Generate X and Y matrices for three-dimensional plots

ndgri d Generate arrays for multidimensional functions and interpolation

ones Create array of all ones

rand Uniformly distributed random numbers and arrays randn Normally distributed random numbers and arrays

zeros Create array of all zeros

Operators and Operations

- "Special Characters"
- "Arithmetic Operations"
- "Bit-wise Operations"
- "Relational Operations"

- "Logical Operations"
- "Set Operations"
- "Date and Time Operations"

Special Characters

:	Specify range of array elements
()	Pass function arguments, or prioritize operations
[]	Construct array
{ }	Construct cell array
	Decimal point, or structure field separator
	Continue statement to next line
,	Array row element separator
;	Array column element separator
%	Insert comment line into code
!	Command to operating system
=	Assignment

Arithmetic Operations

+	Plus
_	Minus
•	Decimal point
=	Assignment
*	Matrix multiplication
/	Matrix right division
\	Matrix left division
^	Matrix power
1	Matrix transpose
. *	Array multiplication (element-wise)
./	Array right division (element-wise)
. \	Array left division (element-wise)
. ^	Array power (element-wise)
. '	Array transpose

Bit-wise Operations

-	
bi tand	Bit-wise AND
bi t cmp	Bit-wise complement
bi tor	Bit-wise OR
bi tmax	Maximum floating-point integer
bitset	Set bit at specified position
bi tshi ft	Bit-wise shift
bi tget	Get bit at specified position

Bit-wise XOR bi txor

Relational Operations

Less than <

Less than or equal to <=

Greater than >

Greater than or equal to >=

Equal to == ~= Not equal to

Logical Operations

& Logical AND Logical OR Logical NOT

al l Test to determine if all elements are nonzero

Test for any nonzero elements any

fi nd Find indices and values of nonzero elements

is* Detect state

i sa Detect object of given class

i skeyword Determine if string is MATLAB keyword i svarname Determine if string is valid variable name

l ogi cal Convert numeric values to logical

xor Logical EXCLUSIVE OR

Set Operations

intersect Set intersection of two vectors

i smember Detect members of set

Return set difference of two vectors setdi ff setxor Set exclusive or of two vectors Set union of two vectors uni on

Unique elements of vector uni que

Date and Time Operations

cal endar Calendar for specified month cl ock Current time as date vector

cputi me Elapsed CPU time date Current date string datenum Serial date number

datestr Convert serial date number to string

datevec Date components End of month eomday

etime Elapsed time

now Current date and time ti c, toc Stopwatch timer weekday Day of the week

Programming in MATLAB

- "M-File Functions and Scripts"
- "Evaluation of Expressions and Functions"
- · "Variables and Functions in Memory"
- "Control Flow"
- "Function Handles"
- "Object-Oriented Programming"
- · "Error Handling"
- "MEX Programming"

M-File Functions and Scripts

() Pass function arguments
% Insert comment line into code
. . . Continue statement to next line

depf un List dependent functions of M-file or P-file depdi r List dependent directories of M-file or P-file

function Function M-files i nput Request user input i nput name Input argument name

mf i l ename Name of currently running M-file
nargi n Number of function input arguments
nargout Number of function output arguments
nargotk Check number of input arguments
validate number of output arguments
create preparsed pseudocode file (P-file)

script Describes script M-file

varargi n Accept variable number of arguments varargout Return variable number of arguments

Evaluation of Expressions and Functions

builtin Execute builtin function from overloaded method cellfun Apply function to each element in cell array eval Interpret strings containing MATLAB expressions

eval c Evaluate MATLAB expression with capture

eval i n Evaluate expression in workspace

feval Evaluate function

i skeyword Determine if item is MATLAB keyword i svarname Determine if item is valid variable name

pause Halt execution temporarily

run Run script that is not on current path

script Describes script M-file

symvar Determine symbolic variables in expression

tic, toc Stopwatch timer

Variables and Functions in Memory

assi gni n Assign value to workspace variable

gl obal Define global variables

i nmem
i sgl obal
mi sl ocked
ml ock
pack
Determine if item is global variable
True if M-file cannot be cleared
Prevent clearing M-file from memory
Allow clearing M-file from memory
Consolidate workspace memory
Define participate and the

persistent Define persistent variable

rehash Refresh function and file system caches

Control Flow

break Terminate execution of for loop or while loop

case Case switch catch Begin catch block

continue Pass control to next iteration of for or while loop

el se Conditionally execute statements el sei f Conditionally execute statements

end Terminate conditional statements, or indicate last index

error Display error messages

for Repeat statements specific number of times

if Conditionally execute statements otherwise Default part of switch statement return Return to invoking function

switch Switch among several cases based on expression

try Begin try block

while Repeat statements indefinite number of times

Function Handles

cl ass Return object's class name (e.g. function_handle)

feval Evaluate function

function_handle

Describes function handle data type

functions Return information about function handle

func2str Constructs function name string from function handle isa Detect object of given class (e.g. function_handle)

i sequal Determine if function handles are equal

str2func Constructs function handle from function name string

Object-Oriented Programming

MATLAB Classes and Objects

cl ass Create object or return class of object fi el dnames List public fields belonging to object, Establish inferior class relationship

i sa Detect object of given class

i sobject Determine if item is MATLAB OOPs object

l oadobj User-defined extension of l oad function for user objects

methods Display method names

methodsvi ew saveobj Displays information on all methods implemented by class User-defined extension of save function for user objects Subsasgn Overloaded method for A(I) = B, $A\{I\} = B$, and A. fi el d=B

subsi ndex Overloaded method for X(A)

subsref Overloaded method for A(I), A{I} and A. field substruct Create structure argument for subsasgn or subsref

superi or to Establish superior class relationship

Java Classes and Objects

cel l Convert Java array object to cell array class Return class name of Java object clear Clear Java packages import list depfun List Java classes used by M-file exist Detect if item is Java class

fi el dnames List public fields belonging to object,

i mport Add package or class to current Java import list i nmem List names of Java classes loaded into memory

i sa Detect object of given class

i sj ava Determine whether object is Java object

j avaArray Constructs Java array j avaMethod Invokes Java method j avaObj ect Constructs Java object

methods Display methods belonging to class

met hodsvi ew Display information on all methods implemented by class

whi ch Display package and class name for method

Error Handling

catch Begin catch block of try/catch statement

error Display error message

ferror Query MATLAB about errors in file input or output lasterr Return last error message generated by MATLAB lastwarn Return last warning message issued by MATLAB

try Begin try block of try/catch statement

warni ng Display warning message

MEX Programming

dbmex Enable MEX-file debugging

i nmem Return names of currently loaded MEX-files

mex Compile MEX-function from C or Fortran source code

mexext Return MEX-filename extension

File I/O

Functions to read and write data to files of different format types.

Category	Description
"Filename Construction"	Get path, directory, filename information; construct filenames
"Opening, Loading, Saving Files"	Open files; transfer data between files and MATLAB workspace
"Low-Level File I/O"	Low-level operations that use a file identifier (e.g., fopen, fseek, fread)
"Text Files"	Delimited or formatted I/O to text files
"Spreadsheets"	Excel and Lotus 123 files
"Scientific Data"	CDF, FITS, HDF formats
"Audio and Audio/Video"	General audio functions; SparcStation, Wave, AVI files
"Images"	Graphics files

To see a listing of file formats that are readable from MATLAB, go to ${\tt file}$ formats.

Filename Construction

filepartsReturn parts of filenamefilesepReturn directory separator for this platformfullfileBuild full filename from partstempdirReturn name of system's temporary directorytempnameReturn unique string for use as temporary filename

Opening, Loading, Saving Files

i mportdata Load data from various types of files load Load all or specific data from MAT or ASCII file

open Open files of various types using appropriate editor or program

save Save all or specific data to MAT or ASCII file

Low-Level File I/O

fcl ose Close one or more open files

feof Test for end-of-file

ferror Query MATLAB about errors in file input or output
fget1 Return next line of file as string without line terminator(s)
fgets Return next line of file as string with line terminator(s)
fopen Open file or obtain information about open files

fprintf Write formatted data to file

fread Read binary data from file

frewind Rewind open file

fscanf
fseek
fseek
ftell
Get file position indicator
fwrite

Read formatted data from file
Set file position indicator
Get file position indicator
Write binary data to file

Text Files

textread

csvread Read numeric data from text file, using comma delimiter

Write numeric data to text file, using comma delimiter

Write numeric data from text file, specifying your own delimiter

Write numeric data to text file, specifying your own delimiter

Write numeric data to text file, specifying your own delimiter

Read data from text file, specifying format for each value

Spreadsheets

Microsoft Excel Functions

xl sfi nfo Determine if file contains Microsoft Excel (. xl s) spreadsheet

xl sread Read Microsoft Excel spreadsheet file (. xl s)

Lotus123 Functions

wk1read Read Lotus123 WK1 spreadsheet file into matrix wk1wri te Write matrix to Lotus123 WK1 spreadsheet file

Scientific Data

Common Data Format (CDF)

cdfi nfo Return information about CDF file

cdfread Read CDF file

Flexible Image Transport System

fitsinfo Return information about FITS file

fitsread Read FITS file

Hierarchical Data Format (HDF)

hdf Interface to HDF files

hdfi nfo Return information about HDF or HDF-EOS file

hdfread Read HDF file

Audio and Audio/Video

- "General"
- "SPARCstation-Specific Sound Functions"
- "Microsoft WAVE Sound Functions"
- "Audio Video Interleaved (AVI) Functions"
- "Microsoft Excel Functions"
- "Lotus123 Functions"

General

audi opl ayer Create audio player object audi orecorder Perform real-time audio capture

beep Produce beep sound

l i n2mu Convert linear audio signal to mu-law mu2l i n Convert mu-law audio signal to linear

sound Convert vector into sound soundsc Scale data and play as sound

SPARCstation-Specific Sound Functions

auread Read NeXT/SUN (. au) sound file auwri te Write NeXT/SUN (. au) sound file

Microsoft WAVE Sound Functions

wavpl ay Play sound on PC-based audio output device wavread Read Microsoft WAVE (. wav) sound file wavrecord wavwrite Write Microsoft WAVE (. wav) sound file

Audio Video Interleaved (AVI) Functions

addframe Add frame to AVI file avi file Create new AVI file

avi i nf o Return information about AVI file

avi read Read AVI file close Close AVI file

movi e2avi Create AVI movie from MATLAB movie

Images

i mf i nf o Return information about graphics file

i mread Read image from graphics file i mwri te Write image to graphics file

Graphics

2-D graphs, specialized plots (e.g., pie charts, histograms, and contour plots), function plotters, and Handle Graphics functions.

Category	Description
Basic Plots and Graphs	Linear line plots, log and semilog plots
Annotating Plots	Titles, axes labels, legends, mathematical symbols
Specialized Plotting	Bar graphs, histograms, pie charts, contour plots, function plotters
Bit-Mapped Images	Display image object, read and write graphics file, convert to movie frames
Printing	Printing and exporting figures to standard formats
Handle Graphics	Creating graphics objects, setting properties, finding handles

Basic Plots and Graphs

box	Axis box for 2-D and 3-D plots
errorbar	Plot graph with error bars
hol d	Hold current graph
l ogl og	Plot using log-log scales
pol ar	Polar coordinate plot
pl ot	Plot vectors or matrices.
pl ot 3	Plot lines and points in 3-D space
plotyy	Plot graphs with Y tick labels on the left and right
semilogx	Semi-log scale plot
semilogy	Semi-log scale plot
subpl ot	Create axes in tiled positions
=	_

Annotating Plots

cl abel Add contour labels to contour plot datetick Date formatted tick labels

gtext Place text on 2-D graph using mouse 1 egend Graph legend for lines and patches

texl abel Produce the TeX format from character string

title Titles for 2-D and 3-D plots

xl abel X-axis labels for 2-D and 3-D plots yl abel Y-axis labels for 2-D and 3-D plots

zl abel Z-axis labels for 3-D plots

Specialized Plotting

• "Area, Bar, and Pie Plots"

• "Contour Plots"

• "Direction and Velocity Plots"

• "Discrete Data Plots"

• "Function Plots"

• "Histograms"

· "Polygons and Surfaces"

· "Scatter Plots"

Area, Bar, and Pie Plots

area Area plot bar Vertical bar chart

barh Horizontal bar chart
bar3 Vertical 3-D bar chart
bar3h Horizontal 3-D bar chart

pareto Pareto char pi e Pie plot pi e3 3-D pie plot

Contour Plots

contour Contour (level curves) plot contourc Contour computation contourf Filled contour plot

ezcont our Easy to use contour plotter
ezcont ourf Easy to use filled contour plotter

Direction and Velocity Plots

comet Comet plot comet 3 3-D comet plot compass Compass plot feather Feather plot

qui ver Quiver (or velocity) plot qui ver3 3-D quiver (or velocity) plot

Discrete Data Plots

stem Plot discrete sequence data stem3 Plot discrete surface data

stairs Stairstep graph

Function Plots

ezcontour Easy to use contour plotter
ezcontourf Easy to use filled contour plotter
ezmesh Easy to use 3-D mesh plotter

ezmeshc Easy to use combination mesh/contour plotter

ezpl ot Easy to use function plotter

ezpl ot 3 Easy to use 3-D parametric curve plotter ezpol ar Easy to use polar coordinate plotter ezsurf Easy to use 3-D colored surface plotter

ezsurfc Easy to use combination surface/contour plotter

fpl ot Plot a function

Histograms

hi st Plot histograms hi stc Histogram count

rose Plot rose or angle histogram

Polygons and Surfaces

convhul l Convex hull cyl i nder Generate cylinder del aunay Delaunay triangulation

dsearch Search Delaunay triangulation for nearest point

el l i psoi d Generate ellipsoid

fill Draw filled 2-D polygons

fill3 Draw filled 3-D polygons in 3-space in polygon True for points inside a polygonal region

pcol or Pseudocolor (checkerboard) plot

pol yarea Area of polygon ri bbon Ribbon plot

slice Volumetric slice plot sphere Generate sphere tsearch Search for enclosing Delaunay triangle

voronoi Voronoi diagram waterfal l Waterfall plot

Scatter Plots

pl otmatrix Scatter plot matrix scatter Scatter plot scatter3 3-D scatter plot

Bit-Mapped Images

frame2i m Convert movie frame to indexed image

i mage Display image object

i magesc Scale data and display image object i mf i nf o Information about graphics file i m2f rame Convert image to movie frame i mread Read image from graphics file i mwrite Write image to graphics file

i nd2rgb Convert indexed image to RGB image

Printing

ori ent Hardcopy paper orientation pageset updl g Page position dialog box

print Print graph or save graph to file

pri nt dl g Print dialog box

pri nt opt Configure local printer defaults pri nt previ ew saveas Preview figure to be printed Save figure to graphic file

Handle Graphics

• Finding and Identifying Graphics Objects

• Object Creation Functions

• Figure Windows

• Axes Operations

Finding and Identifying Graphics Objects

al l chi l d Find all children of specified objects

copyobj Make copy of graphics object and its children

del et e Delete files or graphics objects

findal l Find all graphics objects (including hidden handles)

findobj Find objects with specified property values

gca Get current Axes handle

gcbo Return object whose callback is currently executing gcbf Return handle of figure containing callback object

gco Return handle of current object

get Get object properties

i shandle True if value is valid object handle

rotate Rotate objects about specified origin and direction

set Set object properties

Object Creation Functions

axes Create axes object

figure Create figure (graph) windows i mage Create image (2-D matrix)

light Create light object (illuminates Patch and Surface)

1 i ne Create line object (3-D polylines)
patch Create patch object (polygons)

rectangle Create rectangle object (2-D rectangle)

surface Create surface (quadrilaterals) text Create text object (character strings)

ui context menu (popup associated with object)

Figure Windows

capture Screen capture of the current figure

cl c Clear figure window

cl f Clear figure

cl ose
cl osereq
Close specified window
Default close request function
Complete any pending drawing
Get current figure handle

newpl ot Graphics M-file preamble for NextPl ot property

refresh Refresh figure

saveas Save figure or model to desired output format

Axes Operations

axi s Plot axis scaling and appearance

cl a Clear Axes

gca Get current Axes handle

grid Grid lines for 2-D and 3-D plots

3-D Visualization

Create and manipulate graphics that display 2-D matrix and 3-D volume data, controlling the view, lighting and transparency.

Category	Description
Surface and Mesh Plots	Plot matrices, visualize functions of two variables, specify colormap
View Control	Control the camera viewpoint, zooming, rotation, aspect ratio, set axis limits
Lighting	Add and control scene lighting
Transparency	Specify and control object transparency
Volume Visualization	Visualize gridded volume data

Surface and Mesh Plots

- Creating Surfaces and Meshes
- Domain Generation
- Color Operations
- Colormaps

Creating Surfaces and Meshes

hi dden	Mesh hidden line removal mode
meshc	Combination mesh/contourplot
mesh	3-D mesh with reference plane
peaks	A sample function of two variables
surf	3-D shaded surface graph
surface	Create surface low-level objects
surfc	Combination surf/contourplot
surfl	3-D shaded surface with lighting
tetramesh	Tetrahedron mesh plot
trimesh	Triangular mesh plot
tri pl ot	2-D triangular plot
tri surf	Triangular surface plot

Domain Generation

gri ddata Data gridding and surface fitting

meshgrid Generation of X and Y arrays for 3-D plots

Color Operations

bri ghten Brighten or darken color map
caxi s Pseudocolor axis scaling
col orbar Display color bar (color scale)

col ordef Set up color defaults

col ormap
graymon
Set the color look-up table (list of colormaps)
Graphics figure defaults set for grayscale monitor
Hue-saturation-value to red-green-blue conversion

rgb2hsv RGB to HSVconversion

rgbpl ot Plot color map
shadi ng Color shading mode
spi nmap Spin the colormap
surfnorm 3-D surface normals

whi tebg Change axes background color for plots

Colormaps

autumn Shades of red and yellow color map
bone Gray-scale with a tinge of blue color map
contrast Gray color map to enhance image contrast
cool Shades of cyan and magenta color map

copper Linear copper-tone color map

flag Alternating red, white, blue, and black color map

gray Linear gray-scale color map hot Black-red-yellow-white color map hsv Hue-saturation-value (HSV) color map

j et Variant of HSV lines Line color colormap prism Colormap of prism colors

spring Shades of magenta and yellow color map summer Shades of green and yellow colormap winter Shades of blue and green color map

View Control

- Controlling the Camera Viewpoint
- Setting the Aspect Ratio and Axis Limits
- Object Manipulation

Selecting Region of Interest

Controlling the Camera Viewpoint

camdol l y Move camera position and target

caml ookat View specific objects Camorbit Orbit about camera target

campan Rotate camera target about camera position

campos Set or get camera position camproj Set or get projection type

camrol l Rotate camera about viewing axis

camtarget Set or get camera target
camup Set or get camera up-vector
camva Set or get camera view angle
camzoom Zoom camera in or out

vi ew 3-D graph viewpoint specification.
vi ewmtx Generate view transformation matrices

Setting the Aspect Ratio and Axis Limits

daspect Set or get data aspect ratio

pbaspect Set or get plot box aspect ratio

xlim Set or get the current x-axis limits

ylim Set or get the current y-axis limits

zlim Set or get the current z-axis limits

Object Manipulation

reset Reset axis or figure

rotate3d Interactively rotate the view of a 3-D plot sel ectmoveresi zeInteractively select, move, or resize objects

zoom Zoom in and out on a 2-D plot

Selecting Region of Interest

dragrect Drag XOR rectangles with mouse

rbbox Rubberband box

Lighting

caml i ght Cerate or position Light
l i ght Light object creation function

lightangle Position light in sphereical coordinates

lighting Lighting mode

material Material reflectance mode

Transparency

al pha Set or query transparency properties for objects in current axes

al phamap
al i m
Specify the figure alphamap
Set or query the axes alpha limits

Volume Visualization

conepl ot Plot velocity vectors as cones in 3-D vector field

contours lice Draw contours in volume slice plane

curl Compute curl and angular velocity of vector field

di vergence Compute divergence of vector field flow Generate scalar volume data

interpstreamspeedInterpolate streamline vertices from vector-field magnitudes

i socaps
i socol ors
i sonormal s
Compute isosurface end-cap geometry
Compute colors of isosurface vertices
Compute normals of isosurface vertices
Extract isosurface data from volume data

reducepatch Reduce number of patch faces

reducevol ume Reduce number of elements in volume data set

shrinkfaces Reduce size of patch faces slice Draw slice planes in volume

smooth3 Smooth 3-D data

stream2 Compute 2-D stream line data stream3 Compute 3-D stream line data

streamline Draw stream lines from 2- or 3-D vector data streamparticles Draws stream particles from vector volume data streamribbon Draws stream ribbons from vector volume data

streamslice Draws well-spaced stream lines from vector volume data

streamtube Draws stream tubes from vector volume data

surf2patch Convert surface data to patch data subvol ume Extract subset of volume data set

vol umebounds Return coordinate and color limits for volume (scalar and vector)

Creating Graphical User Interfaces

Predefined dialog boxes and functions to control GUI programs.

Category	Description
Predefined Dialog Boxes	Dialog boxes for error, user input, waiting, etc.
Deploying User Interfaces	Launching GUIs, creating the handles structure
Developing User Interfaces	Starting GUIDE, managing application data, getting user input
User Interface Objects	Creating GUI components
Finding and Identifying Objects	Finding object handles from callbacks
GUI Utility Functions	Moving objects, text wrapping
Controlling Program Execution	Wait and resume based on user input

Predefined Dialog Boxes

di al og	Create dialog box
errordl g	Create error dialog box
hel pdl g	Display help dialog box
i nput dl g	Create input dialog box
listdlg	Create list selection dialog box
msgbox	Create message dialog box
pagedl g	Display page layout dialog box
pri nt dl g	Display print dialog box
questdlg	Create question dialog box
ui getfi l e	Display dialog box to retrieve name of file for reading
ui putfile	Display dialog box to retrieve name of file for writing
ui set col or	Set Col orSpec using dialog box
ui setfont	Set font using dialog box
wai tbar	Display wait bar
warndl g	Create warning dialog box

Deploying User Interfaces

gui data
gui handl es
movegui
openfi g

Store or retrieve application data
Create a structure of handles
Move GUI figure onscreen
Open or raise GUI figure

Developing User Interfaces

gui de Open GUI Layout Editor i nspect Display Property Inspector

Working with Application Data

get appdata
i sappdata
rmappdata
set appdata
Set appdata

Get value of application data
True if application data exists
Remove application data
Specify application data

Interactive User Input

gi nput Graphical input from a mouse or cursor waitforbuttonpressWait for key/buttonpress over figure

User Interface Objects

menu Generate menu of choices for user input

ui contextmenu Create context menu

ui control Create user interface control ui menu Create user interface menu

Finding and Identifying Objects

findal l Find all graphics objects

findfigs Display off-screen visible figure windows

gcbf Return handle of figure containing callback object gcbo Return handle of object whose callback is executing

GUI Utility Functions

sel ect moveresi zeSelect, move, resize, or copy axes and uicontrol graphics objects textwrap

Return wrapped string matrix for given uicontrol

Controlling Program Execution

ui resumeResumes program execution halted with ui wai tui wai tHalts program execution, restart with ui resume

Purpose

Matrix and array arithmetic

Syntax

Description

MATLAB has two different types of arithmetic operations. Matrix arithmetic operations are defined by the rules of linear algebra. Array arithmetic operations are carried out element-by-element. The period character (.) distinguishes the array operations from the matrix operations. However, since the matrix and array operations are the same for addition and subtraction, the character pairs . + and . – are not used.

- + Addition or unary plus. A+B adds A and B. A and B must have the same size, unless one is a scalar. A scalar can be added to a matrix of any size.
- Subtraction or unary minus. A–B subtracts B from A. A and B must have the same size, unless one is a scalar. A scalar can be subtracted from a matrix of any size.
- * Matrix multiplication. C = A*B is the linear algebraic product of the matrices A and B. More precisely,

$$C(i, j) = \sum_{k=1}^{n} A(i, k)B(k, j)$$

For nonscalar A and B, the number of columns of A must equal the number of rows of B. A scalar can multiply a matrix of any size.

- .* Array multiplication. A.*B is the element-by-element product of the arrays A and B. A and B must have the same size, unless one of them is a scalar.
- / Slash or matrix right division. B/A is roughly the same as B*i nv(A). More precisely, $B/A = (A' \ B')'$. See \.

- Array right division. A. /B is the matrix with elements A(i,j)/B(i,j). A and B must have the same size, unless one of them is a scalar.
- Backslash or matrix left division. If A is a square matrix, A\B is roughly the same as i nv(A) *B, except it is computed in a different way. If A is an n-by-n matrix and B is a column vector with n components, or a matrix with several such columns, then $X = A \setminus B$ is the solution to the equation AX = B computed by Gaussian elimination (see "Algorithm" for details). A warning message prints if A is badly scaled or nearly singular.

If A is an m-by-n matrix with m \sim = n and B is a column vector with m components, or a matrix with several such columns, then X = A\B is the solution in the least squares sense to the under- or overdetermined system of equations AX = B. The effective rank, k, of A, is determined from the QR decomposition with pivoting (see "Algorithm" for details). A solution X is computed which has at most k nonzero components per column. If k < n, this is usually not the same solution as pi nv(A) *B, which is the least squares solution with the smallest norm, |X| = A

- Array left division. A. \B is the matrix with elements B(i,j)/A(i,j). A and B must have the same size, unless one of them is a scalar.
- ^ Matrix power. X^p is X to the power p, if p is a scalar. If p is an integer, the power is computed by repeated squaring. If the integer is negative, X is inverted first. For other values of p, the calculation involves eigenvalues and eigenvectors, such that if [V, D] = eig(X), then $X^p = V*D$. p/V.

If x is a scalar and P is a matrix, x^P is x raised to the matrix power P using eigenvalues and eigenvectors. X^P , where X and P are both matrices, is an error.

- . ^ Array power. A. ^B is the matrix with elements A(i,j) to the B(i,j) power. A and B must have the same size, unless one of them is a scalar.
- Matrix transpose. A' is the linear algebraic transpose of A. For complex matrices, this is the complex conjugate transpose.
- Array transpose. A. ' is the array transpose of A. For complex matrices, this does not involve conjugation.

Remarks

The arithmetic operators have M-file function equivalents, as shown:

Binary addition	A+B	plus(A, B)
Unary plus	+A	uplus(A)
Binary subtraction	A–B	minus(A, B)
Unary minus	-A	umi nus(A)
Matrix multiplication	A*B	mtimes(A,B)
Array-wise multiplication	A. *B	times(A,B)
Matrix right division	A/B	mrdi vi de(A, B)
Array-wise right division	A. /B	rdi vi de(A, B)
Matrix left division	$A \setminus B$	ml di vi de(A, B)
Array-wise left division	A. \B	l di vi de (A, B)
Matrix power	A^B	<pre>mpower(A, B)</pre>
Array-wise power	A. ^B	power(A, B)
Complex transpose	A'	ctranspose(A)
Matrix transpose	A. '	transpose(A)

Examples

Here are two vectors, and the results of various matrix and array operations on them, printed with format ${\tt rat.}$

(x+i *y) '	1 - 4i	2 - 5i	3 - 6i	
(x+i *y). '	1 + 4i	2 + 5i	3 + 6i	

Algorithm

The specific algorithm used for solving the simultaneous linear equations denoted by $X = A \setminus B$ and $X = B \setminus A$ depends upon the structure of the coefficient matrix A.

- If A is a triangular matrix, or a permutation of a triangular matrix, then X can be computed quickly by a permuted backsubstitution algorithm. The check for triangularity is done for full matrices by testing for zero elements and for sparse matrices by accessing the sparse data structure. Most nontriangular matrices are detected almost immediately, so this check requires a negligible amount of time.
- If A is symmetric, or Hermitian, and has positive diagonal elements, then a
 Cholesky factorization is attempted (see chol). If A is found to be positive
 definite, the Cholesky factorization attempt is successful and requires less
 than half the time of a general factorization. Nonpositive definite matrices
 are usually detected almost immediately, so this check also requires little
 time. If successful, the Cholesky factorization is

```
A = R' *R
```

where R is upper triangular. The solution X is computed by solving two triangular systems,

```
X = R \setminus (R' \setminus B)
```

If A is sparse, a symmetric minimum degree preordering is applied (see symmed and spparms). The algorithm is:

- If A is Hessenberg, it is reduced to an upper triangular matrix and that system is solved via substitution.
- If A is square, but not a permutation of a triangular matrix, or is not Hermitian with positive elements, or the Cholesky factorization fails, then a general triangular factorization is computed by Gaussian elimination with partial pivoting (see l u). This results in

```
A = L*U
```

where L is a permutation of a lower triangular matrix and $\mbox{\bf U}$ is an upper triangular matrix. Then X is computed by solving two permuted triangular systems.

```
X = U \setminus (L \setminus B)
```

If A is sparse, a nonsymmetric minimum degree preordering is applied (see col mmd and spparms). The algorithm is

• If A is not square and is full, then Householder reflections are used to compute an orthogonal-triangular factorization.

```
A*P = Q*R
```

where P is a permutation, Q is orthogonal and R is upper triangular (see ${\rm qr}).$ The least squares solution X is computed with

```
X = P*(R\setminus(Q'*B)
```

• If A is not square and is sparse, then MATLAB computes a least squares solution using the sparse qr factorization of A.

Note Backslash is not implemented for matrices A that are not square, and are also sparse and complex.

MATLAB uses LAPACK routines to compute the various full matrix factorizations:

Matrix	Real	Complex
Full square, symmetric (Hermitian) positive definite	DLANGE, DPOTRF, DPOTRS, DPOCON	ZLANGE, ZPOTRF, ZPOTRS ZPOCON
Full square, general case	DLANGE, DGESV, DGECON	ZLANGE, ZGESV, ZGECON
Full non-square	DGEQPF, DORMQR, DTRTRS	ZGEQPF, ZORMQR, ZTRTRS

For other cases (triangular and Hessenberg) MATLAB does not use LAPACK.

Diagnostics

From matrix division, if a square A is singular:

Warning: Matrix is singular to working precision.

From element-wise division, if the divisor has zero elements:

Warning: Divide by zero.

The matrix division returns a matrix with each element set to Inf; the element-wise division produces NaNs or Infs where appropriate.

If the inverse was found, but is not reliable:

Warning: Matrix is close to singular or badly scaled. Results may be inaccurate. RCOND = xxx

From matrix division, if a nonsquare A is rank deficient:

Warning: Rank deficient, rank = xxx tol = xxx

Purpose

Relational operations

Syntax

A < B A > B A <= B A >= B

A == B $A \sim= B$

Description

The relational operators are <, \le , >, \ge , ==, and \sim =. Relational operators perform element-by-element comparisons between two arrays. They return an array of the same size, with elements set to logical true (1) where the relation is true, and elements set to logical false (0) where it is not.

The operators <, \le , >, and \ge use only the real part of their operands for the comparison. The operators == and $\sim=$ test real and imaginary parts.

To test if two strings are equivalent, use strcmp, which allows vectors of dissimilar length to be compared.

Examples

If one of the operands is a scalar and the other a matrix, the scalar expands to the size of the matrix. For example, the two pairs of statements:

```
X = 5; X >= [1 2 3; 4 5 6; 7 8 10]

X = 5*ones(3,3); X >= [1 2 3; 4 5 6; 7 8 10]
```

produce the same result:

ans =

1 1 1
1 1 0

0

0

0

Relational Operators < > <= >= == ~=

See Also all, any, find, strcmp

The logical operators &, \mid , \sim

Logical Operators &

~

Purpose

Logical operations

Syntax

A & B
A | B
~A

Description

The symbols &, |, and \sim are the logical operators AND, OR, and NOT. They work element-wise on arrays, with 0 representing logical false (F), and anything nonzero representing logical true (T). The & operator does a logical AND, the | operator does a logical OR, and \sim A complements the elements of A. The function xor(A, B) implements the exclusive OR operation. Truth tables for these operators and functions follow.

Inputs A	В	and A&B	or A B	xor (A, B)	NOT ~A
0	0	0	0	0	1
0	1	0	1	1	1
1	0	0	1	1	0
1	1	1	1	0	0

The precedence for the logical operators with respect to each other is:

- 1 not has the highest precedence.
- 2 and and or have equal precedence, and are evaluated from left to right.

Remarks

The logical operators have M-file function equivalents, as shown:

and	A&B	and(A, B)	
or	A B	or(A, B)	
not	~A	not (A)	

Precedence of & and | Operators

MATLAB always gives the & operator precedence over the | operator. Although MATLAB typically evaluates expressions from left to right, the

expression $a \mid b\&c$ is evaluated as $a \mid (b\&c)$. It is a good idea to use parentheses to explicitly specify the intended precedence of statements containing combinations of & and \mid .

Partial Evaluation

Within the context of an if or while expression, MATLAB does not necessarily evaluate all parts of a logical expression. In some cases it is possible, and often advantageous, to determine whether an expression is true or false through only partial evaluation.

For example, if A equals zero in statement 1 below, then the expression evaluates to fal se, regardless of the value of B. In this case, there is no need to evaluate B and MATLAB does not do so. In statement 2, if A is nonzero, then the expression is true, regardless of B. Again, MATLAB does not evaluate the latter part of the expression.

You can use this property to your advantage to cause MATLAB to evaluate a part of an expression only if a preceding part evaluates to the desired state.

Examples

Here are some examples of using partial evaluation.

```
while (b \sim= 0) & (a/b > 18.5)
if exist('myfun.m') & (myfun(x) >= y)
if iscell(A) & all(cellfun('isreal', A))
```

The relational operators: <, <=, >=, ==, $\sim=$ ì

Special Characters []() ${}$ = '...,; %!

Purpose Special characters

Syntax [] () {} = ' , ; % !

Description

Brackets are used to form vectors and matrices. [6.99.64 sqrt(-1)] is a vector with three elements separated by blanks. [6.9,9.64,i] is the same thing. [1+j2-j3] and [1+j2-j3] are not the same. The first has three elements, the second has five.

[11 12 13; 21 22 23] is a 2-by-3 matrix. The semicolon ends the first row.

Vectors and matrices can be used inside [] brackets. [A B; C] is allowed if the number of rows of A equals the number of rows of B and the number of columns of A plus the number of columns of B equals the number of columns of C. This rule generalizes in a hopefully obvious way to allow fairly complicated constructions.

A = [] stores an empty matrix in A. A(m, :) = [] deletes row m of A. A(:, n) = [] deletes column n of A. A(n) = [] reshapes A into a column vector and deletes the third element.

[A1, A2, A3. . .] = function assigns function output to multiple variables.

For the use of [and] on the left of an "=" in multiple assignment statements, see l u, ei g, svd, and so on.

{ } Curly braces are used in cell array assignment statements. For example,

 $A(2, 1) = \{[1\ 2\ 3;\ 4\ 5\ 6]\}, or A\{2, 2\} = ('str').$ See help paren for more information about $\{\}$.

Special Characters [](){} = ' , ; %!

- Parentheses are used to indicate precedence in arithmetic expressions in the usual way. They are used to enclose arguments of functions in the usual way. They are also used to enclose subscripts of vectors and matrices in a manner somewhat more general than usual. If X and V are vectors, then X(V) is $[X(V(1)), X(V(2)), \ldots, X(V(n))]$. The components of V must be integers to be used as subscripts. An error occurs if any such subscript is less than 1 or greater than the size of X. Some examples are
 - X(3) is the third element of X.
 - X([1 2 3]) is the first three elements of X.

See help paren for more information about ().

If X has n components, X(n:-1:1) reverses them. The same indirect subscripting works in matrices. If V has m components and W has n components, then A(V, W) is the m-by-n matrix formed from the elements of A whose subscripts are the elements of V and W For example, A([1,5],:) = A([5,1],:) interchanges rows 1 and 5 of A.

- Used in assignment statements. B = A stores the elements of A in B.
 is the relational equals operator. See the Relational Operators page.
- Matrix transpose. X' is the complex conjugate transpose of X. X. ' is the nonconjugate transpose.

Quotation mark. 'any text' is a vector whose components are the ASCII codes for the characters. A quotation mark within the text is indicated by two quotation marks.

- Decimal point. 314/100, 3.14 and .314e1 are all the same. Element-by-element operations. These are obtained using . * , .^ , . /, or . \. See the Arithmetic Operators page.
- Field access. A. (field) and A(i). field, when A is a structure, access the contents of field.
- .. Parent directory. See cd.
- ... Continuation. Three or more points at the end of a line indicate continuation.

Special Characters []() ${}$ = '...,; %!

- Comma. Used to separate matrix subscripts and function arguments. Used to separate statements in multistatement lines. For multi-statement lines, the comma can be replaced by a semicolon to suppress printing.
- Semicolon. Used inside brackets to end rows. Used after an expression or statement to suppress printing or to separate statements.
- % Percent. The percent symbol denotes a comment; it indicates a logical end of line. Any following text is ignored. MATLAB displays the first contiguous comment lines in a M-file in response to a help command.
- ! Exclamation point. Indicates that the rest of the input line is issued as a command to the operating system. On the PC, adding & to the end of the ! command line, as in ! di r &, causes the output to appear in a separate window.

Remarks

Some uses of special characters have M-file function equivalents, as shown:

Horizontal concatenation	[A, B, C]	horzcat (A, B, C)
Vertical concatenation	[A; B; C]	vertcat(A, B, C)
Subscript reference	A(i,j,k)	$subsref(A,S).Seehelp\\subsref.$
Subscript assignment	A(i,j,k) = B	subsasgn(A, S, B). See hel p subsasgn.

Create vectors, array subscripting, and for loop iterations

Description

The colon is one of the most useful operators in MATLAB. It can create vectors, subscript arrays, and specify for iterations.

The colon operator uses the following rules to create regularly spaced vectors:

- j: k is the same as [j, j+1, ..., k]
- j: k is empty if j > k
- j:i:k is the same as $[j,j+i,j+2i,\ldots,k]$
- j:i:k is empty if i > 0 and j > k or if i < 0 and j < k

where i, j, and k are all scalars.

Below are the definitions that govern the use of the colon to pick out selected rows, columns, and elements of vectors, matrices, and higher-dimensional arrays:

- A(:,j) is the j-th column of A
- A(i,:) is the i-th row of A
- A(:,:) is the equivalent two-dimensional array. For matrices this is the same as A.
- A(j:k) is A(j), A(j+1),..., A(k)
- A(:,j:k) is A(:,j), A(:,j+1),..., A(:,k)
- A(:,:,k) is the kth page of three-dimensional array A.
- A(i,j,k,:) is a vector in four-dimensional array A. The vector includes A(i,j,k,1), A(i,j,k,2), A(i,j,k,3), and so on.
- A(:) is all the elements of A, regarded as a single column. On the left side of an assignment statement, A(:) fills A, preserving its shape from before. In this case, the right side must contain the same number of elements as A.

Colon:

Examples

Using the colon with integers,

$$D = 1:4$$

results in

$$D = 1 2 3 4$$

Using two colons to create a vector with arbitrary real increments between the elements,

$$E = 0:.1:.5$$

results in

The command

$$A(:,:,2) = pascal(3)$$

generates a three-dimensional array whose first page is all zeros.

$$A(:,:,2) = \\ 1 & 1 & 1 \\ 1 & 2 & 3 \\ 1 & 3 & 6$$

See Also

 $for,\,l\,i\,nspace,\,l\,ogspace,\,reshape$

Purpose Absolute value and complex magnitude

Syntax Y = abs(X)

Description abs (X) returns the absolute value, |X|, for each element of X.

If X is complex, abs(X) returns the complex modulus (magnitude),

 $abs(X) = sqrt(real(X).^2 + imag(X).^2)$

Examples abs(-5)

ans = 5

abs(3+4i)

ans = 5

See Also angle, sign, unwrap

Inverse cosine and inverse hyperbolic cosine

Syntax

Y = acos(X)Y = acosh(X)

Description

The acos and acosh functions operate element-wise on arrays. The functions' domains and ranges include complex values. All angles are in radians.

 $Y = a\cos(X)$ returns the inverse cosine (arccosine) for each element of X. For real elements of X in the domain [-1,1], $a\cos(X)$ is real and in the range $[0,\pi]$. For real elements of X outside the domain [-1,1], $a\cos(X)$ is complex.

 $Y = a\cosh(X)$ returns the inverse hyperbolic cosine for each element of X.

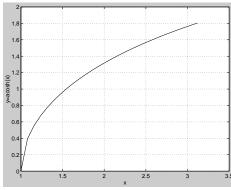

Examples

Graph the inverse cosine function over the domain $-1 \le x \le 1$, and the inverse hyperbolic cosine function over the domain $1 \le x \le \pi$.

```
x = -1:.05:1; plot(x, acos(x))

x = 1: pi/40: pi; plot(x, acosh(x))
```

Algorithm

acos and acosh use these algorithms.

$$\cos^{-1}(z) = -i \log \left[z + i(1-z^2)^{\frac{1}{2}} \right]$$

$$\cosh^{-1}(z) = \log \left[z + (z^2 - 1)^{\frac{1}{2}} \right]$$

See Also

cos, cosh

Inverse cotangent and inverse hyperbolic cotangent

Syntax

Y = acot(X)Y = acoth(X)

Description

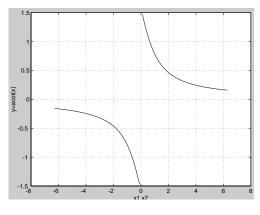

The acot and acoth functions operate element-wise on arrays. The functions' domains and ranges include complex values. All angles are in radians.

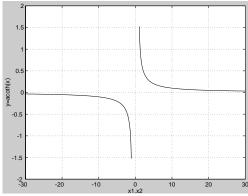

Y = acot(X) returns the inverse cotangent (arccotangent) for each element of X.

Y = acoth(X) returns the inverse hyperbolic cotangent for each element of X.

Examples

Graph the inverse cotangent over the domains $-2\pi \le x < 0$ and $0 < x \le 2\pi$, and the inverse hyperbolic cotangent over the domains $-30 \le x < -1$ and $1 < x \le 30$.

Algorithm

acot and acoth use these algorithms.

$$\cot^{-1}(z) = \tan^{-1}\left(\frac{1}{z}\right)$$
$$\coth^{-1}(z) = \tanh^{-1}\left(\frac{1}{z}\right)$$

See Also

cot, coth

Inverse cosecant and inverse hyperbolic cosecant

Syntax

Y = acsc(X)Y = acsch(X)

Description

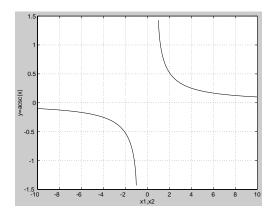

The acsc and acsch functions operate element-wise on arrays. The functions' domains and ranges include complex values. All angles are in radians.

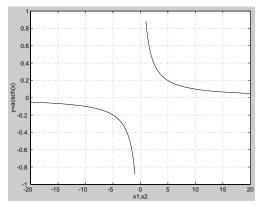

Y = acsc(X) returns the inverse cosecant (arccosecant) for each element of X.

Y = acsch(X) returns the inverse hyperbolic cosecant for each element of X.

Examples

Graph the inverse cosecant over the domains $-10 \le x < -1$ and $1 < x \le 10$, and the inverse hyperbolic cosecant over the domains $-20 \le x \le -1$ and $1 \le x \le 20$.

Algorithm

acsc and acsch use these algorithms.

$$\csc^{-1}(z) = \sin^{-1}\left(\frac{1}{z}\right)$$

$$\operatorname{csch}^{-1}(z) = \sinh^{-1}\left(\frac{1}{z}\right)$$

Create an ActiveX control in a figure window.

Syntax

```
h =actxcontrol (progid [, position [, handle ...
[, callback |{event1 eventhandler1; ...
event2 eventhandler2; ...}]]])
```

Arguments

progi d

String that is the name of the control to create. The control vendor provides this string.

positi on

Position vector containing the x and y location and the xsi ze and ysi ze of the control, expressed in pixel units as $[x \ y \ xsi \ ze \ ysi \ ze]$. Defaults to $[20 \ 20 \ 60 \ 60]$.

handl e

Handle Graphics handle of the figure window in which the control is to be created. If the control should be invisible, use the handle of an invisible figure window. Defaults to gcf.

call back

Name of an M-function that accepts a variable number of arguments. This function will be called whenever the control triggers an event. Each argument is converted to a MATLAB string; the first argument is always a string that represents the numerical value of the event that was triggered. These numerical values are defined by the control. (See the section, "Writing Event Handlers" in *MATLAB External Interfaces*, for more information on handling control events.)

event

Triggered event specified by either number or name.

eventhandl er

Name of an M-function that accepts a variable number of arguments. This function will be called whenever the control triggers the event associated with it. The first argument is the activex object, the second number represents the numerical value of the event that was triggered. Note that the second number is not converted to a string as is the case in the "callback" M-file style. These values are defined by the control. See "Writing Event Handlers" in *MATLAB External Interfaces* for more information on handling control events.

Note There are two ways to handle events. You can create a single callback or you can specify a cell array that contains pairs of events and event handlers. In the cell array format, specify events by either number or name. Each control defines event numbers and names. There is no limit to the number of pairs that can be specified in the cell array. Although using the single callback method may be easier in some cases, using the cell array technique creates more efficient code that results in better performance.

Returns

A MATLAB activex object that represents the default interface for this control or server. Use the get, set, invoke, propedit, release, and delete methods on this object. A MATLAB error will be generated if this call fails.

Description

Create an ActiveX control at a particular location within a figure window. If the parent figure window is invisible, the control will be invisible. The returned MATLAB activex object represents the default interface for the control. This interface must be released through a call to release when it is no longer needed to free the memory and resources used by the interface. Note that releasing the interface does not delete the control itself (use the delete command to delete the control.)

For an example callback event handler, see the file sampev. m in the tool box\matlab\wi nfun directory.

Example

Callback style:

```
f = figure ('pos', [100 200 200 200]);
% create the control to fill the figure
h = actxcontrol ('MWSAMP. MwsampCtrl.1', [0 0 200 200], ...
gcf, 'sampev')

Cell array style:
h = actxcontrol ('SELECTOR. SelectorCtrl.1', ...
[0 0 200 200], f, {-600 'myclick'; -601 'my2click'; ...
-605 'mymoused'})

h = actxcontrol ('SELECTOR. SelectorCtrl.1', ...
[0 0 200 200], f, {'Click' 'myclick'; ...
```

```
'DblClick' 'my2click'; 'MouseDown' 'mymoused'})
where the event handlers, myclick. m, my2click. m, and mymoused. m are
function myclick(varargin)
disp('Single click function')

function my2click(varargin)
disp('Double click function')

function mymoused(varargin)
disp('You have reached the mouse down function')
disp('The X position is: ')
varargin(5)
disp('The Y position is: ')
varargin(6)
```

You can use the same event handler for all the events you want to monitor using the cell array pairs. Response time will be better than using the callback style.

For example

```
h = actxcontrol('SELECTOR. SelectorCtrl.1', ...
[0 0 200 200], f, {'Click' 'allevents'; ...
'DblClick' 'allevents'; 'MouseDown' 'allevents'})
and allevents. m is
function allevents(varargin)
if (varargin{2} = -600)
    disp ('Single Click Event Fired')
elseif (varargin{2} = -601)
    disp ('Double Click Event Fired')
elseif (varargin{2} = -605)
    disp ('Mousedown Event Fired')
end
```

Create an ActiveX automation server and return an activex object for the server's default interface.

Syntax

h = actxserver (progid [, MachineName])

Arguments

progi d

This is a string that is the name of the control to instantiate. This string is provided by the control or server vendor and should be obtained from the vendor's documentation. For example, the progi d for Microsoft Excel is Excel. Appl i cation.

Machi neName

This is the name of a remote machine on which the server is to be run. This argument is optional and is used only in environments that support Distributed Component Object Model (DCOM) — see "Using MATLAB As a DCOM Server Client" in *MATLAB External Interfaces*. This can be an IP address or a DNS name.

Returns

An acti vex object that represents the server's default interface. Use the get, set, i nvoke, rel ease, and del ete methods on this object. A MATLAB error will be generated if this call fails.

Description

Create an ActiveX automation server and return a MATLAB activex object that represents the server's default interface. Local/Remote servers differ from controls in that they are run in a separate address space (and possibly on a separate machine) and are not part of the MATLAB process. Additionally, any user interface that they display will be in a separate window and will not be attached to the MATLAB process. Examples of local servers are Microsoft Excel and Microsoft Word. Note that automation servers do not use callbacks or event handlers.

Example

```
% Launches Microsoft Excel and makes main frame window visible. 
 h = actxserver ('Excel.Application') 
 set (h, 'Visible', 1);
```

addframe

Purpose

Add a frame to an Audio Video Interleaved (AVI) file.

Syntax

```
avi obj = addframe(avi obj, frame)
avi obj = addframe(avi obj, frame1, frame2, frame3, . . .)
avi obj = addframe(avi obj, mov)
avi obj = addframe(avi obj, h)
```

Description

avi obj = addframe(avi obj, frame) appends the data in frame to the AVI file identified by avi obj, which was created by a previous call to avi file. frame can be either an indexed image (m-by-n) or a truecolor image (m-by-n-by-3) of double or uint8 precision. If frame is not the first frame added to the AVI file, it must be consistent with the dimensions of the previous frames.

 $add frame\ returns\ a\ handle\ to\ the\ updated\ AVI\ file\ object,\ avi\ obj\ .\ For\ example,\ add frame\ updates\ the\ Tot\ al\ Frames\ property\ of\ the\ AVI\ file\ object\ each\ time\ it\ adds\ a\ frame\ to\ the\ AVI\ file.$

avi obj = addframe(avi obj, frame1, frame2, frame3,...) adds multiple frames to an AVI file.

avi obj = addframe(avi obj, mov) appends the frame(s) contained in the MATLAB movie, mov, to the AVI file, avi obj. MATLAB movies that store frames as indexed images use the colormap in the first frame as the colormap for the AVI file, unless the colormap has been previously set.

avi obj = addframe (avi obj, h) captures a frame from the figure or axis handle h, and appends this frame to the AVI file. addframe renders the figure into an offscreen array before appending it to the AVI file. This ensures that the figure is written correctly to the AVI file even if the figure is obscured on the screen by another window or screen saver.

Note If an animation uses XOR graphics, you must use getframe to capture the graphics into a frame of a MATLAB movie. You can then add the frame to an AVI movie using the addframe syntax, avi obj = addframe(avi obj, mov). See the example for an illustration.

Example

This example calls addframe to add frames to the AVI file object, avi obj .

```
fig=figure;
set(fig, 'DoubleBuffer', 'on');
set(gca, 'xlim', [-80 80], 'ylim', [-80 80], ...
    'nextplot', 'replace', 'Visible', 'off')

aviobj = avifile('example.avi')

x = -pi:.1:pi;
radius = 0:length(x);
for i=1:length(x)
    h = patch(sin(x)*radius(i), cos(x)*radius(i), ...
        [abs(cos(x(i))) 0 0]);
    set(h, 'EraseMode', 'xor');
    frame = getframe(gca);
    aviobj = addframe(aviobj, frame);
end

aviobj = close(aviobj);
```

addpath

Purpose

Add directories to MATLAB search path

Graphical Interface

As an alternative to the addpath function, use the **Set Path** dialog box. To open it, select **Set Path** from the **File** menu in the MATLAB desktop.

Syntax

```
addpath('directory')
addpath('dir','dir2','dir3' ...)
addpath('dir','dir2','dir3' ...'-flag')
addpath dir1 dir2 dir3 ... -flag
```

Description

 $addpath('\ di\ rectory')\ prepends\ the\ specified\ directory\ to\ MATLAB's\ current\ search\ path,\ that\ is,\ it\ adds\ them\ to\ the\ front\ of\ the\ path.\ Use\ the\ full\ pathname\ for\ di\ rectory.$

 $addpath('dir', 'dir2', 'dir3' \dots)$ prepends all the specified directories to the path. Use the full pathname for each dir.

 $addpath('di\,r'\,,'di\,r2'\,,'di\,r3'\,\ldots\,'-fl\,ag'\,)\quad either\ prepends\ or\ appends$ the specified directories to the path depending on the value of fl ag.

flag Argument	Result
0 or begi n	Prepend specified directories
1 or end	Append specified directories

addpath dir1 dir2 dir3 ... -flag is the unquoted form of the syntax.

Examples

For the current path, viewed by typing path,

MATLABPATH

c: \matl ab\tool box\generalc: \matl ab\tool box\opsc: \matl ab\tool box\strfun

you can add c: $\mbox{\mbox{$\mbox{mymfiles}$ to the front of the path by typing}}$

 $addpath(\ 'c: \ \ 'matlab \ 'mymfiles'\)$

Verify that the files were added to the path by typing $% \left\{ \mathbf{r}^{\prime}\right\} =\mathbf{r}^{\prime}$

path

and MATLAB returns

MATLABPATH

c: \matlab\mymfiles

c: \matlab\tool box\general

c: \matl ab\tool box\ops

c: \matlab\tool box\strfun

See Also path, pathtool, genpath, rehash, rmpath

airy

Purpose

Airy functions

Syntax

$$W = \operatorname{ai} \operatorname{ry}(Z)$$

$$W = \operatorname{ai} \operatorname{ry}(k, Z)$$

$$[W, i \operatorname{err}] = \operatorname{ai} \operatorname{ry}(k, Z)$$

Definition

The Airy functions form a pair of linearly independent solutions to

$$\frac{d^2W}{dZ^2} - ZW = 0$$

The relationship between the Airy and modified Bessel functions is

$$Ai(Z) = \left[\frac{1}{\pi}\sqrt{Z/3}\right] K_{1/3}(\zeta)$$

$$Bi(Z) = \sqrt{Z/3} \ [I_{-1/3}(\zeta) + I_{1/3}(\zeta)]$$

where

$$\zeta = \frac{2}{3}Z^{3/2}$$

Description

 $W = \operatorname{airy}(Z)$ returns the Airy function, $\operatorname{Ai}(Z)$, for each element of the complex array Z.

W = ai ry(k, Z) returns different results depending on the value of k.

k	Returns	
0	The same result as ai ry(Z).	
1	The derivative, $Ai'(Z)$.	
2	The Airy function of the second kind, $Bi(Z)$.	
3	The derivative, $Bi'(Z)$.	

[W, ierr] = airy(k, Z) also returns an array of error flags.

i err = 1 Illegal arguments.

i err = 2 Overflow. Return Inf.

i err = 3 Some loss of accuracy in argument reduction.

i err = 4 Unacceptable loss of accuracy, Z too large.

i err = 5 No convergence. Return NaN.

Set or query the axes alpha limits

Syntax

```
al pha_limits = alim
alim([amin amax])
alim_mode = alim('mode')
alim('alim_mode')
alim(axes_handle,...)
```

Description

al pha_limits = alim returns the alpha limits (the axes ALim property) of the current axes.

alim([amin amax]) sets the alpha limits to the specified values. amin is the value of the data mapped to the first alpha value in the alphamap, and amax is the value of the data mapped to the last alpha value in the alphamap. Data values in between are linearly interpolated across the alphamap, while data values outside are clamped to either the first or last alphamap value, whichever is closest.

alim_mode = alim('mode') returns the alpha limits mode (the axes ALimMode property) of the current axes.

alim('alim_mode') sets the alpha limits mode on the current axes. alim_mode can be:

- auto MATLAB automatically sets the alpha limits based on the alpha data of the objects in the axes.
- manual MATLAB does not change the alpha limits.

al i $m(axes_handl\ e, ...)$ operates on the specified axes.

Test to determine if all elements are nonzero

Syntax

$$B = all(A)$$

 $B = all(A, dim)$

Description

B = all(A) tests whether *all* the elements along various dimensions of an array are nonzero or logical true (1).

If A is a vector, all (A) returns logical true (1) if all of the elements are nonzero, and returns logical false (0) if one or more elements are zero.

If A is a matrix, all (A) treats the columns of A as vectors, returning a row vector of 1s and 0s.

If A is a multidimensional array, all (A) treats the values along the first non-singleton dimension as vectors, returning a logical condition for each vector.

B = all(A, dim) tests along the dimension of A specified by scalar dim.

Examples

Given,

$$A = [0.53 \ 0.67 \ 0.01 \ 0.38 \ 0.07 \ 0.42 \ 0.69]$$

then B = (A < 0.5) returns logical true (1) only where A is less than one half:

The all function reduces such a vector of logical conditions to a single condition. In this case, all (B) yields 0.

This makes all particularly useful in if statements,

where code is executed depending on a single condition, not a vector of possibly conflicting conditions.

Applying the all function twice to a matrix, as in all(all(A)), always reduces it to a scalar condition.

```
all(all(eye(3)))
ans =
0
```

alpha

Purpose

Set transparency properties for objects in current axes

Syntax

```
al pha(face_al pha)
al pha(al pha_data)
al pha(al pha_data_mappi ng)
al pha(obj ect_handl e, . . . )
```

Description

al pha sets one of three transparency properties, depending on what arguments you specify with the call to this function.

FaceAlpha

al pha(face_al pha) set the FaceAl pha property of all image, patch, and surface objects in the current axes. You can set face_al pha to:

- a scalar set the FaceAl pha property to the specified value (for images, set the Al phaData property to the specified value)
- 'flat' set the FaceAl pha property to flat
- 'interp' set the FaceAl pha property to interp
- 'texture' set the FaceAl pha property to texture
- 'opaque' set the FaceAl pha property to 1
- \bullet ' $cl\ ear'$ set the FaceAl pha property to 0

See Specifying a Single Transparency Value for more information.

AlphaData (Surface Objects)

al pha(al pha_data) sets the Al phaData property of all surface objects in the current axes. You can set al pha_data to:

- a matrix the same size as CData sets the Al phaData property to the specified values
- $\bullet\,$ ' $x'\,$ set the Al phaData property to be the same as XData
- $\bullet\,$ ' y' set the Al phaData property to be the same as YData
- 'z' set the Al phaData property to be the same as ZData
- 'color' set the AlphaData property to be the same as CData

 'rand' – set the Al phaData property to a matrix of random values equal in size to CData

AlphaData (Image Objects)

al pha(al pha_data) sets the Al phaData property of all image objects in the current axes. You can set al pha_data to:

- a matrix the same size as CData sets the Al phaData property to the specified value
- 'x' ignored
- 'y' ignored
- 'z' ignored
- 'color' set the AlphaData property to be the same as CData
- 'rand' set the Al phaData property to a matrix of random values equal in size to CData

FaceVertexAlphaData (Patch Objects)

al pha(al pha_data) sets the FaceVertexAl phaData property of all patch objects in the current axes. You can set al pha_data to:

- a matrix the same size as FaceVertexCData sets the FaceVertexAl phaData property to the specified value
- 'x' set the FaceVertexAl phaData property to be the same as Vertices(:, 1)
- 'y' set the FaceVertexAl phaData property to be the same as Vertices(:, 2)
- 'z' set the FaceVertexAl phaData property to be the same as Vertices(:, 3)
- 'color' set the FaceVertexAl phaData property to be the same as FaceVertexCData
- 'rand' set the FaceVertexAl phaData property to random values

See Mapping Data to Transparency for more information.

AlphaDataMapping

al pha(al pha_data_mappi ng) sets the Al phaDataMappi ng property of all image, patch, and surface objects in the current axes. You can set al pha_data_mappi ng to:

- 'scal ed' set the Al phaDataMappi ng property to scal ed
- 'di rect' set the Al phaDataMappi ng property to di rect
- 'none' set the Al phaDataMapping property to none

al pha(obj ect_handl e, val ue) set the transparency property only on the object identified by obj ect_handl e

See Also

Transparency in 3-D Visualization

Specify the figure alphamap (transparency)

Syntax

```
al phamap(al pha_map)
al phamap('parameter')
al phamap('parameter', length)
al phamap('parameter', del ta)
al phamap(figure_handle,...)
al pha_map = al phamap
al pha_map = al phamap(figure_handle)
al pha_map = al phamap('parameter')
```

Description

al phamap enables you to set or modify a figure's Al phamap property. Unless you specify a figure handle as the first argument, al phamap operates on the current figure.

al phamap(al pha_map) set the Al phaMap of the current figure to the specified m-by-1 array of alpha values.

al phamap('parameter') create a new or modify the current alphamap. You can specify the following parameters:

- ullet defaul t set the Al phaMap property to the figure's default alphamap
- rampup create a linear alphamap with increasing opacity (default 1 ength equals the current alphamap length)
- rampdown create a linear alphamap with decreasing opacity (default l ength equals the current alphamap length)
- vup create an alphamap that is opaque in the center and becomes more transparent linearly towards the beginning and end (default l ength equals the current alphamap length)
- vdown create an alphamap that is transparent in the center and becomes more opaque linearly towards the beginning and end (default l ength equals the current alphamap length)
- i ncrease modify the alphamap making it more opaque (default del ta is . 1, which is added to the current values)
- decrease modify the alphamap making it more transparent (default del ta is . 1, which is subtracted from the current values)

alphamap

• spi n – rotate the current alphamap (default del ta is 1; note that delta must be an integer)

al phamap('parameter', length) creates a new alphamap with the length specified by length (used with parameters: rampup, rampdown, vup, vdown)

al phamap('parameter', delta) modifies the existing alphamap using the value specified by delta (used with parameters: increase, decrease, spin).

al phamap (fi gure_handl e, \dots) performs the operation on the alphamap of the figure identified by fi gure_handl e.

al pha_map = al phamap return the current alphamap.

al pha_map = al phamap(fi gure_handle) returns the current alphamap from the figure identified by fi gure_handle.

al pha_map = al phamap('parameter') retruns the alphamap modified by the parameter, but does not set the Al phaMap property.

Phase angle

Syntax

$$P = angle(Z)$$

Description

 $P=angl\,e(Z)$ returns the phase angles, in radians, for each element of complex array Z. The angles lie between $\pm\pi$.

For complex Z, the magnitude and phase angle are given by

$$R = abs(Z)$$
 % magnitude
theta = angle(Z) % phase angle

and the statement

$$Z = R. *exp(i*theta)$$

converts back to the original complex Z.

Examples

```
Z =
```

```
1. 0000 - 1. 0000i
                     2. 0000 + 1. 0000i
                                           3. 0000 - 1. 0000i
                                                                 4. 0000 + 1. 0000i
1. 0000 + 2. 0000i
                     2. 0000 - 2. 0000i
                                           3. 0000 + 2. 0000i
                                                                  4. 0000 - 2. 0000i
1. 0000 - 3. 0000i
                     2. 0000 + 3. 0000i
                                           3. 0000 - 3. 0000i
                                                                  4. 0000 + 3. 0000i
1. 0000 + 4. 0000i
                     2. 0000 - 4. 0000i
                                           3. 0000 + 4. 0000i
                                                                 4. 0000 - 4. 0000i
```

$$P = angle(Z)$$

$$P =$$

Algorithm

angle can be expressed as:

$$angle(z) = i mag(log(z)) = atan2(i mag(z), real(z))$$

Test for any nonzeros

Syntax

$$B = any(A)$$

 $B = any(A, dim)$

Description

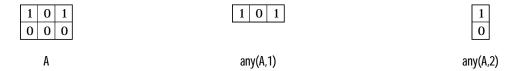

B = any(A) tests whether *any* of the elements along various dimensions of an array are nonzero or logical true (1).

If A is a vector, any (A) returns logical true (1) if any of the elements of A are nonzero, and returns logical false (0) if all the elements are zero.

If A is a matrix, any (A) treats the columns of A as vectors, returning a row vector of 1s and 0s.

If A is a multidimensional array, any (A) treats the values along the first non-singleton dimension as vectors, returning a logical condition for each vector.

B = any(A, dim) tests along the dimension of A specified by scalar dim

Examples

Given.

$$A = [0.53 \ 0.67 \ 0.01 \ 0.38 \ 0.07 \ 0.42 \ 0.69]$$

then B = (A < 0.5) returns logical true (1) only where A is less than one half:

$$0 \quad 0 \quad 1 \quad 1 \quad 1 \quad 1 \quad 0$$

The any function reduces such a vector of logical conditions to a single condition. In this case, any (B) yields 1.

This makes any particularly useful in if statements,

```
if any(A < 0.5)
    do something
end</pre>
```

where code is executed depending on a single condition, not a vector of possibly conflicting conditions.

Applying the any function twice to a matrix, as in any (any (A)) , always reduces it to a scalar condition.

```
any(any(eye(3)))
ans =
1
```

max, mean, medi an, mi n, prod, std, sum, trapz

Area fill of a two-dimensional plot

Syntax

```
area(Y)
area(X, Y)
area(..., ymi n)
area(..., 'PropertyName', PropertyValue,...)
h = area(...)
```

Description

An area plot displays elements in Y as one or more curves and fills the area beneath each curve. When Y is a matrix, the curves are stacked showing the relative contribution of each row element to the total height of the curve at each *x* interval.

area(Y) plots the vector Y or the sum of each column in matrix Y. The x-axis automatically scales depending on l ength(Y) when Y is a vector and on size(Y, 1) when Y is a matrix.

 $\operatorname{area}(X,Y)$ plots Y at the corresponding values of X. If X is a vector, $l \operatorname{ength}(X)$ must equal $l \operatorname{ength}(Y)$ and X must be monotonic. If X is a matrix, $\operatorname{si} \operatorname{ze}(X)$ must equal $\operatorname{si} \operatorname{ze}(Y)$ and each column in X must be monotonic. To make a vector or matrix monotonic, use sort .

area(..., ymin) specifies the lower limit in the y direction for the area fill. The default ymin is 0.

area(..., PropertyName', PropertyValue,...) specifies property name and property value pairs for the patch graphics object created by area.

h = area(...) returns handles of patch graphics objects. area creates one patch object per column in Y.

Remarks

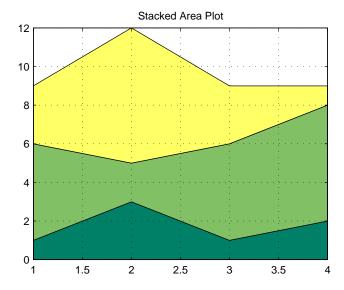

area creates one curve from all elements in a vector or one curve per column in a matrix. The colors of the curves are selected from equally spaced intervals throughout the entire range of the colormap.

Examples

Plot the values in Y as a stacked area plot.

$$Y = [1, 5, 3; 3, 2, 7;$$

```
1, 5, 3;
2, 6, 1];
area(Y)
grid on
colormap summer

Inverse secant and inverse hyperbolic secant

Syntax

Y = asec(X)Y = asech(X)

Description

The asec and asech functions operate element-wise on arrays. The functions' domains and ranges include complex values. All angles are in radians.

Y = asec(X) returns the inverse secant (arcsecant) for each element of X.

 $Y = \operatorname{asech}(X)$ returns the inverse hyperbolic secant for each element of X.

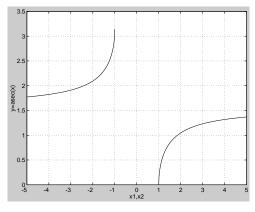

Examples

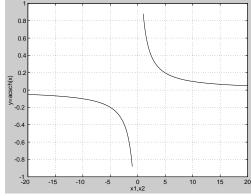

Graph the inverse secant over the domains $1 \le x \le 5$ and $-5 \le x \le -1$, and the inverse hyperbolic secant over the domain $0 < x \le 1$.

```
x1 = -5:0.01:-1; \quad x2 = 1:0.01:5;

plot(x1, asec(x1), x2, asec(x2))

x = 0.01:0.001:1; \quad plot(x, asech(x))
```

asec, asech

Algorithm

asec and asech use these algorithms.

$$\sec^{-1}(z) = \cos^{-1}\left(\frac{1}{z}\right)$$
$$\operatorname{sech}^{-1}(z) = \cosh^{-1}\left(\frac{1}{z}\right)$$

See Also

sec, sech

Inverse sine and inverse hyperbolic sine

Syntax

Y = asi n(X)Y = asi nh(X)

Description

The asi n and asi nh functions operate element-wise on arrays. The functions' domains and ranges include complex values. All angles are in radians.

 $Y=asi\,n(X)$ returns the inverse sine (arcsine) for each element of X. For real elements of X in the domain [-1,1], $asi\,n(X)$ is in the range $[-\pi/2,\pi/2]$. For real elements of X outside the range [-1,1], $asi\,n(X)$ is complex.

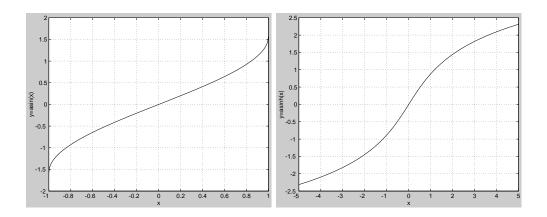

Y = asi nh(X) returns the inverse hyperbolic sine for each element of X.

Examples

Graph the inverse sine function over the domain $-1 \le x \le 1$, and the inverse hyperbolic sine function over the domain $-5 \le x \le 5$.

```
x = -1:.01:1; plot(x, asin(x))

x = -5:.01:5; plot(x, asinh(x))
```

asin, asinh

Algorithm

asi n and asi nh use these algorithms.

$$\sin^{-1}(z) = -i \log \left[iz + (1-z^2)^{\frac{1}{2}} \right]$$

$$sinh^{-1}(z) = log \left[z + (z^2 + 1)^{\frac{1}{2}} \right]$$

si n, si nh

Assign a value to a workspace variable

Syntax

```
assignin(ws, 'var', val)
```

Description

assignin(ws, 'var', val) assigns the value val to the variable var in the workspace ws. var is created if it doesn't exist. ws can have a value of 'base' or 'caller' to denote the MATLAB base workspace or the workspace of the caller function.

The assi gni n function is particularly useful for these tasks:

- Exporting data from a function to the MATLAB workspace
- Within a function, changing the value of a variable that is defined in the workspace of the caller function (such as a variable in the function argument list)

Remarks

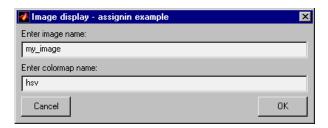

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the M-file. Note the base and caller workspaces are equivalent in the context of an M-file that is invoked from the MATLAB command line.

Examples

This example creates a dialog box for the image display function, prompting a user for an image name and a colormap name. The assignin function is used to export the user–entered values to the MATLAB workspace variables i mfile and cmap.

```
prompt = {'Enter image name:','Enter colormap name:'};
title = 'Image display - assignin example';
lines = 1;
def = {'my_image','hsv'};
answer = inputdlg(prompt, title, lines, def);
assignin('base','imfile', answer{1});
assignin('base','cmap', answer{2});
```

assignin

See Also evalin

Inverse tangent and inverse hyperbolic tangent

Syntax

Y = atan(X)Y = atanh(X)

Description

The atan and atanh functions operate element-wise on arrays. The functions' domains and ranges include complex values. All angles are in radians.

Y = atan(X) returns the inverse tangent (arctangent) for each element of X.

For real elements of X, at an(X) is in the range $[-\pi/2, \pi/2]$.

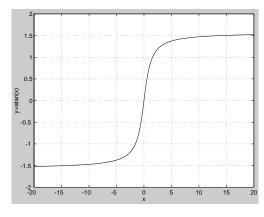

Y = atanh(X) returns the inverse hyperbolic tangent for each element of X.

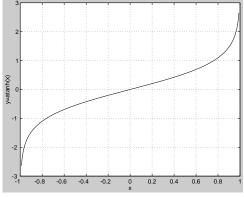

Examples

Graph the inverse tangent function over the domain $-20 \le x \le 20$, and the inverse hyperbolic tangent function over the domain -1 < x < 1.

```
x = -20: 0.01: 20; plot(x, atan(x))
```

x = -0.99: 0.01: 0.99; plot(x, atanh(x))

atan, atanh

Algorithm

at an amd at anh use these algorithms.

$$\tan^{-1}(z) = \frac{i}{2} \log \left(\frac{i+z}{i-z} \right)$$

$$\tanh^{-1}(z) = \frac{1}{2} \log \left(\frac{1+z}{1-z}\right)$$

See Also

atan2, tan, tanh

Four-quadrant inverse tangent

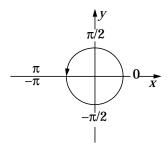

Syntax

P = atan2(Y, X)

Description

P = atan2(Y, X) returns an array P the same size as X and Y containing the element-by-element, four-quadrant inverse tangent (arctangent) of the real parts of Y and X. Any imaginary parts are ignored.

Elements of P lie in the closed interval [-pi ,pi], where pi is MATLAB's floating-point representation of π . The specific quadrant is determined by si gn(Y) and si gn(X) .

This contrasts with the result of at an(Y/X), which is limited to the interval $[-\pi/2, \pi/2]$, or the right side of this diagram.

Examples

Any complex number z = x + iy is converted to polar coordinates with

```
r = abs(z)
theta = atan2(i mag(z), real(z))
```

To convert back to the original complex number:

$$z = r *exp(i *theta)$$

This is a common operation, so MATLAB provides a function, angle (z), that simply computes at an 2 (i mag(z), real (z)).

atan, atanh, tan, tanh

Create an audio player object

Syntax

y = audi opl ayer(x, Fs)

y = audi opl ayer(x, Fs, nbi ts)

Description

Note To use all of the audi opl ayer features, your system needs a properly installed and configured sound card with 8- and 16-bit I/O, two channels, and support for sampling rates of up to 48 kHz.

 $y = audi \, opl \, ayer(x, Fs)$ returns a handle to an audio player object $y \, using$ input audio signal x. The input signal x can be a vector or two-dimensional array containing $si \, ngl \, e$, doubl e, int8, uint8, or int16 MATLAB data types. The input sample values for $si \, ngl \, e$ and doubl e data must be between -1 and 1. For int8, uint8 and int16 data, the ranges of sample values are -128 to 127, 0 to 255, and -32768 to 32767, respectively.

Fs is the sampling rate in Hz to use for playback. Valid values for Fs depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, and 44100 Hz.

 $y = audi \, opl \, ayer(x, Fs, \, nbi \, ts) \, returns \, a \, handle \, to \, an \, audio \, player \, object \, where \, nbi \, ts \, is \, the \, bit \, quantization \, to \, use \, for \, si \, ngl \, e \, or \, doubl \, e \, data \, types. \, This is \, an \, optional \, parameter \, with \, a \, default \, value \, of \, 16. \, Valid \, values \, for \, nbi \, ts \, are \, 8 \, and \, 16. \, You \, do \, not \, need \, to \, specify \, nbi \, ts \, for \, i \, nt \, 8 \, or \, ui \, nt \, 8 \, or \, for \, i \, nt \, 16 \, data \, because \, the \, quantization \, is \, set \, automatically \, to \, 8 \, or \, 16, \, respectively.$

After you create an audio player object, you can use the methods listed below on that object. y in each function is the name of the returned audio player. Each

audioplayer

of these methods can use a "dot" notation. For example, pl $\operatorname{ay}(y)$ and y. pl ay are equivalent.

Method	Description
play(y) play(y, start) play(y, [start stop]) play(y, range)	Starts playback from the beginning and plays to the end, or from start sample to the end, or from start sample to stop sample. The values of start and stop can be specified in a two-element vector range.
pl aybl ocki ng(y) pl aybl ocki ng(y, start) pl aybl ocki ng(y, [start stop]) pl aybl ocki ng(y, range)	Same as play, but does not return control until playback completes.
stop(y)	Stops playback.
pause(y)	Pauses playback.
resume(y)	Restarts playback from where playback was paused.
i spl ayi ng(y)	Indicates whether playback is in progress. If 0, playback is not in progress. If 1, playback is in progress.
di spl ay(y) di sp(y) get(y)	Displays all property information about audio player y.

Audio player objects have the properties listed below. To set a user-settable property use this syntax $\,$

```
\operatorname{set}(y, \ '\operatorname{property1'}, \ \operatorname{value}, '\operatorname{property2'}, \operatorname{value}, \ldots)
```

To view a read-only property

```
get(y, 'property') % Displays 'property' setting.
```

Property	Description	Туре
Туре	Name of the object's class	read-only
SampleRate	Sampling frequency in Hz	user-settable
BitsPerSample	Number of bits per sample	read-only
NumberOfChannels	Number of channels	read-only
Total Samples	Total length, in samples, of the audio data	read-only
Runni ng	Status of the audio player ('on' or 'off')	read-only
CurrentSampl e	Current sample being played by the audio output device (If it is not playing, current sample is the next sample to be played with pl ay or resume.)	read-only
UserData	User data of any type	user-settable
Tag	User-specified object label string	user-settable

Example

Load a sample audio file, create an audio player object, and play the audio at a higher sampling rate. y contains the audio samples and Fs is the sampling rate. You can use any of the audi oplayer functions listed above on the player.

```
load handel;
player=audioplayer(y, Fs);
player.play([1 (player.SampleRate*3)]);
```

To stop the playback, use this command:

```
\mathsf{stop}(\mathsf{pl}\,\mathsf{ayer})\,; \hspace{1cm} \mathsf{\%}\,\,\mathsf{Equi}\,\mathsf{val}\,\mathsf{ent}\,\,\mathsf{to}\,\,\mathsf{pl}\,\mathsf{ayer}.\,\mathsf{stop}
```

See Also

audi orecorder, sound, wavpl ay, wavwrite, wavread, get, set, methods

audiorecorder

Purpose

Create an audio recorder object

Syntax

y = audi orecorder

y = audiorecorder(Fs, nbits, channels)

Description

Note To use all of the audio recorder object features, your system must have a properly installed and configured sound card with 8- and 16-bit I/O and support for sampling rates of up to 48 kHz.

y = audi orecorder returns a handle to an 8-kHz, 8-bit, mono audio recorder.

y = audi orecorder(Fs, nbits, channels) returns a handle to an audio recorder using the sampling rate, Fs, in Hz, the sample size of nbits, and the number of channels. Fs can be any sampling rate supported by the audio hardware. Common sampling rates are 8000, 11025, 22050, and 44000. The value of nbits must be 8 or 16. For mono or stereo, channels must be 1 or 2, respectively.

After you create an audio recorder object, you can use the methods listed below on that object. y in each function is the name of the returned audio recorder. Each of these methods can use a "dot" notatation. For example, record(y) and y. record are equivalent.

Method	Description
record(y) record(y, length)	Starts recording. Records for 1 ength number of seconds.
recordbl ocki ng(y) recordbl ocki ng(y, l ength)	Same as record but does not return control until recording completes.
stop(y)	Stops recording.
pause(y)	Pauses recording.
resume(y)	Restarts recording from where recording was paused.

Method	Description
i srecordi ng(y)	Indicates whether recording is in progress. If 0, recording is not in progress. If 1, recording is in progress.
pl ay(y)	Creates an audi opl ayer, plays the recorded audio data, and returns a handle to the created audi opl ayer.
getpl ayer(y)	Creates an audi opl ayer and returns a handle to the created audi opl ayer.
getaudi odata(y) getaudi odata(y, 'type')	Returns the recorded audio data to the MATLAB workspace. type is a string containing the desired data type. Supported data types are double, single, int16, int8, or uint8. If type is omitted, it defaults to 'double'. For double and single, the array contains values between -1 and 1. For int8, values are between -128 to 127, for uint8, values are from 0 to 255, and for int16, values are from -32768 to 32767. If the recording is in mono, the returned array has one column. If it is in stereo, the array has two columns—one for each channel.
di spl ay(y) di sp(y) get (y)	Displays all property information about audio recorder y.

Audio recorder objects have the properties listed below. To set a user-settable property use this syntax $\,$

```
set(y, 'property1', value, 'property2', value,...)
```

To view a read-only property

get(y, 'property')

%displays'property'setting.

Property	Description	Туре
Туре	Name of the object's class	read-only
SampleRate	Sampling frequency in Hz	read-only
BitsPerSample	Number of bits per recorded sample	read-only
NumberOfChannels	Number of channels of recorded audio	read-only
Total Samples	Total length, in samples, of the recording	read-only
Runni ng	Status of the audio recorder ('on' or 'off')	read-only
CurrentSample	Current sample being recorded by the audio output device (If it is not recording, current sample is the next sample to be recorded with record or resume.).	read-only
UserData	User data of any type	user-settable
NumberOfBuffers	Number of buffers used for recording (You should adjust this only if you have skips, dropouts, etc. in your recording.)	user-settable
BufferLength	Length in seconds of buffer (You should adjust this only if you have skips, dropouts, etc. in your recording.)	user-settable
Tag	User-specified object label string	user-settable

Examples

Example 1

Using a microphone, record 3.5 seconds of 44.1-kHz, 16-bit, stereo data, and then return the data to the MATLAB workspace as a double array.

```
recorder = audi orecorder(44100, 16, 2);
recordbl ocki ng(recorder, 3. 5);
audi oarray=getaudi odata(recorder);
```

Example 2

Using a microphone, record 8-bit, 22-kHz mono data, play it back, record again and return the data to the MATLAB workspace as a ui nt8 array.

```
mi crecorder = audi orecorder(22050, 8, 1);
record(mi crecorder);
% Now, speak into mi crophone

stop(mi crecorder);
speechpl ayer = pl ay(mi crecorder);
% Now, listen to the recording

stop(speechpl ayer);
speechdata = getaudi odata(mi crecorder, 'ui nt8');
```

Remarks

The current implementation of Audi oRecorder is not intended for long, high sample rate recording because it uses system memory for storage and does not use disk buffering. When large recordings are attempted, MATLAB performance may degrade.

auread

Purpose

Read NeXT/SUN (. au) sound file

Graphical Interface

As an alternative to auread, use the Import Wizard. To activate the Import Wizard, select **Import data** from the **File** menu.

Syntax

```
y = auread('aufile')
[y, Fs, bits] = auread('aufile')
[...] = auread('aufile', N)
[...] = auread('aufile', [N1, N2])
siz = auread('aufile', 'size')
```

Description

y = auread('aufile') loads a sound file specified by the string aufile, returning the sampled data in y. The . au extension is appended if no extension is given. Amplitude values are in the range [-1, +1]. auread supports multi-channel data in the following formats:

- 8-bit mu-law
- 8-, 16-, and 32-bit linear
- floating-point

[y, Fs, bits] = auread('aufile') returns the sample rate (Fs) in Hertz and the number of bits per sample (bits) used to encode the data in the file.

 $[\dots]$ = auread('aufile', N) returns only the first N samples from each channel in the file.

[...] = auread('aufile', [N1 N2]) returns only samples N1 through N2 from each channel in the file.

siz = auread('aufile', 'size') returns the size of the audio data contained in the file in place of the actual audio data, returning the vector $siz = [samples \ channels]$.

See Also

auwrite, wavread

Purpose Write NeXT/SUN (. au) sound file

Syntax auwrite(y, 'aufile')

auwrite(y, Fs, 'aufile')
auwrite(y, Fs, N, 'aufile')

auwrite(y, Fs, N, 'method', 'aufile')

Description auwrite(y, 'aufile') writes a sound file specified by the string aufile. The

data should be arranged with one channel per column. Amplitude values outside the range [-1, +1] are clipped prior to writing. auwrite supports multi-channel data for 8-bit mu-law, and 8- and 16-bit linear formats.

auwrite(y, Fs, 'aufile') specifies the sample rate of the data in Hertz.

auwrite(y, Fs, N, 'aufile') selects the number of bits in the encoder.

Allowable settings are N = 8 and N = 16.

 $auwrite(y,Fs,N,'\,method'\,,'\,aufil\,e'\,)\,\,allows\,\,selection\,\,of\,\,the\,\,encoding$

method, which can be either mu or li near. Note that mu-law files must be 8-bit.

By default, method = 'mu'.

See Also auread, wavwrite

Create a new Audio Video Interleaved (AVI) file

Syntax

```
avi obj = avi file(filename)
avi obj =
avi file(filename, 'PropertyName', value, 'PropertyName', value, ...)
```

Description

avi obj = avi file(filename) creates an AVI file, giving it the name specified in filename, using default values for all AVI file object properties. If filename does not include an extension, avi file appends . avi to the filename. AVI is a file format for storing audio and video data.

avi file returns a handle to an AVI file object, avi obj . You use this object to refer to the AVI file in other functions. An AVI file object supports properties and methods that control aspects of the AVI file created.

avi obj = avi file(filename, 'Param', Value, 'Param', Value, ...) creates an AVI file with the specified parameter settings. This table lists available parameters.

Parameter	Value		Default
'colormap'	An m-by-3 matrix defining the colormap to be used for indexed AVI movies, where m must be no greater than 256 (236 if using I ndeo compression). You must set this parameter before calling addframe, unless you are using addframe with the MATLAB movie syntax.		There is no default colormap.
'compression'	A text string specifying which compression codec to use.		
	On Windows: 'Indeo3' 'Indeo5' 'Cinepak' 'MSVC' 'None'	On Unix: 'None'	' I ndeo3' , on Windows. 'None' on Unix.

Parameter	Value	Default
	To use a custom compression codec, specify the four-character code that identifies the codec (typically included in the codec documentation). The addframe function reports an error if it can not find the specified custom compressor.	
'fps'	A scalar value specifying the speed of the AVI movie in frames per second (fps).	15 fps
'keyframe'	For compressors that support temporal compression, this is the number of key frames per second.	2 key frames per second.
'name'	A descriptive name for the video stream. This parameter must be no greater than 64 characters long.	The default is the filename.
' qual i ty'	A number between 0 and 100. This parameter has no effect on uncompressed movies. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.	75

You can also use structure syntax to set AVI file object properties. For example, to set the quality property to 100 use the following syntax:

```
avi obj = avi file(filename);
avi obj . Quality = 100;
```

Example

This example shows how to use the avi file function to create the AVI file example. avi .

```
fig=figure;
set(fig, 'DoubleBuffer', 'on');
```

Return information about an Audio Video Interleaved (AVI) file

Syntax

fileinfo = aviinfo(filename)

Description

 $file info = avi info (file name) \ returns \ a \ structure \ whose fields \ contain information about the AVI file specified in the string, file name. If file name does not include an extension, then . avi is used. The file must be in the current working directory or in a directory on the MATLAB path.$

The set of fields in the fileinfo structure are shown below.

Field Name	Description	
Audi oFormat	A string containing the name of the format used to store the audio data, if audio data is present	
Audi oRate	An integer indicating the sample rate in Hertz of the audio stream, if audio data is present	
Filename	A string specifying the name of the file	
FileModDate	A string containing the modification date of the file	
Fi l eSi ze	An integer indicating the size of the file in bytes	
FramesPerSecond	An integer indicating the desired frames per second	
Hei ght	An integer indicating the height of the AVI movie in pixels	
ImageType	A string indicating the type of image. Either 'truecol or' for a truecolor (RGB) image, or 'indexed' for an indexed image.	
NumAudi oChannels	An integer indicating the number of channels in the audio stream, if audio data is present	
NumFrames	An integer indicating the total number of frames in the movie	

aviinfo

Field Name	Description
NumCol ormapEntri es	An integer specifying the number of colormap entries
Quality	A number between 0 and 100 indicating the video quality in the AVI file. Higher quality numbers indicate higher video quality; lower quality numbers indicate lower video quality. This value is not always set in AVI files and therefore may be inaccurate.
Vi deoCompressi on	A string containing the compressor used to compress the AVI file. If the compressor is not Microsoft Video 1, Run Length Encoding (RLE), Cinepak, or Intel Indeo, avi i nfo returns a four-character code.
Wi dth	An integer indicating the width of the AVI movie in pixels

See also

avi fi l e, avi read

Purpose Read an Audio Video Interleaved (AVI) file.

Syntax mov = avi read(filename)

mov = avi read(filename, index)

Description

 $mov = avi\ read(filename)$ reads the AVI movie filename into the MATLAB movie structure mov. If filename does not include an extension, then . avi is used. Use the movie function to view the movie, mov. On UNIX, filename must be an uncompressed AVI file.

mov has two fields, cdata and col ormap. The content of these fields varies depending on the type of image.

Image Type	mov.cdata Field	mov.colormap Field
Truecol or	height-by-width-by-3 array	Empty
Indexed	height-by-width array	m-by-3 array

 $mov = avi\ read(filename, index)\ reads only the frame(s)\ specified by index.$ index can be a single index or an array of indices into the video stream. In AVI files, the first frame has the index value 1, the second frame has the index value 2, and so on.

See also aviinfo, avifile, movie

Create axes graphics object

Syntax

```
axes
axes('PropertyName', PropertyValue,...)
axes(h)
h = axes(...)
```

Description

axes is the low-level function for creating axes graphics objects.

axes creates an axes graphics object in the current figure using default property values.

axes('PropertyName', PropertyValue,...) creates an axes object having the specified property values. MATLAB uses default values for any properties that you do not explicitly define as arguments.

axes(h) makes existing axes h the current axes. It also makes h the first axes listed in the figure's Children property and sets the figure's CurrentAxes property to h. The current axes is the target for functions that draw image, line, patch, surface, and text graphics objects.

h = axes(...) returns the handle of the created axes object.

Remarks

MATLAB automatically creates an axes, if one does not already exist, when you issue a command that draws image, light, line, patch, surface, or text graphics objects.

The axes function accepts property name/property value pairs, structure arrays, and cell arrays as input arguments (see the set and get commands for examples of how to specify these data types). These properties, which control various aspects of the axes object, are described in the "Axes Properties" section.

Use the set function to modify the properties of an existing axes or the get function to query the current values of axes properties. Use the gca command to obtain the handle of the current axes.

The axi s (not axes) function provides simplified access to commonly used properties that control the scaling and appearance of axes.

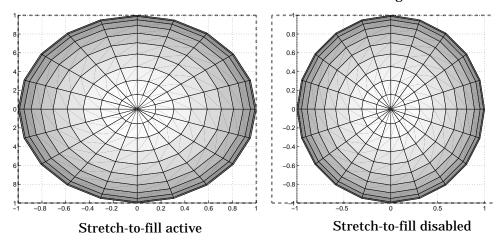

While the basic purpose of an axes object is to provide a coordinate system for plotted data, axes properties provide considerable control over the way MATLAB displays data.

Stretch-to-Fill

By default, MATLAB stretches the axes to fill the axes position rectangle (the rectangle defined by the last two elements in the Posi ti on property). This results in graphs that use the available space in the rectangle. However, some 3-D graphs (such as a sphere) appear distorted because of this stretching, and are better viewed with a specific three-dimensional aspect ratio.

Stretch-to-fill is active when the DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all auto (the default). However, stretch-to-fill is turned off when the DataAspectRatio, PlotBoxAspectRatio, or CameraViewAngle is user-specified, or when one or more of the corresponding modes is set to manual (which happens automatically when you set the corresponding property value).

This picture shows the same sphere displayed both with and without the stretch-to-fill. The dotted lines show the axes Posi ti on rectangle.

When stretch-to-fill is disabled, MATLAB sets the size of the axes to be as large as possible within the constraints imposed by the Position rectangle without introducing distortion. In the picture above, the height of the rectangle constrains the axes size.

Examples

Zooming

Zoom in using aspect ratio and limits:

Zoom in and out using the CameraVi ewAngle:

```
sphere set(gca, 'CameraVi ewAngle', get(gca, 'CameraVi ewAngle')-5) set(gca, 'CameraVi ewAngle', get(gca, 'CameraVi ewAngle')+5)
```

Note that both examples disable MATLAB's stretch-to-fill behavior.

Positioning the Axes

The axes Positi on property enables you to define the location of the axes within the figure window. For example,

```
h = axes('Position', position_rectangle)
```

creates an axes object at the specified position within the current figure and returns a handle to it. Specify the location and size of the axes with a rectangle defined by a four-element vector,

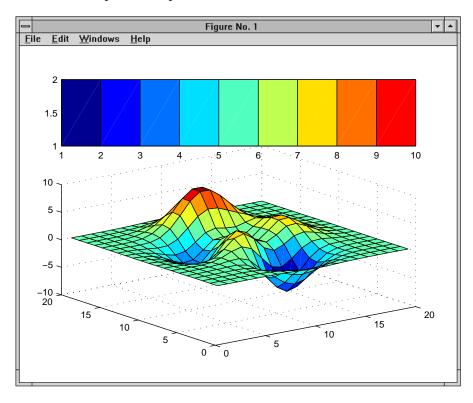

```
position_rectangle = [left, bottom, width, height];
```

The left and bottom elements of this vector define the distance from the lower-left corner of the figure to the lower-left corner of the rectangle. The width and height elements define the dimensions of the rectangle. You specify these values in units determined by the Units property. By default, MATLAB uses normalized units where (0,0) is the lower-left corner and (1.0,1.0) is the upper-right corner of the figure window.

You can define multiple axes in a single figure window:

```
axes('position',[.1 .1 .8 .6])
mesh(peaks(20));
axes('position',[.1 .7 .8 .2])
pcolor([1:10;1:10]);
```

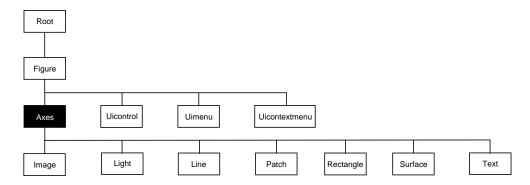

In this example, the first plot occupies the bottom two-thirds of the figure, and the second occupies the top third.

Object Hierarchy

Setting Default Properties

You can set default axes properties on the figure and root levels:

```
set(0, 'DefaultAxesPropertyName', PropertyValue,...)
set(gcf, 'DefaultAxesPropertyName', PropertyValue,...)
```

where *PropertyName* is the name of the axes property and PropertyValue is the value you are specifying. Use set and get to access axes properties.

Property List

The following table lists all axes properties and provides a brief description of each. The property name links take you an expanded description of the properties.

Property Name	Property Description	Property Value
Controlling Style and	Appearance	,
Box	Toggle axes plot box on and off	Values: on, off Default: off
Cl i ppi ng	This property has no effect; axes are always clipped to the figure window	
Gri dLi neStyl e	Line style used to draw axes grid lines	Values: -,, : , , none Default: : (dotted line)

Property Name	Property Description	Property Value
Layer	Draw axes above or below graphs	Values: bottom, top Default: bottom
Li neStyl eOrder	Sequence of line styles used for multiline plots	Values: Li neSpec Default: – (solid line for)
Li neWi dth	Width of axis lines, in points (1/72" per point)	Values: number of points Default: 0.5 points
Sel ecti onHi ghl i ght	Highlight axes when selected (Sel ected property set to on)	Values: on, off Default: on
Ti ckDi r	Direction of axis tick marks	Values: i n, out Default: i n (2-D), out (3-D)
Ti ckDi rMode	Use MATLAB or user-specified tick mark direction	Values: auto, manual Default: auto
Ti ckLength	Length of tick marks normalized to axis line length, specified as two-element vector	Values: [2-D 3-D] Default: [0. 01 0. 025}
Vi si bl e	Make axes visible or invisible	Values: on, off Default: on
XGrid, YGrid, ZGrid	Toggle grid lines on and off in respective axis	Values: on, off Default: off
General Information Abo	ut the Axes	
Children	Handles of the images, lights, lines, patches, surfaces, and text objects displayed in the axes	Values: vector of handles
Current Poi nt	Location of last mouse button click defined in the axes data units	Values: a 2-by-3 matrix
HitTest	Specify whether axes can become the current object (see figure Current Obj ect property)	Values: on, off Default: on

Property Name	Property Description	Property Value
Parent	Handle of the figure window containing the axes	Values: scalar figure handle
Position	Location and size of axes within the figure	Values: [left bottom width height] Default: [0. 1300 0. 1100 0. 7750 0. 8150] in normalized Units
Selected	Indicate whether axes is in a "selected" state	Values: on, off Default: on
Tag	User-specified label	Values: any string Default: '' (empty string)
Туре	The type of graphics object (read only)	Value: the string ' axes'
Uni ts	Units used to interpret the Position property	Values: i nches, centi meters, characters, normal i zed, poi nts, pi xel s Default: normal i zed
UserData	User-specified data	Values: any matrix Default: [] (empty matrix)
Selecting Fonts and La	abels	
FontAngl e	Select italic or normal font	Values: normal, italic, oblique Default: normal
FontName	Font family name (e.g., Helvetica, Courier)	Values: a font supported by your system or the string Fi xedWi dth Default: Typically Helvetica
FontSi ze	Size of the font used for title and labels	Values: an integer in FontUni ts Default: 10

Property Name	Property Description	Property Value	
FontUnits	Units used to interpret the FontSi ze property	Values: points, normalized, inches, centimeters, pixels Default: points	
FontWeight	Select bold or normal font	Values: normal, bold, light, demi Default: normal	
Title	Handle of the title text object	Values: any valid text object handle	
XLabel, YLabel, ZLabel	Handles of the respective axis label text objects	Values: any valid text object handle	
XTi ckLabel , YTi ckLabel , ZTi ckLabel	Specify tick mark labels for the respective axis	Values: matrix of strings Defaults: numeric values selected automatically by MATLAB	
XTi ckLabel Mode, YTi ckLabel Mode, ZTi ckLabel Mode	Use MATLAB or user-specified tick mark labels	Values: auto, manual Default: auto	
Controlling Axis Scaling			
XAxi sLocati on	Specify the location of the <i>x</i> -axis	Values: top, bottom Default: bottom	
YAxi sLocati on	Specify the location of the <i>y</i> -axis	Values: right left Default: left	
XDir, YDir, ZDir	Specify the direction of increasing values for the respective axes	Values: normal, reverse Default: normal	
XLi m, YLi m, ZLi m	Specify the limits to the respective axes	Values: [min max] Default: min and max determined automatically by MATLAB	

Property Name	Property Description	Property Value	
XLi mMode, YLi mMode, ZLi mMode	Use MATLAB or user-specified values for the respective axis limits	Values: auto, manual Default: auto	
XMi norGri d, YMi norGri d, ZMi norGri d	Determines whether MATLAB displays gridlines connecting minor tick marks in the respective axis.	Values: on, off Default: off	
XMi norTi ck, YMi norTi ck, ZMi norTi ck	Determines whether MATLAB displays minor tick marks in the respective axis.	Values: on, off Default: off	
XScale, YScale, ZScale	Select linear or logarithmic scaling of the respective axis	Values: li near, log Default: li near (changed by plotting commands that create nonlinear plots)	
XTi ck, YTi ck, ZTi ck	Specify the location of the axis ticks marks	Values: a vector of data values locating tick marks Default: MATLAB automatically determines tick mark placement	
XTi ckMode, YTi ckMode, ZTi ckMode	Use MATLAB or user-specified values for the respective tick mark locations	Values: auto, manual Default: auto	
Controlling the View			
CameraPosition	Specify the position of point from which you view the scene	Values: [x, y, z] axes coordinates Default: automatically determined by MATLAB	
CameraPositionMode	Use MATLAB or user-specified camera position	Values: auto, manual Default: auto	

Property Name	Property Description	Values: [x, y, z] axes coordinates Default: automatically determined by MATLAB	
CameraTarget	Center of view pointed to by camera		
CameraTargetMode	Use MATLAB or user-specified camera target	Values: auto, manual Default: auto	
CameraUpVector	Direction that is oriented up	Values: [x, y, z] axes coordinates Default: automatically determined by MATLAB	
CameraUpVectorMode	Use MATLAB or user-specified camera up vector	Values: auto, manual Default: auto	
CameraVi ewAngl e	Camera field of view	Values: angle in degrees between 0 and 180 Default: automatically determined by MATLAB	
CameraVi ewAngl eMode	Use MATLAB or user-specified camera view angle	Values: auto, manual Default: auto	
Projection	Select type of projection	Values: orthographi c, perspecti ve Default: orthographi c	
Controlling the Axes Aspe	ect Ratio		
DataAspectRatio	Relative scaling of data units	Values: three relative values [dx dy dz] Default: automatically determined by MATLAB	
DataAspectRatioMode	Use MATLAB or user-specified data aspect ratio	Values: auto, manual Default: auto	

Property Name	Property Description	Property Value	
PlotBoxAspectRatio	Relative scaling of axes plot box	Values: three relative values [dx dy dz] Default: automatically determined by MATLAB	
PlotBoxAspectRatioMode	Use MATLAB or user-specified plot box aspect ratio	Values: auto, manual Default: auto	
Controlling Callback Routin	ne Execution		
BusyAction	Specify how to handle events that interrupt execution callback routines	Values: cancel, queue Default: queue	
ButtonDownFcn	Define a callback routine that executes when a button is pressed over the axes	Values: string Default: an empty string	
CreateFcn	Define a callback routine that executes when an axes is created	Values: string Default: an empty string	
DeleteFcn	Define a callback routine that executes when an axes is created	Values: string Default: an empty string	
Interrupti bl e	Control whether an executing callback routine can be interrupted	Values: on, off Default: on	
UI ContextMenu	Associate a context menu with the axes	Values: handle of a Uicontextmenu	
Specifying the Rendering N	Лоde		
DrawMode	Specify the rendering method to use with the Painters renderer	Values: normal, fast Default: normal	
Targeting Axes for Graphic	cs Display		
Handl eVi si bi l i ty	Control access to a specific axes' handle	Values: on, call back, off Default: on	

Property Name	Property Description	Property Value	
NextPl ot	Determine the eligibility of the axes for displaying graphics	Values: add, repl ace, repl acechi l dren Default: repl ace	
Properties that Specify Tra	ansparency		
ALi m	Alpha axis limits	Values: [ami n amax]	
ALi mMode	Alpha axis limits mode	Values: auto manual Default: auto	
Properties that Specify Co	lor		
Ambi entLi ghtCol or	Color of the background light in a scene	Values: Col orSpec Default: [1 1 1]	
CLi m	Control how data is mapped to colormap	Values: [cmin cmax] Default: automatically determined by MATLAB	
CLi mMode	Use MATLAB or user-specified values for CLi m	Values: auto, manual Default: auto	
Color	Color of the axes background	Values: none, Col orSpec Default: none	
Col or0rder	Line colors used for multiline plots	Values: m-by-3 matrix of RGB values Default: depends on color scheme used	
XColor, YColor, ZColor	Colors of the axis lines and tick marks	Values: Col orSpec Default: depends on current color scheme	

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Editor is an interactive tool that enables you to see and change object property values.
- The set and get commands enable you to set and query the values of properties

To change the default value of properties see Setting Default Property Values.

Axes Property Descriptions

This section lists property names along with the types of values each accepts. Curly braces {} enclose default values.

ALi m [ami n, amax]

Alpha axis limits. A two-element vector that determines how MATLAB maps the Al phaData values of surface, patch and image objects to the figure's alphamap. amin is the value of the data mapped to the first alpha value in the alphamap, and amax is the value of the data mapped to the last alpha value in the alphamap. Data values in between are linearly interpolated across the alphamap, while data values outside are clamped to either the first or last alphamap value, whichever is closest.

When ALi mMode is auto (the default), MATLAB assigns amin the minimum data value and amax the maximum data value in the graphics object's Al phaData. This maps Al phaData elements with minimum data values to the first alphamap entry and those with maximum data values to the last alphamap entry. Data values in between are mapped linearly to the values

If the axes contains multiple graphics objects, MATLAB sets ALi m to span the range of all objects' Al phaData (or FaceVertexAl phaData for patch objects).

ALi mMbde {auto} | manual

Alpha axis limits mode. In auto mode, MATLAB sets the ALi m property to span the Al phaData limits of the graphics objects displayed in the axes. If ALi mMode is manual, MATLAB does not change the value of ALi m when the Al phaData limits of axes children change. Setting the ALi m property sets ALi mMode to manual.

AmbientLightColor ColorSpec

The background light in a scene. Ambient light is a directionless light that shines uniformly on all objects in the axes. However, if there are no visible light

objects in the axes, MATLAB does not use Ambi entLi ghtCol or. If there are light objects in the axes, the Ambi entLi ghtCol or is added to the other light sources.

AspectRatio (Obsolete)

This property produces a warning message when queried or changed. It has been superseded by the DataAspectRatio[Mode] and PlotBoxAspectRatio[Mode] properties.

Box on $| \{off\}$

Axes box mode. This property specifies whether to enclose the axes extent in a box for 2-D views or a cube for 3-D views. The default is to not display the box.

BusyAction cancel | {queue}

Callback routine interruption. The BusyActi on property enables you to control how MATLAB handles events that potentially interrupt executing callback routines. If there is a callback routine executing, subsequently invoked callback routines always attempt to interrupt it. If the Interruptible property of the object whose callback is executing is set to on (the default), then interruption occurs at the next point where the event queue is processed. If the Interruptible property is off, the BusyActi on property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are:

- cancel discard the event that attempted to execute a second callback routine.
- queue queue the event that attempted to execute a second callback routine until the current callback finishes.

ButtonDownFcn string

Button press callback routine. A callback routine that executes whenever you press a mouse button while the pointer is within the axes, but not over another graphics object displayed in the axes. For 3-D views, the active area is defined by a rectangle that encloses the axes.

Define this routine as a string that is a valid MATLAB expression or the name of an M-file. The expression executes in the MATLAB workspace.

CameraPosition [x, y, z] axes coordinates

The location of the camera. This property defines the position from which the camera views the scene. Specify the point in axes coordinates.

If you fix CameraVi ewAngl e, you can zoom in and out on the scene by changing the CameraPosition, moving the camera closer to the CameraTarget to zoom in and farther away from the CameraTarget to zoom out. As you change the CameraPosition, the amount of perspective also changes, if Projection is perspective. You can also zoom by changing the CameraVi ewAngl e; however, this does not change the amount of perspective in the scene.

CameraPositionMode {auto} | manual

Auto or manual CameraPosition. When set to auto, MATLAB automatically calculates the CameraPosition such that the camera lies a fixed distance from the CameraTarget along the azimuth and elevation specified by vi ew. Setting a value for CameraPosition sets this property to manual.

CameraTarget [x, y, z] axes coordinates

Camera aiming point. This property specifies the location in the axes that the camera points to. The CameraTarget and the CameraPosition define the vector (the view axis) along which the camera looks.

```
CameraTargetMode {auto} | manual
```

 $\label{lem:autoor} \textit{Auto or manual CameraTarget placement}. When this property is auto, \\ \textit{MATLAB automatically positions the CameraTarget at the centroid of the axes plotbox. Specifying a value for CameraTarget sets this property to manual.}$

```
CameraUpVector [x, y, z] axes coordinates
```

Camera rotation. This property specifies the rotation of the camera around the viewing axis defined by the CameraTarget and the CameraPosi ti on properties. Specify CameraUpVector as a three-element array containing the x, y, and z components of the vector. For example, $\begin{bmatrix} 0 & 1 & 0 \end{bmatrix}$ specifies the positive y-axis as the up direction.

The default CameraUpVector is $[0\ 0\ 1]$, which defines the positive z-axis as the up direction.

```
CameraUpVectorMode { auto} | manual
```

Default or user-specified up vector. When CameraUpVectorMode is auto, MATLAB uses a value of $[0\ 0\ 1]$ (positive z-direction is up) for 3-D views and

[0 1 0] (positive y-direction is up) for 2-D views. Setting a value for CameraUpVector sets this property to manual.

CameraVi ewAngl e scalar greater than 0 and less than or equal to 180 (angle in degrees)

The field of view. This property determines the camera field of view. Changing this value affects the size of graphics objects displayed in the axes, but does not affect the degree of perspective distortion. The greater the angle, the larger the field of view, and the smaller objects appear in the scene.

CameraVi ewAngl eMode { auto } | manual

Auto or manual Camera View Angle. When in auto mode, MATLAB sets Camera View Angle to the minimum angle that captures the entire scene (up to 180°).

The following table summarizes MATLAB's automatic camera behavior.

CameraView Angle	Camera Target	Camera Position	Behavior
auto	auto	auto	CameraTarget is set to plot box centroid, CameraVi ewAngl e is set to capture entire scene, CameraPosition is set along the view axis.
auto	auto	manual	CameraTarget is set to plot box centroid, CameraVi ewAngl e is set to capture entire scene.
auto	manual	auto	CameraVi ewAngl e is set to capture entire scene, CameraPosition is set along the view axis.
auto	manual	manual	CameraVi ewAngl e is set to capture entire scene.
manual	auto	auto	CameraTarget is set to plot box centroid, CameraPosition is set along the view axis.
manual	auto	manual	CameraTarget is set to plot box centroid
manual	manual	auto	CameraPosition is set along the view axis.
manual	manual	manual	All Camera properties are user-specified.

Children vector of graphics object handles

Children of the axes. A vector containing the handles of all graphics objects rendered within the axes (whether visible or not). The graphics objects that can be children of axes are images, lights, lines, patches, surfaces, and text. You can change the order of the handles and thereby change the stacking of the objects on the display.

The text objects used to label the *x*-, *y*-, and *z*-axes are also children of axes, but their Handl eVi si bi lity properties are set to call back. This means their handles do not show up in the axes Children property unless you set the Root ShowHi ddenHandles property to on.

CLi m [cmi n, cmax]

Color axis limits. A two-element vector that determines how MATLAB maps the CData values of surface and patch objects to the figure's colormap. cmin is the value of the data mapped to the first color in the colormap, and cmax is the value of the data mapped to the last color in the colormap. Data values in between are linearly interpolated across the colormap, while data values outside are clamped to either the first or last colormap color, whichever is closest.

When CLi mMode is auto (the default), MATLAB assigns cmin the minimum data value and cmax the maximum data value in the graphics object's CData. This maps CData elements with minimum data value to the first colormap entry and with maximum data value to the last colormap entry.

If the axes contains multiple graphics objects, MATLAB sets CLi m to span the range of all objects' CData.

CLi mMode {auto} | manual

Color axis limits mode. In auto mode, MATLAB sets the CLi m property to span the CData limits of the graphics objects displayed in the axes. If CLi mMode is manual, MATLAB does not change the value of CLi m when the CData limits of axes children change. Setting the CLi m property sets this property to manual.

Clipping {on} | off

This property has no effect on axes.

Color {none} | ColorSpec

Color of the axes back planes. Setting this property to none means the axes is transparent and the figure color shows through. A Col or Spec is a three-element RGB vector or one of MATLAB's predefined names. Note that while the default value is none, the matlabrc. m file may set the axes color to a specific color.

Col orOrder m-by-3 matrix of RGB values

Colors to use for multiline plots. Col or Order is an *m*-by-3 matrix of RGB values that define the colors used by the pl ot and pl ot 3 functions to color each line plotted. If you do not specify a line color with pl ot and pl ot 3, these functions cycle through the Col or Order to obtain the color for each line plotted. To obtain the current Col or Order, which may be set during startup, get the property value:

```
get(gca, 'ColorOrder')
```

Note that if the axes NextPl ot property is set to repl ace (the default), high-level functions like pl ot reset the Col orOrder property before determining the colors to use. If you want MATLAB to use a Col orOrder that is different from the default, set NextPl ot to repl acechildren. You can also specify your own default Col orOrder.

CreateFcn string

Callback routine executed during object creation. This property defines a callback routine that executes when MATLAB creates an axes object. You must define this property as a default value for axes. For example, the statement,

```
set(0, 'DefaultAxesCreateFcn', 'set(gca, ''Color'', ''b'')')
```

defines a default value on the Root level that sets the current axes' background color to blue whenever you (or MATLAB) create an axes. MATLAB executes this routine after setting all properties for the axes. Setting this property on an existing axes object has no effect.

The handle of the object whose CreateFcn is being executed is accessible only through the Root Call backObj ect property, which can be queried using gcbo.

CurrentPoint 2-by-3 matrix

Location of last button click, in axes data units. A 2-by-3 matrix containing the coordinates of two points defined by the location of the pointer. These two

points lie on the line that is perpendicular to the plane of the screen and passes through the pointer. The 3-D coordinates are the points, in the axes coordinate system, where this line intersects the front and back surfaces of the axes volume (which is defined by the axes x, y, and z limits).

The returned matrix is of the form:

MATLAB updates the CurrentPoi nt property whenever a button-click event occurs. The pointer does not have to be within the axes, or even the figure window; MATLAB returns the coordinates with respect to the requested axes regardless of the pointer location.

DataAspectRatio [dx dy dz]

Relative scaling of data units. A three-element vector controlling the relative scaling of data units in the x, y, and z directions. For example, setting this property to $\begin{bmatrix} 1 & 2 & 1 \end{bmatrix}$ causes the length of one unit of data in the x direction to be the same length as two units of data in the y direction and one unit of data in the z direction.

Note that the DataAspectRatio property interacts with the PlotBoxAspectRatio, XLimMode, YLimMode, and ZLimMode properties to control how MATLAB scales the *x*-, *y*-, and *z*-axis. Setting the DataAspectRatio will disable the stretch-to-fill behavior, if DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all auto. The

following table describes the interaction between properties when stretch-to-fill behavior is disabled.

X-, Y-, Z-Limits	DataAspect Ratio	PlotBox AspectRatio	Behavior
auto	auto	auto	Limits chosen to span data range in all dimensions.
auto	auto	manual	Limits chosen to span data range in all dimensions. DataAspectRatio is modified to achieve the requested PlotBoxAspectRatio within the limits selected by MATLAB.
auto	manual	auto	Limits chosen to span data range in all dimensions. PlotBoxAspectRatio is modified to achieve the requested DataAspectRatio within the limits selected by MATLAB.
auto	manual	manual	Limits chosen to completely fit and center the plot within the requested PlotBoxAspectRatio given the requested DataAspectRatio (this may produce empty space around 2 of the 3 dimensions).
manual	auto	auto	Limits are honored. The DataAspectRatio and PlotBoxAspectRatio are modified as necessary.
manual	auto	manual	Limits and PlotBoxAspectRatio are honored. The DataAspectRatio is modified as necessary.
manual	manual	auto	Limits and DataAspectRatio are honored. The PlotBoxAspectRatio is modified as necessary.
1 manual 2 auto	manual	manual	The 2 automatic limits are selected to honor the specified aspect ratios and limit. See "Examples"
2 or 3 manual	manual	manual	Limits and DataAspectRatio are honored; the PlotBoxAspectRatio is ignored.

DataAspectRatioMode(auto) | manual

User or MATLAB controlled data scaling. This property controls whether the values of the DataAspectRatio property are user defined or selected automatically by MATLAB. Setting values for the DataAspectRatio property automatically sets this property to manual. Changing DataAspectRatioMode to manual disables the stretch-to-fill behavior, if DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all auto.

Del eteFcn string

Delete axes callback routine. A callback routine that executes when the axes object is deleted (e.g., when you issue a delete or a close command). MATLAB executes the routine before destroying the object's properties so the callback routine can query these values.

The handle of the object whose DeleteFcn is being executed is accessible only through the Root CallbackObject property, which can be queried using gcbo.

DrawMode {normal} | fast

Rendering method. This property controls the method MATLAB uses to render graphics objects displayed in the axes, when the figure Renderer property is painters.

- normal mode draws objects in back to front ordering based on the current view in order to handle hidden surface elimination and object intersections.
- fast mode draws objects in the order in which you specify the drawing commands, without considering the relationships of the objects in three dimensions. This results in faster rendering because it requires no sorting of objects according to location in the view, but may produce undesirable results because it bypasses the hidden surface elimination and object intersection handling provided by normal DrawMode.

When the figure Renderer is zbuffer, DrawMode is ignored, and hidden surface elimination and object intersection handling are always provided.

FontAngle {normal} | italic | oblique

Select italic or normal font. This property selects the character slant for axes text. normal specifies a nonitalic font. italic and oblique specify italic font.

FontName A name such as Couri er or the string Fi xedWi dth

Font family name. The font family name specifying the font to use for axes labels. To display and print properly, Font Name must be a font that your system supports. Note that the x-, y-, and z-axis labels do not display in a new font until you manually reset them (by setting the XLabel , YLabel , and ZLabel properties or by using the xlabel , ylabel , or zlabel command). Tick mark labels change immediately.

Specifying a Fixed-Width Font

If you want an axes to use a fixed-width font that looks good in any locale, you should set FontName to the string Fi xedWi dth:

```
set(axes_handle, 'FontName', 'Fi xedWidth')
```

This eliminates the need to hardcode the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan where multibyte character sets are used). A properly written MATLAB application that needs to use a fixed-width font should set FontName to Fi xedWi dth (note that this string is case sensitive) and rely on Fi xedWi dthFontName to be set correctly in the end-user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root Fi xedWi dthFontName property to the appropriate value for that locale from startup. m.

Note that setting the root Fi xedWi dthFontName property causes an immediate update of the display to use the new font.

FontSize Font size specified in FontUnits

Font size. An integer specifying the font size to use for axes labels and titles, in units determined by the FontUnits property. The default point size is 12. The x-, y-, and z-axis text labels do not display in a new font size until you manually reset them (by setting the XLabel, YLabel, or ZLabel properties or by using the xlabel, ylabel, or zlabel command). Tick mark labels change immediately.

```
FontUnits {points} | normalized | inches | centimeters | pixels
```

Units used to interpret the FontSi ze *property.* When set to normal i zed, MATLAB interprets the value of FontSi ze as a fraction of the height of the axes. For example, a normal i zed FontSi ze of 0.1 sets the text characters to a

font whose height is one tenth of the axes' height. The default units (points), are equal to 1/72 of an inch.

```
FontWeight {normal} | bold | light | demi
```

Select bold or normal font. The character weight for axes text. The x-, y-, and z-axis text labels do not display in bold until you manually reset them (by setting the XLabel, YLabel, and ZLabel properties or by using the xlabel, ylabel, or zlabel commands). Tick mark labels change immediately.

```
GridLineStyle - \mid -- \mid \{:\} \mid -. \mid \text{none}
```

Line style used to draw grid lines. The line style is a string consisting of a character, in quotes, specifying solid lines (–), dashed lines (–), dotted lines(:), or dash-dot lines (–.). The default grid line style is dotted. To turn on grid lines, use the grid command.

```
HandleVisibility {on} | callback | off
```

Control access to object's handle by command-line users and GUIs. This property determines when an object's handle is visible in its parent's list of children. Handl eVi si bility is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

Handles are always visible when HandleVi si bility is on.

Setting Handl eVi si bility to call back causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.

Setting Handl eVi si bility to off makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string) and so temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes get, findobj, gca, gcf, gco, newplot, cla, clf, and close.

When a handle's visibility is restricted using call back or off, the object's handle does not appear in its parent's Children property, figures do not appear in the Root's Currentfigure property, objects do not appear in the Root's CallbackObject property or in the figure's CurrentObject property, and axes do not appear in their parent's Currentaxes property.

You can set the Root ShowHi ddenHandl es property to on to make all handles visible, regardless of their Handl eVi si bility settings (this does not affect the values of the Handl eVi si bility properties).

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HitTest {on} | off

Selectable by mouse click. HitTest determines if the axes can become the current object (as returned by the gco command and the figure CurrentObject property) as a result of a mouse click on the axes. If HitTest is off, clicking on the axes selects the object below it (which is usually the figure containing it).

Interruptible {on} | off

Callback routine interruption mode. The Interrupti ble property controls whether an axes callback routine can be interrupted by subsequently invoked callback routines. Only callback routines defined for the ButtonDownFcn are affected by the Interrupti ble property. MATLAB checks for events that can interrupt a callback routine only when it encounters a drawnow, figure, getframe, or pause command in the routine. See the BusyActi on property for related information.

Setting Interruptible to on allows any graphics object's callback routine to interrupt callback routines originating from an axes property. Note that MATLAB does not save the state of variables or the display (e.g., the handle returned by the gca or gcf command) when an interruption occurs.

Layer {bottom} | top

Draw axis lines below or above graphics objects. This property determines if axis lines and tick marks draw on top or below axes children objects for any 2-D view (i.e., when you are looking along the x-, y-, or z-axis). This is useful for placing grid lines and tick marks on top of images.

Li neStyl e0rder Li neSpec

Order of line styles and markers used in a plot. This property specifies which line styles and markers to use and in what order when creating multiple-line plots. For example,

```
set(gca, 'LineStyleOrder', '-*|: |o')
```

sets Li neStyl e0rder to solid line with asterisk marker, dotted line, and hollow circle marker. The default is (–), which specifies a solid line for all data plotted. Alternatively, you can create a cell array of character strings to define the line styles:

```
set(gca, 'LineStyleOrder', {'-*', ':', 'o'})
```

MATLAB supports four line styles, which you can specify any number of times in any order. MATLAB cycles through the line styles only after using all colors defined by the Col orOrder property. For example, the first eight lines plotted use the different colors defined by Col orOrder with the first line style. MATLAB then cycles through the colors again, using the second line style specified, and so on.

You can also specify line style and color directly with the pl ot and pl ot 3 functions or by altering the properties of the line objects.

Note that, if the axes NextPl ot property is set to repl ace (the default), high-level functions like pl ot reset the Li neStyl e0rder property before determining the line style to use. If you want MATLAB to use a Li neStyl e0rder that is different from the default, set NextPl ot to repl acechil dren. You can also specify your own default Li neStyl e0rder.

Li neWi dth linewidth in points

Width of axis lines. This property specifies the width, in points, of the *x*-, *y*-, and *z*-axis lines. The default line width is 0.5 points (1 point = $^{1}/_{72}$ inch).

```
NextPlot add | {replace} | replacechildren
```

Where to draw the next plot. This property determines how high-level plotting functions draw into an existing axes.

- add use the existing axes to draw graphics objects.
- repl ace reset all axes properties, except Position, to their defaults and delete all axes children before displaying graphics (equivalent to clareset).

 repl acechi l dren — remove all child objects, but do not reset axes properties (equivalent to cl a).

The newpl of function simplifies the use of the NextPl of property and is used by M-file functions that draw graphs using only low-level object creation routines. See the M-file pcol or. m for an example. Note that figure graphics objects also have a NextPl of property.

Parent figure handle

Axes parent. The handle of the axes' parent object. The parent of an axes object is the figure in which it is displayed. The utility function gcf returns the handle of the current axes' Parent. You can reparent axes to other figure objects.

PlotBoxAspectRatio [px py pz]

Relative scaling of axes plotbox. A three-element vector controlling the relative scaling of the plot box in the x-, y-, and z-directions. The plot box is a box enclosing the axes data region as defined by the x-, y-, and z-axis limits.

Note that the Pl otBoxAspectRatio property interacts with the DataAspectRatio, XLi mMode, YLi mMode, and ZLi mMode properties to control the way graphics objects are displayed in the axes. Setting the Pl otBoxAspectRatio disables stretch-to-fill behavior, if DataAspectRatioMode, Pl otBoxAspectRatioMode, and CameraVi ewAngleMode are all auto.

PlotBoxAspectRatioMode{auto} | manual

User or MATLAB controlled axis scaling. This property controls whether the values of the Pl otBoxAspectRati o property are user defined or selected automatically by MATLAB. Setting values for the Pl otBoxAspectRati o property automatically sets this property to manual. Changing the Pl otBoxAspectRati oMode to manual disables stretch-to-fill behavior, if DataAspectRati oMode, Pl otBoxAspectRati oMode, and CameraVi ewAngl eMode are all auto.

Position four-element vector

Position of axes. A four-element vector specifying a rectangle that locates the axes within the figure window. The vector is of the form:

[left bottom width height]

where left and bottom define the distance from the lower-left corner of the figure window to the lower-left corner of the rectangle. wi dth and hei ght are the dimensions of the rectangle. All measurements are in units specified by the Units property.

When axes stretch-to-fill behavior is enabled (when DataAspectRati oMode, Pl otBoxAspectRati oMode, CameraVi ewAngl eMode are all auto), the axes are stretched to fill the Positi on rectangle. When stretch-to-fill is disabled, the axes are made as large as possible, while obeying all other properties, without extending outside the Positi on rectangle

Projection {orthographic} | perspective

Type of projection. This property selects between two projection types:

- orthographi c This projection maintains the correct relative dimensions of graphics objects with regard to the distance a given point is from the viewer.
 Parallel lines in the data are drawn parallel on the screen.
- perspective This projection incorporates foreshortening, which allows you
 to perceive depth in 2-D representations of 3-D objects. Perspective
 projection does not preserve the relative dimensions of objects; a distant line
 segment displays smaller than a nearer line segment of the same length.
 Parallel lines in the data may not appear parallel on screen.

Selected on | off

Is object selected. When you set this property to on, MATLAB displays selection "handles" at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback routine to set this property to on, thereby indicating that the axes has been selected.

SelectionHighlight {on} | off

Objects highlight when selected. When the Selected property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When SelectionHighlight is off, MATLAB does not draw the handles.

Tag string (GUIDE sets this property)

User-specified object label. The Tag property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to

define object handles as global variables or pass them as arguments between callback routines.

For example, suppose you want to direct all graphics output from an M-file to a particular axes, regardless of user actions that may have changed the current axes. To do this, identify the axes with a Tag:

```
axes('Tag', 'Special Axes')
```

Then make that axes the current axes before drawing by searching for the Tag with findobj:

```
axes(findobj('Tag', 'Special Axes'))
```

TickDir in out

Direction of tick marks. For 2-D views, the default is to direct tick marks inward from the axis lines; 3-D views direct tick marks outward from the axis line.

```
TickDirMode {auto} | manual
```

Automatic tick direction control. In auto mode, MATLAB directs tick marks inward for 2-D views and outward for 3-D views. When you specify a setting for Ti ckDi r, MATLAB sets Ti ckDi rMode to manual . In manual mode, MATLAB does not change the specified tick direction.

```
TickLength [2DLength 3DLength]
```

Length of tick marks. A two-element vector specifying the length of axes tick marks. The first element is the length of tick marks used for 2-D views and the second element is the length of tick marks used for 3-D views. Specify tick mark lengths in units normalized relative to the longest of the visible X-, Y-, or Z-axis annotation lines.

```
Title handle of text object
```

Axes title. The handle of the text object that is used for the axes title. You can use this handle to change the properties of the title text or you can set Title to the handle of an existing text object. For example, the following statement changes the color of the current title to red:

```
set(get(gca, 'Title'), 'Color', 'r')
```

To create a new title, set this property to the handle of the text object you want to use:

```
set(gca, 'Title', text('String', 'New Title', 'Color', 'r'))
```

However, it is generally simpler to use the title command to create or replace an axes title:

```
title('New Title', 'Color', 'r')
```

Type string (read only)

Type of graphics object. This property contains a string that identifies the class of graphics object. For axes objects, Type is always set to 'axes'.

UIContextMenu handle of a uicontextmenu object

Associate a context menu with the axes. Assign this property the handle of a Uicontextmenu object created in the axes' parent figure. Use the ui contextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the axes.

```
Units inches | centimeters | {normalized} | points | pixels | characters
```

Position units. The units used to interpret the Position property. All units are measured from the lower-left corner of the figure window.

- normal i zed units map the lower-left corner of the figure window to (0,0) and the upper-right corner to (1.0, 1.0).
- inches, centimeters, and points are absolute units (one point equals $^{1}/_{72}$ of an inch).
- Character units are defined by characters from the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

UserData matrix

User specified data. This property can be any data you want to associate with the axes object. The axes does not use this property, but you can access it using the set and get functions.

Vi ew Obsolete

The functionality provided by the View property is now controlled by the axes camera properties — CameraPosition, CameraTarget, CameraUpVector, and CameraVi ewAngl e. See the view command.

Visible {on} | off

Visibility of axes. By default, axes are visible. Setting this property to off prevents axis lines, tick marks, and labels from being displayed. The visible property does not affect children of axes.

XAxisLocation top | {bottom}

Location of x-axis tick marks and labels. This property controls where MATLAB displays the x-axis tick marks and labels. Setting this property to top moves the x-axis to the top of the plot from its default position at the bottom.

YAxisLocation right | {left}

Location of y-axis tick marks and labels. This property controls where MATLAB displays the y-axis tick marks and labels. Setting this property to right moves the y-axis to the right side of the plot from its default position on the left side. See the plotyy function for a simple way to use two y-axes.

Properties That Control the X-, Y-, or Z-Axis

XColor, YColor, ZColorColorSpec

Color of axis lines. A three-element vector specifying an RGB triple, or a predefined MATLAB color string. This property determines the color of the axis lines, tick marks, tick mark labels, and the axis grid lines of the respective *x*-, *y*-, and *z*-axis. The default color axis color is black. See Col or Spec for details on specifying colors.

XDir, YDir, ZDir {normal} | reverse

Direction of increasing values. A mode controlling the direction of increasing axis values. axes form a right-hand coordinate system. By default:

x-axis values increase from left to right. To reverse the direction of increasing x values, set this property to reverse.

```
set(gca, 'XDir', 'reverse')
```

• *y*-axis values increase from bottom to top (2-D view) or front to back (3-D view). To reverse the direction of increasing *y* values, set this property to reverse.

```
set(gca, 'YDir', 'reverse')
```

• z-axis values increase pointing out of the screen (2-D view) or from bottom to top (3-D view). To reverse the direction of increasing z values, set this property to reverse.

```
set(gca, 'ZDir', 'reverse')
```

XGrid, **YGrid**, **ZGrid** on $| \{off\}$

Axis gridline mode. When you set any of these properties to on, MATLAB draws grid lines perpendicular to the respective axis (i.e., along lines of constant x, y, or zvalues). Use the grid command to set all three properties on or off at once.

```
set(gca, 'XGrid', 'on')
```

XLabel, YLabel, ZLabel handle of text object

Axis labels. The handle of the text object used to label the *x*, *y*, or *z*-axis, respectively. To assign values to any of these properties, you must obtain the handle to the text string you want to use as a label. This statement defines a text object and assigns its handle to the XLabel property:

```
set(get(gca, 'XLabel'), 'String', 'axis label')
```

MATLAB places the string 'axis label' appropriately for an x-axis label. Any text object whose handle you specify as an XLabel, YLabel, or ZLabel property is moved to the appropriate location for the respective label.

Alternatively, you can use the xl abel, yl abel, and zl abel functions, which generally provide a simpler means to label axis lines.

```
XLim, YLim, ZLim [minimum maximum]
```

Axis limits. A two-element vector specifying the minimum and maximum values of the respective axis.

Changing these properties affects the scale of the x-, y-, or z-dimension as well as the placement of labels and tick marks on the axis. The default values for these properties are $[0\ 1]$.

```
XLi mMode, YLi mMode, ZLi mMode auto | manual
```

MATLAB or user-controlled limits. The axis limits mode determines whether MATLAB calculates axis limits based on the data plotted (i.e., the XData, YData, or ZData of the axes children) or uses the values explicitly set with the XLi m, YLi m, or ZLi m property, in which case, the respective limits mode is set to manual.

```
XMinorGrid, YMinorGrid, ZMinorGridon | {off}
```

Enable or disable minor gridlines. When set to on, MATLAB draws gridlines aligned with the minor tick marks of the respective axis. Note that you do not have to enable minor ticks to display minor grids.

```
XMinorTick, YMinorTick, ZMinorTickon | {off}
```

Enable or disable minor tick marks. When set to on, MATLAB draws tick marks between the major tick marks of the respective axis. MATLAB automatically determines the number of minor ticks based on the space between the major ticks.

```
XScale, YScale, ZScale{linear} | log
```

Axis scaling. Linear or logarithmic scaling for the respective axis. See also loglog, semilogx, and semilogy.

XTick, YTick, ZTickvector of data values locating tick marks

Tick spacing. A vector of x-, y-, or z-data values that determine the location of tick marks along the respective axis. If you do not want tick marks displayed, set the respective property to the empty vector, []. These vectors must contain monotonically increasing values.

XTickLabel, YTickLabel, ZTickLabelstring

Tick labels. A matrix of strings to use as labels for tick marks along the respective axis. These labels replace the numeric labels generated by MATLAB. If you do not specify enough text labels for all the tick marks, MATLAB uses all of the labels specified, then reuses the specified labels.

For example, the statement,

```
set(\texttt{gca}, \texttt{'XTi}\, \texttt{ckLabel'}, \{\texttt{'0ne'}; \texttt{'Two'}; \texttt{'Three'}; \texttt{'Four'}\})
```

labels the first four tick marks on the *x*-axis and then reuses the labels until all ticks are labeled.

Labels can be specified as cell arrays of strings, padded string matrices, string vectors separated by vertical slash characters, or as numeric vectors (where each number is implicitly converted to the equivalent string using num2str). All of the following are equivalent:

```
set(gca, 'XTi ckLabel', {'1';'10';'100'})
set(gca, 'XTi ckLabel', '1|10|100')
```

```
set(gca, 'XTi ckLabel', [1; 10; 100])
set(gca, 'XTi ckLabel', ['1 ';'10'])
```

Note that tick labels do not interpret TeX character sequences (however, the Title, XLabel, YLabel, and ZLabel properties do).

```
XTickMode, YTickMode, ZTickMode{auto} | manual
```

MATLAB or user controlled tick spacing. The axis tick modes determine whether MATLAB calculates the tick mark spacing based on the range of data for the respective axis (auto mode) or uses the values explicitly set for any of the XTi ck, YTi ck, and ZTi ck properties (manual mode). Setting values for the XTi ck, YTi ck, or ZTi ck properties sets the respective axis tick mode to manual.

XTickLabel Mode, YTickLabel Mode, ZTickLabel Mode { auto } | manual

MATLAB or user determined tick labels. The axis tick mark labeling mode determines whether MATLAB uses numeric tick mark labels that span the range of the plotted data (auto mode) or uses the tick mark labels specified with the XTi ckLabel, YTi ckLabel, or ZTi ckLabel property (manual mode). Setting values for the XTi ckLabel, YTi ckLabel, or ZTi ckLabel property sets the respective axis tick label mode to manual.

Purpose

Axis scaling and appearance

Syntax

```
axis([xmin xmax ymin ymax])
axis([xmin xmax ymin ymax zmin zmax cmin cmax])
v = axis
axis auto
axis manual
axis tight
axis fill
axis ij
axis xy
axis equal
axis image
axis square
axis vis3d
axis normal
axis off
axis on
[mode, visibility, direction] = axis('state')
```

Description

axi s manipulates commonly used axes properties. (See Algorithm section.)

axis([xmin xmax ymin ymax]) sets the limits for the x- and y-axis of the current axes.

axis([xmin xmax ymin ymax zmin zmax cmin cmax]) sets the *x*-, *y*-, and *z*-axis limits and the color scaling limits (see caxis) of the current axes.

 $v=axi\,s$ returns a row vector containing scaling factors for the *x*-, *y*-, and *z*-axis. v has four or six components depending on whether the current axes is 2-D or 3-D, respectively. The returned values are the current axes' XLi m, Yl i m, and ZLi m properties.

axi s auto sets MATLAB to its default behavior of computing the current axes' limits automatically, based on the minimum and maximum values of x, y, and z data. You can restrict this automatic behavior to a specific axis. For example, axi s ' auto x' computes only the x-axis limits automatically; axi s ' auto yz' computes the y- and z-axis limits automatically.

 $axi\ s$ manual and $axi\ s$ ($axi\ s$) freezes the scaling at the current limits, so that if hold is on, subsequent plots use the same limits. This sets the XLi mMode, YLi mMode, and ZLi mMode properties to manual.

axi s tight sets the axis limits to the range of the data.

axis fill sets the axis limits to the range of the data.

axis ij places the coordinate system origin in the upper-left corner. The *i*-axis is vertical, with values increasing from top to bottom. The *j*-axis is horizontal with values increasing from left to right.

axi s xy draws the graph in the default Cartesian axes format with the coordinate system origin in the lower-left corner. The *x*-axis is horizontal with values increasing from left to right. The *y*-axis is vertical with values increasing from bottom to top.

axi s equal sets the aspect ratio so that the data units are the same in every direction. The aspect ratio of the x-, y-, and z-axis is adjusted automatically according to the range of data units in the x, y, and z directions.

axis i mage is the same as axis equal except that the plot box fits tightly around the data.

axi s square makes the current axes region square (or cubed when three-dimensional). MATLAB adjusts the *x*-axis, *y*-axis, and *z*-axis so that they have equal lengths and adjusts the increments between data units accordingly.

axi s vi s3d freezes aspect ratio properties to enable rotation of 3-D objects and overrides stretch-to-fill.

axi s normal automatically adjusts the aspect ratio of the axes and the aspect ratio of the data units represented on the axes to fill the plot box.

axis off turns off all axis lines, tick marks, and labels.

axi s on turns on all axis lines, tick marks, and labels.

[mode, visibility, direction] = axis('state') returns three strings indicating the current setting of axes properties:

Output Argument	Strings Returned		
mode	'auto' 'manual'		
vi si bi l i ty	'on' 'off'		
di recti on	'xy' 'ij'		

 $mode\ is\ auto\ if\ XLi\ mMode,\ YLi\ mMode,\ and\ ZLi\ mMode\ are\ all\ set\ to\ auto.\ If\ XLi\ mMode,\ YLi\ mMode,\ or\ ZLi\ mMode\ is\ manual\ .$

Examples

The statements

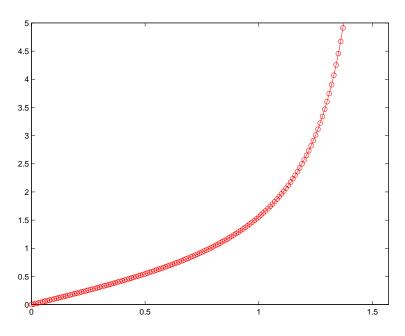

```
x = 0:.025: pi/2;
plot(x, tan(x), '-ro')
```

use the automatic scaling of the *y*-axis based on ymax = tan(1.57), which is well over 1000:

The right figure shows a more satisfactory plot after typing

axis([0 pi/2 0 5])

Algorithm

When you specify minimum and maximum values for the x-, y-, and z-axes, axi s sets the XLi m, Yl i m, and ZLi m properties for the current axes to the respective minimum and maximum values in the argument list. Additionally, the XLi mMode, YLi mMode, and ZLi mMode properties for the current axes are set to manual.

axi s auto sets the current axes' XLi mMode, YLi mMode, and ZLi mMode properties to 'auto' .

 $axi\ s$ manual sets the current axes' XLi mMode, YLi mMode, and ZLi mMode properties to 'manual ' .

axis

The following table shows the values of the axes properties set by axis equal, axis normal, axis square, and axis image.

Axes Property	axis equal	axis normal	axis square	axis tightequal
DataAspectRatio	[1 1 1]	not set	not set	[1 1 1]

Properties of axes graphics objects

Purpose

Improve accuracy of computed eigenvalues

Syntax

Description

[T, B] = bal ance(A) returns a permutation of a diagonal matrix T whose elements are integer powers of two, and a balanced matrix B so that B = T A T. If A is symmetric, then B = A and T is the identity matrix.

B = balance(A) returns just the balanced matrix B.

Remarks

Nonsymmetric matrices can have poorly conditioned eigenvalues. Small perturbations in the matrix, such as roundoff errors, can lead to large perturbations in the eigenvalues. The condition number of the eigenvector matrix,

```
cond(V) = norm(V) * norm(i nv(V))
where
```

$$[V, T] = ei g(A)$$

relates the size of the matrix perturbation to the size of the eigenvalue perturbation. Note that the condition number of A itself is irrelevant to the eigenvalue problem.

Balancing is an attempt to concentrate any ill conditioning of the eigenvector matrix into a diagonal scaling. Balancing usually cannot turn a nonsymmetric matrix into a symmetric matrix; it only attempts to make the norm of each row equal to the norm of the corresponding column. Furthermore, the diagonal scale factors are limited to powers of two so they do not introduce any roundoff error.

Note MATLAB's eigenvalue function, eig(A), automatically balances A before computing its eigenvalues. Turn off the balancing with eig(A, 'nobal ance').

Examples

This example shows the basic idea. The matrix A has large elements in the upper right and small elements in the lower left. It is far from being symmetric.

Balancing produces a diagonal T matrix with elements that are powers of two and a balanced matrix B that is closer to symmetric than A.

```
[T, B] = balance(A)
T =
   1. 0e+03 *
    2.0480
                                0
                     0
         0
               0.0320
                                0
         0
                     0
                          0.0003
B =
    1.0000
               1.5625
                          1.2207
    0.6400
               1.0000
                          0.7813
    0.8192
               1. 2800
                          1.0000
```

To see the effect on eigenvectors, first compute the eigenvectors of A.

Note that all three vectors have the first component the largest. This indicates V is badly conditioned; in fact cond(V) is 8. 7766e+003. Next, look at the eigenvectors of B.

Now the eigenvectors are well behaved and cond(V) is 1. 4421. The ill conditioning is concentrated in the scaling matrix; cond(T) is 8192.

This example is small and not really badly scaled, so the computed eigenvalues of A and B agree within roundoff error; balancing has little effect on the computed results.

Algorithm

The eig function automatically uses balancing to prepare its input matrix. bal ance uses LAPACK routines DGEBAL (real) and ZGEBAL (complex). If you request the output T, it also uses the LAPACK routines DGEBAK (real) and ZGEBAK (complex).

Limitations

Balancing can destroy the properties of certain matrices; use it with some care. If a matrix contains small elements that are due to roundoff error, balancing may scale them up to make them as significant as the other elements of the original matrix.

bar, barh

Purpose

Bar chart

Syntax

```
bar(Y)
bar(x, Y)
bar(..., wi dth)
bar(..., 'style')
bar(..., Li neSpec)
h = bar(...)
barh(...)
```

Description

A bar chart displays the values in a vector or matrix as horizontal or vertical bars.

bar (Y) draws one bar for each element in Y. If Y is a matrix, bar groups the bars produced by the elements in each row. The x-axis scale ranges from 1 to length (Y) when Y is a vector, and 1 to si ze (Y, 1), which is the number of rows, when Y is a matrix.

bar(x, Y) draws a bar for each element in Y at locations specified in x, where x is a monotonically increasing vector defining the x-axis intervals for the vertical bars. If Y is a matrix, bar clusters the elements in the same row in Y at locations corresponding to an element in x.

bar(..., width) sets the relative bar width and controls the separation of bars within a group. The default width is 0.8, so if you do not specify x, the bars within a group have a slight separation. If width is 1, the bars within a group touch one another.

bar(..., 'style') specifies the style of the bars. 'style' is 'grouped' or 'stacked'.'group' is the default mode of display.

- 'grouped' displays *n* groups of *m* vertical bars, where *n* is the number of rows and *m* is the number of columns in Y. The group contains one bar per column in Y.
- 'stacked' displays one bar for each row in Y. The bar height is the sum of the elements in the row. Each bar is multi-colored, with colors corresponding to

distinct elements and showing the relative contribution each row element makes to the total sum.

bar (..., Li neSpec) displays all bars using the color specified by Li neSpec.

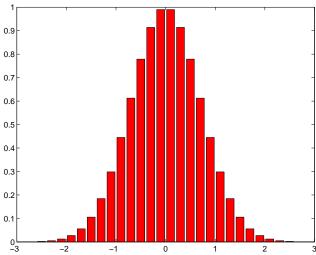

h = bar(...) returns a vector of handles to patch graphics objects. bar creates one patch graphics object per column in Y.

barh(...), and h = barh(...) create horizontal bars. Y determines the bar length. The vector x is a monotonic vector defining the y-axis intervals for horizontal bars.

Examples

Plot a bell shaped curve:

```
x = -2.9:0.2:2.9;
bar(x, exp(-x. *x))
col ormap hsv
```

Create four subplots showing the effects of various bar arguments:

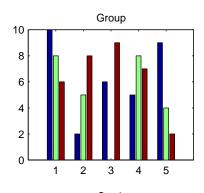

```
Y = round(rand(5, 3) *10);
subplot(2, 2, 1)
bar(Y, 'group')
title 'Group'
```

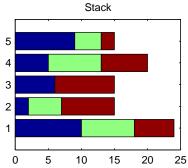

subpl ot (2, 2, 2)
bar(Y, 'stack')
title 'Stack'

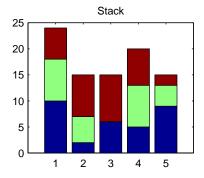

subpl ot (2, 2, 3)
barh(Y, 'stack')
title 'Stack'

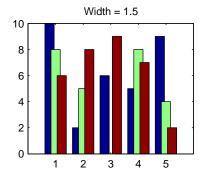

subpl ot (2, 2, 4)
bar(Y, 1. 5)

title'Width = 1.5'

See Also

bar3, ColorSpec, patch, stairs, hist

Purpose

Three-dimensional bar chart

Syntax

```
bar3(Y)
bar3(x, Y)
bar3(..., wi dth)
bar3(..., 'style')
bar3(..., Li neSpec)
h = bar3(...)
bar3h(...)
h = bar3h(...)
```

Description

bar3 and bar3h draw three-dimensional vertical and horizontal bar charts.

bar3(Y) draws a three-dimensional bar chart, where each element in Y corresponds to one bar. When Y is a vector, the x-axis scale ranges from 1 to length(Y). When Y is a matrix, the x-axis scale ranges from 1 to si ze(Y, 2), which is the number of columns, and the elements in each row are grouped together.

bar3(x, Y) draws a bar chart of the elements in Y at the locations specified in x, where x is a monotonic vector defining the y-axis intervals for vertical bars. If Y is a matrix, bar3 clusters elements from the same row in Y at locations corresponding to an element in x. Values of elements in each row are grouped together.

bar3(..., wi dth) sets the width of the bars and controls the separation of bars within a group. The default wi dth is 0. 8, so if you do not specify x, bars within a group have a slight separation. If wi dth is 1, the bars within a group touch one another.

bar3(..., 'style') specifies the style of the bars. 'style' is 'detached', 'grouped', or 'stacked'. 'detached' is the default mode of display.

- 'detached' displays the elements of each row in Y as separate blocks behind one another in the *x* direction.
- 'grouped' displays *n* groups of *m* vertical bars, where *n* is the number of rows and *m* is the number of columns in Y. The group contains one bar per column in Y.

• 'stacked' displays one bar for each row in Y. The bar height is the sum of the elements in the row. Each bar is multi-colored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

bar3(..., Li neSpec) displays all bars using the color specified by Li neSpec.

h = bar3(...) returns a vector of handles to patch graphics objects. bar3 creates one patch object per column in Y.

bar3h(...) and h = bar3h(...) create horizontal bars. Y determines the bar length. The vector x is a monotonic vector defining the y-axis intervals for horizontal bars.

Examples

This example creates six subplots showing the effects of different arguments for bar3. The data Y is a seven-by-three matrix generated using the cool colormap:

```
Y = cool(7);
subplot(3, 2, 1)
bar3(Y, 'detached')
title('Detached')

subplot(3, 2, 2)
bar3(Y, 0. 25, 'detached')
title('Width = 0. 25')

subplot(3, 2, 3)
bar3(Y, 'grouped')
title('Grouped')

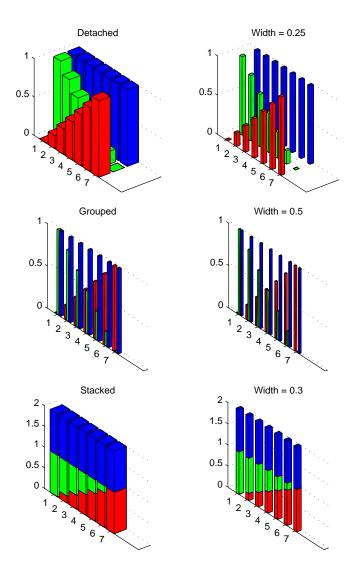

subplot(3, 2, 4)
bar3(Y, 0. 5, 'grouped')
title('Width = 0. 5')
```

bar3, bar3h

```
subpl ot (3, 2, 5)
bar3(Y, 'stacked')
title('Stacked')

subpl ot (3, 2, 6)
bar3(Y, 0. 3, 'stacked')
title('Width = 0. 3')

colormap([1 0 0; 0 1 0; 0 0 1])
```

See Also bar, Li neSpec, patch

base2dec

Purpose Base to decimal number conversion

Syntax d = base2dec('strn', base)

Description d = base2dec('strn', base) converts the string number strn of the specified

base into its decimal (base 10) equivalent. base must be an integer between 2 and 36. If 'strn' is a character array, each row is interpreted as a string in the

specified base.

Examples The expression base2dec('212', 3) converts 212₃ to decimal, returning 23.

See Also dec2base

Purpose Produce a beep sound

Syntax beep

beep on beep off s = beep

Description beep produces you computer's default beep sound

beep on turns the beep on

beep off turn the beep off

s = beep returns the current beep mode (on or of f)

besselh

Purpose

Bessel functions of the third kind (Hankel functions)

Syntax

H = besselh(nu, K, Z)

H = besselh(nu, Z)

H = besselh(nu, 1, Z, 1)

H = besselh(nu, 2, Z, 1)

[H, ierr] = besselh(...)

Definitions

The differential equation

$$z^{2} \frac{d^{2} y}{dz^{2}} + z \frac{dy}{dz} + (z^{2} - v^{2}) y = 0$$

where v is a nonnegative constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*. $J_{\nu}(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger v. $Y_{\nu}(z)$ is a second solution of Bessel's equation—linearly independent of $J_{\nu}(z)$ —defined by

$$Y_{v}(z) = \frac{J_{v}(z)\cos(v\pi) - J_{-v}(z)}{\sin(v\pi)}$$

The relationship between the Hankel and Bessel functions is

$$H_{V}^{(1)}(z) = J_{V}(z) + i Y_{V}(z)$$

$$H2_{\nu}(z) = J_{\nu}(z) - i Y_{\nu}(z)$$

Description

H = besselh(nu, K, Z) for K = 1 or 2 computes the Hankel functions

 $H_{\nu}^{(1)}(z)$ or $H_{\nu}^{(2)}(z)$ for each element of the complex array Z. If nu and Z are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector and the other is a column vector, the result is a two-dimensional table of function values.

H = besselh(nu, Z) uses K = 1.

 $\mathbf{H} = \operatorname{besselh}(\operatorname{nu}, 1, \mathbf{Z}, 1) \text{ scales } H_{\mathbf{V}}^{(1)}(z) \text{ by } \exp(-\mathrm{i} * z).$

 $\mathbf{H} = \operatorname{besselh}(\operatorname{nu},\, \mathbf{2},\, \mathbf{Z},\, \mathbf{1}) \, \, \operatorname{scales} \, \, H_{\nu}^{(2)}(z) \, \, \operatorname{by} \, \exp(\, + \mathbf{i} \, * \mathbf{z}) \, .$

[H, i err] = bessel h(...) also returns an array of error flags:
 i err = 1 Illegal arguments.
 i err = 2 Overflow. Return I nf.
 i err = 3 Some loss of accuracy in argument reduction.
 i err = 4 Unacceptable loss of accuracy, Z or nu too large.
 i err = 5 No convergence. Return NaN.

Purpose

Modified Bessel functions

Syntax

 $I = bessel\,i\,(nu,\,Z)$ Modified Bessel function of the 1st kind $K = bessel\,k(nu,\,Z)$ Modified Bessel function of the 2nd kind

I = besseli(nu, Z, 1) K = besselk(nu, Z, 1)

[I,ierr] = besseli(...)

[K, ierr] = besselk(...)

Definitions

The differential equation

$$z^{2}\frac{d^{2}y}{dz^{2}} + z\frac{dy}{dz} - (z^{2} + v^{2})y = 0$$

where v is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

 $I_{\rm v}(z)$ and $I_{\rm -v}(z)$ form a fundamental set of solutions of the modified Bessel's equation for noninteger v. $K_{\rm v}(z)$ is a second solution, independent of $I_{\rm v}(z)$.

 $I_{\nu}(z)$ and $K_{\nu}(z)$ are defined by

$$I_{v}(z) = \left(\frac{z}{2}\right)^{v} \sum_{k=0}^{\infty} \frac{\left(\frac{z^{2}}{4}\right)^{k}}{k! \Gamma(v+k+1)}$$

$$K_{\nu}(z) = \left(\frac{\pi}{2}\right) \frac{I_{-\nu}(z) - I_{\nu}(z)}{\sin(\nu\pi)}$$

where $\Gamma(a)$ is the gamma function.

Description

I = bessel i (nu, Z) computes modified Bessel functions of the first kind, $I_{\rm v}(z)$, for each element of the array Z. The order nu need not be an integer, but must be real. The argument Z can be complex. The result is real where Z is positive.

If nu and Z are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector

and the other is a column vector, the result is a two-dimensional table of function values.

```
K={\rm bessel}\,k({\rm nu},Z) computes modified Bessel functions of the second kind, K_v(z), for each element of the complex array Z.
```

```
I = besseli(nu, Z, 1) computes besseli(nu, Z).*exp(-abs(real(Z))).
```

```
K = bessel k(nu, Z, 1) computes bessel k(nu, Z).*exp(Z).
```

[I, ierr] = besseli(...) and [K, ierr] = besselk(...) also return an array of error flags:

```
i err = 1 Illegal arguments.
```

i err = 2 Overflow. Return I nf.

i err = 3 Some loss of accuracy in argument reduction.

i err = 4 Unacceptable loss of accuracy, Z or nu too large.

i err = 5 No convergence. Return NaN.

Purpose

Bessel functions

Syntax

J = bessel j (nu, Z) Bessel function of the 1st kind Y = bessel y(nu, Z) Bessel function of the 2nd kind

J = besselj(nu, Z, 1)

Y = bessely(nu, Z, 1)

[J, ierr] = besselj (nu, Z)

[Y, ierr] = bessely(nu, Z)

Definition

The differential equation

$$z^{2}\frac{d^{2}y}{dz^{2}} + z\frac{dy}{dz} + (z^{2} - v^{2})y = 0$$

where ν is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.

 $J_{\nu}(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν . $J_{\nu}(z)$ is defined by

$$J_{v}(z) = \left(\frac{z}{2}\right)^{v} \sum_{k=0}^{\infty} \frac{\left(-\frac{z^{2}}{4}\right)^{k}}{k! \Gamma(v+k+1)}$$

where $\Gamma(a)$ is the gamma function.

 $Y_{\nu}(z)$ is a second solution of Bessel's equation that is linearly independent of $J_{\nu}(z)$ and defined by

$$Y_{\nu}(z) = \frac{J_{\nu}(z)\cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}$$

Description

 $J=bessel\,j$ (nu, Z) computes Bessel functions of the first kind, $J_{\nu}(z)$, for each element of the complex array Z. The order nu need not be an integer, but must be real. The argument Z can be complex. The result is real where Z is positive.

If nu and Z are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector

besselj, bessely

and the other is a column vector, the result is a two-dimensional table of function values.

Y = bessel y(nu, Z) computes Bessel functions of the second kind, $Y_{v}(z)$, for real, nonnegative order nu and argument Z.

J = besselj(nu, Z, 1) computes besselj(nu, Z).*exp(-abs(imag(Z))).

Y = bessely(nu, Z, 1) computes $bessely(nu, Z) \cdot *exp(-abs(imag(Z)))$.

 $[J, i\,err] = besselj(nu, Z)$ and $[Y, i\,err] = bessely(nu, Z)$ also return an array of error flags:

i err = 1 Illegal arguments.

i err = 2 Overflow. Return Inf.

i err = 3 Some loss of accuracy in argument reduction.

i err = 4 Unacceptable loss of accuracy, Z or nu too large.

i err = 5 No convergence. Return NaN.

Remarks

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind,

$$H_{V}^{(1)}(z) = J_{V}(z) + i Y_{V}(z)$$

$$H_{v}^{(2)}(z) = J_{v}(z) - i Y_{v}(z)$$

where $J_{\nu}(z)$ is bessel j , and $Y_{\nu}(z)$ is bessel y. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see bessel h).

beta, betainc, betain

Purpose

Beta functions

Syntax

B = beta(Z, W)

I = betainc(X, Z, W)

L = betaln(Z, W)

Definition

The beta function is

$$B(z, w) = \int_0^1 t^{z-1} (1-t)^{w-1} dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

where $\Gamma(z)$ is the gamma function. The incomplete beta function is

$$I_X(z, w) = \frac{1}{B(z, w)} \int_0^x t^{z-1} (1-t)^{w-1} dt$$

Description

 $B = \mathrm{beta}(Z, W)$ computes the beta function for corresponding elements of the complex arrays Z and W. The arrays must be the same size (or either can be scalar).

I = betainc(X, Z, W) computes the incomplete beta function. The elements of X must be in the closed interval [0,1].

 $L = betal\,n(Z,W)$ computes the natural logarithm of the beta function, $l\,og(beta(Z,W))$, without computing beta(Z,W). Since the beta function can range over very large or very small values, its logarithm is sometimes more useful.

Examples

format rat beta((0:10)',3)

ans =

1/0

1/3

1/12

1/30

1/60

1/105

```
1/168
1/252
1/360
1/495
1/660
```

In this case, with integer arguments,

```
beta(n, 3)
= (n-1)!*2!/(n+2)!
= 2/(n*(n+1)*(n+2))
```

is the ratio of fairly small integers and the rational format is able to recover the exact result.

```
For x = 510, betal n(x, x) = -708. 8616, which is slightly less than log(real min). Here beta(x, x) would underflow (or be denormal).
```

Algorithm

```
beta(z, w) = exp(gammal n(z) + gammal n(w) - gammal n(z+w))
betal n(z, w) = gammal n(z) + gammal n(w) - gammal n(z+w)
```

Purpose

BiConjugate Gradients method

Syntax

```
x = bicg(A, b)
bicg(A, b, tol)
bicg(A, b, tol, maxit)
bicg(A, b, tol, maxit, M)
bicg(A, b, tol, maxit, M1, M2)
bicg(A, b, tol, maxit, M1, M2, x0)
bicg(afun, b, tol, maxit, mfun1, mfun2, x0, p1, p2, ...)
[x, flag] = bicg(A, b, ...)
[x, flag, relres] = bicg(A, b, ...)
[x, flag, relres, iter] = bicg(A, b, ...)
[x, flag, relres, iter, resvec] = bicg(A, b, ...)
```

Description

x = bi cg(A, b) attempts to solve the system of linear equations A*x = b for x. The n-by-n coefficient matrix A must be square and the column vector b must have length n. A can be a function afun such that afun(x) returns A*x and afun(x, 'transp') returns A'*x.

If bi cg converges, a message to that effect is displayed. If bi cg fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual norm(b-A*x)/norm(b) and the iteration number at which the method stopped or failed.

bi cg(A, b, tol) specifies the tolerance of the method. If tol is [], then bi cg uses the default, 1e-6.

bi cg(A, b, tol, maxit) specifies the maximum number of iterations. If maxit is [], then bi cg uses the default, min(n, 20).

bi cg(A, b, tol, maxit, M) and bi cg(A, b, tol, maxit, M1, M2) use the preconditioner M or M = M1*M2 and effectively solve the system i nv(M)*A*x = i nv(M)*b for x. If M is [] then bi cg applies no preconditioner. Mcan be a function mfun such that mfun(x) returns M\x and mfun(x, 'transp') returns M'\x.

bi cg(A, b, tol, maxit, M1, M2, x0) specifies the initial guess. If x0 is [], then bi cg uses the default, an all-zero vector.

bi cg(afun, b, tol, maxi t, m1fun, m2fun, x0, p1, p2, ...) passes parameters p1, p2, ... to functions afun(x, p1, p2, ...) and afun(x, p1, p2, ..., 'transp'), and similarly to the preconditioner functions m1fun and m2fun.

[x, flag] = bi cg(A, b, ...) also returns a convergence flag.

Flag	Convergence
0	bicg converged to the desired tolerance tol within maxit iterations.
1	bicg iterated maxit times but did not converge.
2	Preconditioner M was ill-conditioned.
3	bi cg stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during bi cg became too small or too large to continue computing.

Whenever fl ag is not 0, the solution x returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the fl ag output is specified.

[x, flag, relres] = bicg(A, b, ...) also returns the relative residual norm(b-A*x)/norm(b). If flag is 0, relres <= tol.

[x, flag, relres, iter] = bicg(A, b, ...) also returns the iteration number at which x was computed, where 0 <= iter <= maxit.

[x, flag, rel res, i ter, resvec] = bicg(A, b, ...) also returns a vector of the residual norms at each iteration including norm(b-A*x0).

Examples Example 1.

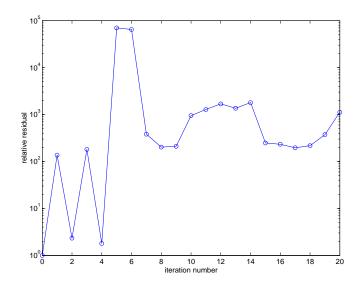

```
n = 100;
on = ones(n, 1);
A = spdiags([-2*on 4*on -on], -1:1, n, n);
b = sum(A, 2);
tol = 1e-8;
```

```
maxit = 15;
  M1 = \text{spdiags}([\text{on}/(-2) \text{ on}], -1: 0, n, n);
  M2 = \text{spdiags}([4*\text{on -on}], 0: 1, n, n);
  x = bicg(A, b, tol, maxit, M1, M2, []);
  bicg converged at iteration 9 to a solution with relative
  resi dual 5.3e-009
Alternatively, use this matrix-vector product function
  function y = afun(x, n, transp_flag)
  if (nargin > 2) & strcmp(transp_flag, 'transp')
       y = 4 * x;
       y(1: n-1) = y(1: n-1) - 2 * x(2: n);
       y(2:n) = y(2:n) - x(1:n-1);
  el se
       y = 4 * x;
       y(2:n) = y(2:n) - 2 * x(1:n-1);
       y(1: n-1) = y(1: n-1) - x(2: n);
  end
as input to bi cg.
      x1 = bi cg(@afun, b, tol, maxit, M1, M2, [], n);
Example 2. Start with A = west 0479 and make the true solution the vector of
all ones.
  load west0479;
  A = west0479;
  b = sum(A, 2);
You can accurately solve A*x = b using backslash since A is not so large.
  x = A \setminus b;
  norm(b-A*x) / norm(b)
  ans =
       1.2454e-017
Now try to solve A*x = b with bi cg.
  [x, flag, relres, iter, resvec] = bicg(A, b)
```

```
flag = 1 relres = 1 iter = 0
```

The value of fl ag indicates that bi cg iterated the default 20 times without converging. The value of i ter shows that the method behaved so badly that the initial all-zero guess was better than all the subsequent iterates. The value of rel res supports this: rel res = norm(b-A*x) /norm(b) = norm(b) /norm(b) = 1. You can confirm that the unpreconditioned method oscillates rather wildly by plotting the relative residuals at each iteration.

```
semilogy(0: 20, resvec/norm(b), '-o')
xlabel('iteration number')
ylabel('relative residual')
```

Now, try an incomplete LU factorization with a drop tolerance of 1e- 5 for the preconditioner.

The zero on the main diagonal of the upper triangular U1 indicates that U1 is singular. If you try to use it as a preconditioner,

the method fails in the very first iteration when it tries to solve a system of equations involving the singular U1 using backslash. bi cg is forced to return the initial estimate since no other iterates were produced.

Try again with a slightly less sparse preconditioner.

```
[L2, U2] = luinc(A, 1e-6)

nnz(L2)

ans =

6231

nnz(U2)

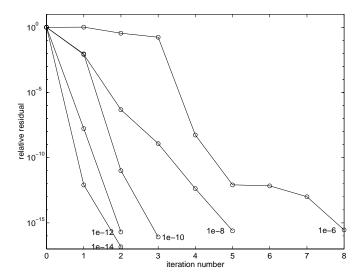

ans =
```

4559

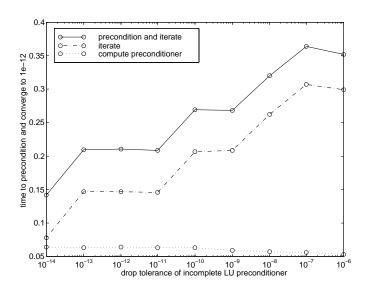

This time U2 is nonsingular and may be an appropriate preconditioner.

and bi cg converges to within the desired tolerance at iteration number 8. Decreasing the value of the drop tolerance increases the fill-in of the incomplete factors but also increases the accuracy of the approximation to the original matrix. Thus, the preconditioned system becomes closer to $i \, nv(U) \, *i \, nv(L) \, *L*U*x = i \, nv(U) \, *i \, nv(L) \, *b$, where L and U are the true LU factors, and closer to being solved within a single iteration.

The next graph shows the progress of bi cg using six different incomplete LU factors as preconditioners. Each line in the graph is labeled with the drop tolerance of the preconditioner used in bi cg.

This does not give us any idea of the time involved in creating the incomplete factors and then computing the solution. The following graph plots the drop tolerance of the incomplete LU factors against the time to compute the preconditioner, the time to iterate once the preconditioner has been computed, and their sum, the total time to solve the problem. The time to produce the factors does not increase very quickly with the fill-in, but it does slow down the average time for an iteration. Since fewer iterations are performed, the total time to solve the problem decreases. west0479 is quite a small matrix, only 139-by-139, and preconditioned bi cg still takes longer than backslash.

bicgstab

Purpose

BiConjugate Gradients Stabilized method

Syntax

```
x = bicgstab(A, b)
bicgstab(A, b, tol)
bicgstab(A, b, tol, maxit)
bicgstab(A, b, tol, maxit, M)
bicgstab(A, b, tol, maxit, M1, M2)
bicgstab(A, b, tol, maxit, M1, M2, x0)
bicgstab(afun, b, tol, maxit, m1fun, m2fun, x0, p1, p2, ...)
[x, flag] = bicgstab(A, b, ...)
[x, flag, relres] = bicgstab(A, b, ...)
[x, flag, relres, iter] = bicgstab(A, b, ...)
[x, flag, relres, iter, resvec] = bicgstab(A, b, ...)
```

Description

x = bi cgstab(A, b) attempts to solve the system of linear equations A*x=b for x. The n-by-n coefficient matrix A must be square and the column vector b must have length n. A can be a function afun such that afun(x) returns A*x.

If bi cgstab converges, a message to that effect is displayed. If bi cgstab fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual norm(b-A*x) / norm(b) and the iteration number at which the method stopped or failed.

bi cgstab(A, b, tol) specifies the tolerance of the method. If tol is [], then bi cgstab uses the default, 1e-6.

bi cgstab(A, b, tol, maxit) specifies the maximum number of iterations. If maxit is [], then bi cgstab uses the default, min(n, 20).

bi cgstab(A, b, tol, maxi t, M) and bi cgstab(A, b, tol, maxi t, M1, M2) use preconditioner M or M = M1*M2 and effectively solve the system i nv(M) *A*x = i nv(M) *b for x. If M is [] then bi cgstab applies no preconditioner. M can be a function that returns $M \setminus x$.

bi cgstab(A, b, tol, maxit, M1, M2, x0) specifies the initial guess. If x0 is [], then bi cgstab uses the default, an all zero vector.

```
bi cgstab(afun, b, tol, maxi t, m1fun, m2fun, x0, p1, p2, ...) passes parameters p1, p2, ... to functions afun(x, p1, p2, ...), m1fun(x, p1, p2, ...), and m2fun(x, p1, p2, ...).
```

[x, flag] = bi cgstab(A, b, ...) also returns a convergence flag.

Flag	Convergence
0	bi cgstab converged to the desired tolerance tol within maxit iterations.
1	bi cgstab iterated maxi t times but did not converge.
2	Preconditioner M was ill-conditioned.
3	bi cgstab stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during bi cgstab became too small or too large to continue computing.

Whenever fl ag is not 0, the solution x returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the fl ag output is specified.

[x, flag, relres] = bi cgstab(A, b, ...) also returns the relative residual norm(b-A*x)/norm(b). If flag is 0, relres <= tol.

[x, flag, relres, iter] = bicgstab(A, b, ...) also returns the iteration number at which x was computed, where $0 \le iter \le maxit$. iter can be an integer +0.5, indicating convergence half way through an iteration.

[x, flag, rel res, i ter, resvec] = bi cgstab(A, b, ...) also returns a vector of the residual norms at each half iteration, including norm(b-A*x0).

Example Example 1.

```
A = gallery('wilk', 21);
b = sum(A, 2);
tol = 1e-12;
maxit = 15;
```

```
\label{eq:maximum} \begin{split} &M1 = diag([10:-1:1\ 1\ 1:10]);\\ &x = bicgstab(A,b,tol,maxit,M1,[],[]);\\ &bicgstab \ converged \ at \ iteration \ 12.5 \ to \ a \ solution \ with \ relative \\ &residual \ 1.2e-014 \end{split}
```

Alternatively, use this matrix-vector product function

```
function y = afun(x, n)

y = [0;

x(1: n-1)] + [((n-1)/2: -1: 0)';

(1: (n-1)/2)'] .*x + [x(2: n);

0];
```

and this preconditioner backsolve function

```
function y = mfun(r, n)

y = r . / [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];

as inputs to bi cgstab
```

```
x1 = bi cgstab(@afun, b, tol, maxit, @mfun, [], [], 21);
```

Note that both afun and mfun must accept bi cgstab's extra input n=21.

Example 2.

```
load west0479;
A = west0479;
b = sum(A, 2);
[x, flag] = bi cgstab(A, b)
```

flag is 1 because bi cgstab does not converge to the default tolerance 1e-6 within the default 20 iterations.

```
[L1, U1] = luinc(A, 1e-5);

[x1, flag1] = bicgstab(A, b, 1e-6, 20, L1, U1)
```

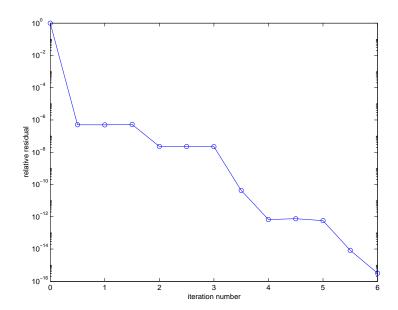

fl ag1 is 2 because the upper triangular U1 has a zero on its diagonal. This causes bi cgst ab to fail in the first iteration when it tries to solve a system such as U1*y = r using backslash.

```
[L2, U2] = l ui nc(A, 1e-6);

[x2, flag2, rel res2, iter2, resvec2] = bi cgstab(A, b, 1e-15, 10, L2, U2)
```

fl ag2 is 0 because bi cgstab converges to the tolerance of 3. 1757e-016 (the value of rel res2) at the sixth iteration (the value of i ter2) when preconditioned by the incomplete LU factorization with a drop tolerance of 1e-6. resvec2(1) = norm(b) and resvec2(13) = norm(b-A*x2). You can follow the progress of bi cgstab by plotting the relative residuals at the halfway point and end of each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0: 0. 5: iter2, resvec2/norm(b), '-o')
xlabel('iteration number')
ylabel('relative residual')
```

bin2dec

Purpose Binary to decimal number conversion

Syntax bi n2dec(bi narystr)

Description bi n2dec(bi narystr) interprets the binary string bi narystr and returns the

equivalent decimal number.

Examples bi n2dec('010111') returns 23.

See Also ${\rm dec}2{\rm bi}\,n$

bitand

Purpose Bit-wise AND

Syntax C = bi tand(A, B)

Description C = bi tand(A, B) returns the bit-wise AND of two nonnegative integer

arguments A and B. To ensure the operands are integers, use the ceil, fix,

floor, and round functions.

Examples The five-bit binary representations of the integers 13 and 27 are 01101 and

11011, respectively. Performing a bit-wise AND on these numbers yields

01001, or 9.

C = bitand(13, 27)

C =

9

See Also bitcmp, bitget, bitmax, bitor, bitset, bitshift, bitxor

bitcmp

Purpose Complement bits

Syntax C = bitcmp(A, n)

Description C = bitcmp(A, n) returns the bit-wise complement of A as an n-bit

floating-point integer (flint).

Example With eight-bit arithmetic, the ones' complement of 01100011 (99, decimal) is

10011100 (156, decimal).

C = bitcmp(99, 8)

C =

156

See Also bitand, bitget, bitmax, bitor, bitset, bitshift, bitxor

bitget

Purpose

Get bit

Syntax

C = bitget(A, bit)

Description

C = bitget(A, bit) returns the value of the bit at position bit in A. Operand A must be a nonnegative integer, and bit must be a number between 1 and the number of bits in the floating-point integer (flint) representation of A (52 for IEEE flints). To ensure the operand is an integer, use the ceil, fix, floor, and round functions.

Example

The dec2bin function converts decimal numbers to binary. However, you can also use the bit get function to show the binary representation of a decimal number. Just test successive bits from most to least significant:

See Also

bitand, bitcmp, bitmax, bitor, bitset, bitshift, bitxor

bitmax

Purpose Maximum floating-point integer

Syntax bi tmax

bi t max returns the maximum unsigned floating-point integer for your computer. It is the value when all bits are set, namely the value $2^{53}-1$. Description

See Also bitand, bitcmp, bitget, bitor, bitset, bitshift, bitxor

bitor

Purpose Bit-wise OR

Syntax C = bitor(A, B)

Description C = bi tor (A, B) returns the bit-wise OR of two nonnegative integer

arguments A and B. To ensure the operands are integers, use the ceil, fix,

floor, and round functions.

Examples The five-bit binary representations of the integers 13 and 27 are 01101 and

11011, respectively. Performing a bit-wise OR on these numbers yields 11111,

or 31.

C = bitor(13, 27)

C =

31

See Also bitand, bitcmp, bitget, bitmax, bitset, bitshift, bitxor

Purpose Set bit

Syntax C = bitset(A, bit)

C = bitset(A, bit, v)

Description C = bitset(A, bit) sets bit position bit in A to 1 (on). A must be a nonnegative

integer and $bi\ t$ must be a number between 1 and the number of bits in the floating-point integer (flint) representation of A (52 for IEEE flints). To ensure the operand is an integer, use the ceil, fix, floor, and round functions.

C = bitset(A, bit, v) sets the bit at position bit to the value v, which must be either 0 or 1.

Examples Setting the fifth bit in the five-bit binary representation of the integer 9 (01001) yields 11001, or 25.

C = bitset(9, 5)

C =

25

See Also bitand, bitcmp, bitget, bitmax, bitor, bitshift, bitxor

bitshift

Purpose

Bit-wise shift

Syntax

C = bitshift(A, k, n) C = bitshift(A, k)

Description

C=bitshift(A,k,n) returns the value of A shifted by k bits. If k>0, this is same as a multiplication by 2^k (left shift). If k<0, this is the same as a division by 2^k (right shift). An equivalent computation for this function is

 $C = fix(A*2^k).$

If the shift causes C to overflow n bits, the overflowing bits are dropped. A must contain nonnegative integers between 0 and BI TMAX, which you can ensure by using the ceil, fix, floor, and round functions.

C = bitshift(A, k) uses the default value of n = 53.

Examples

Shifting 1100 (12, decimal) to the left two bits yields 110000 (48, decimal).

C = bitshift(12, 2)

C =

48

See Also

bitand, bitcmp, bitget, bitmax, bitor, bitset, bitxor, fix

Purpose Bit-wise XOR

Syntax C = bitxor(A, B)

Description C = bi txor(A, B) returns the bit-wise XOR of the two arguments A and B. Both

A and B must be integers. You can ensure this by using the ceil, fix, floor,

and round functions.

Examples The five-bit binary representations of the integers 13 and 27 are 01101 and

11011, respectively. Performing a bit-wise XOR on these numbers yields 10110,

or 22.

C = bitxor(13, 27)

C = 22

See Also bitand, bitcmp, bitget, bitmax, bitor, bitset, bitshift

blanks

Purpose A string of blanks

 $\textbf{Syntax} \qquad \qquad bl \ anks(n)$

Description blanks(n) is a string of n blanks.

Examples blanks is useful with the display function. For example,

disp(['xxx' blanks(20) 'yyy'])

displays twenty blanks between the strings ' xxx' and ' yyy'.

di sp(bl anks(n)') moves the cursor down n lines.

See Also clc, format, home

Purpose Construct a block diagonal matrix from input arguments

Syntax out = bl kdi ag(a, b, c, d, ...)

Description out = bl kdi ag(a, b, c, d, ...), where a, b, c, d, ... are matrices, outputs a block diagonal matrix of the form

 $\begin{bmatrix} a & 0 & 0 & 0 & 0 \\ 0 & b & 0 & 0 & 0 \\ 0 & 0 & c & 0 & 0 \\ 0 & 0 & 0 & d & 0 \\ 0 & 0 & 0 & 0 & \dots \end{bmatrix}$

The input matrices do not have to be square, nor do they have to be of equal size.

bl kdi ag works not only for matrices, but for any MATLAB objects which support horzcat and vertcat operations.

See Also di ag

box

Purpose Control axes border

Syntax box on

box off

box(axes_handle,...)

Description box on displays the boundary of the current axes.

box off does not display the boundary of the current axes.

box toggles the visible state of the current axes' boundary.

 $box(axes_handl\,e,\dots)$ uses the axes specified by $axes_handl\,e$ instead of the

current axes.

Algorithm The box function sets the axes Box property to on or off.

See Also axes, grid

Purpose Terminate execution of a for loop or while loop

Syntax break

 $\textbf{Description} \qquad \qquad \text{break terminates the execution of a for or while loop. Statements in the loop}$

that appear after the break statement, are not executed.

In nested loops, break exits only from the loop in which it occurs. Control

passes to the statement that follows the end of that loop.

Remarks If you use break outside of a for or while loop in a MATLAB script or function,

break terminates the script or function at that point.

If break is executed in an if, switch-case, or try-catch statement, it termi-

nates the statement at that point.

Examples The example below shows a while loop that reads the contents of the file fft. m

into a MATLAB character array. A break statement is used to exit the while loop when the first empty line is encountered. The resulting character array

contains the M-file help for the fft program.

```
fid = fopen('fft.m','r');
s = '';
while ~feof(fid)
  line = fgetl(fid);
  if isempty(line), break, end
  s = strvcat(s,line);
end
disp(s)
```

See Also for, while, end, continue, return

brighten

Purpose

Brighten or darken colormap

Syntax

bri ghten(beta)
bri ghten(h, beta)

newmap = bri ghten(beta)
newmap = bri ghten(cmap, beta)

Description

bri ght en increases or decreases the color intensities in a colormap. The modified colormap is brighter if 0 < beta < 1 and darker if -1 < beta < 0.

bri ghten(beta) replaces the current colormap with a brighter or darker colormap of essentially the same colors. bri ghten(beta), followed by bri ghten(-beta), where beta < 1, restores the original map.

brighten(h, beta) brightens all objects that are children of the figure having the handle h.

newmap = brighten(beta) returns a brighter or darker version of the current colormap without changing the display.

 $newmap = brighten(cmap, beta) \ returns \ a \ brighter \ or \ darker \ version \ of \ the \\ colormap \ cmap \ without \ changing \ the \ display.$

Examples

Brighten and then darken the current colormap:

beta = .5; brighten(beta);
beta = -.5; brighten(beta);

Algorithm

The values in the colormap are raised to the power of gamma, where gamma is

$$\gamma = \begin{cases} 1 - \beta, & \beta > 0 \\ \frac{1}{1 + \beta}, & \beta \le 0 \end{cases}$$

brighten has no effect on graphics objects defined with true color.

See Also

col ormap, rgbpl ot

Purpose Execute builtin function from overloaded method

Syntax builtin(function, x1, ..., xn)

[y1, ..., yn] = builtin(function, x1, ..., xn)

Description builtin is used in methods that overload builtin functions to execute the

original builtin function. If function is a string containing the name of a

builtin function, then

builtin(function, x1, ..., xn) evaluates that function at the given

arguments.

 $[y_1, ..., y_n] = builtin(function, x_1, ..., x_n)$ returns multiple output

arguments.

Remarks builtin(...) is the same as feval (...) except that it calls the original builtin

version of the function even if an overloaded one exists. (For this to work you

must never overload builtin.)

See Also feval

Purpose Solve two-point boundary value problems (BVPs) for ordinary differential equations Syntax sol = bvp4c(odefun, bcfun, solinit) sol = bvp4c(odefun, bcfun, solinit, options) sol = bvp4c(odefun, bcfun, solinit, options, p1, p2...) **Arguments** odefun A function that evaluates the differential equations f(x, y). It can have the form dydx = odefun(x, y)dydx = odefun(x, y, p1, p2, ...)dydx = odefun(x, y, parameters)dydx = odefun(x, y, parameters, p1, p2, ...)where x is a scalar corresponding to x, and y is a column vector corresponding to y. parameters is a vector of unknown parameters, and $p1, p2, \ldots$ are known parameters. The output dydx is a column vector. bcfun A function that computes the residual in the boundary conditions bc(y(a), y(b)). It can have the form res = bcfun(ya, yb)res = bcfun(ya, yb, p1, p2, ...)res = bcfun(ya, yb, parameters) res = bcfun(ya, yb, parameters, p1, p2, ...) where ya and yb are column vectors corresponding to y(a) and y(b). parameters is a vector of unknown parameters, and p1, p2, . . . are known parameters. The output res is a column vector. sol i ni t A structure with fields: Ordered nodes of the initial mesh. Boundary X conditions are imposed at a = solinit. x(1) and b = sol i ni t. x(end). Initial guess for the solution such that y sol i ni t. y(:, i) is a guess for the solution at the

node sol i ni t. x(i).

parameters Optional. A vector that provides an initial guess for unknown parameters.

The structure can have any name, but the fields must be named x, y, and parameters. You can form sol i ni t with the helper function bypi ni t. See bypi ni t for details.

options Optional integration argument. A structure you create using the bypset function. See bypset for details.

 $p1,\,p2.\dots$ Optional. Known parameters that the solver passes to odefun, bcfun, and all the functions the user specifies in options.

Description

sol = bvp4c(odefun, bcfun, solinit) integrates a system of ordinary differential equations of the form

$$y' = f(x, y)$$

on the interval [a,b] subject to general two-point boundary conditions

$$bc(y(a), y(b)) = 0$$

The bvp4c solver can also find unknown parameters p for problems of the form

$$y' = f(x, y, p)$$

$$bc(y(a), y(b), p) = 0$$

where p corresponds to parameters. You provide bvp4c an initial guess for any unknown parameters in sol i nit. parameters. The bvp4c solver returns the final values of these unknown parameters in sol. parameters.

bvp4c produces a solution that is continuous on [a,b] and has a continuous first derivative there. Use the function deval and the output sol of bvp4c to evaluate the solution at specific points xi nt in the interval [a,b].

$$sxint = deval(sol, xint)$$

The structure sol returned by bvp4c has the following fields:

sol.x	Mesh selected by bvp4c
sol.y	Approximation to $y(x)$ at the mesh points of sol . x
sol.yp	Approximation to $y'(x)$ at the mesh points of sol. x

sol. parameters Values returned by bvp4c for the unknown parameters,

if any

sol . sol ver 'bvp4c'

The structure sol can have any name, and bvp4c creates the fields x, y, yp, parameters, and solver.

sol = bvp4c(odefun, bcfun, solinit, options) solves as above with default integration properties replaced by the values in options, a structure created with the bvpset function. See bvpset for details.

sol = bvp4c(odefun, bcfun, solinit, options, p1, p2...) passes constant known parameters, p1, p2, ..., to odefun, bcfun, and all the functions the user specifies in options. Use options = [] as a placeholder if no options are set.

Examples

Example 1. Boundary value problems can have multiple solutions and one purpose of the initial guess is to indicate which solution you want. The second order differential equation

$$y'' + |y| = 0$$

has exactly two solutions that satisfy the boundary conditions

$$y(0) = 0$$

$$y(4) = -2$$

Prior to solving this problem with bvp4c, you must write the differential equation as a system of two first order ODEs

$$y_1' = y_2$$

$$y_2' = -|y_1|$$

Here $y_1 = y$ and $y_2 = y'$. This system has the required form

$$y' = f(x, y)$$

$$bc(y(a), y(b)) = 0$$

The function f and the boundary conditions bc are coded in MATLAB as functions twoode and twobc.

```
function dydx = twoode(x, y)

dydx = [ y(2)

-abs(y(1))];

function res = twobc(ya, yb)

res = [ ya(1)

yb(1) + 2];
```

Form a guess structure consisting of an initial mesh of five equally spaced points in [0,4] and a guess of constant values $y_1(x) \equiv 1$ and $y_2(x) \equiv 0$ with the command

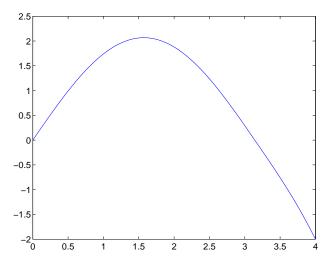

```
solinit = bvpinit(linspace(0, 4, 5), [1 0]);
```

Now solve the problem with

```
sol = bvp4c(@twoode, @twobc, solinit);
```

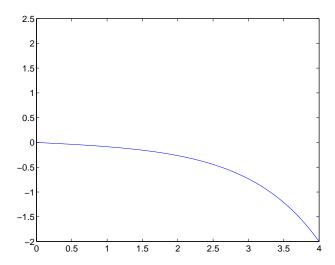

Evaluate the numerical solution at 100 equally spaced points and plot y(x) with

```
x = linspace(0, 4);
y = deval(sol, x);
plot(x, y(1,:));
```

You can obtain the other solution of this problem with the initial guess

Example 2. This boundary value problem involves an unknown parameter. The task is to compute the fourth (q=5) eigenvalue λ of Mathieu's equation

$$y'' + (\lambda - 2 q \cos 2x) y = 0$$

Because the unknown parameter λ is present, this second order differential equation is subject to *three* boundary conditions

$$y'(0) = 0$$
$$y'(\pi) = 0$$

y(0) = 1

It is convenient to use subfunctions to place all the functions required by bvp4c in a single M-file.

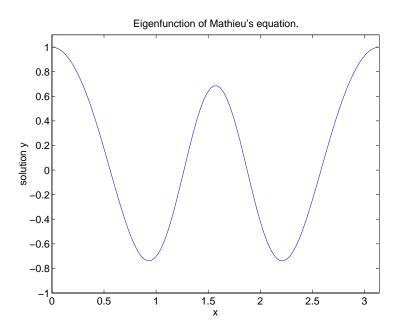

```
function mat4bvp
lambda = 15;
solinit = bvpinit(linspace(0, pi, 10), @mat4init, lambda);
sol = bvp4c(@mat4ode, @mat4bc, solinit);
```

```
fprintf('The fourth eigenvalue is approximately %7.3f.\n',...
       sol.parameters)
xint = linspace(0, pi);
Sxint = deval(sol, xint);
plot(xint, Sxint(1, :))
axis([0 pi -1 1.1])
title('Eigenfunction of Mathieu''s equation.')
xl abel ('x')
ylabel ('solution y')
% -----
function dydx = mat4ode(x, y, lambda)
q = 5;
dydx = [y(2)]
        - (lambda - 2*q*cos(2*x))*y(1) ];
function res = mat4bc(ya, yb, lambda)
res = [
        ya(2)
        yb(2)
       ya(1)-1 ];
function yinit = mat4init(x)
yi ni t = [cos(4*x)]
         -4*\sin(4*x) ]:
```

The differential equation (converted to a first order system) and the boundary conditions are coded as subfunctions mat 4ode and mat 4bc, respectively. Because unknown parameters are present, these functions must accept three input arguments, even though some of the arguments are not used.

The guess structure solinit is formed with bvpinit. An initial guess for the solution is supplied in the form of a function $\max 4i$ nit. We chose $y = \cos 4x$ because it satisfies the boundary conditions and has the correct qualitative behavior (the correct number of sign changes). In the call to bvpinit, the third argument (lambda = 15) provides an initial guess for the unknown parameter λ .

After the problem is solved with bvp4c, the field sol . parameters returns the value $~\lambda = 17.097~$, and the plot shows the eigenfunction associated with this eigenvalue.

Algorithms

bvp4c is a finite difference code that implements the three-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a C^1 -continuous solution that is fourth order accurate uniformly in [a,b]. Mesh selection and error control are based on the residual of the continuous solution.

References

[1] Shampine, L.F., M.W. Reichelt, and J. Kierzenka, "Solving Boundary Value Problems for Ordinary Differential Equations in MATLAB with bvp4c," available at ftp://ftp.mathworks.com/pub/doc/papers/bvp/.

Purpose Extract properties from the options structure created with bypset

Syntax val = bvpget(options, 'name')

val = bvpget(options, 'name', default)

Description

val = bvpget(options, 'name') extracts the value of the named property from the structure options, returning an empty matrix if the property value is not specified in options. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. [] is a valid options argument.

val = bvpget(options, 'name', default) extracts the named property as
above, but returns val = default if the named property is not specified in
options. For example,

```
val = bvpget(opts, 'RelTol', 1e-4);
```

returns val = 1e-4 if the Rel Tol is not specified in opts.

See Also

bvp4c, bvpi ni t, bvpset, deval

bvpinit

Purpose

Form the initial guess for bvp4c

Syntax

```
solinit = bvpinit(x, v)
solinit = bvpinit(x, v, parameters)
solinit = bvpinit(sol, [anew bnew])
solinit = bvpinit(sol, [anew bnew], parameters)
```

Description

sol i ni t = bvpi ni t(x, v) forms the initial guess for bvp4c in common circumstances.

x is a vector that specifies an initial mesh. If you want to solve the boundary value problem (BVP) on [a,b], then specify x(1) as a and x(end) as b. The function bvp4c adapts this mesh to the solution, so often a guess like x = 1 in space (a,b,10) suffices. However, in difficult cases, you must place mesh points where the solution changes rapidly. The entries of x must be ordered and distinct, so if a < b, then $x(1) < x(2) < \ldots < x(end)$, and similarly for a > b.

v is a guess for the solution. It can be either a vector, or a function:

- Vector For each component of the solution, bvpi ni t replicates the corresponding element of the vector as a constant guess across all mesh points. That is, $\mathbf{v}(\mathbf{i})$ is a constant guess for the i th component $\mathbf{y}(\mathbf{i},:)$ of the solution at all the mesh points in \mathbf{x} .
- Function For a given mesh point, the function must return a vector whose elements are guesses for the corresponding components of the solution. The function must be of the form

```
y = guess(x)
```

where x is a mesh point and y is a vector whose length is the same as the number of components in the solution. For example, if you use @guess, bvpi ni t calls this function for each mesh point y(:,j) = guess(x(j)).

sol i ni t = bvpi ni t(x, v, parameters) indicates that the BVP involves unknown parameters. Use the vector parameters to provide a guess for all unknown parameters.

sol i ni t is a structure with the following fields. The structure can have any name, but the fields must be named x, y, and parameters.

x Ordered nodes of the initial mesh.

y Initial guess for the solution with solinit. y(:,i) a guess for the solution at the node solinit. x(i).

parameters Optional. A vector that provides an initial guess for unknown parameters.

sol i ni t = bvpi ni t (sol, [anew bnew]) forms an initial guess on the interval [anew bnew] from a solution sol on an interval [a, b]. The new interval must be larger than the previous one, so either anew <= a < b <= bnew or anew >= a > b >= bnew. The solution sol is extrapolated to the new interval. If sol contains parameters, they are copied to sol i ni t.

solinit = bvpinit(sol,[anew bnew], parameters) forms solinit as
described above, but uses parameters as a guess for unknown parameters in
solinit.

@ (functi on_handl e), bvp4c, bvpget, bvpset, deval

bvpset

Purpose Create/alter boundary value problem (BVP) options structure

Syntax options = bvpset('name1', value1, 'name2', value2,...)

options = bvpset(oldopts'name1', value1,...)

options = bvpset(oldopts, newopts)

bvpset

Description

opti ons = bvpset('name1', value1, 'name2', value2,...) creates a structure opti ons in which the named properties have the specified values. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names.

options = bvpset(oldopts, 'name1', value1, \dots) alters an existing options structure oldopts.

options = bvpset(oldopts, newopts) combines an existing options structure oldopts with a new options structure newopts. Any new properties overwrite corresponding old properties.

bypset with no input arguments displays all property names and their possible values.

BVP Properties These properties are available.

Property	Value	Description
Rel Tol	Positive scalar {1e-3}	A relative tolerance that applies to all components of the residual vector. The computed solution $S(x)$ is the exact solution of $S'(x) = F(x, S(x)) + \operatorname{res}(x)$. On each subinterval of the mesh, the residual $\operatorname{res}(x)$ satisfies $\ (\operatorname{res}(i)/\operatorname{max}(\operatorname{abs}(F(i)),\operatorname{AbsTol}(i)/\operatorname{RelTol}))\ \le \operatorname{RelTol}$
AbsTol	Positive scalar or vector {1e-6}	An absolue tolerance that applies to all components of the residual vector. Elements of a vector of tolerances apply to corresponding components of the residual vector.

Property	Value	Description				
Vectori zed	on {off}	Set on to inform bvp4c that you have coded the ODE function F so that $F([x1 \ x2 \], [y1 \ y2 \])$ returns $[F(x1,y1) \ F(x2,y2) \]$. That is, your ODE function can pass to the solver a whole array of column vectors at once. This allows the solver to reduce the number of function evaluations, and may significantly reduce solution time.				
FJacobi an	Function	Analytic partial derivatives of ODEFUN. For example, when solving $y' = f(x, y)$, set this property to <code>@FJAC</code> if <code>DFDY = FJAC(X, Y)</code> evaluates the Jacobian of f with respect to y . If the problem involves unknown parameters p , <code>[DFDY, DFDP] = FJAC(X, Y, P)</code> must also return the partial derivative of f with respect to p .				
BCJacobi an	Function	Analytic partial derivatives of BCFUN. For example, for boundary conditions $bc(ya, yb) = 0$, set this property to @BCJAC if [DBCDYA, DBCDYB] = BCJAC(YA, YB) evaluates the partial derivatives of bc with respect to ya and to yb . If the problem involves unknown parameters p , then [DBCDYA, DBCDYB, DBCDP] = BCJAC(YA, YB, P) must also return the partial derivative of bc with respect to p .				
Nmax	positive integer {floor(1000/n)}	Maximum number of mesh points allowed.				
Stats	on {off}	Display computational cost statistics.

bvpval

Purpose

Evaluate the numerical solution of a boundary value problem (BVP) using the output of bvp4c

Note bypval is obsolete and will be removed in the future. Please use deval instead.

Syntax

sxi nt = bvpval (sol, xi nt)

Description

sxint = bvpval (sol, xint) uses sol, the output of bvp4c, to evaluate the solution of a boundary value problem at each element of the vector xint. For each i, sxint(:,i) is the solution corresponding to xint(i).

Purpose Calendar

Syntax

c = calendar
c = calendar(d)
c = calendar(y, m)

cal endar(...)

Description

c = cal endar returns a 6-by-7 matrix containing a calendar for the current month. The calendar runs Sunday (first column) to Saturday.

 $c = cal \, endar(d)$, where d is a serial date number or a date string, returns a calendar for the specified month.

 $c = cal \, endar(y, m)$, where y and m are integers, returns a calendar for the specified month of the specified year.

cal endar (...) displays the calendar on the screen.

Examples

The command:

cal endar (1957, 10)

reveals that the Space Age began on a Friday (on October 4, 1957, when Sputnik 1 was launched).

Syntax

```
\begin{split} & \text{camdolly}(dx,\,dy,\,dz) \\ & \text{camdolly}(dx,\,dy,\,dz,\,'\textit{targetmode'}) \\ & \text{camdolly}(dx,\,dy,\,dz,\,'\textit{targetmode'},\,'\textit{coordsys'}) \\ & \text{camdolly}(axes\_handle,\dots) \end{split}
```

Description

camdolly moves the camera position and the camera target by the specified amounts.

camdol ly(dx, dy, dz) moves the camera position and the camera target by the specified amounts (see "Coordinate Systems").

camdol ly(dx, dy, dz, 'targetmode') The targetmode argument can take on two values that determine how MATLAB moves the camera:

- movetarget (default) move both the camera and the target
- fixtarget move only the camera

camdol ly(dx, dy, dz, 'targetmode', 'coordsys') The coordsys argument can take on three values that determine how MATLAB interprets dx, dy, and dz:

Coordinate Systems

 camera (default) – move in the camera's coordinate system. dx moves left/ right, dy moves down/up, and dz moves along the viewing axis. The units are normalized to the scene.

For example, setting dx to 1 moves the camera to the right, which pushes the scene to the left edge of the box formed by the axes position rectangle. A negative value moves the scene in the other direction. Setting dz to 0.5 moves the camera to a position halfway between the camera position and the camera target

- pi xel s interpret dx and dy as pixel offsets. dz is ignored.
- data interpret dx, dy, and dz as offesets in axes data coordinates.

camdolly (axes_handle,...) operates on the axes identified by the first argument, axes_handle. When you do not specify an axes handle, camdolly operates on the current axes.

Remarks

camdolly sets the axes CameraPosition and CameraTarget properties, which in turn causes the CameraPositionMode and CameraTargetMode properties to be set to manual.

Examples

This example moves the camera along the *x*- and *y*-axes in a series of steps.

```
surf(peaks)
axis vis3d
t = 0: pi/20: 2*pi;
dx = sin(t)./40;
dy = cos(t)./40;
for i = 1:length(t);
    camdolly(dx(i), dy(i), 0)
    drawnow
end
```

See Also

axes, campos, camproj, camtarget, camup, camva

The axes properties CameraPosition, CameraTarget, CameraUpVector, CameraViewAngle, Projection

See Defining Scenes with Camera Graphics for more information on camera properties.

Purpose

Create or move a light object in camera coordinates

Syntax

```
camlight headlight
camlight right
camlight left
camlight
camlight
camlight(az, el)
camlight(...'style')
camlight(light_handle,...)
light_handle = camlight(...')
```

Description

 $caml\ i\ ght\ (\ '\ headl\ i\ ght\ ')$ creates a light at the camera position.

 $caml\ i\ ght\ ('\ ri\ ght')\ creates\ a\ light\ right\ and\ up\ from\ camera.$

caml i ght('left') creates a light left and up from camera.

caml i ght with no arguments is the same as caml i ght ('ri ght').

caml i ght (az, el) creates a light at the specified azimuth (az) and elevation (el) with respect to the camera position. The camera target is the center of rotation and az and el are in degrees.

caml i ght (\dots , ' $styl\ e^{\cdot}$) The style argument can take on the two values:

- local (default) the light is a point source that radiates from the location in all directions.
- infinite the light shines in parallel rays.

 $camlight(light_handle,...)$ uses the light specified in $light_handle$.

light_handle = camlight(...) returns the light's handle.

Remarks

caml i ght sets the light object Posi ti on and Styl e properties. A light created with caml i ght will not track the camera. In order for the light to stay in a constant position relative to the camera, you must call caml i ght whenever you move the camera.

Examples

This example creates a light positioned to the left of the camera and then repositions the light each time the camera is moved:

```
surf(peaks)
axis vis3d
h = camlight('left');
for i = 1:20;
    camorbit(10,0)
    camlight(h,'left')
    drawnow;
end
```

Purpose Position the camera to view an object or group of objects

Syntax caml ookat (obj ect_handl es)

 $caml\ ook at\ (axes_handl\ e)$

caml ookat

Description caml ookat (object_handles) views the objects identified in the vector

object_handles. The vector can contain the handles of axes children.

 $caml\ ook at\ (axes_handl\ e)\ views\ the\ objects\ that\ are\ children\ of\ the\ axes$

identified by axes_handle.

caml ookat views the objects that are in the current axes.

Remarks caml ookat moves the camera position and camera target while preserving the

 $relative\ view\ direction\ and\ camera\ view\ angle.\ The\ object\ (or\ objects)\ being$

viewed roughly fill the axes position rectangle.

caml ookat sets the axes CameraPosition and CameraTarget properties.

Examples

This example creates three spheres at different locations and then progressively positions the camera so that each sphere is the object around which the scene is composed:

```
[x \ y \ z] = sphere;
s1 = surf(x, y, z);
hold on
s2 = surf(x+3, y, z+3);
s3 = surf(x, y, z+6);
daspect([1 1 1])
vi ew (30, 10)
camproj perspective
caml ookat (gca) % Compose the scene around the current axes
pause(2)
caml ookat(s1)
                % Compose the scene around sphere s1
pause(2)
caml ookat (s2)
                % Compose the scene around sphere s2
pause(2)
caml ookat (s3)
                % Compose the scene around sphere s3
pause(2)
caml ookat (gca)
```

See Also

campos, camtarget

Purpose

Rotate the camera position around the camera target

Syntax

```
camorbit(dtheta, dphi)
camorbit(dtheta, dphi, 'coordsys')
camorbit(dtheta, dphi, 'coordsys', 'direction')
camorbit(axes_handle,...)
```

Description

camorbit(dtheta, dphi) rotates the camera position around the camera target by the amounts specified in dtheta and dphi (both in degrees). dtheta is the horizontal rotation and dphi is the vertical rotation.

camorbit(dtheta, dphi, 'coordsys') The coordsys argument determines the center of rotation. It can take on two values:

- data (default) rotate the camera around an axis defined by the camera target and the direction (default is the positive z direction).
- camera rotate the camera about the point defined by the camera target.

camorbit (dtheta, dphi, 'coordsys', 'direction') The direction argument, in conjunction with the camera target, defines the axis of rotation for the data coordinate system. Specify direction as a three-element vector containing the x, y, and z-components of the direction or one of the characters, x, y, or z, to indicate $[1\ 0\ 0], [0\ 1\ 0],$ or $[0\ 0\ 1]$ respectively.

camorbi t (axes_handle, \dots) operates on the axes identified by the first argument, axes_handle. When you do not specify an axes handle, camorbi t operates on the current axes.

Examples

Compare rotation in the two coordinate systems with these for loops. The first rotates the camera horizontally about a line defined by the camera target point and a direction that is parallel to the *y*-axis. Visualize this rotation as a cone formed with the camera target at the apex and the camera position forming the base:

```
surf(peaks)
axis vis3d
for i=1:36
    camorbit(10,0,'data',[0 1 0])
    drawnow
```

end

Rotation in the camera coordinate system orbits the camera around the axes along a circle while keeping the center of a circle at the camera target.

```
surf(peaks)
axis vis3d
for i=1:36
    camorbit(10,0,'camera')
    drawnow
end
```

See Also

axes, axi s('vis3d'), camdolly, campan, camzoom, camroll

campan

Purpose

Rotate the camera target around the camera position

Syntax

```
campan(dtheta, dphi)
campan(dtheta, dphi, 'coordsys')
campan(dtheta, dphi, 'coordsys', 'direction')
campan(axes_handle,...)
```

Description

campan(dtheta, dphi) rotates the camera target around the camera position by the amounts specified in dtheta and dphi (both in degrees). dtheta is the horizontal rotation and dphi is the vertical rotation.

campan(dtheta, dphi, 'coordsys') The coordsys argument determines the center of rotation. It can take on two values:

- data (default) rotate the camera target around an axis defined by the camera position and the direction (default is the positive z direction)
- camera rotate the camera about the point defined by the camera target.

campan(dtheta, dphi, 'coordsys', 'direction') The direction argument, in conjunction with the camera position, defines the axis of rotation for the data coordinate system. Specify direction as a three-element vector containing the x, y, and z-components of the direction or one of the characters, x, y, or z, to indicate $\begin{bmatrix} 1 & 0 & 0 \end{bmatrix}$, $\begin{bmatrix} 0 & 1 & 0 \end{bmatrix}$, or $\begin{bmatrix} 0 & 0 & 1 \end{bmatrix}$ respectively.

campan (axes_handle,...) operates on the axes identified by the first argument, axes_handle. When you do not specify an axes handle, campan operates on the current axes.

See Also

axes, camdolly, camorbit, camtarget, camzoom, camroll

Purpose

Set or query the camera position

Syntax

```
campos
campos([camera_position])
campos('mode')
campos('auto'
campos('manual')
campos(axes_handle,...)
```

Description

campos with no arguments returns the camera position in the current axes.

campos([camera_position]) sets the position of the camera in the current axes to the specified value. Specify the position as a three-element vector containing the x-, y-, and z-coordinates of the desired location in the data units of the axes.

campos('mode') returns the value of the camera position mode, which can be either auto (the default) or manual.

campos('auto') sets the camera position mode to auto.

 ${\tt campos('\,manual\,')}$ sets the camera position mode to manual .

campos (axes_handle,...) performs the set or query on the axes identified by the first argument, axes_handle. When you do not specify an axes handle, campos operates on the current axes.

Remarks

campos sets or queries values of the axes CameraPosition and CameraPositionMode properties. The camera position is the point in the Cartesian coordinate system of the axes from which you view the scene.

Examples

This example moves the camera along the *x*-axis in a series of steps:

```
surf(peaks)
axis vis3d off
for x = -200:5:200
    campos([x, 5, 10])
    drawnow
end
```

campos

axis, camproj, camtarget, camup, camva

The axes properties CameraPosition, CameraTarget, CameraUpVector, CameraViewAngle, Projection

Purpose Set or query the projection type

Syntax camproj

camproj (proj ecti on_type)
camproj (axes_handl e, . . .)

Description The projection type determines whether MATLAB uses a perspective or

orthographic projection for 3-D views.

camproj with no arguments returns the projection type setting in the current

axes.

camproj (' proj ecti on_type') sets the projection type in the current axes to

the specified value. Possible values for $proj\ ecti\ on_type$ are: orthographi c

and perspective.

camproj (axes_handle, \dots) performs the set or query on the axes identified by

the first argument, axes_handl e. When you do not specify an axes handle,

camproj operates on the current axes.

Remarks camproj sets or queries values of the axes object Projection property.

See Also campos, camtarget, camup, camva

The axes properties CameraPosition, CameraTarget, CameraUpVector,

CameraVi ewAngl e, Projection

camroll

Purpose Rotate the camera about the view axis

Syntax camroll(dtheta)

camroll(axes_handle, dtheta)

Description camrol l (dtheta) rotates the camera around the camera viewing axis by the

amounts specified in dtheta (in degrees). The viewing axis is defined by the

line passing through the camera position and the camera target.

camrol l (axes_handl e, dtheta) operates on the axes identified by the first argument, axes_handl e. When you do not specify an axes handle, camrol l

operates on the current axes.

Remarks camrol 1 set the axes CameraUpVector property and thereby also sets the

CameraUpVectorMode property to manual.

See Also axes, axi s('vi s3d'), camdolly, camorbit, camzoom, campan

Set or query the location of the camera target

Syntax

```
camtarget
```

camtarget([camera_target])
camtarget('mode')
camtarget('auto')
camtarget('manual')
camtarget(axes_handle,...)

Description

The camera target is the location in the axes that the camera points to. The camera remains oriented toward this point regardless of its position.

camtarget with no arguments returns the location of the camera target in the current axes.

camtarget([camera_target]) sets the camera target in the current axes to the specified value. Specify the target as a three-element vector containing the x-, y-, and z-coordinates of the desired location in the data units of the axes.

camtarget ('mode') returns the value of the camera target mode, which can be either auto (the default) or manual.

 $camtarget (\ '\ auto'\)\ sets\ the\ camera\ target\ mode\ to\ auto.$

 ${\tt camtarget}\,(\,{}^{\scriptscriptstyle '}\,{\tt manual}\,{}^{\scriptscriptstyle '}\,)\,$ sets the camera target mode to manual .

camtarget (axes_handl e, . . .) performs the set or query on the axes identified by the first argument, axes_handl e. When you do not specify an axes handle, camtarget operates on the current axes.

Remarks

camtarget sets or queries values of the axes object Cameratarget and CameraTargetMode properties.

When the camera target mode is auto, MATLAB positions the camera target at the center of the axes plot box.

Examples

This example moves the camera position and the camera target along the *x*-axis in a series of steps:

surf(peaks);

camtarget

```
axis vis3d
xp = linspace(-150, 40, 50);
xt = linspace(25, 50, 50);
for i=1:50
          campos([xp(i), 25, 5]);
          camtarget([xt(i), 30, 0])
          drawnow
end
```

See Also

axis, camproj, campos, camup, camva

The axes properties CameraPosition, CameraTarget, CameraUpVector, CameraViewAngle, Projection

Set or query the camera up vector

Syntax

```
camup
camup([up_vector])
camup('mode')
camup('auto')
camup('manual')
camup(axes_handle,...)
```

Description

The camera up vector specifies the direction that is oriented up in the scene.

camup with no arguments returns the camera up vector setting in the current axes.

camup([up_vector]) sets the up vector in the current axes to the specified value. Specify the up vector as x-, y-, and z-components. See Remarks.

camup('mode') returns the current value of the camera up vector mode, which can be either auto (the default) or manual.

<code>camup('auto')</code> sets the camera up vector mode to auto. In auto mode, MATLAB uses a value for the up vector of $[0\ 1\ 0]$ for 2-D views. This means the z-axis points up.

camup('manual') sets the camera up vector mode to manual. In manual mode, MATLAB does not change the value of the camera up vector.

camup(axes_handle,...) performs the set or query on the axes identified by the first argument, axes_handle. When you do not specify an axes handle, camup operates on the current axes.

Remarks

camup sets or queries values of the axes object CameraUpVector and CameraUpVectorMode properties.

Specify the camera up vector as the x-, y-, and z-coordinates of a point in the axes coordinate system that forms the directed line segment PQ, where P is the point (0,0,0) and Q is the specified x-, y-, and z-coordinates. This line always points up. The length of the line PQ has no effect on the orientation of the scene. This means a value of $\begin{bmatrix} 0 & 0 & 1 \end{bmatrix}$ produces the same results as $\begin{bmatrix} 0 & 0 & 25 \end{bmatrix}$.

camup

See Also

axis, camproj, campos, camtarget, camva

The axes properties CameraPosition, CameraTarget, CameraUpVector, CameraViewAngle, Projection

Set or query the camera view angle

Syntax

```
camva
```

```
camva(vi ew_angl e)
camva(' mode')
camva(' auto')
camva(' manual')
camva(axes_handl e, ...)
```

Description

The camera view angle determines the field of view of the camera. Larger angles produce a smaller view of the scene. You can implement zooming by changing the camera view angle.

camva with no arguments returns the camera view angle setting in the current axes.

 $camva(vi\ ew_angl\ e)$ sets the view angle in the current axes to the specified value. Specify the view angle in degrees.

camva('mode') returns the current value of the camera view angle mode, which can be either auto (the default) or manual. See Remarks.

camva('auto') sets the camera view angle mode to auto.

 $\mbox{\it camva('manual')}$ sets the camera view angle mode to $\mbox{\it manual}$. See Remarks.

camva(axes_handl e, . . .) performs the set or query on the axes identified by the first argument, axes_handl e. When you do not specify an axes handle, camva operates on the current axes.

Remarks

camva sets or queries values of the axes object CameraVi ewAngl e and CameraVi ewAngl eMode properties.

When the camera view angle mode is auto, MATLAB adjusts the camera view angle so that the scene fills the available space in the window. If you move the camera to a different position, MATLAB changes the camera view angle to maintain a view of the scene that fills the available area in the window.

Setting a camera view angle or setting the camera view angle to manual disables MATLAB's stretch-to-fill feature (stretching of the axes to fit the window). This means setting the camera view angle to its current value,

```
camva(camva)
```

can cause a change in the way the graph looks. See the Remarks section of the axes reference page for more information.

Examples

This example creates two pushbuttons, one that zooms in and another that zooms out.

```
uicontrol('Style', 'pushbutton',...
'String', 'Zoom In',...
'Position', [20 20 60 20],...
'Callback', 'if camva <= 1; return; else; camva(camva-1); end');
uicontrol('Style', 'pushbutton',...
'String', 'Zoom Out',...
'Position', [100 20 60 20],...
'Callback', 'if camva >= 179; return; else; camva(camva+1); end');
```

Now create a graph to zoom in and out on:

```
surf(peaks);
```

Note the range checking in the callback statements. This keeps the values for the camera view angle in the range, greater than zero and less than 180.

See Also

```
axis, camproj, campos, camup, camtarget
```

The axes properties CameraPosition, CameraTarget, CameraUpVector, CameraViewAngle, Projection

Purpose Zoom in and out on a scene

Syntax camzoom(zoom_factor)

camzoom(axes_handle,...)

Description camzoom(zoom_factor) zooms in or out on the scene depending on the value

specified by zoom_factor. If zoom_factor is greater than 1, the scene appears larger; if zoom_factor is greater than zero and less than 1, the scene appears

smaller.

camzoom(axes_handl e, ...) operates on the axes identified by the first argument, axes_handl e. When you do not specify an axes handle, camzoom

operates on the current axes.

Remarks camzoom sets the axes CameraVi ewAngl e property, which in turn causes the

CameraVi ewAngl eMode property to be set to manual. Note that setting the

CameraVi ewAngl e property disables MATLAB's stretch-to-fill feature (stretching of the axes to fit the window). This may result in a change to the

aspect ratio of your graph. See the axes function for more information on this

behavior.

See Also axes, camdolly, camorbit, campan, camroll, camva

capture

Purpose capture is obsolete in Release 11 (5.3). getframe provides the same

functionality and supports TrueColor displays by returning TrueColor images.

Syntax capture

capture(h)

[X, cmap] = capture(h)

Description capture creates a bitmap copy of the contents of the current figure, including

any uicontrol graphics objects. It creates a new figure and displays the bitmap $% \left(1\right) =\left(1\right) \left(1\right) \left$

copy as an image graphics object in the new figure.

capture(h) creates a new figure that contains a copy of the figure identified by

h.

 $\label{eq:continuous} [\,\textbf{X},\,\texttt{cmap}\,] \ = \ \texttt{capture}(\,\textbf{h}) \ \ \textbf{returns} \ \textbf{an image matrix} \ \textbf{X} \ \textbf{and} \ \textbf{a} \ \textbf{colormap}. \ \textbf{You}$

display this information using the statements

col ormap(cmap)
i mage(X)

Remarks The resolution of a bitmap copy is less than that obtained with the print

command.

See Also i mage, print

Transform Cartesian coordinates to polar or cylindrical

Syntax

[THETA, RHO, Z] = cart2pol(X, Y, Z)[THETA, RHO] = cart2pol(X, Y)

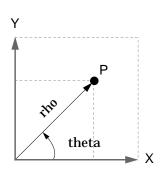

Description

[THETA, RHO, Z] = cart2pol (X, Y, Z) transforms three-dimensional Cartesian coordinates stored in corresponding elements of arrays X, Y, and Z, into cylindrical coordinates. THETA is a counterclockwise angular displacement in radians from the positive x-axis, RHO is the distance from the origin to a point in the x-y plane, and Z is the height above the x-y plane. Arrays X, Y, and Z must be the same size (or any can be scalar).

[THETA, RHO] = cart2pol(X, Y) transforms two-dimensional Cartesian coordinates stored in corresponding elements of arrays X and Y into polar coordinates.

Algorithm

The mapping from two-dimensional Cartesian coordinates to polar coordinates, and from three-dimensional Cartesian coordinates to cylindrical coordinates is

Two-Dimensional Mapping theta = atan2(y, x)rho = $sqrt(x.^2 + y.^2)$

z P z theta X

Three-Dimensional Mapping theta = atan2(y, x) rho = sqrt(x. 2 + y. 2) z = z

See Also

cart2sph, pol 2cart, sph2cart

cart2sph

Purpose Transform Cartes

Transform Cartesian coordinates to spherical

Syntax

[THETA, PHI, R] = cart2sph(X, Y, Z)

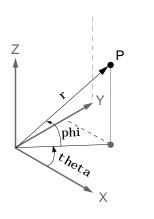

Description

[THETA, PHI, R] = cart2sph(X, Y, Z) transforms Cartesian coordinates stored in corresponding elements of arrays X, Y, and Z into spherical coordinates. Azimuth THETA and elevation PHI are angular displacements in radians measured from the positive x-axis, and the x-y plane, respectively; and R is the distance from the origin to a point.

Arrays X, Y, and Z must be the same size.

Algorithm

The mapping from three-dimensional Cartesian coordinates to spherical coordinates is

theta = atan2(y, x)phi = $atan2(z, sqrt(x.^2 + y.^2))$ r = $sqrt(x.^2+y.^2+z.^2)$

See Also

cart2pol, pol2cart, sph2cart

Case switch

Description

case is part of the switch statement syntax, which allows for conditional execution.

A particular case consists of the case statement itself, followed by a case expression, and one or more statements.

A case is executed only if its associated case expression (case_expr) is the first to match the switch expression (switch_expr).

Examples

The general form of the switch statement is:

```
switch switch_expr
    case case_expr
    statement,..., statement
    case {case_expr1, case_expr2, case_expr3,...}
    statement,..., statement
...
    otherwise
        statement,..., statement
end
```

See Also

switch

Concatenate arrays

Syntax

$$C = cat(dim, A, B)$$

$$C = cat(dim, A1, A2, A3, A4...)$$

Description

C = cat(dim, A, B) concatenates the arrays A and B along dim.

C = cat(dim, A1, A2, A3, A4, ...) concatenates all the input arrays (A1, A2, A3, A4, and so on) along dim.

cat(2, A, B) is the same as [A, B] and cat(1, A, B) is the same as [A; B].

Remarks

When used with comma separated list syntax, $cat(dim, C\{:\})$ or cat(dim, C. field) is a convenient way to concatenate a cell or structure array containing numeric matrices into a single matrix.

Examples

Given,

concatenating along different dimensions produces:

$$C = cat(1, A, B)$$

$$C = cat(2, A, B)$$

$$C = cat(3, A, B)$$

The commands

$$A = magic(3)$$
; $B = pascal(3)$;
 $C = cat(4, A, B)$;

produce a 3-by-3-by-1-by-2 array.

See Also

num2cell

The special character []

Begin catch block

Description

The general form of a try statement is:

```
try,
statement,
...,
statement,
catch,
statement,
...,
statement,
end
```

Normally, only the statements between the try and catch are executed. However, if an error occurs while executing any of the statements, the error is captured into lasterr, and the statements between the catch and end are executed. If an error occurs within the catch statements, execution stops unless caught by another try...catch block. The error string produced by a failed try block can be obtained with lasterr.

See Also

end, eval, evalin, try

Color axis scaling

Syntax

```
caxis([cmin cmax])
caxis auto
caxis manual
```

caxis(caxis) v = caxis

caxis(axes_handle,...)

Description

caxis controls the mapping of data values to the colormap. It affects any surfaces, patches, and images with indexed CData and CDataMapping set to scaled. It does not affect surfaces, patches, or images with true color CData or with CDataMapping set to direct.

caxi $s([cmi\ n\ cmax])$ sets the color limits to specified minimum and maximum values. Data values less than $cmi\ n$ or greater than cmax map to $cmi\ n$ and cmax, respectively. Values between $cmi\ n$ and cmax linearly map to the current colormap.

caxi s auto lets MATLAB compute the color limits automatically using the minimum and maximum data values. This is MATLAB's default behavior. Color values set to Inf map to the maximum color, and values set to —Inf map to the minimum color. Faces or edges with color values set to NaN are not drawn.

caxis manual and caxis (caxis) freeze the color axis scaling at the current limits. This enables subsequent plots to use the same limits when hold is on.

 $v = caxi \, s \, returns \, a \, two\text{-element row vector containing the } [\, cmi \, n \, \, cmax] \, currently in use.$

caxi s(axes_handle, \dots) uses the axes specified by axes_handle instead of the current axes.

Remarks

caxi s changes the CLi m and CLi mMode properties of axes graphics objects.

How Color Axis Scaling Works

Surface, patch, and image graphics objects having indexed CData and CDataMapping set to scaled, map CData values to colors in the figure colormap

each time they render. CData values equal to or less than cmin map to the first color value in the colormap, and CData values equal to or greater than cmax map to the last color value in the colormap. MATLAB performs the following linear transformation on the intermediate values (referred to as C below) to map them to an entry in the colormap (whose length is m, and whose row index is referred to as i ndex below).

```
i ndex = fi x((C-cmi n)/(cmax-cmi n)*m)+1
```

Examples

Create (X, Y, Z) data for a sphere and view the data as a surface.

```
[X, Y, Z] = sphere;
C = Z;
surf(X, Y, Z, C)
```

Values of C have the range $[-1\ 1]$. Values of C near -1 are assigned the lowest values in the colormap; values of C near 1 are assigned the highest values in the colormap.

To map the top half of the surface to the highest value in the color table, use

```
caxis([-1 \ 0])
```

To use only the bottom half of the color table, enter

```
caxis([-1 \ 3])
```

which maps the lowest CData values to the bottom of the colormap, and the highest values to the middle of the colormap (by specifying a cmax whose value is equal to cmi n plus twice the range of the CData).

The command

```
caxis auto
```

resets axis scaling back to auto-ranging and you see all the colors in the surface. In this case, entering

```
caxi s
```

returns

 $[-1 \ 1]$

Adjusting the color axis can be useful when using images with scaled color data. For example, load the image data and colormap for Cape Cod, Massachusetts.

```
load cape
```

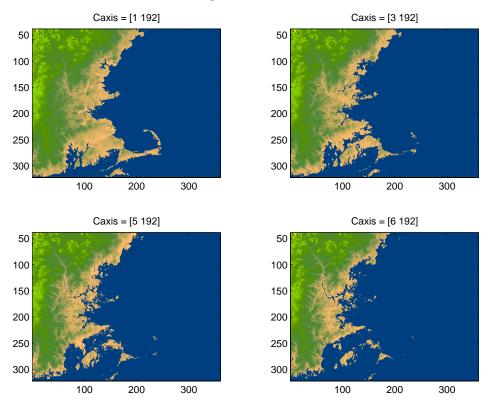

This command loads the images data X and the image's colormap map into the workspace. Now display the image with CDataMappi ng set to scal ed and install the image's colormap.

```
i mage(X, 'CDataMappi ng', 'scal ed')
col ormap(map)
```

MATLAB sets the color limits to span the range of the image data, which is 1 to 192:

```
caxi s
ans =
1 192
```

The blue color of the ocean is the first color in the colormap and is mapped to the lowest data value (1). You can effectively move sealevel by changing the lower color limit value. For example,

Axes Color Limits

Purpose Change working directory Graphical As an alternative to the cd function, use the **Current Directory** field in the Interface MATLAB desktop toolbar. Syntax cdw = cdcd('directory') cd('..') cd directory or cd ... **Description** cd prints out the current working directory. w = cd assigns the current working directory to w. cd('di rectory') sets the current working directory to di rectory. Use the full pathname for di rectory. On UNIX platforms, the character ~ is interpreted as the user's root directory. cd('..') changes the current working directory to the directory above it. cd directory or cd . . is the unquoted form of the syntax. **Examples** On UNIX cd('/usr/local/matlab/toolbox/demos') changes the current working directory to demos. On Windows cd('C:\TOOLBOX\MATLAB\DEMOS') changes the current working directory to DEMOS. Then typing cd .. changes the current working directory to MATLAB.

Convert complex diagonal form to real block diagonal form

Syntax

$$[V, D] = cdf2rdf(V, D)$$

Description

If the eigensystem $[V, D] = \operatorname{eig}(X)$ has complex eigenvalues appearing in complex-conjugate pairs, $\operatorname{cdf2rdf}$ transforms the system so D is in real diagonal form, with 2-by-2 real blocks along the diagonal replacing the complex pairs originally there. The eigenvectors are transformed so that

$$X = V*D/V$$

continues to hold. The individual columns of V are no longer eigenvectors, but each pair of vectors associated with a 2-by-2 block in D spans the corresponding invariant vectors.

Examples

The matrix

has a pair of complex eigenvalues.

$$[V, D] = ei g(X)$$

$$D =$$

Converting this to real block diagonal form produces

$$[V, D] = cdf2rdf(V, D)$$

cdf2rdf

V =

D =

Algorithm

The real diagonal form for the eigenvalues is obtained from the complex form using a specially constructed similarity transformation.

eig, rsf2csf

Purpose Return details about a CDF file

Syntax info = cdfinfo(file)

Description info = cdfinf

info = cdfinfo(file) returns information about the Common Data Format (CDF) file specified in the string, file. The function returns a structure, info, that contains the fields shown in the following table.

Field	Description	Return Type
FileModDate	Date the file was last modified	String
Filename	Name of the file	String
FileSettings	Library settings used to create the file	Structure array
Fi l eSi ze	Size of the file, in bytes	Double
Format	File format (CDF)	String
Format Versi on	Version of the CDF library used to create the file	String
Gl obal Attri butes	Global metadata	Structure array
Subfiles	Filenames containing the CDF file's data, if it is a multifile CDF	Cell array
Vari abl eAttri butes	Metadata for the variables	Structure array
Vari abl es	Details about the variables in the file	Cell array

The GlobalAttributes and VariableAttributes Fields

Gl obal Attri butes and Vari able Attri butes are structure arrays that each contain one field for each global or variable attribute respectively. The name of the field corresponds to the name of an attribute. The data in that field, contained in a cell array, represents the entry values for that attribute.

For Vari abl eAttri butes, the attribute data resides in an N-by-2 cell array, where N is the number of variables. The first column of this cell array contains the variable names associated with the entries. The second column contains the entry values.

Note Attribute names may not match the names of the attributes in the CDF file exactly. Because attribute names can contain characters that are illegal in MATLAB field names, they may be translated into legal field names. Illegal characters that appear at the beginning of attributes are removed; other illegal characters are replaced with underscores ('_'). If an attribute's name is modified, the attribute's internal number is appended to the end of the field name. For example, Vari abl e%Attri bute might become Vari abl e_Attri bute_013.

The Variables Field

The Variables field of the returned info structure is an N-by-6 cell array, where N is the number of variables. The six columns of the cell array contain the following information.

Column No.	Description	Return Type
1	Name of the variable	String
2	Dimensions of the variable, as returned by the size function	Double array
3	Number of records assigned for the variable	Double
4	Data type of the variable, as stored in the CDF file	String
5	Record and dimension variance settings for the variable	String
6	Sparsity of the variable's records	String

Column 5 - Record and Dimension Variance

This is a string indicating either true or fal se for one or more types of variance in the variable's values. The single T or F to the left of the slash designates whether values vary by record. The zero or more T or F letters to the right of the slash designate whether values vary at each dimension. Here are some examples.

```
T/ for a scalar variable

F/T for a one-dimensional variable

T/TFF for a three-dimensional variable
```

Column 6 - Record Sparsity

'Status%C1'

'B_gse%C1'

'B_nsigma%C1'

• 'Full'

This is a string holding one of three possible values:

```
'Sparse (padded)'
• 'Sparse (nearest)'
  info = cdfinfo('example.cdf')
  info =
                 Filename: 'example.cdf'

Read data from a CDF file

Syntax

```
data = cdfread(file)
data = cdfread(file, 'records', recnum, ...)
data = cdfread(file, 'variables', varnames, ...)
data = cdfread(file, 'slices', dimensionvalues, ...)
[data, inf0] = cdfread(file, ...)
```

Description

data = cdfread(file) reads all of the variables from each record of the Common Data Format (CDF) file specified in the string, file. The function returns a cell array, in which each row contains a record and each column represents a variable.

data = cdfread(file, 'records', recnums, ...) reads only those records specified in the vector, recnums. The record numbers are zero-based. The function returns a cell array having length(recnums) number of rows and as many columns as there are variables.

data = cdfread(file, 'variables', varnames, ...) reads only those variables specified in the 1-by-N or N-by-1 cell array of strings, varnames. Data is returned in a cell array having length(varnames) number of columns and a row for each record requested.

data = cdfread(file, 'slices', dimensi onvalues, ...) reads specific values from the records of one variable in the CDF file. The N-by-3 matrix, dimensi onvalues, indicates which records are to be read by specifying start, interval, and count parameters for each of the N dimensions of the variable. The start parameter is zero-based.

The number of rows in dimensi onval ues must be less than or equal to the number dimensions of the variable. Unspecified rows default to $[0\ 1\ M]$, where M is the total number of values in a record. This causes cdfread to read every value from those dimensions.

Because you can read just one variable at a time, you must also include a 'vari ables' parameter with this syntax.

[data, inf0] = cdfread(file, ...) also returns details about the CDF file in the info structure.

Examples

Read all of the data from the file.

```
data = cdfread('example.cdf');
```

Read just the data from variable 'Time'.

```
data = cdfread('example.cdf', 'Variable', {'Time'});
```

Read the first value in the first dimension, the second value in the second dimension, the first and third values in the third dimension, and all values in the remaining dimension of the variable 'multidimensional'.

```
data = cdfread('example.cdf', 'Variable', ...
{'multidimensional'}, 'Slices', [0 1 1; 1 1 1; 0 2 2]);
```

This is similar to reading the whole variable into ' $\mbox{\tt data}$ ', and then using the MATLAB command

```
data\{1\}(1, 2, [1 3], :)
```

cdfinfo

Purpose Round toward infinity

Syntax B = ceil(A)

Description B = ceil(A) rounds the elements of A to the nearest integers greater than or

equal to A. For complex A, the imaginary and real parts are rounded

independently.

Examples

```
a = [-1.9, -0.2, 3.4, 5.6, 7, 2.4+3.6i]
```

a =

Columns 1 through 4

- 1. 9000 - 0. 2000

3.4000

5.6000

Columns 5 through 6

7.0000

2. 4000 + 3. 6000i

ceil(a)

ans =

Columns 1 through 4

- 1. 0000 0

4.0000

Create cell array

Syntax

```
c = cell(n)
c = cell(m, n) or c = cell([m n])
c = cell(m, n, p, ...) or c = cell([m n p ...])
c = cell(size(A))
c = cell(javaobj)
```

Description

c = cell(n) creates an n-by-n cell array of empty matrices. An error message appears if n is not a scalar.

c = cell(m, n) or c = cell([m, n]) creates an m-by-n cell array of empty matrices. Arguments m and n must be scalars.

c = cell(m, n, p, ...) or c = cell([m n p ...]) creates an m-by-n-by-p-... cell array of empty matrices. Arguments m, n, p,... must be scalars.

 $c = cell(\mathbf{size}(A))$ creates a cell array the same size as A containing all empty matrices.

c = cell(javaobj) converts a Java array or Java object, javaobj, into a MATLAB cell array. Elements of the resulting cell array will be of the MATLAB type (if any) closest to the Java array elements or Java object.

Examples

This example creates a cell array that is the same size as another array, A.

The next example converts an array of j ava. l ang. String objects into a MATLAB cell array.

```
strArray = java_array('java.lang.String',3);
strArray(1) = java.lang.String('one');
strArray(2) = java.lang.String('two');
strArray(3) = java.lang.String('three');

cellArray = cell(strArray)
cellArray =
    'one'
    'two'
    'three'
```

See Also

num2cell, ones, rand, randn, zeros

Convert cell array to structure array

Syntax

```
s = cell 2 struct(c, fields, dim)
```

Description

s = cell 2 struct(c, fields, dim) creates a structure array, s, from the information contained within cell array, c.

The fields argument specifies field names for the structure array. fields can be a character array or a cell array of strings.

The dimargument controls which axis of the cell array is to be used in creating the structure array. The length of c along the specified dimension must match the number of fields named in fields. In other words, the following must be true.

```
size(c, dim) == length(fields) % if fields is a cell array

size(c, dim) == size(fields, 1) % if fields is a char array
```

Examples

The cell array, c, in this example contains information on trees. The three columns of the array indicate the common name, genus, and average height of a tree.

```
c = {'birch', 'betula', 65;  'maple', 'acer', 50}
c =
   'birch'  'betula'  [65]
   'maple'  'acer'  [50]
```

To put this information into a structure with the fields name, genus, and height, use cell2struct along the second dimension of the 2-by-3 cell array.

```
fields = {'name', 'genus', 'height'};
s = cell2struct(c, fields, 2);
```

This yields the following 2-by-1 structure array.

See Also

fieldnames, struct2cell

celldisp

Purpose

Display cell array contents.

Syntax

celldisp(C)
celldisp(C, name)

Description

celldisp(C) recursively displays the contents of a cell array.

celldisp(C, name) uses the string name for the display instead of the name of the first input (or ans).

Example

Use celldisp to display the contents of a 2-by-3 cell array:

$$C{2, 1} = 1 2 3 4$$

$$C{2, 2} = -5$$

$$C{2, 3} = abc$$

See Also

cellplot

Apply a function to each element in a cell array

Syntax

D = cellfun('fname', C)
D = cellfun('size', C, k)

D = cellfun('isclass', C, classname)

Description

D = cell fun('fname', C) applies the function fname to the elements of the cell array C and returns the results in the double array D. Each element of D contains the value returned by fname for the corresponding element in C. The output array D is the same size as the cell array C.

These functions are supported:

Function	Return Value	
isempty	true for an empty cell element	
i sl ogi cal	true for a logical cell element	
i sreal	true for a real cell element	
length	Length of the cell element	
ndi ms	Number of dimensions of the cell element	
prodofsi ze	Number of elements in the cell element	

D = cell fun('size', C, k) returns the size along the k-th dimension of each element of C.

D = cell fun('isclass', C, 'classname') returns true for each element of C that matches classname. This function syntax returns false for objects that are a subclass of classname.

Limitations

If the cell array contains objects, cell fun does not call overloaded versions of the function fname.

Example

Consider this 2-by-3 cell array:

$$C\{1, 1\} = [1 2; 4 5];$$

 $C\{1, 2\} = 'Name';$

```
C\{1, 3\} = pi;
  C\{2, 1\} = 2 + 4i;
  C\{2, 2\} = 7;
  C{2, 3} = magic(3);
cell fun returns a 2-by-3 double array:
  D = cellfun('isreal',C)
  D =
        1
              1
                    1
        0 1
                    1
  len = cellfun('length', C)
  len =
        2
              4
                    1
              1
                    3
        1
  isdbl = cellfun('isclass', C, 'double')
  i sdbl =
        1
              0
                    1
        1
              1
                    1
```

See Also

isempty, islogical, isreal, length, ndims, size

Graphically display the structure of cell arrays

Syntax

```
cellplot(c)
cellplot(c, 'legend')
handles = cellplot(...)
```

Description

 $cel\,l\,pl\,ot\,(c)\,$ displays a figure window that graphically represents the contents of c. Filled rectangles represent elements of vectors and arrays, while scalars and short text strings are displayed as text.

cellplot(c, 'legend') also puts a legend next to the plot.

handles = cellplot(c) displays a figure window and returns a vector of surface handles.

Limitations

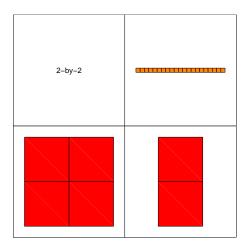

The cellplot function can display only two-dimensional cell arrays.

Examples

Consider a 2-by-2 cell array containing a matrix, a vector, and two text strings:

```
c{1, 1} = '2-by-2';
c{1, 2} = 'eigenvalues of eye(2)';
c{2, 1} = eye(2);
c{2, 2} = eig(eye(2));
```

The command cellplot(c) produces:

cellstr

Purpose

Create cell array of strings from character array

Syntax

c = cellstr(S)

Description

c = cellstr(S) places each row of the character array S into separate cells of c. Use the char function to convert back to a string matrix.

Examples

Given the string matrix

The following command returns a 3-by-1 cell array.

See Also

iscellstr, strings

Purpose

Conjugate Gradients Squared method

Syntax

```
x = cgs(A, b)
cgs(A, b, tol)
cgs(A, b, tol, maxit)
cgs(A, b, tol, maxit, M)
cgs(A, b, tol, maxit, M1, M2)
cgs(A, b, tol, maxit, M1, M2, x0)
cgs(afun, b, tol, maxit, m1fun, m2fun, x0, p1, p2, ...)
[x, flag] = cgs(A, b, ...)
[x, flag, relres] = cgs(A, b, ...)
[x, flag, relres, iter] = cgs(A, b, ...)
[x, flag, relres, iter, resvec] = cgs(A, b, ...)
```

Description

x = cgs(A, b) attempts to solve the system of linear equations A*x = b for x. The n-by-n coefficient matrix A must be square and the column vector b must have length n. A can be a function afun such that afun(x) returns A*x.

If cgs converges, a message to that effect is displayed. If cgs fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual norm(b-A*x)/norm(b) and the iteration number at which the method stopped or failed.

cgs(A, b, tol) specifies the tolerance of the method, tol. If tol is [], then cgs uses the default, 1e-6.

cgs(A, b, tol, maxit) specifies the maximum number of iterations, maxit. If maxit is [] then cgs uses the default, min(n, 20).

cgs(A, b, tol, maxit, M) and cgs(A, b, tol, maxit, M1, M2) use the preconditioner M or M = M1*M2 and effectively solve the system inv(M)*A*x = inv(M)*b for x. If M is [] then cgs applies no preconditioner. M can be a function that returns $M \setminus x$.

cgs(A, b, tol, maxit, M1, M2, x0) specifies the initial guess x0. If x0 is [], then cgs uses the default, an all-zero vector.

```
cgs (afun, b, tol, maxi t, m1fun, m2fun, x0, p1, p2, ...) passes parameters p1, p2, ... to functions afun(x, p1, p2, ...), m1fun(x, p1, p2, ...), and m2fun(x, p1, p2, ...)
```

[x, flag] = cgs(A, b, ...) returns a solution x and a flag that describes the convergence of cgs.

Flag	Convergence
0	cgs converged to the desired tolerance tol within maxit iterations.
1	cgs iterated maxi t times but did not converge.
2	Preconditioner M was ill-conditioned.
3	cgs stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during cgs became too small or too large to continue computing.

Whenever fl ag is not 0, the solution x returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the fl ag output is specified.

[x, flag, relres] = cgs(A, b, ...) also returns the relative residual norm(b-A*x)/norm(b). If flag is 0, then relres <= tol.

[x, flag, rel res, i ter] = cgs(A, b, ...) also returns the iteration number at which x was computed, where 0 <= i ter <= maxi t.

[x, flag, rel res, i ter, resvec] = cgs(A, b, ...) also returns a vector of the residual norms at each iteration, including norm(b-A*x0).

Examples Example 1.

```
A = gallery('wilk', 21);
b = sum(A, 2);
tol = 1e-12;    maxit = 15;
M1 = diag([10:-1:1 1 1:10]);
x = cgs(A, b, tol, maxit, M1, [], []);
```

Alternatively, use this matrix-vector product function

```
function y = afun(x, n)

y = [0;

x(1: n-1)] + [((n-1)/2: -1: 0)';

(1: (n-1)/2)'] .*x + [x(2: n);

0];
```

and this preconditioner backsolve function

```
function y = mfun(r, n)

y = r . / [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];

as inputs to cgs.

x1 = cgs(@afun, b, tol, maxit, @mfun, [], [], 21);
```

Note that both afun and mfun must accept cgs's extra input n=21.

Example 2.

```
load west0479
A = west0479
b = sum(A, 2)
[x, flag] = cgs(A, b)
```

flag is 1 because cgs does not converge to the default tolerance 1e-6 within the default 20 iterations.

```
[L1, U1] = luinc(A, 1e-5)

[x1, flag1] = cgs(A, b, 1e-6, 20, L1, U1)
```

fl ag1 is 2 because the upper triangular U1 has a zero on its diagonal, and cgs fails in the first iteration when it tries to solve a system such as U1*y = r for y with backslash.

```
[L2, U2] = lui nc(A, 1e-6)

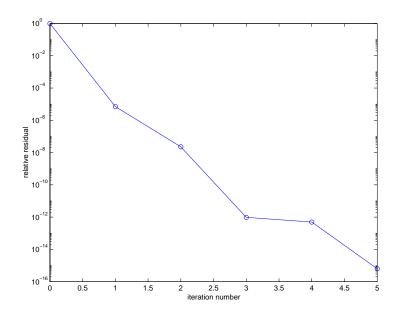

[x2, flag2, rel res2, iter2, resvec2] = cgs(A, b, 1e-15, 10, L2, U2)
```

fl ag2 is 0 because cgs converges to the tolerance of 6.344e-16 (the value of rel res2) at the fifth iteration (the value of i ter2) when preconditioned by the incomplete LU factorization with a drop tolerance of 1e-6.

```
resvec2(1) = norm(b) and resvec2(6) = norm(b-A*x2). You can follow the
```

progress of cgs by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0) with

```
semilogy(0:iter2, resvec2/norm(b), '-o')
xlabel('iteration number')
ylabel('relative residual')
```

[2] Sonneveld, Peter, "CGS: A fast Lanczos-type solver for nonsymmetric linear systems", *SIAM J. Sci. Stat. Comput.*, January 1989, Vol. 10, No. 1, pp. 36-52.

Purpose

Create character array (string)

Syntax

```
S = char(X)
S = char(C)
S = char(t1, t2, t3...)
```

Description

S = char(X) converts the array X that contains positive integers representing character codes into a MATLAB character array (the first 127 codes are ASCII). The actual characters displayed depend on the character set encoding for a given font. The result for any elements of X outside the range from 0 to 65535 is not defined (and may vary from platform to platform). Use double to convert a character array into its numeric codes.

S = char(C) when C is a cell array of strings, places each element of C into the rows of the character array s. Use cell str to convert back.

 $S = \operatorname{char}(t1, t2, t3, \ldots)$ forms the character array S containing the text strings $T1, T2, T3, \ldots$ as rows, automatically padding each string with blanks to form a valid matrix. Each text parameter, Ti, can itself be a character array. This allows the creation of arbitrarily large character arrays. Empty strings are significant.

Remarks

Ordinarily, the elements of A are integers in the range 32:127, which are the printable ASCII characters, or in the range 0:255, which are all 8-bit values. For noninteger values, or values outside the range 0:255, the characters printed are determined by fix(rem(A, 256)).

Examples

To print a 3-by-32 display of the printable ASCII characters:

```
ascii = char(reshape(32:127,32,3)') ascii = ! " # $ % & ' ( ) *+ , - . / 0 1 2 3 4 5 6 7 8 9 : ; < = > ? @ A B C D E F G H I J K L M N 0 P Q R S T U V W X Y Z [ \ ] ^ _ ' a b c d e f g h i j k l m n o p q r s t u v w x y z { | } ~
```

char

Purpose

Check file into source control system

Graphical Interface

As an alternative to the checkin function, use **Source Control Check In** in the Editor, Simulink, or Stateflow **File** menu.

Syntax

```
checkin('filename','comments','string')
checkin({'filename1','filename2','filename3', ...},'comments',
    'string')
checkin('filename','option','value', ...)
```

Description

checkin('filename','comments','string') checks in the filenamed filename to the source control system. Use the full pathname for the filename. You must save the file before checking it in. The file can be open or closed when you use checkin. The string argument is a MATLAB string containing check-in comments for the source control system. You must supply the comments argument and 'string'.

checkin({'filename1', 'filename2', 'filename3', ...}, 'comments', 'string') checks in the files named filename1 through filenamen to the source control system. Use the full pathnames for the files. Additional arguments apply to all files checked in.

checki n(' fi l ename', ' option', ' value', ...) provides additional checki n options. The option and value arguments are shown in the table below.

option Argument	Purpose	value Argument
'force'	When set to on, filename is checked in even if the file has not changed since it was checked out. The default value for force is off.	'on' 'off' (default)
'lock'	When set to on, filename remains checked out. Comments are submitted. The default value for lock is off.	'on' 'off' (default)

You can check in a file that you checked out in a previous MATLAB session or that you checked out directly from your source control system.

Examples

Example 1 - Check in a File with Comments

Typing

 $\lab{checkin('/matlab/mymfiles/clock.m','comments','Adjustment\ for\ Y2K')}$

checks in the file /matlab/mymfiles/clock. m to the source control system with the comment Adjustment for Y2K.

Example 2 - Check in Multiple Files with Comments

Typing

```
checkin({'/matlab/mymfiles/clock.m', ...
'/matlab/mymfiles/calendar.m'}, 'comments', 'Adjustment for Y2K')
```

checks two files into the source control system using the same comment for each.

Example 3 - Check a File in and Keep It Checked out

Typing

```
checkin('/matlab/mymfiles/clock.m','comments','Adjustment for Y2K','lock','on')
```

checks the file $\mbox{\tt /matlab/mymfiles/clock}.$ m into the source control system and keeps the file checked out.

See Also

checkout, cmopts, undocheckout

Purpose Check file out of source control system

Graphical Interface

As an alternative to the checkout function, use **Source Control Check Out** in the Editor, Simulink, or Stateflow **File** menu.

Syntax

```
checkout('filename')
checkout({'filename1','filename2','filename3', ...})
checkout('filename','option','value', ...)
```

Description

checkout ('filename') checks out the file named filename from the source control system. filename must be the full pathname for the file. The file can be open or closed when you use checkout.

checkout ($\{ ' \text{ fil ename 1'}, ' \text{ fil ename 2'}, ' \text{ fil ename 3'}, \ldots \}$) checks out the files named fil ename1 through fil enamen from the source control system. Use the full pathnames for the files. Additional arguments apply to all files checked out.

checkout ('filename', 'option', 'value', ...) provides additional checkout options. The option and value arguments are shown in the following table.

option Argument	Purpose	value Argument
'force'	When set to on, the checkout is forced, even if you already have the file checked out. This is effectively an undocheckout followed by a checkout. When force is set to off, you can't check out the file if you already have it checked out.	' on' ' off' (default)
'lock'	When set to on, the checkout gets the file, allows you to write to it, and locks the file so that access to the file for others is read only. When set to off, the checkout gets a read-only version of the file, allowing another user to check out the file for updating. With lock set to off, you don't have to check in a file after checking it out.	'on' (default) 'off'
' revi si on'	Checks out the specified revision of the file.	'version_num'

If you end the MATLAB session, the file remains checked out. You can check in the file from within MATLAB during a later session, or directly from your source control system.

Examples

Example 1 - Check out a File

Typing

checkout('/matlab/mymfiles/clock.m')

checks out the file $\mbox{\sc matl}$ ab/mymf i l es/cl ock. m from the source control system.

Example 2 - Check out Multiple Files

Typing

```
checkout({'/matlab/mymfiles/clock.m',...
'/matlab/mymfiles/calendar.m'})
```

checks out /matlab/mymfiles/clock. m and /matlab/mymfiles/calendar. m from the source control system.

Example 3 - Force a Checkout, Even If File Is Already Checked out Typing

```
checkout('/matlab/mymfiles/clock.m', 'force', 'on')
```

checks out /matl ab/mymfil es/cl ock. m even if cl ock. m is already checked out to you.

Example 4 - Check out Specified Revision of File

Typing

```
checkout('/matlab/mymfiles/clock.m', 'revision', '1.1')
```

checks out revision 1.1 of clock.m.

checki n, cmopts, undocheckout

Purpose

Cholesky factorization

Syntax

$$R = \text{chol}(X)$$

 $[R, p] = \text{chol}(X)$

Description

The chol function uses only the diagonal and upper triangle of X. The lower triangular is assumed to be the (complex conjugate) transpose of the upper. That is, X is Hermitian.

 $R = \operatorname{chol}(X)$, where X is positive definite produces an upper triangular R so that R' * R = X. If X is not positive definite, an error message is printed.

 $[R, p] = \operatorname{chol}(X)$, with two output arguments, never produces an error message. If X is positive definite, then p is 0 and R is the same as above. If X is not positive definite, then p is a positive integer and R is an upper triangular matrix of order q = p-1 so that R' * R = X(1:q, 1:q).

Examples

The binomial coefficients arranged in a symmetric array create an interesting positive definite matrix.

```
n = 5:
X = pascal(n)
X =
    1
          1
                1
                      1
                            1
    1
          2
                3
                      4
                            5
    1
          3
                6
                     10
                           15
     1
          4
               10
                     20
                           35
     1
          5
               15
                     35
                           70
```

It is interesting because its Cholesky factor consists of the same coefficients, arranged in an upper triangular matrix.

Destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element.

$$X(n, n) = X(n, n) - 1$$

Now an attempt to find the Cholesky factorization fails.

Algorithm

chol uses the the LAPACK subroutines DPOTRF (real) and ZPOTRF (complex).

chol i nc, chol update

cholinc

Purpose

Sparse incomplete Cholesky and Cholesky-Infinity factorizations

Syntax

```
R = cholinc(X, droptol)
R = cholinc(X, options)
R = cholinc(X, '0')
[R, p] = cholinc(X, '0')
R = cholinc(X, 'inf')
```

Description

cholinc produces two different kinds of incomplete Cholesky factorizations: the drop tolerance and the 0 level of fill-in factorizations. These factors may be useful as preconditioners for a symmetric positive definite system of linear equations being solved by an iterative method such as pcg (Preconditioned Conjugate Gradients). cholinc works only for sparse matrices.

 $R = \text{chol}\,i\,nc(X, droptol\,)$ performs the incomplete Cholesky factorization of X, with drop tolerance droptol.

R = cholinc(X, options) allows additional options to the incomplete Cholesky factorization. options is a structure with up to three fields:

droptol Drop tolerance of the incomplete factorization

mi chol Modified incomplete Cholesky rdi ag Replace zeros on the diagonal of R

Only the fields of interest need to be set.

dropt ol is a non-negative scalar used as the drop tolerance for the incomplete Cholesky factorization. This factorization is computed by performing the incomplete LU factorization with the pivot threshold option set to 0 (which forces diagonal pivoting) and then scaling the rows of the incomplete upper triangular factor, U, by the square root of the diagonal entries in that column. Since the nonzero entries U(i,j) are bounded below by dropt ol *norm(X(:,j)) (see lui nc), the nonzero entries R(i,j) are bounded below by the local drop tolerance dropt ol *norm(X(:,j)) /R(i,i).

Setting droptol = 0 produces the complete Cholesky factorization, which is the default.

mi chol stands for modified incomplete Cholesky factorization. Its value is either 0 (unmodified, the default) or 1 (modified). This performs the modified incomplete LU factorization of X and scales the returned upper triangular factor as described above.

rdi ag is either 0 or 1. If it is 1, any zero diagonal entries of the upper triangular factor R are replaced by the square root of the local drop tolerance in an attempt to avoid a singular factor. The default is 0.

 $R=\operatorname{chol}\operatorname{inc}(X,\,{}^{'}0^{'})$ produces the incomplete Cholesky factor of a real sparse matrix that is symmetric and positive definite using no fill-in. The upper triangular R has the same sparsity pattern as $\operatorname{tri}\operatorname{u}(X)$, although R may be zero in some positions where X is nonzero due to cancellation. The lower triangle of X is assumed to be the transpose of the upper. Note that the positive definiteness of X does not guarantee the existence of a factor with the required sparsity. An error message results if the factorization is not possible. If the factorization is successful, $R'\ *R$ agrees with X over its sparsity pattern.

 $[R, p] = \operatorname{chol} \operatorname{inc}(X, '0')$ with two output arguments, never produces an error message. If R exists, p is 0. If R does not exist, then p is a positive integer and R is an upper triangular matrix of size q-by-n where q = p-1. In this latter case, the sparsity pattern of R is that of the q-by-n upper triangle of X. R' *R agrees with X over the sparsity pattern of its first q rows and first q columns.

 $R=\mbox{cholinc}(X,\mbox{'inf'})$ produces the Cholesky-Infinity factorization. This factorization is based on the Cholesky factorization, and additionally handles real positive semi-definite matrices. It may be useful for finding a solution to systems which arise in interior-point methods. When a zero pivot is encountered in the ordinary Cholesky factorization, the diagonal of the Cholesky-Infinity factor is set to Inf and the rest of that row is set to 0. This forces a 0 in the corresponding entry of the solution vector in the associated system of linear equations. In practice, X is assumed to be positive semi-definite so even negative pivots are replaced with a value of Inf.

Remarks

The incomplete factorizations may be useful as preconditioners for solving large sparse systems of linear equations. A single 0 on the diagonal of the upper triangular factor makes it singular. The incomplete factorization with a drop tolerance prints a warning message if the upper triangular factor has zeros on the diagonal. Similarly, using the rdi ag option to replace a zero diagonal only

gets rid of the symptoms of the problem, but it does not solve it. The preconditioner may not be singular, but it probably is not useful, and a warning message is printed.

The Cholesky-Infinity factorization is meant to be used within interior-point methods. Otherwise, its use is not recommended.

Examples

Example 1.

Start with a symmetric positive definite matrix, S.

```
S = del sq(numgrid('C', 15));
```

S is the two-dimensional, five-point discrete negative Lapacian on the grid generated by numgri $d(\,{}^{_{}}\,C^{_{}}\,,\,15)$.

Compute the Cholesky factorization and the incomplete Cholesky factorization of level 0 to compare the fill-in. Make S singular by zeroing out a diagonal entry and compute the (partial) incomplete Cholesky factorization of level 0.

```
C = chol(S);

R0 = cholinc(S, '0');

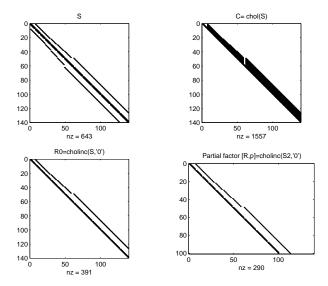

S2 = S; S2(101, 101) = 0;

[R, p] = cholinc(S2, '0');
```

Fill-in occurs within the bands of S in the complete Cholesky factor, but none in the incomplete Cholesky factor. The incomplete factorization of the singular S2 stopped at row p = 101 resulting in a 100-by-139 partial factor.

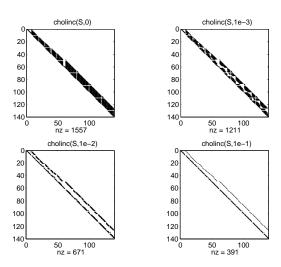

```
D1 = (R0' *R0). *spones(S) - S;
D2 = (R' *R). *spones(S2) - S2;
```

D1 has elements of the order of eps, showing that R0'*R0 agrees with S over its sparsity pattern. D2 has elements of the order of eps over its first 100 rows and first 100 columns, D2(1:100,:) and D2(:,1:100).

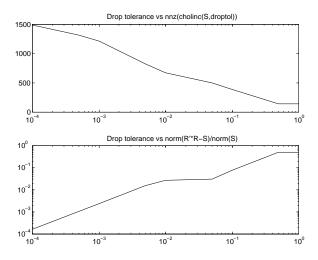

Example 2.

The first subplot below shows that cholinc(S,0), the incomplete Cholesky factor with a drop tolerance of 0, is the same as the Cholesky factor of S. Increasing the drop tolerance increases the sparsity of the incomplete factors, as seen below.

Example 3.

The Hilbert matrices have (i,j) entries 1/(i+j-1) and are theoretically positive definite:

In practice, the Cholesky factorization breaks down for larger matrices:

```
H20 = sparse(hilb(20));
[R, p] = chol(H20);
p =
    14
```

For hilb(20), the Cholesky factorization failed in the computation of row 14 because of a numerically zero pivot. You can use the Cholesky-Infinity factorization to avoid this error. When a zero pivot is encountered, cholinc places an Inf on the main diagonal, zeros out the rest of the row, and continues with the computation:

```
Rinf = cholinc(H20, 'inf');
```

In this case, all subsequent pivots are also too small, so the remainder of the upper triangular factor is:

ful l (Ri nf (14: end, 14: end))						
ans =						
Inf	0	0	0	0	0	0
0	Inf	0	0	0	0	0
0	0	Inf	0	0	0	0
0	0	0	Inf	0	0	0
0	0	0	0	Inf	0	0
0	0	0	0	0	Inf	0
0	0	0	0	0	0	Inf

Limitations

cholinc works on square sparse matrices only. For cholinc (X, '0') and cholinc (X, 'inf'). X must be real.

Algorithm

R = cholinc(X, droptol) is obtained from $[L, U] = l \, \text{uinc}(X, \text{options})$, where options. droptol = droptol and options. thresh = 0. The rows of the uppertriangular U are scaled by the square root of the diagonal in that row, and this scaled factor becomes R.

 $R = \operatorname{chol} \operatorname{inc}(X, \operatorname{options})$ is produced in a similar manner, except the rdi ag option translates into the udi ag option and the milu option takes the value of the michol option.

 $R = \operatorname{chol} \operatorname{i} \operatorname{nc}(X, '0')$ is based on the "KJI" variant of the Cholesky factorization. Updates are made only to positions which are nonzero in the upper triangle of X.

R = chol i nc(X, 'i nf') is based on the algorithm in Zhang [2].

Purpose

Rank 1 update to Cholesky factorization

Syntax

```
R1 = chol update(R, x)
R1 = chol update(R, x, '+')
R1 = chol update(R, x, '-')
[R1, p] = chol update(R, x, '-')
```

Description

R1 = chol update(R, x) where R = chol(A) is the original Cholesky factorization of A, returns the upper triangular Cholesky factor of $A + x^*x'$, where x is a column vector of appropriate length. chol update uses only the diagonal and upper triangle of R. The lower triangle of R is ignored.

R1 = chol update(R, x, '+') is the same as R1 = chol update(R, x).

R1 = chol update(R, x, '-') returns the Cholesky factor of $A - x^*x'$. An error message reports when R is not a valid Cholesky factor or when the downdated matrix is not positive definite and so does not have a Cholesky factorization.

[R1, p] = chol update(R, x, '-') will not return an error message. If p is 0, R1 is the Cholesky factor of A - x*x'. If p is greater than 0, R1 is the Cholesky factor of the original A. If p is 1, chol update failed because the downdated matrix is not positive definite. If p is 2, chol update failed because the upper triangle of R was not a valid Cholesky factor.

Remarks

chol update works only for full matrices.

Example

$$R = chol(A)$$

cholupdate

This is called a rank one update to A since rank(x*x') is 1:

R1 = cholupdate(R, x)

Instead of computing the Cholesky factor with $R1 = \text{chol}(A + x^*x')$, we can use chol update:

```
R1 =
    1.0000
               1.0000
                                     1.0000
                          1.0000
         0
               1.0000
                          2.0000
                                     3.0000
         0
                    0
                          1.0000
                                     3.0000
         0
                    0
                               0
                                     1.4142
```

Next destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element of A. The downdated matrix is:

Compare chol with chol update:

```
R1 = chol(A-x*x')
??? Error using ==> chol
Matrix must be positive definite.
R1 = cholupdate(R, x, '-')
??? Error using ==> cholupdate
Downdated matrix must be positive definite.
```

However, subtracting 0. 5 from the last element of A produces a positive definite matrix, and we can use chol update to compute its Cholesky factor:

```
x = [0 \ 0 \ 0 \ 1/sqrt(2)]';
R1 = cholupdate(R, x, '-')
R1 =
     1.0000
                1.0000
                           1.0000
                                       1.0000
          0
                1.0000
                           2.0000
                                       3.0000
          0
                     0
                           1.0000
                                       3.0000
          0
                     0
                                 0
                                       0.7071
```

Algorithm

chol update uses the algorithms from the LINPACK subroutines ZCHUD and ZCHDD. chol update is useful since computing the new Cholesky factor from scratch is an $O(N^3)$ algorithm, while simply updating the existing factor in this way is an $O(N^2)$ algorithm.

cla

Purpose Clear current axes

Syntax cla

cla reset

Description cl a deletes from the current axes all graphics objects whose handles are not

hidden (i.e., their Handl eVi si bi l i ty property is set to on).

cla reset deletes from the current axes all graphics objects regardless of the setting of their Handl eVi si bility property and resets all axes properties,

except Position and Units, to their default values.

Remarks The cl a command behaves the same way when issued on the command line as

it does in callback routines – it does not recognize the Handl eVi si bi l i ty setting of cal l back. This means that when issued from within a callback routine, cl a deletes only those objects whose Handl eVi si bi l i ty property is set

to on.

See Also clf, hold, newplot, reset

Purpose

Contour plot elevation labels

Syntax

```
clabel (C, h)
clabel (C, h, v)
clabel (C, h, 'manual')
clabel (C)
clabel (C, v)
clabel (C, 'manual')
```

Description

The clabel function adds height labels to a two-dimensional contour plot.

clabel (C, h) rotates the labels and inserts them in the contour lines. The function inserts only those labels that fit within the contour, depending on the size of the contour.

cl abel (C, h, v) creates labels only for those contour levels given in vector v, then rotates the labels and inserts them in the contour lines.

cl abel (C, h, 'manual') places contour labels at locations you select with a mouse. Press the left mouse button (the mouse button on a single-button mouse) or the space bar to label a contour at the closest location beneath the center of the cursor. Press the **Return** key while the cursor is within the figure window to terminate labeling. The labels are rotated and inserted in the contour lines.

cl abel (C) adds labels to the current contour plot using the contour structure C output from contour. The function labels all contours displayed and randomly selects label positions.

cl abel (C, v) labels only those contour levels given in vector v.

cl abel (C, 'manual') places contour labels at locations you select with a mouse.

Remarks

When the syntax includes the argument h, this function rotates the labels and inserts them in the contour lines (see Example). Otherwise, the labels are displayed upright and a '+' indicates which contour line the label is annotating.

Examples

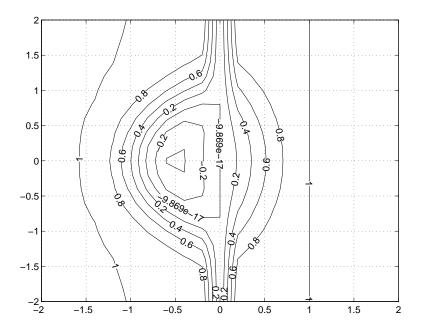

Generate, draw, and label a simple contour plot.

```
[x, y] = meshgrid(-2: .2: 2);

z = x. ^exp(-x. ^2-y. ^2);

[C, h] = contour(x, y, z);

clabel(C, h);
```

See Also

contour, contourc, contourf

Purpose

Create object or return class of object

Syntax

```
str = class(object)
obj = class(s, 'class_name')
obj = class(s, 'class_name', parent1, parent2...)
obj = class(struct([]), 'class_name', parent1, parent2...)
```

Description

str = class(object) returns a string specifying the class of object.

The following table lists the object class names that may be returned. All except the last one are MATLAB classes.

cel l	Cell array
char	Characters array
doubl e	Double-precision floating point number array
function handle	Array of values for calling functions indirectly
int8	8-bit signed integer array
i nt 16	16-bit signed integer array
i nt 32	32-bit signed integer array
sparse	2-D real (or complex) sparse array
struct	Structure array
ui nt8	8-bit unsigned integer array
ui nt 16	16-bit unsigned integer array
ui nt 32	32-bit unsigned integer array
'matlab_class_name'	Name of user-defined MATLAB class
' j ava_cl ass_name'	Name of Java class

obj = class(s, 'class_name') creates an object of MATLAB class 'class_name' using structure s as a template. This syntax is valid only in a function named class_name. m in a directory named @class_name (where 'class_name' is the same as the string passed into class).

obj = $class(s, 'class_name', parent1, parent2, ...)$ creates an object of MATLAB class 'class_name' that inherits the methods and fields of the parent objects parent1, parent2, and so on. Structure s is used as a template for the object.

obj = class(struct([]), 'class_name', parent1, parent2,...) creates an object of MATLAB class 'class_name' that inherits the methods and fields of the parent objects parent1, parent2, and so on. Specifying the empty structure, struct([]), as the first argument ensures that the object created contains no fields other than those that are inherited from the parent objects.

Examples

To return in nameStr the name of the class of Java object j

```
nameStr = class(j)
```

To create a user-defined MATLAB object of class pol ynom

p = class(p, 'polynom')

The "MATLAB Classes and Objects" and the "Calling Java from MATLAB" chapters in *Programming and Data Types*.

Purpose Clear Command Window

Graphical Interface

As an alternative to the cl c function, use **Clear Command Window** in the

MATLAB desktop Edit menu.

Syntax cl c

Description cl c clears all input and output from the Command Window display, giving you

a "clean screen."

After using cl c, you cannot use the scroll bar to see the history of functions,

but still can use the up arrow to see one previous line at a time.

Examples Use cl c in an M-file to always display output in the same starting position on

the screen.

See Also clear, clf, close, home

clear

Purpose

Remove items from workspace, freeing up system memory

Graphical Interface

As an alternative to the clear function, use **Clear Workspace** in the MATLAB desktop **Edit** menu, or in the context menu in the Workspace browser.

Syntax

```
clear
clear name
clear name1 name2 name3 ...
clear global name
clear keyword
clear('name1','name2','name3',...)
```

Description

cl ear removes all variables from the workspace. This frees up system memory.

clear name removes just the M-file or MEX-file function or variable name from the workspace. You can use wildcards (*) to remove items selectively. For example, clear my* removes any variables whose names begin with the string my. It removes debugging breakpoints in M-files and reinitializes persistent variables, since the breakpoints for a function and persistent variables are cleared whenever the M-file is changed or cleared. If name is global, it is removed from the current workspace, but left accessible to any functions declaring it global. If name has been locked by ml ock, it remains in memory.

Use a partial path to distinguish between different overloaded versions of a function. For example, clear inline/display clears only the display method for inline objects, leaving any other implementations in memory.

clear name1 name2 name3 ... removes name1, name2, and name3 from the workspace.

clear global name removes the global variable name. If name is global, clear name removes name from the current workspace, but leaves it accessible to any functions declaring it global. Use clear global name to completely remove a global variable.

clear keyword clears the items indicated by keyword.

Keyword	Items Cleared
al l	Removes all variables, functions, and MEX-files from memory, leaving the workspace empty. Using clear all removes debugging breakpoints in M-files and reinitializes persistent variables, since the breakpoints for a function and persistent variables are cleared whenever the M-file is changed or cleared. When issued from the Command Window prompt, also removes the Java packages import list.
classes	The same as clear all, but also clears MATLAB class definitions. If any objects exist outside the workspace (e.g., in user data or persistent variables in a locked M-file), a warning is issued and the class definition is not cleared. Issue a clear classes function if the number or names of fields in a class are changed.
functions	Clears all the currently compiled M-functions and MEX-functions from memory. Using clear function removes debugging breakpoints in the function M-file and reinitializes persistent variables, since the breakpoints for a function and persistent variables are cleared whenever the M-file is changed or cleared.
gl obal	Clears all global variables from the workspace.
i mport	Removes the Java packages import list. It can only be issued from the Command Window prompt. It cannot be used in a function.
vari abl es	Clears all variables from the workspace.

clear ('name1', 'name2', 'name3', \dots) is the function form of the syntax. Use this form when the variable name or function name is stored in a string.

Remarks

When you use clear in a function, it has the following effect on items in your function and base workspaces:

- clear name If name is the name of a function, the function is cleared in both the function workspace and in your base workspace.
- clear **functions** All functions are cleared in both the function workspace and in your base workspace.
- clear **global** All global variables are cleared in both the function workspace and in your base workspace.
- clear all All functions, global variables, and classes are cleared in both the function workspace and in your base workspace.

Limitations

 cl ear does not affect the amount of memory allocated to the MATLAB process under UNIX.

Examples

Given a workspace containing the following variables

Si ze	Bytes	Class
	· ·	
3x4	1200	cell array
1x1		j ava. awt. Frame
1x1	8	double array (global)
1x1	8	double array (global)
1x1	1	int8 array
	3x4 1x1 1x1 1x1	3x4 1200 1x1 1x1 8 1x1 8

You can clear a single variable, xi nt, by typing

```
clear xint
```

To clear all global variables, type

```
clear global
whos
Name Size Bytes Class

c 3x4 1200 cell array
frame 1x1 java.awt.Frame
```

To clear all compiled M- and MEX-functions from memory, type clear functions. In the case shown below, clear functions was unable to clear one M-file function, testfun, from memory because the function is locked.

```
clear functions % Attempt to clear all functions.

inmem
ans =
'testfun' % One M-file function remains in memory.

mislocked testfun
ans =
1 % This function is locked in memory.

Once you unlock the function from memory, you can clear it.

munlock testfun
clear functions
inmem
```

Empty cell array: 0-by-1

clear (serial)

Purpose Remove a serial port object from the MATLAB workspace

Syntax clear obj

Arguments obj A serial port object or an array of serial port objects.

Description clear obj removes obj from the MATLAB workspace.

Remarks

If obj is connected to the device and it is cleared from the workspace, then obj remains connected to the device. You can restore obj to the workspace with the instrfind function. A serial port object connected to the device has a Status property value of open.

To disconnect obj from the device, use the fclose function. To remove obj from memory, use the delete function. You should remove invalid serial port objects from the workspace with clear.

If you use the help command to display help for clear, then you need to supply the pathname shown below.

help serial/private/clear

Example

This example creates the serial port object s, copies s to a new variable scopy, and clears s from the MATLAB workspace. s is then restored to the workspace with i nstrfi nd and is shown to be identical to scopy.

Properties

Status

Purpose Clear current figure window

Syntax cl f

clf reset

Description cl f deletes from the current figure all graphics objects whose handles are not

hidden (i.e., their Handl eVi si bi l i ty property is set to on).

clf reset deletes from the current figure all graphics objects regardless of the setting of their Handl eVi si bility property and resets all figure properties, except Position, Units, PaperPosition, and PaperUnits to their default

values.

Remarks The cl f command behaves the same way when issued on the command line as

it does in callback routines — it does not recognize the Handl eVi si bi l i ty setting of cal l back. This means that when issued from within a callback routine, cl f deletes only those objects whose Handl eVi si bi l i ty property is set

to on.

See Also cla, clc, hold, reset

clipboard

Purpose

Copy and paste strings to and from the system clipboard.

Graphical Interface As an alternative to $\operatorname{cl} i$ pboard, use the Import Wizard. To use the Import Wizard to copy data from the clipboard, select **Paste Special** from the **Edit**

menu.

Syntax

```
clipboard('copy', data)
str = clipboard('paste')
```

data = clipboard('pastespecial')

Description

clipboard('copy', data) sets the clipboard contents to data. If data is not a character array, clipboard uses mat2str to convert it to a string.

str = clipboard('paste') returns the current contents of the clipboard as a
string or as an empty string (''), if the current clipboard content cannot be
converted to a string.

data = clipboard('pastespecial') returns the current contents of the clipboard as an array using uii mport.

Note Requires an active X display on Unix and Java elsewhere.

See Also

load, ui i mport

Purpose Current time as a date vector

Syntax c = clock

Description c = cl ock returns a 6-element date vector containing the current date and

time in decimal form:

c = [year month day hour minute seconds]

The first five elements are integers. The seconds element is accurate to several digits beyond the decimal point. The statement fix(clock) rounds to integer

display format.

See Also cputi me, datenum, datevec, eti me, ti c, toc

Delete specified figure

Syntax

close
close(h)
close name
close all
close all hidden
status = close(...)

Description

close deletes the current figure or the specified figure(s). It optionally returns the status of the close operation.

close deletes the current figure (equivalent to close(gcf)).

close(h) deletes the figure identified by h. If h is a vector or matrix, close deletes all figures identified by h.

close name deletes the figure with the specified name.

close all deletes all figures whose handles are not hidden.

 ${\it cl}\ {\it ose}\ {\it al}\ {\it ll}\ {\it hi}\ {\it dden}\ {\it deletes}\ {\it all}\ {\it figures}\ {\it including}\ {\it those}\ {\it with}\ {\it hidden}\ {\it handles}.$

status = close(...) returns 1 if the specified windows have been deleted and 0 otherwise.

Remarks

The close function works by evaluating the specified figure's CloseRequestFcn property with the statement:

```
eval (get(h, 'CloseRequestFcn'))
```

The default CloseRequestFcn, closereq, deletes the current figure using delete(get(0, 'CurrentFigure')). If you specify multiple figure handles, close executes each figure's CloseRequestFcn in turn. If MATLAB encounters an error that terminates the execution of a CloseRequestFcn, the figure is not deleted. Note that using your computer's window manager (i.e., the **Close** menu item) also calls the figure's CloseRequestFcn.

If a figure's handle is hidden (i.e., the figure's HandleVi si bility property is set to call back or off and the root ShowHiddenHandles property is set on), you

must specify the hi dden option when trying to access a figure using the all option.

To delete all figures unconditionally, use the statements:

```
set(0, 'ShowHi ddenHandles', 'on')
delete(get(0, 'Children'))
```

The delete function does not execute the figure's Cl oseRequestFcn; it simply deletes the specified figure.

The figure Cl oseRequestFcn allows you to either delay or abort the closing of a figure once the cl ose function has been issued. For example, you can display a dialog box to see if the user really wants to delete the figure or save and clean up before closing.

del ete, fi gure, gcf

The figure Handl eVi si bility property

The root ShowHi ddenHandl es property

close (avifile)

Purpose Close Audio Video Interleaved (AVI) file

Syntax avi obj = cl ose(avi obj)

Description avi obj = close(avi obj) finishes writing and closes the AVI file associated

with avi obj , which is an AVI file object, created using the avi ${\rm fi}\,{\rm l}\,{\rm e}$ function.

See Also avi file, addframe, movi e2avi

closereq

Purpose Default figure close request function

Syntax closereq

Description closereq delete the current figure.

See Also The figure CloseRequestFcn property

cmopts

Purpose

Get name of source control system

Graphical Interface As an alternative to cmopts, use preferences. Select **File** -> **Preferences** in the MATLAB desktop, and then select **General** -> **Source Control**.

Syntax

cmopts

Description

cmopts returns the name of the source control system you selected using preferences, which is one of the following:

clearcase customverctrl pvcs rcs sourcesafe

If you have not selected a source control system, cmopts returns

none

Specifying a Source Control System

To specify the source control system:

1 From the MATLAB Editor window or from a Simulink or Stateflow model window, select **File** -> **Source Control** -> **Preferences**.

The **Preferences** dialog box opens.

- **2** In the left pane, click the + for **General**, and then select **Source Control**. The currently selected system is shown.
- **3** Select the system you want to use from the **Source control system** list.
- 4 Click OK.

For more information, see source control preferences.

Examples

Type cmopts and MATLAB returns rcs, meaning the source control system specified in preferences is RCS.

checkin, checkout, customverctrl

Column approximate minimum degree permutation

Syntax

```
p = col amd(S)
p = col amd(S, knobs)
```

[p, stats] = col amd(S)

[p, stats] = col amd(S, knobs)

Description

 $p = col \ amd(S)$ returns the column approximate minimum degree permutation vector for the sparse matrix S. For a non-symmetric matrix S, S(:,p) tends to have sparser LU factors than S. The Cholesky factorization of S(:,p)' * S(:,p) also tends to be sparser than that of S'*S.

knobs is a two-element vector. If S is m-by-n, then rows with more than (knobs(1))*n entries are ignored. Columns with more than (knobs(2))*m entries are removed prior to ordering, and ordered last in the output permutation p. If the knobs parameter is not present, then $knobs(1) = knobs(2) = spparms('wh_frac')$.

stats is an optional vector that provides data about the ordering and the validity of the matrix S.

stats(1)	Number of dense or empty rows ignored by col amd
stats(2)	Number of dense or empty columns ignored by col and
stats(3)	Number of garbage collections performed on the internal data structure used by col amd (roughly of size $2.\ 2*nnz(S) + 4*m + 7*n\ integers)$
stats(4)	0 if the matrix is valid, or 1 if invalid
stats(5)	Rightmost column index that is unsorted or contains duplicate entries, or 0 if no such column exists
stats(6)	Last seen duplicate or out-of-order row index in the column index given by stats(5), or 0 if no such row index exists
stats(7)	Number of duplicate and out-of-order row indices

Although, MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to col amd. For this reason, col amd verifies that S is valid:

colamd

- If a row index appears two or more times in the same column, col amd ignores the duplicate entries, continues processing, and provides information about the duplicate entries in stats(4: 7).
- If row indices in a column are out of order, col amd sorts each column of its internal copy of the matrix S (but does not repair the input matrix S), continues processing, and provides information about the out-of-order entries in stats(4:7).
- If S is invalid in any other way, col amd cannot continue. It prints an error message, and returns no output arguments (p or stats).

The ordering is followed by a column elimination tree post-ordering.

Note col amd tends to be faster than col mmd and tends to return a better ordering.

Sparse Matrix Algorithms Research at the University of Florida: http://www.cise.ufl.edu/research/sparse/

Sparse column minimum degree permutation

Syntax

p = col mmd(S)

Description

 $p = col \, mmd(S)$ returns the column minimum degree permutation vector for the sparse matrix S. For a nonsymmetric matrix S, this is a column permutation p such that S(:, p) tends to have sparser LU factors than S.

The col mmd permutation is automatically used by \setminus and / for the solution of nonsymmetric and symmetric indefinite sparse linear systems.

Use spparms to change some options and parameters associated with heuristics in the algorithm.

Algorithm

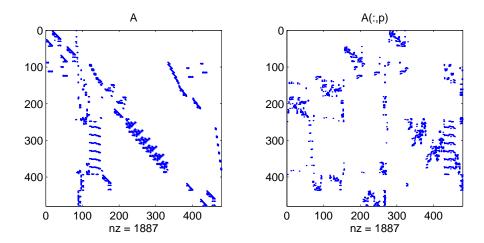

The minimum degree algorithm for symmetric matrices is described in the review paper by George and Liu [1]. For nonsymmetric matrices, MATLAB's minimum degree algorithm is new and is described in the paper by Gilbert, Moler, and Schreiber [2]. It is roughly like symmetric minimum degree for A' *A, but does not actually form A' *A.

Each stage of the algorithm chooses a vertex in the graph of A' *A of lowest degree (that is, a column of A having nonzero elements in common with the fewest other columns), eliminates that vertex, and updates the remainder of the graph by adding fill (that is, merging rows). If the input matrix S is of size m-by-n, the columns are all eliminated and the permutation is complete after n stages. To speed up the process, several heuristics are used to carry out multiple stages simultaneously.

Examples

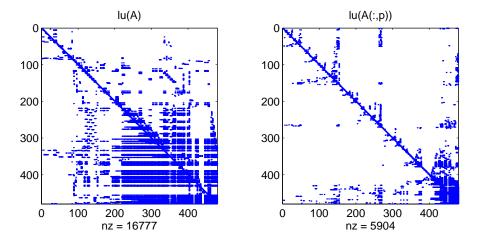

The Harwell-Boeing collection of sparse matrices and the MATLAB demos directory include a test matrix WEST0479. It is a matrix of order 479 resulting from a model due to Westerberg of an eight-stage chemical distillation column. The spy plot shows evidence of the eight stages. The column ordering scrambles this structure.

```
load west0479
A = west0479;
p = col mmd(A);
spy(A)
spy(A(:,p))
```

Comparing the spy plot of the LU factorization of the original matrix with that of the reordered matrix shows that minimum degree reduces the time and storage requirements by better than a factor of 2.8. The nonzero counts are 16777 and 5904, respectively.

```
spy(lu(A))
spy(lu(A(:,p)))
```

Display colorbar showing the color scale

Syntax

```
col orbar
col orbar('vert')
col orbar('hori z')
col orbar(h)
h = col orbar(...)
col orbar(..., 'peer', axes_handl e)
```

Description

The col orbar function displays the current colormap in the current figure and resizes the current axes to accommodate the colorbar.

col orbar updates the most recently created colorbar or, when the current axes does not have a colorbar, col orbar adds a new vertical colorbar.

col orbar('vert') adds a vertical colorbar to the current axes.

col orbar('hori z') adds a horizontal colorbar to the current axes.

col orbar(h) uses the axes h to create the colorbar. The colorbar is horizontal if the width of the axes is greater than its height, as determined by the axes Posi ti on property.

h = colorbar(...) returns a handle to the colorbar, which is an axes graphics object.

 $colorbar(..., 'peer', axes_handl e)$ creates a colorbar associated with the axes axes_handl e instead of the current axes.

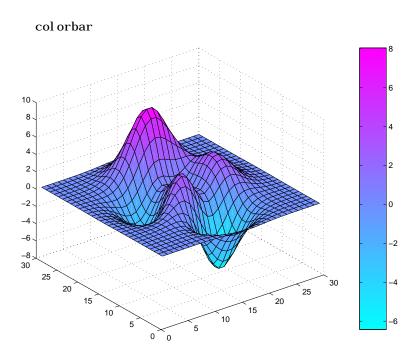

Remarks

col orbar works with two-dimensional and three-dimensional plots.

Examples

Display a colorbar beside the axes.

```
surf(peaks(30))
colormap cool
```

See Also colormap

colordef

Purpose

Sets default property values to display different color schemes

Syntax

colordef white colordef black colordef none

 $colordef(fig, color_option)$

h = colordef('new', color_option)

Description

col ordef enables you to select either a white or black background for graphics display. It sets axis lines and labels to show up against the background color.

col ordef white sets the axis background color to white, the axis lines and labels to black, and the figure background color to light gray.

col ordef black sets the axis background color to black, the axis lines and labels to white, and the figure background color to dark gray.

col ordef none sets the figure coloring to that used by MATLAB Version 4 (essentially a black background).

 $colordef(fig, color_option)$ sets the color scheme of the figure identified by the handle fig to the color option 'white', 'black', or 'none'.

 $h = colordef('new', color_option)$ returns the handle to a new figure created with the specified color options (i.e., 'white', 'black', or 'none').

Remarks

col ordef affects only subsequently drawn figures, not those currently on the display. This is because col ordef works by setting default property values (on the root or figure level). You can list the currently set default values on the root level with the statement:

```
get(0, 'defaults')
```

You can remove all default values using the reset command:

```
reset(0)
```

See the get and reset references pages for more information.

See Also

whi tebg

Set and get the current colormap

Syntax

```
colormap(map)
```

col ormap('default')
cmap = col ormap

Description

A colormap is an m-by-3 matrix of real numbers between 0.0 and 1.0. Each row is an RGB vector that defines one color. The kth row of the colormap defines the k-th color, where map(k, :) = [r(k) g(k) b(k)]) specifies the intensity of red, green, and blue.

col ormap(map) sets the colormap to the matrix map. If any values in map are outside the interval $[0\ 1]$, MATLAB returns the error: Col ormap must have values in $[0\ 1]$.

colormap('default') sets the current colormap to the default colormap.

cmap = colormap; retrieves the current colormap. The values returned are in the interval [0 1].

Specifying Colormaps

M-files in the col or directory generate a number of colormaps. Each M-file accepts the colormap size as an argument. For example,

```
colormap(hsv(128))
```

creates an hsv colormap with 128 colors. If you do not specify a size, MATLAB creates a colormap the same size as the current colormap.

Supported Colormaps

MATLAB supports a number of colormaps.

- \bullet autumn varies smoothly from red, through orange, to yellow.
- bone is a grayscale colormap with a higher value for the blue component.
 This colormap is useful for adding an "electronic" look to grayscale images.
- col orcube contains as many regularly spaced colors in RGB colorspace as possible, while attempting to provide more steps of gray, pure red, pure green, and pure blue.

colormap

- cool consists of colors that are shades of cyan and magenta. It varies smoothly from cyan to magenta.
- copper varies smoothly from black to bright copper.
- fl ag consists of the colors red, white, blue, and black. This colormap completely changes color with each index increment.
- gray returns a linear grayscale colormap.
- hot varies smoothly from black, through shades of red, orange, and yellow, to white.
- hsv varies the hue component of the hue-saturation-value color model. The colors begin with red, pass through yellow, green, cyan, blue, magenta, and return to red. The colormap is particularly appropriate for displaying periodic functions. hsv(m) is the same as hsv2rgb([h ones(m, 2)]) where h is the linear ramp, h = (0: m-1) '/m.
- j et ranges from blue to red, and passes through the colors cyan, yellow, and orange. It is a variation of the hsv colormap. The j et colormap is associated with an astrophysical fluid jet simulation from the National Center for Supercomputer Applications. See the "Examples" section.
- lines produces a colormap of colors specified by the axes ColorOrder property and a shade of gray.
- pi nk contains pastel shades of pink. The pink colormap provides sepia tone colorization of grayscale photographs.
- pri sm repeats the six colors red, orange, yellow, green, blue, and violet.
- spring consists of colors that are shades of magenta and yellow.
- summer consists of colors that are shades of green and yellow.
- whi te is an all white monochrome colormap.
- winter consists of colors that are shades of blue and green.

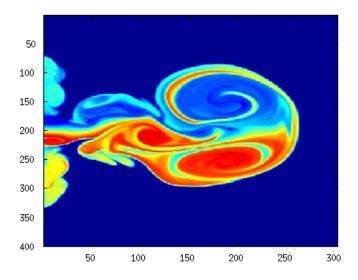

Examples

The images and colormaps demo, i magedemo, provides an introduction to colormaps. Select **Color Spiral** from the menu. This uses the pcol or function to display a 16-by-16 matrix whose elements vary from 0 to 255 in a rectilinear spiral. The hsv colormap starts with red in the center, then passes through yellow, green, cyan, blue, and magenta before returning to red at the outside end of the spiral. Selecting **Colormap Menu** gives access to a number of other colormaps.

The rgbpl of function plots colormap values. Try rgbpl of (hsv), rgbpl of (gray), and rgbpl of (hot).

The following commands display the fluj et data using the j et colormap.

load flujet
i mage(X)
colormap(jet)

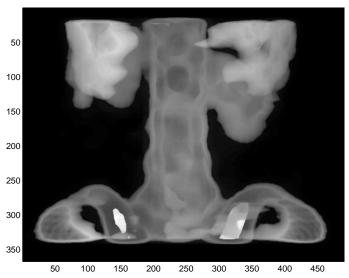

The demos directory contains a CAT scan image of a human spine. To view the image, type the following commands:

load spine
i mage(X)

colormap

colormap bone

Algorithm

Each figure has its own $\hbox{\it Col}$ or map property. $\hbox{\it col}$ or map is an M-file that sets and gets this property.

See Also

brighten, caxis, contrast, hsv2rgb, pcolor, rgb2hsv, rgbpl ot The Colormap property of figure graphics objects.

Color specification

Description

Col or Spec is not a command; it refers to the three ways in which you specify color in MATLAB:

- RGB triple
- Short name
- · Long name

The short names and long names are MATLAB strings that specify one of eight predefined colors. The RGB triple is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color; the intensities must be in the range [0 1]. The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	у	yellow
[1 0 1]	m	magenta
[0 1 1]	С	cyan
[1 0 0]	r	red
[0 1 0]	g	green
[0 0 1]	b	bl ue
[1 1 1]	w	white
[0 0 0]	k	black

Remarks

The eight predefined colors and any colors you specify as RGB values are not part of a figure's colormap, nor are they affected by changes to the figure's colormap. They are referred to as *fixed* colors, as opposed to *colormap* colors.

Examples

To change the background color of a figure to green, specify the color with a short name, a long name, or an RGB triple. These statements generate equivalent results:

whitebg('g')

ColorSpec

```
whitebg('green')
whitebg([0 1 0]);
```

You can use Col or Spec anywhere you need to define a color. For example, this statement changes the figure background color to pink:

```
set(gcf, 'Color', [1, 0. 4, 0. 6])
```

See Also

bar, bar3, colordef, colormap, fill, fill3, whitebg

Sparse column permutation based on nonzero count

Syntax

j = colperm(S)

Description

 $j = col \, perm(S)$ generates a permutation vector j such that the columns of S(:,j) are ordered according to increasing count of nonzero entries. This is sometimes useful as a preordering for LU factorization; in this case use lu(S(:,j)).

If S is symmetric, then $j = \operatorname{col}\operatorname{perm}(S)$ generates a permutation j so that both the rows and columns of S(j,j) are ordered according to increasing count of nonzero entries. If S is positive definite, this is sometimes useful as a preordering for Cholesky factorization; in this case use $\operatorname{chol}(S(j,j))$.

Algorithm

The algorithm involves a sort on the counts of nonzeros in each column.

Examples

The n-by-n arrowhead matrix

```
A = [ones(1, n); ones(n-1, 1) speye(n-1, n-1)]
```

has a full first row and column. Its LU factorization, $l\,u(A)$, is almost completely full. The statement

```
j = colperm(A)
```

returns $j = [2: n \ 1]$. So A(j,j) sends the full row and column to the bottom and the rear, and lu(A(j,j)) has the same nonzero structure as A itself.

On the other hand, the Bucky ball example,

```
B = bucky
```

has exactly three nonzero elements in each row and column, so $j = \text{col}\,\text{perm}(B)$ is the identity permutation and is no help at all for reducing fill-in with subsequent factorizations.

Two-dimensional comet plot

Syntax

```
comet(y)
comet(x, y)
comet(x, y, p)
```

Description

A comet plot is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

comet (y) displays a comet plot of the vector y.

comet(x, y) displays a comet plot of vector y versus vector x.

comet(x, y, p) specifies a comet body of length p*l ength(y). p defaults to 0. 1.

Remarks

Note that the trace left by comet is created by using an EraseMode of none, which means you cannot print the plot (you get only the comet head) and it disappears if you cause a redraw (e.g., by resizing the window).

Examples

Create a simple comet plot:

```
 \begin{array}{l} t &= 0:.01:2*pi; \\ x &= \cos(2*t).*(\cos(t).^2); \\ y &= \sin(2*t).*(\sin(t).^2); \\ comet(x,y); \end{array}
```

See Also

comet3

Purpose Three-dimensional comet plot

Syntax comet3(z)

comet3(x, y, z)comet3(x, y, z, p)

Description

A comet plot is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

comet 3(z) displays a three-dimensional comet plot of the vector z.

comet 3(x, y, z) displays a comet plot of the curve through the points [x(i), y(i), z(i)].

comet3(x, y, z, p) specifies a comet body of length p*length(y).

Remarks

Note that the trace left by comet 3 is created by using an EraseMode of none, which means you cannot print the plot (you get only the comet head) and it disappears if you cause a redraw (e.g., by resizing the window).

Examples

Create a three-dimensional comet plot.

```
t = -10*pi : pi /250: 10*pi;
comet3((cos(2*t).^2).*sin(t), (sin(2*t).^2).*cos(t), t);
```

See Also

comet

compan

Purpose

Companion matrix

Syntax

A = compan(u)

Description

A = compan(u) returns the corresponding companion matrix whose first row is -u(2:n)/u(1), where u is a vector of polynomial coefficients. The eigenvalues of compan(u) are the roots of the polynomial.

Examples

The polynomial $(x-1)(x-2)(x+3) = x^3 - 7x + 6$ has a companion matrix given by

$$u = [1 \quad 0 \quad -7 \quad 6]$$

$$A = compan(u)$$

$$A = \begin{bmatrix} 0 & 7 & -6 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$$

The eigenvalues are the polynomial roots:

eig(compan(u))
ans =
-3.0000
2.0000
1.0000

This is also roots(u).

See Also

eig, poly, polyval, roots

Plot arrows emanating from the origin

Syntax

```
compass(X, Y)
compass(Z)
compass(..., Li neSpec)
h = compass(...)
```

Description

A compass plot displays direction or velocity vectors as arrows emanating from the origin. X, Y, and Z are in Cartesian coordinates and plotted on a circular grid.

compass (X, Y) displays a compass plot having n arrows, where n is the number of elements in X or Y. The location of the base of each arrow is the origin. The location of the tip of each arrow is a point relative to the base and determined by [X(i), Y(i)].

compass (Z) displays a compass plot having n arrows, where n is the number of elements in Z. The location of the base of each arrow is the origin. The location of the tip of each arrow is relative to the base as determined by the real and imaginary components of Z. This syntax is equivalent to compass(real (Z), imag(Z)).

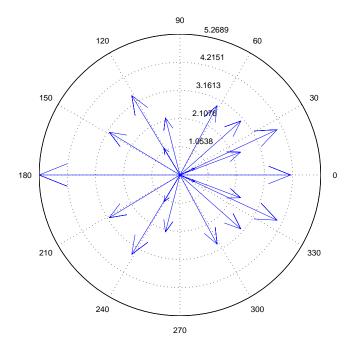

compass(..., Li neSpec) draws a compass plot using the line type, marker symbol, and color specified by Li neSpec.

h = compass(...) returns handles to line objects.

Examples

Draw a compass plot of the eigenvalues of a matrix.

```
Z = eig(randn(20, 20));
compass(Z)
```

See Also feather, Li neSpec, rose

Construct complex data from real and imaginary components

Syntax

```
c = compl ex(a, b)

c = compl ex(a)
```

Description

c = compl ex(a, b) creates a complex output, c, from the two real inputs.

```
c = a + bi
```

The output is the same size as the inputs, which must be scalars or equally sized vectors, matrices, or multi-dimensional arrays of the same data type.

Note If b is all zeros, c is complex and the value of all its imaginary components is 0. In contrast, the result of the addition a+0i returns a strictly real result.

 $c = compl \ ex(a)$ for real a returns the complex result c with real part a and 0 as the value of all imaginary components. Even though the value of all imaginary components is 0, c is complex and i sreal (c) returns false.

The complex function provides a useful substitute for expressions such as

$$a + i*b$$
 or $a + j*b$

in cases when the names "i" and "j" may be used for other variables (and do not equal $\sqrt{-1}$), when a and b are not double-precision, or when b is all zero.

Example

Create complex ui nt 8 vector from two real ui nt 8 vectors.

```
a = uint8([1;2;3;4])
b = uint8([2;2;7;7])
c = complex(a, b)
c =
    1.0000 + 2.0000i

Identify information about computer on which MATLAB is running

Syntax

str = computer

[str, maxsize] = computer

[str, maxsize, endian] = computer

Description

str = computer returns the string str with the computer type on which MATLAB is running.

[str, maxsize] = computer returns the integer maxsize, which contains the maximum number of elements allowed in an array with this version of MATLAB.

[str, maxsize, endian] = computer also returns either 'L' for little endian byte ordering or 'B' for big endian byte ordering.

The list of supported computers changes as new computers are added and others become obsolete. A typical list follows.

str	Computer
ALPHA	Compaq Alpha (OSF1)
HP700	HP 9000/700 (HP-UX 10.20)
HPUX	HP PA-RISC (HP-UX 11.00)
I BM_RS	IBM RS6000 workstation (AIX)
GLNX86	Linux on PC
PCWI N	Microsoft Windows
SGI	Silicon Graphics (IRIX/IRIX64)
S0L2	Sun Solaris 2 SPARC workstation

Remarks

SGI64 users prior to R12 must migrate to SGI with R12. LNX86 users prior to R12 must migrate to GLNX86 with R12.

computer

Purpose Condition number with respect to inversion

Syntax c = cond(X)

c = cond(X, p)

Description

The *condition number* of a matrix measures the sensitivity of the solution of a system of linear equations to errors in the data. It gives an indication of the accuracy of the results from matrix inversion and the linear equation solution. Values of cond(X) and cond(X, p) near 1 indicate a well-conditioned matrix.

c = cond(X) returns the 2-norm condition number, the ratio of the largest singular value of X to the smallest.

c = cond(X, p) returns the matrix condition number in p-norm:

norm(X, p) * norm(inv(X), p)

If p is	Then $cond(X, p)$ returns the	
1	1-norm condition number	
2	2-norm condition number	
'fro'	Frobenius norm condition number	
i nf	Infinity norm condition number	

Algorithm

The algorithm for cond (when p = 2) uses the singular value decomposition, svd.

condeig

Purpose Condition number with respect to eigenvalues

Syntax c = condeig(A)

[V, D, s] = condeig(A)

Description

c = condeig(A) returns a vector of condition numbers for the eigenvalues of A. These condition numbers are the reciprocals of the cosines of the angles between the left and right eigenvectors.

```
[V, D, s] = condei g(A) is equivalent to
```

```
[V, D] = eig(A);

s = condeig(A);
```

Large condition numbers imply that A is near a matrix with multiple eigenvalues.

bal ance, cond, ei g

1-norm condition number estimate

Syntax

c = condest(A)
[c, v] = condest(A)

Description

c = condest(A) computes a lower bound C for the 1-norm condition number of a square matrix A.

c = condest(A, t) changes t, a positive integer parameter equal to the number of columns in an underlying iteration matrix. Increasing the number of columns usually gives a better condition estimate but increases the cost. The default is t = 2, which almost always gives an estimate correct to within a factor 2.

[c, v] = condest(A) also computes a vector v which is an approximate null vector if c is large. v satisfies norm(A*v, 1) = norm(A, 1)*norm(v, 1)/c.

Note condest invokes rand. If repeatable results are required then invoke rand('state',j), for some j, before calling this function.

This function is particularly useful for sparse matrices.

condest uses block 1-norm power method of Higham and Tisseur [1].

cond, norm, normest

Reference

[1] Higham, N. J. and F. Tisseur, "A Block Algorithm for Matrix 1-Norm Estimation, with an Application to 1-Norm Pseudospectra," *SIAM Journal Matrix Anal. Appl.*, Vol. 21, No. 4, 2000, pp.1185-1201.

Plot velocity vectors as cones in a 3-D vector field

Syntax

```
conepl ot (X, Y, Z, U, V, W, Cx, Cy, Cz)
conepl ot (U, V, W, Cx, Cy, Cz)
conepl ot (..., s)
conepl ot (..., col or)
conepl ot (..., 'qui ver')
conepl ot (X, Y, Z, U, V, W, 'noi nterp')
h = conepl ot (...)
```

Description

conepl ot (X, Y, Z, U, V, W, Cx, Cy, Cz) plots velocity vectors as cones pointing in the direction of the velocity vector and having a length proportional to the magnitude of the velocity vector.

- X, Y, Z define the coordinates for the vector field.
- U, V, W define the vector field. These arrays must be the same size, monotonic, and 3-D plaid (such as the data produced by meshgri d).
- Cx, Cy, Cz define the location of the cones in vector field. The section "Starting Points for Stream Plots" in Visualization Techniques provides more information on defining starting points.

```
conepl ot (U, V, W, Cx, Cy, Cz) (omitting the X, Y, and Z arguments) assumes [X, Y, Z] = meshgrid(1: n, 1: m, 1: p) where [m, n, p] = size(U).
```

conepl ot (...,s) MATLAB automatically scales the cones to fit the graph and then stretches them by the scale factor s. If you do not specify a value for s, MATLAB uses a value of 1. Use s=0 to plot the cones without automatic scaling.

conepl ot (..., col or) interpolates the array col or onto the vector field and then colors the cones according to the interpolated values. The size of the col or array must be the same size as the U, V, W arrays. This option works only with cones (i.e., not with the qui ver option).

conepl ot $(\dots,$ ' qui ver') draws arrows instead of cones (see qui ver3 for an illustration of a quiver plot).

conepl ot (..., 'method') specifies the interpolation method to use. method can be: linear, cubic, nearest. linear is the default (see interp3 for a discussion of these interpolation methods)

conepl ot (X, Y, Z, U, V, W, 'nointerp') does not interpolate the positions of the cones into the volume. The cones are drawn at positions defined by X, Y, Z and are oriented according to U, V, W. Arrays X, Y, Z, U, V, W must all be the same size.

h = conepl ot (...) returns the handle to the patch object used to draw the cones. You can use the set command to change the properties of the cones.

Remarks

conepl ot automatically scales the cones to fit the graph, while keeping them in proportion to the respective velocity vectors.

It is usually best to set the data aspect ratio of the axes before calling conepl ot. You can set the ratio using the daspect command,

Examples

This example plots the velocity vector cones for vector volume data representing the motion of air through a rectangular region of space. The final graph employs a number of enhancements to visualize the data more effectively. These include:

- Cone plots indicate the magnitude and direction of the wind velocity.
- Slice planes placed at the limits of the data range provide a visual context for the cone plots within the volume.
- Directional lighting provides visual queues as to the orientation of the cones.
- View adjustments compose the scene to best reveal the information content
 of the data by selecting the view point, projection type, and magnification.

1. Load and Inspect Data

The winds data set contains six 3-D arrays: u, v, and w specify the vector components at each of the coordinate specified in x, y, and z. The coordinates define a lattice grid structure where the data is sampled within the volume.

It is useful to establish the range of the data to place the slice planes and to specify where you want the cone plots (mi n, max).

```
load wind

xmin = min(x(:));

xmax = max(x(:));

ymin = min(y(:));

ymax = max(y(:));

zmin = min(z(:));
```

2. Create the Cone Plot

- Decide where in data space you want to plot cones. This example selects the full range of x and y in eight steps and the range 3 to 15 in four steps in z (linspace, meshgrid).
- Use daspect to set the data aspect ratio of the axes before calling conepl ot so MATLAB can determine the proper size of the cones.
- Draw the cones, setting the scale factor to 5 to make the cones larger than the default size.
- Set the coloring of each cone (FaceCol or, EdgeCol or).

```
daspect([2, 2, 1])
xrange = linspace(xmin, xmax, 8);
yrange = linspace(ymin, ymax, 8);
zrange = 3: 4: 15;
[cx cy cz] = meshgrid(xrange, yrange, zrange);
hcones = coneplot(x, y, z, u, v, w, cx, cy, cz, 5);
set(hcones, 'FaceColor', 'red', 'EdgeColor', 'none')
```

3. Add the Slice Planes

- Calculate the magnitude of the vector field (which represents wind speed) to generate scalar data for the slice command.
- Create slice planes along the x-axis at xmi n and xmax, along the y-axis at ymax, and along the z-axis at zmi n.
- Specify interpolated face color so the slice coloring indicates wind speed and do not draw edges (hol d, slice, FaceColor, EdgeColor).

```
\label{eq:continuous_problem} $$ \operatorname{hold} \ on $$ \operatorname{wind\_speed} = \operatorname{sqrt}(u.^2 + v.^2 + w.^2); $$ \operatorname{hsurfaces} = \operatorname{slice}(x, y, z, \operatorname{wind\_speed}, [\operatorname{xmin}, \operatorname{xmax}], \operatorname{ymax}, \operatorname{zmin}); $$ \operatorname{set}(\operatorname{hsurfaces}, \operatorname{FaceColor'}, \operatorname{interp'}, \operatorname{EdgeColor'}, \operatorname{none'}) $$ \operatorname{hold} \ off $$
```

4. Define the View

- Use the axi s command to set the axis limits equal to the range of the data.
- Orient the vi ew to azimuth = 30 and elevation = 40 (rotate3d is a useful command for selecting the best view).
- Select perspective projection to provide a more realistic looking volume (camproj).
- Zoom in on the scene a little to make the plot as large as possible (camzoom).

```
axis tight; view(30,40); axis off camproj perspective; camzoom(1.5)
```

5. Add Lighting to the Scene

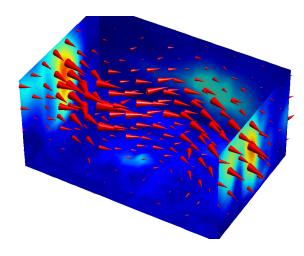

The light source affects both the slice planes (surfaces) and the cone plots (patches). However, you can set the lighting characteristics of each independently.

- Add a light source to the right of the camera and use Phong lighting give the
 cones and slice planes a smooth, three-dimensional appearance (caml i ght,
 lighting).
- Increase the value of the Ambi entStrength property for each slice plane to improve the visibility of the dark blue colors. (Note that you can also specify a different colormap to change to coloring of the slice planes.)

coneplot

• Increase the value of the DiffuseStrength property of the cones to brighten particularly those cones not showing specular reflections.

```
camlight right; lighting phong
set(hsurfaces, 'AmbientStrength', .6)
set(hcones, 'DiffuseStrength', .8)
```

continue

Purpose

Pass control to the next iteration of for or while loop

Syntax

conti nue

Description

continue passes control to the next iteration of the for or while loop in which it appears, skipping any remaining statements in the body of the loop.

In nested loops, continue passes control to the next iteration of the for or while loop enclosing it.

Examples

The example below shows a continue loop that counts the lines of code in the file, magic. m, skipping all blank lines and comments. A continue statement is used to advance to the next line in magic. m without incrementing the count whenever a blank line or comment line is encountered.

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) | strncmp(line,'%',1)
        continue
    end
    count = count + 1;
end
disp(sprintf('%d lines',count));
```

Two-dimensional contour plot

Syntax

contour(Z)
contour(Z, n)
contour(Z, v)
contour(X, Y, Z)
contour(X, Y, Z, n)
contour(X, Y, Z, v)
contour(..., Li neSpec)
[C, h] = contour(...)

Description

A contour plot displays isolines of matrix Z. Label the contour lines using clabel.

cont our (Z) draws a contour plot of matrix Z, where Z is interpreted as heights with respect to the x-y plane. Z must be at least a 2-by-2 matrix. The number of contour levels and the values of the contour levels are chosen automatically based on the minimum and maximum values of Z. The ranges of the x- and y-axis are [1:n] and [1:m], where [m,n] = size(Z).

 $contour\left(Z,\,n\right)\;draws\;a\;contour\;plot\;of\;matrix\;Z\;with\;n\;contour\;levels.$

 $\label{eq:contour} \begin{aligned} & \text{contour}\,(Z,\,v) \ draws\ a\ contour\ plot\ of\ matrix}\ Z\ with\ contour\ lines\ at\ the\ data\\ & \text{values\ specified\ in\ vector}\ v.\ The\ number\ of\ contour\ levels\ is\ equal\ to\ l\ ength(v)\ . \end{aligned}$ To draw a single contour\ of\ level\ i\ ,\ use\ contour(Z,\ [i\ i\])\ . \end{aligned}

contour (X, Y, Z), contour (X, Y, Z, n), and contour (X, Y, Z, v) draw contour plots of Z. X and Y specify the x- and y-axis limits. When X and Y are matrices, they must be the same size as Z, in which case they specify a surface as surf does.

contour(..., Li neSpec) draws the contours using the line type and color specified by Li neSpec. contour ignores marker symbols.

[C, h] = contour(...) returns the contour matrix C (see contourc) and a vector of handles to graphics objects. cl abel uses the contour matrix C to create the labels. contour creates patch graphics objects unless you specify Li neSpec, in which case contour creates line graphics objects.

contour

Remarks

If you do not specify Li neSpec, col ormap and caxi s control the color.

If X or Y is irregularly spaced, contour calculates contours using a regularly spaced contour grid, then transforms the data to X or Y.

Examples

To view a contour plot of the function

$$z = xe^{(-x^2-y^2)}$$

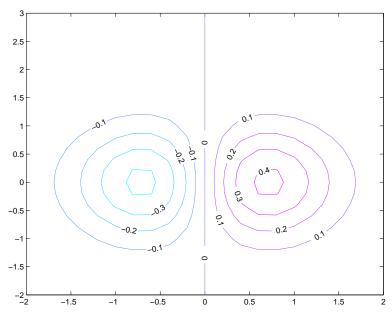

over the range $-2 \le x \le 2$, $-2 \le y \le 3$, create matrix Z using the statements

$$[X, Y] = meshgrid(-2: .2: 2, -2: .2: 3);$$

 $Z = X. *exp(-X. ^2-Y. ^2);$

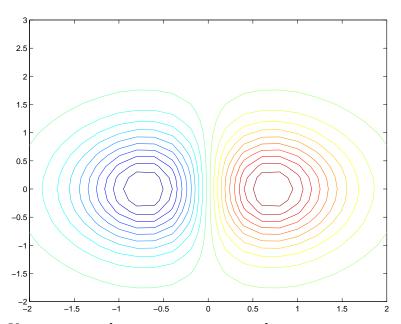

Then, generate a contour plot of Z.

```
[C, h] = contour(X, Y, Z);
clabel(C, h)
colormap cool
```

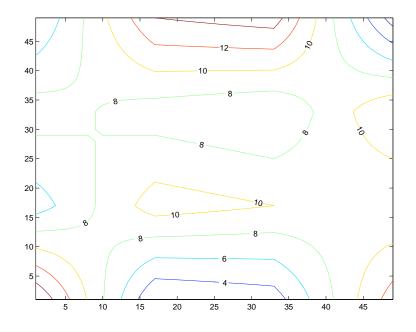

View the same function over the same range with 20 evenly spaced contour lines and colored with the default colormap j et.

contour(X, Y, Z, 20)

Use interp2 and contour to create smoother contours.

```
Z = magic(4);
[C, h] = contour(interp2(Z, 4));
clabel(C, h)
```

See Also

clabel, contour3, contourc, contourf, interp2, qui ver

Three-dimensional contour plot

Syntax

contour3(Z)
contour3(Z, n)
contour3(Z, v)
contour3(X, Y, Z)
contour3(X, Y, Z, n)
contour3(X, Y, Z, v)
contour3(..., Li neSpec)
[C, h] = contour3(...)

Description

contour3 creates a three-dimensional contour plot of a surface defined on a rectangular grid.

contour3(Z) draws a contour plot of matrix Z in a three-dimensional view. Z is interpreted as heights with respect to the x-y plane. Z must be at least a 2-by-2 matrix. The number of contour levels and the values of contour levels are chosen automatically. The ranges of the x- and y-axis are [1:n] and [1:m], where [m,n] = size(Z).

contour3(Z, n) draws a contour plot of matrix Z with n contour levels in a three-dimensional view.

 $\label{eq:contour} \begin{array}{l} \text{contour}\,3(Z,\,v) \ draws\ a\ contour\ plot\ of\ matrix}\ Z\ with\ contour\ lines\ at\ the \\ \text{values\ specified\ in\ vector}\ v.\ The\ number\ of\ contour\ levels\ is\ equal\ to\ l\ ength(v)\ . \\ To\ draw\ a\ single\ contour\ of\ level\ i\ ,\ use\ contour(Z,\ [i\ i\])\ . \end{array}$

contour3(X, Y, Z), contour3(X, Y, Z, n), and contour3(X, Y, Z, v) use X and Y to define the x- and y-axis limits. If X is a matrix, X(1, :) defines the x-axis. If Y is a matrix, Y(:, 1) defines the y-axis. When X and Y are matrices, they must be the same size as Z, in which case they specify a surface as surf does.

contour3(..., Li neSpec) draws the contours using the line type and color specified by Li neSpec.

[C, h] = contour3(...) returns the contour matrix C as described in the function contourc and a column vector containing handles to graphics objects. contour3 creates patch graphics objects unless you specify Li neSpec, in which case contour3 creates line graphics objects.

Remarks

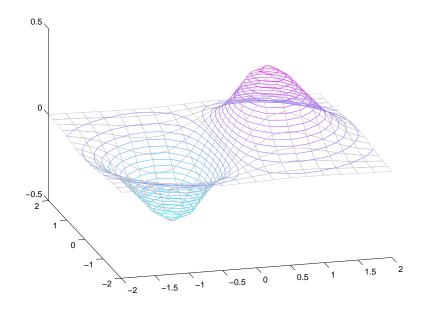

If you do not specify Li neSpec, col ormap and caxi s control the color.

If X or Y is irregularly spaced, contour3 calculates contours using a regularly spaced contour grid, then transforms the data to X or Y.

Examples

Plot the three-dimensional contour of a function and superimpose a surface plot to enhance visualization of the function.

```
\label{eq:contour} \begin{split} &[X,Y] = meshgrid([-2:.25:2])\,;\\ &Z = X. *exp(-X. ^2-Y. ^2)\,;\\ &contour3(X,Y,Z,30)\\ &surface(X,Y,Z,'EdgeColor',[.8.8.8],'FaceColor','none')\\ &grid off\\ &view(-15,25)\\ &colormap cool \end{split}
```

See Also

contour, contourc, mesh
c, meshgri $\ensuremath{\mathrm{d}}$, surfc

Low-level contour plot computation

Syntax

```
C = contourc(Z)
C = contourc(Z, n)
C = contourc(Z, v)
C = contourc(x, y, Z)
C = contourc(x, y, Z, n)
C = contourc(x, y, Z, v)
```

Description

contourc calculates the contour matrix C used by contour, contour3, and contourf. The values in Z determine the heights of the contour lines with respect to a plane. The contour calculations use a regularly spaced grid determined by the dimensions of Z.

C = contourc(Z) computes the contour matrix from data in matrix Z, where Z must be at least a 2-by-2 matrix. The contours are isolines in the units of Z. The number of contour lines and the corresponding values of the contour lines are chosen automatically.

C = contourc(Z, n) computes contours of matrix Z with n contour levels.

C = contourc(Z, v) computes contours of matrix Z with contour lines at the values specified in vector v. The length of v determines the number of contour levels. To compute a single contour of level i, use $contourc(Z, [i \ i \])$.

C = contourc(x, y, Z), C = contourc(x, y, Z, n), and C = contourc(x, y, Z, v) compute contours of Z using vectors x and y to determine the x- and y-axis limits. x and y must be monotonically increasing.

Remarks

C is a two-row matrix specifying all the contour lines. Each contour line defined in matrix C begins with a column that contains the value of the contour (specified by v and used by cl abel), and the number of (x, y) vertices in the contour line. The remaining columns contain the data for the (x, y) pairs.

```
C = [val ue1 \ xdata(1) \ xdata(2)...val ue2 \ xdata(1) \ xdata(2)...;

dim1 \ ydata(1) \ ydata(2)...dim2 \ ydata(1) \ ydata(2)...]
```

Specifying irregularly spaced x and y vectors is not the same as contouring irregularly spaced data. If x or y is irregularly spaced, contour calculates

contourc

contours using a regularly spaced contour grid, then transforms the data to \boldsymbol{x} or $\boldsymbol{y}.$

Filled two-dimensional contour plot

Syntax

contourf(Z)
contourf(Z, n)
contourf(Z, v)
contourf(X, Y, Z)
contourf(X, Y, Z, n)
contourf(X, Y, Z, v)
[C, h, CF] = contourf(...)

Description

A filled contour plot displays isolines calculated from matrix Z and fills the areas between the isolines using constant colors. The color of the filled areas depends on the current figure's colormap.

contourf (Z) draws a contour plot of matrix Z, where Z is interpreted as heights with respect to a plane. Z must be at least a 2-by-2 matrix. The number of contour lines and the values of the contour lines are chosen automatically.

contourf (Z, n) draws a contour plot of matrix Z with n contour levels.

 ${\tt contourf}\left(Z,v\right)\,$ draws a contour plot of matrix Z with contour levels at the values specified in vector v.

contourf (X, Y, Z), contourf (X, Y, Z, n), and contourf (X, Y, Z, v) produce contour plots of Z using X and Y to determine the x- and y-axis limits. When X and Y are matrices, they must be the same size as Z, in which case they specify a surface as surf does.

[C, h, CF] = contourf(...) returns the contour matrix C as calculated by the function contourc and used by clabel, a vector of handles h to patch graphics objects, and a contour matrix CF for the filled areas.

Remarks

If X or Y is irregularly spaced, contourf calculates contours using a regularly spaced contour grid, then transforms the data to X or Y.

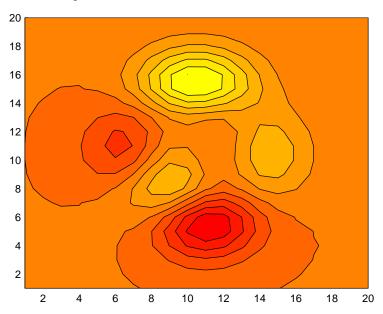

Examples

Create a filled contour plot of the peaks function.

```
[C, h] = contourf(peaks(20), 10);

Draw contours in volume slice planes

Syntax

```
 \begin{array}{l} contoursl\,i\,ce(X,\,Y,\,Z,\,V,\,Sx,\,Sy,\,Sz)\\ contoursl\,i\,ce(X,\,Y,\,Z,\,V,\,Xi\,,\,Yi\,,\,Zi\,)\\ contoursl\,i\,ce(V,\,Sx,\,Sy,\,Sz)\,,\,contoursl\,i\,ce(V,\,Xi\,,\,Yi\,,\,Zi\,)\\ contoursl\,i\,ce(\dots,\,n)\\ contoursl\,i\,ce(\dots,\,cval\,s)\\ contoursl\,i\,ce(\dots,\,[\,cv\,\,cv]\,)\\ contoursl\,i\,ce(\dots,\,[\,rmethod'\,)\\ h\,=\,contoursl\,i\,ce(\dots) \end{array}
```

Description

contourslice(X, Y, Z, V, Sx, Sy, Sz) draws contours in the x-, y-, and z-axis aligned planes at the points in the vectors Sx, Sy, Sz. The arrays X, Y, and Z define the coordinates for the volume V and must be monotonic and S-D plaid (such as the data produced by meshgrid). The color at each contour is determined by the volume V, which must be an S-p-volume array.

contours lice (X, Y, Z, V, Xi, Yi, Zi) draws contours through the volume V along the surface defined by the arrays Xi, Yi, Zi.

contourslice(V, Sx, Sy, Sz) and contourslice(V, Xi, Yi, Zi) (omitting the X, Y, and Z arguments) assumes [X, Y, Z] = meshgrid(1: n, 1: m, 1: p) where [m, n, p] = size(v).

contours lice(\dots , n) draws n contour lines per plane, overriding the automatic value.

contours lice(\dots , cvals) draws length(cval) contour lines per plane at the values specified in vector cvals.

contours lice(..., [cv cv]) computes a single contour per plane at the level cv.

contours lice(..., 'method') specifies the interpolation method to use. method can be: linear, cubic, nearest. nearest is the default except when the contours are being drawn along the surface defined by Xi, Yi, Zi, in which case linear is the default (see interp3 for a discussion of these interpolation methods).

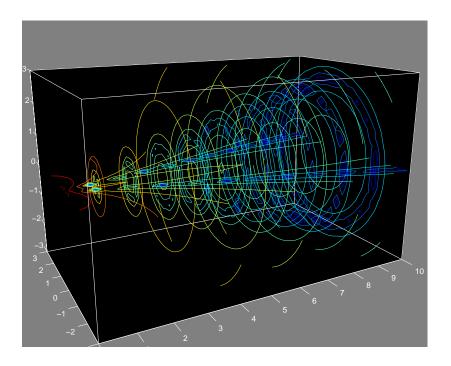

h = contourslice(...) returns a vector of handles to patch objects that are used to implement the contour lines.

Examples

This example uses the flow data set to illustrate the use of contoured slice planes (type help flow for more information on this data set). Notice that this example:

- Specifies a vector of l ength = 9 for Sx, an empty vector for the Sy, and a scalar value (0) for Sz. This creates nine contour plots along the x direction in the y-z plane, and one in the x-y plane at z = 0.
- Uses 1 i nspace to define a ten-element linearly spaced vector of values from -8 to 2 that specifies the number of contour lines to draw at each interval.
- Defines the view and projection type (camva, camproj, campos)
- Sets figure (gcf) and axes (gca) characteristics.

```
 \begin{array}{l} [x\;y\;z\;v] = flow; \\ h = contourslice(x,y,z,v,[1:9],[],[0],linspace(-8,2,10)); \\ axis([0,10,-3,3,-3,3]); \; daspect([1,1,1]) \\ camva(24); \; camproj \; perspective; \\ campos([-3,-15,5]) \\ set(gcf,'Color',[.5,.5,.5],'Renderer','zbuffer') \\ set(gca,'Color','black','XColor','white', ... \\ 'YColor','white','ZColor','white') \\ box \; on \\ \end{array}
```

 $i\,sosurface,\,smooth 3,\,subvol\,ume,\,reducevol\,ume$

contrast

Purpose Grayscale colormap for contrast enhancement

Syntax cmap = contrast(X)

cmap = contrast(X, m)

Description The contrast function enhances the contrast of an image. It creates a new gray

colormap, cmap, that has an approximately equal intensity distribution. All

three elements in each row are identical.

cmap = contrast(X) returns a gray colormap that is the same length as the

current colormap.

cmap = contrast(X, m) returns an m-by-3 gray colormap.

Examples Add contrast to the clown image defined by X.

load clown;

cmap = contrast(X);

i mage(X);

col ormap(cmap);

See Also brighten, colormap, i mage

Convolution and polynomial multiplication

Syntax

w = conv(u, v)

Description

w = conv(u, v) convolves vectors u and v. Algebraically, convolution is the same operation as multiplying the polynomials whose coefficients are the elements of u and v.

Definition

Let $m = l \, ength(u)$ and $n = l \, ength(v)$. Then w is the vector of length m+n-1 whose kth element is

$$w(k) = \sum_{j} u(j) v(k+1-j)$$

The sum is over all the values of j which lead to legal subscripts for u(j) and v(k+1-j), specifically j = max(1, k+1-n): min(k, m). When m = n, this gives

$$\begin{array}{lll} w(1) &=& u(1) * v(1) \\ w(2) &=& u(1) * v(2) + u(2) * v(1) \\ w(3) &=& u(1) * v(3) + u(2) * v(2) + u(3) * v(1) \\ \dots && \\ w(n) &=& u(1) * v(n) + u(2) * v(n-1) + \dots + u(n) * v(1) \\ \dots && \\ w(2*n-1) &=& u(n) * v(n) \end{array}$$

Algorithm

The convolution theorem says, roughly, that convolving two sequences is the same as multiplying their Fourier transforms. In order to make this precise, it is necessary to pad the two vectors with zeros and ignore roundoff error. Thus, if

conv2, convn, deconv, filter

 ${\tt convmt}\,x$ and ${\tt xcorr}$ in the Signal Processing Toolbox

Two-dimensional convolution

Syntax

C = conv2(A, B)

C = conv2(hcol, hrow, A)

C = conv2(..., 'shape')

Description

C = conv2(A, B) computes the two-dimensional convolution of matrices A and B. If one of these matrices describes a two-dimensional finite impulse response (FIR) filter, the other matrix is filtered in two dimensions.

The size of C in each dimension is equal to the sum of the corresponding dimensions of the input matrices, minus one. That is, if the size of A is [ma, na] and the size of B is [mb, nb], then the size of C is [ma+mb-1, na+nb-1].

C = conv2(hcol, hrow, A) convolves A separably with hcol in the column direction and hrow in the row direction. hcol and hrow are both vectors. If hcol is a column vector and hrow is a row vector, this case is the same as C = conv2(hcol*hrow, A).

C = conv2(..., 'shape') returns a subsection of the two-dimensional convolution, as specified by the shape parameter:

full Returns the full two-dimensional convolution (default).

same Returns the central part of the convolution of the same size as A.

valid Returns only those parts of the convolution that are computed without the zero-padded edges. Using this option, C has size [ma-mb+1, na-nb+1] when all(size(A) >= size(B)). Otherwise conv2 returns [].

Algorithm

conv2 uses a straightforward formal implementation of the two-dimensional convolution equation in spatial form. If a and b are functions of two discrete variables, n_1 and n_2 , then the formula for the two-dimensional convolution of a and b is

$$c(n_1, n_2) = \sum_{k_1 = -\infty}^{\infty} \sum_{k_2 = -\infty}^{\infty} a(k_1, k_2) \ b(n_1 - k_1, n_2 - k_2)$$

In practice however, conv2 computes the convolution for finite intervals.

Note that matrix indices in MATLAB always start at 1 rather than 0. Therefore, matrix elements A(1, 1), B(1, 1), and C(1, 1) correspond to mathematical quantities a(0,0), b(0,0), and c(0,0).

Examples

Example 1. For the 'same' case, conv2 returns the central part of the convolution. If there are an odd number of rows or columns, the "center" leaves one more at the beginning than the end.

This example first computes the convolution of A using the default ('full') shape, then computes the convolution using the 'same' shape. Note that the array returned using 'same' corresponds to the underlined elements of the array returned using the default shape.

```
A = rand(3):
B = rand(4);
C = conv2(A, B)
                                  % C is 6-by-6
C =
    0. 1838 0. 2374 0. 9727 1. 2644 0. 7890 0. 3750
    0.6929 1.2019 1.5499 2.1733 1.3325 0.3096
    0.\ 5627 \quad 1.\ 5150 \quad \underline{2.\ 3576} \quad \underline{3.\ 1553} \quad \underline{2.\ 5373} \quad 1.\ 0602
    0.\ 9986 \quad \  2.\ 3811 \quad \  \  \underline{3.\ 4302} \quad \  \  \underline{3.\ 5128} \quad \  \  \underline{2.\ 4489} \quad \  \  0.\ 8462
    0. 3089 1. 1419 1. 8229 2. 1561 1. 6364 0. 6841
    0. 3287 0. 9347 1. 6464 1. 7928 1. 2422 0. 5423
Cs = conv2(A, B, 'same')
                                  % Cs is the same size as A: 3-by-3
Cs =
    2, 3576 3, 1553 2, 5373
    3. 4302 3. 5128 2. 4489
    1.8229 2.1561 1.6364
```

Example 2. In image processing, the Sobel edge finding operation is a two-dimensional convolution of an input array with the special matrix

```
s = [1 \ 2 \ 1; \ 0 \ 0 \ 0; \ -1 \ -2 \ -1];
```

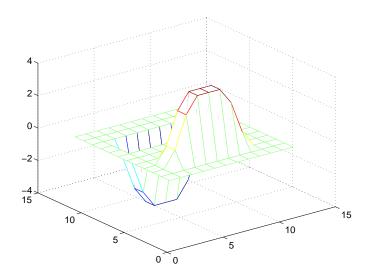

These commands extract the horizontal edges from a raised pedestal.

```
A = zeros(10);
```

```
A(3:7, 3:7) = ones(5);

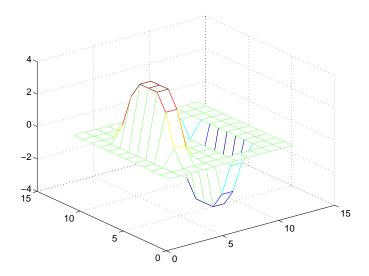

H = conv2(A, s);

mesh(H)
```

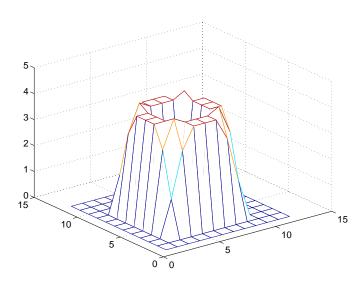

Transposing the filter s extracts the vertical edges of A.

```
V = conv2(A, s');
figure, mesh(V)
```

This figure combines both horizontal and vertical edges.

conv2

See Also conv., convn, filter2

xcorr2 in the Signal Processing Toolbox

Convex hull

Syntax

$$K = \text{convhul } l(x, y)$$

 $[K, a] = \text{convhul } l(x, y)$

Description

K = convhul l(x, y) returns indices into the x and y vectors of the points on the convex hull.

[K, a] = convhull(x, y) also returns the area of the convex hull.

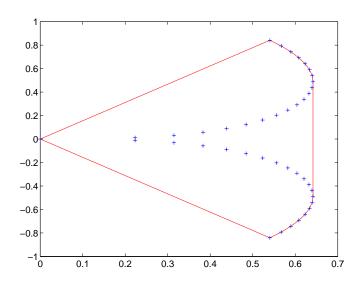

Note convhull is based on qhull [2]. For information about qhull, see http://www.geom.umn.edu/software/qhull/. For copyright information, see http://www.geom.umn.edu/software/download/COPYING.html.

Visualization

Use plot to plot the output of convhull.

Examples

```
xx = -1:.05:1; yy = abs(sqrt(xx));
[x, y] = pol 2cart(xx, yy);
k = convhul l(x, y);
pl ot(x(k), y(k), 'r-', x, y, 'b+')
```

convhull

Reference

[1] Barber, C. B., D.P. Dobkin, and H.T. Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," *ACM Transactions on Mathematical Software*, Vol. 22, No. 4, Dec. 1996, p. 469-483. Available in HTML format at http://www.acm.org/pubs/citations/journals/toms/1996-22-4/p469-barber/and in PostScript format at ftp://geom.umn.edu/pub/software/qhull-96.ps.

[2] National Science and Technology Research Center for Computation and Visualization of Geometric Structures (The Geometry Center), University of Minnesota. 1993.

Purpose n-D convex hull

Syntax K = convhulln(X)

[K, v] = convhulln(X)

Description

 $K = \text{convhul} \ln(X)$ returns the indices K of the points in X that comprise the facets of the convex hull of X. X is an M-by-M-n array representing M points in M-D space. If the convex hull has M-facets then M-facets

 $[K, v] = \text{convhul} \ln(X)$ also returns the volume v of the convex hull.

Note convhulln is based on qhull [2]. For information about qhull, see http://www.geom.umn.edu/software/qhull/. For copyright information, see http://www.geom.umn.edu/software/download/COPYING.html.

Visualization

Plotting the output of convhul l n depends on the value of n:

- For n = 2, use plot as you would for convhul 1.
- For n = 3, you can use tri surf to plot the output. The calling sequence is K = convhull(X); tri surf (K, (X(:, 1), X(:, 2), X(:, 3))

For more control over the color of the facets, use patch to plot the output. For an example, see "Tessellation and Interpolation of Scattered Data in Higher Dimensions" in the MATLAB documentation.

• You cannot plot convhul l n output for n > 3.

convhulln

[2] National Science and Technology Research Center for Computation and Visualization of Geometric Structures (The Geometry Center), University of Minnesota. 1993.

Purpose N-dimensional convolution

Syntax C = convn(A, B)

C = convn(A, B, 'shape')

Description C = convn(A, B) computes the N-dimensional convolution of the arrays A and

B. The size of the result is size(A) + size(B) - 1.

C = convn(A, B, 'shape') returns a subsection of the N-dimensional convolution, as specified by the shape parameter:

'full' Returns the full N-dimensional convolution (default).

'same' Returns the central part of the result that is the same size as A.

'valid' Returns only those parts of the convolution that can be computed

without assuming that the array A is zero-padded. The size of the

result is

 $\max(\operatorname{size}(A) - \operatorname{size}(B) + 1, 0)$

See Also conv, conv2

Copy file

Graphical Interface

As an alternative to the copyfile function, you can copy files using the Current Directory browser. To open it, select **Current Directory** from the **View** menu in the MATLAB desktop.

Syntax

```
copyfile source dest
copyfile source dest writable
status = copyfile('source', 'dest',...)
[status, msg] = copyfile('source', 'dest',...)
```

Description

copyfile source dest copies the file, source, to directory or file, dest. The source and dest arguments may be absolute pathnames or pathnames relative to the current directory. The pathname to dest must exist, but dest cannot be an existing filename in the current directory.

copyfile source dest **writable** makes the destination file writable following the file copy.

status = copyfile('source', 'dest', ...) returns a status of 1 if the file is copied successfully and 0 otherwise.

[status, msg] = copyfile('source', 'dest',...) returns status and a nonempty error message string when an error occurs.

Example

To make a copy of a file in the same directory,

```
copyfile myfun. m myfun2. m
```

To copy a file to another directory, keeping the same filename,

```
file_copied = copyfile('myfun.m','../testfun/private')
file_copied =
    1
```

See Also

del ete, mkdi r

Copy graphics objects and their descendants

Syntax

new_handl e = copyobj (h, p)

Description

copyobj creates copies of graphics objects. The copies are identical to the original objects except the copies have different values for their Parent property and a new handle. The new parent must be appropriate for the copied object (e.g., you can copy a line object only to another axes object).

new_handl e = copyobj (h, p) copies one or more graphics objects identified by h and returns the handle of the new object or a vector of handles to new objects. The new graphics objects are children of the graphics objects specified by p.

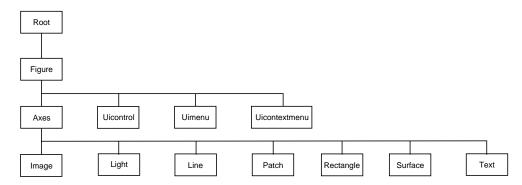

Remarks

h and p can be scalars or vectors. When both are vectors, they must be the same length and the output argument, new_handle, is a vector of the same length. In this case, new_handle(i) is a copy of h(i) with its Parent property set to p(i).

When h is a scalar and p is a vector, h is copied once to each of the parents in p. Each new_handl e(i) is a copy of h with its Parent property set to p(i), and length(new_handl e) equals l ength(p).

When h is a vector and p is a scalar, each new_handl e(i) is a copy of h(i) with its Parent property set to p. The length of new_handl e equals l = p(h).

Graphics objects are arranged as a hierarchy. Here, each graphics object is shown connected below its appropriate parent object.

Examples

Copy a surface to a new axes within a different figure.

Note that while the surface is copied, the colormap (figure property), view, and grid (axes properties) are not copies.

See Also

```
findobj, gcf, gca, gco, get, set
```

Parent property for all graphics objects

Purpose Correlation coefficients

Syntax S = corrcoef(X)

S = corrcoef(x, y)

Description S = corrcoef(X) returns a matrix of correlation coefficients calculated from

an input matrix whose rows are observations and whose columns are variables. The matrix S = corrcoef(X) is related to the covariance matrix C = cov(X)

by

 $S(i, j) = \frac{C(i, j)}{\sqrt{C(i, i) C(j, j)}}$

corrcoef(X) is the zeroth lag of the covariance function, that is, the zeroth lag of xcov(x, 'coeff') packed into a square array.

S = corrcoef(x, y) where x and y are column vectors is the same as $corrcoef([x \ y])$.

See Also cov, mean, std

xcorr, xcov in the Signal Processing Toolbox

Purpose Cosine and hyperbolic cosine

Syntax Y = cos(X)

 $Y = \cosh(X)$

Description The cos and cosh functions operate element-wise on arrays. The functions'

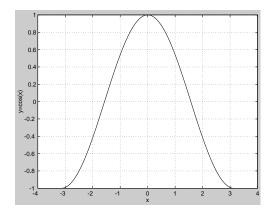

domains and ranges include complex values. All angles are in radians.

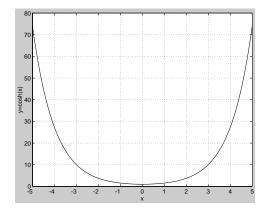

Y = cos(X) returns the circular cosine for each element of X.

Y = cosh(X) returns the hyperbolic cosine for each element of X.

Examples Graph the cosine function over the domain $-\pi \le x \le \pi$, and the hyperbolic cosine function over the domain $-5 \le x \le 5$.

x = -pi : 0.01: pi; plot(x, cos(x))x = -5: 0.01: 5; plot(x, cosh(x))

The expression $\cos(\text{pi}/2)$ is not exactly zero but a value the size of the floating-point accuracy, eps, because pi is only a floating-point approximation to the exact value of π .

cos and cosh use these algorithms.

$$\cos(x+iy) = \cos(x)\cosh(y) - i\sin(x)\sin(y)$$

$$\cos(z) = \frac{e^{iz} + e^{-iz}}{2}$$

$$\cosh(z) = \frac{e^{z} + e^{-z}}{2}$$

See Also

acos, acosh

Cotangent and hyperbolic cotangent

Syntax

$$Y = \cot(X)$$

 $Y = \coth(X)$

Description

The cot and coth functions operate element-wise on arrays. The functions' domains and ranges include complex values. All angles are in radians.

 $Y = \cot(X)$ returns the cotangent for each element of X.

Y = coth(X) returns the hyperbolic cotangent for each element of X.

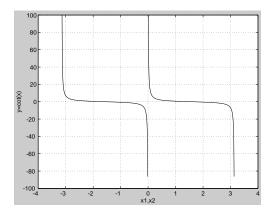

Examples

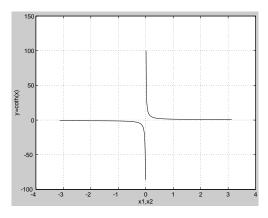

Graph the cotangent and hyperbolic cotangent over the domains $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi + 0.01: 0.01: -0.01;  x2 = 0.01: 0.01: pi - 0.01;

pl ot(x1, cot(x1), x2, cot(x2))

pl ot(x1, coth(x1), x2, coth(x2))
```

Algorithm

cot and coth use these algorithms.

$$\cot(z) = \frac{1}{\tan(z)}$$

$$coth(z) = \frac{1}{\tanh(z)}$$

See Also

acot, acoth

Covariance matrix

Syntax

$$C = cov(X)$$

 $C = cov(x, y)$

Description

C = cov(x) where x is a vector returns the variance of the vector elements. For matrices where each row is an observation and each column a variable, cov(x) is the covariance matrix. di ag(cov(x)) is a vector of variances for each column, and $sqrt(di \, ag(cov(x)))$ is a vector of standard deviations.

C = cov(x, y), where x and y are column vectors of equal length, is equivalent to $cov([x \ y])$.

Remarks

cov removes the mean from each column before calculating the result.

The covariance function is defined as

$$cov(x_1, x_2) = E[(x_1 - \mu_1)(x_2 - \mu_2)]$$

where E is the mathematical expectation and $\mu_i = Ex_i$.

Examples

Consider $A = \begin{bmatrix} -1 & 1 & 2 \\ \vdots & -2 & 3 & 1 \end{bmatrix}$; 4 0 3]. To obtain a vector of variances for each column of A:

Compare vector v with covariance matrix C:

The diagonal elements C(i,i) represent the variances for the columns of A. The off-diagonal elements C(i,j) represent the covariances of columns i and j.

Sort complex numbers into complex conjugate pairs

Syntax

B = cpl xpai r(A)

B = cpl xpai r(A, tol)

B = cpl xpai r(A, [], di m)

B = cpl xpai r(A, tol, dim)

Description

 $B = \operatorname{cpl} x \operatorname{pair}(A)$ sorts the elements along different dimensions of a complex array, grouping together complex conjugate pairs.

The conjugate pairs are ordered by increasing real part. Within a pair, the element with negative imaginary part comes first. The purely real values are returned following all the complex pairs. The complex conjugate pairs are forced to be exact complex conjugates. A default tolerance of 100*eps relative to abs(A(i)) determines which numbers are real and which elements are paired complex conjugates.

If A is a vector, $\operatorname{cpl} \operatorname{xpai} r(A)$ returns A with complex conjugate pairs grouped together.

If A is a matrix, cpl xpai r(A) returns A with its columns sorted and complex conjugates paired.

If A is a multidimensional array, cpl xpai r(A) treats the values along the first non-singleton dimension as vectors, returning an array of sorted elements.

B = cpl xpai r(A, tol) overrides the default tolerance.

 $B = cpl \, xpai \, r(A, [], dim)$ sorts A along the dimension specified by scalar dim.

 $B = cpl \, xpai \, r(A, tol, dim)$ sorts A along the specified dimension and overrides the default tolerance.

Diagnostics

If there are an odd number of complex numbers, or if the complex numbers cannot be grouped into complex conjugate pairs within the tolerance, cpl xpai r generates the error message

Complex numbers can't be paired.

cputime

Purpose Elapsed CPU time

Syntax cputime

Description cput i me returns the total CPU time (in seconds) used by MATLAB from the

time it was started. This number can overflow the internal representation and

wrap around.

Examples The following code returns the CPU time used to run surf (peaks (40)).

t = cputime; surf(peaks(40)); e = cputime-t

e = 0. 4667

See Also clock, etime, tic, toc

Vector cross product

Syntax

Description

C = cross(A, B) returns the cross product of the vectors A and B. That is, $C = A \times B$. A and B must be 3-element vectors. If A and B are multidimensional arrays, cross returns the cross product of A and B along the first dimension of length 3.

C = cross(A, B, dim) where A and B are multidimensional arrays, returns the cross product of A and B in dimension dim. A and B must have the same size, and both size(A, dim) and size(B, dim) must be 3.

Remarks

To perform a dot (scalar) product of two vectors of the same size, use c = dot(a, b).

Examples

The cross and dot products of two vectors are calculated as shown:

See Also

dot

Cosecant and hyperbolic cosecant

Syntax

$$Y = \csc(x)$$

 $Y = \operatorname{csch}(x)$

Description

The csc and csch functions operate element-wise on arrays. The functions' domains and ranges include complex values. All angles are in radians.

 $Y = \csc(x)$ returns the cosecant for each element of x.

 $Y = \operatorname{csch}(x)$ returns the hyperbolic cosecant for each element of x.

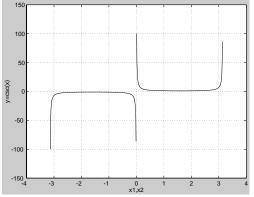

Examples

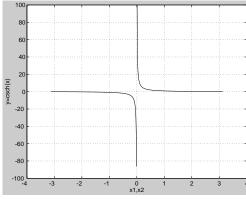

Graph the cosecant and hyperbolic cosecant over the domains $-\pi < x < 0 \;$ and $0 < x < \pi$.

```
x1 = -pi + 0.01: 0.01: -0.01;  x2 = 0.01: 0.01: pi - 0.01;

pl ot(x1, csc(x1), x2, csc(x2))

pl ot(x1, csch(x1), x2, csch(x2))
```

Algorithm

csc and csch use these algorithms.

$$\csc(z) = \frac{1}{\sin(z)}$$

$$\operatorname{csch}(z) = \frac{1}{\sinh(z)}$$

acsc, acsch

Read a comma-separated value file

Syntax

Description

```
M = csvread('filename')
```

M = csvread('filename', row, col)

M = csvread('filename', row, col, range)

M = csvread('filename') reads a comma-separated value formatted file, filename. The result is returned in M. The file can only contain numeric values.

M = csvread('filename', row, col) reads data from the comma-separated value formatted file starting at the specified row and column. The row and column arguments are zero-based, so that row=0 and col=0 specifies the first value in the file.

M = csvread('filename', row, col, range) reads only the range specified. Specify the range using the notation, [R1 C1 R2 C2] where (R1,C1) is the upper-left corner of the data to be read and (R2,C2) is the lower-right corner. The range can also be specified using spreadsheet notation as in range = 'A1.. B7'.

Remarks

csvread fills empty delimited fields with zero. Data files having lines that end with a nonspace delimiter, such as a semicolon, produce a result that has an additional last column of zeros.

Examples

Given the file, $csvl\,i\,st.\,dat$ that contains the comma-separated values

02, 04, 06, 08, 10, 12

03, 06, 09, 12, 15, 18

05, 10, 15, 20, 25, 30

07, 14, 21, 28, 35, 42

11, 22, 33, 44, 55, 66

To read the entire file, use

csvread('csvlist.dat')

ans =

2 4 6 8 10 12 3 6 9 12 15 18

To read the matrix starting with zero-based row 2, column 0 and assign it to the variable, m,

To read the matrix bounded by zero-based (2,0) and (3,3) and assign it to m,

$$m = csvread('csvlist.dat', 2, 0, [2, 0, 3, 3])$$

$$\mathbf{m} =$$

See Also

csvwrite, dl mread, textread, wklread, file formats, i mportdata, ui i mport

Write a comma-separated value file

Syntax

csvwrite('filename', M)
csvwrite('filename', M, row, col)

Description

csvwrite('filename', M) writes matrix Minto filename as comma-separated values.

csvwrite('filename', M, row, col) writes matrix Minto filename starting at the specified row and column offset. The row and column arguments are zero-based, so that row=0 and C=0 specifies the first value in the file.

Examples

The following example creates a comma-separated value file from the matrix, \mathbf{m}

```
m = [3 6 9 12 15; 5 10 15 20 25; 7 14 21 28 35; 11 22 33 44 55];
csvwrite('csvlist.dat', m)
type csvlist.dat
3, 6, 9, 12, 15
5, 10, 15, 20, 25
7, 14, 21, 28, 35
11, 22, 33, 44, 55
```

The next example writes the matrix to the file, starting at a column offset of 2.

```
csvwrite('csvlist.dat', m, 0, 2)
type csvlist.dat

,, 3, 6, 9, 12, 15
,, 5, 10, 15, 20, 25
,, 7, 14, 21, 28, 35
,, 11, 22, 33, 44, 55
```

See Also

csvread, dl mwrite, textread, wk1write, file formats, i mportdata, uii mport

Cumulative product

Syntax

B = cumprod(A)
B = cumprod(A, dim)

Description

B = cumprod(A) returns the cumulative product along different dimensions of an array.

If A is a vector, cumprod(A) returns a vector containing the cumulative product of the elements of A.

If A is a matrix, cumprod(A) returns a matrix the same size as A containing the cumulative products for each column of A.

If A is a multidimensional array, cumprod(A) works on the first nonsingleton dimension.

B = cumprod(A, dim) returns the cumulative product of the elements along the dimension of A specified by scalar dim. For example, cumprod(A, 1) increments the first (row) index, thus working along the rows of A.

Examples

See Also

cumsum, prod, sum

Cumulative sum

Syntax

B = cumsum(A)
B = cumsum(A, di m)

Description

B = cumsum(A) returns the cumulative sum along different dimensions of an array.

If A is a vector, cumsum(A) returns a vector containing the cumulative sum of the elements of A.

If A is a matrix, cumsum(A) returns a matrix the same size as A containing the cumulative sums for each column of A.

If A is a multidimensional array, cumsum(A) works on the first nonsingleton dimension.

B = cumsum(A, di m) returns the cumulative sum of the elements along the dimension of A specified by scalar di m. For example, cumsum(A, 1) works across the first dimension (the rows).

Examples

See Also

cumprod, prod, sum

Cumulative trapezoidal numerical integration

Syntax

Z = cumtrapz(Y)
Z = cumtrapz(X, Y)
Z = cumtrapz(... dim)

Description

Z = cumtrapz(Y) computes an approximation of the cumulative integral of Y via the trapezoidal method with unit spacing. To compute the integral with other than unit spacing, multiply Z by the spacing increment.

For vectors, cumtrapz(Y) is a vector containing the cumulative integral of Y.

For matrices, cumtrapz(Y) is a matrix the same size as Y with the cumulative integral over each column.

For multidimensional arrays, $\operatorname{cumt} \operatorname{rapz}(Y)$ works across the first nonsingleton dimension.

Z = cumtrapz(X, Y) computes the cumulative integral of Y with respect to X using trapezoidal integration. X and Y must be vectors of the same length, or X must be a column vector and Y an array whose first nonsingleton dimension is $l \cdot \text{ength}(X)$. cumtrapz operates across this dimension.

If X is a column vector and Y an array whose first nonsingleton dimension is $l \, ength(X)$, cumtrapz(X, Y) operates across this dimension.

Z = cumtrapz(X, Y, dim) or cumtrapz(Y, DIM) integrates across the dimension of Y specified by scalar dim. The length of X must be the same as size(Y, dim).

Example

cumtrapz

See Also

cumsum, trapz

Computes the curl and angular velocity of a vector field

Syntax

```
[curl x, curl y, curl z, cav] = curl (X, Y, Z, U, V, W)
[curl x, curl y, curl z, cav] = curl (U, V, W)
[curl z, cav] = curl (X, Y, U, V)
[curl z, cav] = curl (U, V)
[curl x, curl y, curl z] = curl (...), [curl x, curl y] = curl (...)
cav = curl (...)
```

Description

[curl x, curl y, curl z, cav] = curl (X, Y, Z, U, V, W) computes the curl and angular velocity perpendicular to the flow (in radians per time unit) of a 3-D vector field U, V, W. The arrays X, Y, Z define the coordinates for U, V, W and must be monotonic and 3-D plaid (as if produced by meshgri d).

 $[\operatorname{curl} x, \operatorname{curl} y, \operatorname{curl} z, \operatorname{cav}] = \operatorname{curl} (U, V, W)$ assumes X, Y, and Z are determined by the expression:

```
[X Y Z] = meshgrid(1:n, 1:m, 1:p)
where [m, n, p] = size(U).
```

[curl z, cav] = curl (X, Y, U, V) computes the curl z-component and the angular velocity perpendicular to z (in radians per time unit) of a 2-D vector field U, V. The arrays X, Y define the coordinates for U, V and must be monotonic and 2-D plaid (as if produced by meshgri d).

 $[\operatorname{curl} z, \operatorname{cav}] = \operatorname{curl} (U, V)$ assumes X and Y are determined by the expression:

```
[X Y] = meshgrid(1: n, 1: m)
```

where [m, n] = size(U).

 $[\operatorname{curl} x, \operatorname{curl} y, \operatorname{curl} z] = \operatorname{curl} (\ldots), \operatorname{curl} x, \operatorname{curl} y] = \operatorname{curl} (\ldots)$ returns only the curl.

cav = curl (...) returns only the curl angular velocity.

Examples

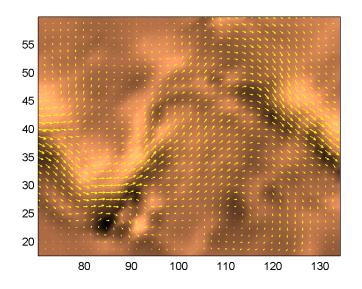

This example uses colored slice planes to display the curl angular velocity at specified locations in the vector field.

```
load wind
cav = curl (x, y, z, u, v, w);
slice(x, y, z, cav, [90 134], [59], [0]);
shading interp
daspect([1 1 1]); axis tight
colormap hot(16)
camlight
```

This example views the curl angular velocity in one plane of the volume and plots the velocity vectors (qui ver) in the same plane.

```
load wind k=4; x=x(:,:,k);\ y=y(:,:,k);\ u=u(:,:,k);\ v=v(:,:,k); cav = curl (x,y,u,v); pcol or (x,y,cav); shading interphold on; quiver (x,y,u,v,'y') hold off colormap copper
```

See Also streamri bbon, di vergence

customverctrl

Purpose Allow custom source control system

Syntax customverctrl(filename, arguments)

Description This function is supplied for customers who want to integrate a version control

system that is not supported with MATLAB. This function must conform to the structure of one of the supported version control systems, for example RCS. See

the files clearcase. m, pvcs. m, rcs. m, and sourcesafe. m in

\$matlabroot\toolbox\matlab\verctrl as examples.

See Also checki n, checkout, cmopts, undocheckout

Generate cylinder

Syntax

```
[X, Y, Z] = cylinder
[X, Y, Z] = cylinder(r)
[X, Y, Z] = cylinder(r, n)
cylinder(...)
```

Description

cyl i nder generates x, y, and z coordinates of a unit cylinder. You can draw the cylindrical object using surf or mesh, or draw it immediately by not providing output arguments.

[X, Y, Z] = cyl i nder returns the x, y, and z coordinates of a cylinder with a radius equal to 1. The cylinder has 20 equally spaced points around its circumference.

 $[X, Y, Z] = \operatorname{cylinder}(r)$ returns the x, y, and z coordinates of a cylinder using r to define a profile curve. cylinder treats each element in r as a radius at equally spaced heights along the unit height of the cylinder. The cylinder has 20 equally spaced points around its circumference.

 $[X, Y, Z] = \operatorname{cylinder}(r, n)$ returns the x, y, and z coordinates of a cylinder based on the profile curve defined by vector r. The cylinder has n equally spaced points around its circumference.

cylinder(...), with no output arguments, plots the cylinder using surf.

Remarks

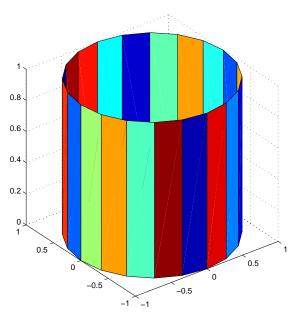

cyl i nder treats its first argument as a profile curve. The resulting surface graphics object is generated by rotating the curve about the *x*-axis, and then aligning it with the *z*-axis.

Examples

 $Create\ a\ cylinder\ with\ randomly\ colored\ faces.$

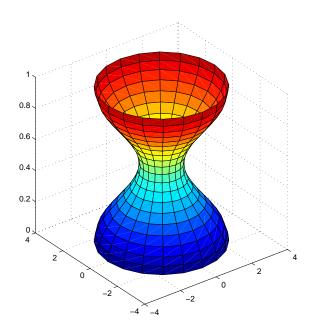

```
cylinder
axis square
h = findobj('Type','surface');
```

Generate a cylinder defined by the profile function $2+\sin n(t)$.

```
t = 0: pi /10: 2*pi;
[X, Y, Z] = cylinder(2+cos(t));
surf(X, Y, Z)
axis square
```

See Also sphere, surf

Set or query the axes data aspect ratio

Syntax

```
daspect
daspect([aspect_ratio])
daspect('mode')
daspect('auto')
daspect('manual')
daspect(axes_handle,...)
```

Description

The data aspect ratio determines the relative scaling of the data units along the x-, y-, and z-axes.

daspect with no arguments returns the data aspect ratio of the current axes.

daspect ([aspect_ratio]) sets the data aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the x-, y-, and z-axis scaling (e.g., [1 1 3] means one unit in x is equal in length to one unit in y and three unit in z).

 $\label{lem:daspect('mode')} as pect ratio \ mode, which \ can \ be \ either \ auto \ (the \ default) \ or \ manual \ . See \ Remarks.$

daspect('auto') sets the data aspect ratio mode to auto.

 $\label{lem:daspect} {\tt daspect\,('\,manual\,')} \ \ {\tt sets} \ the \ {\tt data} \ \ {\tt aspect} \ {\tt ratio} \ \ {\tt mode} \ to \ {\tt manual} \ .$

daspect (axes_handle,...) performs the set or query on the axes identified by the first argument, axes_handle. When you do not specify an axes handle, daspect operates on the current axes.

Remarks

daspect sets or queries values of the axes object DataAspectRatio and DataAspectRatioMode properties.

When the data aspect ratio mode is auto, MATLAB adjusts the data aspect ratio so that each axis spans the space available in the figure window. If you are displaying a representation of a real-life object, you should set the data aspect ratio to [1 1 1] to produce the correct proportions.

Setting a value for data aspect ratio or setting the data aspect ratio mode to manual disables MATLAB's stretch-to-fill feature (stretching of the axes to fit

the window). This means setting the data aspect ratio to a value, including its current value,

```
daspect (daspect)
```

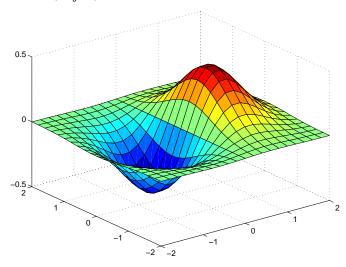

can cause a change in the way the graphs look. See the Remarks section of the axes description for more information.

Examples

The following surface plot of the function $z = xe^{(-x^2-y^2)}$ is useful to illustrate the data aspect ratio. First plot the function over the range $-2 \le x \le 2$, $-2 \le y \le 2$,

$$[x, y] = meshgrid([-2:.2:2]);$$

 $z = x. *exp(-x.^2 - y.^2);$
 $surf(x, y, z)$

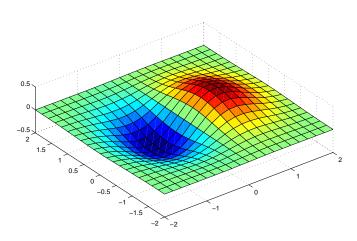

Querying the data aspect ratio shows how MATLAB has drawn the surface.

Setting the data aspect ratio to $[1\ 1\ 1]$ produces a surface plot with equal scaling along each axis.

daspect

daspect([1 1 1])

date

Purpose Current date string

Syntax str = date

Description str = date returns a string containing the date in dd-mmm-yyyy format.

See Also clock, datenum, now

datenum

Purpose

Serial date number

Syntax

N = datenum(DT)

N = datenum(DT, P)

N = datenum(Y, M, D)

N = datenum(Y, M, D, H, MI, S)

Description

The datenum function converts date strings and date vectors (defined by datevec) into serial date numbers. Date numbers are serial days elapsed from some reference date. By default, the serial day 1 corresponds to 1-Jan-0000.

N = datenum(DT) converts the date string or date vector DT into a serial date number. Date strings with two-character years, e.g., 12-j une-12, are assumed to lie within the 100-year period centered about the current year.

Note If DT is a string, it must be in one of the date formats 0, 1, 2, 6, 13, 14, 15, or 16 as defined by datestr.

N = datenum(DT, P) uses the specified pivot year as the starting year of the 100-year range in which a two-character year resides. The default pivot year is the current year minus 50 years.

N = datenum(Y, M, D) returns the serial date number for corresponding elements of the Y, M, and D (year, month, day) arrays. Y, M, and D must be arrays of the same size (or any can be a scalar). Values outside the normal range of each array are automatically "carried" to the next unit.

N = datenum(Y, M, D, H, MI, S) returns the serial date number for corresponding elements of the Y, M, D, H, MI, and S (year, month, hour, minute, and second) array values. Y, M, D, H, MI, and S must be arrays of the same size (or any can be a scalar).

Examples

Convert a date string to a serial date number.

```
n = datenum('19-May-1995')
n =
728798
```

Specifying year, month, and day, convert a date to a serial date number.

```
n = datenum(1994, 12, 19)
n = 728647
```

Convert a date string to a serial date number using the default pivot year

Convert the same date string to a serial date number using 1900 as the pivot year.

```
n = datenum('12-june-12', 1900)

n = 698507
```

See Also

datestr, datevec, now

datestr

Purpose

Date string format

Syntax

str = datestr(DT, dateform)
str = datestr(DT, dateform, P)

Description

The datestr function converts serial date numbers (defined by datenum) and date vectors (defined by datevec) into date strings.

str = datestr(DT, dateform) converts a single date vector, or each element of an array of serial date numbers to a date string. Date strings with two-character years, e.g., 12-j une-12, are assumed to lie within the 100-year period centered about the current year.

str = datestr(DT, dateform, P) uses the specified pivot year as the starting year of the 100-year range in which a two-character year resides. The default pivot year is the current year minus 50 years.

The optional argument dateform specifies the date format of the result. dateform can be either a number or a string:

dateform (number)	dateform (string)	Example
0	' dd- mmm- yyyy HH: MM: SS'	01-Mar-2000 15:45:17
1	' dd- mmm- yyyy'	01-Mar-2000
2	'mm/dd/yy'	03/01/00
3	' mmm'	Mar
4	' m'	M
5	' mm'	03
6	' mm/dd'	03/01
7	' dd'	01
8	' ddd'	Wed
9	' d'	W
10	' уууу'	2000

dateform (number)	dateform (string)	Example
11	'yy'	00
12	'mmmyy'	Mar00
13	' HH: MM: SS'	15: 45: 17
14	' HH: MM: SS PM'	3: 45: 17 PM
15	' HH: MM'	15: 45
16	' HH: MM PM'	3: 45 PM
17	' QQ- YY'	Q1-01
18	' QQ'	Q1
19	' dd/mm'	01/03
20	' dd/mm/yy'	01/03/00
21	' mmm. dd. yyyy HH: MM: SS'	Mar. 01, 2000 15: 45: 17
22	' mmm. dd. yyyy'	Mar. 01. 2000
23	' mm/dd/yyyy'	03/01/2000
24	' dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01
26	'yyyy/mm/dd'	2000/03/01
27	' QQ- YYYY'	Q1-2001
28	'mmmyyyy'	Mar2000
29 (ISO 8601)	' yyyy- mm- dd'	2000-03-01
30 (ISO 8601)	'yyyymmddTHHMMSS'	20000301T154517
31	' yyyy- mm- dd HH: MM: SS'	2000-03-01 15:45:17

datestr

NOTE date form numbers 0, 1, 2, 6, 13, 14, 15, 16, and 23 produce a string suitable for input to date num or datevec. Other date string formats will not work with these functions.

Time formats like 'h: m: s', 'h: m: s. s', 'h: m pm', ... may also be part of the input array DT. If you do not specify date form, or if you specify date form as - 1, the date string format defaults to

- 1 if DT contains date information only (01-Mar-1995)
- if DT contains time information only (03:45 PM)
- o if DT is a date vector, or a string that contains both date and time information (01-Mar-1995 03:45)

See Also

date, datetick, datenum, datevec

Purpose Label tick lines using dates

 $\textbf{Syntax} \qquad \qquad \text{datetick}(\texttt{tickaxis})$

datetick(tickaxis, dateform)

Description

dateti ck(ti ckaxi s) labels the tick lines of an axis using dates, replacing the default numeric labels. ti ckaxi s is the string 'x', 'y', or 'z'. The default is 'x'. dateti ck selects a label format based on the minimum and maximum limits of the specified axis.

datetick(tickaxis, dateform) formats the labels according to the integer dateform (see table). To produce correct results, the data for the specified axis must be serial date numbers (as produced by datenum).

dateform (number)	dateform (string)	Example
0	' dd- mmm- yyyy HH: MM: SS'	01-Mar-2000 15: 45: 17
1	' dd- mmm- yyyy'	01-Mar-2000
2	' mm/dd/yy'	03/01/00
3	' mmm'	Mar
4	' m'	M
5	' mm'	03
6	'mm/dd'	03/01
7	' dd'	01
8	' ddd'	Wed
9	' d'	W
10	'yyyy'	2000
11	'yy'	00
12	'mmmyy'	Mar00
13	'HH: MM: SS'	15: 45: 17

dateform (number)	dateform (string)	Example
14	' HH: MM: SS PM'	3: 45: 17 PM
15	' HH: MM'	15: 45
16	' HH: MM PM'	3: 45 PM
17	' QQ- YY'	Q1-01
18	' QQ'	Q1
19	' dd/mm'	01/03
20	' dd/mm/yy'	01/03/00
21	' mmm. dd. yyyy HH: MM: SS'	Mar. 01, 2000 15: 45: 17
22	' mmm. dd. yyyy'	Mar. 01. 2000
23	' mm/dd/yyyy'	03/01/2000
24	' dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01
26	' yyyy/mm/dd'	2000/03/01
27	' QQ- YYYY'	Q1-2001
28	'mmmyyyy'	Mar2000

Remarks

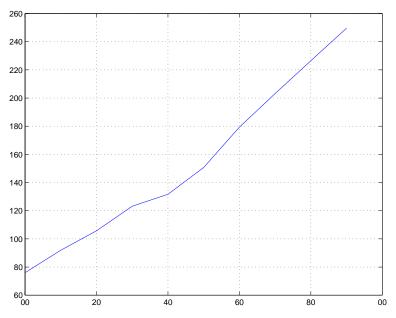

datetick calls datestr to convert date numbers to date strings.

To change the tick spacing and locations, set the appropriate axes property (i.e., XTi ck, YTi ck, or ZTi ck) before calling dateti ck.

Example

Consider graphing population data based on the 1990 U.S. census:

See Also

The axes properties XTi $\operatorname{ck},$ YTi $\operatorname{ck},$ and ZTi $\operatorname{ck}.$

datenum, datestr

Date components

```
C = datevec(A)
C = datevec(A, P)
[Y, M, D, H, MI, S] = datevec(A)
```

Description

C = datevec(A) splits its input into an n-by-6 array with each row containing the vector [Y, M, D, H, MI, S]. The first five date vector elements are integers. Input A can either consist of strings of the sort produced by the datestr function, or scalars of the sort produced by the datenum and now functions. Date strings with two-character years, e.g., 12-j une- 12, are assumed to lie within the 100-year period centered about the current year.

C = datevec(A, P) uses the specified pivot year as the starting year of the 100-year range in which a two-character year resides. The default pivot year is the current year minus 50 years.

[Y, M, D, H, MI, S] = datevec(A) returns the components of the date vector as individual variables.

When creating your own date vector, you need not make the components integers. Any components that lie outside their conventional ranges affect the next higher component (so that, for instance, the anomalous June 31 becomes July 1). A zeroth month, with zero days, is allowed.

Examples

An example of using a string as input:

```
datevec('12/24/1984')

ans =

1984 12 24 0 0 0
```

An example of using a serial date number as input:

ans = 1984 12 24 0 0 0

See Also clock, datenum, datestr, now

dbclear

Purpose

Clear breakpoints

Graphical Interface

As an alternative to the dbcl ear function, there are various ways to clear breakpoints using the Editor/Debugger.

Syntax

dbclear all

dbclear **all in** mfile dbclear **in** mfile

dbclear **in** mfile **at** lineno dbclear **in** mfile **at** subfun

dbclear if error dbclear if warning dbclear if naninf dbclear if infnan

Description

dbcl ear **all** removes all breakpoints in all M-files, as well as pauses set for error, warning, and naninf/infnan using dbst op.

dbclear all in mfile removes breakpoints in mfile.

dbclear in mfile removes the breakpoint set at the first executable line in mfile.

dbclear **in** mfile **at** lineno removes the breakpoint set at the line number lineno in mfile.

dbclear in mfile at subfun removes the breakpoint set at the subfunction subfun in mfile.

dbclear if error removes the pause set using dbstop if error.

dbclear if warning removes the pause set using dbstop if warning.

 $\label{thm:continuous} \mbox{dbcl ear } \mbox{ if } \mbox{naninf.}$

dbclear if infnan removes the pause set using dbstop if infnan.

Remarks

The at, in, and if keywords, familiar to users of the UNIX debugger dbx, are optional.

dbclear

See Also

 $\mbox{dbcont},\mbox{dbdown},\mbox{dbquit},\mbox{dbstack},\mbox{dbstatus},\mbox{dbstep},\mbox{dbstop},\mbox{dbtype},\mbox{dbup},\mbox{partial}\mbox{path}$

dbcont

Purpose Resume execution

Graphical As an alternative to the dbcont function, you can select Continue from the **Interface**

Debug menu in the Editor/Debugger.

Syntax dbcont

Description dbcont resumes execution of an M-file from a breakpoint. Execution continues

until either another breakpoint is encountered, an error occurs, or MATLAB

returns to the base workspace prompt.

See Also dbcl ear, dbdown, dbqui t, dbstack, dbstatus, dbstep, dbstop, dbtype, dbup **Purpose** Change local workspace context

Graphical Interface

As an alternative to the dbdown function, you can select **Step In** from the

Debug menu in the Editor/Debugger.

Syntax dbdown

Description dbdown changes the current workspace context to the workspace of the called

M-file when a breakpoint is encountered. You must have issued the dbup function at least once before you issue this function. dbdown is the opposite of

dbup.

Multiple dbdown functions change the workspace context to each successively executed M-file on the stack until the current workspace context is the current

breakpoint. It is not necessary, however, to move back to the current

breakpoint to continue execution or to step to the next line.

See Also dbcl ear, dbcont, dbquit, dbstack, dbstatus, dbstep, dbstop, dbtype, dbup

Numerically evaluate double integral

Syntax

- q = dbl quad(fun, xmi n, xmax, ymi n, ymax)
- q = dbl quad(fun, xmi n, xmax, ymi n, ymax, tol)
- q = dbl quad(fun, xmi n, xmax, ymi n, ymax, tol, method)
- q = dbl quad(fun, xmi n, xmax, ymi n, ymax, tol, method, p1, p2, ...)

Description

 $q = dbl \ quad(fun, xmi \ n, xmax, ymi \ n, ymax) \ calls the quad function to evaluate the double integral <math>fun(x, y)$ over the rectangle $xmi \ n <= x <= xmax$, $ymi \ n <= y <= ymax$. fun(x, y) must accept a vector x and a scalar y and return a vector of values of the integrand.

 $q = dbl \, quad(fun, xmi \, n, xmax, ymi \, n, ymax, tol)$ uses a tolerance tol instead of the default, which is 1. 0e-6.

 $q = dbl \, quad(fun, xmi \, n, xmax, ymi \, n, ymax, tol, method)$ uses the specified quadrature function instead of the default quad. Valid values for method are equadl or a function handle of a user-defined quadrature method that has the same calling sequence as quad and quadl.

dbl quad(fun, xmi n, xmax, ymi n, ymax, tol, method, p1, p2, ...) passes the additional parameters p1, p2, ... to fun(x, y, p1, p2, ...). Use [] as a placeholder if you do not specify tol or method.

dbl quad(fun, xmi n, xmax, ymi n, ymax, [], [], p1, p2, ...) is the same as dbl quad(fun, xmi n, xmax, ymi n, ymax, 1. e-6, @quad, p1, p2, ...)

Example

fun can be an inline object

```
Q = dbl quad(i nl i ne('y*si n(x) + x*cos(y)'), pi, 2*pi, 0, pi)
```

or a function handle

```
Q = dbl quad(@integrnd, pi, 2*pi, 0, pi)
```

where integrnd. m is an M-file.

```
function z = integrnd(x, y)

z = y*sin(x)+x*cos(y);
```

The integrand function integrates y*sin(x)+x*cos(y) over the square pi <= x <= 2*pi, 0 <= y <= pi. Note that the integrand can be evaluated with a vector x and a scalar y.

Nonsquare regions can be handled by setting the integrand to zero outside of the region. For example, the volume of a hemisphere is

```
 \begin{split} & dbl\, quad(i\, nl\, i\, ne(\,'\, sqrt(\, max(\, 1\text{-}\, (x.\,\, ^2\text{+}y.\,\, ^2)\,,\, 0)\,)\,\,'\,)\,,\, \text{-}\, 1,\, 1,\, \text{-}\, 1,\, 1) \\ \\ & or \\ & dbl\, quad(\,i\, nl\, i\, ne(\,'\, sqrt(\, 1\text{-}\, (x.\,\, ^2\text{+}y.\,\, ^2\text{-}2)\,)\,.\,\, ^*(x.\,\, ^2\text{+}y.\,\, ^2\text{-}2\text{-}1)\,\,'\,)\,,\, \text{-}\, 1,\, 1,\, \text{-}\, 1,\, 1} \\ & ) \end{split}
```

See Also

inline, quad, quadl, @ (function handle)

dbmex

Purpose Enable MEX-file debugging

Syntax dbmex on

dbmex off
dbmex stop
dbmex print

Description dbmex on enables MEX-file debugging for UNIX platforms. It is not supported

on the Sun Solaris platform. To use this option, first start MATLAB from within a debugger by typing: matlab - Ddebugger, where debugger is the name

of the debugger.

dbmex off disables MEX-file debugging.

dbmex **stop** returns to the debugger prompt.

dbmex print displays MEX-file debugging information.

Remarks On Sun Solaris platforms, dbmex is not supported. See the Technical Support

solution 23388 at http://www.mathworks.com/support/solutions/data/

23388. shtml for an alternative method of debugging.

See Also dbcl ear, dbcont, dbdown, dbquit, dbstack, dbstatus, dbstep, dbstop, dbtype,

dbup

Purpose Quit debug mode

Graphical As an alternative to the dbquit function, you can select **Exit Debug Mode** from

Interface the **Debug** menu in the Editor/Debugger.

Syntax dbqui t

Description dbquit immediately terminates the debugger and returns control to the base

workspace prompt. The M-file being processed is not completed and no results

are returned.

All breakpoints remain in effect.

See Also dbcl ear, dbcont, dbdown, dbstack, dbstatus, dbstep, dbstop, dbtype, dbup

dbstack

Purpose Display function call stack

Graphical Interface As an alternative to the dbstack function, you can use the **Stack** field in the Editor/Debugger toolbar.

Syntax dbstack

[ST, I] = dbstack

Description

dbstack displays the line numbers and M-file names of the function calls that led to the current breakpoint, listed in the order in which they were executed. The line number of the most recently executed function call (at which the current breakpoint occurred) is listed first, followed by its calling function, which is followed by its calling function, and so on, until the topmost M-file function is reached.

[ST, I] = dbstack returns the stack trace information in an m-by-1 structure ST with the fields:

name Function name

line Function line number

The current workspace index is returned in I.

Examples dbstack

In /usr/local/matlab/toolbox/matlab/cond.m at line 13
In test1.m at line 2

In test.m at line 3

See Also dbcl ear, dbcont, dbdown, dbquit, dbstatus, dbstep, dbstop, dbtype, dbup

Purpose List all breakpoints

Graphical Interface As an alternative to the dbstatus function, you can see breakpoint icons for a file that is open in the Editor/Debugger.

Syntax dbstatus

dbstatus function
s = dbstatus(...)

Description

dbstatus lists all breakpoints in effect including error, warning, and naninf.

dbstatus functi on displays a list of the line numbers for which breakpoints are set in the specified M-file.

s = dbstatus(...) returns the breakpoint information in an m-by-1 structure with the fields:

name Function name

line Function line number

cond Condition string (error, warning, or

nani nf)

Use dbstatus class/function or dbstatus private/function or dbstatus class/private/function to determine the status for methods, private functions, or private methods (for a class named class). In all of these forms you can further qualify the function name with a subfunction name as in dbstatus function/subfunction.

See Also

dbcl ear, dbcont, dbdown, dbquit, dbstack, dbstep, dbstop, dbtype, dbup

dbstep

Purpose

Execute one or more lines from current breakpoint

Graphical Interface As an alternative to the dbst ep function, you can select **Step** from the **Debug** menu in the Editor/Debugger.

Syntax

dbstep

dbstep nlines dbstep **in**

Description

This function allows you to debug an M-file by following its execution from the current breakpoint. At a breakpoint, the dbstep function steps through execution of the current M-file one line at a time or at the rate specified by nlines.

dbst ep, by itself, executes the next executable line of the current M-file. dbst ep steps over the current line, skipping any breakpoints set in functions called by that line.

dbstep nlines executes the specified number of executable lines.

dbstep in steps to the next executable line. If that line contains a call to another M-file, execution resumes with the first executable line of the called file. If there is no call to an M-file on that line, dbstep in is the same as dbstep.

See Also

dbclear, dbcont, dbdown, dbquit, dbstack, dbstatus, dbstop, dbtype, dbup

Set breakpoints in M-file function

Graphical Interface

As an alternative to the dbstop function, you can use the **Breakpoints** menu or the breakpoint alley in the Editor/Debugger.

Syntax

dbstop in mfile

dbstop in mfile at lineno dbstop in mfile at subfun

dbstop if error dbstop if all error dbstop if warning dbstop if naninf dbstop if infnan

Description

dbstop in mfile temporarily stops execution of mfile when you run it, at the first executable line, putting MATLAB in debug mode. mfile must be in a directory that is on the search path or in the current directory. If you have graphical debugging enabled, the MATLAB Debugger opens with a breakpoint at the first executable line of mfile. You can then use the debugging utilities, review the workspace, or issue any valid MATLAB function. Use dbcont or dbstep to resume execution of mfile. Use dbquit to exit from the Debugger.

dbstop in mfile at lineno temporarily stops execution of mfile when you run it, just prior to execution of the line whose number is lineno, putting MATLAB in debug mode. mfile must be in a directory that is on the search path or in the current directory. If you have graphical debugging enabled, the MATLAB Debugger opens mfile with a breakpoint at line lineno. If that line is not executable, execution stops and the breakpoint is set at the next executable line following lineno. When execution stops, you can use the debugging utilities, review the workspace, or issue any valid MATLAB function. Use dbcont or dbstep to resume execution of mfile. Use dbquit to exit from the Debugger.

dbst op in mfile at subfun temporarily stops execution of mfile when you run it, just prior to execution of the subfunction subfun, putting MATLAB in debug mode. mfile must be in a directory that is on the search path or in the current directory. If you have graphical debugging enabled, the MATLAB Debugger opens mfile with a breakpoint at the subfunction specified by

subfun. You can then use the debugging utilities, review the workspace, or issue any valid MATLAB function. Use dbcont or dbstep to resume execution of mfile. Use dbquit to exit from the Debugger.

dbstop if error stops execution when any M-file you subsequently run produces a run-time error, putting MATLAB in debug mode, paused at the line that generated the error. The M-file must be in a directory that is on the search path or in the current directory. It does not include run-time errors that are detected within a try... catch block. You cannot resume execution after an error. Use dbquit to exit from the Debugger.

dbstop if all error is the same as dbstop if error, except that it stops execution on any type of run-time error, including errors that are detected within a try... catch block.

dbstop if warning stops execution when any M-file you subsequently run produces a run-time warning, putting MATLAB in debug mode, paused at the line that generated the warning. The M-file must be in a directory that is on the search path or in the current directory. Use dbcont or dbstep to resume execution.

dbstop if naninf stops execution when any M-file you subsequently run encounters an infinite value (Inf), putting MATLAB in debug mode, paused at the line where Inf was encountered. The M-file must be in a directory that is on the search path or in the current directory. Use dbcont or dbstep to resume execution. Use dbquit to exit from the Debugger.

dbstop if infnan stops execution when any M-file you subsequently run encounters a value that is not a number (NaN), putting MATLAB in debug mode, paused at the line where NaN was encountered. The M-file must be in a directory that is on the search path or in the current directory. Use dbcont or dbstep to resume execution. Use dbquit to exit from the Debugger.

Remarks

The at, in, and if keywords, familiar to users of the UNIX debugger dbx, are optional.

Examples

The file buggy, used in these examples, consists of three lines.

```
function z = buggy(x)

n = l ength(x);

z = (1:n)./x;
```

Example 1 – Stop at First Executable Line

The statements

```
dbstop in buggy buggy(2:5)
```

stop execution at the first executable line in buggy

```
n = length(x);
```

The function

dbstep

advances to the next line, at which point, you can examine the value of n.

Example 2 - Stop if Error

dbstop if error

Because buggy only works on vectors, it produces an error if the input x is a full matrix. The statements

```
buggy(magic(3))
produce
    ??? Error using ==> ./
    Matrix dimensions must agree.
    Error in ==> c: \buggy. m
    On line 3 ==> z = (1:n)./x;
    K»
```

and put MATLAB in debug mode.

Example 3 - Stop if Inf

In buggy, if any of the elements of the input ${\bf x}$ are zero, a division by zero occurs. The statements

```
dbstop if naninf
buggy(0: 2)
```

produce

```
Warning: Divide by zero. > In c:\buggy.m at line 3 K»
```

and put MATLAB in debug mode.

Purpose List M-file with line numbers

Graphical Interface

As an alternative to the dbtype function, you can see an M-file with line

numbers by opening it in the Editor/Debugger.

Syntax dbtype function

dbtype function start: end

Description dbtype function displays the contents of the specified M-file function with

line numbers preceding each line. function must be the name of an M-file

function or a MATLABPATH relative partial pathname.

 $dbtype \ function \ start: end \ displays \ the \ portion \ of \ the \ file \ specified \ by \ a$

range of line numbers.

See Also dbcl ear, dbcont, dbdown, dbquit, dbstack, dbstatus, dbstep, dbstop, dbup,

parti al path

dbup

Purpose Change local workspace context

Graphical Interface As an alternative to the dbup function, you can select **Step In** from the **Debug** menu in the Editor/Debugger.

Syntax dbup

Description This function allows you to examine the calling M-file by using any other

MATLAB function. In this way, you determine what led to the arguments being

passed to the called function.

dbup changes the current workspace context (at a breakpoint) to the workspace

of the calling M-file.

Multiple dbup functions change the workspace context to each previous calling

M-file on the stack until the base workspace context is reached. (It is not necessary, however, to move back to the current breakpoint to continue

execution or to step to the next line.)

See Also dbcl ear, dbcont, dbdown, dbquit, dbstack, dbstatus, dbstep, dbstop, dbtype

Set up advisory link

Syntax

```
rc = ddeadv(channel, 'item', 'callback')
```

rc = ddeadv(channel, 'item', 'callback', 'upmtx')

rc = ddeadv(channel, 'item', 'callback', 'upmtx', format)

rc = ddeadv(channel, 'item', 'callback', 'upmtx', format, timeout)

Description

ddeadv sets up an advisory link between MATLAB and a server application. When the data identified by the item argument changes, the string specified by the callback argument is passed to the eval function and evaluated. If the advisory link is a hot link, DDE modifies upmtx, the update matrix, to reflect the data in item.

If you omit optional arguments that are not at the end of the argument list, you must substitute the empty matrix for the missing argument(s).

If successful, ddeady returns 1 in variable, rc. Otherwise it returns 0.

Arguments

channel Conversation channel from ddei ni t.

i tem String specifying the DDE item name for the advisory link.

Changing the data identified by i tem at the server triggers the

advisory link.

callback String specifying the callback that is evaluated on update

notification. Changing the data identified by i tem at the server causes call back to get passed to the eval function to be

evaluated.

upmtx (optional) String specifying the name of a matrix that holds data sent with an update notification. If upmtx is included, changing

item at the server causes upmtx to be updated with the revised data. Specifying upmtx creates a hot link. Omitting upmtx or specifying it as an empty string creates a warm link. If upmtx exists in the workspace, its contents are overwritten. If upmtx

does not exist. it is created.

ddeady

format (optional)

Two-element array specifying the format of the data to be sent on update. The first element specifies the Windows clipboard format to use for the data. The only currently supported format is cf_text, which corresponds to a value of 1. The second element specifies the type of the resultant matrix. Valid types are numeric (the default, which corresponds to a value of 0) and string (which corresponds to a value of 1). The default format array is [1 0].

timeout (optional)

Scalar specifying the time-out limit for this operation. timeout is specified in milliseconds. (1000 milliseconds = 1 second). If advisory link is not established within timeout milliseconds, the function fails. The default value of timeout is three seconds.

Examples

Set up a hot link between a range of cells in Excel (Row 1, Column 1 through Row 5, Column 5) and the matrix x. If successful, display the matrix:

```
rc = ddeadv(channel, 'r1c1: r5c5', 'di sp(x)', 'x');
```

Communication with Excel must have been established previously with a ddei ni t command.

See Also

ddeexec, ddei ni t, ddepoke, ddereg, ddeterm, ddeunadv

Purpose Send string for execution

Syntax rc = ddeexec(channel, 'command')

rc = ddeexec(channel, 'command', 'item')

rc = ddeexec(channel, 'command', 'item', timeout)

Description ddeexec sends a string for execution to another application via an established

DDE conversation. Specify the string as the command argument.

If you omit optional arguments that are not at the end of the argument list, you

must substitute the empty matrix for the missing argument(s).

If successful, ddeexec returns 1 in variable, rc. Otherwise it returns 0.

Arguments Conversation channel from ddei ni t.

command String specifying the command to be executed.

i tem String specifying the DDE item name for execution. This

(optional) argument is not used for many applications. If your application requires this argument, it provides additional information for

command Consult your conver documentation for more

command. Consult your server documentation for more

information.

ti meout Scalar specifying the time-out limit for this operation. ti meout

(optional) is specified in milliseconds. (1000 milliseconds = 1 second). The

default value of timeout is three seconds.

Examples Given the channel assigned to a conversation, send a command to Excel:

rc = ddeexec(channel, '[formula.goto("r1c1")]')

Communication with Excel must have been established previously with a

ddei ni t command.

See Also ddeady, ddei ni t, ddepoke, ddereg, ddeterm, ddeunady

ddeinit

Purpose Initiate DDE conversation

Syntax channel = ddeinit('service', 'topic')

Description channel = ddei ni t (' servi ce', ' topi c') returns a channel handle assigned

to the conversation, which is used with other MATLAB DDE functions. 'service' is a string specifying the service or application name for the conversation. 'topic' is a string specifying the topic for the conversation.

Examples To initiate a conversation with Excel for the spreadsheet 'stocks. xls':

channel = ddeinit('excel', 'stocks.xls')

channel = 0.00

See Also ddeady, ddeexec, ddepoke, ddereq, ddeterm, ddeunady

Send data to application

Syntax

rc = ddepoke(channel, 'item', data)

rc = ddepoke(channel, 'item', data, format)

rc = ddepoke(channel, 'item', data, format, timeout)

Description

ddepoke sends data to an application via an established DDE conversation. ddepoke formats the data matrix as follows before sending it to the server application:

- String matrices are converted, element by element, to characters and the resulting character buffer is sent.
- Numeric matrices are sent as tab-delimited columns and carriage-return, line-feed delimited rows of numbers. Only the real part of nonsparse matrices are sent.

If you omit optional arguments that are not at the end of the argument list, you must substitute the empty matrix for the missing argument(s).

If successful, ddepoke returns 1 in variable, rc. Otherwise it returns 0.

Arguments

String specifying the DDE item for the data sent. Item is the item

server data entity that is to contain the data sent in the data

argument.

data Matrix containing the data to send.

format. Scalar specifying the format of the data requested. The value (optional) indicates the Windows clipboard format to use for the data

transfer. The only format currently supported is cf_text,

which corresponds to a value of 1.

ti meout Scalar specifying the time-out limit for this operation. ti meout (optional)

is specified in milliseconds. (1000 milliseconds = 1 second). The

default value of ti meout is three seconds.

Examples

Assume that a conversation channel with Excel has previously been established with ddei ni t. To send a 5-by-5 identity matrix to Excel, placing the data in Row 1, Column 1 through Row 5, Column 5:

ddepoke

```
rc = ddepoke(channel, 'r1c1:r5c5', eye(5));
```

See Also

ddeadv, ddeexec, ddei ni t, ddereq, ddeterm, ddeunadv

Purpose Request data from application

Syntax data = ddereq(channel, ' i tem')

data = ddereq(channel, 'item', format)

data = ddereg(channel, 'item', format, timeout)

Description

ddereq requests data from a server application via an established DDE conversation. ddereq returns a matrix containing the requested data or an empty matrix if the function is unsuccessful.

If you omit optional arguments that are not at the end of the argument list, you must substitute the empty matrix for the missing argument(s).

If successful, ddereq returns a matrix containing the requested data in variable, data. Otherwise, it returns an empty matrix.

Arguments

channel	Conversation	channel	from	ddei ni t.

item String specifying the server application's DDE item name for

the data requested.

format Two-element array specifying the format of the data requested. (optional) The first element specifies the Windows clipboard format to

The first element specifies the Windows clipboard format to use. The only currently supported format is cf_text, which corresponds to a value of 1. The second element specifies the type of the resultant matrix. Valid types are numeric (the

default, which corresponds to 0) and string (which

corresponds to a value of 1). The default format array is $[1 \ 0]$.

timeout Scalar specifying the time-out limit for this operation. timeout (optional) is specified in milliseconds. (1000 milliseconds = 1 second). The

default value of ti meout is three seconds.

Examples

Assume that we have an Excel spreadsheet stocks. xls. This spreadsheet contains the prices of three stocks in row 3 (columns 1 through 3) and the number of shares of these stocks in rows 6 through 8 (column 2). Initiate conversation with Excel with the command:

```
channel = ddeinit('excel', 'stocks. xls')
```

DDE functions require the rxcy reference style for Excel worksheets. In Excel terminology the prices are in r3c1: r3c3 and the shares in r6c2: r8c2.

To request the prices from Excel:

To request the number of shares of each stock:

See Also

ddeadv, ddeexec, ddei ni t
, ddepoke, ddeterm, ddeunadv

Purpose Terminate DDE conversation

Syntax rc = ddeterm(channel)

Description rc = ddeterm(channel) accepts a channel handle returned by a previous call

to ddei nit that established the DDE conversation. ddeterm terminates this conversation. rc is a return code where 0 indicates failure and 1 indicates

success.

Examples To close a conversation channel previously opened with ddei ni t:

rc = ddeterm(channel)

rc =

1.00

See Also ddeady, ddeexec, ddei ni t, ddepoke, ddereq, ddeunady

ddeunadv

Purpose Release advisory link

Syntax rc = ddeunadv(channel, ' *i tem*')

rc = ddeunadv(channel, 'item', format)

rc = ddeunadv(channel, 'item', format, timeout)

Description

ddeunadv releases the advisory link between MATLAB and the server application established by an earlier ddeadv call. The channel, *i tem*, and format must be the same as those specified in the call to ddeadv that initiated the link. If you include the timeout argument but accept the default format, you must specify format as an empty matrix.

If successful, ddeunady returns 1 in variable, rc. Otherwise it returns 0.

Arguments

i tem String specifying the DDE item name for the advisory link.

Changing the data identified by i tem at the server triggers the

advisory link.

format Two-element array. This must be the same as the format

(optional) argument for the corresponding ddeadv call.

timeout Scalar specifying the time-out limit for this operation. timeout (optional) is specified in milliseconds. (1000 milliseconds = 1 second). The

default value of ti meout is three seconds.

Example

To release an advisory link established previously with ddeadv:

```
rc = ddeunadv(channel, 'r1c1:r5c5')
rc =
```

1.00

Deal inputs to outputs

Syntax

$$[Y1, Y2, Y3, ...] = deal(X)$$

 $[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)$

Description

[Y1, Y2, Y3, ...] = deal(X) copies the single input to all the requested outputs. It is the same as Y1 = X, Y2 = X, Y3 = X, ...

```
[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...) is the same as Y1 = X1; Y2 = X2; Y3 = X3; ...
```

Remarks

deal is most useful when used with cell arrays and structures via comma separated list expansion. Here are some useful constructions:

[S. field] = deal(X) sets all the fields with the name field in the structure array S to the value X. If S doesn't exist, use [S(1:m). field] = deal(X).

 $[X\{:\}] = deal (A. field)$ copies the values of the field with name field to the cell array X. If X doesn't exist, use $[X\{1:m\}] = deal (A. field)$.

 $[Y1, Y2, Y3, \dots] = deal(X\{:\})$ copies the contents of the cell array X to the separate variables Y1, Y2, Y3, ...

 $[Y1, Y2, Y3, \dots] = deal (S. field)$ copies the contents of the fields with the name field to separate variables $Y1, Y2, Y3, \dots$

Examples

Use deal to copy the contents of a 4-element cell array into four separate output variables.

```
C = {rand(3) ones(3, 1) eye(3) zeros(3, 1)};
[a, b, c, d] = deal(C{:})
a =

0.9501    0.4860    0.4565
    0.2311    0.8913    0.0185
    0.6068    0.7621    0.8214
b =
```

```
1
       1
       1
  c =
       1
           0
               0
       0
               0
       0
           0
               1
  d =
       0
       0
       0
Use deal to obtain the contents of all the name fields in a structure array:
  A. name = 'Pat'; A. number = 176554;
  A(2). name = 'Tony'; A(2). number = 901325;
  [name1, name2] = deal(A(:).name)
  name1 =
  Pat
  name2 =
  Tony
```

Strip trailing blanks from the end of a string

Syntax

```
str = deblank(str)
c = deblank(c)
```

Description

str = deblank(str) removes the trailing blanks from the end of a character string str.

 $c = debl\,ank(c)$, when c is a cell array of strings, applies debl ank to each element of c.

The debl ank function is useful for cleaning up the rows of a character array.

Examples

```
A{1, 1} = 'MATLAB ';
A{1, 2} = 'SI MULI NK ';
A{2, 1} = 'Tool boxes ';
A{2, 2} = 'The MathWorks ';

A =

'MATLAB 'SI MULI NK 'Tool boxes 'The MathWorks

debl ank(A)

ans =

'MATLAB' 'SI MULI NK' 'The MathWorks'
```

dec2base

Purpose Decimal number to base conversion

Syntax str = dec2base(d, base)

str = dec2base(d, base, n)

Description str = dec2base(d, base) converts the nonnegative integer d to the specified

base.d must be a nonnegative integer smaller than 2^52, and base must be an

integer between 2 and 36. The returned argument str is a string.

str = dec2base(d, base, n) produces a representation with at least n digits.

Examples The expression dec2base(23, 2) converts 23₁₀ to base 2, returning the string

' 10111'.

See Also base2dec

Purpose Decimal to binary number conversion

Syntax str = dec2bin(d)

str = dec2bin(d, n)

 ${\tt str} = {\tt dec2bi}\,n(d)$ returns the binary representation of d as a string. d must be a nonnegative integer smaller than 2^{52} . Description

str = dec2bi n(d, n) produces a binary representation with at least n bits.

Examples

ans =

10111

See Also bi n2dec, dec2hex

dec2hex

Purpose Decimal to hexadecimal number conversion

Syntax str = dec2hex(d)

str = dec2hex(d, n)

Description str = dec2hex(d) converts the decimal integer d to its hexadecimal

representation stored in a MATLAB string. d must be a nonnegative integer smaller than 2^{52} .

str = dec2hex(d, n) produces a hexadecimal representation with at least n

digits.

Examples To convert decimal 1023 to hexadecimal,

dec2hex(1023)

ans = 3FF

See Also dec2bin, format, hex2dec, hex2num

Deconvolution and polynomial division

Syntax

$$[q, r] = deconv(v, u)$$

Description

[q, r] = deconv(v, u) deconvolves vector u out of vector v, using long division. The quotient is returned in vector q and the remainder in vector r such that v = conv(u, q) + r.

If u and v are vectors of polynomial coefficients, convolving them is equivalent to multiplying the two polynomials, and deconvolution is polynomial division. The result of dividing v by u is quotient q and remainder r.

Examples

If

$$u = [1 \ 2 \ 3 \ 4]$$

 $v = [10 \ 20 \ 30]$

the convolution is

Use deconvolution to recover u:

This gives a quotient equal to v and a zero remainder.

Algorithm

deconv uses the filter primitive.

conv, resi due

default4

Purpose MATLAB Version 4.0 figure and axes defaults

Syntax default4

default4(h)

Description default 4 sets figure and axes defaults to match MATLAB Version 4.0 defaults.

default4(h) only affects the figure with handle h.

See Also col ordef

Discrete Laplacian

Syntax

$$L = del 2(U)$$

$$L = del 2(U, h)$$

$$L = del 2(U, hx, hy)$$

$$L = del 2(U, hx, hy, hz, ...)$$

Definition

If the matrix U is regarded as a function u(x, y) evaluated at the point on a square grid, then $4*del\ 2(U)$ is a finite difference approximation of Laplace's differential operator applied to u, that is:

$$I = \frac{\nabla^{2} u}{4} = \frac{1}{4} \left(\frac{d^{2} u}{dx^{2}} + \frac{d^{2} u}{dy^{2}} \right)$$

where:

$$I_{ij} = \frac{1}{4}(u_{i+1, j} + u_{i-1, j} + u_{i, j+1} + u_{i, j-1}) - u_{i, j}$$

in the interior. On the edges, the same formula is applied to a cubic extrapolation.

For functions of more variables u(x, y, z, ...), del 2(U) is an approximation,

$$I = \frac{\nabla^{2} u}{2 N} = \frac{1}{2 N} \left(\frac{d^{2} u}{dx^{2}} + \frac{d^{2} u}{dy^{2}} + \frac{d^{2} u}{dz^{2}} + \dots \right)$$

where N is the number of variables in u.

Description

L = del 2(U) where U is a rectangular array is a discrete approximation of

$$I = \frac{\nabla^2 u}{4} = \frac{1}{4} \left(\frac{d^2 u}{dx^2} + \frac{d^2 u}{dy^2} \right)$$

The matrix L is the same size as U with each element equal to the difference between an element of U and the average of its four neighbors.

 $-L = del \, 2(U)$ when U is an multidimensional array, returns an approximation of

$$\frac{\nabla^2 u}{2N}$$

where N is ndi ms(u).

L = del 2(U, h) where H is a scalar uses H as the spacing between points in each direction (h=1 by default).

 $L = del\,2(U,hx,hy)$ when U is a rectangular array, uses the spacing specified by hx and hy. If hx is a scalar, it gives the spacing between points in the x-direction. If hx is a vector, it must be of length si ze(u,2) and specifies the x-coordinates of the points. Similarly, if hy is a scalar, it gives the spacing between points in the y-direction. If hy is a vector, it must be of length $si\,ze(u,1)$ and specifies the y-coordinates of the points.

L = del 2(U, hx, hy, hz, ...) where U is multidimensional uses the spacing given by hx, hy, hz, ...

Examples

The function

$$u(x, y) = x^2 + y^2$$

has

$$\nabla^2 u = 4$$

For this function, 4*del 2(U) is also 4.

di ff, gradi ent

delaunay

Purpose

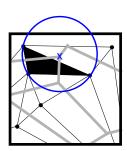

Delaunay triangulation

Syntax

TRI = del aunay(x, y)

Definition

Given a set of data points, the *Delaunay triangulation* is a set of lines connecting each point to its natural neighbors. The Delaunay triangulation is related to the Voronoi diagram— the circle circumscribed about a Delaunay triangle has its center at the vertex of a Voronoi polygon.

Delaunay triangle

Voronoi polygon

Description

TRI = del aunay(x, y) for the data points defined by vectors x and y, returns a set of triangles such that no data points are contained in any triangle's circumscribed circle. Each row of the m-by-3 matrix TRI defines one such triangle and contains indices into x and y. If the original data points are collinear or x is empty, the triangles cannot be computed and del aunay returns an empty matrix.

Remarks

The Delaunay triangulation is used by: gri ddata (to interpolate scattered data), voronoi (to compute the voronoi diagram), and is useful by itself to create a triangular grid for scattered data points.

The functions dsearch and tsearch search the triangulation to find nearest neighbor points or enclosing triangles, respectively.

Note delaunay is based on qhull [2]. For information about qhull, see http://www.geom.umn.edu/software/qhull/. For copyright information, see http://www.geom.umn.edu/software/download/COPYING.html.

Visualization

Use one of these functions to plot the output of del aunay:

tri pl ot Displays the triangles defined in the m-by-3 matrix TRI . See

Example 1.

tri surf Displays each triangle defined in the m-by-3 matrix TRI as a

surface in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For

example

trisurf(TRI, x, y, zeros(size(x)))

See Example 2.

tri mesh

Displays each triangle defined in the m-by-3 matrix TRI as a mesh in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example,

```
trimesh(TRI, x, y, zeros(size(x)))
```

produces almost the same result as tri pl ot, except in 3-D space. See Example 2.

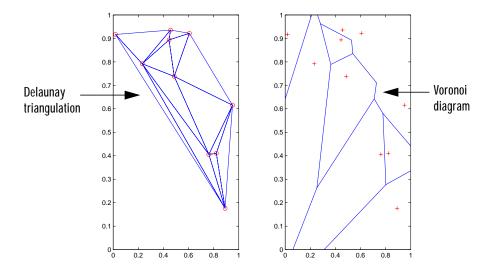

Examples

Example 1. Plot the Delaunay triangulation for 10 randomly generated points.

```
rand('state', 0);
x = rand(1, 10);
y = rand(1, 10);
TRI = del aunay(x, y);
subplot(1, 2, 1), ...
triplot(TRI, x, y)
axis([0 1 0 1]);
hold on;
plot(x, y, 'or');
hold off
```

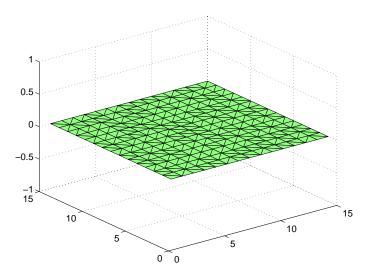

Compare the Voronoi diagram of the same points:

```
[vx, vy] = voronoi (x, y, TRI);
subplot (1, 2, 2), ...
plot (x, y, 'r+', vx, vy, 'b-'), ...
axis([0 1 0 1])
```

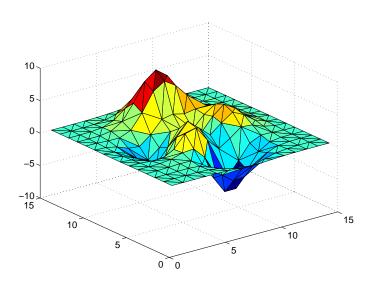

Example 2. Create a 2-D grid then use tri surf to plot its Delaunay triangulation in 3-D space by using 0s for the third dimension.

```
[x, y] = meshgrid(1:15, 1:15);
tri = del aunay(x, y);
tri surf(tri, x, y, zeros(size(x)))
```

Next, generate peaks data as a 15-by-15 matrix, and use that data with the Delaunay triangulation to produce a surface in 3-D space.

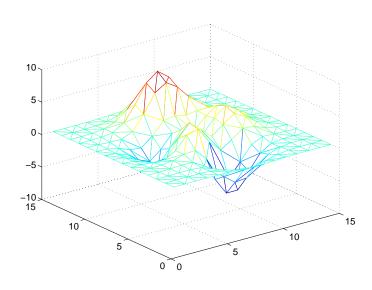

```
z = peaks(15);
tri surf(tri, x, y, z)
```

delaunay

You can use the same data with tri mesh to produce a mesh in 3-D space.

trimesh(tri, x, y, z)

3-D Delaunay tessellation

Syntax

TES = del aunay3(x, y, z)

Description

TES = del aunay3(x, y, z) returns an array TES, each row of which contains the indices of the points in (x, y, z) that make up a tetrahedron in the tessellation of (x, y, z). TES is a numtes-by-4 array where numtes is the number of facets in the tessellation. x, y, and z are vectors of equal length. If the original data points are collinear or x, y, and z define an insufficient number of points, the triangles cannot be computed and del aunay3 returns an empty matrix.

Note del aunay3 is based on qhull [2]. For information about qhull, see http://www.geom.umn.edu/software/qhull/. For copyright information, see http://www.geom.umn.edu/software/download/COPYING.html.

Visualization

Use tetramesh to plot del aunay3 output. tetramesh displays the tetrahedrons defined in TES as mesh. tetramesh uses the default transparency parameter value 'FaceAl pha' = 0.9.

Example

This example generates a 3-D Delaunay tessellation, then uses tetramesh to plot the tetrahedrons that form the corresponding simplex. camorbit rotates the camera position to provide a meaningful view of the figure.

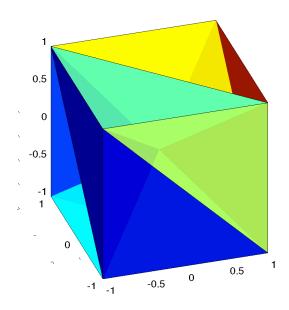

```
d = [-1 1];
[x, y, z] = meshgrid(d, d, d);  % A cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
% [x, y, z] are corners of a cube plus the center.
Tes = delaunay3(x, y, z)

Tes =

9 7 3 5
1 9 3 5
1 2 9 5
4 9 7 3
```

delaunay3

X = [x(:) y(:) z(:)];tetramesh(Tes, X); camorbit(20, 0)

delaunayn

Purpose

n-D Delaunay tessellation

Syntax

T = del aunayn(X)

Description

 $T = del \ aunayn(X)$ computes a set of simplices such that no data points of X are contained in any circumspheres of the simplices. The set of simplices forms the Delaunay tessellation. X is an m-by-n array representing m points in n-D space. T is a numt-by-(n+1) array where each row contains the indices into X of the vertices of the corresponding simplex.

Note del aunayn is based on qhull [2]. For information about qhull, see http://www.geom.umn.edu/software/qhull/. For copyright information, see http://www.geom.umn.edu/software/download/COPYING.html.

Visualization

Plotting the output of del aunayn depends of the value of n:

- For n = 2, use triplot, trisurf, or trimesh as you would for delaunay.
- For n = 3, use tetramesh as you would for del aunay3.
 For more control over the color of the facets, use patch to plot the output. For an example, see "Tessellation and Interpolation of Scattered Data in Higher Dimensions" in the MATLAB documentation.
- You cannot plot del aunayn output for n > 3.

Example

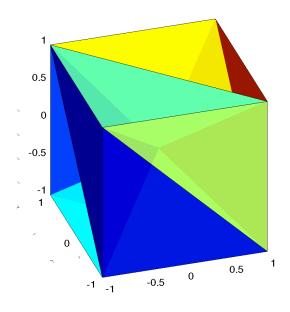

This example generates an n-D Delaunay tessellation, where n = 3.

```
\begin{array}{lll} d = [-1 \ 1]; \\ [x,y,z] = meshgrid(d,d,d); & \text{$M$ cube} \\ x = [x(:);0]; \\ y = [y(:);0]; \\ z = [z(:);0]; \\ & [x,y,z] \text{ are corners of a cube plus the center.} \\ X = [x(:) \ y(:) \ z(:)]; \\ Tes = delaunayn(X) \\ \end{array}
```

Purpose De

Delete files or graphics objects

Graphical Interface

As an alternative to the del et e function, you can delete files using the Current Directory browser. To open it, select **Current Directory** from the **View** menu

in the MATLAB desktop.

Syntax

delete filename

del ete(h)

del ete(' filename')

Description

delete filename deletes the named file from the disk. The filename may include an absolute pathname or a pathname relative to the current directory. The filename may also include wildcards, (*).

del ete(h) deletes the graphics object with handle h. The function deletes the object without requesting verification even if the object is a window.

 $del\ ete('\ fi\ l\ ename')$ is the function form of $del\ ete.$ Use this form when the filename is stored in a string.

Note MATLAB does not ask for confirmation when you enter the delete command. To avoid accidentally losing files or graphics objects that you need, make sure that you have accurately specified the items you want deleted.

Examples

To delete all files with a . mat extension in the \dots /mytests/ directory,

del ete('../mytests/*.mat')

To delete a directory, use $!\operatorname{rmdi} r$ rather than $\operatorname{del}\operatorname{ete}.$

!rmdir mydirectory

See Also

dir, type

delete (activex)

Purpose Delete an ActiveX control or server.

Syntax del ete (a)

Arguments a

An acti vex object previously returned from actxcontrol, actxserver, get, or

i nvoke.

Description Delete an ActiveX control or server. This is different than releasing an

interface, which releases and invalidates only that interface. del et e releases all outstanding interfaces and deletes the ActiveX server or control itself.

Example del ete (a)

Purpose Remove a serial port object from memory

Syntax del ete(obj)

Arguments obj A serial port object or an array of serial port objects.

Description del ete(obj) removes obj from memory.

Remarks

When you delete obj, it becomes an *invalid* object. Since you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the clear command. If multiple references to objects in the workspace, then deleting one reference invalidates the remaining references.

If you attempt to delete obj while it is connected to the device, then an error is returned. A connected serial port object has a Status property value of open. You can disconnect obj from the device with the fcl ose function.

If you use the help command to display help for delete, then you need to supply the pathname shown below.

help serial/delete

Example

This example creates the serial port object s, connects s to the device, writes and reads text data, disconnects s from the device, removes s from memory using del ete, and then removes s from the workspace using cl ear.

```
s = serial('COM1');
fopen(s)
fprintf(s,'*IDN?')
idn = fscanf(s);
fclose(s)
delete(s)
clear s
```

Properties Status

depdir

Purpose

List the dependent directories of an M-file or P-file

Syntax

```
list = depdir('file_name');
[list, prob_files, prob_sym, prob_strings] = depdir('file_name');
[...] = depdir('file_name1', 'file_name2',...);
```

Description

The depdi r function lists the directories of all of the functions that a specified M-file or P-file needs to operate. This function is useful for finding all of the directories that need to be included with a runtime application and for determining the runtime path.

list = depdir('file_name') creates a cell array of strings containing the directories of all the M-files and P-files that file_name. m or file_name. p uses. This includes the second-level files that are called directly by file_name, as well as the third-level files that are called by the second-level files, and so on.

[list, prob_files, prob_sym, prob_strings] = depdir('file_name') creates three additional cell arrays containing information about any problems with the depdir search. prob_files contains filenames that depdir was unable to parse. prob_sym contains symbols that depdir was unable to find. prob_strings contains callback strings that depdir was unable to parse.

[...] = depdi r('file_name1', 'file_name2',...) performs the same operation for multiple files. The dependent directories of all files are listed together in the output cell arrays.

Example

```
list = depdir('mesh')
```

See Also

depfun

List the dependent functions of an M-file or P-file

Syntax

```
list = depfun('file_name');
[list, builtins, classes] = depfun('file_name');
[list, builtins, classes, prob_files, prob_sym, eval_strings, ...
    called_from, java_classes] = depfun('file_name');
[...] = depfun('file_name1', 'file_name2', ...);
[...] = depfun('fig_file_name');
[...] = depfun(..., '-toponly');
```

Description

The depf un function lists all of the functions and scripts, as well as built-in functions, that a specified M-file needs to operate. This is useful for finding all of the M-files that you need to compile for a MATLAB runtime application.

list = depfun('file_name') creates a cell array of strings containing the paths of all the files that file_name. m uses. This includes the second-level files that are called directly by file_name. m, as well as the third-level files that are called by the second-level files, and so on.

Note If depfun reports that "These files could not be parsed:" or if the prob_files output below is nonempty, then the rest of the output of depfun might be incomplete. You should correct the problematic files and invoke depfun again.

 $[list,builtins,classes] = depfun('file_name') \ creates three cell arrays containing information about dependent functions. list contains the paths of all the files that file_name and its subordinates use. builtins contains the built-in functions that file_name and its subordinates use. classes contains the MATLAB classes that file_name and its subordinates use.$

[list, builtins, classes, prob_files, prob_sym, eval_strings, . . . called_from, java_classes] = depfun('file_name') creates additional cell arrays or structure arrays containing information about any problems with the depfun search and about where the functions in list are invoked. The additional outputs are:

- prob_files, which indicates which files depfun was unable to parse, find, or access. Parsing problems can arise from MATLAB syntax errors. prob_files is a structure array whose fields are:
 - name, which gives the names of the files
 - listindex, which tells where the files appeared in list
 - errmsg, which describes the problems
- prob_sym, which indicates which symbols depf un was unable to resolve as functions or variables. It is a structure array whose fields are:
 - fcn_i d, which tells where the files appeared in l i st
 - name, which gives the names of the problematic symbols
- eval_stri ngs, which indicates usage of these evaluation functions: eval, eval c, eval i n, feval. When preparing a runtime application, you should examine this output to determine whether an evaluation function invokes a function that does not appear in list. The output eval_strings is a structure array whose fields are:
 - fcn_name, which give the names of the files that use evaluation functions
 - lineno, which gives the line numbers in the files where the evaluation functions appear
- called_from, a cell array of the same length as list. This cell array is arranged so that

```
list(called\_from{i}) returns all functions in file\_name that invoke the function list{i}.
```

• j ava_cl asses, a cell array of Java class names that file_name and its subordinates use

[...] = depfun('file_name1', 'file_name2',...) performs the same operation for multiple files. The dependent functions of all files are listed together in the output arrays.

[...] = depfun('fig_file_name') looks for dependent functions among the callback strings of the GUI elements that are defined in the . fig or . mat file named fig_file_name.

[...] = depfun(..., '-toponly') differs from the other syntaxes of depfun in that it examines *only* the files listed explicitly as input arguments. It does

not examine the files on which they depend. In this syntax, the flag ' - toponl y' must be the last input argument.

Notes

- 1 If depf un does not find a file called hgi nfo. mat on the path, then it creates one. This file contains information about Handle Graphics callbacks.
- 2 If your application uses toolbar items from MATLAB's default figure window, then you must include 'FigureToolBar.fig' in your input to depfun.
- 3 If your application uses menu items from MATLAB's default figure window, then you must include 'Fi gureMenuBar. fi g' in your input to depfun.
- 4 Because many built-in Handle Graphics functions invoke newpl ot, the list produced by depfun always includes the functions on which newpl ot is dependent:
 - 'matlabroot\tool box\matlab\graphi cs\newpl ot. m'
 - 'matlabroot\tool box\matlab\graphi cs\closereq. m'
 - ' matlabroot\tool box\matlab\graphi cs\gcf. m'
 - ' matlabroot\tool box\matlab\graphi cs\gca. m'
 - 'matlabroot\tool box\matlab\graphi cs\pri vate\clo. m'
 - ' matlabroot\tool box\matlab\general \@char\del ete. m'
 - ' matlabroot\tool box\matlab\l ang\nargchk. m'
 - 'matlabroot\toolbox\matlab\uitools\allchild.m'
 - ' matlabroot\tool box\matlab\ops\setdiff. m'
 - 'matlabroot\toolbox\matlab\ops\@cell\setdiff.m'
 - 'matlabroot\toolbox\matlab\iofun\filesep. m'
 - ' matlabroot\tool box\matlab\ops\uni que. m'
 - ' matlabroot\tool box\matlab\el mat\repmat. m'
 - ' matlabroot\tool box\matlab\datafun\sortrows. m'
 - 'matlabroot\toolbox\matlab\strfun\deblank.m'
 - 'matlabroot\toolbox\matlab\ops\@cell\unique.m'
 - 'matlabroot\toolbox\matlab\strfun\@cell\deblank.m'
 - 'matlabroot\toolbox\matlab\datafun\@cell\sort.m'
 - 'matlabroot\toolbox\matlab\strfun\cellstr.m'
 - ' matlabroot\tool box\matlab\datatypes\i scell. m'
 - ' matlabroot\tool box\matlab\strfun\i scell str. m'
 - ' matlabroot\tool box\matlab\datatypes\cellfun. dll'

depfun

```
list = depfun('mesh'); % Files mesh. m depends on
list = depfun('mesh','-toponly') % Files mesh. m depends on
directly
[list, builtins, classes] = depfun('gca');
See Also
depdir
```

Matrix determinant

Syntax

d = det(X)

Description

d = det(X) returns the determinant of the square matrix X. If X contains only integer entries, the result d is also an integer.

Remarks

Using $\det(X) == 0$ as a test for matrix singularity is appropriate only for matrices of modest order with small integer entries. Testing singularity using $\operatorname{abs}(\det(X)) <= \operatorname{tol}\operatorname{erance}$ is not recommended as it is difficult to choose the correct tolerance. The function $\operatorname{cond}(X)$ can check for singular and nearly singular matrices.

Algorithm

The determinant is computed from the triangular factors obtained by Gaussian elimination $% \left(1\right) =\left(1\right) +\left(1\right) +\left$

Examples

The statement $A = [1 \ 2 \ 3; \ 4 \ 5 \ 6; \ 7 \ 8 \ 9]$

produces

This happens to be a singular matrix, so d = det(A) produces d = 0. Changing A(3, 3) with A(3, 3) = 0 turns A into a nonsingular matrix. Now d = det(A) produces d = 27.

cond, condest, inv, lu, rref

The arithmetic operators \setminus , /

Remove linear trends.

Syntax

```
y = detrend(x)
```

y = detrend(x, 'constant')

y = detrend(x, 'linear', bp)

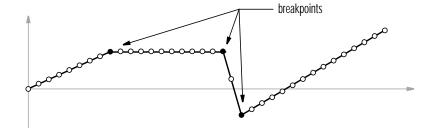

Description

detrend removes the mean value or linear trend from a vector or matrix, usually for FFT processing.

y = detrend(x) removes the best straight-line fit from vector x and returns it in y. If x is a matrix, detrend removes the trend from each column.

y = detrend(x, 'constant') removes the mean value from vector x or, if x is a matrix, from each column of the matrix.

y = detrend(x, 'linear', bp) removes a continuous, piecewise linear trend from vector x or, if x is a matrix, from each column of the matrix. Vector bp contains the indices of the breakpoints between adjacent linear segments. The breakpoint between two segments is defined as the data point that the two segments share.

 $\det \text{rend}(x, ' \text{linear'})$, with no breakpoint vector specified, is the same as $\det \text{rend}(x)$.

Example

$$sig = [0 \ 1 \ -2 \ 1 \ 0 \ 1 \ -2 \ 1 \ 0];$$

$$trend = [0 \ 1 \ 2 \ 3 \ 4 \ 3 \ 2 \ 1 \ 0];$$

x = sig+trend;

y = detrend(x, 'linear', 5)

% signal with no linear trend

% two-segment linear trend

 $\% \ signal \ with \ added \ trend$

% breakpoint at 5th element

y =

- 0. 0000
- 1.0000
- 2. 0000
- 1.0000
- 0.0000
- 1.0000
- 2. 0000
 - 1.0000
- 0. 0000

Note that the breakpoint is specified to be the fifth element, which is the data point shared by the two segments.

Algorithm

detrend computes the least-squares fit of a straight line (or composite line for piecewise linear trends) to the data and subtracts the resulting function from the data. To obtain the equation of the straight-line fit, use polyfit.

See Also

pol yfi t

deval

Purpose Evaluate the solution of a differential equation problem

Syntax sxi nt = deval (sol, xi nt)

Description sxi nt = deval (sol, xint) evaluates the solution of a differential equation

problem at each element of the vector xi nt. For each i, sxi nt (:,i) is the

solution corresponding to xi nt(i).

The input argument sol is a structure returned by an initial value problem solver (ode45, ode23, ode113, ode15s, ode23s, ode23t, ode23tb) or the boundary value problem solver (bvp4c). The ordered row vector sol. x contains the independent variable. For each i, the column sol. y(:,i) contains the solution at sol. x(i). The structure sol also contains data needed for interpolating the solution in (x(i), x(i+1)). The form of this data depends on the solver that creates sol. The field sol. solver contains the name of that

solver.

Elements of xi nt must be in the interval [sol. x(1), sol. x(end)].

See Also ODE solvers: ode45, ode23, ode113, ode15s, ode23t, ode23tb

BVP solver: bvp4c

Diagonal matrices and diagonals of a matrix

Syntax

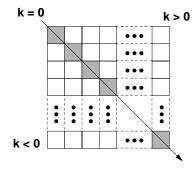

X = di ag(v, k)X = di ag(v)

v = di ag(X, k)

v = di ag(X)

Description

 $X=di\,ag(v,k)$ when v is a vector of n components, returns a square matrix X of order n+abs(k), with the elements of v on the kth diagonal. k=0 represents the main diagonal, k>0 above the main diagonal, and k<0 below the main diagonal.

 $X = di \, ag(v)$ puts v on the main diagonal, same as above with k = 0.

 $v = di \ ag(X, k)$ for matrix X, returns a column vector v formed from the elements of the kth diagonal of X.

 $v = di \, ag(X)$ returns the main diagonal of X, same as above with k = 0.

Examples

diag(diag(X)) is a diagonal matrix.

sum(diag(X)) is the trace of X.

The statement

diag(-m:m) + diag(ones(2*m, 1), 1) + diag(ones(2*m, 1), -1)

produces a tridiagonal matrix of order 2*m+1.

diag

See Also

spdiags, tril, triu

Purpose Create and display dialog box

Syntax h = di al og(' PropertyName', PropertyVal ue, ...)

Description h = di al og(' *PropertyName*', PropertyVal ue, ...) returns a handle to a

dialog box. This function creates a figure graphics object and sets the figure properties recommended for dialog boxes. You can specify any valid figure

property value.

See Also errordl g, fi gure, hel pdl g, i nputdl g, pagedl g, pri ntdl g, questdl g, ui wai t,

ui resume, warndl g

diary

Purpose

Save session to a file

Syntax

di ary

diary('filename')

diary **off** diary **on**

diary filename

Description

The di ary function creates a log of keyboard input and the resulting output (except it does not include graphics). The output of di ary is an ASCII file, suitable for printing or for inclusion in reports and other documents. If you do not specify filename, MATLAB creates a file named di ary in the current directory.

di ary toggles di ary mode on and off. To see the status of di ary, type $get(\mathbf{0}, '\mathbf{Di}\,\mathbf{ary}')$. MATLAB returns either on or off indicating the di ary status.

diary('filename') writes a copy of all subsequent keyboard input and the resulting output (except it does not include graphics) to the named file. If the file already exists, output is appended to the end of the file. You cannot use a filename called off or on. To see the name of the diary file, use $get(\mathbf{0}, '\mathbf{DiaryFile}')$. Type $get(\mathbf{0}, '\mathbf{DiaryName}')$, and MATLAB returns filename.

di ary off suspends the diary.

diary on resumes diary mode using the current filename, or the default filename diary if none has yet been specified.

diary filename is the unquoted form of the syntax.

See Also

Command History window

Differences and approximate derivatives

Syntax

$$Y = di ff(X)$$

 $Y = di ff(X, n)$
 $Y = di ff(X, n, di m)$

Description

Y = di ff(X) calculates differences between adjacent elements of X.

If X is a vector, then diff(X) returns a vector, one element shorter than X, of differences between adjacent elements:

$$[X(2)-X(1) \ X(3)-X(2) \ \dots \ X(n)-X(n-1)]$$

If X is a matrix, then diff(X) returns a matrix of row differences:

$$[X(2: m, :) - X(1: m-1, :)]$$

In general, diff(X) returns the differences calculated along the first non-singleton (si ze(X, dim) > 1) dimension of X.

Y = di ff(X, n) applies di ff recursively n times, resulting in the nth difference. Thus, di ff(X, 2) is the same as di ff(di ff(X)).

Y = diff(X, n, dim) is the nth difference function calculated along the dimension specified by scalar dim. If order n equals or exceeds the length of dimension dim, diff returns an empty array.

Remarks

Since each iteration of diff reduces the length of X along dimension di m, it is possible to specify an order n sufficiently high to reduce di m to a singleton (si ze(X, di m) = 1) dimension. When this happens, diff continues calculating along the next nonsingleton dimension.

Examples

The quantity $\operatorname{diff}(y)$. $\operatorname{/diff}(x)$ is an approximate derivative.

$$x = [1 \ 2 \ 3 \ 4 \ 5];$$

 $y = di ff(x)$
 $y =$

$$1 \quad 1 \quad 1 \quad 1$$

$$z = di ff(x, 2)$$

$$z =$$

 $0 \qquad 0 \qquad 0$ Given, A = rand(1,3,2,4); diff(A) is the first-order difference along dimension 2. diff(A,3,4) is the third-order difference along dimension 4.

See Also gradient, prod, sum

Display directory listing

Graphical Interface

As an alternative to the dir function, use the Current Directory browser. To open it, select **Current Directory** from the **View** menu in the MATLAB desktop.

Syntax

```
dir
dir name
files = dir('name')
```

Description

dir lists the files in the current working directory.

dir name lists the specified files. The name argument can be a pathname, filename, or can include both. You can use absolute and relative pathnames and wildcards.

files = dir('directory') returns the list of files in the specified directory (or the current directory, if di rname is not specified) to an m-by-1 structure with the fields:

name	Filename
date	Modification date
bytes	Number of bytes allocated to the file
i sdi r	1 if name is a directory; 0 if not

Examples

To view the MAT files in your current working directory,

```
dir *java*.mat
java_array.mat javafrmobj.mat testjava.mat
```

To view the M-files in the MATLAB audi o directory, type

```
dir(fullfile(matlabroot, 'toolbox/matlab/audio/*.m'))
```

```
Contents. m lin2mu. m sound. m wavread. m auread. m mu2lin. m soundsc. m wavrecord. m auwrite. m saxis. m wavplay. m wavwrite. m
```

To return the list of files to the variable audi o_files, type

See Also

```
audi o_files=dir(fullfile(matlabroot, 'tool box/matlab/audio/
*.m'))

MATLAB returns the information in a structure array.

audi o_files =
    12x1 struct array with fields:
        name
        date
        bytes
        isdir

Index into the structure to access a particular item. For example,
    audi o_files(3). name
    ans =
        auwrite. m
cd, delete, filebrowser, ls, type, what
```

Purpose Display text or array

Description $\operatorname{disp}(X)$ displays an array, without printing the array name. If X contains a

text string, the string is displayed.

Another way to display an array on the screen is to type its name, but this

prints a leading "X =, " which is not always desirable.

Note that disp does not display empty arrays.

Examples One use of di sp in an M-file is to display a matrix with column labels:

disp(' Corn Oats Hay') disp(rand(5,3))

which results in

Corn	0ats	Hay
0. 2113	0.8474	0. 2749
0. 0820	0. 4524	0.8807
0. 7599	0.8075	0. 6538
0. 0087	0. 4832	0. 4899
0. 8096	0. 6135	0. 7741

See Also format, int2str, num2str, rats, sprintf

disp (serial)

Purpose Display serial port object summary information

Syntax obj

di sp(obj)

Arguments obj A serial port object or an array of serial port objects.

Description obj or di sp(obj) displays summary information for obj.

Remarks In addition to the syntax shown above, you can display summary information for obj by excluding the semicolon when:

• Creating a serial port object

• Configuring property values using the dot notation

Use the display summary to quickly view the communication settings, communication state information, and information associated with read and write operations.

Example The following commands display summary information for the serial port

object s.

s = serial('COM1') s.BaudRate = 300

 \mathbf{s}

Overloaded method to display an object

Syntax

di spl ay(X)

Description

 $di \, spl \, ay(X)$ prints the value of a variable or expression, X. MATLAB calls $di \, spl \, ay(X)$ when it interprets a variable or expression, X, that is not terminated by a semicolon. For example, $si \, n(A)$ calls $di \, spl \, ay$, while $si \, n(A)$; does not.

If X is an instance of a MATLAB class, then MATLAB calls the display method of that class, if such a method exists. If the class has no display method or if X is not an instance of a MATLAB class, then the MATLAB builtin display function is called.

Examples

A typical implementation of display calls disp to do most of the work and looks like this.

```
function display(X)
if isequal(get(0, 'FormatSpacing'), 'compact')
    disp([inputname(1) ' =']);
    disp(X)
else
    disp(' ')
    disp([inputname(1) ' =']);
    disp(' ');
    disp(X)
end
```

The expression magi c(3), with no terminating semicolon, calls this function as display(magi c(3)).

As an example of a class display method, the function below implements the display method for objects of the MATLAB class, polynom.

```
function display(p)
% POLYNOM/DISPLAY Command window display of a polynom
disp(' ');
disp([inputname(1),' = '])
disp(' ');
disp([' ' char(p)])
disp(' ');
```

The statement

```
p = polynom([1 \ 0 \ -2 \ -5])
```

creates a pol ynom object. Since the statement is not terminated with a semicolon, the MATLAB interpreter calls di spl ay(p), resulting in the output

```
p = x^3 - 2x - 5
```

See Also

disp, ans, sprintf, special characters

Computes the divergence of a vector field

Syntax

```
di v = di vergence(X, Y, Z, U, V, W)
di v = di vergence(U, V, W)
di v = di vergence(X, Y, U, V)
di v = di vergence(U, V)
```

Description

 $di v = di \, vergence(X, Y, Z, U, V, W)$ computes the divergence of a 3-D vector field U, V, W. The arrays X, Y, Z define the coordinates for U, V, W and must be monotonic and 3-D plaid (as if produced by meshgri d).

 $\operatorname{div} = \operatorname{divergence}(U, V, W)$ assumes X, Y, and Z are determined by the expression:

```
[X \ Y \ Z] = meshgrid(1: n, 1: m, 1: p)
where [m, n, p] = size(U).
```

 $di v = di \, vergence(X, Y, U, V)$ computes the divergence of a 2-D vector field U, V. The arrays X, Y define the coordinates for U, V and must be monotonic and 2-D plaid (as if produced by meshgri d).

 $di\ v = di\ vergence(U,\ V)$ assumes X and Y are determined by the expression:

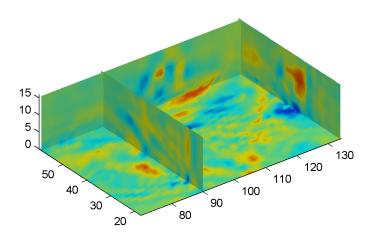

```
[X Y] = meshgrid(1: n, 1: m)
where [m, n] = size(U).
```

Examples

This example displays the divergence of vector volume data as slice planes using color to indicate divergence.

```
load wind
div = divergence(x, y, z, u, v, w);
slice(x, y, z, div, [90 134], [59], [0]);
shading interp
daspect([1 1 1])
camlight
```

divergence

streamtube, curl, isosurface

Purpose Read an ASCII delimited file into a matrix

Graphical Interface As an alternative to dl mread, use the Import Wizard. To activate the Import Wizard, select **Import data** from the **File** menu.

Syntax

M = dl mread(filename, delimiter)
M = dl mread(filename, delimiter, R, C)
M = dl mread(filename, delimiter, range)

Description

M = dl mread(filename, delimiter) reads numeric data from the ASCII delimited file filename, using the specified delimiter. A comma (,) is the default delimiter. Use '\t' to specify a tab delimiter.

 $M = dl \ mread(filename, delimiter, R, C)$ reads numeric data from the ASCII delimited file filename, using the specified delimiter. The values R and C specify the row and column where the upper-left corner of the data lies in the file. R and C are zero based so that R=0, C=0 specifies the first value in the file, which is the upper left corner.

 $M = dl \, mread(filename, delimiter, range)$ reads the range specified by range = [R1 C1 R2 C2] where (R1, C1) is the upper-left corner of the data to be read and (R2, C2) is the lower-right corner. range can also be specified using spreadsheet notation as in range = 'A1..B7'.

Remarks

dl mread fills empty delimited fields with zero. Data files having lines that end with a non-space delimiter, such as a semi-colon, produce a result that has an additional last column of zeros.

See Also

dl mwrite, textread, csvread, csvwrite, wk1read, wk1write

dlmwrite

Purpose Write a matrix to an ASCII delimited file

Syntax dl mwrite(filename, M, delimiter)

dl mwrite(filename, M, delimiter, R, C)

Description dl mwrite(filename, M, delimiter) writes matrix Minto an ASCII-format file,

using delimiter to separate matrix elements. The data is written to the upper left-most cell of the spreadsheet filename. A comma (,) is the default delimiter.

Use '\t' to produce tab-delimited files.

dl mwrite(filename, M, delimiter, R, C) writes matrix A into an ASCII-format file, using delimiter to separate matrix elements. The data is written to the spreadsheet filename, starting at spreadsheet cell R and C, where R is the row offset and C is the column offset. R and C are zero based so that R=0, C=0

specifies the first value in the file, which is the upper left corner.

Remarks The resulting file is readable by spreadsheet programs.

See Also dl mread, csvwrite, csvread, wk1write, wk1read

Dulmage-Mendelsohn decomposition

Syntax

```
p = dmperm(A)
[p, q, r] = dmperm(A)
[p, q, r, s] = dmperm(A)
```

Description

If A is a reducible matrix, the linear system Ax = b can be solved by permuting A to a block upper triangular form, with irreducible diagonal blocks, and then performing block backsubstitution. Only the diagonal blocks of the permuted matrix need to be factored, saving fill and arithmetic in the blocks above the diagonal.

p=dmperm(A) returns a row permutation p so that if A has full column rank, A(p,:) is square with nonzero diagonal. This is also called a *maximum matching*.

[p,q,r] = dmperm(A) where A is a square matrix, finds a row permutation p and a column permutation q so that A(p,q) is in block upper triangular form. The third output argument r is an integer vector describing the boundaries of the blocks: The kth block of A(p,q) has indices r(k):r(k+1)-1.

[p, q, r, s] = dmperm(A), where A is not square, finds permutations p and q and index vectors r and s so that A(p, q) is block upper triangular. The blocks have indices (r(i):r(i+1)-1, s(i):s(i+1)-1).

If A is not square, the first block may have more columns and the last block may have more rows. All other blocks are square. dmperm permutes nonzeros to the diagonals of square blocks, but does not do this for non-square blocks.

In graph theoretic terms, the diagonal blocks correspond to strong Hall components of the adjacency graph of A.

sprank

doc

Purpose Display online documentation in MATLAB Help browser

Graphical Interface As an alternative to the doc function, use the Help browser **Search** tab. Set the **Search type** to **Function Name**, type the function name, and click **Go**.

Syntax doc

doc function
doc toolbox/

doc tool box/function

Description doc opens the Help browser, if it is not already running.

doc functi on displays the reference page for the MATLAB function functi on in the Help browser. If functi on is overloaded, doc displays the reference page for the first functi on on the search path and lists the overloaded functions in the MATLAB Command Window. If a reference page for the function does not exist, doc displays M-file help in the Help browser.

doc tool box/ displays the Roadmap page, a summary of the most pertinent documentation for tool box, in the Help browser.

doc tool box/functi on displays the reference page for functi on that belongs to the specified tool box, in the Help browser.

See Also hel p, hel pbrowser, l ookfor, type, web

Display location of help file directory for UNIX platforms

Syntax

docopt

[doccmd, options, docpath] = docopt

Description

docopt displays the location of the online help files directory (online documentation location) for UNIX platforms if the web function is used with the -browser option. It is also used for UNIX platforms that do not support Java GUIs – see the R12 Release Notes for more information about these platforms. You specify where the online help directory will be located when you install MATLAB. It can be on a disk or CD-ROM drive in your local system. If you relocate your online help file directory, edit the docopt. m file, changing the location in it. (For Windows and the UNIX platforms that support Java GUIs, select File -> Preferences -> Help to view or change the documentation location.)

[doccmd, options, docpath] = docopt displays three strings: doccmd, options, and docpath.

doccmd The function that doc uses to display MATLAB documentation.

The default is netscape.

options Additional configuration options for use with documd.

docpath The path to the MATLAB online help files. If docpath is empty,

the doc function assumes the help files are in the default

location.

Remarks

To globally replace the online help file directory location, update <code>Smatlabroot/toolbox/local/docopt.m.</code>

To override the global setting, copy Smatl abroot/tool box/l ocal/docopt. m to SHOME/matl ab/docopt. m and make changes there. For the changes to take effect in the current MATLAB session, SHOME/matl ab must be on your MATLAB path.

Execute a DOS command and return result

Syntax

```
dos command
status = dos('command')
[status, result] = dos('command')
[status, result] = dos('command', '-echo')
```

Description

dos command calls upon the shell to execute the given command for Windows systems.

status = dos('command') returns completion status to the status variable.

[status, result] = dos('command') in addition to completion status, returns the result of the command to the result variable.

[status, result] = dos('command', '-echo') forces the output to the Command Window, even though it is also being assigned into a variable.

Both console (DOS) programs and Windows programs may be executed, but the syntax causes different results based on the type of programs. Console programs have st dout and their output is returned to the result variable. They are always run in an iconified DOS or Command Prompt Window except as noted below. Console programs never execute in the background. Also, MATLAB will always wait for the st dout pipe to close before continuing execution. Windows programs may be executed in the background as they have no st dout.

The ampersand, &, character has special meaning. For console programs this causes the console to open. Omitting this character will cause console programs to run iconically. For Windows programs, appending this character will cause the application to run in the background. MATLAB will continue processing.

Examples

The following example performs a directory listing, returning a zero (success) in s and the string containing the listing in w.

```
[s, w] = dos('dir');
```

To open the DOS 5.0 editor in a DOS window

```
dos('edit &')
```

To open the notepad editor and return control immediately to MATLAB

```
dos('notepad file.m &')
```

The next example returns a one in s and an error message in w because foo is not a valid shell command.

```
[s, w] = dos('foo')
```

This example echoes the results of the dir command to the Command Window as it executes as well as assigning the results to w.

```
[s, w] = dos('dir', '-echo');
```

See Also

Special Characters (!), uni x

dot

Purpose

Vector dot product

Syntax

$$C = dot(A, B)$$

 $C = dot(A, B, dim)$

Description

C = dot(A, B) returns the scalar product of the vectors A and B. A and B must be vectors of the same length. When A and B are both column vectors, dot(A, B) is the same as A'*B.

For multidimensional arrays A and B, dot returns the scalar product along the first non-singleton dimension of A and B. A and B must have the same size.

C = dot(A, B, dim) returns the scalar product of A and B in the dimension dim.

Examples

The dot product of two vectors is calculated as shown:

$$a = [1 \ 2 \ 3]; b = [4 \ 5 \ 6];$$
 $c = dot(a, b)$

$$c = 32$$

See Also

cross

double

Purpose Convert to double-precision

Syntax doubl e(X)

Description doubl e(x) returns the double-precision value for X. If X is already a

double-precision array, double has no effect.

Remarks double is called for the expressions in for, if, and while loops if the expression

isn't already double-precision. doubl e should be overloaded for any object when

it makes sense to convert it to a double-precision value.

dragrect

Purpose

Drag rectangles with mouse

Syntax

```
[finalrect] = dragrect(initialrect)
```

[finalrect] = dragrect(initialrect, stepsize)

Description

[final rect] = dragrect(initial rect) tracks one or more rectangles anywhere on the screen. The n-by-4 matrix, initial rect, defines the rectangles. Each row of initial rect must contain the initial rectangle position as [left bottom width height] values. dragrect returns the final position of the rectangles in final rect.

[fi nal rect] = dragrect (i ni ti al rect, stepsi ze) moves the rectangles in increments of stepsi ze. The lower-left corner of the first rectangle is constrained to a grid of size equal to stepsi ze starting at the lower-left corner of the figure, and all other rectangles maintain their original offset from the first rectangle.

[final rect] = dragrect(...) returns the final positions of the rectangles when the mouse button is released. The default stepsize is 1.

Remarks

dragrect returns immediately if a mouse button is not currently pressed. Use dragrect in a ButtonDownFcn, or from the command line in conjunction with waitforbuttonpress to ensure that the mouse button is down when dragrect is called. dragrect returns when you release the mouse button.

If the drag ends over a figure window, the positions of the rectangles are returned in that figure's coordinate system. If the drag ends over a part of the screen not contained within a figure window, the rectangles are returned in the coordinate system of the figure over which the drag began

Example

Drag a rectangle that is 50 pixels wide and 100 pixels in height.

```
waitforbuttonpress
point1 = get(gcf, 'CurrentPoint') % button down detected
rect = [point1(1,1) point1(1,2) 50 100]
[r2] = dragrect(rect)
```

See Also

rbbox, waitforbuttonpress

Purpose Complete pending drawing events

Syntax drawnow

Description drawnow flushes the event queue and updates the figure window.

Remarks Other events that cause MATLAB to flush the event queue and draw the figure windows include:

- Returning to the MATLAB prompt
- A pause statement
- A wai tforbuttonpress statement
- A wai tfor statement
- A getframe statement
- A fi gure statement

Examples Executing the statements,

```
x = -pi : pi / 20: pi ;

pl ot (x, cos(x))

drawnow

title('A Short Title)
```

title('A Short Title')

grid on

as an M-file updates the current figure after executing the drawnow function and after executing the final statement.

See Also waitfor, pause, waitforbuttonpress

dsearch

Purpose Search for nearest point

Syntax K = dsearch(x, y, TRI, xi, yi)

K = dsearch(x, y, TRI, xi, yi, S)

Description K = dsearch(x, y, TRI, xi, yi) returns the index into x and y of the nearest

point to the point (xi, yi). dsearch requires a triangulation TRI of the points x,y obtained using del aunay. If xi and yi are vectors, K is a vector of the same size.

K = dsearch(x, y, TRI, xi, yi, S) uses the sparse matrix S instead of

computing it each time:

S = sparse(TRI(:, [1 1 2 2 3 3]), TRI(:, [2 3 1 3 1 2]), 1, nxy, nxy)

where nxy = prod(size(x)).

See Also del aunay, tsearch, voronoi

n-D nearest point search

Syntax

k = dsearchn(X, T, XI)

k = dsearchn(X, T, XI, outval)

k = dsearchn(X, XI)

[k, d] = dsearchn(X, ...)

Description

k = dsearchn(X, T, XI) returns the indices k of the closest points in X for each point in XI. X is an m-by-n matrix representing m points in n-D space. XI is a p-by-n matrix, representing p points in n-D space. T is a numt-by-n+1 matrix, a tessellation of the data X generated by del aunayn. The output k is a column vector of length p.

k = dsearchn(X, T, XI, outval) returns the indices k of the closest points in X for each point in XI, unless a point is outside the convex hull. If XI(J,:) is outside the convex hull, then K(J) is assigned outval, a scalar double. Inf is often used for outval. If outval is [], then k is the same as in the case k = dsearchn(X, T, XI).

k = dsearchn(X, XI) performs the search without using a tessellation. With large X and small XI, this approach is faster and uses much less memory.

[k, d] = dsearchn(X, ...) also returns the distances d to the closest points. d is a column vector of length p.

See Also

tsearch, dsearch, tsearchn, griddatan, del aunayn

echo

Purpose

Echo M-files during execution

Syntax

echo on echo off echo

echo fcnname on echo fcnname off echo fcnname echo on all echo off all

Description

The echo command controls the echoing of M-files during execution. Normally, the commands in M-files do not display on the screen during execution. Command echoing is useful for debugging or for demonstrations, allowing the commands to be viewed as they execute.

The echo command behaves in a slightly different manner for script files and function files. For script files, the use of echo is simple; echoing can be either on or of f, in which case any script used is affected.

echo on Turns on the echoing of commands in all script files.

echo off Turns off the echoing of commands in all script files.

echo Toggles the echo state.

With function files, the use of echo is more complicated. If echo is enabled on a function file, the file is interpreted, rather than compiled. Each input line is then displayed as it is executed. Since this results in inefficient execution, use echo only for debugging.

echo fcnname on Turns on echoing of the named function file.

echo fcnname off Turns off echoing of the named function file.

echo fcnname Toggles the echo state of the named function file.

echo on all Set echoing on for all function files.
echo off all Set echoing off for all function files.

See Also

function

Purpose Edit or create M-file

Graphical Interface

As an alternative to the edit function, select **New** or **Open** from the **File** menu in the MATLAB desktop.

Syntax

edi t

edit fun.m edit file.ext edit class/fun edit private/fun

edit class/private/fun

Description

edi t opens a new editor window.

edit fun. m opens the M-file fun. min the default editor. If fun. m does not exist, a prompt appears asking if you want to create a new file titled fun. m. After clicking **Yes**, the Editor/Debugger creates a blank file titled fun. m. If you do not want the prompt to appear in this situation, check that box in the prompt or specify it in preferences for "Prompt" on page 7-38. If you type edit fun and there is no file fun, fun. m opens in the default editor.

edit file. ext opens the specified text file.

edit class/fun, edit private/fun, or edit class/private/fun can be used to edit a method, private function, or private method (for the class named class).

Remarks

To specify the default editor for MATLAB, select **Preferences** from the **File** menu. On the **Editor/Debugger** panel, select MATLAB's Editor/Debugger or specify another.

UNIX Users

If you run MATLAB with the -nodi spl ay startup option, or run without the DI SPLAY environment variable set, edit uses the External Editor command. It does not use the MATLAB Editor/Debugger, but instead uses the default editor defined for your system in <code>Smatlabroot/X11/app-defaults/Matlab</code>.

You can specify the editor that the edit function uses or specify editor options by adding the following line to your own . Xdefaults file, located in ~home.

matlab*externalEditorCommand: SEDITOR - option \$FILE

where:

- SEDITOR is the name of your default editor, for example, emacs; leaving it as SEDITOR means your default system editor will be used.
- option is an option flag for the specified editor.
- **\$FILE** means the filename you type with the edit command will open in the specified editor.

Then, before starting MATLAB, run

```
xrdb -merge ~home/. Xdefaults
```

For the HP 700 platform, the default editor is instead defined in \mbox{smatl} abroot/tool box/matl ab/general /edit. m. To change it, open the file edit. m and edit the line

```
eval(['!$EDITOR "' file '" &']);
```

See Also

open, type

Find eigenvalues and eigenvectors

Syntax

```
d = eig(A)
d = eig(A, B)
[V, D] = eig(A)
[V, D] = eig(A, 'nobal ance')
[V, D] = eig(A, B)
[V, D] = eig(A, B, flag)
```

Description

d = eig(A) returns a vector of the eigenvalues of matrix A.

Note If S is sparse and symmetric, you can use d = eig(S) to returns the eigenvalues of S. To request eigenvectors, and in all other cases, use eigs to find the eigenvalues or eigenvectors of sparse matrices.

 $d=ei\,g(A,B)\,$ returns a vector containing the generalized eigenvalues, if A and B are square matrices.

 $[V, D] = \operatorname{eig}(A)$ produces matrices of eigenvalues (D) and eigenvectors (V) of matrix A, so that A*V = V*D. Matrix D is the *canonical form* of A—a diagonal matrix with A's eigenvalues on the main diagonal. Matrix V is the *modal matrix*—its columns are the eigenvectors of A.

For eig(A), the eigenvectors are scaled so that the norm of each is 1.0.

If W is a matrix such that W *A = D*W, the columns of W are the *left eigenvectors* of A. Use [W, D] = eig(A.'); W = conj(W) to compute the left eigenvectors.

[V,D] = eig(A, 'nobal ance') finds eigenvalues and eigenvectors without a preliminary balancing step. Ordinarily, balancing improves the conditioning of the input matrix, enabling more accurate computation of the eigenvectors and eigenvalues. However, if a matrix contains small elements that are really due to roundoff error, balancing may scale them up to make them as significant as the other elements of the original matrix, leading to incorrect eigenvectors. Use the nobal ance option in this event. See the bal ance function for more details.

[V, D] = eig(A, B) produces a diagonal matrix D of generalized eigenvalues and a full matrix V whose columns are the corresponding eigenvectors so that A*V = B*V*D.

[V, D] = eig(A, B, flag) specifies the algorithm used to compute eigenvalues and eigenvectors. flag can be:

' chol ' Computes the generalized eigenvalues of A and B using the Cholesky factorization of B. This is the default for symmetric (Hermitian) A and symmetric (Hermitian) positive definite B.

' qz' Ignores the symmetry, if any, and uses the QZ algorithm as it would for nonsymmetric (non-Hermitian) A and B.

Remarks

The eigenvalue problem is to determine the nontrivial solutions of the equation

$$Ax = \lambda x$$

where A is an n-by-n matrix, x is a length n column vector, and λ is a scalar. The n values of λ that satisfy the equation are the *eigenvalues*, and the corresponding values of x are the *right eigenvectors*. In MATLAB, the function eig solves for the eigenvalues λ , and optionally the eigenvectors x.

The *generalized* eigenvalue problem is to determine the nontrivial solutions of the equation

$$Ax = \lambda Bx$$

where both A and B are n-by-n matrices and λ is a scalar. The values of λ that satisfy the equation are the *generalized eigenvalues* and the corresponding values of x are the *generalized right eigenvectors*.

If B is nonsingular, the problem could be solved by reducing it to a standard eigenvalue problem

$$B^{-1}Ax = \lambda x$$

Because B can be singular, an alternative algorithm, called the QZ method, is necessary.

When a matrix has no repeated eigenvalues, the eigenvectors are always independent and the eigenvector matrix V *diagonalizes* the original matrix A if applied as a similarity transformation. However, if a matrix has repeated

eigenvalues, it is not similar to a diagonal matrix unless it has a full (independent) set of eigenvectors. If the eigenvectors are not independent then the original matrix is said to be *defective*. Even if a matrix is defective, the solution from eig satisfies A*X = X*D.

Examples

The matrix

$$B = \begin{bmatrix} 3 & -2 & -.9 & 2*eps \\ -2 & 4 & 1 & -eps \\ -eps/4 & eps/2 & -1 & 0 \\ -.5 & -.5 & .1 & 1 \end{bmatrix};$$

has elements on the order of roundoff error. It is an example for which the nobal ance option is necessary to compute the eigenvectors correctly. Try the statements

```
[VB, DB] = eig(B)

B*VB - VB*DB

[VN, DN] = eig(B, 'nobal ance')

B*VN - VN*DN
```

Algorithm

MATLAB uses LAPACK routines to compute eigenvalues and eigenvectors:

Case	Routine
Real symmetric A	DSYEV
Real nonsymmetric A:	
• With preliminary balance step	DGEEV (with SCLFAC = 2 instead of 8 in DGEBAL)
• d = eig(A, 'nobal ance')	DGEHRD, DHSEQR
• $[V, D] = eig(A, 'nobal ance')$	DGEHRD, DORGHR, DHSEQR, DTREVC
Hermitian A	ZHEEV

Case	Routine
Non-Hermitian A:	
With preliminary balance step	ZGEEV (with SCLFAC = 2 instead of 8 in ZGEBAL)
• d = eig(A, 'nobal ance')	ZGEHRD, ZHSEQR
• [V, D] = eig(A, 'nobal ance')	ZGEHRD, ZUNGHR, ZHSEQR, ZTREVC
Real symmetric A, symmetric positive definite B. Special case: ei g(A, B, 'qz') for real A, B (same as real nonsymmetric A, real general B)	DSYGV
	DGGEV
Real nonsymmetric A, real general B	DGGEV
Complex Hermitian A, Hermitian positive definite B.	ZHEGV

Find a few eigenvalues and eigenvectors of a square large sparse matrix

Syntax

```
d = eigs(A)
d = eigs(A, B)
d = eigs(A, k)
d = eigs(A, B, k)
d = eigs(A, k, sigma)
d = eigs(A, B, k, sigma)
d = eigs(A, k, sigma, options)
d = eigs(A, B, k, sigma, options)
d = eigs(Afun, n)
d = eigs(Afun, n, B)
d = eigs(Afun, n, k)
d = eigs(Afun, n, B, k)
d = eigs(Afun, n, k, sigma)
d = eigs(Afun, n, B, k, sigma)
d = eigs(Afun, n, k, sigma, options)
d = eigs(Afun, n, B, k, sigma, options)
d = eigs(Afun, n, k, sigma, options, p1, p2...)
d = eigs(Afun, n, B, k, sigma, options, p1, p2...)
[V, D] = eigs(A, ...)
[V, D] = eigs(Afun, n, ...)
[V, D, flag] = eigs(A, ...)
[V, D, flag] = eigs(Afun, n, ...)
```

Description

d = eigs(A) returns a vector of A's six largest magnitude eigenvalues.

[V, D] = eigs(A) returns a diagonal matrix D of A's six largest magnitude eigenvalues and a matrix V whose columns are the corresponding eigenvectors.

[V, D, flag] = eigs(A) also returns a convergence flag. If flag is 0 then all the eigenvalues converged; otherwise not all converged.

ei gs(Afun, n) accepts the function Afun instead of the matrix A. y = Afun(x) should return y = A*x, where x is an n-by-1 vector, and n is the size of A. The matrix A represented by Afun is assumed to be real and nonsymmetric. In all these calling sequences, ei gs(A, . . .) can be replaced by ei gs(Afun, n, . . .).

```
ei gs(A, B) solves the generalized eigenvalue problem A*V == B*V*D. B must
be symmetric (or Hermitian) positive definite and the same size as A.
ei gs(A, [],...) indicates the standard eigenvalue problem A*V == V*D.
```

ei gs(A, k) and ei gs(A, B, k) return the k largest magnitude eigenvalues.

eigs(A, k, sigma) and eigs(A, B, k, sigma) return k eigenvalues based on si gma, which can take any of the following values:

scalar	The eigenvalues closest to si gma. If A is a function, Afun
(real or complex,	must return $Y = (A-si gma*B) \setminus x (i.e., Y = A \setminus x when$
including 0)	si gma = 0). Note, B need only be symmetric (Hermitian)
	positive semi-definite.

' 1 m' Largest magnitude (default).

'sm' Smallest magnitude. Same as si gma = 0. If A is a function,

Afun must return $Y = A \setminus x$. Note, B need only be symmetric (Hermitian) positive semi-definite.

For real symmetric problems, the following are also options:

' l a' Largest algebraic ('lr' in MATLAB 5)

'sa' Smallest algebraic ('sr' in MATLAB 5)

'be' Both ends (one more from high end if k is odd)

Smallest imaginary part

For nonsymmetric and complex problems, the following are also options:

'lr' Largest real part 'sr' Smallest real part ' l i ' Largest imaginary part 'si'

Note The MATLAB 5 value si gma = 'be' is obsolete for nonsymmetric and complex problems.

 $ei\,gs(A,\,K,\,si\,gma,\,opts)\,$ and $ei\,gs(A,\,B,\,k,\,si\,gma,\,opts)\,$ specify an options structure:

Parameter	Description	Default Value
options.issym	1 if A or A- si gma*B represented by Af un is symmetric, 0 otherwise.	0
options.isreal	1 if A or A- si gma*B represented by Afun is real, 0 otherwise.	1
options. tol	Convergence: abs(lamda_computed-lamda_true) < tol*abs(lamda_computed).	eps
options. maxit	Maximum number of iterations.	300
opti ons. p	Number of basis vectors. $p \ge 2k$ ($p \ge 2k+1$ real nonsymmetric) advised. Note: p must satisfy $k for real symmetric,k+1 otherwise.$	2k
options.v0	Starting vector.	Randomly generated by ARPACK
opti ons. di sp	Diagnostic information display level.	1
options. chol B	1 if B is really its Cholesky factor chol (B), 0 otherwise.	0
options.permB	Permutation vector permB if sparse B is really chol (B(permB, permB)).	1: n

 $\textbf{Note} \ \ \text{MATLAB 5 options stagtol} \ \ \text{and cheb are no longer allowed}.$

```
ei gs(Afun, n, k, si gma, opts, p1, p2, ...) and ei gs(Afun, n, B, k, si gma, opts, p1, p2, ...) provide for additional arguments which are passed to Afun(x, p1, p2, ...).
```

Remarks

d = eigs(A, k) is not a substitute for

```
d = eig(full(A))
d = sort(d)
d = d(end-k+1:end)
```

but is most appropriate for large sparse matrices. If the problem fits into memory, it may be quicker to use eig(full(A)).

Algorithm

eigs provides the reverse communication required by the Fortran library ARPACK, namely the routines DSAUPD, DSEUPD, DNAUPD, DNEUPD, ZNAUPD, and ZNEUPD.

Examples

Example 1: This example shows the use of function handles.

```
A = del sq(numgri d('C', 15));
d1 = eigs(A, 5, 'sm');
```

Equivalently, if dnRk is the following one-line function:

```
function y = dnRk(x, R, k)

y = (del sq(numgrid(R, k))) * x;
```

then pass dnRk's additional arguments, 'C' and 15, to eigs.

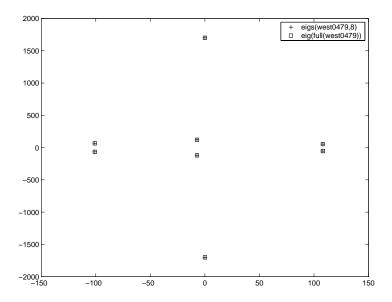

```
n = size(A, 1);
opts.issym = 1;
d2 = eigs(@dnRk, n, 5, 'sm', opts, 'C', 15);
```

Example 2: west 0479 is a real 479-by-479 sparse matrix with both real and pairs of complex conjugate eigenvalues. eige computes all 479 eigenvalues. eigenvalues easily picks out the largest magnitude eigenvalues.

This plot shows the 8 largest magnitude eigenvalues of west 0479 as computed by eig and eigs.

```
load west0479
d = eig(full(west0479))
dlm = eigs(west0479, 8)
```

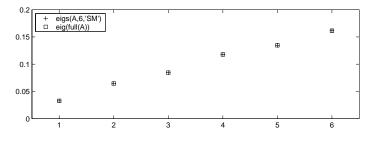

```
[dum, ind] = sort(abs(d));
plot(dlm, 'k+')
hold on
plot(d(ind(end-7:end)), 'ks')
hold off
legend('eigs(west0479, 8)', 'eig(full(west0479))')
```

Example 3: A = del sq(numgri d('C', 30)) is a symmetric positive definite matrix of size 632 with eigenvalues reasonably well-distributed in the interval (0 8), but with 18 eigenvalues repeated at 4. The eig function computes all 632 eigenvalues. It computes and plots the six largest and smallest magnitude eigenvalues of A successfully with:

```
A = del sq(numgri d('C', 30));
d = eig(full(A));
[dum, ind] = sort(abs(d));
dl m = eigs(A);
dsm = eigs(A, 6, 'sm');
```

```
subpl ot (2, 1, 1)
pl ot (dl m, 'k+')
hold on
plot(d(ind(end: -1: end-5)), 'ks')
hold off
l \operatorname{egend}('\operatorname{eigs}(A)', '\operatorname{eig}(\operatorname{full}(A))', 3)
set(gca, 'XLim', [0.5 6.5])
subplot (2, 1, 2)
plot(dsm, 'k+')
hold on
plot(d(ind(1:6)), 'ks')
hold off
l \, egend(' \, ei \, gs(A, \, 6, \, ' \, ' \, sm' \, ') \, ' \, , \, ' \, ei \, g(ful \, l \, (A)) \, ' \, , \, 2)
set(gca, 'XLim', [0.5 6.5])
    7.95
                                      ₽
     7.9
    7.85
              eigs(A)
             eig(full(A))
                                                   4
                                                               5
                          2
                                      3
```

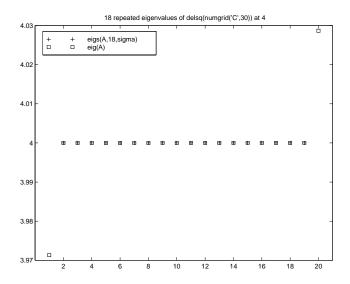

However, the repeated eigenvalue at 4 must be handled more carefully. The call ei gs(A, 18, 4. 0) to compute 18 eigenvalues near 4.0 tries to find eigenvalues of A $\,$ 4. 0*I. This involves divisions of the form 1/

(1 ambda - 4.0), where 1 ambda is an estimate of an eigenvalue of A. As 1 ambda gets closer to 4.0, eigs fails. We must use sigma near but not equal to 4 to find those 18 eigenvalues.

$$sigma = 4 - 1e-6$$

[V, D] = $eigs(A, 18, sigma)$

The plot shows the 20 eigenvalues closest to 4 that were computed by eig, along with the 18 eigenvalues closest to 4 - 1e-6 that were computed by eigs.

Jacobi elliptic functions

Syntax

$$[SN, CN, DN] = ellipj(U, M)$$

 $[SN, CN, DN] = ellipj(U, M, tol)$

Definition

The Jacobi elliptic functions are defined in terms of the integral:

$$u = \int_0^{\phi} \frac{d\theta}{(1 - m\sin^2\theta)^{\frac{1}{2}}}$$

Then

$$sn(u) = \sin\phi, \ cn(u) = \cos\phi, \ dn(u) = (1 - m\sin^2\phi)^{\frac{1}{2}}, \ am(u) = \phi$$

Some definitions of the elliptic functions use the modulus k instead of the parameter m. They are related by

$$k^2 = m = \sin^2 \alpha$$

The Jacobi elliptic functions obey many mathematical identities; for a good sample, see [1].

Description

 $[SN, CN, DN] = el \ li \ pj \ (U, M)$ returns the Jacobi elliptic functions SN, CN, and DN, evaluated for corresponding elements of argument U and parameter M. Inputs U and M must be the same size (or either can be scalar).

 $[SN, CN, DN] = el \ li \ pj \ (U, M, tol)$ computes the Jacobi elliptic functions to accuracy tol. The default is eps; increase this for a less accurate but more quickly computed answer.

Algorithm

ellipj computes the Jacobi elliptic functions using the method of the arithmetic-geometric mean [1]. It starts with the triplet of numbers:

$$a_0 = 1$$
, $b_0 = (1 - m)^{\frac{1}{2}}$, $c_0 = (m)^{\frac{1}{2}}$

ellipj

ellipj computes successive iterates with

$$a_{i} = \frac{1}{2}(a_{i-1} + b_{i-1})$$

$$b_{i} = (a_{i-1}b_{i-1})^{\frac{1}{2}}$$

$$c_{i} = \frac{1}{2}(a_{i-1} - b_{i-1})$$

Next, it calculates the amplitudes in radians using:

$$\sin(2\phi_{n-1}-\phi_n) = \frac{c_n}{a_n}\sin(\phi_n)$$

being careful to unwrap the phases correctly. The Jacobian elliptic functions are then simply:

$$sn(u) = \sin\phi_0$$

$$cn(u) = \cos\phi_0$$

$$dn(u) = (1 - m \cdot sn(u)^2)^{\frac{1}{2}}$$

Limitations

The ellipj function is limited to the input domain $0 \le m \le 1$. Map other values of Minto this range using the transformations described in [1], equations 16.10 and 16.11. U is limited to real values.

Complete elliptic integrals of the first and second kind

Syntax

$$K = ellipke(M)$$

$$[K, E] = ellipke(M)$$

Definition

The complete elliptic integral of the first kind [1] is

$$K(m) = F(\pi/2|m)$$

where F, the elliptic integral of the first kind, is

$$K(m) = \int_0^1 \left[(1 - t^2)(1 - mt^2) \right]^{\frac{-1}{2}} dt = \int_0^{\frac{\pi}{2}} (1 - m\sin^2\theta)^{\frac{-1}{2}} d\theta$$

The complete elliptic integral of the second kind

$$E(m) = E(K(m)) = E\langle \pi/2 | m \rangle$$

is

$$E(m) = \int_0^1 (1 - t^2)^{\frac{-1}{2}} (1 - mt^2)^{\frac{1}{2}} dt = \int_0^{\frac{\pi}{2}} (1 - m\sin^2\theta)^{\frac{1}{2}} d\theta$$

Some definitions of K and E use the modulus k instead of the parameter m. They are related by

$$k^2 = m = \sin^2 \alpha$$

Description

 $K = el\,l\,i\,pke(M)$ returns the complete elliptic integral of the first kind for the elements of M

[K, E] = ellipke(M) returns the complete elliptic integral of the first and second kinds.

 $\label{eq:KE} \begin{tabular}{ll} [K,E] = ellipke(M,tol) & computes the Jacobian elliptic functions to accuracy tol. The default is eps; increase this for a less accurate but more quickly computed answer. \\ \end{tabular}$

ellipke

Algorithm

 ${\it el\,l\,i}$ pke computes the complete elliptic integral using the method of the arithmetic-geometric mean described in [1], section 17.6. It starts with the triplet of numbers

$$a_0 = 1$$
, $b_0 = (1 - m)^{\frac{1}{2}}$, $c_0 = (m)^{\frac{1}{2}}$

ellipke computes successive iterations of a_i , b_i , and c_i with

$$a_{i} = \frac{1}{2}(a_{i-1} + b_{i-1})$$

$$b_{i} = (a_{i-1}b_{i-1})^{\frac{1}{2}}$$

 $c_i = \frac{1}{2}(a_{i-1} - b_{i-1})$

stopping at iteration n when $cn \approx 0$, within the tolerance specified by eps. The complete elliptic integral of the first kind is then

$$K(m) = \frac{\pi}{2a_n}$$

Limitations

el l i pke is limited to the input domain $0 \le m \le 1$.

Purpose Generate ellipsoid

Syntax [x, y, z] = ellipsoid(xc, yc, zc, xr, yr, zr, n)

[x, y, z] = ellipsoid(xc, yc, zc, xr, yr, zr)

ellipsoid(...)

Description [x, y, z] = ellipsoid(xc, yc, zc, xr, yr, zr, n) generates three n+1-by-n+1

matrices so that surf(x, y, z) produces an ellipsoid with center (xc, yc, zc)

and radii (xr, yr, zr).

[x, y, z] = ellipsoid(xc, yc, zc, xr, yr, zr) uses n = 20.

el l i psoi d(...) with no output arguments graphs the ellipsoid as a surface.

Algorithm ellipsoid generates the data using the following equation:

 $\frac{(x-xc)^{2}}{xr^{2}} + \frac{(y-yc)^{2}}{yr^{2}} + \frac{(z-zc)^{2}}{zr^{2}}$

See Also cylinder, sphere, surf

Conditionally execute statements

Syntax

```
if expression
    statements1
else
    statements2
end
```

Description

el se is used to delineate an alternate block of statements. If *expressi* on evaluates as fal se, MATLAB executes the one or more commands denoted here as *statements2*.

A true expression has either a logical true or nonzero value. For nonscalar expressions, (for example, "if (matrix A is less than matrix B)"), true means that every element of the resulting matrix has a logical true or nonzero value.

Expressions usually involve relational operations such as (count < limit) or i sreal (A). Simple expressions can be combined by logical operators (&, |,~) into compound expressions such as: (count < limit) & ((height - offset) >= 0).

See if for more information.

Examples

In this example, if both of the conditions are not satisfied, then the student fails the course.

```
if ((attendance >= 0.90) & (grade_average >= 60))
   pass = 1;
else
   fail = 1;
end;
```

See Also

if, elseif, end, for, while, switch, break, return, relational_operators, logical_operators $\,$

Conditionally execute statements

Syntax

if expression1
 statements1
elseif expression2
 statements2
end

Description

If expressi on1 evaluates as fal se and expressi on2 as true, MATLAB executes the one or more commands denoted here as statements2.

A true expression has either a logical true or nonzero value. For nonscalar expressions, (for example, is matrix A less then matrix B), true means that every element of the resulting matrix has a logical true or nonzero value.

Expressions usually involve relational operations such as (count < limit) or i sreal (A). Simple expressions can be combined by logical operators (&, |,~) into compound expressions such as: (count < limit) & ((height - offset) >= 0).

See if for more information.

Remarks

el se i f, with a space between the el se and the i f, differs from el sei f, with no space. The former introduces a new, nested i f, which must have a matching end. The latter is used in a linear sequence of conditional statements with only one terminating end.

The two segments shown below produce identical results. Exactly one of the four assignments to x is executed, depending upon the values of the three logical expressions, A, B, and C.

```
if A
                                                   if A
     x = a
                                                          \mathbf{x} = \mathbf{a}
el se
                                                    elseif B
     if B
                                                          x = b
          x = b
                                                    elseif C
     else
                                                          \mathbf{x} = \mathbf{c}
           if C
                                                    el se
                \mathbf{x} = \mathbf{c}
                                                          x = d
           el se
                                                    end
                  x = d
```

end end end

Examples

Here is an example showing if, else, and elseif.

```
for m = 1: k
    for n = 1: k
    if m == n
        a(m, n) = 2;
    el sei f abs(m-n) == 2
        a(m, n) = 1;
    el se
        a(m, n) = 0;
    end
    end
end
```

For k=5 you get the matrix

a =

See Also

if, else, end, for, while, switch, break, return, relational_operators, logical_operators $% \left(1\right) =\left(1\right) \left(1\right$

Terminate for, while, switch, try, and if statements or indicate last index

Syntax

```
while expression% (or if, for, or try)
    statements
end
B = A(index: end, index)
```

Description

end is used to terminate for, while, switch, try, and if statements. Without an end statement, for, while, switch, try, and if wait for further input. Each end is paired with the closest previous unpaired for, while, switch, try, or if and serves to delimit its scope.

The end command also serves as the last index in an indexing expression. In that context, end = (si ze(x, k)) when used as part of the kth index. Examples of this use are X(3: end) and X(1, 1: 2: end-1). When using end to grow an array, as in X(end+1)=5, make sure X(end+1)=5.

You can overload the end statement for a user object by defining an end method for the object. The end method should have the calling sequence end(obj,k,n), where obj is the user object, k is the index in the expression where the end syntax is used, and n is the total number of indices in the expression. For example, consider the expression

```
A(end-1,:)
```

MATLAB will call the end method defined for A using the syntax

```
end(A, 1, 2)
```

Examples

This example shows end used with the for and if statements.

```
for k = 1: n

if a(k) == 0

a(k) = a(k) + 2;

end

end
```

In this example, end is used in an indexing expression.

```
A = magic(5)
```

B = A(end, 2: end)

B =

18 25 2 9

Syntax	Y = erf(X)	Error function
Jyiilax	I = eII(A)	Elloi lunction

$$Y = erfc(X)$$
 Complementary error function

$$Y = erfcx(X)$$
 Scaled complementary error function

$$X = erfinv(Y)$$
 Inverse error function

$$X = erfcinv(Y)$$
 Inverse complementary error function

Definition

The error function $\operatorname{erf}(X)$ is twice the integral of the Gaussian distribution with 0 mean and variance of 1/2.

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

The complementary error function erfc(X) is defined as

$$\operatorname{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_{x}^{\infty} e^{-t^2} dt = 1 - \operatorname{erf}(x)$$

The scaled complementary error function erfcx(X) is defined as

$$\operatorname{erfcx}(X) = e^{X^2} \operatorname{erfc}(X)$$

For large X, erfcx(X) is approximately $\left(\frac{1}{\sqrt{\pi}}\right)\frac{1}{X}$

Description

Y = erf(X) returns the value of the error function for each element of real array X.

Y = erfc(X) computes the value of the complementary error function.

Y = erfcx(X) computes the value of the scaled complementary error function.

X = erfinv(Y) returns the value of the inverse error function for each element of Y. Elements of Y must be in the interval $[-1 \ 1]$. The function erfinv satisfies y = erf(x) for $-1 \le y \le 1$ and $-\infty \le x \le \infty$.

 $X = \operatorname{erfci} \operatorname{nv}(Y)$ returns the value of the inverse of the complementary error function for each element of Y. Elements of Y must be in the interval $[0\ 2]$. The function erfci nv satisfies $y = \operatorname{erfc}(x)$ for $2 \ge y \ge 0$ and $-\infty \le x \le \infty$.

erf, erfc, erfcx, erfinv, erfcinv

Remarks

The relationship between the complementary error function erfc and the standard normal probability distribution returned by the Statistics Toolbox function normal is

$$\operatorname{normcdf}(x) = 0.5 * \operatorname{erfc}(-x/\sqrt{2})$$

The relationship between the inverse complementary error function erfci nv and the inverse standard normal probability distribution returned by the Statistics Toolbox function normi nv is

norminv(
$$p$$
) = $-\sqrt{2}$ * erfcinv($2p$)

Examples

erfinv(1) is Inf

erfinv(-1) is -Inf.

For abs(Y) > 1, erfinv(Y) is NaN.

Algorithms

For the error functions, the MATLAB code is a translation of a Fortran program by W. J. Cody, Argonne National Laboratory, NETLIB/SPECFUN, March 19, 1990. The main computation evaluates near-minimax rational approximations from [1].

For the inverse of the error function, rational approximations accurate to approximately six significant digits are used to generate an initial approximation, which is then improved to full accuracy by one step of Halley's method.

References

[1] Cody, W. J., "Rational Chebyshev Approximations for the Error Function," *Math. Comp.*, pgs. 631-638, 1969

Purpose Display error messages

Syntax error('error_message')

Description error('error_message') displays an error message and returns control to the

keyboard. The error message contains the input string *error_message*.

The error command has no effect if *error_message* is a null string.

Examples The error command provides an error return from M-files.

```
function foo(x, y)
if nargin ~= 2
    error('Wrong number of input arguments')
end
```

The returned error message looks like:

```
» foo(pi)
??? Error using ==> foo
Wrong number of input arguments
```

See Also dbstop, disp, lasterr, warning, errordlg

Plot error bars along a curve

Syntax

```
errorbar(Y, E)
errorbar(X, Y, E)
errorbar(X, Y, L, U)
errorbar(..., Li neSpec)
h = errorbar(...)
```

Description

Error bars show the confidence level of data or the deviation along a curve.

errorbar(Y, E) plots Y and draws an error bar at each element of Y. The error bar is a distance of E(i) above and below the curve so that each bar is symmetric and 2*E(i) long.

errorbar (X, Y, E) plots X versus Y with symmetric error bars 2*E(i) long. X, Y, E must be the same size. When they are vectors, each error bar is a distance of E(i) above and below the point defined by (X(i), Y(i)). When they are matrices, each error bar is a distance of E(i, j) above and below the point defined by (X(i, j), Y(i, j)).

errorbar(X, Y, L, U) plots X versus Y with error bars L(i) + U(i) long specifying the lower and upper error bars. X, Y, L, and U must be the same size. When they are vectors, each error bar is a distance of L(i) below and U(i) above the point defined by (X(i), Y(i)). When they are matrices, each error bar is a distance of L(i, j) below and U(i, j) above the point defined by (X(i, j), Y(i, j)).

errorbar(..., Li neSpec) draws the error bars using the line type, marker symbol, and color specified by Li neSpec.

h = errorbar(...) returns a vector of handles to line graphics objects.

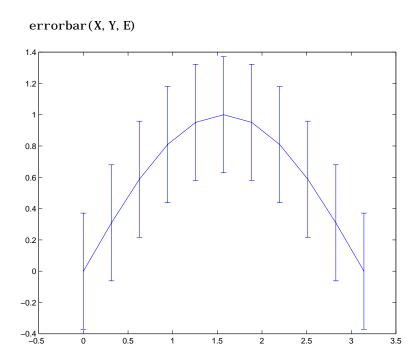

Remarks

When the arguments are all matrices, errorbar draws one line per matrix column. If X and Y are vectors, they specify one curve.

Examples

Draw symmetric error bars that are two standard deviation units in length.

```
X = 0: pi /10: pi;
Y = si n(X);
E = std(Y) *ones(si ze(X));
```

See Also LineSpec, plot, std

Create and display an error dialog box

Syntax

```
errordl g
errordl g('errorstring')
errordl g('errorstring','dl gname')
errordl g('errorstring','dl gname','on')
h = errordl g(...)
```

Description

errordl g creates an error dialog box, or if the named dialog exists, errordl g pops the named dialog in front of other windows.

errordl g displays a dialog box named ' Error Di al og' that contains the string ' This is the default error string. '

errordl g('errorstring') displays a dialog box named 'Error Di alog' that contains the string 'errorstring'.

errordl g('errorstring', 'dl gname') displays a dialog box named 'dl gname' that contains the string 'errorstring'.

errordl g('errorstring', 'dl gname', 'on') specifies whether to replace an existing dialog box having the same name. 'on' brings an existing error dialog having the same name to the foreground. In this case, errordl g does not create a new dialog.

h = errordl g(...) returns the handle of the dialog box.

Remarks

MATLAB sizes the dialog box to fit the string 'errorstring'. The error dialog box has an OK pushbutton and remains on the screen until you press the OK button or the **Return** key. After pressing the button, the error dialog box disappears.

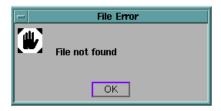

The appearance of the dialog box depends on the windowing system you use.

Examples

The function

```
errordlg('File not found', 'File Error');
```

displays this dialog box on a UNIX system:

etime

Purpose Elapsed time

Syntax e = etime(t2, t1)

Description e = etime(t2, t1) returns the time in seconds between vectors t1 and t2. The

two vectors must be six elements long, in the format returned by clock:

T = [Year Month Day Hour Minute Second]

Examples Calculate how long a 2048-point real FFT takes.

Limitations As currently implemented, the etime function fails across month and year

boundaries. Since etime is an M-file, you can modify the code to work across

these boundaries if needed.

See Also clock, cputime, tic, toc

Purpose Elimination tree **Syntax** p = etree(A)p = etree(A, 'col') p = etree(A, 'sym') [p, q] = etree(...) Description p = etree(A) returns an elimination tree for the square symmetric matrix whose upper triangle is that of A. p(j) is the parent of column j in the tree, or 0 if j is a root. p = etree(A, 'col') returns the elimination tree of A'*A. p = etree(A, 'sym') is the same as p = etree(A). [p, q] = etree(...) also returns a postorder permutation q of the tree. See Also treel ayout, treeplot, etreeplot

etreeplot

Purpose Plot elimination tree

Syntax etreeplot(A)

etreeplot(A, nodeSpec, edgeSpec)

Description etreepl ot (A) plots the elimination tree of A (or A+A', if non-symmetric).

 $etreepl \ ot \ (A, nodeSpec, edgeSpec) \ allows \ optional \ parameters \ nodeSpec \ and \ edgeSpec \ to \ set \ the \ node \ or \ edge \ color, \ marker, \ and \ linestyle. \ Use \ ' ' \ to \ omit$

one or both.

See Also etree, treepl ot, treel ayout

Execute a string containing a MATLAB expression

Syntax

```
eval (expressi on)
eval (expressi on, catch_expr)
[a1, a2, a3, ...] = eval (functi on(b1, b2, b3, ...))
```

Description

eval (expressi on) executes expressi on, a string containing any valid MATLAB expression. You can construct expressi on by concatenating substrings and variables inside square brackets:

```
expression = [string1, int2str(var), string2,...]
```

eval (expressi on, catch_expr) executes expressi on and, if an error is detected, executes the catch_expr string. If expressi on produces an error, the error string can be obtained with the lasterr function. This syntax is useful when expressi on is a string that must be constructed from substrings. If this is not the case, use the try... catch control flow statement in your code.

[a1, a2, a3, ...] = eval (function(b1, b2, b3, ...)) executes function with arguments b1, b2, b3, ..., and returns the results in the specified output variables.

Remarks

Using the eval output argument list is recommended over including the output arguments in the expression string. The first syntax below avoids strict checking by the MATLAB parser and can produce untrapped errors and other unexpected behavior.

Examples

This for loop generates a sequence of 12 matrices named M1 through M12:

```
for n = 1:12
    magic_str = ['M',int2str(n),' = magic(n)'];
    eval (magic_str)
end
```

This example uses a function showdemo that runs a MATLAB demo selected by the user. If an error is encountered, a message is displayed that names the demo that failed.

```
function showdemo(demos)
errstring = 'Error running demo: ';
n = input('Select a demo number: ');
eval(demos(n,:),'[errstring demos(n,:)]')
% ---- end of file showdemo.m -----
D = ['odedemo'; 'quademo'; 'fitdemo'];
showdemo(D)
Select a demo number: 2
ans =
```

Error running demo: quademo

The next example executes the size function on a 3-dimensional array, returning the array dimensions in output variables d1, d2, and d3.

```
A = magi c(4);

A(:,:,2) = A';

[d1, d2, d3] = eval('size(A)')

d1 =

4

d2 =

4

d3 =

2
```

See Also

assignin, catch, evalin, feval, lasterr, try

Purpose Evaluate MATLAB expression with capture

Syntax T = eval c(S)

T = evalc(s1, s2)

 $[T, X, Y, Z, \dots] = evalc(S)$

Description T = eval c(S) is the same as eval (S) except that anything that would normally

be written to the command window is captured and returned in the character

array T (lines in T are separated by \n characters).

T = eval c(s1, s2) is the same as eval (s1, s2) except that any output is

captured into T.

[T, X, Y, Z, ...] = eval c(S) is the same as [X, Y, Z, ...] = eval (S) except

that any output is captured into T.

Remark When you are using eval c, di ary, more, and i nput are disabled.

See Also diary, eval, evalin, input, more

Execute a string containing a MATLAB expression in a workspace

Syntax

```
evalin(ws,expression)
[a1, a2, a3, ...] = evalin(ws, expression)
evalin(ws, expression, catch_expr)
```

Description

eval in (ws, expression) executes expression, a string containing any valid MATLAB expression, in the context of the workspace ws. ws can have a value of 'base' or 'caller' to denote the MATLAB base workspace or the workspace of the caller function. You can construct expression by concatenating substrings and variables inside square brackets:

```
expression = [string1, int2str(var), string2, ...]
```

 $[a1, a2, a3, \dots] = evalin(ws, expression)$ executes expression and returns the results in the specified output variables. Using the evalin output argument list is recommended over including the output arguments in the expression string:

```
evalin(ws, '[a1, a2, a3, ...] = function(var)')
```

The above syntax avoids strict checking by the MATLAB parser and can produce untrapped errors and other unexpected behavior.

eval in (ws, expression, catch_expr) executes expression and, if an error is detected, executes the catch_expr string. If expression produces an error, the error string can be obtained with the lasterr function. This syntax is useful when expression is a string that must be constructed from substrings. If this is not the case, use the try... catch control flow statement in your code.

Remarks

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the M-file. Note, the base and caller workspaces are equivalent in the context of an M-file that is invoked from the MATLAB command line.

Examples

This example extracts the value of the variable var in the MATLAB base workspace and captures the value in the local variable v:

```
v = evalin('base', 'var');
```

evalin

Limitation eval in cannot be used recursively to evaluate an expression. For example, a

sequence of the form evalin('caller', 'evalin(''caller'', ''x'')')

doesn't work.

See Also assignin, catch, eval, feval, lasterr, try

Check if a variable or file exists

Graphical Interface

As an alternative to the exi st function, use the Workspace browser or the Current Directory Browser. To open either, select **Workspace** or **Current Directory** from the **View** menu in the MATLAB desktop.

Syntax

```
exist item
exist item kind
a = exist('item',...)
```

Description

exist item returns the status of the variable or file, item:

- 0 If i tem does not exist.
- 1 If the variable i tem exists in the workspace.
- 2 If i tem is an M-file or a file of unknown type.
- 3 If i tem is a MEX-file on your MATLAB search path.
- 4 If i tem is an MDL-file on your MATLAB search path.
- 5 If i tem is a built-in MATLAB function.
- $\label{eq:constraints} \textbf{6} \qquad \text{If i tem is a P-file on your MATLAB search path.}$
- 7 If i tem is a directory.
- 8 If i tem is a Java class.

If item specifies a filename, that filename may include an extension to preclude conflicting with other similar filenames. For example, exist('file. ext').

MEX, MDL, and P-files must be on the MATLAB search path for exist to return the values shown above. If i tem is found, but is not on the MATLAB search path, exist('item') returns 2, because it considers i tem to be an unknown file type.

Any other file type or directory specified by item is not required to be on the MATLAB search path to be recognized by exist. If the file or directory is not on the search path, then item must specify either a full pathname, a partial pathname relative to MATLABPATH, or a partial pathname relative to your current directory.

If i tem is a Java class, then exist('item') returns an 8. However, if item is a Java class file, then exist('item') returns a 2.

exi st item *ki nd* returns logical true (1), if an item of the specified kind is found; otherwise, it returns 0. The *ki nd* argument may be one of the following:

builtin Checks only for built-in functions.
class Checks only for Java classes.
dir Checks only for directories.
file Checks only for files or directories.
var Checks only for variables.

a = exist('item', ...) returns the status of the variable or file in variable a.

Remarks

To check for the existence of more than one variable, use the i smember function. For example,

Examples

This example uses exist to check whether a MATLAB function is a built-in function or a file.

```
type = exist('plot')
type =
    5
```

pl ot is a built-in function.

In the following example, exist returns 8 on the Java class, Welcome, and returns 2 on the Java class file, Welcome. class.

```
exist Welcome
ans =
    8

exist javaclasses/Welcome.class
ans =
    2
```

indicates there is a Java class Wel come and a Java class file Wel come. class.

dir, help, lookfor, partial path, what, which, who

Purpose Terminate MATLAB (same as qui t)

Graphical As an alternative to the exit function, select **Exit MATLAB** from the **File**

Interface menu or click the close box in the MATLAB desktop.

Syntax exi t

Description exit ends the current MATLAB session. It is the same as quit. See quit for

termination options.

See Also qui t

exp

Purpose Exponential

Syntax $Y = \exp(X)$

Description The exp function is an elementary function that operates element-wise on

arrays. Its domain includes complex numbers.

 $Y = \exp(X)$ returns the exponential for each element of X. For complex

 $z = x + i^* y$, it returns the complex exponential $e^z = e^x(\cos(y) + i\sin(y))$.

Remark Use expm for matrix exponentials.

See Also expm, log, log10, expi nt

Purpose Exponential integral

Syntax $Y = \exp i \operatorname{nt}(X)$

Definitions The exponential integral computed by this function is defined as

$$E_1(x) = \int_x^\infty \frac{e^{-t}}{t} dt$$

Another common definition of the exponential integral function is the Cauchy principal value integral

$$Ei(x) = \int_{-\infty}^{x} \frac{e^{t}}{t} dt$$

which, for real positive x, is related to expi nt as

$$E_1(-x) = -Ei(x) - i\pi$$

Description Y = expint(X) evaluates the exponential integral for each element of X.

References [1] Abramowitz, M. and I. A. Stegun. *Handbook of Mathematical Functions.* Chapter 5, New York: Dover Publications, 1965.

Matrix exponential

Syntax

Y = expm(X)

 $A = \begin{bmatrix} 1 \end{bmatrix}$

Description

 $Y = \exp(X)$ raises the constant e to the matrix power X. The expm function produces complex results if X has nonpositive eigenvalues.

Use exp for the element-by-element exponential.

Algorithm

expm is a built-in function that uses the Padé approximation with scaling and squaring. You can see the coding of this algorithm in the expm1 demo.

Note The expm1, expm2, and expm3 demos illustrate the use of Padé approximation, Taylor series approximation, and eigenvalues and eigenvectors, respectively, to compute the matrix exponential.

References [1] and [2] describe and compare many algorithms for computing a matrix exponential. The built-in method, expm, is essentially method 3 of [2].

Examples

This example computes and compares the matrix exponential of A and the exponential of A.

0

1

Notice that the diagonal elements of the two results are equal. This would be true for any triangular matrix. But the off-diagonal elements, including those below the diagonal, are different.

eye

Purpose Identity matrix

Syntax Y = eye(n)

Y = eye(m, n)

Y = eye(size(A))

Description Y = eye(n) returns the n-by-n identity matrix.

 $Y = \exp(m, n)$ or $\exp([m \ n])$ returns an m-by-n matrix with 1's on the

diagonal and 0's elsewhere.

Y = eye(size(A)) returns an identity matrix the same size as A.

Limitations The identity matrix is not defined for higher-dimensional arrays. The

assignment y = eye([2, 3, 4]) results in an error.

See Also ones, rand, randn, zeros

Easy to use contour plotter

Syntax

ezcontour(f)

ezcontour(f, domain)
ezcontour(..., n)

Description

ezcontour(f) plots the contour lines of f(x,y), where f is a string that represents a mathematical function of two variables, such as x and y.

The function f is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$. MATLAB chooses the computational grid according to the amount of variation that occurs; if the function f is not defined (singular) for points on the grid, then these points are not plotted.

ezcontour (f, domai n) plots f(x,y) over the specified domai n. domai n can be either a 4-by-1 vector [xmin, xmax, ymin, ymax] or a 2-by-1 vector [min, max] (where min < x < max, min < y < max).

If f is a function of the variables u and v (rather than x and y), then the domain endpoints umin, umax, vmin, and vmax are sorted alphabetically. Thus, ezcont our ('u^2 - v^3', [0, 1], [3, 6]) plots the contour lines for u^2 - v^3 over 0 < u < 1, 3 < v < 6.

ezcont our (..., n) plots f over the default domain using an n-by-n grid. The default value for n is 60.

ezcont our automatically adds a title and axis labels.

Remarks

Array multiplication, division, and exponentiation are always implied in the expression you pass to ezcontour. For example, the MATLAB syntax for a contour plot of the expression,

$$sqrt(x.^2 + y.^2)$$

is written as:

ezcontour('sqrt(
$$x^2 + y^2$$
)')

That is, x^2 is interpreted as x. 2 in the string you pass to ezcont our.

Examples

The following mathematical expression defines a function of two variables, x and y.

$$f(x, y) = 3(1-x)^2 e^{-x^2-(y+1)^2} - 10\left(\frac{x}{5} - x^3 - y^5\right) e^{-x^2-y^2} - \frac{1}{3}e^{-(x+1)^2-y^2}$$

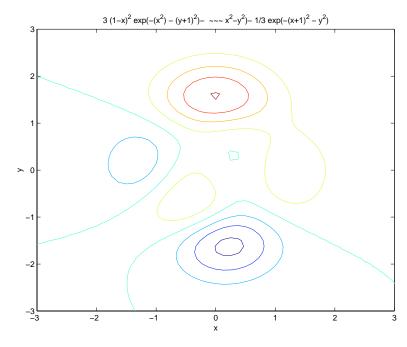

ezcont our requires a string argument that expresses this function using MATLAB syntax to represent exponents, natural logs, etc. This function is represented by the string:

$$f = ['3*(1-x)^2*exp(-(x^2)-(y+1)^2)', ... '-10*(x/5 - x^3 - y^5)*exp(-x^2-y^2)', ... '-1/3*exp(-(x+1)^2 - y^2)'];$$

For convenience, this string is written on three lines and concatenated into one string using square brackets.

Pass the string variable f to ezcont our along with a domain ranging from -3 to 3 and specify a computational grid of 49-by-49:

ezcontour(f, [-3, 3], 49)

In this particular case, the title is too long to fit at the top of the graph so MATLAB abbreviates the string.

ezcontour

See Also

contour, ezcontourf, ezmesh, ezmeshc, ezpl ot , ezpl ot 3, ezpol ar , ezsurf, ezsurfc

Easy to use filled contour plotter

Syntax

ezcontourf(f)

ezcontourf(f, domai n)
ezcontourf(..., n)

Description

ezcontourf(f) plots the contour lines of f(x,y), where f is a string that represents a mathematical function of two variables, such as x and y.

The function f is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$. MATLAB chooses the computational grid according to the amount of variation that occurs; if the function f is not defined (singular) for points on the grid, then these points are not plotted.

ezcontourf (f, domai n) plots f(x,y) over the specified domai n. domai n can be either a 4-by-1 vector [xmin, xmax, ymin, ymax] or a 2-by-1 vector [min, max] (where, min < x < max, min < y < max).

If f is a function of the variables u and v (rather than x and y), then the domain endpoints umin, umax, vmin, and vmax are sorted alphabetically. Thus, ezcont our $f('u^2 - v^3', [0, 1], [3, 6])$ plots the contour lines for $u^2 - v^3$ over 0 < u < 1, 3 < v < 6.

ezcontourf (...,n) plots fover the default domain using an n-by-n grid. The default value for n is 60.

ezcont ourf automatically adds a title and axis labels.

Remarks

Array multiplication, division, and exponentiation are always implied in the expression you pass to ezcontourf. For example, the MATLAB syntax for a filled contour plot of the expression,

is written as:

```
\operatorname{ezcontourf}(\operatorname{'sqrt}(x^2 + y^2))
```

That is, x^2 is interpreted as x. 2 in the string you pass to ezcont our f.

Examples

The following mathematical expression defines a function of two variables, x and y.

$$f(x, y) = 3(1-x)^2 e^{-x^2-(y+1)^2} - 10\left(\frac{x}{5}-x^3-y^5\right)e^{-x^2-y^2} - \frac{1}{3}e^{-(x+1)^2-y^2}$$

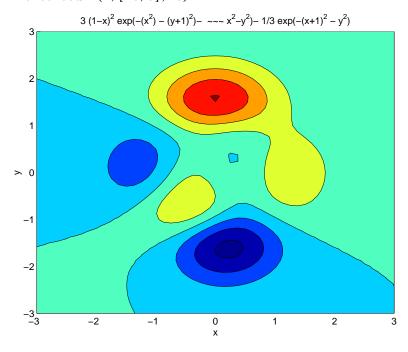

ezcont ourf requires a string argument that expresses this function using MATLAB syntax to represent exponents, natural logs, etc. This function is represented by the string:

$$f = ['3*(1-x)^2*exp(-(x^2)-(y+1)^2)', ... \\ '-10*(x/5-x^3-y^5)*exp(-x^2-y^2)', ... \\ '-1/3*exp(-(x+1)^2-y^2)'];$$

For convenience, this string is written on three lines and concatenated into one string using square brackets.

Pass the string variable f to ezcont ourf along with a domain ranging from -3 to 3 and specify a grid of 49-by-49:

ezcontourf(f, [-3, 3], 49)

In this particular case, the title is too long to fit at the top of the graph so MATLAB abbreviates the string.

ezcontourf

See Also

contourf, ezcontour, ezmesh, ezmeshc, ezpl ot , ezpl ot 3, ezpol ar , ezsurf, ezsurfc

Easy to use 3-D mesh plotter

Syntax

```
\begin{split} & ezmesh(f) \\ & ezmesh(f, domai\, n) \\ & ezmesh(x, y, z) \\ & ezmesh(x, y, z, [smi\, n, smax, tmi\, n, tmax]) \text{ or } ezmesh(x, y, z, [mi\, n, max]) \\ & ezmesh(\dots, n) \\ & ezmesh(\dots, 'ci\, rc') \end{split}
```

Description

ezmesh(f) creates a graph of f(x,y), where f is a string that represents a mathematical function of two variables, such as x and y.

The function f is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$. MATLAB chooses the computational grid according to the amount of variation that occurs; if the function f is not defined (singular) for points on the grid, then these points are not plotted.

ezmesh(f, domai n) plots f over the specified domai n. domai n can be either a 4-by-1 vector [xmin, xmax, ymin, ymax] or a 2-by-1 vector [min, max] (where, min < x < max, min < y < max).

If f is a function of the variables u and v (rather than x and y), then the domain endpoints umin, umax, vmin, and vmax are sorted alphabetically. Thus, ezmesh('u^2 - v^3', [0, 1], [3, 6]) plots u^2 - v^3 over 0 < u < 1, 3 < v < 6.

ezmesh(x, y, z) plots the parametric surface x = x(s,t), y = y(s,t), and z = z(s,t) over the square: $-2\pi < s < 2\pi$, $-2\pi < t < 2\pi$.

ezmesh(x, y, z, [smin, smax, tmin, tmax]) or ezmesh(x, y, z, [min, max]) plots the parametric surface using the specified domain.

ezmesh(..., n) plots f over the default domain using an n-by-n grid. The default value for n is 60.

ezmesh(..., 'circ') plots f over a disk centered on the domain.

Remarks

 ${\tt rotate3d}$ is always on. To rotate the graph, click and drag with the mouse.

Array multiplication, division, and exponentiation are always implied in the expression you pass to ezmesh. For example, the MATLAB syntax for a mesh plot of the expression,

$$sqrt(x.^2 + y.^2);$$

$$ezmesh('sqrt(x^2 + y^2)')$$

That is, x^2 is interpreted as x. 2 in the string you pass to ezmesh.

Examples

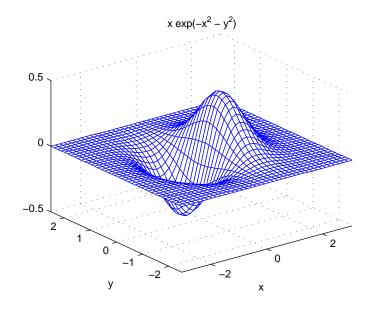

This example visualizes the function,

$$f(x, y) = xe^{-x^2 - y^2}$$

with a mesh plot drawn on a 40-by-40 grid. The mesh lines are set to a uniform blue color by setting the colormap to a single color:

$$ezmesh('x*exp(-x^2-y^2)', 40)$$

 $colormap [0 0 1]$

See Also

ezcontour, ezcontourf, ezmeshc, ezpl ${\tt ot}$, ezpl ${\tt ot}$ 3, ezpol ${\tt ar}$, ezsurf, ezsurfc, mesh

Easy to use combination mesh/contour plotter

Syntax

```
\begin{split} & ezmeshc(f) \\ & ezmeshc(f, domai \, n) \\ & ezmeshc(x, y, z) \\ & ezmeshc(x, y, z, [smi \, n, smax, tmi \, n, tmax]) \text{ or } ezmeshc(x, y, z, [mi \, n, max]) \\ & ezmeshc(\dots, n) \\ & ezmeshc(\dots, 'ci \, rc') \end{split}
```

Description

ezmeshc(f) creates a graph of f(x,y), where f is a string that represents a mathematical function of two variables, such as x and y.

The function f is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$. MATLAB chooses the computational grid according to the amount of variation that occurs; if the function f is not defined (singular) for points on the grid, then these points are not plotted.

ezmeshc(f, domai n) plots f over the specified domai n. domai n can be either a 4-by-1 vector [xmin, xmax, ymin, ymax] or a 2-by-1 vector [min, max] (where, min < x < max, min < y < max).

If f is a function of the variables u and v (rather than x and y), then the domain endpoints umin, umax, vmin, and vmax are sorted alphabetically. Thus, ezmeshc('u^2 - v^3', [0, 1], [3, 6]) plots u^2 - v^3 over 0 < u < 1, 3 < v < 6.

ezmeshc(x, y, z) plots the parametric surface x = x(s,t), y = y(s,t), and z = z(s,t) over the square: $-2\pi < s < 2\pi$, $-2\pi < t < 2\pi$.

ezmeshc(x, y, z, [smin, smax, tmin, tmax]) or ezmeshc(x, y, z, [min, max]) plots the parametric surface using the specified domain.

ezmeshc(..., n) plots f over the default domain using an n-by-n grid. The default value for n is 60.

 $\operatorname{ezmeshc}(\ldots, '\operatorname{ci}\operatorname{rc}')$ plots f over a disk centered on the domain.

Remarks

 ${\tt rotate3d}$ is always on. To rotate the graph, click and drag with the mouse.

Array multiplication, division, and exponentiation are always implied in the expression you pass to ezmeshc. For example, the MATLAB syntax for a mesh/contour plot of the expression,

$$ezmeshc('sqrt(x^2 + y^2)')$$

That is, x^2 is interpreted as x. in the string you pass to ezmeshc.

Examples

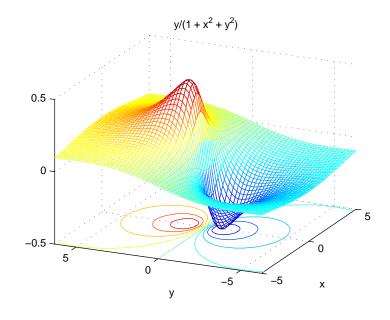

Create a mesh/contour graph of the expression,

$$f(x, y) = \frac{y}{1 + x^2 + y^2}$$

over the domain -5 < x < 5, -2*pi < y < 2*pi:

$$ezmeshc('y/(1 + x^2 + y^2)', [-5, 5, -2*pi, 2*pi])$$

Use the mouse to rotate the axes to better observe the contour lines (this picture uses a view of azimuth = -65.5 and elevation = 26).

See Also

ezcontour, ezcontourf, ezmesh, ezplot, ezplot3, ezpolar, ezsurf, ezsurfc, meshc

Easy to use function plotter

Syntax

```
ezpl ot (f)
ezpl ot (f, [mi n, max])
ezpl ot (f, [xmi n, xmax, ymi n, ymax])
ezpl ot (x, y)
ezpl ot (x, y, [tmi n, tmax])
ezpl ot (..., fi gure)
```

Description

ezpl ot (f) plots the expression f = f(x) over the default domain: $-2\pi < x < 2\pi$.

ezpl ot (f, [mi n, max]) plots f = f(x) over the domain: mi n < x < max.

For implicitly defined functions, f = f(x,y):

ezpl ot (f) plots f(x,y) = 0 over the default domain $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

ezplot(f, [xmi n, xmax, ymi n, ymax]) plots f(x,y) = 0 over xmi n < x < xmax and ymi n < y < ymax.

ezplot (f, [mi n, max]) plots f(x,y) = 0 over mi n < x < max and mi n < y < max.

If f is a function of the variables u and v (rather than x and y), then the domain endpoints umin, umax, vmin, and vmax are sorted alphabetically. Thus, ezpl ot ('u^2 - v^2 - 1', [-3, 2, -2, 3]) plots u^2 - v^2 - 1 = 0 over -3 < u < 2, -2 < v < 3.

ezpl ot (x, y) plots the parametrically defined planar curve x = x(t) and y = y(t) over the default domain $0 < t < 2\pi$.

ezplot(x, y, [tmi n, tmax]) plots x = x(t) and y = y(t) over tmi n < t < tmax.

ezpl ot $(\dots,figure)$ plots the given function over the specified domain in the figure window identified by the handle figure.

Remarks

Array multiplication, division, and exponentiation are always implied in the expression you pass to ezpl ot. For example, the MATLAB syntax for a plot of the expression,

which represents an implicitly defined function, is written as:

$$ezplot('\,x^{\wedge}2\ -\ y^{\wedge}2'\,)$$

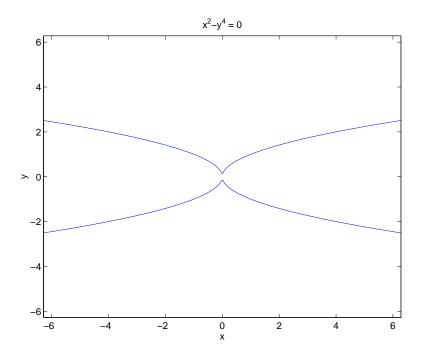

That is, $x^{\wedge}2$ is interpreted as $x.\ ^{\wedge}2$ in the string you pass to ezpl ot .

Examples

This example plots the implicitly defined function,

$$x^2 - y^4 = 0$$

over the domain $[-2\pi, 2\pi]$:

Easy to use 3-D parametric curve plotter

Syntax

$$ezplot3(x, y, z)$$

 $ezplot3(x, y, z, [tmin, tmax])$
 $ezplot3(..., 'animate')$

Description

ezpl ot 3(x, y, z) plots the spatial curve x = x(t), y = y(t), and z = z(t) over the default domain $0 < t < 2\pi$.

ezplot3(x, y, z, [tmi n, tmax]) plots the curve x = x(t), y = y(t), and z = z(t) over the domain tmi n < t < tmax.

ezplot3(..., 'ani mate') produces an animated trace of the spatial curve.

Remarks

Array multiplication, division, and exponentiation are always implied in the expression you pass to ezpl ot 3. For example, the MATLAB syntax for a plot of the expression,

$$x = s. /2, y = 2. *s, z = s. ^2;$$

which represents a parametric function, is written as:

ezpl ot3('
$$s/2^{\scriptscriptstyle '}$$
 , ' $2^*s^{\scriptscriptstyle '}$, ' $s^{\scriptscriptstyle \wedge}2^{\scriptscriptstyle '}$)

That is, s/2 is interpreted as s. /2 in the string you pass to ezpl ot 3.

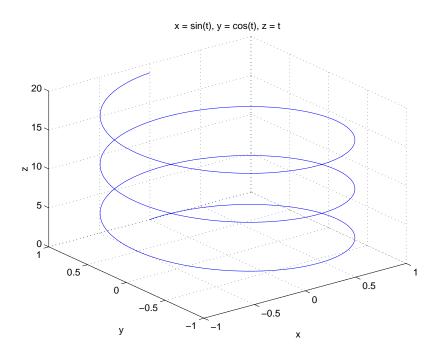

Examples

This example plots the parametric curve,

$$x = \sin t$$
, $y = \cos t$, $z = t$

over the domain $[0,6\pi]$:

$$ezplot3('sin(t)', 'cos(t)', 't', [0, 6*pi])$$

See Also ezcontour, ezcontourf, ezmesh, ezmeshc, ezplot, ezpolar, ezsurf, ezsurfc, plot3

Purpose Easy to use polar coordinate plotter

 $\textbf{Syntax} \qquad \quad \operatorname{ezpol}\operatorname{ar}(f)$

ezpolar(f,[a,b])

Description ezpol ar(f) plots the polar curve rho = f(theta) over the default domain 0 < 1

theta $< 2\pi$.

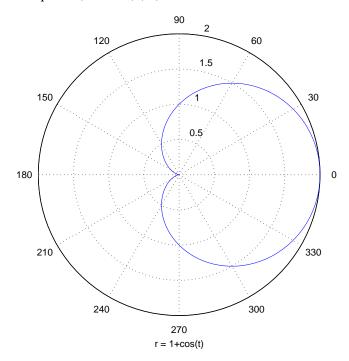

ezpolar(f, [a, b]) plots f for a < theta < b.

Examples This example creates a polar plot of the function,

1 + cos(t)

over the domain $[0, 2\pi]$:

ezpolar('1+cos(t)')

See Also

ezplot, ezplot3, ezsurf, plot, plot3, polar

Easy to use 3-D colored surface plotter

Syntax

```
\begin{array}{l} ezsurf(f) \\ ezsurf(f,domain) \\ ezsurf(x,y,z) \\ ezsurf(x,y,z,[smin,smax,tmin,tmax]) \ or \ ezsurf(x,y,z,[min,max]) \\ ezsurf(\ldots,n) \\ ezsurf(\ldots,'circ') \end{array}
```

Description

ezsurf (f) creates a graph of f(x,y), where f is a string that represents a mathematical function of two variables, such as x and y.

The function f is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$. MATLAB chooses the computational grid according to the amount of variation that occurs; if the function f is not defined (singular) for points on the grid, then these points are not plotted.

ezsurf (f, domai n) plots f over the specified domai n. domai n can be either a 4-by-1 vector [xmin, xmax, ymin, ymax] or a 2-by-1 vector [min, max] (where, min < x < max, min < y < max).

If f is a function of the variables u and v (rather than x and y), then the domain endpoints umin, umax, vmin, and vmax are sorted alphabetically. Thus, ezsurf ('u^2 - v^3', [0, 1], [3, 6]) plots u^2 - v^3 over 0 < u < 1, 3 < v < 6.

ezsurf (x, y, z) plots the parametric surface x = x(s,t), y = y(s,t), and z = z(s,t) over the square: $-2\pi < s < 2\pi$, $-2\pi < t < 2\pi$.

ezsurf (x, y, z, [smin, smax, tmin, tmax]) or ezsurf (x, y, z, [min, max]) plots the parametric surface using the specified domain.

ezsurf (..., n) plots f over the default domain using an n-by-n grid. The default value for n is 60.

ezsurf(..., 'circ') plots f over a disk centered on the domain.

Remarks

rotate3d is always on. To rotate the graph, click and drag with the mouse.

Array multiplication, division, and exponentiation are always implied in the expression you pass to ezsurf. For example, the MATLAB syntax for a surface plot of the expression,

$$sqrt(x.^2 + y.^2);$$

$$ezsurf('sqrt(x^2 + y^2)')$$

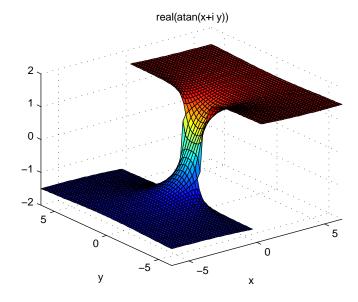

That is, x^2 is interpreted as x. 2 in the string you pass to ezsurf.

Examples

ezsurf does not graph points where the mathematical function is not defined (these data points are set to NaNs, which MATLAB does not plot). This example illustrates this filtering of singularities/discontinuous points by graphing the function,

$$f(x, y) = real(atan(x + iy))$$

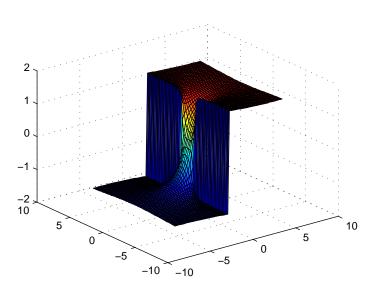

over the default domain $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$:

Using surf to plot the same data produces a graph without filtering of discontinuities (as well as requiring more steps):

```
[x, y] = meshgrid(linspace(-2*pi, 2*pi, 60));
z = real(atan(x+i.*y));
```

surf(x, y, z)

Note also that ezsurf creates graphs that have axis labels, a title, and extend to the axis limits.

See Also

ezcontour, ezcontourf, ezmesh, ezmeshc, ezplot, ezpolar, ezsurfc, surf

Easy to use combination surface/contour plotter

Syntax

```
\begin{array}{l} ezsurfc(f)\\ ezsurfc(f,domai\,n)\\ ezsurfc(x,y,z)\\ ezsurfc(x,y,z,[smi\,n,smax,tmi\,n,tmax]) \ or \ ezsurfc(x,y,z,[mi\,n,max])\\ ezsurfc(\ldots,n)\\ ezsurfc(\ldots,'ci\,rc') \end{array}
```

Description

ezsurfc(f) creates a graph of f(x,y), where f is a string that represents a mathematical function of two variables, such as x and y.

The function f is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$. MATLAB chooses the computational grid according to the amount of variation that occurs; if the function f is not defined (singular) for points on the grid, then these points are not plotted.

ezsurfc(f, domai n) plots f over the specified domai n. domai n can be either a 4-by-1 vector [xmin, xmax, ymin, ymax] or a 2-by-1 vector [min, max] (where, min < x < max, min < y < max).

If f is a function of the variables u and v (rather than x and y), then the domain endpoints umin, umax, vmin, and vmax are sorted alphabetically. Thus, ezsurfc('u^2 - v^3', [0, 1], [3, 6]) plots u^2 - v^3 over 0 < u < 1, 3 < v < 6.

ezsurf c(x, y, z) plots the parametric surface x = x(s,t), y = y(s,t), and z = z(s,t) over the square: $-2\pi < s < 2\pi$, $-2\pi < t < 2\pi$.

ezsurfc(x, y, z, [smin, smax, tmin, tmax]) or ezsurfc(x, y, z, [min, max]) plots the parametric surface using the specified domain.

ezsurf c(..., n) plots f over the default domain using an n-by-n grid. The default value for n is 60.

ezsurfc(..., 'circ') plots fover a disk centered on the domain.

Remarks

 ${\tt rotate3d}$ is always on. To rotate the graph, click and drag with the mouse.

Array multiplication, division, and exponentiation are always implied in the expression you pass to ezsurfc. For example, the MATLAB syntax for a surface/contour plot of the experssion,

$$ezsurfc('sqrt(x^2 + y^2)')$$

That is, x^2 is interpreted as x. 2 in the string you pass to ezsurf c.

Examples

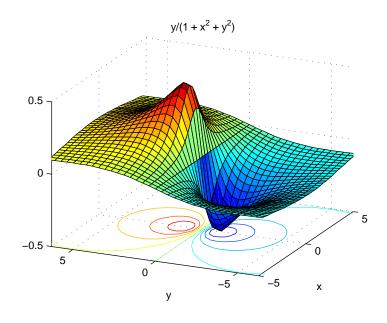

Create a surface/contour plot of the expression,

$$f(x, y) = \frac{y}{1 + x^2 + y^2}$$

over the domain -5 < x < 5, -2*pi < y < 2*pi, with a computational grid of size 35-by-35:

$$ezsurfc('y/(1 + x^2 + y^2)', [-5, 5, -2*pi, 2*pi], 35)$$

Use the mouse to rotate the axes to better observe the contour lines (this picture uses a view of azimuth = -65.5 and elevation = 26)
