Type II supernovae. A typical type II supernova results from a star somewhat over 8 solar masses, on the main sequence, that spends its last years as a red supergiant burning progressively heavier fuels in its center. The radius of the star, after hydrogen has burned and the star is part way through helium burning, is roughly 500 solar radii, and its luminosity is already about 100,000 times that of the Sun. Each burning stage is shorter than the previous one. The last stage turns silicon and sulfur into a ball of roughly 1.4 solar masses of iron. Once iron has been produced, no more nuclear energy is available. *See* SUPERGIANT STAR.

A combination of instabilities now leads to the implosion of the iron core to a neutron star. When the density at the center reaches several times that of the atomic nucleus, the collapse halts and briefly springs back owing to the short-range repulsive component of the nuclear force. But the energy of this bounce is soon dissipated, and a hot young neutron star remains which, over the next few seconds, radiates away its heat and binding energy as neutrinos. *See* NEUTRINO; STRONG NUCLEAR INTERACTIONS.

The energy output in these neutrinos is enormous, about 3×10^{46} joules or 15% of the rest mass of the Sun converted to energy; rivaling the luminosity of the rest of the observable universe in light. A small fraction of these neutrinos, about 0.3%, are absorbed in reactions with neutrons and protons in the regions just outside the neutron star and deposit their energy. Even this small amount of energy is much greater than the gravitational binding of the remaining part of the star external to the newly formed neutron star. A bubble of radiation is inflated by the neutrino energy deposition, the outer boundary of which expands supersonically, driving a shock wave through the rest of the star and ejecting it with high velocity. The main energy of the explosion, though, is carried away as neutrinos. This general picture was confirmed when a neutrino burst of the predicted energy and duration was detected February 23, 1987, from the Large Magellanic Cloud in conjunction with SN 1987A. *See* NEUTRINO ASTRONOMY; SHOCK WAVE.

Nucleosynthesis. Supernovae are major element factories, responsible for producing most of the elements in nature heavier than nitrogen. The largest yields are of the more abundant elements, including oxygen, silicon, magnesium, neon, iron, and a portion of carbon, but dozens of other elements are also made. *See* NUCLEOSYNTHESIS.

Type Ia cosmological applications. Because of their brightness and the regularity of their light curves, type Ia supernovae have long been used as standard candles to survey cosmological distances. More recently it has been realized that the relatively small variation that occurs in the peak brilliance of such supernovae may be correlated with their decline rates. Use of this so-called Phillips relation allows even greater precision in distance determination. Using type Ia supernovae in this fashion reveals a surprising result. Two independent analyses show that the expansion rate of the universe is not slowing as might be expected long after the big bang, but is actually accelerating. The pull of gravity can only cause deceleration, so the acceleration is attributed to an invisible form of dark energy that enters into the cosmological equations as a repulsive term. *See* ASTROPHYSICS, HIGH-ENERGY; COSMOLOGY; STAR; STELLAR EVOLUTION; UNIVERSE; VARIABLE STAR. [S.E.Wo.]

Superoxide chemistry A branch of chemistry that deals with the reactivity of the superoxide ion (O_2^-), a one-electron (e^-) adduct of molecular oxygen (dioxygen; O_2) formed by the combination of O_2 and e^-. Because 1–15% of the O_2 that is respired by mammals goes through the O_2^- oxidation state, the biochemistry and reaction chemistry of the species are important to those concerned with oxygen toxicity, carcinogenesis, and aging. Although the name superoxide has prompted many to assume an exceptional degree of reactivity for O_2^-, the use of the prefix in fact was chosen to indicate stoichiometry. Superoxide was the name given in 1934 to the newly synthesized potassium salt (KO_2) to differentiate its two-oxygens-per-metal stoichiometry from that of most other metal–oxygen compounds (NA_2O, Na_2O_2, NaOH, Fe_2O_3).

Ionic salts of superoxide (yellow-to-orange solids), which form from the reaction of dioxygen with metals such as potassium, rubidium, or cesium, are paramagnetic, with one unpaired electron per two oxygen atoms.

In 1969, by means of electron spin resonance (ESR) spectroscopy, superoxide ion was detected as a respiratory intermediate, and metalloproteins were discovered that catalyze the disproportionation of superoxide, that is, superoxide dismutases (SODs), as shown in the reaction below.

$$2O_2^- + 2H^+ \xrightarrow{\text{SOD}} O_2 + H_2O_2$$

The biological function of superoxide dismutases is believed to be the protection of living cells against the toxic effects of superoxide. The possibility that superoxide might be an important intermediate in aerobic life provided an impetus to the study of superoxide reactivity.

The most general and universal property of O_2^- is its tendency to act as a strong BrØnsted base. Its strong proton affinity manifests itself in any media. Another characteristic of O_2^- is its ability to act as a moderate one-electron reducing agent. *See* Acid and base; Oxidation-reduction.

In general, superoxide ion chemistry does not appear to be sufficiently robust to make superoxide ion a toxin. However, it can interact with protons, halogenated carbons, and carbonyl compounds to yield peroxy radicals that are toxic. *See* Oxygen toxicity; Reactive intermediates.

Superoxide does not appear to have exceptional reactivity. Nevertheless, superoxide will continue to be an interesting species for study because of the multiplicity of its chemical reactions and because of its importance as an intermediate in reactions that involve dioxygen and hydrogen peroxide. *See* Bioinorganic chemistry; Oxygen. [D.T.S.]

Superplastic forming A process for shaping superplastic materials, a unique class of crystalline materials that exhibit exceptionally high tensile ductility. Superplastic materials may be stretched in tension to elongations typically in excess of 200% and more commonly in the range of 400–2000%. There are rare reports of higher tensile elongations reaching as much as 8000%. The high ductility is obtained only for superplastic materials and requires both the temperature and rate of deformation (strain rate) to be within a limited range. The temperature and strain rate required depend on the specific material. A variety of forming processes can be used to shape these materials; most of the processes involve the use of gas pressure to induce the deformation under isothermal conditions at the suitable elevated temperature. The tools and dies used, as well as the superplastic material, are usually heated to the forming temperature. The forming capability and complexity of configurations producible by the processing methods of superplastic forming greatly exceed those possible with conventional sheet forming methods, in which the materials typically exhibit 10–50% tensile elongation. *See* Superplasticity.

There are a number of commercial applications of superplastic forming and combined superplastic forming and diffusion bonding, including aerospace, architectural, and ground transportation uses. Examples are wing access panels in the Airbus A310 and A320, bathroom sinks in the Boeing 737, turbo-fan-engine cooling-duct components, external window frames in the space shuttle, front covers of slot machines, and architectural siding for buildings. *See* Metal forming. [C.H.Ha.]

Superplasticity The unusual ability of some metals and alloys to elongate uniformly thousands of percent at elevated temperatures, much like hot polymers or glasses. Under normal creep conditions, conventional alloys do not stretch uniformly, but form a necked-down region and then fracture after elongations of only 100% or less. The most important requirements for obtaining superplastic behavior include a very small metal grain size, a well-rounded (equiaxed) grain shape, a deformation temperature greater than one-half the melting point, and a slow deformation rate. *See* Alloy; Creep (materials); Eutectics.

Superplasticity is important to technology primarily because large amounts of deformation can be produced under low loads. Thus, conventional metal-shaping processes (for example, rolling, forging, and extrusion) can be conducted with smaller, and cheaper equipment. Nonconventional forming methods can also be used; for instance, vacuum-forming techniques, borrowed from the plastics industry, have been applied to sheet metal to form car panels, refrigerator door linings, and TV chassis parts. *See* Metal forming; Plasticity. [E.E.U.]

Superposition principle The principle, obeyed by many equations describing physical phenomena, that a linear combination of the solutions of the equation is also a solution.

An effect is proportional to a cause in a variety of phenomena encountered at the level of fundamental physical laws as well as in practical applications. When this is true, equations which describe such a phenomenon are known as linear, and their solutions obey the superposition principle. Thus, when $f, g, h, \cdots$, solve the linear equation, then s ($s = \alpha f + \beta g + \gamma h + \cdots$, where $\alpha, \beta, \gamma, \cdots$, are coefficients) also satisfies the same equation. *See* Linear algebra; Linearity.

For example, an electric field is proportional to the charge that generates it. Consequently, an electric force caused by a collection of charges is given by a superposition—a vector sum—of the forces caused by the individual charges. The same is true for the magnetic field and its cause—electric currents. Each of these facts is connected with the linearity of Maxwell's equations, which describe electricity and magnetism. *See* Electric field; Maxwell's equations.

The superposition principle is important both because it simplifies finding solutions to complicated linear problems (they can be decomposed into sums of solutions of simpler problems) and because many of the fundamental laws of physics are linear. Quantum mechanics is an especially important example of a fundamental theory in which the superposition principle is valid and of profound significance. This property has proved most useful in studying implications of quantum theory, but it is also a source of the key conundrum associated with its interpretation.

Its effects are best illustrated in the double-slit superposition experiment, in which the wave function representing a quantum object such as a photon or electron can propagate toward a detector plate through two openings (slits). As a consequence of the superposition principle, the wave will be a sum of two wave functions, each radiating from its respective slit. These two waves interfere with each other, creating a pattern of peaks and troughs, as would the waves propagating on the surface of water in an analogous experimental setting. However, while this pattern can be easily understood for the normal (for example, water or sound) waves resulting from the collective motion of vast numbers of atoms, it is harder to understand its origin in quantum mechanics, where the wave describes an individual quantum, which can be detected, as a single particle, in just one spot along the detector (for example, photographic) plate. The interference pattern will eventually emerge as a result of many such individual quanta, each of which apparently exhibits both wave (interference-pattern) and particle (one-by-one detection) characteristics. This ambivalent nature of quantum phenomena is known as the wave-particle duality. *See* Interference of waves; Quantum mechanics. [W.H.Z.]

Superposition theorem (electric networks)

Essentially, that it is permissible, if there are two or more sources of electromotive force in a linear electrical network, to compute at any element of the network the response of voltage or of current that results from one source alone, and then the response resulting from another source alone, and so on for all sources, and finally to compute the total response to all sources acting together by adding these individual responses.

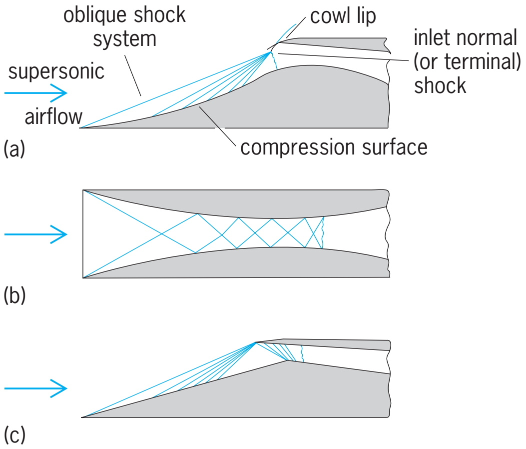
Thus, if a load of constant resistance is supplied with electrical energy from a linear network containing two batteries, two generators, or one battery and one generator, it would be correct to find the current that would be supplied to the load by one source (the other being reduced to zero), then to find the current that would be supplied to the load by the second source (the first source now being reduced to zero), and finally to add the two currents so computed to find the total current that would be produced in the load by the two sources acting simultaneously.

By means of the principle of superposition, effects are added instead of causes. This principle seems so intuitively valid that there is far greater danger of applying superposition where it is incorrect than of failing to apply it where it is correct. It must be recognized that for superposition to be correct the relation between cause and effect must be linear. [H.H.Sk.]

Supersaturation A solution is at the saturation point when dissolved solute in its crystallizes from it at the same rate at which it dissolves. Under prescribed experimental conditions of temperature and pressure, a solution can contain at saturation only one fixed amount of dissolved solute. However, it is possible to prepare relatively stable solutions which contain a quantity of a dissolved solute greater than that of the saturation value provided solute phase is absent. Such solutions are said to be supersaturated. They can be prepared by changing the experimental conditions of a system so that greater solubility is obtained, perhaps by heating the solution, and then carefully returning the system to or near its original state. The addition of solute phase will immediately relieve supersaturation. Solutions in which there is no spontaneous formation of solute phase for extended periods of time are said to be metastable. There is no sharp line of demarcation between an unstable and metastable solution. The process whereby initial aggregates within a supersaturated solution develop spontaneously into particles of new stable phase is known as nucleation. The greater the degree of supersaturation, the greater will be the number of nuclei formed. *See* Nucleation; Phase equilibrium; Precipitation (chemistry). [L.Go./R.W.Mu.]

Supersonic diffuser A passive compressor (or shaped duct) in which gas enters at a velocity greater than the speed of sound, is decelerated in a contracting section, and reaches sonic speed at a throat.

Supersonic compression systems can be categorized to three basic types (see illustration). External-compression inlets have the supersonic diffusion taking place at or ahead of the cowl lip (or throat station) and generally employ one or more oblique waves ahead of the normal shock. Internal-compression inlets accomplish supersonic diffusion internally downstream of the cowl lip. Deceleration of the flow is produced by a number of weak reflecting waves in a gradually convergent channel. The third system is a combination of external and internal compression and appears to represent an effective compromise. [J.F.C.; L.J.O.]

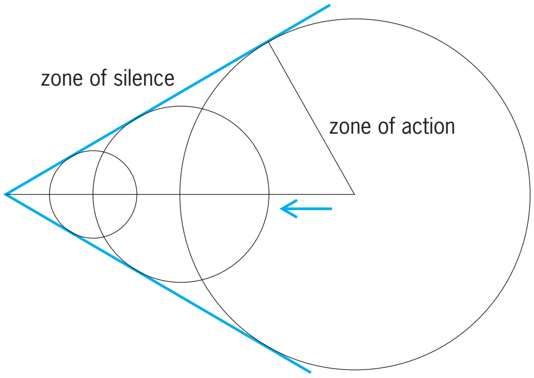


Basic supersonic compression systems. (*a*) External compression. (*b*) Internal compression. (*c*) Combination of external and internal compression.

Supersonic flight Relative motion of a solid body and a gas at a velocity greater than that of sound propagation under the same conditions. The general characteristics of supersonic flight can be understood by considering the laws of propagation of a disturbance or pressure impulse, in a compressible fluid.

If the fluid is at rest, the pressure impulse propagates uniformly with the velocity of sound in all directions, the effect always acting along an ever-increasing spherical surface. If, however, the source of the impulse is placed in a uniform stream, the impulse will be carried by the stream simultaneously with its propagation at sonic velocity relative to the stream. Hence the resulting propagation is faster in the direction of the stream and slower against the stream. If the velocity of the stream past the source of disturbance is supersonic, the effect of the impulse is restricted to a cone whose vertex is the source of the impulse and whose vertex angle decreases from 90° (corresponding to Mach number equal to 1) to smaller and smaller values as the Mach number of the stream increases (see illustration). If the source of the pressure impulse travels through the air at rest, the conditions are analogous. *See* Mach number.

Consider the supersonic motion of a wing moving into air at rest. Because signals cannot propagate ahead of the wing, the presence of the wing has no effect on the undisturbed air until the wing passes through it. Hence there must be an abrupt change in the properties of the undisturbed air as it begins to flow over the wing. This abrupt change takes place in a shock wave which



Generation of Mach wave by body at supersonic velocity; zones of action and silence are separated.

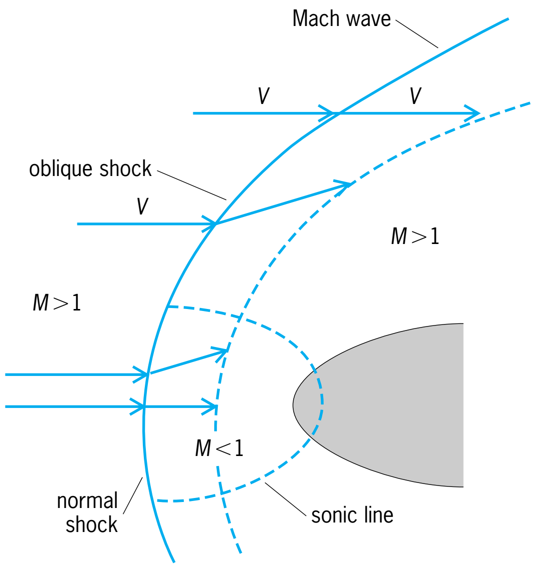
is attached to the leading edge of the wing, provided that the leading edge is sharp and the flight Mach number is sufficiently large. As the air passes through the shock wave, its pressure, temperature, and density are markedly increased.

Further aft of the leading edge, the pressure of the air is decreased as the air expands over the surface of the wing. Hence the pressure acting on the front part of the wing is higher than the ambient pressure, and the pressure acting on the rear part of the wing is lower than the ambient pressure. The pressure difference between front and rear parts produces a drag, even in the absence of skin friction and flow separation. The wing produces a system of compression and expansion waves which move with it. This phenomenon is similar to that of a speedboat moving with a velocity greater than the velocity of the surface waves. Because of this analogy, supersonic drag is called wave drag. It is peculiar to supersonic flight, and it may represent the major portion of the total drag of a body. *See* Hypersonic flight; Subsonic flight; Transonic flight. [J.E.Sc.]

Supersonic flow Fluid motion in which the Mach number M, defined as the speed of the fluid relative to the sonic speed in the same medium, is more than unity. It is, however, common to call the flow transonic when $0.8 < M < 1.4$, and hypersonic when $M > 5$. *See* Mach number.

Mach waves. A particle moving in a compressible medium, such as air, emits acoustic disturbances in the form of spherical waves. These waves propagate at the speed of sound ($M = 1$). If the particle moves at a supersonic speed, the generated waves cannot propagate upstream of the particle. The spherical waves are enveloped in a circular cone called the Mach cone. The generators of the Mach cone are called Mach lines or Mach waves.

Shock waves. When a fluid at a supersonic speed approaches an airfoil (or a high-pressure region), no information is communicated ahead of the airfoil, and the flow adjusts to the downstream conditions through a shock wave. Shock waves propagate faster than Mach waves, and the flow speed changes abruptly from supersonic to less supersonic or subsonic across the wave. Similarly, other properties change discontinuously across the wave. A Mach wave is a shock wave of minimum strength. A normal shock is a plane shock normal to the direction of flow, and an oblique shock is inclined at an angle to the direction of flow. The velocity upstream of a shock wave is always supersonic. Downstream of an oblique shock, the velocity may be subsonic resulting in a strong shock, or supersonic resulting in a weak shock. The downstream velocity component normal to any shock wave is always subsonic. There is no change in the tangential velocity component across the shock.



Typical normal shock, oblique shock, and Mach wave pattern in supersonic flow past a blunt body. *M* is the Mach number and *V* is the particle speed. The curved line parallel to normal and oblique shock waves indicates the end of the velocity vectors.

In a two-dimensional supersonic flow around a blunt body (see illustration), a normal shock is formed directly in front of the body, and extends around the body as a curved oblique shock. At a sufficient distance away, the flow field is unaffected by the presence of the body, and no discontinuity in velocity occurs. The shock then reduces to a Mach wave. *See* Compressible flow; Fluid flow; Supersonic flight. [M.A.S.]

Superstring theory A proposal for a unified theory of all interactions, including gravity. At present, the strong, weak, and electromagnetic interactions are accounted for within the framework of the standard model. This model correctly describes experiments up to the highest energies performed so far, and gives a complete description of the elementary particles and their interactions down to distances of the order of 10^{-18} m. Nevertheless, it has serious limitations, and attempts to overcome them and to unify the forces of nature have been only partly successful. Moreover, these attempts have left standing fundamental difficulties in reconciling gravitation and the laws of quantum mechanics. Superstring theory represents an ambitious program to unify all of the interactions observed in nature, including gravitation, in a theory with no unexplained parameters. In other words, this theory, if successful, should be able to account for all of the particles observed in nature and their interactions. *See* Elementary particle; Fundamental interactions.

String concept. In string theory, the fundamental objects are not point particles, as in standard theories of elementary particles, but one-dimensional extended objects, the open and closed strings. In such a theory, what are usually called the elementary particles are simply particular quantum states of the string. In superstring theories, space-time is ten-dimensional (space is nine-dimensional). If such theories are to describe nature, six dimensions must be “curled up” or “compact.” The main consequence of such extra dimensions is the existence of certain very massive particles. *See* Space-time.

The essential features of string theories can be understood by analogy with the strings of a musical instrument. Such strings vibrate at a characteristic frequency, as well as any integer multiple of that frequency. Each of these modes of vibration (so-called normal modes) can be excited by plucking or striking the string. In classical physics, the amplitudes of vibration of each mode can take on a continuum of values. If there were a string of atomic dimensions, subject to the laws of quantum mechanics, the energies of this quantum string could take on only discrete values, corresponding to particular quantum states. *See* Quantum mechanics; Vibration.

The strings of superstring theory are quite similar. The main difference is that they obey Einstein’s principles of special relativity. As a result, since each quantum state has a particular energy, it has a definite mass. Thus, each state of the string behaves as a particle of definite mass. Because it is possible, in principle, to pump an arbitrarily large amount of energy into the string, the theory contains an infinity of different types of particles of arbitrarily large mass. The interactions of these particles are governed by the ways in which the strings themselves interact. To be consistent with the principles of relativity, a string can interact only by splitting into two strings or by joining together with another string to form a third string. As a result, the interactions of strings are nearly unique. This geometric picture of string interactions translates into a precise set of rules for calculating the interaction of individual string states, that is, particles. *See* Relativity.

Classical solutions. Obtaining a description of superstring theory analogous to quantum field theory is an active topic of research. However, even though the equations that describe this field theory are not completely known at present, it is known how to find classical solutions of these equations, and by various techniques, an enormous number of such solutions have been found. These include states in which space-time has any dimension between one and ten, and states with many bizarre symmetries and spectra. Each of these solutions then corresponds to a possible ground state of the system. The theories built around some of these states look very much like the real world. Not only are four dimensions flat while six are compact, but they possess gauge symmetries close to that of the standard model. Some have three or four generations of quarks and leptons, as well as light Higgs particles, which are of crucial importance in the standard model. Many of these solutions possess space-time supersymmetry. *See* GAUGE THEORY; HIGGS BOSON; LEPTON; QUARKS.

However, if the theory does describe nature, it must have some mechanism that chooses one of the possible ground states. Because the masses and couplings of the elementary particles depend only on the choice of ground state, determining this true ground state will yield a set of predictions for these quantities. If string theory is a correct theory, these predictions must agree with the experimental values. [M.Di.]

Supersymmetry A conjectured enhanced symmetry of the laws of nature that would relate two fundamental observed classes of particles, bosons and fermions.

All particles can be classified as fermions, such as the electron and quarks, or bosons, such as the photon and graviton. A fundamental characteristic distinguishing these two classes is that they carry different quantum-mechanical spin. If the amount of spin of an elementary particle is measured in terms of the fundamental quantum unit of angular momentum—$\hbar$, equal to Planck's constant divided by 2π—then bosons always have integer amounts of spin (that is, 0, 1, 2 . . .), while fermions have odd half-integer amounts of spin (that is, 1/2, 3/2, 5/2, . . .). *See* SPIN (QUANTUM MECHANICS).

There is seemingly a fundamental distinction between particles with differing amounts of spin. For example, bosons like to act collectively (Bose-Einstein statistics), producing such distinctive behavior as the laser, while, conversely, fermions obey the Pauli exclusion principle (and the Pauli-Dirac statistics), which disallows two identical fermions to be in the same state, and explains the stability of matter. Moreover, all the symmetries that are observed in the world relate different particles of the same spin. *See* BOSE-EINSTEIN STATISTICS; FERMI-DIRAC STATISTICS; QUANTUM STATISTICS; SYMMETRY LAWS (PHYSICS).

In contrast, supersymmetry would relate bosons and fermions. This would be a remarkable step forward in understanding the physical world. However, if supersymmetry were realized as an exact symmetry, the particles so related should have almost all their characteristics, such as mass and charge, preserved. Explicitly, any fermion of spin 1/2 should have a boson superpartner of spin 0, while any gauge boson of spin 1 should have a fermion superpartner of spin 1/2. This is apparently a disaster for the idea of supersymmetry since it predicts, for instance, that there should exist a spin-0 boson partner of the electron, the selectron, with electric charge and mass equal to that of the electron. Such a particle would be easy to detect and is certainly ruled out by very many experiments.

The crucial caveat to this negative result is the condition that supersymmetry be realized as an exact symmetry. A fundamental concept of modern physics is spontaneously broken symmetry. Physics displays many examples of symmetries that are exact symmetries of the fundamental equations describing a system, but not of their solutions. In particle physics the spontaneous breaking of a symmetry usually results in a difference in the masses of the particles related by the symmetry; the amount of breaking can be quantified by this mass difference. *See* SYMMETRY BREAKING.

If supersymmetry is broken by a large amount, then all the superpartners have masses much greater than the particles that are currently observed, and there is little hope of seeing evidence for supersymmetry. However, evidence that supersymmetry is broken by only a moderate amount comes from examination of the properties of the fundamental forces at high energy.

Of the four fundamental forces, the three excluding gravity are very similar in their basic formulation; they are all described by gauge theories, generalizations of the quantum theory of electromagnetism, and quantum electrodynamics (QED). The strength of electrical interaction between two electrons can be quantified in terms of a number, the coupling constant α_1. However, the quantity α_1 is actually not a constant, but depends on the energies at which the interaction strength is measured. In fact, the interaction strengths, α_1, α_2, and α_3, of the three forces (excluding gravity) all depend on energy, μ. The couplings $\alpha_{1,2,3}$ satisfy differential equations—renormalization group equations—that depend on the types of elementary particles that exist with mass at or below the energy scale μ and that are charged with respect to each of the three interactions. If the fundamental particles include not only the observed particles but also their superpartners, taken to have masses not greater than 1000 GeV heavier than their (observed) partners, then from the renormalization group equations, the couplings α_i are predicted to meet (unify) at a huge energy of 2×10^{16} GeV. In contrast, if either supersymmetry is not an underlying symmetry of the world, or it is very badly broken so that the superpartners are very massive, the couplings fail to unify at a single point. *See* FUNDAMENTAL INTERACTIONS; GAUGE THEORY; QUANTUM ELECTRODYNAMICS; RENORMALIZATION.

Although the unification of couplings is the most significant indication that supersymmetry is a new law of nature, there are a number of other hints in this same direction. By observing the large-scale motions of the galaxies, the average density of large volumes of the universe can be deduced, resulting in a value that is substantially greater than that directly observed in luminous matter such as stars and hot gas. Therefore, a substantial fraction of the mass of the universe must be composed of some form of nonluminous or dark matter. Remarkably, many attractive models of supersymmetry predict that the lightest of all the superpartners is a weakly interacting massive particle with just the right characteristics to be this dark matter. *See* COSMOLOGY; UNIVERSE; WEAKLY INTERACTING MASSIVE PARTICLE (WIMP). [J.M.R.]

Suppression (electricity) The process or technique of reducing electrical interference to acceptable levels or to situations having no adverse effect. Suppression techniques may be applied to the interference source, the intervening path, the victim or receptor, or any combination. Normal strategy for interference control is to first suppress the source, if possible, since it may disturb many victims.

For intentional transmitters, suppressing interference may include reducing or eliminating harmonic radiations, restricting the bandwidth, or restricting levels of unnecessary or excessive modulation sidebands. These are usually accomplished by radio frequency filters. *See* ELECTRIC FILTER.

For many devices involving incidental radiators, such as brush-type motors and fluorescent lights, interference suppression may require both filtering and shielding. Electrical filtering may take the form of transient surge suppressors, feed-through capacitors, electromagnetic interference (EMI) filters, ferrite absorbers, isolation transformers, or Faraday shielded isolation transformers. *See* ELECTRIC PROTECTIVE DEVICES.

Shielding to control radiation involves using metal boxes, cases, cabinet housings, or metalized plastic versions thereof. Since the interconnecting cables between equipment offer the greatest threat as an “antenna farm,” the dominant suppression technique is to shield the cables, wires, or harnesses. For the best protection from electromagnetic interference, the cable shield should be designed as an extension of the box or equipment shield. Other forms of interference hardening of cables include twisting parallel wire pairs, multiple-layer shields, and absorbing jackets. Where possible, best electromagnetic compatibility performance is obtained by replacing the signal cables with fiber-optic links. *See* ELECTRICAL SHIELDING.

From a system point of view, the radiated emission propensity or pickup susceptibility of interconnected equipment is proportional to the maximum length or dimension and frequency until this length corresponds to an electrical length of about one-half wavelength. Thus, to help suppress electromagnetic interference, the corresponding frequency should not fall within the passband of victims or receptors. *See* ELECTRICAL INTERFERENCE; ELECTROMAGNETIC COMPATIBILITY. [D.R.J.W.]

Supramolecular chemistry A highly interdisciplinary field covering the chemical, physical, and biological features of complex chemical species held together and organized by means of intermolecular (noncovalent) bonding interactions. *See* CHEMICAL BONDING; INTERMOLECULAR FORCES.

When a substrate binds to an enzyme or a drug to its target, and when signals propagate between cells, highly selective interactions occur between the partners that control the processes. Supramolecular chemistry is concerned with the study of the basic features of these interactions and with their implementation in biological systems as well as in specially designed nonnatural ones. In addition to biochemistry, its roots extend into organic chemistry and the synthetic procedures for receptor construction, into coordination chemistry and metal ion-ligand complexes, and into physical chemistry and the experimental and theoretical studies of interactions. *See* BIOINORGANIC CHEMISTRY; ENZYME; LIGAND; PHYSICAL ORGANIC CHEMISTRY; PROTEIN.

The field started with the selective binding of alkali metal cations by natural as well as synthetic macrocyclic and macropolycyclic ligands, the crown ethers and cryptands. This led to the emergence of molecular recognition as a new domain of chemical research that, by encompassing all types of molecular components and interactions as well as both oligo and polymolecular entities, became supramolecular chemistry. It underwent rapid growth with the development of synthetic receptor molecules of numerous types for the strong and selective binding of cationic, anionic, or neutral complementary substrates of organic, inorganic, or biological nature by means of various interactions (electrostatic, hydrogen bonding, van der Waals, and donor-acceptor). Molecular recognition implies the (molecular) storage and the (supramolecular) retrieval and processing of molecular structural (geometrical and interactional) information. *See* HYDROGEN BOND; MACROCYCLIC COMPOUND; MOLECULAR RECOGNITION.

Many types of receptor molecules have been explored (crown ethers, cryptands, cyclodextrins, calixarenes, cavitands, cyclophanes, cryptophanes, and so on), and many others may be imagined for the binding of complementary substrates of chemical or biological significance. They allow, for instance, the development of substrate-specific sensors or the recognition of structural features in biomolecules (for example, nucleic acid probes, affinity cleavage reagents, and enzyme inhibitors). *See* BIOPOLYMER; CYCLOPHANE; ENZYME INHIBITION.

A major step in the development of supramolecular chemistry over the last 20 years involved the design of systems capable of spontaneously generating well-defined, supramolecular entities by self-assembly under a given set of conditions.

The information necessary for supramolecular self-assembly to take place is stored in the components, and the program that it follows operates via specific interactional algorithms based on binding patterns and molecular recognition events. Thus, rather than being preorganized, constructed entities, these systems may be considered as self-organizing, programmed supramolecular systems.

Self-assembly and self-organization have recently been implemented in numerous types of organic and inorganic systems. By clever use of metal coordination, hydrogen bonding, and donor-acceptor interactions, researchers have achieved the spontaneous formation of a variety of novel and intriguing species such as inorganic double and triple helices termed helicates, catenates, threaded entities (rotaxanes), cage compounds, grids of metal ions, and so on.

Another major development concerns the design of molecular species displaying the ability to perform self-replication, based on components containing suitable recognition groups and reactive functions. Self-recognition processes involve the spontaneous selection of the correct partner(s) in a self-assembly event—for instance, the correct ligand strand in helicate formation.

A major area of interest is the design of supramolecular devices built on photoactive, electroactive, or ionoactive components, operating respectively with photons, electrons, or ions. Thus, a variety of photonic devices based on photoinduced energy and electron transfer may be imagined. Molecular wires, ion carriers, and channels facilitate the flow of electrons and ions through membranes. Such functional entities represent entries into molecular photonics, electronics, and ionics, which deal with the storage, processing, and transfer of materials, signals, and information at the molecular and supramolecular levels. Dynamic and mechanical devices exploit the control of motion within molecular and supramolecular entities. *See* INORGANIC PHOTOCHEMISTRY; ION TRANSPORT; PHOTOCHEMISTRY.

The design of systems that are controlled, programmed, and functionally self-organized by means of molecular information contained in their components represents new horizons in supramolecular chemistry and provides an original approach to nanoscience and nanotechnology. In particular, the spontaneous but controlled generation of well-defined, functional supramolecular architectures of nanometric size through self-organization—supramolecular nanochemistry—represents a means of performing programmed engineering and processing of nanomaterials. It offers a powerful alternative to the demanding procedures of nanofabrication and nanomanipulation, bypassing the need for external intervention. A rich variety of architectures, properties, and processes should result from this blending of supramolecular chemistry with materials science. *See* NANOCHEMISTRY; NANOTECHNOLOGY. [J.M.Le.]

Surface (geometry) A two-dimensional geometric figure (a collection of points) in three-dimensional space. The simplest example is a plane—a flat surface. Some other common surfaces are spheres, cylinders, and cones, the names of which are also used to describe the three-dimensional geometric figures that are enclosed (or partially enclosed) by those surfaces. In a similar way, cubes, parallelepipeds, and other polyhedra are surfaces. *See* CUBE; POLYHEDRON; SOLID (GEOMETRY).

Any bounded plane region has a measure called the area. If a surface is approximated by polygonal regions joined at their edges, an approximation to the area of the surface is obtained by summing the areas of these regions. The area of a surface is the limit of this sum if the number of polygons increases while their areas all approach zero. *See* AREA; CALCULUS; INTEGRATION; PLANE GEOMETRY; POLYGON.

Methods of description. The shape of a surface can be described by several methods. The simplest is to use the commonly accepted name of the surface, such as sphere or cube. In mathematical discussions, surfaces are normally defined by one or more equations, each of which gives information about a relationship that exists between coordinates of points of the surface, using some suitable coordinate system. *See* COORDINATE SYSTEMS.

Some surfaces are conveniently described by explaining how they might be formed. If a curve, called the generator in three-dimensional space, is allowed to move in some manner, then each position the generator occupies during this motion is a collection of points, and the set of all such points constitutes a surface that can be said to be swept out by the generator. In particular, if the generator is a straight line, a ruled surface is formed. If the generator is a straight line and the motion is such that all positions of the generator are parallel, a cylindrical surface (or just cylinder) is formed. If the generator is a straight line and all positions of the generator have a common point of intersection, a conical surface (or just cone) is formed. A ruled surface that could be bent to lie in a plane (the bending to take place without stretching or tearing) is called a developable surface. *See* CONE; CYLINDER.

Dihedron. A dihedron is the surface formed by bending a plane along a line in that plane. More formally, a dihedron is the union of two half-planes that share the same boundary line.

Quadric surfaces. A surface whose implicit equation $F(x, y, z) = 0$ is second degree is a quadric surface, a three-dimensional analog of a conic section. A plane section of a quadric surface is either a conic section or one of its degenerate forms (a point, a line, parallel lines, or intersecting lines). *See* CONIC SECTION; QUADRIC SURFACE.

Surfaces of revolution. When a plane curve (the generator) is revolved about a line in that plane (the axis of revolution, or just axis), a surface of revolution can be said to be swept out. The resulting surface will be symmetric about the axis of revolution.

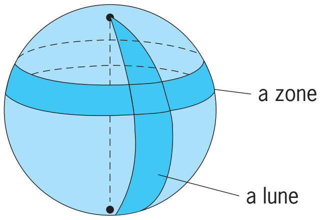
A circular cylinder (a quadric surface) is formed when the generator and the axis of revolution are distinct parallel lines. If the generator is only a segment of a line (rather than the entire line), a bounded circular cylinder is generated.

A circular cone is a quadric surface formed when a straight-line generator intersects the axis of revolution at an acute angle. The cone consists of two parts, the nappes, joined at the point of intersection, which is the vertex of the cone.

A sphere (a quadric surface) is usually defined as a collection of points in three-dimensional space at a fixed distance (the radius) from a given point (the center). However, a sphere can also be defined as the surface of revolution formed when a semicircle (or the entire circle) is revolved about its diameter.

The intersection of any plane with a sphere will be a circle (except for tangent planes). Such a circle is called, respectively, a great circle or a small circle, depending on whether or not the plane contains the center of the sphere.

If only part of a semicircle is revolved about the diameter, a part of a sphere called a zone is formed. If a semicircle is revolved about its diameter through an angle less than one revolution, the surface swept out is a lune (see illustration). *See* SPHERE.



Sphere, with a zone and a lune.

A spheroid (also called an ellipsoid of revolution) is the quadric surface generated when an ellipse is revolved about either its major or minor axis. If the revolving is about the minor axis of the ellipse, the surface can be thought of as a flattened sphere, called an oblate spheroid. If the revolving is about the major axis, the surface can be thought of as a stretched sphere, called a prolate spheroid. A circular paraboloid is the quadric surface formed when a parabola is revolved about its axis. *See* ELLIPSE; PARABOLA.

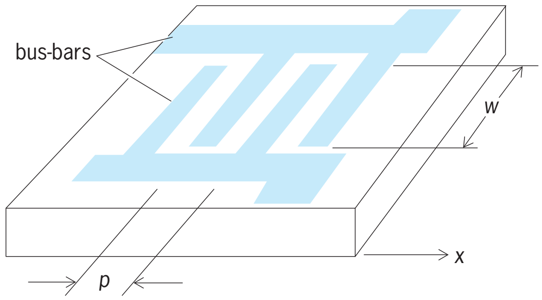
A circular hyperboloid is the quadric surface formed when a hyperbola is revolved about either its transverse axis or its conjugate axis. The surface will be, respectively, a hyperboloid of one sheet or two sheets, depending on whether the revolving is about the conjugate axis or the transverse axis of the hyperbola. *See* HYPERBOLA.

A torus is generated when a circle is revolved about a line that does not intersect the circle. This doughnut-shaped surface has the property that not all points on the surface have the same sign of curvature. *See* DIFFERENTIAL GEOMETRY; TORUS. [H.L.Ba.]

Surface-acoustic-wave devices

Devices which employ surface acoustic waves (SAW) in the analog processing of electronic signals with frequencies in the range 10^7–10^9 Hz.

Surface acoustic waves which contain both compressional and shear components in phase quadrature, propagating nondispersively along and bound to solid surfaces, were discovered by Lord Rayleigh in the 1880s. As an example, earthquakes furnish sources for propagating these waves on the Earth's surface. It is of importance for electronic applications that if the solid is a piezoelectric material, the surface acoustic energy is complemented by a small amount of electric energy. This electric energy provides the physical mechanism for the coupling between conventional electromagnetic signals and propagating SAW. The coupling is attained by means of inter-digital transducers (IDT). SAW devices have led to a versatile microminiature technology for analog signal processing in the frequency range 10^7–10^9 Hz. Notable devices include bandpass filters, resonators, oscillators, pulse compression filters, and fast Fourier transform processors. Application areas include the color television consumer market, radar, sonar, communication systems, and nondestructive testing. *See* PIEZOELECTRICITY.



Interdigital construction of surface acoustic-wave transducer. *x* is a band-pass filter characteristic.

In the basic arrangement, a piezoelectric substrate, often crystalline quartz, has a polished upper surface on which two transducers are deposited. The input transducer is connected, via fine bonded leads, to the electric source through an electrical matching network. The output transducer drives the load, usually 50 ohms, through another electrical matching network. Because these transducers are bidirectional, they lead to devices with at least 6 decibels (dB) loss even in the passband. The unwanted acoustic waves are absorbed by terminations at the ends of the piezoelectric substrate. A metal baffle serves to isolate electromagnetically the two transducers.

The transducers consist of a set of metal interdigital electrodes, each a few hundred nanometers thick, fed from two bus-bars (see illustration). For this transducer arrangement the period p of the interdigital electrode structure is constant and equals one surface acoustic wavelength λ_0 at the center of frequency f_0 of the response. The width of the metal electrodes is typically $p/4$, being 100 micrometers at 10^7 Hz and 1 μm at 10^9 Hz. The electrode overlap distance w is also constant and defines the acoustic beam width, which is typically 40 wavelengths. *See* TRANSDUCER.

The 100-μm electrodes are readily fabricated by using techniques standard to the semiconductor integrated circuit industry of metallization: photoresist, masking, and chemical etching. The 1-μm electrodesrequire more sophisticated processing techniques. These include conformable optical masks and x-ray lithography coupled with sputter etching by radio-frequency and ion-beam methods for even finer resolutions. *See* INTEGRATED CIRCUITS. [J.H.Co.]

Surface and interfacial chemistry Chemical processes that occur at the phase boundary between gas–liquid, liquid–liquid, liquid–solid, or gas–solid interfaces.

The chemistry and physics at surfaces and interfaces govern a wide variety of technologically significant processes. Chemical reactions for the production of low-molecular-weight hydrocarbons for gasoline by the cracking and reforming of the high-molecular-weight hydrocarbons in oil are catalyzed at acidic oxide materials. Surface and interfacial chemistry are also relevant to adhesion, corrosion control, tribology (friction and wear), microelectronics, and biocompatible materials. In the last case, schemes to reduce bacterial adhesion while enhancing tissue integration are critical to the implantation of complex prosthetic devices, such as joint replacements and artificial hearts. *See* CRACKING; HETEROGENEOUS CATALYSIS; MEDICAL CHEMICAL ENGINEERING; PROSTHESIS; SURFACE PHYSICS.

Interactions with the substrate may alter the electronic structure of the adsorbate. Those interactions that lower the activation energy of a chemical reaction result in a catalytic process. Adsorption of reactants on a surface also confines the reaction to two dimensions as opposed to the three dimensions available for a homogeneous process. The two-dimentional confinement of reactants in a bimolecular event seems to drive biochemical processes with higher reaction efficiencies at proteins and lipid membranes. *See* ADSORPTION.

A limitation in the study of surfaces and interfaces rests with the low concentrations of the participants in the chemical process. Concentrations of reactants at surfaces are on the order of 10^{-10} to 10^{-8} mole/cm^2. Such low concentrations pose a sensitivity problem from the perspective of surface analysis. Experimental techniques with high sensitivity are required to examine the low concentrations of a surface species at interfaces.

Electron spectroscopy methods are widely used in the study of surfaces because of the small penetration depth of electrons through solids. This attribute makes electron spectroscopy inherently surface-sensitive, since only a few of the outermost atomic layers are accessible. The methods of electron spectroscopy used in surface studies have several common characteristics (see table). A source provides the incident radiation to the sample, which can be in the form of electrons, x-radiation, or ultraviolet radiation. Electron beams are generated from the thermionic emission of metal filaments or metal oxide pellets. The incident radiation induces an excitation at the surface of the sample, which alters the energy distribution of electrons that leave the surface. This distribution provides a diagnostic of the composition or structure of the interface. *See* ELECTRON SPECTROSCOPY.

Optical spectroscopy techniques (visible and infrared) are also useful for probing the chemical composition and molecular arrangement of surface species. Typical application configurations are the transmission and reflection (both external and internal) modes. Transmission spectroscopy relies on the passage of the probe beam through the sample. External and internal reflection spectroscopies involve the reflection of the probe beam from a medium with a lower refractive index to a medium with a higher refractive index, and from a higher to lower refractive index, respectively. The sample support must be optically transparent to the probe beam for the internal reflection mode. In both cases, the substrates are polished to a smooth, mirrorlike finish. *See* SPECTROSCOPY. [M.M.W.; M.D.P.]

Surface coating A substance applied to other materials to change the surface properties, such as color, gloss, resistance to wear or chemical attack, or permeability, without changing the bulk properties. Surface coatings include such materials as paints, varnishes, enamels, oils, greases, waxes, concrete, lacquers, powder coatings, metal coatings, and fire-retardant formulations. In general, organic coatings are based on a vehicle, usually a resin, which, after being spread out in a relatively thin film, changes to a solid. This change, called drying, may be due entirely to evaporation (solvent or water), or it may be caused by a chemical reaction, such as oxidation or polymerization. Opaque materials called pigments, dispersed in the vehicle, contribute color, opacity, and increased durability and resistance.

Organic coatings are usually referred to as decorative or protective, depending upon whether the primary reason for their use is to change (or preserve) the appearance or to protect the surface. Often both purposes are involved. *See* DRIER (PAINT); DRYING OIL; ELECTROPLATING OF METALS; LACQUER; METAL COATINGS; PAINT; PIGMENT (MATERIAL); PRIMER (SURFACE COATING); SHELLAC; THINNER; VARNISH. [C.R.Ma.; C.W.Si.]

Surface condenser A heat-transfer device used to condense a vapor, usually steam, by absorbing its latent heat in a cooling fluid, ordinarily water. Most surface condensers consist of a chamber containing a large number of corrosion-resisting alloy tubes through which cooling water flows. The vapor contacts the outside surface of the tubes and is condensed on them. The tubes are arranged so that the cooling water passes through the vapor space one or more times. Air coolers are normally an

Surface-sensitive experimental techniques

Technique	Source*	Detectors	Level of information
Auger electron spectroscopy (AES)	Electrons 2–3 keV	Cylindrical mirror of retarding field	Elemental composition
X-ray photoelectron spectroscopy (XPS)	X-rays 1254 eV (Mg) 1487 eV (Al)	Hemispherical or cylindrical mirror	Elemental composition and oxidation state
Ultraviolet photoelectron spectroscopy (UPS)	UV radiation 21 eV He(I) 41 ev He(II)	Hemispherical or cylindrical mirror	Electronic properties of adsorbate and/or bulk material
Energy loss spectroscopy (ELS)	Electrons 507–1000 eV	Electron energy analyzer	Electronic structure of surface
High-resolution electron energy loss spectroscopy (HREELS)	Electrons 1–10 eV	Electron energy analyzer	Vibrational losses
Low-energy electron diffraction (LEED)	Electrons 20–500 eV	Retarding fields and phosphorescent screen	Surface structure or periodicity
Infrared spectroscopy (IRS)	Photons	Mercury-cadmium-telluride or indium antimony	Molecular identity
Optical ellipsometry	Photons	Photomultiplier	Adsorbate layer thickness
Scanning tunneling microscopy (STM)	Tunneling current	Ammeter	Substrate roughness and texture

*Mg = magnesium; Al = aluminum; He = helium.

integral part of the condenser but may be separate and external to it. The condensate is removed by a condensate pump and the noncondensables by a vacuum pump. *See* STEAM CONDENSER; VAPOR CONDENSER. [J.F.Se.]

Surface hardening of steel The selective hardening of the surface layer of a steel product by one of several processes which involve changes in microstructure with or without changes in composition. Surface hardening imparts a combination of properties to the finished product not produced by bulk heat treatment alone. Among these properties are high wear resistance and good toughness or impact properties, increased resistance to failure by fatigue resulting from cyclic loading, and resistance to surface indentation by localized loads. The use of surface hardening frequently is also favored by lower costs and greater flexibility in manufacturing.

The principal surface hardening processes are: (1) carburizing, (2) the modified carburizing processes of carbonitriding, cyaniding, and liquid carburizing, (3) nitriding, (4) flame hardening and induction hardening, and (5) surface working. Carburizing introduces carbon into the surface layer of low-carbon steel parts and converts that layer into high-carbon steel, which can be quench-hardened by appropriate heat treatment. Carbonitriding, cyaniding, and liquid carburizing, in addition to supplying carbon, introduce nitrogen into the surface layer; this element permits lower case-hardening temperatures and has a beneficial effect on the subsequent heat treatment. In nitriding, only nitrogen is supplied, and reacts with special alloy elements present in the steel. Whereas the foregoing processes change the composition of the surface layer, flame hardening and induction hardening depend on a heat treatment applied selectively to the surface layer of a medium-carbon steel. Surface working by shot peening, surface rolling, or prestressing improved fatigue resistance by producing a stronger case, compressive stresses, and a smoother surface. *See* HEAT TREATMENT (METALLURGY); STEEL. [M.B.B.; C.F.F.]

Surface mining A mining method in which the overburden (earth and rocks) is stripped away completely to reach the underlying coal or other minerals. It has been popularly called strip mining. Surface mining of coal has increased steadily to the point where, in the United States, over 60% of the coal is obtained from such mining activities. Large-scale draglines, shovels, scrapers, front-end loaders, and dozers can reach seams as deep as 1000 ft (305 m) in some open-pit operations, while smaller-size equipment is used effectively in hilly terrain.

Surface mining is safer than underground mining because the miners are not exposed to such potential hazards as roof falls, to explosions caused by methane gas or dust ignitions, and to coal-worker pneumoconiosis (black lung) caused by long-term exposure to respirable coal dust. *See* RESPIRATORY SYSTEM DISORDERS; UNDERGROUND MINING.

Surface mining is also a more productive method of mining coal. Surface mines average 31 tons (28 metric tons) per worker per day, with some of the larger mines achieving 50 to 90 tons (45 to 82 metric tons) per worker per day. In underground mines the overall daily productivity per worker is about 11 tons (10 metric tons).

There are three general methods of surface mining: contour mining, area mining, and open-pit mining, with variations within each. The contour mining method is practiced commonly in rolling or mountainous terrain where the seams of coal outcrop at the mountain slopes. Mining generally begins by removing the overburden above the coal seam by starting at the outcrop, and proceeding along the hillside. The removed overburden (the spoil) must be essentially hauled back into the mined-out pit, the exposed highwall buried, and the mined land returned approximately to the original contour.

The area mining method is favored where the terrain is flat or only slightly rolling and where the mine site includes large stretches of land. The first cut, often referred to as a box cut, results in a long pit with a highwall on both sides of the cut. Overburden from the first pit is placed in a convenient hollow or else stored to be available later for filling the final cut. A second cut is started adjacent to the first cut into which the second cut's overburden is placed. Strip by strip, the mining thus proceeds across the property. This type of mining is usually conducted with giant draglines or shovels.

The open-pit mining method is most often used where the coal beds are extremely thick, as in the subbituminous and lignite areas of the West and Southwest in the United States, and in the brown-coal areas of the world such as those in Germany. Open-pit operations generally use the bench-mining approach, in which a series of benches or terraces forms the open pit. Benches are about 200 to 1500 ft (61 to 457 m) wide. Each bench gives access to a 30–50-ft (9–15 m) highwall. Side benches are created for hauling the overburden around the pit to the reclamation area. With proper planning, reclamation can proceed at the same time as mining, so that the pit would seem to move as forward areas are opened and rear areas are restored. *See* OPEN PIT MINING.

During reclamation all disturbed areas must be restored to enhance wherever practical the premining wildlife and fish habitats. Streams and other drainages must be revegetated to provide natural cover along their banks. *See* COAL; COAL MINING; LAND RECLAMATION; MINING. [N.P.Ch.]

Surface physics The study of the structure and dynamics of atoms and their associated electron clouds in the vicinity of a surface, usually at the boundary between a solid and a low-density gas. Surface physics deals with those regions of large and rapid variations of atomic and electron density that occur in the vicinity of an interface between the two "bulk" components of a two-phase system. In conventional usage, surface physics is distinguished from interface physics by the restriction of the scope of the former to interfaces between a solid (or liquid) and a low-density gas, often at ultrahigh-vacuum pressures $p = 10^{-10}$ torr (1.33×10^{-8} newton/m^2 or 10^{-13} atm). *See* SOLID-STATE PHYSICS.

Surface physics is concerned with two separate but complementary areas of investigation into the properties of such solid-"vacuum" interfaces. Interest centers on the experimental determination and theoretical prediction of surface composition and structure (that is, the masses, charges, and positions of surface species), of the dynamics of surface atoms (such as surface diffusion and vibrational motion), and of the energetics and dynamics of electrons in the vicinity of a surface (such as electron density profiles and localized electronic surface states). As a practical matter, however, the nature and dynamics of surface species are determined experimentally by scattering and emission measurements involving particles or electromagnetic fields (or both) external to the surface itself. Thus, a second major interest in surface physics is the study of the interaction of external entities (that is, atoms, ions, electrons, electromagnetic fields, or mechanical probes) with solids at their vacuum interfaces. It is this aspect of surface physics that most clearly distinguishes it from conventional solid-state physics, because quite different scattering, emission, and local probe experiments are utilized to examine surface as opposed to bulk properties.

Techniques for characterizing the solid-vacuum interface are based on one of three simple physical mechanisms for achieving surface sensitivity. The first, which is the basis for field emission, field ionization, and scanning tunneling microscopy (STM), is the achievement of surface sensitivity by utilizing electron tunneling through the potential-energy barrier at a surface. This concept provides the basis for the development of STM to directly examine the atomic structure of surfaces by measuring with atomic resolution the tunneling current at various positions along a surface. It also has been utilized for direct determinations of the energies of individual electronic orbitals of adsorbed complexes via the measurement of the energy distributions either of emitted electrons or of Auger electrons emitted in the process of neutralizing a slow (energy $E \sim 10$ eV) external ion. *See* FIELD-EMISSION MICROSCOPY; SCANNING TUNNELING MICROSCOPE; TUNNELING IN SOLIDS.

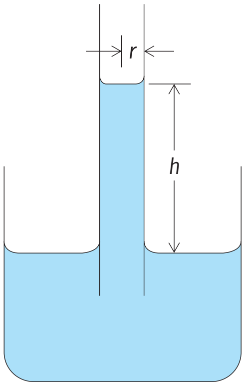
The second mechanism for achieving surface sensitivity is the examination of the elastic scattering or emission of particles which interact strongly with the constituents of matter, for example, "low energy" ($E \lesssim 10^3$ eV) electrons, thermal atoms and molecules, or "slow" (300 eV $\lesssim E \lesssim 10^3$ eV) ions. Since such entities lose appreciable ($\Delta E \sim 10$ eV) energy in distances of the order of tenths of a nanometer, typical electron analyzers with resolutions of tenths of an electronvolt are readily capable of identifying scattering and emission processes which occur in the upper few atomic layers of a solid. This second mechanism is responsible for the surface sensitivity of photoemission, Auger electron, electron characteristic loss, low-energy electron diffraction (LEED), and ion scattering spectroscopy techniques. The strong particle-solid interaction criterion that renders these measurements surface-sensitive is precisely the opposite of that used in selecting bulk solid-state spectroscopies. In this case, weak particle-solid interactions (that is, penetrating radiation) are desired in order to sample the bulk of the specimen via, for example, x-rays, thermal neutrons, or fast ($E \gtrsim 10^4$ eV) electrons. These probes, however, can sometimes be used to study surface properties by virtue of special geometry, for example, the use of glancing-angle x-ray diffraction to determine surface atomic structure. *See* AUGER EFFECT; ELECTRON DIFFRACTION; ELECTRON SPECTROSCOPY; PHOTOEMISSION; X-RAY CRYSTALLOGRAPHY.

The third mechanism for achieving surface sensitivity is the direct measurement of the force on a probe in mechanical contact or near contact with the surface. At near contact, the van der Waals force can be measured directly by probes of suitable sensitivity. After contact is made, a variety of other forces dominate, for example, the capillary force for solid surfaces covered with thin layers of adsorbed liquid (that is, most solid surfaces in air at atmospheric pressure). When this mechanism is utilized via measuring the deflection of a sharp tip mounted on a cantilever near a surface, the experiment is referred to as atomic force microscopy (AFM) and results in maps of the force across the surface. Under suitable circumstances, atomic resolution can be achieved by this method as well as by STM. Atomic force microscopy opens the arena of microscopic surface characterization of insulating samples as well as electrochemical and biochemical interfaces at atmospheric pressure. Thus, its development is a major driving force for techniques based on surface physics. *See* INTERMOLECULAR FORCES.

Another reason for the renaissance in surface physics is the capability to generate in a vacuum chamber special surfaces that approximate the ideal of being atomically flat. These surfaces may be prepared by cycles of fast-ion bombardment, thermal outgassing, and thermal annealing for bulk samples (for example, platelets with sizes of the order of 1 cm × 1 cm × 1 mm), molecular beam epitaxy of a thin surface layer on a suitably prepared substrate, or field evaporation of etched tips for field-ion microscopes. Alternatively, the sample may be cleaved in a vacuum chamber. In such a fashion, reasonable facsimiles of uncontaminated, atomically flat solid-vacuum interfaces of many metals and semiconductors have been prepared and subsequently characterized by various spectroscopic techniques. Such characterizations must be carried out in an ultrahigh vacuum ($p \sim 10^{-8}$ N/m^2) so that the surface composition and structure are not altered by gas adsorption during the course of the measurements. *See* EPITAXIAL STRUCTURES. [C.B.D.]

Surface tension

The force acting in the surface of a liquid, tending to minimize the area of the surface. Surface forces, or more generally, interfacial forces, govern such phenomena as the wetting or nonwetting of solids by liquids, the capillary rise of liquids in fine tubes and wicks, and the curvature of free-liquid surfaces. The action of detergents and antifrothing agents and the flotation separation of minerals depend upon the surface tensions of liquids.



Rise of liquid in capillary tube.

In the body of a liquid, the time-averaged force exerted on any given molecule by its neighbors is zero. Even though such a molecule may undergo diffusive displacements because of random collisions with other molecules, there exist no directed forces upon it of long duration. It is equally likely to be momentarily displaced in one direction as in any other. In the surface of a liquid, the situation is quite different; beyond the free surface, there exist no molecules to counteract the forces of attraction exerted by molecules in the interior for molecules in the surface. In consequence, molecules in the surface of a liquid experience a net attraction toward the interior of a drop. These centrally directed forces cause the droplet to assume a spherical shape, thereby minimizing both the free energy and surface area.

Liquids which wet the walls of fine capillary tubes rise to a height which depends upon the tube radius, the surface tension, the liquid density, and the contact angle between the solid and the liquid (measured through the liquid). In the illustration a liquid of a certain density is shown as having risen to a height h in a capillary whose radius is r. A balance exists between the force exerted by gravity on the mass of liquid raised in the capillary and the opposing force caused by surface tension.

Detergents, soaps, and flotation agents owe their usefulness to their ability to lower the surface tension of water, thereby stabilizing the formation of small bubbles of air. At the same time, the interfacial tension between solid particles and the liquid phase is lowered, so that the particles are more readily wetted and floated after attachment to air bubbles. *See* FLOTATION; INTERFACE OF PHASES; SURFACTANT. [N.H.N.]

Surface water

A term commonly used to designate the water flowing in stream channels. The term is sometimes used in a broader sense as opposed to "subsurface water." In this sense, surface water includes water in lakes, marshes, glaciers, and reservoirs as well as that flowing in streams. In the broadest sense, surface water is all the water on the surface of the Earth and thus includes the water of the oceans. Subsurface water includes water in the root zone of the soil and ground water flowing or stored in the rock mantle of the Earth. Subsurface water differs from surface water in the mechanics of its movement as well as in its location. Surface and subsurface water are two stages of the movement of the Earth's water through the hydrologic cycle. The world's ocean and atmospheric moisture are two other main stages of the grand water cycle of the Earth. *See* HYDROLOGY.

The table gives estimates of the amounts of water in various parts of the hydrologic cycle and their detention periods. It may be noted that surface water on the continents is but a small part of the world's water and that the bulk of that is in freshwater lakes. However, the detention period is also short. This means that the surface-water part, and especially the water in the streams, is rapidly discharged and replenished. That is why

Distribution of the world's supply of water

Location		Volume of water, 10^9 acre-ft*	Percentage total	Detention period, years
World's oceans		1,060,000	97.39	5,000
Surface water on the continents				
Glaciers and polar ice caps	20,000		1.83	2,000
Fresh-water lakes	100		0.0093	100
Saline lakes and inland seas	68		0.0063	50
Average in stream channels	0.25		0.00002	0.05
Total surface water		20,200		700 av
Subsurface water on the continents				
Root zone of the soil	10		0.00094	0.25
Ground water above				
Ground water above 2500 ft	3,700		0.339	5
Ground water below 2500 ft	4,600		0.425	100
Total subsurface water		8,300		
Atmospheric water		115	0.0011	0.03
Total world water (rounded)		1,088,000	100	3,000

*109 acre-ft = 1.233×10^8 ha · m = 1.233×10^{12} m^3.
†2500 ft = 750 m.

surface water, as well as the shallower ground water, is called a renewable resource. Water that has a detention period of more than a generation is not renewed within sufficient time to be so considered. *See* GROUND-WATER HYDROLOGY; RIVER.

Precipitation that reaches the Earth is subdivided by processes of evaporation and infiltration into various routes of subsequent travel. Evaporation from wet land surfaces and from vegetation returns some of the water to the atmosphere immediately. Precipitation that falls at rates less than the local rate of infiltration enters the soil. Some of the infiltrated water is retained in the soil, sustaining plant life, and some reaches the ground water. The precipitation that exceeds the capacity of the soil to absorb water flows overland in the direction of the steepest slope and concentrates in rills and minor channels. During storms most of the water in surface streams is derived from that portion of the precipitation which fails to infiltrate the soil. *See* PRECIPITATION (METEOROLOGY).

The distinction between surface and subsurface water, though useful, should not obscure the fact that water on the surface and water underground is physically connected through pores, cracks, and joints in rock and soil material. In many areas, particularly in humid regions, surface water in stream channels is the visible part of a reservoir, which is partly underground; the water surface of a river is the visible extension of the surface of the ground water. [L.B.L.]

Surfactant A member of the class of materials that, in small quantity, markedly affect the surface characteristics of a system; also known as surface-active agent. In a two-phase system, for example, liquid-liquid or solid-liquid, a surfactant tends to locate at the interface of the two phases, where it introduces a degree of continuity between the two different materials. Soaps and detergents are classic examples of surfactants due to their dual (amphipathic) character. These substances consist of a hydrophobic tail portion, usually a long-chain hydrocarbon, and a hydrophilic polar head group, which is often ionic. A material possessing these characteristics is known as an amphiphile. It tends to dissolve in both aqueous and oil phase and to locate at the oil-water interface. *See* DETERGENT; INTERFACE OF PHASES; SOAP; SURFACE TENSION.

Surfactants are employed to increase the contact of two materials, sometimes known as wettability. Surfactants and surface activity are controlling features in many important systems, including emulsification, detergency, foaming, wetting, lubrication, water repellance, waterproofing, spreading and dispersion, and colloid stability. *See* EMULSION; LUBRICANT; MICELLE.

In general, surfactants are divided into four classes: amphoteric, with zwitterionic head groups; anionic, with negatively charged head groups; cationic, with positively charged head groups; and nonionic, with uncharged hydrophilic head groups. Those with anionic head groups include long-chain fatty acids, sulfosuccinates, alkyl sulfates, phosphates, and sulfonates. Cationic surfactants may be protonated long-chain amines and long-chain quaternary ammonium compounds. The class of amphoteric surfactants is represented by betaines and certain lecithins, while nonionic surfactants include polyethylene oxide, alcohols, and other polar groups.

Quite different materials, such as polymers and clays, can also exhibit surface activity; many polymeric materials, for example, polyvinyl alcohol and polyacrylamide, are excellent stabilizers for a variety of colloid systems. These entities adsorb at the colloid interface and, by means of steric effects, prevent colloid-colloid adhesion and flocculation. Clays readily adsorb other materials or adsorb onto large particles suspended in solution, so that the particle interface consists of charged clay particles, which increase colloid stability by electrostatic and steric effects. *See* ADSORPTION; BENTONITE; CLAY MINERALS; COLLOID; ION EXCHANGE; POLYMER; SURFACE AND INTERFACIAL CHEMISTRY. [J.K.T.]

Surge arrester A protective device designed primarily for connection between a conductor of an electrical system and ground to limit the magnitude of transient overvoltages on equipment. A lightning arrester is really a voltage-surge arrester.

The valve arrester consists of disks of zinc oxide material that exhibit low resistance at high voltage and high resistance at low voltage. By selecting an appropriate configuration of disk material, the arrester will conduct a low current of a few milliamperes at normal system voltage. During conditions of lightning or switching surge overvoltages, the surge current is limited by the circuit; and for the magnitudes of current that can be delivered to the arrester location, the resulting voltage will be limited to controlled values, and to safe levels as well, when insulation levels of equipment are coordinated with the surge arrester protective characteristics.

A typical surge arrester consists of disks of zinc oxide material sized in cross-sectional area to provide desired energy discharge capability, and in axial length proportional to the voltage capability. The disks are then placed in porcelain enclosures to provide physical support and heat removal, and sealed for isolation from contamination in the electrical environment. *See* LIGHTNING; LIGHTNING AND SURGE PROTECTION. [G.D.B.]

Surge suppressor A device that is designed to offer protection against voltage surges on the power line that supplies electrical energy to the sensitive components in electronic devices and systems. The device offers a limited type of protection to computers, television sets, high-fidelity equipment, and similar types of electronic systems.

A voltage surge is generally considered to be a transient wave of voltage on the power line. The amplitude of the surge may be several thousand volts, and the duration may be as short as 1 or 2 milliseconds or as long as about 100 ms. Typical effects can be damage to the electronics or loss of programs and data in computer memories. Many events can cause the surges, including lightning that strikes the power lines at a considerable distance from the home or office; necessary switching of transmission lines by the utilities; and rapid connections or disconnections of large loads, such as air conditioners and motors, from the power line, or even other appliances in the home. Lightning is perhaps the most common. *See* LIGHTNING.

The suppressor acts to limit the peak voltage applied to the electronic device to a level that normally will not cause either damage to the device or software problems in the computers. The device may include a pilot light, a fuse, a clipping circuit, resistors, and a main switch. The clipper circuit is the principal item, and the design of this portion is usually proprietary information. *See* CLIPPING CIRCUIT; FUSE (ELECTRICITY). [E.C.Jo.]

Surgery That branch of medicine which generally treats diseases by operative intervention. Surgical procedures may involve relieving mechanical obstruction of a tubular organ, such as the intestine; or removing a diseased organ, which cannot be salvaged by medical treatment, such as a gangrenous appendix or inflamed gallbladder; or removing a malignant tumor with a margin of normal tissue; or repairing an injured organ, or removing it if the organ is irreparable and its absence is compatible with survival.

The field of surgery has become increasingly specialized, primarily by organ system, so that surgical diseases of the kidney, bladder, and other components of the urinary tract are treated by surgeons called urologists; surgery of the central nervous system, including the brain and spinal cord, is done by neurosurgeons; reconstructive and cosmetic surgery is done primarily by plastic surgeons; general surgeons continue to do most abdominal surgery, some head and neck surgery, and surgery of the soft tissues of the extremities; and surgical diseases of the bones and joints are treated by orthopedic surgeons. Some specialties within surgery have also developed into specialties that are not limited to one organ system, such as surgical oncology (cancer surgery), so that cancers in most parts of the body may be treated by surgeons with special training in malignant diseases. *See* MEDICINE. [R.F.J.]

Surveillance radar Any radar equipment used by civil or military authorities for locating aircraft, ships, or ground vehicles; most commonly, in civil air-traffic management, a radar used by controllers to indicate the position of aircraft aloft or on the airport surface. Two types of air-traffic control surveillance radar are employed internationally. Ground-based conventional, or primary, radar operates by transmitting microwave pulses and detecting the resulting energy reflected from the aircraft body (airframe). Secondary surveillance radar employs cooperative radio receiver-transmitter units (transponders) on the aircraft.

Although secondary radar generally provides more reliable and complete surveillance information than does primary radar, air-traffic authorities use both. In the United States, two major examples are the Federal Aviation Administration's Airport Surveillance Radar (ASR) and Air Route Surveillance Radar (ARSR), the latter shared at some locations with the U.S. Air Force. Both normally operate unattended, their outputs fed by a landline or microwave link to their control positions. Primary radar provides backup coverage for nonequipped aircraft and for aircraft with airframe shielding. Primary radar can also detect potentially hazardous precipitation cells and potentially hostile aircraft or inadvertent intruders. Secondary radar is sometimes used without a primary radar backup for long-range, high-altitude surveillance where all aircraft are transponder-equipped, where airframe shielding is rare, and where the sensitivity disadvantage of primary radar requires costly high-power transmitters. The Federal Aviation Administration has authorized use of certain secondary radars having faster update rates and monopulse accuracy for monitoring aircraft conducting multiple parallel approaches in bad weather. *See* AIR-TRAFFIC CONTROL; MONOPULSE RADAR; RADAR. [R.R.LaF.]

Surveying The measurement of dimensional relationships among points, lines, and physical features on or near the Earth's surface. Basically, surveying determines horizontal distances, elevation differences, directions, and angles. These basic determinations are applied further to the computation of areas and volumes and to the establishment of locations with respect to some coordinate system.

Surveying is typically used to locate and measure property lines; to lay out buildings, bridges, channels, highways, sewers, and pipelines for construction; to locate stations for launching and tracking satellites; and to obtain topographic information for mapping and charting.

Horizontal distances are usually assumed to be parallel to a common plane. Each measurement has both length and direction. Length is expressed in feet or in meters. Direction is expressed as a bearing of the azimuthal angle relationship to a reference meridian, which is the north-south direction. It can be the true meridian, a grid meridian, or some other assumed meridian. The degree-minute-second system of angular expression is standard in the United States.

Reference, or control, is a concept that applies to the positions of lines as well as to their directions. In its simplest form, the position control is an identifiable or understood point of origin for the lines of a survey. Conveniently, most coordinate systems have the origin placed west and south of the area to be surveyed so that all coordinates are positive and in the northeast quadrant.

Vertical measurement adds the third dimension to an object's position. This dimension is expressed as the distance above some reference surface, usually mean sea level, called a datum. Mean sea level is determined by averaging high and low tides during a lunar month.

Horizontal control. The main framework, or control, of a survey is laid out by traverse, triangulation, or trilateration. Some success has been achieved in locating control points from Doppler measurements of passing satellites, from aerial phototriangulation, from satellites photographed against a star background, and from inertial guidance systems. In traverse, adopted for most ordinary surveying, a line or series of lines is established by directly measuring lengths and angles. In triangulation, used mainly for large areas, angles are again directly measured, but distances are computed trigonometrically. This necessitates triangular patterns of lines connecting intervisible points and starting from a baseline of known length. New baselines are measured at intervals. Trigonometric methods are also used in trilateration, but lengths, rather than angles, are measured. The development of electronic distance measurement (EDM) instruments brought trilateration into significant use.

Distance measurement. Traverse distances are usually measured with a surveyor's tape or by EDM, but also may sometimes be measured by stadia, subtense, or trig-traverse.

Whether on sloping or level ground, it is horizontal distances that must be measured. In taping, horizontal components of hillside distances are measured by raising the downhill end of the tape to the level of the uphill end. On steep ground this technique is used with shorter sections of the tape. The raised end is positioned over the ground point with the aid of a plumb bob. Where slope distances are taped along the ground, the slope angle can be measured with the clinometer. The desired horizontal distance can then be computed.

In EDM the time a signal requires to travel from an emitter to a receiver or reflector and back to the sender is converted to a distance readout. The great advantage of electronic distance measuring is its unprecedented precision, speed, and convenience. Further, if mounted directly onto a theodolite, and especially if incorporated into it and electronically coupled to it, the EDM instrument with an internal computer can in seconds measure distance (even slope distance) and direction, then compute the coordinates of the sighted point with all the accuracy required for high-order surveying.

In the stadia technique, a graduated stadia rod is held upright on a point and sighted through a transit telescope set up over another point. The distance between the two points is determined

Fig. 1. Subtense bar. (*Lockwood, Kessler, and Bartlett Inc.*)

from the length of rod intercepted between two horizontal wires in the telescope.

In the subtense technique the transit angle subtended by a horizontal bar of fixed length enables computation of the transit-to-bar distance (Fig. 1). In trig-traverse the subtense bar is replaced by a measured baseline extending at a right angle from the survey line whose distance is desired. The distance calculated in either subtense or trig-traverse is automatically the horizontal distance and needs no correction.

Angular measurement. The most common instrument for measuring angles is the transit or theodolite. It is essentially a telescope that can be rotated a measurable amount about a vertical axis and a horizontal axis. Carefully graduated metal or glass circles concentric with each axis are used to measure the angles. The transit is centered over a point with the aid of either a plumb bob suspended by a string from the vertical axis or (on some theodolites) an optical plummet, which enables the operator to sight along the instrument's vertical axis to the ground through a right-angle prism.

Elevation differences. Elevations may be measured trigonometrically in conjunction with reduction of slope measurements to horizontal distances, but the resulting elevation differences are of low precision.

Most third-order and all second- and first-order measurements are made by differential leveling, wherein a horizontal line of sight of known elevation is sighted on a graduated rod held vertically on the point being checked (Fig. 2). The transit telescope, leveled, may establish the sight line, but more often a specialized leveling instrument is used. For approximate results a hand level may be used.

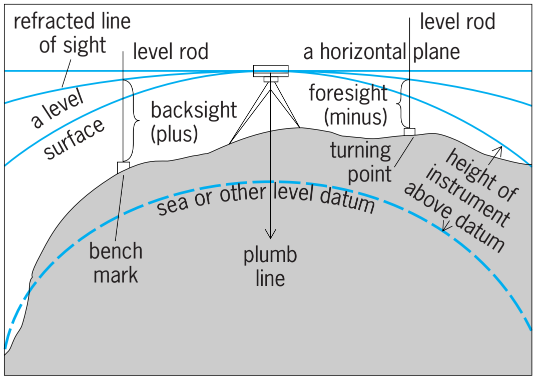


Fig. 2. Theory of differential leveling.

Other methods of measuring elevation include trigonometric leveling which involves calculating height from measurements of horizontal, distance and vertical angle; barometric leveling, a method of determining approximate elevation difference with aid of a barometer; and airborne profiling, in which a radar altimeter on an aircraft is used to obtain ground elevations.

Astronomical observations. To determine meridian direction and geographic latitude, observations are made by a theodolite or transit on Polaris, the Sun, or other stars. Direction of the meridian (geographic north-south line) is needed for direction control purposes; latitude is needed where maps and other sources are insufficient. The simplest meridian determination is made by sighting Polaris at its elongation, as the star is rounding the easterly or westerly extremity of its apparent orbit. An angular correction is applied to the direction of sighting, which is referenced to a line on the ground. The correction value is found in an ephemeris. *See* EPHEMERIS; TOPOGRAPHIC SURVEYING AND MAPPING. [B.A.B.]

Surveying instruments

Instruments used in surveying operations to measure vertical angles, horizontal angles, and distance. Such devices were originally mechanical only, but technological advances led to mechanical-optical devices, optical-electronic devices, and finally, electronic-only devices.

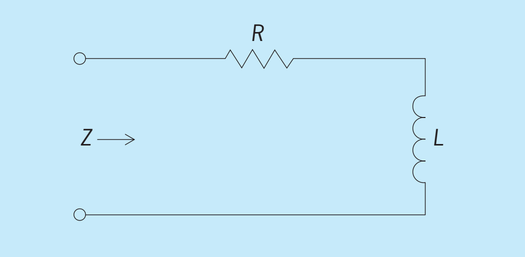
Four types of levels are available: optical, automatic, electronic, and laser. An optical level is used to project a line of sight that is at a 90° angle to the direction of gravity. Both dumpy and tilting types use a precision leveling vial to orient to gravity. The dumpy type was used primarily in the United States, while the tilting type was of European origin and used in the remainder of the world. Automatic levels use a pendulum device, in place of the precision vial, for relating to gravity. The pendulum mechanism is called a compensator. The pendulum has a prism or mirror, as part of the telescope, which is precisely positioned by gravity. The electronic level has a compensator similar to that on an automatic level, but the graduated leveling staff is not observed and read by the operator. The operator has only to point the instrument at a bar-code-type staff, which then can be read by the level itself. The laser levels actually employ three different types of light sources: tube laser, infrared diode, and laser diode. The instrument uses a rotating head to project the laser beam in a level 360° plane. *See* LEVEL MEASUREMENT.

The primary purpose of a transit is to measure horizontal and vertical angles. Circles, one vertical and one horizontal, are used for these measurements. The circles are made of metal or glass and have precision graduations engraved or etched on the surface. A vernier is commonly used to improve the accuracy of the circle reading. The theodolite serves the same purpose as the transit, and they have many similar features. The major differences are that the measuring circles are constructed only of glass and are observed through magnifying optics to increase the accuracy of angular readings. The electronic theodolite uses electronic reading circles in place of the optically read ones. *See* VERNIER.

The U.S. Department of Defense installed a satellite system known as the Global Positioning System for navigation and for establishing the position of planes, ships, vehicles, and so forth. This system uses special receivers and sophisticated software to calculate the longitude and latitude of the receiver. It was discovered early in the program that the distance between two non-moving receivers could be determined very accurately and that the distance between receivers could be many miles apart. This technology has become the standard for highly accurate control surveys, but it is not in general use because of the expense of the precision receivers, the time required for each setup, and the sophistication of the process. *See* SATELLITE NAVIGATION SYSTEMS; SURVEYING. [K.W.K.]

Susceptance

The imaginary part of the admittance of an alternating-current circuit.



Circuit with a resistor and inductor in series.

The admittance, Y, of an alternating current circuit is a complex number given by Eq. (1). The imaginary part, B, is the

$$Y = G + jB \tag{1}$$

susceptance. The units of susceptance like those of admittance are called siemens or mhos. Susceptance may be either positive or negative. For example, the admittance of a capacitor C at frequency ω is given by Eq. (2), and so B is positive. For an inductor L, the admittance is given by Eq. (3), and so B is negative.

$$Y = jC\omega = jB \tag{2}$$

$$Y = -\frac{j}{L\omega} = jB \tag{3}$$

In general, the susceptance of a circuit may depend on the resistors as well as the capacitors and inductors. For example, the circuit in the illustration has impedance given by Eq. (4) and admittance given by Eq. (5), so that the susceptance, given by Eq. (6), depends on the resistor R as well as the inductor L.

$$Z = R + jL\omega \tag{4}$$

$$Y = \frac{1}{R + jL\omega} \tag{5}$$

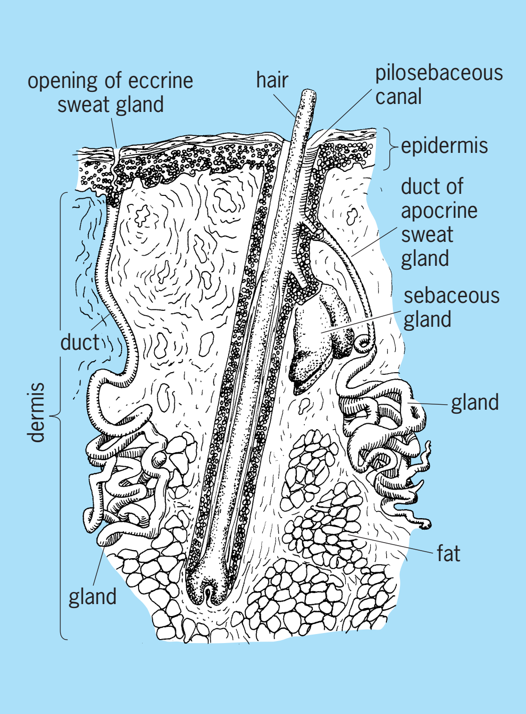
$$B = \frac{-L\omega}{R^2 + L^2\omega^2} \tag{6}$$

See ADMITTANCE; ALTERNATING-CURRENT CIRCUIT THEORY; ELECTRICAL IMPEDANCE. [J.O.S.]

Swamp, marsh, and bog Wet flatlands, where mesophytic vegetation is a really more important than open water, which are commonly developed in filled lakes, glacial pits and potholes, or poorly drained coastal plains or floodplains. Swamp is a term usually applied to a wetland where trees and shrubs are an important part of the vegetative association, and bog implies lack of solid foundation. Some bogs consist of a thick zone of vegetation floating on water.

Unique plant associations characterize wetlands in various climates and exhibit marked zonation characteristics around the edge in response to different thicknesses of the saturated zone above the firm base of soil material. Coastal marshes covered with vegetation adapted to saline water are common on all continents. Presumably many of these had their origin in recent inundation due to post-Pleistocene rise in sea level. *See* GLACIATED TERRAIN; MANGROVE. [L.B.L.]

Sweat gland A coiled, tubular gland found in mammals. There are two kinds, merocrine or eccrine, and apocrine. The latter are generally associated with hair follicles (see illustration). Merocrine glands are distributed extensively over the body in the human, whereas the apoctine variety is restricted to the scalp, nipples, axilla, external auditory meatus, external genitals, and perianal areas. Apocrine sweat glands are more numerous in mammals, with the exception of the chimpanzee and human, in which the merocrine variety predominates. The mammary glands probably represent modified apocrine sweat glands which grow inward and increase in complexity. *See* GLAND; MAMMARY GLAND. [O.E.N.]



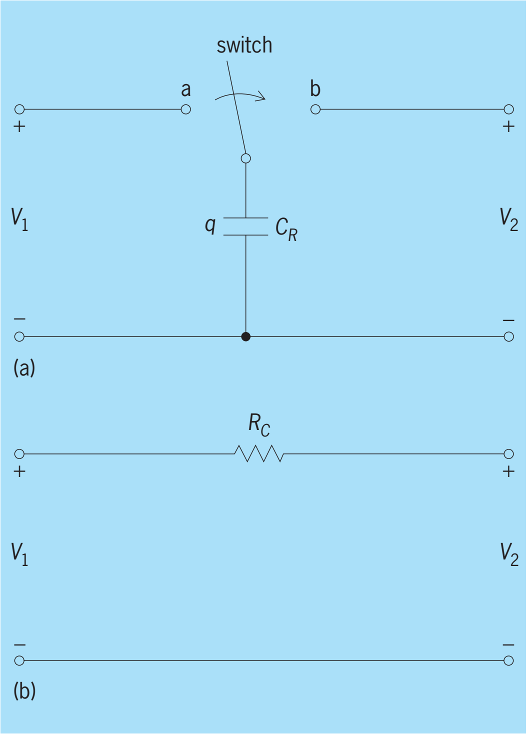
Human skin showing structure of both eccrine and apocrine sweat glands.

Sweetgum The tree *Liquidambar styraciflua*, also called redgum, a deciduous tree of the southeastern United States. It is found northward as far as southwestern Connecticut, and also grows in Central America. Sweetgum is readily distinguished by its five-lobed, or star-shaped, leaves and by the corky wings or ridges usually developed on the twigs. The erect trunk is a dark gray, but the branches are lighter in color. In winter the persistent, spiny seedballs are an excellent diagnostic feature.

Sweetgum is used for furniture, interior trim, railroad ties, cigar boxes, crates, flooring, barrels, woodenware, and wood pulp, and it is one of the most important materials for plywood manufacture. Sweetgum is one of the most desirable ornamental trees, chiefly because of its brilliant autumn coloration. *See* HAMAMELIDALES. [A.H.G./K.P.D.]

Swim bladder A gas-filled sac found in the body cavities of most bony fishes (Osteichthyes). The swim bladder has various functions in different fishes, acting as a float which gives the fish buoyancy, as a lung, as a hearing aid, and as a soundproducing organ. In many fishes it serves two or three of these functions, and in the African and Asiatic knife fishes (Notopteridae) it may serve all four. The swim bladder contains the same gases that make up air, but often in different proportions. [R.McN.A.]

Switched capacitor A module consisting of a capacitor with two metal oxide semiconductor (MOS) switches connected as shown in illus. *a*. These elements in the module are easily realized as an integrated circuit on a silicon chip by using MOS technology. The switched capacitor module is approximately equivalent to a resistor, as shown in illus. *b*. The fact that resistors are relatively difficult to implement gives the switched capacitor a great advantage in integrated-circuit applications requiring resistors. Some of the advantages are that the cost is significantly reduced, the chip area needed is reduced,



Switched capacitor, (*a*) Basic circuit, (*b*) Equivalent resistive circuit.

and precision is increased. Although the switched capacitor can be used for any analog circuit realization such as analog-to-digital or digital-to-analog converters, the most notable application has been to voice-frequency filtering. *See* ANALOG-TO-DIGITAL CONVERTER; DIGITAL-TO-ANALOG CONVERTER; ELECTRIC FILTER; INTEGRATED CIRCUITS. [M.E.V.V.]

Switching circuit A constituent electric circuit of a switching or digital data-processing system which receives, stores, or manipulates information in coded form to accomplish the specified objectives of the system. Examples include digital computers, dial telephone systems, and automatic accounting and inventory systems. *See* DIGITAL COMPUTER; SWITCHING SYSTEMS (COMMUNICATIONS); SWITCHING THEORY.

Physically, switching circuits consist of conducting paths interconnecting discrete-valued electrical devices. The most generally used switching circuit devices are two-valued or binary, such as switches and relays in which manual or electromagnetic actuation opens and closes electric contacts; vacuum and gas-filled electronic tubes, and semiconductor rectifiers and transistors, which do or do not conduct current; and magnetic structures, which can be saturated in either of two directions.

The electrical conditions controlling these switching circuit devices are also generally two-valued or binary, such as open versus closed path, full voltage versus no voltage, large current versus small current, and high resistance versus low resistance. Such two-valued electrical conditions, as applied to the input of a switching circuit, represent either (1) a combination of events or situations which exist or do not exist; (2) a sequence of events or situations which occur in a certain order; or (3) both combinations and sequences of events or situations. The switching circuit responds to such inputs by delivering at its output, also in two-valued terms, new information which is functionally related to the input information.

Functional characteristics of switching circuits are defined by the logical operation and memory capabilities of the discrete devices from which they are assembled, as well as by the means used to interconnect the devices. For example, switching circuits embody such logical relationships as output X is to exist only if input A and B occur simultaneously; and output Y is to exist if either input A or input B occurs. The factor of memory, in turn, enables a switching circuit to hold or retain a given state after the condition that produced the state has passed.

Basic combinational circuits. A combinational switching circuit is one in which a particular set of input conditions always establishes the same output, irrespective of the history of the circuit.

In electronic switching circuits, so-called gates are used to perform logical functions equivalent to these series-parallel networks of switch contacts. In this sense, an electronic gate is an elementary combinational circuit. Gates do not function by physically inserting or removing metallic conduction paths between contacts of manually operated switches or remotely controlled relays. Instead, they function by control of voltage or current levels at their output.

The most commonly encountered gates are the AND and the OR gates. The AND gate produces an output only if all its inputs are concurrently present; an OR gate produces an output if any one or any combination of its inputs is present. *See* LOGIC CIRCUITS.

Basic sequential circuits. A sequential switching circuit is one whose output depends not only upon the present state of its input, but also on what its input conditions have been in the past. Sequential circuits, therefore, require memory elements.

A typical electronic memory element used in sequential circuits is a simple circuit called a flip-flop. A flip-flop consists of two amplifiers connected so that the output of one amplifier is the input of the other. A voltage pulse will set the flip-flop into one of two states, and that state remains until another voltage pulse resets the flip-flop or returns it to its original state. It can therefore be used to remember that an event has taken place.

Figure 1 is an *npn*-transistor flip-flop. When set, transistor A is conducting and transistor B is cut off. When reset, transistor B is conducting and transistor A is cut off. A positive output voltage with respect to ground may be obtained from either transistor to indicate the condition of the flip-flop. *See* TRANSISTOR.

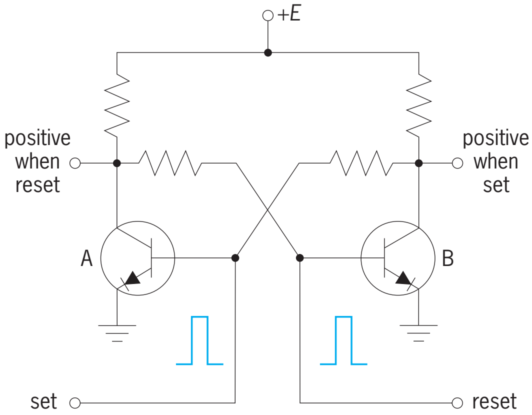


Fig. 1. Transistor switching memory element (flip-flop).

Relays, flip-flops, and similar memory elements provide static, or fixed, memory; they hold the stored information indefinitely, or until they are told to "forget," commonly called "resetting." In contrast, a delay line provides transient memory. A delay line has the property that an electrical signal applied to its input is delayed on its way to the output.

Selecting circuits. A selecting circuit receives the identity (called the address) of a particular item and selects that item from among a number of similar ones. The selectable items are often represented by terminals or leads. Selection usually involves marking the specified terminal or lead by applying to it some electrical condition, such as a voltage or current pulse, or a

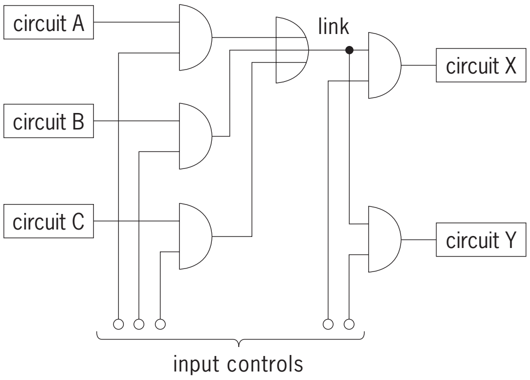

Fig. 2. Connecting circuit using AND and OR gates.

steady-state dc signal. By means of this electrical condition, the selected circuit is alerted, sized, or controlled.

Connecting circuits. A switching system is an aggregate of functional circuit units, some of which must sometimes be directly coupled to each other to interchange information. Figure 2 shows a simple electronic connecting circuit using AND and OR gates. In this arrangement a communication path is provided over a single link from any one of the three functional circuits A, B, C, to either the X or Y circuit by an external control circuit activating the appropriate pair of AND gates. To provide a multilead link, or to provide for other simultaneous interconnections, additional AND gates would, of course, be required. The OR gate maintains separation of the inputs at the common junction point.

Lockout circuits. In switching systems, situations often arise where several similar circuit units are ready at the same instant to request collaboration with another type of functional circuit. Mutual interference among the requesting circuits is prevented by the lockout circuit (sometimes referred to as hunting or finding circuits). In response to concurrent inputs from a number of external circuits, a lockout circuit provides an output indication corresponding to one, and only one, of these circuits at any time.

Translating circuits. Switching systems process information in coded form; the information is generally in the form of numbers. Numerical codes are many and varied, each with its own characteristics and more or less distinct advantages for different switching circuit situations. Therefore, one of the common functional circuits in switching systems is the translating circuit, which translates information received in one code into the same information expressed in another code. These translating circuits are combinational circuits; a given input signal combination representing a code to be translated always produces the same output signals, which represent the desired code.

Register circuits. Information received by a switching system is not always used immediately. It must be stored in register circuits for future use.

In a register circuit the coded information to be stored is applied as input and retained by memory elements of the circuit, and when needed, the registered information is taken as output in the same code or in a different code. Register circuits are devised with a great variety of memory elements and have capacities to store from a few to millions of information bits. A frequently encountered form of register circuit is the shift register. This type of register has the ability to shift its stored digital information internally to positions representing higher or lower numerical values in the code employed. For example, in decimal code registration a digit may be shifted from the units to the tens position. An obvious use of such registers is in digital computers when, for example, partial multiplication products have to be lined up for addition.

Counting circuits. One of the most frequently encountered circuits in switching systems is the counting circuit whose function, in general, is to detect and count repeated current or voltage pulses which represent incoming information. [J.A.Pec.]

Switching systems (communications)

The assemblies of switching and control devices provided so that any station in a communications system may be connected as desired with any other station. A telecommunications network consists of transmission systems, switching systems, and stations. Transmission systems carry messages from an originating station to one or more distant stations. They are engineered and installed in sufficient quantities to provide a quality of service commensurate with the cost and expected benefits. To enable the transmission facilities to be shared, stations are connected to and reached through switching system nodes that are part of most telecommunications networks. Switching systems act under built-in control to direct messages toward their ultimate destination or address.

Most switching systems, known as central or end offices in the public network and as private branch exchanges (PBXs) when applied to business needs, are used to serve stations. These switching systems are at nodes that are strategically and centrally located with respect to the community of interest of the served stations. With improvements in technology, it has become practical to distribute switching nodes closer to stations. In some cases to serve stations within a premise, switching is distributed to take place at the stations themselves. A smaller number of systems serve as tandem (intermediate) switching offices for large urban areas or toll (long-distance) offices for interurban switching. These end and intermediate office functions are sometimes combined in the same switching system. *See* PRIVATE BRANCH EXCHANGE.

Switching system fundamentals. Telecommunications switching systems generally perform three basic functions: they transmit signals over the connection or over separate channels to convey the identity of the called (and sometimes the calling) address (for example, the telephone number), and alert (ring) the called station; they establish connections through a switching network for conversational use during the entire call; and they process the signal information to control and supervise the establishment and disconnection of the switching network connection.

In some data or message switching when real-time communication is not needed, the switching network is replaced by a temporary memory for the storage of messages. This type of switching is known as store-and-forward switching.

Signaling and control. The control of circuit switching systems is accomplished remotely by a specific form of data communications known as signaling. Switching systems are connected with one another by telecommunication channels known as trunks. They are connected with the served stations or terminals by lines.

In some switching systems the signals for a call directly control the switching devices over the same path for which transmission is established. For most modern switching systems the signals for identifying or addressing the called station are received by a central control that processes calls on a time-shared basis. Central controls receive and interpret signals, select and establish communication paths, and prepare signals for transmission. These signals include addresses for use at succeeding nodes or for alerting (ringing) the called station.

Most electronic controls are designed to process calls not only by complex logic but also by logic tables or a program of instructions stored in bulk electronic memory. The tabular technique is known as action translator (AT). The electronic memory is now the most accepted technique and is known as stored program control (SPC). Either type of control may be distributed among the switching devices rather than residing centrally. Microprocessors on integrated circuit chips are a popular form of distributed stored program control. *See* COMPUTER STORAGE TECHNOLOGY; INTEGRATED CIRCUITS; MICROPROCESSOR.

Common channel signaling (CCS) comprises a network of separate data communication paths used for transmitting all signaling information between offices. It became practical as a result of processor control. To reduce the number of data channels between all switching nodes, a signaling network of signal switching nodes is introduced. The switching nodes, known as signal transfer points (STPs), are fully interconnected with each other and the switching offices they serve. All links and signal transfer points are duplicated to ensure reliable operation. Each stored-program-control toll switching system connects to the two signal transfer points in its region.

Switching fabrics. Space and time division are the two basic techniques used in establishing connections. When an individual conductor path is established through a switch for the duration of a call, the system is known as space division. When the transmitted speech signals are sampled and the samples multiplexed in time so that high-speed electronic devices may be used simultaneously by several calls, the switch is known as time division.

Most switching is now automatic. The switching fabric frequently comprises two primary-secondary arrangements: first, the line link (LL) frames on which the telephone lines appear and, second, the trunk link (TL) frames on which the trunks appear. A switching entity may grow to a maximum of 60 line link and 30 trunk link frames. Each line link frame is interconnected with every trunk link frame by a network of links called junctors. Each line link frame has a basic capacity for 290 telephone lines and may be supplemented in 50-line increments to a maximum of 590 lines. The size used in a particular office depends upon the calling rate and holding time of the assigned lines.

Electronic switching. Stored program control has become the principal type of control for all types of new switching systems throughout the world, including toll, private branch, data, and Telex systems. Two types of data are stored in the memories of electronic switching systems. One type is the data associated with the progress of the call, such as the dialed address of the called line. Another type, known as the translation data, contains infrequently changing information, such as the type of service subscribed to by the calling line and the information required for routing calls to called numbers. These translation data, like the program, are stored in a memory which is easily read but protected to avoid accidental erasure. This information may be readily changed, however, to meet service needs. The flexibility of a stored program also aids in the administration and maintenance of the service so that system faults may be located quickly.

Untethered switched services. Modern mobile radio service has a considerable dependency on switching. The territory served by a radio carrier is divided into cells of varying geographical size, from microcells that might serve the floors of a business or domicile to cells several miles across that provide a space diversity for serving low-power radios.

Switching systems reach each radio cell site that detects, by signal strength, when a vehicle is about to move from one cell to another. The switching system then selects a frequency and land line for the communication to continue on another channel in a different cell without interruption. This is known as cellular mobile radio service and is used not only for voice but also facsimile and other forms of telecommunication. *See* MOBILE RADIO; TELEPHONE; TELEPHONE SERVICE. [A.E.J.]

Sycamore American sycamore (*Platanus occidentalis*) a member of the plane tree family, known also as American plane tree, buttonball, or buttonwood, and ranging from southern Maine to Nebraska and south into Texas and northern Florida. It has the most massive trunk of any American hardwood. Characteristic are the white patches which are exposed when outer layers of the bark slough off; the simple, large, lobed leaves whose stalks completely cover the conical winter buds; and the spherical fruit heads that are always borne singly in the American species and persist throughout the winter. The tough, coarse-grained wood is difficult to work, but is useful for butchers' blocks, saddle trees, vehicles, tobacco and cigar boxes, crates, and slack cooperage. *See* ROSALES. [A.H.G./K.P.D.]

Sycettida An order of the subclass Calcaronea in the class Calcarea. This order comprises a rather diverse group of calcareous sponges, and includes the families Sycettidae, Heteropiidae, Grantiidae, Amphoriscidae, and Lelapiidae. Choanocytes with apical nuclei are limited to flagellated chambers and never occur lining the general spongocoel. The family Sycettidae resembles the contrasting order Leucosoleniida in lacking the true dermal membrane or cortex possessed by the other five families. The most massive skeleton (of bundles of modified triradiate spicules) is found in the family Lelapiidae. *See* CALCAREA; LEUCOSOLENIIDA. [W.D.R.H.]

Syenite A phaneritic (visibly crystalline) plutonic rock with granular texture composed largely of alkali feldspar (orthoclase, microcline, usually perthitic) with subordinate plagioclase (oligoclase) and dark-colored (mafic) minerals (biotite, amphibole, and pyroxene). If sodic plagioclase (oligoclase or andesine) exceeds the quantity of alkali feldspar, the rock is called monzonite. Monzonites are generally light to medium gray, but syenites are found in a wide variety of colors (gray, green, pink, red), some of which make the material ideal for use as ornamental stone. Syenite is an uncommon plutonic rock and usually occurs in relatively small bodies (dikes, sills, stocks, and small irregular plutons). *See* IGNEOUS ROCKS. [C.A.C.]

Symbiotic star A double star system in the late stage of stellar evolution. Since the symbiotic phase represents a brief span in the life of the binary, symbiotic stars are rare objects. The "near-official" list of symbiotic stars contains 188 safe entries; 15 of them extragalactic, and 30 suspected candidates.

Symbiotics are always associated with a nebular environment. The spectra indicate the presence of a cool M-type star with a surface temperature below 4000 K, and a hot nebula quite similar to a planetary nebula. The light output is variable on time scales of days, months, and years. *See* ASTRONOMICAL SPECTROSCOPY; LIGHT CURVES; NEBULA; PLANETARY NEBULA; VARIABLE STAR.

Evidence has accumulated that all symbiotics are double stars with periods between one year and many dozens of years. Their orbits are sufficiently wide for the two stars not to be in direct contact, and both stars lie safely within their Roche lobe. Thus, for the two stars stellar evolution proceeds over the whole main-sequence lifetime practically uninfluenced by the partner. That changes dramatically in the later stages of their evolution. *See* DOPPLER EFFECT; ECLIPSING VARIABLE STARS.

The gas temperature in the symbiotic nebula, approximately 15,000 K, is much too low to collisionally ionize the atoms in the nebula to the observed degree. The nebular gas must be radiatively ionized by a small, very hot star. Observations and model calculations show the cool star to be a red giant. For the hot star, temperatures between 50,000 and 200,000 K are found. The star's size is that of a white dwarf or of a central star in a planetary nebula, between $\sim$0.01 and $\sim$0.1 solar radius.

The symbiotic nebula has, as a rule, the same chemical composition as expected from red giants. This is taken as evidence that the red giant suffers considerable mass loss. Symbiotics began as stars with masses of the order of 5 solar masses. The more massive star evolved faster through the main sequence, and when it arrived in the red giant region, shed most of its mass through a stellar wind. That material can occasionally still be detected in the wider environment. The star has become a hot white dwarf. The originally less massive star has retained its mass and has now entered the red giant phase, with large mass loss. *See* STELLAR EVOLUTION; WHITE DWARF STAR.

A fraction of the mass lost by the red giant is captured by the white dwarf. The accretion liberates gravitational energy which can convert into radiative energy and be responsible for some of the irregular luminosity variations. When the white dwarf has accumulated a critical mass of hydrogen, thermonuclear reactions on its surface lead to an energy outburst lasting over 100 years. The energy production outburst can reach many thousand times that of the Sun. The mechanism resembles a nova explosion. However, a classical nova has higher peak energy output and shorter duration than a symbiotic nova. *See* Cataclysmic variable; Nova.

Observations have shown traces of the mass formerly lost by the hot star. However, as roted above, the bulk of the matter now detected as an ionized nebula is due to the present mass loss of the red giant in its stellar wind. In its active phase the white dwarf may have a stellar wind of its own. In that case the nebular environment will be strongly structured by the collision of the two winds. This leads to shock zones with temperatures of several million kelvins. The origin of bipolar gaseous jets observed in several symbiotics is not yet known. Observational evidence indicates that the white dwarf possesses a strong magnetic field which could play a major role. [H.N.]

Symbolic computing The process of manipulating numbers and variables according to the rules of mathematical logic. Variables are used to represent a real number or a set of real numbers to exact precision. Numbers can be added, subtracted, multiplied, and divided. Numerical calculations or numerical computations involve performing these operations. For example, if the symbol $*$ is used to represent multiplication and / is used to represent division, then the equation

$$(3 * 5 - 1)/7 = 2$$

represents a numerical computation whose result is 2. In mathematics, it is also possible to use symbols to represent numbers and to do computations with the symbols. For example,

$$ax + b = 0 \quad (\text{with } a \neq 0)$$

can also be expressed as

$$x = -\frac{b}{a}$$

In this calculation or computation, the mathematical rules for subtraction and division are obeyed. The symbol x is treated as an unknown or variable that is to be solved for, and a and b as parameters representing unknown but fixed numbers.

In the 1990s, mathematical software packages became available that could manipulate symbols according to the rules of mathematics. They are also called symbolic computational packages and are programming environments, since any real number has a decimal expansion. These packages have the ability to obtain exact answers as symbols. For example, if

$$x^2 - 2 = 0, \quad x > 0$$

were entered into a symbolic computation package, the software package would return the answer

$$x = \sqrt{2}$$

The software package also allows the user to then ask for an approximation to 2 to any number of digits. The decimal units for 2 are determined using an algorithm that performs numerical calculation (called a numerical algorithm). Symbolic computation packages allow both symbolic and numerical computation. *See* Algorithm; Computer programming; Mathematical software.

The capability of small computers and hand-held calculators to do extremely complicated calculations in a small amount of time led to the development of mathematical software packages that could do symbolic manipulation. These symbolic manipulation packages (also called computer algebra systems or symbolic computation systems) can do algebra, trigonometry, number theory, calculus, ordinary and partial differential equations, matrix algebra, and other areas of mathematics by manipulating the symbols according to the rules of mathematics much faster than armies of mathematicians. The answers are given exactly in symbolic form and can then be approximated numerically using routines in the package.

The advent of visualization on the computer has made it possible for these packages to plot data or functions in many forms. The functions are entered symbolically, and the software evaluates them numerically so that numbers can be plotted. The graphs generated by the plot routines can be labeled, rotated, or animated, among many other possibilities.

Hand-held calculators can perform symbolic manipulation, graph data or functions, and be programmed to carry out a sequence of operations. Mathematical software packages have been developed that can perform symbolic manipulation, graph data or functions, and be programmed using routines in the package. These packages run on most commonly used operating systems. They can also be called by computer programs to perform manipulations in the program. There are packages that do statistics, computational finance, computational physics, and computational chemistry. *See* Calculators; Operating system; Programming languages. [J.So.]

Symmetrodonta A group of extinct mammals that range from the Late Triassic to Late Cretaceous. Their fossil remains have been found in Mesozoic deposits worldwide. These small insectivorous or carnivorous mammals are the size of a shrew or mouse. They are considered to be distant relatives of the more derived therian mammals, including the extinct eupantotheres, such as dryolestids and the living placental and marsupial mammals.

Symmetrodonts are characterized by a distinctive feature: the main cusps of their cheek teeth are arranged in a symmetrical triangle. The triangular upper and lower cheek teeth fill in the gaps between the adjacent teeth of the opposite tooth row, and are specialized for crushing insects or slicing worms. However, symmetrodonts lack a basinlike heel in the lower teeth that would allow the grinding of the ingested food in the more derived living therian mammals and their kin. Symmetrodonts are also distinguished from more derived therians by lacking the angle on the mandible.

Symmetrodonts are classified as the order Symmetrodonta of the class Mammalia. Three families are notable among the diverse symmetrodonts: Kuehneotheriidae considered to be close to the ancestry of all other therian mammals; Amphidontidae; and Spalacotheriidae, which are characterized by the highly acute triangular cheek teeth and are the most diverse symmetrodont family. [Z.L.]

Symmetry breaking A deviation from exact symmetry. According to modern physical theory the fundamental laws of physics possess a very high degree of symmetry. Several deep insights into nature arise in understanding why specific physical systems, or even the universe as a whole, exhibit less symmetry than the laws themselves.

Spontaneous symmetry breaking. This mechanism occurs in quite diverse circumstances. The most symmetrical solutions of the fundamental equations governing a given system may be unstable, so that in practice the system is found to be in a less symmetrical, but stable, state. When this occurs, the symmetry is said to have been broken spontaneously.

For example, the laws of physics are unchanged by any translation in space, but a crystalline lattice is unchanged only by special classes of translations. A crystal does retain a large amount of symmetry, for it is unchanged by those finite translations, but this falls far short of the full symmetry of the underlying laws. *See* Crystal structure.

Another example is provided by ferromagnetic materials. The spins of electrons within such materials are preferentially aligned in some particular direction, the axis of the poles of the magnet. The laws of physics governing the interactions among these spins are unchanged by any rotation in space, but the aligned configuration of spins has less symmetry. Indeed, it is left unchanged only by rotations about the polar axis. *See* FERROMAGNETISM.

In both these examples, the loss of symmetry is associated with the appearance of order. This is a general characteristic of spontaneous symmetry breaking.

Consequences. There is a cluster of important observable consequences associated with spontaneous symmetry breaking.

Nambu-Goldstone bosons are a class of low-energy excitations associated with gentle variations of the order. Thus, there is a class of excitations of the ferromagnet, the magnons, that exist as a consequence of the spontaneous symmetry breaking, and that have very low energy. Similarly, in the case of crystals, phonons are associated with gentle distortions of the lattice structure. *See* MAGNON; PHONON.

At high temperatures the energy gained by assuming an ordered structure is increasingly outweighed by the entropy loss associated with the constraints it imposes, and at some point it will no longer be favorable to have spontaneous symmetry breaking in thermal equilibrium. Changes from broken symmetry to unbroken symmetry are marked by phase transitions. For a magnet, the transition occurs at the Curie temperature. For a crystal, it is melting into a liquid or sublimation into a gas. *See* CURIE TEMPERATURE; ENTROPY; PHASE TRANSITIONS; THERMODYNAMIC PRINCIPLES.

Defects are imperfections in the ordering. The most familiar examples are domain walls in magnets. *See* CRYSTAL DEFECTS; DOMAIN (ELECTRICITY AND MAGNETISM).

In systems with long-range forces as well as spontaneous symmetry breaking, it need no longer be true that gradual changes require only a small input of energy, because even distant regions interact significantly. Thus, the Nambu-Goldstone bosons no longer have very low energies, and they are not easily excited. Conversely, the system will exhibit a special rigidity, with strong correlations between distant points. These ideas are central to modern theories of superconductivity and of particle physics (the Higgs mechanism). *See* ELECTROWEAK INTERACTION; HIGGS BOSON; SUPERCONDUCTIVITY. [F.Wil.]

Symmetry laws (physics)

The physical laws which are expressions of symmetries. The term symmetry, as it is used in mathematics and the exact sciences, refers to a special property of bodies or of physical laws, namely that they are left unchanged by transformations which, in general, might have changed them. For example, the geometric form of a sphere is not changed by any rotation of the sphere around its center, and so a sphere can be said to be symmetric under rotations. Symmetry can be very powerful in constraining form. Indeed, referring to the same example, the only sort of surface which is symmetric under arbitrary rotations is a sphere.

The concept that physical laws exhibit symmetry is more subtle. A naive formulation would be that a physical law exhibits symmetry if there is some transformation of the universe that might have changed the form of the law but in reality does not. However, the comparison of different universes is generally not feasible or desirable. A more fruitful definition of the symmetry of physical law exploits locality, the principle that the behavior of a given system is only slightly affected by the behavior of other bodies far removed from it in space or time. Because of locality, it is possible to define symmetry by using transformations that do not involve the universe as a whole but only a suitably isolated portion of it. Thus the statement that the laws of physics are symmetric under rotations means that (say) astronauts in space would not be able to orient themselves—to determine a preferred direction—by experiments internal to their space station. They could do this only by referring to weak effects from distant objects, such as the light of distant stars or the small residual gravity of Earth.

Symmetries of space and time. Perhaps the most basic and profound symmetries of physical laws are symmetry under translation in time and under translations in space.

The statement that fundamental physical laws are symmetric under translation in time is equivalent to the statement that these laws do not change or evolve. Time-translation symmetry is supposed to apply, fundamentally, to simple isolated systems. Large complicated systems, and in particular the universe as a whole, do of course age and evolve. Thus in constructing the big-bang model of cosmology, it is assumed that the properties of individual electrons or protons do not change in time, although of course the state of the universe as a whole, according to the model, has changed quite drastically.

The statement that fundamental laws are symmetric under translations in space is another way of formulating the homogeneity of space. It is the statement that the laws are the same throughout the universe. It says that the astronauts in the previous example cannot infer their location by local experiments within their space station. The power of this symmetry is that it makes it possible to infer, from observations in laboratories on Earth, the behavior of matter anywhere in the universe.

The symmetry of physical law under rotations, mentioned above, embodies the isotropy of space.

In the mathematical formulation of dynamics, there is an intimate connection between symmetries and conservation laws. Symmetry under time translation implies conservation of energy; symmetry under spatial translations implies conservation of momentum; and symmetry under rotation implies conservation of angular momentum. *See* ANGULAR MOMENTUM; CONSERVATION OF ENERGY; CONSERVATION OF MOMENTUM.

The fundamental postulate of the special theory of relativity, that the laws of physics take the same form for observers moving with respect to one another at a fixed velocity, is clearly another statement about the symmetry of physical law. The idea that physical laws should be unchanged by such transformations was discussed by Galileo, who illustrated it by an observer's inability to infer motion while on a calm sea voyage in an enclosed cabin. The novelty of Einstein's theory arises from combining this velocity symmetry with a second postulate, deduced from experiments, that the speed of light is a universal constant and must take the same value for both stationary and uniformly moving observers. *See* GALILEAN TRANSFORMATIONS; LORENTZ TRANSFORMATIONS; RELATIVITY.

Discrete symmetries. Before 1956, it was believed that all physical laws obeyed an additional set of fundamental symmetries, denoted P, C, and T, for parity, charge conjugation, and time reversal, respectively. Experiments involving particles known as K mesons led to the suggestion that P might be violated in the weak interactions, and violations were indeed observed. This discovery led to questioning—and in some cases overthrow—of other cherished symmetry principles.

Parity, P, roughly speaking, transforms objects into the shapes of their mirror images. If P were a symmetry, the apparent behavior of the images of objects reflected in a mirror would also be the actual behavior of corresponding real objects. *See* PARITY (QUANTUM MECHANICS).

Charge conjugation, C, changes particles into their antiparticles. It is a purely internal transformation; that is, it does not involve space and time. If the laws of physics were symmetric under charge conjugation, the result of an experiment involving antiparticles could be inferred from the corresponding experiment involving particles.

Remarkably, by combining the transformations P and C, a result is obtained, CP, which is much more nearly a valid symmetry than either of its components separately. However, in 1964 it was discovered experimentally that even CP is not quite a valid symmetry.

Although the preceding discussion has emphasized the failure of P, C, and CP to be precise symmetries of physical law, both the strong force responsible for nuclear structure and reactions and the electromagnetic force responsible for atomic structure and chemistry do obey these symmetries. Only the weak force, responsible for beta radioactivity and some relatively slow decays of exotic elementary particles, violates them. Thus these symmetries, while approximate, are quite useful and powerful in nuclear and atomic physics. *See* Electroweak interaction; Fundamental interactions; Weak nuclear interactions.

The operation of time-reversal symmetry, T, involves changing the direction of motion of all particles. For example, it relates reactions of the type $A + B \rightarrow C + D$ to their reverse $C + D \rightarrow A + B$. No direct violation of T has been detected. *See* Time reversal invariance.

Time-reversal symmetry, even if valid, applies in a straightforward way only to elementary processes. It does not, for example, contradict the one-way character of the second law of thermodynamics, which states that entropy can only increase with time. *See* Thermodynamic principles; Time, arrow of.

Fundamental principles of quantum field theory suggest that the combined operation PCT, which involves simultaneously reflecting space, changing particles into antiparticles, and reversing the direction of time, must be a symmetry of physical law. Existing evidence is consistent with this prediction. *See* CPT theorem.

Internal symmetry. Internal symmetries, like C, do not involve transformations in space-time but change one type of particle into another. An important, although approximate, symmetry of this kind is isospin or i-spin symmetry. It is observed experimentally that the strong interactions of the proton and neutron are essentially the same. *See* I-spin.

There have been several successful predictions of the existence and properties of new particles, based on postulates of internal symmetries. Perhaps the most notable was the prediction of the mass and properties of the Ω^- baryon, based on an extension of the symmetry group SU(2) of isospin to a larger approximate SU(3) symmetry acting on strange particles as well. These symmetries were an important hint that the fundamental strong interactions are at some level universal, that is, act on all quarks in the same way, and thus paved the way toward modern quantum chromodynamics, which does implement such universality. *See* Baryon; Group theory; Quantum chromodynamics; Unitary symmetry.

Much simpler mathematically than SU(2) internal symmetry, but quite profound physically, is U(1) internal symmetry. The important case of the electric charge quantum number will be considered. The action of the U(1) internal symmetry transformation with parameter λ is to multiply the wave function of a state of electric charge q by the factor $e^{i\lambda q}$. An amplitude between two states with electric charges q_r and q_s will therefore be multiplied by a factor $e^{i\lambda(q_s - q_r)}$. Since the physical predictions of quantum mechanics depend on such amplitudes, these predictions will be unchanged only if the phase factors multiplying all nonvanishing amplitudes are trivial. This will be true, in turn, only if the amplitudes between states of unequal charge vanish; that is, if charge-changing amplitudes are forbidden, which is just a backhanded way of expressing the conservation of charge. *See* Nonrelativistic quantum theory; Quantum mechanics; Quantum numbers.

Localization of symmetry. The concept of local gauge invariance, which is central to the standard model of fundamental particle interactions, and in a slightly different form to general relativity, may be approached as a generalization of the U(1) internal symmetry transformation, where a parameter λ independent of space and time appears. Such a parameter goes against the spirit of locality, according to which each point in space-time has a certain independence. There is therefore reason to consider a more general symmetry, involving a space-time-dependent transformation in which the wave function is multiplied by $e^{i\lambda(x,t)q(x,t)}$, where $q(x,t)$ is the density of charge at the space-time point (x,t). These transformations are much more general than those discussed above, and invariance under them leads to much more powerful and specific consequences.

For electromagnetism, the required interactions of matter with the electromagnetic field are predicted precisely. Thus, the theory of the electromagnetic field—Maxwell's equations and quantum electrodynamics—can be said to be the unique ideal embodiment of the abstract concept of a space-time-dependent symmetry, that is, of local gauge symmetry. *See* Maxwell's equations; Quantum electrodynamics.

[F.Wil.]

Symmorphosis

Symmorphosis A theory of structural design of biological organisms postulating that structure is quantitativelymatched to functional demand as a result of regulated morphogenesis during growth and maintenance. Symmorphosis is a theory of economic design. In biological organisms, all functions depend on structural design, specifically on the morphometric characteristics of the organs. In general terms, the larger the structure the greater the functional capacity. A central postulate of symmorphosis, as a theory of economic design, is that differences in the functional demand on an organ require quantitative adjustments of its structural design parameters in order to match functional capacity to (maximal) functional demand.

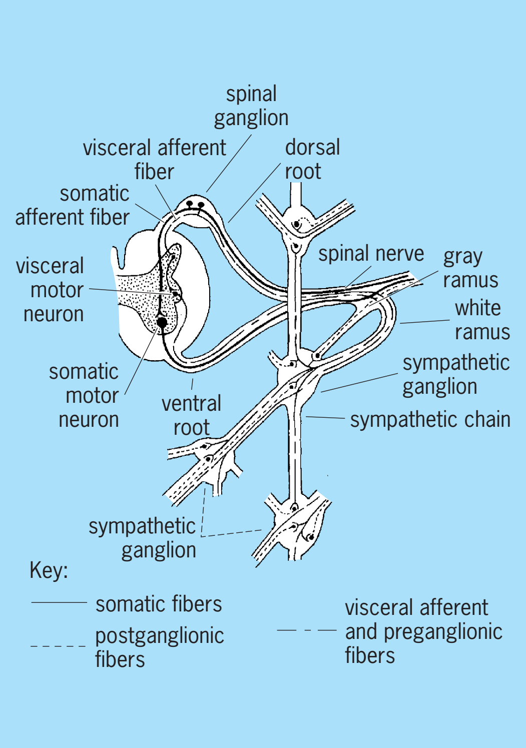
The notion that animals, and humans, should be designed economically follows from common sense, but it is also supported by many observations. Blood vessel architecture ensures blood flow distribution with minimal energy loss. Bone structure is patterned according to stress distribution and also quantitatively adapted to total stress. With training, athletes can specifically adjust the structure of their muscles and of their cardiovascular system to higher functional demands, and these modifications are soon reversed when training is stopped.

The theory of symmorphosis postulates ideal adaptation of structural design to functional capacity. This is, however, hardly a reasonable assumption, because good engineering design of complex systems requires some redundancies as safety factors in view of imperfections in functional performance and variable boundary conditions. By using the concept of symmorphosis, such deviations from idealized economic design can be detected.

[E.R.W.]

Sympathetic nervous system

Sympathetic nervous system The portion of the autonomic nervous system concerned with nonvolitional



The visceral reflex arc and the sympathetic chain. (*After B. A. Houssay et al., Human Physiology, 2d ed., McGraw-Hill, 1955*)

preparation of the organism for emergency situations. *See* AUTONOMIC NERVOUS SYSTEM.

The sympathetic nervous system is best understood in mammals. It consists of two neuron chains from the thoracic and lumbar regions of the spinal cord to viscera and blood vessels. The first or preganglionic neuron has its cell body in the spinal cord and sends its axon to synapse with a postganglionic sympathetic neuron, which lies either in a chain of sympathetic ganglia paralleling the spinal cord or in a sympathetic ganglion near the base of the large blood vessels vascularizing the alimentary viscera. The postganglionic axons are longer than the preganglionic axons and extend to glands or smooth muscles of viscera and blood vessels. Sensory visceral nerve fibers innervate blood vessels and viscera and carry sensory information to the spinal cord, thus providing a visceral reflex (see illustration). *See* NERVOUS SYSTEM (VERTEBRATE); PARASYMPATHETIC NERVOUS SYSTEM. [D.B.W.]

Sympathetic vibration The driving of a mechanical or acoustical system at its resonant frequency by energy from an adjacent system vibrating at this same frequency. Examples include the vibration of wall panels by sounds issuing from a loudspeaker, vibration of machinery components at specific frequencies as the speed of a motor increases, and the use of tuned air resonators under the bars of a xylophone to enhance the acoustic output. Increasing the damping of a vibrating system will decrease the amplitude of its sympathetic vibration but at the same time widen the band of frequencies over which it will partake of sympathetic vibration. *See* RESONANCE (ACOUSTICS AND MECHANICS); VIBRATION. [L.E.K.]

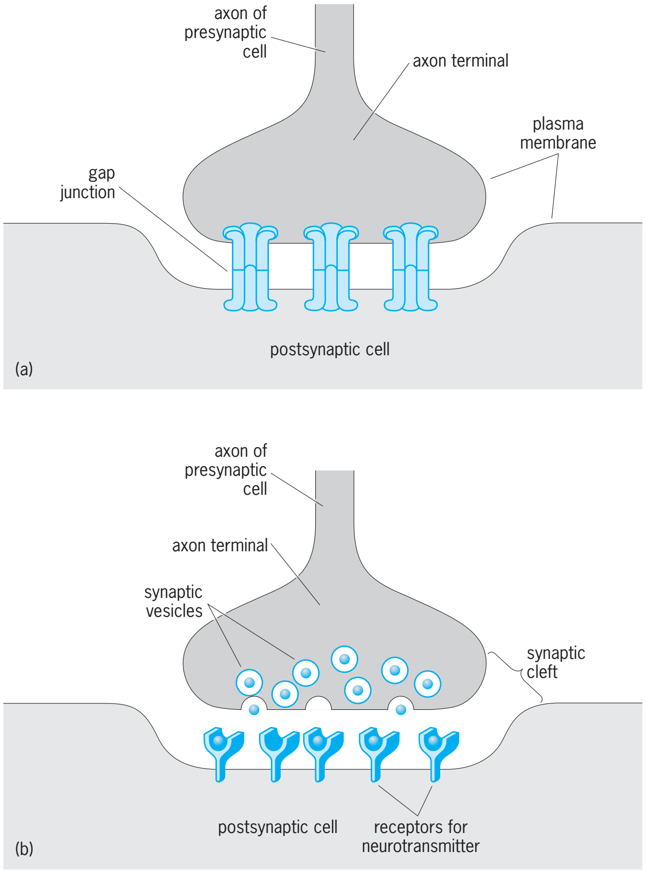
Symphyla A class of the Myriapoda. The symphylans, like the pauropods, are tiny, pale, centipedelike creatures that inhabit humans or soil, or live under debris; in general, they live wherever there is sufficient moisture to preclude excessive water loss. They are similar to the Pauropoda and Diplopoda in being progoneate and anamorphic. Each of their mandibles, like those of millipedes, bears a movable gnathal lobe; at the same time their two pairs of maxillae are more reminiscent of the chilopods and lower insects than of the singly maxillate millipedes and pauropods.

The class consists of three families to which not more than 60 species have been assigned. [R.E.Cr.]

Synapsida A subclass of extinct reptiles, in general characterized by a temporal fenestra that lies below the junction of the postorbital and squamosal bones, a so-called lower temporal opening. In advanced forms, however, the postorbital-squamosal bridge is absent. Mammals arose from this group of reptiles during the Triassic Period. *See* REPTILIA.

Synapsids first appear in the geological record in the Upper Carboniferous. They flourished during the Late Paleozoic and Early Mesozoic but became extinct at about the end of the Triassic. During this span of time they underwent a broad adaptive radiation on land and made minor invasions of aquatic habitats. There were two major phases of this radiation: one early, by pelycosaurs, and the other later (Late Permian and Triassic), by therapsids. *See* PELYCOSAURIA; REPTILIA; THERAPSIDA. [E.C.O.]

Synaptic transmission The physiological mechanisms by which one nerve cell (neuron) influences the activity of an anatomically adjacent neuron with which it is functionally coupled. Brain function depends on interactions of nerve cells with each other and with the gland cells and muscle cells they innervate. The interactions take place at specific sites of contact between cells known as synapses. The synapse is the smallest and most fundamental information-processing unit in the nervous system. By means of different patterns of synaptic connections between neurons, synaptic circuits are constructed during development to carry out the different functional operations of the nervous system. *See* NEURON.



Types of synapses. (*a*) An electrical synapse, showing the plasma membranes of the presynaptic and postsynaptic cells linked by gap junctions. (*b*) A chemical synapse, showing neurotransmitters released by the presynaptic cell diffusing across the synaptic cleft and binding to receptors on the postsynaptic membrane.

The simplest type of synapse is the electrical synapse (see illustration), which consists of an area of unusually close contact between two cells packed with channels that span the two membranes and the cleft between them. Electrical synapses are also known as gap junctions. Electrical and metabolic communication between two cells is established by the components of the gap junctions. A variety of influences, including calcium ions, pH, membrane potential, neurotransmitters, and phosphorylating enzymes, may act on the channels to regulate their conductance in one direction (rectification) or both directions.

Electrical synapses are present throughout the animal kingdom. In vertebrates, they are numerous in the central nervous systems of fish as well as in certain nuclei of the mammalian brain, in regions where rapid transmission and synchronization of activity is important. Electrical synapses also interconnect glial cells in the brain. *See* BIOPOTENTIALS AND IONIC CURRENTS; CELL PERMEABILITY.

The most prevalent type of junction between nerve cells is the chemical synapse (see illustration). At chemical synapses neurotransmitters are released from the presynaptic cell, diffuse across the synaptic clefts, and bind to receptors on the postsynaptic cell. Chemical synapses are found only between nerve cells or between nerve cells and the gland cells and muscle cells that they innervate. The neuromuscular junction, that is, the junction between the axon terminals of a motoneuron and a muscle fiber, is a prototypical chemical synapse. Three basic elements constitute this synapse: a presynaptic process (in this case, the motoneuron axon terminal) containing synaptic vesicles; an end plate (a specialized site of contact between the cells); and a postsynaptic process (in this case, the muscle cell). The postsynaptic membrane contains receptors for the transmitter substance released from the presynaptic terminal.

The chemical substance that serves as the transmitter at the vertebrate neuromuscular junction is acetylcholine (ACh). Within the nerve terminal, acetylcholine is concentrated within small spherical vesicles. At rest, these vesicles undergo exocytosis at low rates, releasing their acetylcholine in quantal packets to diffuse across the cleft and bind to and activate the postsynaptic receptors. Each quantum gives rise to a small depolarization of the postsynaptic membrane. These miniature end-plate potentials are rapid, lasting only some 10 milliseconds, and small in amplitude, only some 500 microvolts, below the threshold for effecting any response in the muscle. They represent the resting secretory activity of the nerve terminal.

When an organism wants to move its muscles, electrical impulses known as action potentials are generated in the motoneurons. These are conducted along the axon and invade the terminal, causing a large depolarization of the presynaptic membrane. This opens special voltage-gated channels for calcium ions, which enter the terminal and bind to special proteins, causing exocytosis of vesicles simultaneously. Calcium ions are the crucial link between the electrical signals in the presynaptic neuron and the chemical signals sent to the postsynaptic neuron. The combined action of this acetylcholine on postsynaptic receptors sets up a large postsynaptic depolarization, which exceeds the threshold for generating an impulse in the surrounding membrane, and causes the muscle to contract. The action of acetylcholine at its receptor is terminated by an enzyme, acetylcholinesterase, which is present in the synaptic cleft and hydrolyzes the acetylcholine to acetate and choline.

In order for neurotransmission to continue, synaptic vesicles have to be regenerated. Vesicles are rapidly and efficiently reformed in the nerve terminal by endocytosis. Specific neurotransmitter transporters within the membrane then fill the synaptic vesicle with appropriate neurotransmitter. The regenerated vesicle either returns to the plasma membrane where it rejoins the releasable pool of vesicles, or remains in the nerve terminal as part of a reserve pool. *See* ACETYLCHOLINE; MUSCLE.

In the central nervous system the presynaptic process containing synaptic vesicles is most often an axon terminal and the postsynaptic process a dendrite, making an axodendritic synapse, but other relationships are also seen. The effect of transmitter on a postsynaptic cell is either excitatory or inhibitory, meaning that it either depolarizes or hyperpolarizes the membrane. Whether a transmitter has an excitatory or inhibitory effect on a cell is determined by the type of ion able to pass through the cell's receptor channels.

There are two principal types of central synapses.

Type 1 central synapses commonly release an amino acid transmitter, such as glutamate, whose action produces an excitatory postsynaptic potential. At low levels of activity the glutamate binds to the glutamate receptor and activates a relatively small conductance increase for sodium and potassium ions. Glutamate is the transmitter at many excitatory synapses throughout the central nervous system. The type 2 central synapse is usually associated with inhibitory synaptic actions. The most common inhibitory transmitter is gamma-amino butyric acid (GABA). Most inhibitory interneurons in different regions of the brain make these kinds of synapses on relay neurons in those regions. The GABA receptor is a complex channel-forming protein with several types of binding sites and several conductance states.

Other classes of synaptic transmitter substances include the biogenic amines, such as the catecholamines, norepinephrine and dopamine, and the indoleamine 5-hydroxytryptamine (also known as serotonin). *See* DOPAMINE; NORADRENERGIC SYSTEM; SEROTONIN.

A final type of transmitter substance consists of a vast array of neuropeptides. They are a diverse group and include substances that stimulate the release of hormones; those that act at synapses in pain pathways in the brain (the endogenous morphinelike substances, enkephalins and endorphins); and many of still undetermined functions. Peptides may act also indirectly, modifying the state of a receptor in its response to other transmitter substances, and they may do this in an activity-dependent manner. In view of the complexity and slow time course of many of their effects, these peptides are often referred to as neuromodulators. *See* ENDORPHINS; HORMONE.

At central synapses, rapid responses to transmitters (typically within milliseconds) are most commonly the result of direct synaptic transmission, in which the receptor itself is the ion channel. Such receptors are referred to as ionotropic. There are, however, other receptor molecules for each of the neurotransmitters, and many of these are not themselves ion channels. They are known as metabotropic receptors, and they affect neurotransmission indirectly via a set of intermediary proteins called G-proteins. Activated G-proteins have a variety of effects on synaptic processes. Some are mediated by direct interactions with ion channels. However, many other effects are mediated by activation of cellular second messenger systems involving messengers such as calcium and cyclic adenosine monophosphate (cyclic AMP). The time courses for effects caused by activation of G-protein-coupled receptors is much longer than that of ionotropic channels (milliseconds), reflecting the lifetime of the activated G-protein subunits (seconds) and second messengers (seconds to minutes). Such longer lasting signals greatly increase the complexity of chemical neurotransmission and synaptic modulation. *See* SECOND MESSENGERS.

The synapse is a dynamic structure whose function is very dependent on its activity state. In this way the synapse is constantly adjusted for its information load. At glutamatergic synapses, high levels of input activity bring about a different transmission state. The buildup of postsynaptic depolarization relieves the normal block of a specialized glutamate receptor channel, permitting influx of calcium ions into the postsynaptic process. Since the conductance of the channel is dependent on the depolarization state of the membrane, it is said to have a voltage-gated property, in addition to being ligand-gated by its transmitter. The calcium ion acts as a second messenger to bring about a long-lasting increase in synaptic efficacy, a process known as long-term potentiation. The conjunction of increased pre- and postsynaptic activity to give an increase in synaptic efficacy is called Hebbian, and is believed to be the type of plasticity mechanism involved in learning and memory. *See* LEARNING MECHANISMS; MEMORY.

The synapse is one of the primary targets of drug actions. The first example to be identified was the arrow poison curare, which blocks neuromuscular transmission by binding to acetylcholine receptor sites. Many toxic agents have their actions on specific types of receptors; organic fluorophosphates, for example, are widely used pesticides that bind to and inactivate acetylcholinesterase. Most psychoactive drugs exert their effects at the synaptic level. *See* NERVOUS SYSTEM (VERTEBRATE); NEUROBIOLOGY. [G.M.Sh.; P.I.H.]

Synbranchiformes An order of eellike fishes that, unlike true eels, has the premaxillae present as distinct bones. The small gill apertures are often confluent across the breast. The gills are poorly developed, and in some species respiration is accomplished in part by highly vascularized buccopharyngeal pouches. There are no fin spines or pectoral fins, and the median fins, if developed, are continuous. Pelvic fins, if present, are small and located on the throat. The body may be naked or scaled. There is no swim bladder. The group, which has no fossil record, is classified into 2 suborders, 3 families, 7 genera, and 12 species. These serpentine fishes inhabit swamps, caves, and sluggish fresh and brackish waters of tropical America, Australia, eastern and southeastern Asia, the East Indies, and tropical Africa. *See* ACTINOPTERYGII. [R.M.B.]

Syncarida A unique superorder of malacostracan Crustacea, noted particularly for the total lack of a carapace or carapace shield. Two orders are recognized, Anaspidacea and Bathynellacea. The Stygocarididae, at one time considered a distinct order, are now assigned familial rank within the Anaspidacea.

The syncarid body plan is simple, consisting of a cephalon (head and sometimes one thoracic somite), thorax of seven or eight somites, and an abdomen of six somites and telson or five somites and pleotelson (fused sixth somite-telson). Eyes, with apposition optics, may be stalked or sessile, or sometimes absent. There are six to eight thoracic appendages (thoracopods), usually two to five abdominal appendages (pleopods), and uropods. Sexes are separate. Young hatch as immature adults and pass through several molts before reaching maturity.

Extant syncarids are specially adapted to fresh-water, often interstitial environments. Whereas the Anaspidacea are restricted to the Southern Hemisphere (Australia, Tasmania, New Zealand, South America), bathynellids have been found worldwide, except in Antarctica. *See* BATHYNELLACEA; CRUSTACEA; MALACOSTRACA. [P.A.McL.]

Synchronization The process of maintaining one operation in step with another. The commonest example is the electric clock, whose motor rotates at some integral multiple or submultiple of the speed of the alternator in the power station. In television, synchronization is essential in order that the electron beams of receiver picture tubes are at exactly the same spot on the screen at each instant as is the beam in the television camera tube at the transmitter. *See* TELEVISION. [J.Mar.]

Synchronous converter A synchronous machine used to convert alternating current (ac) to direct current (dc), or vice versa. The ac-to-dc converter has been superseded by the mercury arc rectifier (for reasons of efficiency, lower maintenance costs, and less trouble) or by motor-generator sets. Converters are no longer manufactured, but there are converters still in use. *See* DIRECT-CURRENT GENERATOR; SYNCHRONOUS MOTOR. [L.V.B.]

Synchronous motor An alternating-current (ac) motor which operates at a fixed synchronous speed proportional to the frequency of the applied ac power. A synchronous machine may operate as a generator, motor, or capacitor depending only on its applied shaft torque (whether positive, negative, or zero) and its excitation. There is no fundamental difference in the theory, design, or construction of a machine intended for any of these roles, although certain design features are stressed for each of them. In use, the machine may change its role from instant to instant. For these reasons it is preferable not to set up separate theories for synchronous generators, motors, and capacitors. It is better to establish a general theory which is applicable to all three and in which the distinction between them is merely a difference in the direction of the currents and the sign of the torque angles. *See* ALTERNATING-CURRENT GENERATOR; ALTERNATING-CURRENT MOTOR; SYNCHRONOUS CAPACITOR. For special types of synchronous motors *see* HYSTERESIS MOTOR; RELUCTANCE MOTOR. [R.T.S.]

Synchroscope An instrument used for indicating whether two alternating-current (ac) generators or other ac voltage sources are synchronized in time phase with each other. Its main use is in power supply networks where, if two generators are to be operated in parallel or an additional generator is to be coupled into the grid, it is essential that the generator voltages should be matched in amplitude, frequency, and phase.

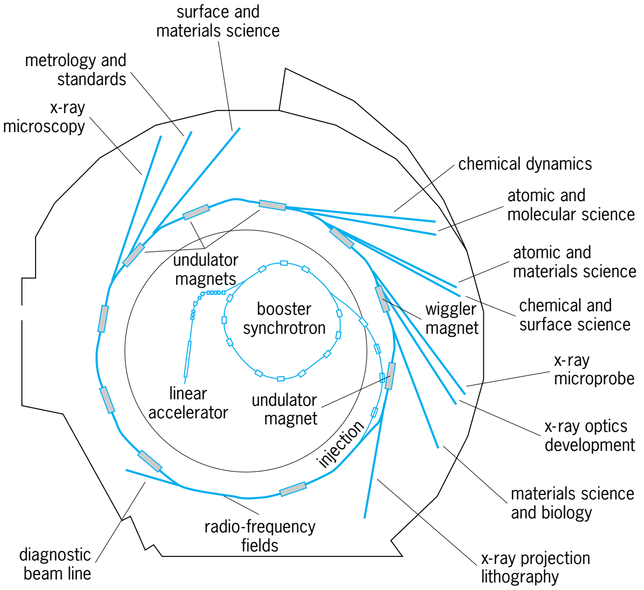
New power stations are often equipped with automatic means of synchronizing generators. But many synchroscopes of the traditional types are still in use and are likely to remain so for many years.

The term synchroscope is also sometimes applied to a special type of cathode-ray oscilloscope designed for observing extremely short pulses, using fast sweeps synchronized with the signal to be observed. *See* ELECTRIC POWER GENERATION; ELECTRIC POWER SYSTEMS; OSCILLOSCOPE. [A.E.Ba.]

Synchrotron radiation Electromagnetic radiation emitted by relativistic charged particles curving in magnetic or electric fields. With the development of electron storage rings, radiation with increasingly high flux, brightness, and coherent power levels has become available for a wide variety of basic and applied research in biology, chemistry, and physics, as well as for applications in medicine and technology. *See* ELECTROMAGNETIC RADIATION; PARTICLE ACCELERATOR; RELATIVISTIC ELECTRODYNAMICS.

Electron storage rings provide radiation from the infrared through the visible, near-ultraviolet, vacuum-ultraviolet, soft-x-ray, and hard-x-ray parts of the electromagnetic spectrum extending to 100 keV and beyond. The flux [photons/(second, unit bandwidth)], brightness (or brilliance) [flux/(unit source size, unit solid angle)], and coherent power (important for imaging applications and proportional to brightness) available for experiments, particularly in the vacuum-ultraviolet, soft-x-ray, and hard-x-ray parts of the spectrum, are many orders of magnitude higher than is available from other sources.

The radiation has many features (natural collimation, high intensity and brightness, broad spectral bandwidth, high polarization, pulsed time structure, small source size, and high-vacuum environment) that make it ideal for a wide variety of applications in experimental science and technology. Very powerful sources of synchrotron radiation in the ultraviolet and x-ray parts of the spectrum became available when high-energy physicists began operating electron synchrotrons in the 1950s. Although synchrotrons produce large amounts of radiation, their cyclic nature results in pulse-to-pulse intensity changes and variations in spectrum and source shape during each cycle. By contrast, the electron-positron storage rings developed for colliding-beam experiments starting in the 1960s offered a constant spectrum and much better stability. Beam lines were constructed on both synchrotrons and storage rings to allow the radiation produced in the bending magnets of these machines to leave the ring vacuum system and reach experimental stations. In most cases the research programs were pursued on a parasitic basis, secondary to the high-energy physics programs.



Layout of the 1.5-GeV Advanced Light Source at Lawrence Berkeley National Laboratory, a low-energy, third-generation synchrotron radiation source. Applications of experimental stations on beam lines are indicated.

Since about 1980, fully dedicated storage ring sources have been completed in several countries. They are called second-generation facilities to distinguish them from the first-generation rings that were built for research in high-energy physics.

Special magnets may be inserted into the straight sections between ring bending magnets to produce beams with extended spectral range or with higher flux and brightness than is possible with the ring bending magnets. These devices, called wiggler and undulator magnets, utilize periodic transverse magnetic fields to produce transverse oscillations of the electron beam with no net deflection or displacement. They provide another order-of-magnitude or more improvement in flux and brightness over ring bending magnets, again opening up new research opportunities. However, their potential goes well beyond their performance levels, in first- and second-generation sources.

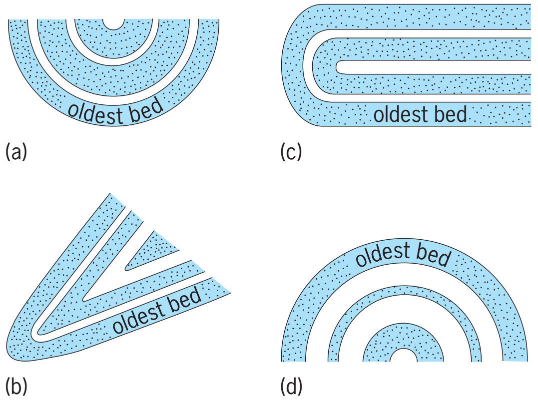
Third-generation sources are storage rings with many straight sections for wiggler and undulator insertion device sources and with a smaller transverse size and angular divergence of the circulating electron beam. The product of the transverse size and divergence is called the emittance. The lower the electron-beam emittance, the higher the photon-beam brightness and coherent power level. With smaller horizontal emittances and with straight sections that can accommodate longer undulators, third-generation rings provide two or more orders of magnitude higher brightness and coherent power level than earlier sources.

One consequence of the extraordinary brilliance of these sources is that the x-ray beam is partially coherent. By aperturing the beam, a fully coherent beam can be obtained, but at the expense of flux. Nonetheless, there is still sufficient flux remaining to explore the use and application of coherent x-ray beams. *See* COHERENCE.

Several third-generation rings are in operation. Low-energy (typically 1–2-GeV) third-generation rings (see illustration) are optimized to produce high-brightness radiation in the vacuum ultraviolet (VUV) and soft x-ray spectral range, up to photon energies of about 2–3 keV. High-energy rings (typically 6–8 GeV) aim at harder x-rays with energies of 10–20 keV and above.

The radiation produced by an electron in circular motion at low energy (speed much less than the speed of light) is weak and rather nondirectional. At relativistic energies (speed close to the speed of light) the radiated power increases markedly, and the emission pattern is folded forward into a cone with a half-opening angle in radians given approximately by $\gamma - 1 = mc^2/E$, where mc^2 is the rest-mass energy of the electron (0.51 MeV) and E is the total energy. Thus, at electron energies of the order of 1 GeV, much of the very strong radiation produced is confined to a forward cone with an instantaneous opening angle of about 1 mrad (0.06°). At higher electron energies this cone is even smaller. The large amount of radiation produced combined with the natural collimation gives synchrotron radiation its intrinsic high brightness. Brightness is further enhanced by the small cross-sectional area of the electron beam, which is as low as 0.01 mm^2 in the third-generation rings. [A.Bi.; D.Mi.; G.She.; H.Win.]

Syncline In its simplest form, a geologic structure marked by the folding of originally horizontal rock layers into a systematically curved, concave upward profile geometry (illus. *a*). A syncline is convex in the direction of the oldest beds in the folded sequence, concave in the direction of the youngest beds. Although typically upright, a syncline may be overturned, recumbent, or upside down (illus. *d*). Synclines occur in all sizes, from microscopic to regional. Profile forms may be curved smoothly (illus. *a*) to sharply angular (illus. *b*). Fold tightness of a syncline, as measured by the angle at which the limbs of the syncline join, may be so gentle that the fold is barely discernible, to so tight that the limbs are virtually parallel to one another (illus. *c*). The orientation of the axis of folding is horizontal to shallowly plunging, but synclines may plunge as steeply as vertical.



Varieties of synclines as seen in profile view. (*a*) Upright syncline with smoothly curved limbs. (*b*) Overturned, sharply angular syncline with planar limbs. (*c*) Recumbent, isoclinal syncline with parallel limbs. (*d*) Upside-down syncline, sometimes called an antiformal syncline.

Synclines are products of the layer-parallel compression that arises commonly during mountain building. The final profile form of the fold reflects the mechanical properties of the rock sequence under the temperature-pressure conditions of folding, and the percentage of shortening required by the deformation. *See* ANTICLINE; FOLD AND FOLD SYSTEMS. [G.H.D.]

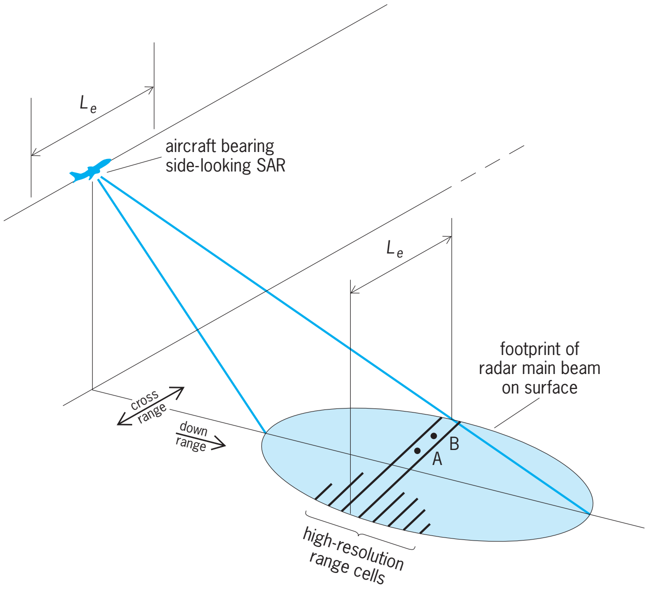
Synthetic aperture radar (SAR) Radar, airborne or satellite-borne, that uses special signal processing to produce high-resolution images of the surface of the Earth (or another object) while traversing a considerable flight path. The technique is somewhat like using an antenna as wide as the flight path traversed, that being the large "synthetic aperture," which would form a very narrow beam. Synthetic aperture radar is extremely valuable in both military and civil remote-sensing applications, providing surface mapping regardless of darkness or weather conditions that hamper other methods.

Resolution is the quality of separating multiple objects clearly. In radar imaging, fine resolution is desired in both the down-range and cross-range dimensions. In radar using pulses, down-range resolution is achieved by using broad-bandwidth pulses, the equivalent of very narrow pulses, allowing the radar to sense separate echoes from objects very closely spaced in range. This technique is called pulse compression; resolution of a few nanoseconds (for example, 5 ns $= 5 \times 10^{-9}$ s gives about 0.75 m or 2.5 ft resolution) is readily achieved in modern radar.

Cross-range resolution is much more difficult to achieve. Generally, the width of the radar's main beam determines the cross-range, or lateral, resolution. For example, a 3° beam width resolves targets at a range of 185 km (100 nautical miles) only if they are separated laterally by more than 100 m (330 ft), not nearly enough resolution for quality imaging.

However, surface objects produce changing Doppler shifts as an airborne radar flies by. In side-looking radar (see illustration), even distant objects actually go from decreasing in range very slightly to increasing in range, producing a Doppler-time function. If the radar can sustain high-quality Doppler processing for as long as the "footprint" of the beam illuminates the scene, these Doppler histories will reveal the lateral placement of objects. In fact, if such processing can be so sustained, the cross-range resolution possible is one-half the physical width of the actual antenna being used, a few feet perhaps. Furthermore, this resolution is independent of range, quite unlike angle-based lateral resolution in conventional radar. *See* DOPPLER EFFECT.

Many synthetic aperture radars use other than just a fixed side-looking beam. Spotlighting involves steering the beam to sustain illumination for a longer time or to illuminate a designated scene at some other angle. The principles remain unchanged:



The basic idea of synthetic aperture radar (SAR); a side-looking case is illustrated. Two example scatterers, A and B, are shown in the ground scene. L_e = maximum flight path length for effective SAR processing.

fine resolution in both down-range and cross-range dimensions (achieved by pulse compression and Doppler processing, respectively) permits imaging with picture cells (pixels) of remarkably fine resolution. Many synthetic aperture radars today achieve pixels of less than 1 m (3 ft) square. [R.T.H.]

Synthetic fuel A gaseous, liquid, or solid fuel that does not occur naturally; also known as synfuel. Synthetic fuels can be made from coal, oil shale, or tar sands. Included in the category are various fuel gases, such as substitute natural gas and synthesis gas. *See* COAL; OIL SAND; OIL SHALE.

Syncrude is a synthetic crude oil, a complex mixture of hydrocarbons somewhat similar to petroleum. It is obtained from coal (liquefaction), from synthesis gas (a mixture of carbon monoxide and hydrogen), or from oil shale and tar sands. Syncrudes generally differ in composition from petroleum; for example, syncrude from coal usually contains more aromatic hydrocarbons than petroleum. Gaseous fuels can be produced from sources other than petroleum and natural gas. *See* PETROLEUM.

The most important source of synthetic crude oil is the tar sand deposit that occurs in northeastern Alberta, Canada. Tar sand is a common term for oil-impregnated sediments that can be found in almost every continent. The routes by which synthetic fuels can be prepared from coal involve either gasification or liquefaction.

Gasification can yield clean gases for combustion or synthesis gas, which has a controlled ratio of hydrogen to carbon monoxide. Catalytic conversion of synthesis gas to liquids (indirect liquefaction) can be carried out in fixed- and fluidized-bed reactors and in dilute-phase systems. Another method for producing synthetic fuels from coal involves gasification of the coal to a fuel gas that may be used as such or as a source of synthetic liquids. *See* COAL GASIFICATION; FLUIDIZATION.

Coal liquefaction is accomplished by four principal methods: direct catalytic hydrogenation, solvent extraction, pyrolysis, and indirect catalytic hydrogenation (of carbon monoxide). *See* COAL LIQUEFACTION; HYDROGENATION; PYROLYSIS; SOLVENT EXTRACTION.

Shale oil is readily produced by the thermal processing of oil shales. The basic technology is available, and commercial plants are operated in many parts of the world. [J.G.S.]

Syphilis A sexually transmitted infection of humans caused by *Treponema pallidum* ssp. *pallidum*, a corkscrew-shaped motile bacterium (spirochete). Due to its narrow width, *T. pallidum* cannot be seen by light microscopy but can be observed with staining procedures (silver stain or immunofluorescence) and with dark-field, phase-contrast, or electron microscopy. The organism is very sensitive to environmental conditions and to physical and chemical agents. The complete genome sequence of the *T. pallidum* Nichols strain has been determined. The nucleotide sequence of the small, circular treponemal chromosome indicates that *T. pallidum* lacks the genetic information for many of the metabolic activities found in other bacteria. Thus, this spirochete is dependent upon the host for most of its nutritional requirements. *See* BACTERIAL GENETICS; ELECTRON MICROSCOPE; IMMUNOFLUORESCENCE.

Syphilis is usually transmitted through direct sexual contact with active lesions and also can be transmitted by contact with infected blood and tissues. If untreated, syphilis progresses through various stages (primary, secondary, latent, and tertiary). Infection begins as an ulcer (chancre) and may eventually involve the cardiovascular and central nervous systems, bones, and joints. Congenital syphilis results from maternal transmission of *T. pallidum* across the placenta to the fetus. *See* SEXUALLY TRANSMITTED DISEASES.

Treponema pallidum is an obligate parasite of humans and does not have a reservoir in animals or the environment. Syphilis has a worldwide distribution. Its incidence varies widely according to geographical location, socioeconomic status, and age group. Although syphilis is controlled in most developed countries, it remains a public health problem in many developing countries. Studies have shown that syphilis is a risk factor for infection with the human immunodeficiency virus (HIV) since syphilitic lesions may act as portals of entry for the virus. There is little natural immunity to syphilis infection or reinfection.

Parenteral penicillin G is the preferred antibiotic for treatment of all stages of syphilis. Alternative antibiotics for syphilis treatment include erythromycin and tetracycline. There is currently no vaccine to prevent syphilis. However, it is anticipated that information obtained from the *T. pallidum* genome sequence will lead to further improvements in diagnostic tests for syphilis and to the eventual development of a vaccine that would prevent infection. *See* ANTIBIOTIC; PUBLIC HEALTH. [L.V.S.]

Systellommatophora A superorder in the subclass Pulmonata containing three families (Rathouisiidae, Veronicellidae, and Onchidiidae) of sluglike mollusks that lack any trace of a shell, have separate external male and female orifices, lack a mantle cavity, have a posterior anus and excretory pore, and bear eyes on the tops of two contractile, but not retractile, tentacles. *See* PULMONATA. [G.A.S.]

System design evaluation A comprehensive and vigorous assessment of the effectiveness and cost of competing system designs, in order to choose the best candidate. System design evaluation is essential within the systems engineering process. It should be embedded appropriately within the process and then pursued continuously as system design and development progress.

The systems engineering process is a morphology for linking technology to customer needs. It is composed of three major activities: synthesis, analysis, and evaluation. Evaluation of each candidate system design is accomplished after receiving design-dependent parameter values for the candidate. It is the specific values for design-dependent parameter's that differentiate (or instance) candidate systems. Each candidate is optimized before being subjected to the design decision schema. It is here that the best candidate is sought (based on the customer's subjective evaluation). *See* SYSTEMS ENGINEERING.

To be comprehensive, system design evaluation must encompass both system effectiveness and life-cycle cost. To be rigorous, evaluation should be pursued with the aid of models and simulation. Even when expert opinion must be used in place of formal analytical approaches, a modeling structure may offer guidance. *See* MODEL THEORY; SIMULATION.

The factors used to evaluate candidate system design must be aggregated to make them apparent. Accordingly, an evaluation process must be followed which combines evaluation factors and decision making. The candidate system design that complies best with the customer's requirement is the preferred choice and may be implemented. *See* DECISION SUPPORT SYSTEM; OPERATIONS RESEARCH; OPTIMIZATION; SYSTEMS ANALYSIS. [W.J.F.]

Systems analysis The application of mathematical methods to the study of complex human physical systems. A system is an arrangement or collection of objects that operate together for a common purpose. The objects may include machines (mechanical, electronic, or robotic), humans (individuals, organizations, or societal groups), and physical and biological entities. Everything excluded from a system is considered to be part of the system's environment. A system functions within its environment. Examples of systems include the solar system, a regional ecosystem, a nation's highway system, a corporation's production system, an area's hospital system, and a missile's guidance system. A system is analyzed so as to better understand the relationships and interactions between the objects that compose it and, where possible, to develop and test strategies for managing the system and for improving its outcomes.

The term "systems analysis" is reserved for the study of systems that include the human element and behavioral relationships between the system's human element and its physical and mechanical components, if any. Examples of public policy systems are the federal government's welfare system, a state's criminal justice system, a county's educational system, a city's public safety system, and an area's waste management system. Examples of industrial systems are a manufacturer's production distribution system and an oil company's exploration, production, refining, and marketing system. Examples with physical environmental components are the atmospheric system and a water supply system. The direct transfer of systems engineering concepts to the study of a system in which the human element must be considered is restricted by limitations in the ability to comprehend and quantify human interactions. (Operations research, a related field of study, is directed toward the analysis of components of such systems. Public policy analysis is the term used for a system study of a governmental problem area.) *See* DECISION THEORY; OPERATIONS RESEARCH; SYSTEMS ENGINEERING.

Systems comprise interrelated objects, with the objects having a number of measurable attributes. A mathematical model of a system attempts to quantify the attributes and to relate the objects mathematically. The resultant model can then be used to study how the real-world system would behave as initial conditions, attribute values, and relationships are varied systematically. *See* MODEL THEORY.

The systems analysis process is an iterative one that cycles repeatedly through the following interrelated and somewhat indistinct phases: (1) problem statement, in which the system is defined in terms of its environment, goals, objectives, constraints, criteria, actors (decision makers, participants in the system, impacted constituency), and other objects and their attributes; (2) alternative designs, in which solutions are identified; (3) mathematical formulation, in which a mathematical description of the system is developed, tested, and validated; (4) evaluation of alternatives, in which the mathematical model is used to evaluate and rank the possible alternative designs by means of the criteria; and (5) selection and implementation of the most preferred solution. The process includes feedback loops in which the outcomes of each phase are reconsidered based on the analyses and outcomes of the other phases. For example, during the implementation phase, constraints may be uncovered that hinder the solution's implementation and thus cause the mathematical model to be reformulated. The analysis process continues until there is evidence that the mathematical structure is suitable; that is, it has enough validity to yield answers that are of value to the system designers or the decision maker. *See* OPTIMIZATION; SIMULATION.

As originally developed, systems analysis studies have been applied to those areas that are "hard" in that they are well defined and well structured in terms of objectives and feasible alternative systems (for example, blood-bank design, and integrated production and inventory processes). The aim of hard systems analysis is to select the best feasible alternative. In contrast, soft systems are concerned with problem areas that involve ill-defined and unstructured situations, especially those that have strong political, social, and human components. These generally involve public and private organizations (for example, design of a welfare system, and structure and impact of a corporate mission statement). The objectives of soft systems and the means to accomplish them are problematical and, in fact, a systemic view of the problem area is not assumed. The aim of soft systems analysis is to find a plan of action that accommodates the different interests of its human actors.

There is also need for further study of large-scale systems, which by definition are most complex. It is important to find ways to describe mathematically the systems that represent the totality of an industrial organization, the pollution concerns of a country and a continent, or the worldwide agricultural system. These are multicriteria problems with the solutions conflicting across criteria, individuals, and countries. The possibility that such systems may be studied in a computer-based laboratory is very promising. But this challenge must be approached cautiously, with the awareness that the methods and models employed are only abstractions to be used with due consideration of the goals of the individual and society. *See* LARGE SYSTEMS CONTROL THEORY; LINEAR SYSTEM ANALYSIS. [S.I.Ga.]

Systems architecture The discipline that combines system elements which, working together, create unique structural and behavioral capabilities that none could produce alone. The word "architecture" is commonly used to describe the underlying structure of networks, command-and-control systems, spacecraft, and computer hardware and software. The degree to which well-designed systems-level architectures are critical to the success of large-scale projects—or the lack thereof to failure—has been dramatically demonstrated. The explosion of technological opportunities and customer demands has driven up the size, complexity, costs, and investment risks of such projects to levels feasible for only major companies and governments. Without sound systems architectures, these projects lack the firm foundation and robust structure on which to build.

Complexity and its consequences. Systems are collections of dissimilar elements which collectively produce results not achievable by the elements separately. Their added value comes from the relationships or interfaces among the elements. (For example, open-loop and closed-loop architectures perform very differently.) But this value comes at a price: a complexity potentially too great to be handled by standard rules or rational analysis alone.

As projects have become ever more complex and multidisciplinary, new structures were needed for projects to succeed. Analytic techniques could not be used to find optimal solutions. Indeed, given the disparate perspectives of different customers, suppliers, and government agencies, unique optimal solutions generally would not exist. Instead, many possibilities might be good enough, with the choice dependent more on ancillary constraints or on the criteria for success than on detailed analysis.

Conceptual phases. As increasingly complex systems were built and used, it became clear that success or failure had been determined very early in their projects. In the early phases all the critical assumptions, constraints, choices, and priorities are made that will determine the end result. Unfortunately, no one knows in the beginning just what the final performance, cost, and schedule will be.

Systems-level architecture specifies how system-level functions and requirements are gathered together in related groups. It indicates how the subsystems are partitioned, the relationships between the subsystems, what communication exists between the subsystems, and what parameters are critical. It makes possible the setting of specifications, the analysis of alternatives at the subsystem level, the beginnings of detailed cost modeling, and the outlines of a procurement strategy.

There rarely is enough information early in the design stage for the client to decide on the relative priority of the requirements without having some idea of what the end system might be. Instead, provisional requirements and alternative system concepts have to be iterated until a satisfactory match is produced. Unavoidably, successful systems architecting in the conceptual phase becomes a joint process in which both client and architect participate heavily. In the ideal situation, the client makes the value judgments and the architect makes the technical decisions.

Systems-level architecture begins with a conceptual model, a top-level abstraction which attempts to discard features deemed not essential at the system level. Such a model is an essential tool of communication between client, architect, and builder, each viewing it from a different perspective. As the system comes into being, the model is progressively refined. *See* SOFTWARE ENGINEERING. [E.Re.]

Systems ecology The analysis of how ecosystem function is determined by the components of an ecosystem and how those components cycle, retain, or exchange energy and nutrients. Systems ecology typically involves the application of computer models that track the flow of energy and materials and predict the responses of systems to perturbations that range from fires to climate change to species extinctions. Systems ecology is closely related to mathematical ecology, with the major difference stemming from systems ecology's focus on energy and nutrient flow and its borrowing of ideas from engineering. Systems ecology is one of the few theoretical tools that can simultaneously examine a system from the level of individuals all the way up to the level of ecosystem dynamics. It is an especially valuable approach for investigating systems so large and complicated that experiments are impossible, and even observations of the entire system are impractical. In these overwhelming settings, the only approach is to break down the research into measurements of components and then assemble a system model that pieces together all components. An important contribution of ecosystem science is the recognition that there are critical ecosystem services such as cleansing of water, recycling of waste materials, production of food and fiber, and mitigation of pestilence and plagues. *See* ECOLOGICAL COMMUNITIES; ECOLOGICAL ENERGETICS; ECOLOGY; ECOSYSTEM; GLOBAL CLIMATE CHANGE; THEORETICAL ECOLOGY. [P.M.Ka.]

Systems engineering A management technology involving the interactions of science, an organization, and its environment as well as the information and knowledge bases that support each. The purpose of systems engineering is to support organizations that desire improved performance. This improvement is generally obtained through the definition, development, and deployment of technological products, services, or processes that support functional objectives and fulfill needs.

Systems engineering has triple bases: a physical (natural) science basis, an organizational and social science basis, and an information science and knowledge basis. The natural science basis involves primarily matter and energy processing. The organizational and social science basis involves human, behavioral, economic, and enterprise concerns. The information science and knowledge basis is derived from the structure and organization inherent in the natural sciences and in the organizational and social sciences.

Systems engineering may also be defined as management technology to assist and support policy making, planning, decision making, and associated resource allocation or action deployment. It accomplishes this by quantitative and qualitative formulation, analysis, and interpretation of the impacts of action alternatives upon the needs perspectives, the institutional perspectives, and the value perspectives of clients to a systems engineering study. Each essential phase of a systems engineering effort—definition, development, and deployment—is associated with formulation, analysis, and interpretation. These enable systems engineers to define the needs for a system, develop the system, and deploy it in an operational setting and provide for maintenance over time, all within time and cost constraints.

Contemporary systems engineering focuses on tools, methods, and metrics, as well as on the engineering of life-cycle processes that enable appropriate use of these tools to produce trustworthy systems. There is also a focus on systems management to enable the wise determination of appropriate processes. *See* SYSTEMS INTEGRATION.

Much contemporary thought concerning innovation, productivity, and quality can be cast into a systems engineering framework. This framework can be valuably applied to systems engineering in general and information technology and software engineering in particular. The information technology revolution provides the necessary tool base that, together with knowledge management–enabled systems engineering and systems management, allows the needed process-level improvements for the development of systems of all types. The large number of ingredients necessary to accomplish needed change fit well within a systems engineering framework. Systems engineering constructs are useful not just for managing big systems engineering projects according to requirements, but for creative management of the organization itself. *See* INFORMATION SYSTEMS ENGINEERING; LARGE SYSTEMS CONTROL THEORY; QUALITY CONTROL; SYSTEMS ANALYSIS. [A.P.Sa.]

Systems integration A discipline that combines processes and procedures from systems engineering, systems management, and product development for the purpose of developing large-scale complex systems. These complex systems involve hardware and software and may be based on existing or legacy systems coupled with new requirements to add significant added functionality. Systems integration generally involves combining products of several contractors to produce the working system. Systems integration applications range from creation of complex inventory tracking systems to designing flight simulation models and reengineering large logistics systems.

Life-cycle activities. Application of systems integration processes and procedures generally follows the life cycle for systems engineering. Minimally, these systems engineering life-cycle phases are requirements definition, design and development, and operations and maintenance. For systems integration, these three phases are usually expanded to include feasibility analysis, program and project plans, logical and physical design, design compatibility and interoperability tests, reviews and evaluations, and graceful system retirement.

Primary uses. Systems integration is essential to the design and development of information systems that automate key operations for business and government. It is required for major procurements for the military services and for private businesses.

Advantages. Systems integration approaches enable early capture of design and implementation needs. The interactions and interfaces across existing system fragments and new requirements are especially critical. It is necessary that interface and intermodule interactions and relationships across components and subsystems that bring together new and existing equipment and software be articulated. The systems integration approach supports this through application of both a top-down and a bottom-up design philosophy; full compliance with audittrail needs, system-level quality assurance, and risk assessment and evaluation; and definition and documentation of all aspects of the program. It also provides a framework that incorporates appropriate systems management application to all program aspects. A principal advantage of this approach is that it disaggregates large and complex issues and problems into well-defined sequences of simpler problems and issues that are easier to understand, manage, and build. *See* INFORMATION SYSTEMS ENGINEERING; SYSTEMS ANALYSIS; SYSTEMS ENGINEERING. [J.D.P.]

Syzygy The alignment of three celestial objects within a solar system (or within any other system of objects in orbit about a star). Syzygy is most often used to refer to the alignment of the Sun, Earth, and Moon at the time of new or full moon. Alignments need not be perfect in order for syzygy to occur: because the orbital planes for any three bodies in the solar system rarely coincide, the geometric centers of three objects that are in syzygy almost never lie along the same line. *See* PHASE; SOLAR SYSTEM.

In general, syzygy occurs whenever an observer on one of the three objects would *see* the other two objects either in opposition or in conjunction. Opposition occurs when two objects appear 180° apart in the sky as viewed from a third object. Conjunction occurs when two objects appear near one another in the sky as seen from a third object.

Solar and lunar eclipses are dramatic results of syzygy. During a solar eclipse, when the Moon is in its new phase, the alignment of the Sun, Earth, and Moon is so nearly perfect that the Moon's shadow falls on the Earth. During a lunar eclipse, which occurs at the time of the full moon, the Moon passes through the Earth's shadow. *See* ECLIPSE.

An occultation is another type of eclipse that can occur during syzygy. For an Earth-based observer, an occultation occurs when the Moon is seen to pass in front of a planet or other member of the solar system. The occultation of a star by the Moon does not qualify as syzygy, since the star is far beyond the limits of the solar system. *See* OCCULTATION. [H.P.C.]

T

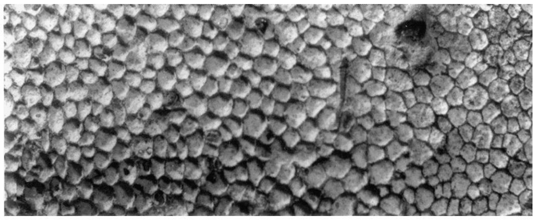
T Tauri star A member of a class of very young, optically visible, solar-mass stars with peculiarities such as variability and evidence for mass loss. T Tauri stars were discovered through their unusually strong emission lines. Many radiate unexpectedly intensely at infrared and ultraviolet wavelengths. Two subclasses have been defined, the classical T Tauri stars, identified from hydrogen-emission-line surveys, and the weak-line, or naked, T Tauri stars, discovered through their x-ray emission. Most of the apparently anomalous properties of T Tauri stars can be attributed to the fact that many are still surrounded by remnants of their parent clouds of gas and dust. *See* Variable star.

The youth of the T Tauri stars was originally suspected because of their association with star-forming clouds. Their erratic brightness variations also indicated that they had not yet become stable. Ages of 100,000–10,000,000 years are confirmed by their effective temperatures and luminosities.

The unusually strong emission lines observed in the spectra of classical T Tauri stars often have the extended wings characteristic of significant mass outflow. Outflow velocities are high, typically 100 km/s (60 mi/s). In optical images, high-velocity, oppositely directed jets can often be seen emanating from the poles of the stars themselves. Although they are already visible, T Tauri stars are evidently still in the process of shedding the dust and gas from which they formed. From theories about how stars form, the remnant material is expected to be distributed in disks. Such disks are the intrinsic source of the excess infrared radiation. The excess ultraviolet emission, as well as the very strong emission lines, may derive from the boundary layer between the rapidly rotating disk and the more slowly rotating star.

The T Tauri disks are similar to the primitive solar nebula, before the planets formed. If, as seems likely, the Sun experienced a T Tauri phase in its early history, T Tauri stars may be the birth sites of other planetary system. *See* Protostar; Solar system; Stellar evolution. [A.I.S.]

Tabulata One of two principal orders of extinct Paleozoic corals. Tabulate corals were exclusively colonial. Polyps secreted slender calcitic (calcium carbonate) tubes (corallites, ranging 0.5–20 mm in diameter, but predominantly 1–3 mm in diameter), polygonal in cross section when in contact, or cylindrical when surrounded by colonial skeletal material (coenenchyme) or not in contact (see illustration). The corallites are almost always partitioned by flat or curved, complete or incomplete plates (tabulae). Septal structures, as spines, or less commonly thin plates radially arranged in corallites, often number 12 when well developed. However, these structures are usually weakly developed or completely absent. The Tabulata is divided into six suborders—Lichenariina, Sarcinulina, Favositina, Halysitina, Heliolitina, and Auloporina—based mainly on the structural arrangement of corallites in the colony and the presence or absence of communication (mural pores or connecting tubules) between adjacent corallites. Tabulate coral colonies could take on a range of external forms. Shape was determined by the interaction of internal controls on colonial growth with prevailing environmental conditions. Tabulate corals were most abundant and diverse in temperate to warm shelf environments, particularly in biostromes and bioherms. Smaller, laminar to domal massive colonies inhabited deeper, cooler waters. They were an important component of true reefs, particularly in back-reef, reef-flat and fore-reef environments, but their limited ability of secure attachment to hard surfaces restricted their contribution to reef framework. *See* Anthozoa; Zoantharia. [C.Scr.]



Widespread tabulate coral *Favosites*. Detail of surface showing polygonal corallites, ×1.5.

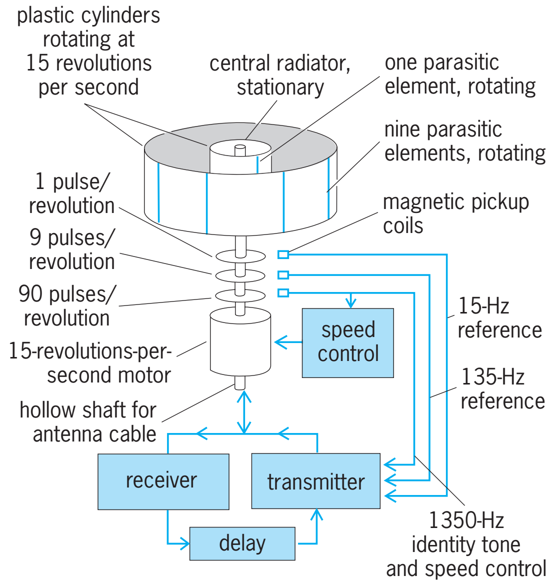
Tacan A member of the rho-theta family of air navigation systems which define an aircraft's position by its distance and bearing to a single beacon. Such systems inherently answer the navigator's questions of "in what direction" and "how far," without additional computation, and are of particular value when the beacon has to be placed on a ship, oil-drilling rig, or small island. The main weakness of such systems is that bearing errors cause spatial error to increase with distance from the beacon. Major attention is therefore given to the reduction of bearing errors.

Tacan allows the distance-measuring equipment (DME) to provide bearing service also, without the large antennas or site errors characteristic of the civil very high-frequency omnidirectional range (VOR). Range and accuracy are the same as DME (300 mi or 480 km, and 0.1 mi or 0.16 km, respectively), with a bearing accuracy of 1°. As in DME, operation is on 252 channels, spaced 1 MHz apart, 962–1213 MHz.

To provide the added bearing service, the DME transponder is first arranged to operate at constant duty cycle. This means that the number of output pulses is held constant, whether the beacon is being interrogated by one or a hundred aircraft.

The total output of the transponder is amplitude-modulated by the rotating directional antenna system (see illustration). At the center of this system is the central radiator connected to the DME transponder, just as in the conventional DME. However, rotating around this radiation at 15 revolutions per second are two concentric dielectric cylinders. The inside one, about 6 in. (15 cm) in diameter, contains a single parasitic reflector which imparts a 15-Hz amplitude modulation to the DME replies, and the outside one, about 33 in. (84 cm) in diameter, contains nine parasitic elements which impart a 135-Hz amplitude modulation. On the same rotating shaft are mounted reference pulse generators which additionally modulate the transmitter with coded pulses, once per revolution for the 15-Hz signal (called the north reference burst) and nine times per revolution for the 135-Hz signal (called the auxiliary reference bursts).

In the airborne receiver the 15- and 135-Hz sine waves are detected and filtered and compared with the decoded reference bursts to provide a two-speed or fine-coarse bearing display whose accuracy and site freedom are superior to those of conventional VOR, yet with a ground antenna system which is small



Tacan transponder with rotating directional antenna system.

enough to mount on a ship's mast. *See* DISTANCE-MEASURING EQUIPMENT; DOPPLER VOR; ELECTRONIC NAVIGATION SYSTEMS; INSTRUMENT LANDING SYSTEM (ILS); RHO-THETA SYSTEM. [S.H.D.]

Tachometer An instrument that measures angular speed, as that of a rotating shaft. The measurement may be in revolutions over an independently measured time interval, as in a revolution counter, or it may be directly in revolutions per minute. The instrument may also indicate the average speed over a time interval or the instantaneous speed. Tachometers are used for direct measurement of angular speed and as elements of control systems to furnish a signal as a function of angular speed. [A.H.W.]

Tachyon A hypothetical faster-than-light particle consistent with the special theory of relativity. According to this theory, a free particle has an energy E and a momentum $\mathbf{p}$ which form a Lorentz four-vector. The length of this vector is a scalar, having the same value in all inertial reference frames. One writes Eq. (1),

$$E^2 - c^2\mathbf{p}^2 = m^2c^4 \qquad (1)$$

where c is the speed of light and the parameter m^2 is a property of the particle, independent of its momentum and energy. Three cases may be considered: m^2 may be positive, zero, or negative. The case $m^2 > 0$ applies for atoms, nuclei, and the macroscopic objects of everyday experience. The positive root m is called the rest-mass. If $m^2 = 0$, the particle is called massless. A few of these are known: the electron neutrino, the muon neutrino, the photon, and the graviton. The name tachyons (after a Greek word for swift) has been given to particles with $m^2 < 0$.

In general, the particle speed is given by Eq. (2). If $m^2 < 0$, Eq. (1) implies $E > c\mathbf{p}$ and Eq. (2) gives $v < c$. If $m^2 = 0$, then

$$v = \frac{c\mathbf{p}}{E}c \qquad (2)$$

$E = c\mathbf{p}$ and $v = c$. In case $m^2 < 0$, one finds $E < c\mathbf{p}$ and $v > c$. Tachyons exist only at faster-than-light speeds. *See* ELEMENTARY PARTICLE; RELATIVITY. [R.H.Go.]

Taconite The name given to the siliceous iron formation from which the high-grade iron ores of the Lake Superior district have been derived. It consists chiefly of fine-grained silica mixed with magnetite and hematite. As the richer iron ores approach exhaustion in the United States, taconite becomes more important as a source of iron. [C.S.Hu.]

Taeniodonta An extinct order of quadrupedal eutherian land mammals known from the early Cenozoic deposits of the Rocky Mountain intermontane basins of western North America and, based on a single tooth of *Ectoganus gliriformis*, from early Cenozoic rocks in South Carolina. The nine known genera of taeniodonts are classified into two families: (1) the medium-size (5–15 kg or 11–33 lb), relatively primitive, omnivorous conoryctids and (2) the larger (15–110 kg or 33–243 lb) and more advanced stylinodontids. Conoryctids developed enlarged canines, but the lower jaws were unspecialized and the cheek teeth were low-crowned, enamel-enclosed, and cuspidate. Stylinodontid taeniodonts developed deep massive jaws, peglike teeth that were ever-growing, large curved canines bearing enamel bands, and large laterally compressed and recurved claws on the front paws. In terms of modern analogs, an advanced stylinodontid may be thought of as an aardvark with the head of a pig. *See* EUTHERIA. [R.M.Scho.]

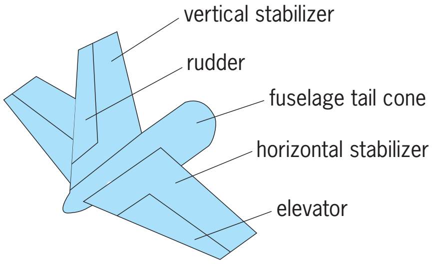
Taiga A zone of forest vegetation encircling the Northern Hemisphere between the arctic-subarctic tundras in the north and the steppes, hardwood forests, and prairies in the south. The chief characteristic of the taiga is the prevalence of forests dominated by conifers. The dominant trees are particular species of spruce, pine, fir, and larch. Other conifers, such as hemlock, white cedar, and juniper, occur locally, and the broad-leaved deciduous trees, birch and poplar, are common associates in the southern taiga regions. Taiga is a Siberian word, equivalent to "boreal forest." *See* TUNDRA.

The northern and southern boundaries of the taiga are determined by climatic factors, of which temperature is most important. However, aridity controls the forest-steppe boundary in central Canada and western Siberia. In the taiga the average temperature in the warmest month, July, is greater than 50°F (10°C), distinguishing it from the forest-tundra and tundra to the north; however, less than four of the summer months have averages above 50°F (10°C), in contrast to the summers of the deciduous forest further south, which are longer and warmer. Taiga winters are long, snowy, and cold—the coldest month has an average temperature below 32°F (0°C). Permafrost occurs in the northern taiga. It is important to note that climate is as significant as vegetation in defining taiga. Thus, many of the world's conifer forests, such as those of the American Pacific Northwest, are excluded from the taiga by their high precipitation and mild winters. [J.C.Ri.]

Tail assembly An assembly at the rear of an airplane, consisting of the tail cone, the horizontal tail, and one or more vertical tails.

The tail assembly, or empennage, of an airplane is normally composed of a vertical tail and a horizontal tail attached to the rear, or tail cone, of the airplane's fuselage. The vertical tail is composed of the vertical stabilizer and the rudder (see illustration). The vertical stabilizer is attached rigidly to the fuselage and is intended to provide stability about a vertical axis through the airplane's center of gravity. The rudder is attached by hinges to the rear of the vertical stabilizer and can rotate from side to side in response to pilot control input. It also contributes to stability, but its main function is to provide a yawing moment about the airplane's vertical (yaw) axis, thereby causing the airplane to yaw (turn) to the left or right. *See* AIRCRAFT RUDDER; FLIGHT CONTROLS; FUSELAGE; STABILIZER (AIRCRAFT).

The horizontal tail, similar to the vertical tail, is composed of the horizontal stabilizer and the elevator. The horizontal stabilizer is fixed rigidly to the fuselage and provides stability about a horizontal axis directed along the wing and through the center of gravity, and known as the pitch axis. The elevator is hinged to the rear of the horizontal stabilizer and rotates up and down as the pilot moves the control column fore and aft. The elevator also contributes to stability about the pitch axis, but its main purpose is to provide a pitching moment about the pitch axis,



Tail assembly parts (normal configuration).

which causes the airplane to nose up or down. *See* ELEVATOR (AIRCRAFT).

Airplanes that operate at supersonic speeds usually have the horizontal tail swept back and in one piece that is movable and is controlled by the motion of the pilot's control stick. Such a surface is frequently called a stabilator. *See* SUPERSONIC FLIGHT.

Many airplanes employ empennages that depart from the normal configuration. *See* AIRPLANE. [B.W.McC.]

Takakiales An order of liverworts in the subclass Jungermanniidae, consisting of a single genus and two species. Some authors put the Takakiales in the Calobryales owing to branching from a prostrate branched stem, lack of rhizoids, copious mucilage secretion, and massive frequently scattered archegonia that lack protective envelopes. However, sporophytes have never been seen, and so it is difficult to demonstrate any meaningful relationship.

The members of the Takakiales consist of a very small gametophyte made up of a branched system of prostrate, leafless stolons and erect, radially organized branches with terete appendages. The "leafy" branches are simple or forked and have a weak central strand of narrow cells enclosed by larger cells. The leafy appendages are small and scalelike below, larger and crowded above, and variable in arrangement. The leaf cells lack oil bodies. Mucilage is secreted by simple filaments on leafy branches and by branched filaments clustered on both leafy and stoloniform branches. The archegonia are scattered and not enclosed by protective structures. *See* BRYOPHYTA; CALOBRYALES. [H.Cr.]

Talc A hydrated magnesium layer silicate (phyllosilicate) with composition close to $Mg_3Si_4O_{10}(OH)_2$. Talc commonly is white, but it may appear pale green or grayish depending on the amount of minor impurities. Talc has a greasy feel and pearly luster, and has been used as one of the hardness standards for rock-forming minerals with the value 1 on the Mohs scale. Because talc is soft, it can be scratched by fingernails. *See* HARDNESS SCALES.

Talc frequently occurs in magnesium-rich metamorphosed serpentinites and siliceous dolomites. Talc-rich rocks include massive soapstones, massive steatite, and foliated talc schists.

Talc is a good insulating material. It has been commonly used in industry as a raw material for ceramics, paints, plastics, cosmetics, papers, rubber, and many other applications. *See* SILICATE MINERALS. [J.G.L.]

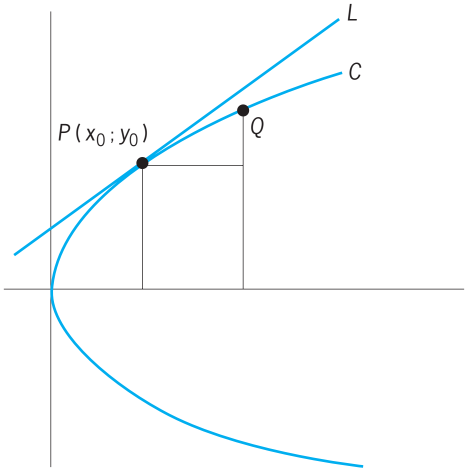
Tall oil A by-product from the pulping of pine wood by the kraft (sulfate) process. In the kraft process the wood is digested under pressure with sodium hydroxide and sodium sulfide. The volatilized gases are condensed to yield sulfate turpentine. During the pulping the alkaline liquor saponifies fats and converts the fatty and resin acids to sodium salts. Concentration of the pulping solution (black liquor) prior to recovery of the inorganic pulping chemicals allows the insoluble soaps to be skimmed from the surface. Acidification of the skimmed soap yields crude tall oil.

Crude tall oil from southern pines contains 40–60% resin acids (rosin), 40–55% fatty acids, and 5–10% neutral constituents. Abietic and dehydroabietic acids comprise over 60% of the resin acids, while oleic and linoleic acids predominate in the fatty acid fraction. Fatty acids from tall oil distillation may contain as much as 10–40% resin acids or as little as 0.5%.

Major uses of tall oil fatty acids as chemical raw materials are in coatings, resins, inks, adhesives, and soaps and detergents, and as flotation agents. Tall oil is an important source of rosin in the United States. *See* PINE TERPENE; ROSIN; WOOD CHEMICALS. [I.S.G.]

Tanaidacea An order of the eumalacostracans of the superorder Peracarida, derived from the genus *Tanais*. These animals have a worldwide distribution and with few exceptions are marine. They occur from the shore down to abyssal depths. They are free-living and benthonic. The order is divided into 2 suborders with 5 families, 44 genera, and about 350 species. The body is linear, more or less cylindrical or dorsoventrally depressed. Thoracic segments 1 and 2 are fused with the head, and the last abdominal segment is fused with the telson. Eight pairs of thoracic legs are present, of which the first pair are maxillipeds, the second pair chelipeds (the first pair of pereiopods), and the following six pairs pereiopods. *See* PERACARIDA. [K.L.]

Tangent A term describing a relationship of two figures (usually of the same dimension) in the neighborhood of a common point. The figures are tangent at a point P if they touch at P but do not intersect in a sufficiently small neighborhood of P. To be more precise, if P denotes a point of a curve C (see illustration), a line L is a tangent to C at P provided L is the limit of lines joining P to a variable point Q of C, as Q approaches P along C (that is, for Q sufficiently close to P, the line PQ is arbitrarily close to L). [L.M.Bl.]



Line *L* tangent to curve *C* at *P*.

Tangerine A name applied to certain varieties of a variable group of loose-skinned citrus fruits belonging to the species *Citrus reticulata*. Although mandarin and tangerine are often used interchangeably to designate the whole group, tangerine is applied more strictly to those varieties (cultivars) having deep-orange or scarlet rinds, whereas the term mandarin is more properly used to include all members of this quite variable group of citrus fruits. *See* MANDARIN.

The fruits are deep orange, loose-skinned, and small to medium-sized, and possess small seeds with green cotyledons. Tangerines are easily peeled and eaten out of hand as fresh fruit. About one-third of the crop is utilized in juice, sherbets, and canned sections. [F.E.G.; C.J.H.]

Tantalite A mineral with compositon (Fe,Mn)Ta_2O_6, an oxide of iron, manganese, and tantalum. Niobium substitutes for tantalum in all proportions; a complete series extends to columbite (Fe,Mn)Nb_2O_6. Pure tantalite is rare. Iron and manganese vary considerably in their relative proportions. Tantalite crystallizes in the orthorhombic system and is common in short prismatic crystals. The hardness is 6 on Mohs scale, and the specific gravity 7.95 (pure tantalite). The luster is submetallic and the color iron black. Tantalite is the principal ore of tantalum. It is found chiefly in granite pegmatites and as a detrital mineral, in some places in important amounts, having weathered from such rocks. The chief producing areas are the Congo and Nigeria. *See* COLUMBITE; HARDNESS SCALES; NIOBIUM; TANTALUM. [C.S.Hu.]

Tantalum A chemical element, symbol Ta, atomic number 73, and atomic weight 180.948. It is a member of the vanadium group of the periodic table and is in the 5*d* transitional series. Oxidation states of IV, III, and II are also known. *See* PERIODIC TABLE; TRANSITION ELEMENTS.

Tantalum metal is used in the manufacture of capacitors for electronic equipment, including citizen band radios, smoke detectors, heart pacemakers, and automobiles. It is also used for heat-transfer surfaces in chemical production equipment, especially where extraordinarily corrosive conditions exist. Its chemical inertness has led to dental and surgical applications. Tantalum forms alloys with a large number of metals. Of special importance is ferrotantalum, which is added to austenitic steels to reduce intergranular corrosion.

The metal is quite inert to acid attack except by hydrofluoric acid. It is very slowly oxidized in alkaline solutions. The halogens and oxygen react with it on heating to form the oxidation-state-V halides and oxide. At high temperature it absorbs hydrogen and combines with nitrogen, phosphorus, arsenic, antimony, silicon, carbon, and boron. Tantalum also forms compounds by direct reaction with sulfur, selenium, and tellurium at elevated temperatures. [E.M.L.]

Tantulocarida A subclass of the Maxillopoda. Tantulocarids are minute ectoparasites, less than 0.01 in. (0.3 mm) in length, that infest deep-sea copepods, isopods, tanaids, and ostracods. As a result of their parasitic mode of life, adult females have lost all resemblance to crustaceans; males are free-living but nonfeeding. Infection of the host occurs at the tantalus larval stage, which is believed to occur immediately after the larva is released. The head, or cephalon, of the tantulus larva is covered by a dorsal shield that may protrude anteriorly to form a rostrum. The mechanism of attachment, the mouth tube, is located on the ventral surface with a distal mouth opening, and is surrounded by an oral disk.

Phylogenetic relations of the Tantulocarida are not clearly understood. Although tantulocarids lack the antennules and antennae characteristic of Crustacea, two clusters of sensory hairs in adult males are probably antennulary in origin. The basic tagmosis exhibited and male gonopore position suggest an affinity with some cirriped taxa. Some researchers include the Tantulocarida as a subclass of the Maxillopoda; others accept it as a distinct class. *See* CIRRIPEDIA; COPEPODA; CRUSTACEA; MAXILLOPODA. [P.A.McL.]

Taper pin A tapered self-holding pin used to connect parts together. Standard taper pins have a diametral tape $^1/_4$ in. to 12 in. (0.6 cm to 30 cm) and are driven in holes drilled and reamed to fit. The pins are made of soft steel or are cyanidehardened. They are sometimes used to connect a hub or collar to a shaft. Taper pins are frequently used to maintain the location of one surface with respect to another. A disadvantage of the taper pin is that the holes must be drilled and reamed after assembly of the connected parts; hence they are not interchangeable. *See* COTTER PIN. [P.H.B.]

Taphonomy A subdiscipline of paleobiology that investigates the processes of preservation and their influence on information in the fossil record. Processes include events that affected the organism during life, the transferral of organic matter from the biosphere to the lithosphere, and physiochemical interactions from the time of burial until collection. Besides the conspicuous fossil characteristics that reveal the organism's morphological and anatomical features, there are often less prominent details that record the fossil's history. Analyses of these details allow paleontologists to understand the mode of death or disarticulation; biological processes that may have modified the remains before burial, including their use by hominids; the response of the part to transport by animals, water, or wind; the residency time in a depositional setting before final entombment; and the alterations of tissues or skeletal parts within a wide range of chemical environments. The processes of fossilization appear to be environmentally site specific, resulting in a mosaic of preservational traits in terrestrial and marine environs. Few fossil assemblages are exactly identical with regard to formative processes, but general patterns exist. An understanding of taphonomic assemblage features within the environmental context allows for a more accurate interpretation of the fossil record.

Fossilized organic remains have successfully passed through several taphonomic stages, including necrology, biostratinomy, and diagenesis. The first taphonomic stage, necrology, generally refers to the death of an organism, although in the case of plants this is not necessarily a precondition. Plants shed many different parts during their life cycle. Death or part loss may be induced either physiologically (old age, disease, or temporal or climatic shedding) or traumatically (sudden catastrophic death or part loss in response to natural perturbations). Organic remains that are composed of more resistant biochemicals or mineralized hard parts have a higher probability of surviving than those composed of more labile and easily degraded compounds.

Biostratinomy involves all the processes and interactions that follow the necrological stage until final burial. Biotic interactions may include the effects of scavenging on carcasses, the use of discarded parts as domiciles, or borings in resistant structural parts. Abiotic processes include mechanical and physical alteration or degradation under different transport conditions (fragmentation and rounding in river channels), orientation or concentration of resistant parts under varying hydrological regimes, or reexposure and reworking of previously buried remains in response to changing geological circumstances. The biostratinomic stage ends when organic remains are covered by or included within sediment such that they are effectively isolated from the effects of biological degradation.

The processes that affect organic remains following burial belong to the third stage, diagenesis. These processes involve the physical (compaction) and chemical (cementation, recrystallization) changes in the sediment before, during, and after lithification. *See* FOSSIL; PALEOBOTANY; PALEOECOLOGY; PALEONTOLOGY; TRACE FOSSILS. [R.A.Ga.]

Tapir An odd-toed ungulate of the family Tapiridae. These animals, with four species, have a discontinuous distribution in South America and Asia and consequently have a theoretical importance biologically.

These animals have a prehensile, trunklike muzzle, a short tail, and small eyes. The forefoot has four toes, the hindfoot three. The female gives birth to a single young after a gestation period of 13 months. Tapirs are nocturnal, timid animals; they spend the daytime hours in dense thickets. [C.B.C.]

Tardigrada A class of microscopic, bilaterally symmetrical invertebrates which are generally less than 1 mm in length. About 400 species are known. Commonly called water bears, bear animalcules, or urslets, they are worldwide in distribution and are found in all habitats.

The tardigrade body consists of an anterior prostomium and five segments. The mouth is located in the prostomium in a centroterminal position. A soft, nonchitinous cuticle surrounds the body and lines the fore- and hindgut. The cuticle may be smooth or sculptured and forms innervated cephalic appendages and spines on the trunk and legs. Four pairs of ventrolateral legs arise from the trunk and terminate in claws or other modified structures. The digestive tract is tubular and more or less lobed due to the presence of diverticular dilations. In the heterotardigrades, separate anal and genital openings occur, while in the eutardigrades there is a single anogenital opening, the cloaca. The sexes are separate and the gonads are unpaired dorsal sacs with paired gonoducts in the male and in theory also in the female. Food storage cells float in the spacious body cavity, the coelom, which lacks a parietal or visceral peritoneum in the adult. Circulatory and respiratory structures are lacking. These animals exhibit the phenomenon known as cell constancy. The number of epidermal cells is the same in all species of a genus.

Tardigrades lay eggs and development is direct. Embryonic development lasts 3–40 days, varying according to the species and surrounding temperature. During their active life of 18 months, tardigrades molt about 12 times. They are unable to feed in the 5–10 days of molting; the buccal cavity requires at least 5 days for renewal.

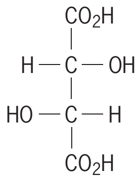
Tardigrada live as active forms, without encystment, only when surrounded by a pellicle of water. They are mainly herbivorous, and feed by piercing the wall of plant cells with their stylets. When the surrounding medium dries up, most tardigrades continue to live as inactive or anabiotic barrel-shaped structures called cysts without any protective cover. Desiccation begins when there is a loss of oxygen from the water. The animal responds by contraction and loss of body water. Dried eggs also survive. Moistened animals usually revive, but anabiosis and revival cannot be repeated indefinitely.

Most species are widely distributed. Dissemination may be by wind, birds, and certain terrestrial animals which transport tardigrade eggs and barrels. The tropics have few species, and Scutechiniscidae are rare on the Antarctic continent. Most tardigrades are terrestrial. They are found among lichens, liverworts, densely growing soft-leaved mosses, and also in rather hard-leaved Pottiacea and Grimmiacea. *See* CELL CONSTANCY; EUTARDIGRADA; HETEROTARDIGRADA; POLYCHAETA. [Ev.M.]

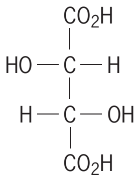
Tarragon A herb of the genus *Artemesia* in the aster family (Asteraceae) that is used as a spice. Tarragon is often divided into French and Russian types. French tarragon can be distinguished by its highly aromatic leaves, low seed set or fertility, and compact growth habit. Due to its long history of vegetative propagation to preserve its fine scent characteristics, French tarragon has all but lost its ability to form viable seeds. Russian tarragon does produce seeds, but the plant is much lower in overall oil content and is not as fine-scented.

Tarragon is a perennial that grows in one season, and then dies back to the ground with frost. In spring the plant sprouts from underground rhizomes and resumes its growth. The leaves contain volatile oil with an odor similar to anise and chervil. *See* ASTERALES; SPICE AND FLAVORING. [S.Kir.]

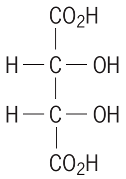
Tartaric acid Any of the stereoisomeric forms of 2,3-dihydroxybutanedioic acid: L(+), D(−), and meso [(**1**), (**2**), and (**3**), respectively]. L(+)-Tartaric acid is present in the juice of various fruits and is produced from grape juice as a by-product of the wine industry. The monopotassium salt precipitates in wine vats, and L(+)-tartaric acid is recovered from this residue. On heating in alkaline solution, the L(+) acid is converted to the racemic mixture of (**1**) and (**2**), plus a small amount of the meso acid (**3**).



(1)



(2)



(3)

Tartaric acid has played a central role in the discovery of several landmark stereochemical phenomena. In 1848, L. Pasteur isolated enantiomers (**1**) and (**2**) by mechanical separation of hemihedral crystals of the racemic mixture. He also used tartaric acid and its salts to demonstrate a distinction between the meso isomer (**3**) and the racemic mixture (**1**) + (**2**), and between enantiomers and diastereoisomers in general. The difference in properties between (**1**) [or (**2**)] and the meso form (**3**) was later a key in establishing the relative configuration of the pentose and hexose sugars.

Both L(+)- and D(−)-tartaric acid and the esters are inexpensive compounds and are used as chiral auxiliary reagents in the oxidation of alkenes to enantiomerically pure epoxides. This method employs a hydroperoxide oxidant, titanium alkoxide catalyst, and L(+)- or D(−)-tartrate, and involves chirality transfer from the tartrate to the product. *See* ASYMMETRIC SYNTHESIS; EPOXIDE.

Tartaric acid has some use as an acidulant in foods and also as a chelating agent. Potassium hydrogen tartrate (cream of tartar) is an ingredient of baking powder. The potassium sodium salt, commonly called Rochelle salt, was the first compound used as a piezoelectric crystal. *See* CHELATION; PIEZOELECTRICITY. [J.A.Mo.]

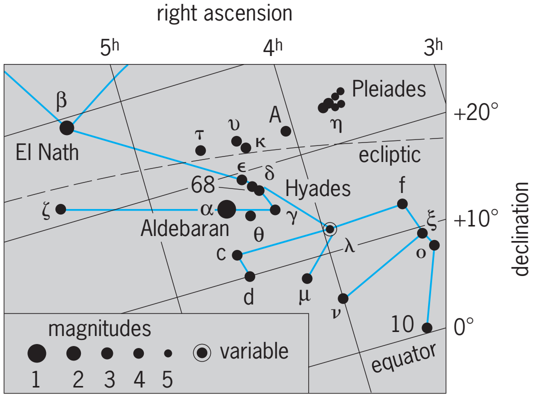
Taste Taste, or gustation, is one of the senses used to detect the chemical makeup of ingested food—that is, to establish its palatability and nutritional composition. Flavor is a complex amalgam of taste, olfaction (smell), and other sensations, including those generated by mechanoreceptor and thermoreceptor sensory cells in the oral cavity. Taste sensory cells respond principally to the water-soluble chemical stimuli present in food, whereas olfactory sensory cells respond to volatile (airborne) compounds. *See* CHEMICAL SENSES; SENSATION.

The sensory organs of gustation are termed taste buds. In humans and most other mammals, taste buds are located on the tongue in the fungiform, foliate, and circumvallate papillae and in adjacent structures of the throat. There are approximately 5000 taste buds in humans, although this number varies tremendously. Taste buds are goblet-shaped clusters of 50 to 100 long slender cells. Microvilli protrude from the apical (upper) end of sensory cells into shallow taste pores. Taste pores open onto the tongue surface and provide access to the sensory cells. Individual sensory nerve fibers branch profusely within taste buds and make contacts (synapses) with taste bud sensory cells. Taste buds also contain supporting and developing taste cells. *See* TONGUE.

The basic taste qualities experienced by humans include sweet, salty, sour, and bitter. (In some species, pure water also strongly stimulates taste bud cells). A fifth taste, umami, is now recognized by many as distinct from the other qualities. Umami is a Japanese term roughly translated as “good taste” and is approximated by the English term “savory.” It refers to the taste of certain amino acids such as glutamate (as in monosodium glutamate) and certain monophosphate nucleotides. These compounds occur naturally in protein-rich foods, including meat, fish, cheese, and certain vegetables.

The middorsum (middle top portion) of the tongue surface is insensitive to all tastes. Only small differences, if any, exist for the taste qualities between different parts of the tongue. No simple direct relationship exists between chemical stimuli and a particular taste quality except, perhaps, for sourness (acidity). Sourness is due to H^+ ions. The taste qualities of inorganic salts are complex, and sweet and bitter tastes are elicited by a wide variety of diverse chemicals. [C.P.; N.Cha.; S.Rop.]

Taurus The Bull, in astronomy, a winter constellation. Taurus is the second sign of the zodiac. The group contains two notable star clusters, the Hyades and the Pleiades. The Hyades is a V-shaped cluster, the V forming the head of the charging bull, with the fiery bright star Aldebaran in the right eye (see illustration). This star has long been used in navigation. Farther west lies the compact, beautiful cluster of six stars, the famous Pleiades. *See* CONSTELLATION; HYADES; PLEIADES. [C.S.Y.]



Line pattern of the constellation Taurus. The grid lines represent the coordinates of the sky. The apparent brightness, or magnitude, of the stars is shown by the sizes of the dots, which are graded by appropriate numbers as indicated.

Tautomerism The reversible interconversion of structural isomers of organic chemical compounds. Such interconversions usually involve transfer of a proton, but anionotropic rearrangements may be reversible and so be classed as tautomeric interconversions. A cyclic system containing the grouping —CONH— is called a lactam, and the isomeric form, —COH═N—, a lactim. These terms have been extended to include the same structures in open-chain compounds when considering the shift of the hydrogen from nitrogen to oxygen.

Molecular grouping (**1**) may in certain substances exist partly or wholly as (**2**). The former constitutes the keto form and the latter the enol form. The existence of an enol in an acyclic system requires that a second carbonyl group (or its equivalent, for example, (**3**) be attached to the same (**4**) as an aldehyde or ketone carbonyl. Thus, ethyl acetoacetate tautomerizes demonstrably, but ethyl malonate does not. Where the enol form includes an aromatic ring such as phenol, the existence of the keto form is often not demonstrable, although in some substances there may be either chemical or spectroscopic evidence for both forms. Closely related to keto-enol tautomerism is the prototropic interconversion of nitro and aci forms of aliphatic nitro compounds such as nitromethane.

$-\mathrm{COCH}<$

(3)

$-\mathrm{CN}<$

(4)

In general, tautomeric forms exist in substances possessing functional groups which can interact additively and which are so placed that intramolecular reaction leads to a stable cyclic system. The cyclic form usually predominates (especially if it contains five or six members). *See* MOLECULAR ISOMERISM. [W.R.V.]

Taxis A mechanism of orientation by means of which an animal moves in a direction related to a source of stimulation. There exists a widely accepted terminology in which the nature of the stimulus is indicated by a prefix such as phototaxis (light), chemotaxis (chemical compounds), geotaxis (gravity), thigmotaxis (contact), rheotaxis (water current), and anemotaxis (air current). The directions toward or away from the stimulus are expressed as positive or negative, respectively. Finally, the sensory and locomotory mechanisms by means of which the orientation is achieved are denoted by a second type of prefix forming a compound noun with taxis. Positive phototropotaxis thus describes a mechanism by means of which an animal carries out a directed movement toward a source of light along a path which permits the animal's paired eyes to receive equal intensities of light throughout the movement. [O.E.L.]

Taxodonta An order of bivalves in subclass Lamellibranchia whose hinge dentition is characterized by a series of numerous similar alternating teeth and sockets. Typical genera of so-called ark shells are *Arca*, *Barbatia*, and *Anadara*.

Ark-shell bivalves are probably distantly related to the true marine mussels (Mytilacea), with which they share certain features of gill ciliation and byssal organization. Formerly the name Taxodonta was used to designate a subclass of bivalves consisting of a mixed group of lamellibranch ark shells and primitive protobranchs. *See* BIVALVIA; LAMELLIBRANCHIA; MOLLUSCA; PROTOBRANCHIA. [W.D.R.-H.]

Taxonomic categories Any one of a number of formal ranks used for organisms in a traditional Linnaean classification. Biological classifications are orderly arrangements of organisms in which the order specifies some relationship. Taxonomic classifications are usually hierarchical and comprise nested groups of organisms. The actual groups are termed taxa. In the hierarchy, a higher taxon may include one or more lower taxa, and as a result the relationships among taxa are expressed as a divergent hierarchy that is formally represented by tree diagrams. In Linnaean classifications, taxonomic categories are devices that provide structure to the hierarchy of taxa without the use of tree diagrams. By agreement, there is a hierarchy of categorical ranks for each major group of organisms, beginning with the categories of highest rank and ending with categories of lowest rank, and while it is not necessary to use all the available categories, they must be used in the correct order (see table).

Conceptually, the hierarchy of categories is different than the hierarchy of taxa. For example, the taxon Cnidaria, which is ranked as a phylum, includes the classes Anthozoa (anemones), Scyphozoa (jellyfishes), and Hydrozoa (hydras). Cnidaria is a particular and concrete group that is composed of parts. Anthozoa is part of, and included in, Cnidaria. However, categorical ranks are quite different. The category "class" is not part of, nor included in, the category "phylum." Rather, the category "class" is a shelf in the hierarchy, a roadmark of relative position. There are many animal taxa ranked as classes, but there is only one "class" in the Linnaean hierarchy. This is an important strength of the system because it provides a way to navigate through a classification while keeping track of relative hierarchical levels with only a few ranks for a great number of organisms.

When Linnaeus invented his categories, there were only class, order, family, genus, and species. These were sufficient to serve the needs of biological diversity in the late eighteenth century, but were quite insufficient to classify the increasing number of species discovered since 1758. As a result, additional categorical levels have been created. These categories may use prefixes,

Categories commonly used in botanical and zoological classifications, from highest to lowest rank

Botanical categories	Zoological categories
Divisio	Phylum
Classis	Class
Ordo	Order
Familia	Family
Genus	Genus
Species	Species

such as super- and sub-, as well as new basic levels such as tribe. An example of a modern expanded botanical hierarchy of ranks between family and species is:

Familia
  Subfamilia
    Tribus
      Subtribus
        Genus
          Subgenus
            Sectio
              Subsectio
                Series
                  Subseries
                    Species

Linnaean categories are the traditional devices used to navigate the hierarchy of taxa. But categories are only conventions, and alternative logical systems, such as those used by phylogenetic systematists (cladists), are frequently used. *See* ANIMAL SYSTEMATICS; CLASSIFICATION, BIOLOGICAL; PHYLOGENY; PLANT TAXONOMY; TAXON; ZOOLOGICAL NOMENCLATURE. [E.O.W.]

Taxonomy The arrangement or classification of objects according to certain criteria. Systematics is a broader term applied to all comparative biology, including taxonomy. For classifying plants and animals, where the term taxonomy is most often applied, the criteria are characters of structure and function.

A given character usually has two or more states. These variations are used as the basis of biological classification, grouping together like species (in which the majority of the character states are alike) and separating unlike species (in which many of the character states are different). Since the acceptance by biologists of the concept of organic evolution, more and more effort has been made to produce systems of classification that conform to phylogenetic (that is, evolutionary) relationships. Taxonomy is thus concerned with classification, but ultimately classification itself depends upon phylogeny—the amount, direction, and sequence of genetic changes. Scientists try to classify lines, or clusters of lines, of descent. This has not always been the case, and in the past various other criteria have been used, such as whether organisms were edible (ancient times) and whether flowers had five stamens or four or some other number (Linnaean times). Modern taxonomists generally agree that the patterns or clusters of diversity they observe in nature, such as the groups of primates, the rodents, and the bats, are the objective results of purely biological processes acting at different times and places in the past. At the least, animal and plant taxonomy provides a method of communication, a system of naming; at the most, taxonomy provides a framework for the embodiment of all comparative biological knowledge. *See* ANIMAL SYSTEMATICS; CLASSIFICATION, BIOLOGICAL; NUMERICAL TAXONOMY; ORGANIC EVOLUTION; PHYLOGENY; PLANT TAXONOMY. [W.H.Wa.]

Tea A small tree, *Camellia* (*Thea*) *sinensis*. A preparation of its leaves dried and cured by various processes; and a beverage made from these leaves. The plant is an evergreen tree of the Theaceae family, native to southeastern Asia, and does best in a warm climate where the rainfall averages 90–200 in. (2200–5000 mm). China, Japan, Taiwan, India, Sri Lanka, and Indonesia are among the leading tea-producing countries, with China contributing about one-half of the world's supply.

Tea leaves contain caffeine, various tannins, aromatic substances attributed to an essential oil, and other materials of a minor nature, including proteins, gums, and sugars. The tannins provide the astringency, the caffeine the stimulating properties. *See* THEALES. [E.L.C.]

Technetium A chemical element, Tc, atomic number 43, discovered by Carlo Perrier and Emilio Segre in 1937. They separated and isolated it from molybdenum (Mo; atomic number 42), which had been bombarded with deuterons in a cyclotron. Technetium does not occur naturally. *See* ATOMIC NUMBER; ELEMENT (CHEMISTRY).

In the periodic table, technetium is located in the middle of the second-row transition series, situated between manganese and rhenium. Because of the lanthanide contraction, the chemistry of technetium is much more like that of rhenium, its third-row congener, than it is like that of manganese. Its location in the center of the periodic table gives technetium a rich and diverse chemistry. Oxidation states -1 to $+7$ are known, and complexes with a wide variety of coordination numbers and geometries have been reported. *See* LANTHANIDE CONTRACTION; PERIODIC TABLE; RHENIUM; TRANSITION ELEMENTS.

The most readily available chemical form of technetium is the ion pertechnetate (TcO_4^-), the starting point for all of its chemistry. In its higher oxidation states ($+4$ to $+7$), technetium is dominated by oxo chemistry, which is dominated by complexes containing one or two multiply bonded oxygen (oxo) groups.

Since about 1979, inorganic chemists have been very interested in understanding and developing the fundamental chemistry of technetium, utilizing the isotope ^{99g}Tc. Most of this interest has arisen from the utility of another isotope of technetium, ^{99m}Tc (where m designates metastable), to diagnostic nuclear medicine. In fact, ^{99m}Tc in some chemical form is used in about 90% of all diagnostic scans performed in hospitals in the United States. The nuclear properties of ^{99m}Tc make it an ideal radionuclide for diagnostic imaging. This technetium isotope has a 6-h half-life, emits a 140-keV gamma ray which is ideal for detection by the gamma cameras used in hospitals, and emits no alpha or beta particles. [S.S.J.]

Technology Systematic knowledge and action, usually of industrial processes but applicable to any recurrent activity. Technology is closely related to science and to engineering. Science deals with humans' understanding of the real world about them—the inherent properties of space, matter, energy, and their interactions. Engineering is the application of objective knowledge to the creation of plans, designs, and means for achieving desired objectives. Technology deals with the tools and techniques for carrying out the plans. [R.S.S./H.B.M.]

Tektite A member of one of several groups of objects that are composed almost entirely of natural glass formed from the melting and rapid cooling of terrestrial rocks by the energy accompanying impacts of large extraterrestrial bodies. Tektites are dark brown to green, show laminar to highly contorted flow structure on weathered surfaces and in thin slices, are brittle with excellent conchoidal fracture, and occur in large masses but are mostly small to microscopic in size.

Five major groups of tektites are known: North American, 34,000,000 years old; Czechoslovakian (moldavites), 15,000,000 years; Ivory Coast, 1,300,000 years old; Russian (irgizites) 1,100,000 years old; and (5) Australasian, 700,000 years old. The North American, Ivory Coast, and Australasian tektites also occur as microtektites in oceanic sediment cores near the areas of their land occurrences. In the land occurrences, virtually all of the tektites are found mixed with surface gravels and recent sediments that are younger than their formation ages.

The chemical compositions of tektites differ from those of ordinary terrestrial rocks principally in that they contain less water and have a greater ratio of ferrous to ferric iron, both of which are almost certainly a result of their very-high-temperature history. [E.A.K.]

Telecast A television broadcast, involving the transmission of the picture and sound portions of the program by separate transmitters at assigned carrier frequencies within the channel assigned to a television station. A telecast is intended for reception by the general public, just as is a radio broadcast. *See* TELEVISION; TELEVISION TRANSMITTER. [J.Mar.]

Telecommunications civil defense system

Warning centers and private-line telecommunications systems that carry vital emergency information and alerts to both the military and the general public. When any possible emergency threatens the security or socioeconomic structure of the United States or any political subdivision, an appropriate warning must be made in order for a reaction to occur within an appropriate period of time. Any such reactions cannot operate without a means of communication to prewarn of impending disaster or attack and to assist the civil defense and military effort after a disaster has occurred.

The Federal Emergency Management Agency has primary responsibility for financial and technical support of the two basic communications systems that meet this need during a crisis situation: the National Warning System (NAWAS) and the Emergency Broadcast System (EBS).

Operating 24 h a day, the National Warning System is a voice-grade service that consists of over 65,000 channel miles (100,000 km) connecting 2300 warning points in the United States with a national primary warning center located with the North American Air Defense (NORAD) Command. Should the primary warning center be rendered inoperative, alternate centers can cover all warning points that were dependent on the inoperative center. Similarly, modern switching facilities are available to replace any portion of the network that may become inoperative. The warning centers are located at key defense installations so that full advantage can be taken of all available information. Warning information can be sent to all points on the network in approximately 15 s. From the 2300 warning points on the network, warning information is relayed through state and local systems to more than 5000 local points in an average time of 7 min.

The mission of the Emergency Broadcast System is to provide the President of the United States with a means of communicating with the general public through the use of nongovernment broadcast stations during the period preceding, during, and following an enemy attack, natural disaster, or other national emergency. The Broadcast System consists of four multipoint private-line services routed to 31 locations at 2400 bits per second. Either of the two point-of-origin, send-receive stations (a primary location and its alternate) can transmit the activation, termination, and National Industry Advisory Council (NIAC) order messages to all other stations. Each point-of-origin send-receive station is equipped with a line controller unit, a 4420 terminal, diagnostic modems, and floppy disk storage units. All other receive-only stations are equipped with 2024 modems and a Model 43 buffered terminal which is programmed to provide an answer with the depression of a key. Activation of a switch at these locations and at the point of origin allows voice confirmation and emergency coordination. *See* RADIO BROADCASTING; TELEPHONE SERVICE. [J.P.McQ.]

Teleconferencing

Broadly, the various ways and means by which people communicate with one another over some distance. In a narrow sense, a teleconference is a two-way, interactive meeting, between relatively small groups of people (approximately 1 to 10 at each end), who usually use permanent teleconferencing facilities. A teleconference involves audio communication between the locations, but may also involve video or graphics. *See* TELEPHONE SERVICE; VIDEOTELEPHONY.

A teleseminar is utilized for educational purposes; it is primarily one-way communication to many destinations from one source. A teleseminar almost always uses audio communication, and may also use video and some form of graphics. A means is provided for the receiving locations to ask questions of the instructor via microphones or telephone handsets.

A telemeeting is often called an ad hoc teleconference, with the ad hoc referring to places, times, participants, and purpose. A telemeeting is similar to a teleseminar in that it is primarily a one-way communication, usually staged or prepared by video program professionals. It may be set up to order, using temporary equipment or circuits.

Computer conferencing is a method for people to communicate by using computers. The medium is quite flexible, as it can be used between just two people, between one and many people, or among many people. Basically, computer conferencing involves typing a message on a computer terminal and transmitting it to one or more destinations electronically. Sophisticated networks are required to accomplish computer conferencing between many users, or a simple data modem and telephone circuit can allow two people at a time to conference. *See* DATA COMMUNICATIONS; LOCAL-AREA NETWORKS; WIDE-AREA NETWORKS.

Currently, the most popular form of teleconferencing by far is the audio conference. Using plain speaker telephones, special speaker phones, corporate private branch exchange (PBX) systems, or special services, most business people use this form of teleconference regularly. Probably next in popularity is the Teleseminar, used for “distance learning,” or formal education and training. The Internet has become a popular medium to facilitate both of these forms of teleconferencing, as high-speed connections such as digital subscriber line (DSL), cable modem, and satellite have become more prevalent. *See* COMMUNICATIONS SATELLITE; INTERNET; PRIVATE BRANCH EXCHANGE. [J.J.B.]

Telegraphy

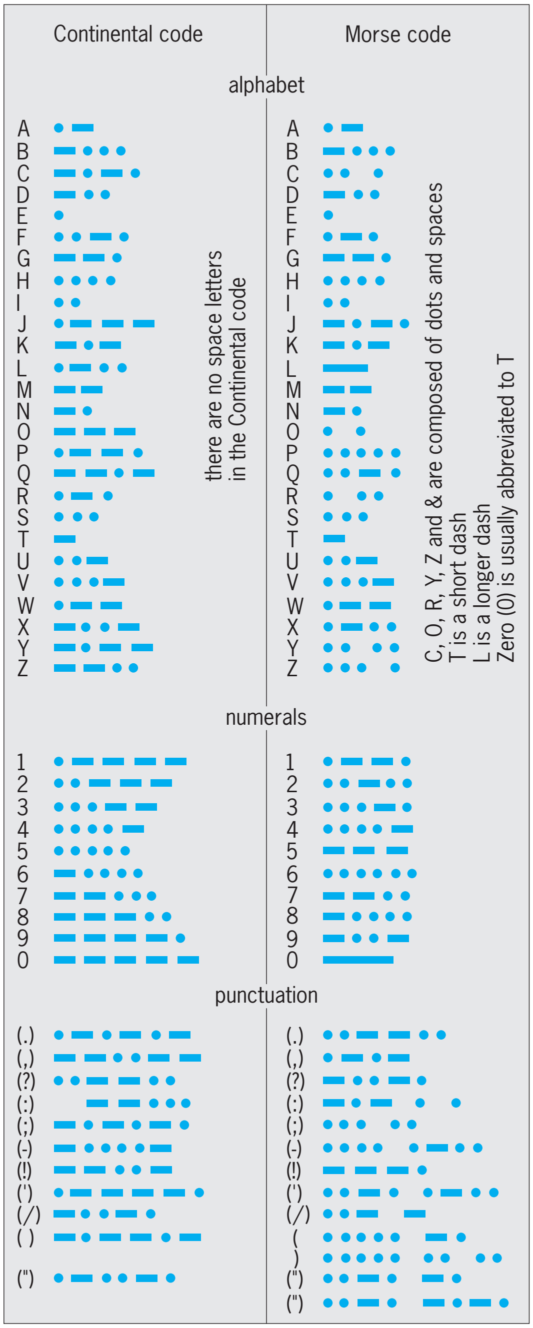
A method of communication employing electrical signaling impulses produced and received manually or by machines. Telegraph signals are transmitted over open wire or cable land lines, submarine cables, or radio. Telegraphy as a communication technique uses essentially a narrow frequency band and a transmission rate adapted to machine operations. *See* ELECTRICAL COMMUNICATIONS.

Early equipment devised by Samuel F. B. Morse consisted of a mechanical transmitter and receiver or register. Operators soon learned to handle messages faster using simple manual keys and audible sounders. Subsequently, telegraph transmission and reception again became mechanized. *See* TELETYPEWRITER EXCHANGE (TWX) SERVICE; TELEX. For other ways in which telegraphy may be used, *see* FACSIMILE; TELEPHOTOGRAPHY; TELETYPESETTER.

Telegraph facilities for use by the general public to transmit messages both domestically and internationally are provided by communication companies and government administrations. Special telegraph facilities include those for news services, distribution of market prices of securities and commodities, and private lines between such points as the factories and offices of a company for the exchange of messages, orders, payroll data, and inventories. Fire and police alarms are a special form of telegraphy. The armed forces have extensive fixed and mobile telegraph systems.

For manual operation, the telegraph code consists of short dot and long dash signals (see illustration). Most automatic printing telegraph circuits, including American cable operation, use a code of five equally spaced signals or units per letter or other symbol perforated into a paper tape. Machines translate automatic teleprinter code to cable code, cable code to automatic code, or, for special applications, make other translations. For stock quotation systems and teletypesetter operation, a six-unit code is used to provide control of machine action. For data transmission or machine control, a seven- or eight-unit code may be used.

A single circuit provides transmission in only one direction at a time. For transmission in both directions simultaneously, a duplex circuit is used. Multiplex (time-division) apparatus provides two, three, or more channels operable in both directions simultaneously over a single circuit. Carrier-current techniques enable several circuits, each comprising one or more communication



Continental code (International Morse) is commonly used for telegraph communication. Morse code (American Morse) continues in use on a few land lines in the United States and Canada.

channels, to operate through the same wide-band wire, cable, or radio facility. *See* MULTIPLEXING.

In automatic transmission, an operator at a manual keyboard, operated like a typewriter, perforates a tape. The tape is fed through an electromechanical or photocell tape reader that drives the tape at a rapid and uniform rate and transmits the electrical code. Interconnecting wire lines or other communication channels carry these code pulses to the receiver. The received impulses may automatically actuate a reperforator to produce a duplicate punched tape for retransmission or later transcription; the impulses may actuate a teletypewriter (also called a teleprinter) to retype the original message; or they may actuate other terminal equipment, such as an accounting machine.

Alternatively, the equipment at both terminals may be teletypewriters, in which keyboard and printing mechanisms are combined in one machine. Such machines use a five-unit code but operate without perforated tape. Business firms that originate and receive numerous messages have such equipment installed at their offices for direct service. Also widely used are facsimile instruments that transmit or reproduce a typed or handwritten message as a picture on electrosensitive paper. [G.Hot]

To achieve speed and accuracy in handling messages en route, direct circuits may be set up from the originaling keyboard to the distant teleprinter. This is done in TWX and Telex services. This mode of system operation is known as circuit switching. If direct channels are not immediately available, or if the volume of traffic calls for a storage interval, the message is transferred by means of perforated tape at switching centers. This mode is known as message switching or store-and-forward switching. Message switching has the advantage of using the channel capacities of trunk lines more fully than do direct connections. It is used in the United States for public telegram service and on leased-wire switched networks. *See* TELEX. [W.E.G.]

In overseas communications, telegraph messages or telegrams are transmitted over high-frequency radio (3–30 MHz), transoceanic submarine cables, or satellite communication channels. A decreasing number of messages are carried on high-frequency radio. These types of overseas channels are also used for private-line service, which is referred to as leased-channel service, and customer-to-customer teletypewriter service, which is known as Telex in the international service. [E.D.B.]

Telemetering The branch of engineering, also called telemetry, which is concerned with collection of measurement data at a distant or inconvenient location, and display of the data at a convenient location. One example of a complex telemetering system is used to measure temperature, pressure, and electrical systems on board a space vehicle in flight, radio the data to a station on Earth, and present the measurements to one or several users in a useful format. Telemetering involves movement of data over great distances, as in the above example, or over just a few meters, as in monitoring activity on the rotating shaft of a gas turbine. It may involve less than 10 measurement points or more than 10,000.

Telemetering involves a number of separate functions: (1) generating an electrical variable which is proportional to each of several physical measurements; (2) converting each electrical variable to a proportional voltage in a common range; (3) combining all measurements into a common stream; (4) moving the combined measurements to the desired receiving location, as by radio link; (5) separating the measurements and identifying each one; (6) processing selected measurements to aid in mission analysis; (7) displaying selected measurements in a useful form for analysis; and (8) storing all measurements for future analysis.

The largest category is commonly called aerospace telemetry, used in testing developmental aircraft and in monitoring low-orbit space vehicles. Other applications include missile and rocket testing, automobile testing, and testing of other moving vehicles.

The version of telemetry commonly used in an industrial application includes supervisory control of remote stations as well as data acquisition from those stations over a bidirectional communications link. The generic term is supervisory control and data acquisition (SCADA); the technology is normally used in electrical power generation and distribution, water distribution, and other wide-area industrial applications. *See* ELECTRIC POWER SYSTEMS; WATER SUPPLY ENGINEERING.

One SCADA application involves monitoring wind direction and velocity as indicated by anemometers located on the approach and departure paths near an airport, so that air-traffic controllers can make pilots aware of dangerous differences in wind direction and velocity, known as wind shear. This type of system is operated over a radio communications link, with the appropriate anemometers being interrogated as their measurements are needed by the computer for wind analysis. Somewhat similar systems are used in oceanographic data collection and analysis, where instrumented buoys send water temperature and other data on command. *See* AERONAUTICAL METEOROLOGY; INSTRUMENTED BUOYS; WIND MEASUREMENT.

Because two-way communication with a complex and distant Earth synchronous satellite or other spacecraft presents a unique challenge, a technology called packet telemetry is in widespread use for these applications. Here, messages between the Earth station and the spacecraft are formed into groups of measurements or commands called packets to facilitate routing and indentification at each end of the link. Each packet begins with a definitive preamble and ends with an error-correcting code for data quality validation. Packet technology is defined by an international committee, the Consultative Committee for Space Data Systems (CCSDA). *See* PACKET SWITCHING; SPACE COMMUNICATIONS.

Many unique systems are in use. A special multichannel medical telemetry system is used on some ambulances to monitor and radio vital signs from a person being transported to a hospital, so that medical staff can prepare to treat the specific condition which caused the emergency. Another system is possibly the oldest user of radio telemetry, the radiosonde. A data collection and transmission system is lifted by a balloon to measure and transmit pressure, temperature, and humidity measurements from various altitudes as an aid to weather prediction. *See* BALLOON; METEOROLOGICAL INSTRUMENTATION. [O.J.S.]

Teleostei The largest, youngest (first appearing in the Upper Triassic), and most successful group of the actinopterygians (rayfin fishes), and a sister group of the Amiidae (bow fins). The 23,600 species of teleosts make up more than half of all recognized species of living vertebrates, and over 96% of all living fish species. There are 494 families, of which 69 are extinct leaving 425 extant families, 43% of which have no fossil record. *See* ACTINOPTERYGII; AMIIFORMES.

Much of the evidence for teleost monophyly and relationships comes from the caudal skeleton and concomitant acquisition of a homocercal tail (upper and lower lobes symmetrical). Other characters of the teleosts include the mobile premaxilla bone, the extension of the posterior myodome (the eye muscle canal) into the basioccipital bone, and the development of the swim bladder. *See* SWIM BLADDER.

The Osteoglossomorpha, Elopomorpha, and Clupeomorpha are now generally regarded as successive clades (groups) above the level of the fossil, paraphyletic pholidophorids. The Clupeomorpha is considered to be the sister group of the Ostariophysi.

Clupeomorpha and Ostariophysi. The Clupeomorpha includes almost 80 genera and some 360 Recent species in three main families: Engraulidae (anchovies), Dussumieridae (round herrings), Clupeidae (herrings), as well as Pristigasteridae. The Ostariophysi make up nearly 75% of the fresh-water fishes of the world (over 6000 species) and include the Cypriniformes (carps, loaches, and relatives), Siluriformes (catfishes), Gymnotiformes (knife fishes, electric eel), and *Chanos*. The Clupeomorpha plus Ostariophysi are the sister group of the Euteleostei. *See* CYPRINIFORMES; OSTEOGLOSSIFORMES; PHOLIDOPHORIFORMES.

Euteleostei. The Euteleostei are by far the largest teleost taxon with more than 22,000 species arranged in some 340 families. They comprise two major lineages, the Protacanthopterygii and the Neognathi.

The Protacanthopterygii (often regarded as lower euteleosteans) include four groups: the salmonoids (salmon and allies; 66 species) and the osmeroids (smelts, salangrids, *Lepidogalaxius*; 72 species), which together are the sister group of the alepocephaloids (slickheads; 60+ species) plus the argentinoids (argentines or herring smelts; 60+ species). The Neognathi, on the other hand, are made up of the esocoids (pike and mudminnows; 10+ species) plus the sister group Neoteleostei. *See* SALMONIFORMES.

The Neoteleostei, with more than 15,319 species, comprise four main clades, the Stomiiformes, Aulopiformes, Myctophiformes, and Acanthomorpha (paracanthopterygians plus acanthopterygians). The acanthopterygians are the largest subgroup of the Euteleostei, distributed among 12 orders and 218 families. The Perciformes form the largest of these orders with 9293 species. *See* PERCIFORMES. [B.Ga.]

Teleostomi This name was originally proposed by R. Owen to include bony fishes with a terminal mouth, excluding the lungfishes or Dipnoi. Later, it was employed in a more inclusive sense to mean a class of fishes, including the bony fishes or subclasses Osteichthyes, and the extinct subclass Acanthodii. Together with class Chondrichthyes and class Placodermi, it forms the group of jawed fishes or Gnathostomata. *See* ACANTHODII; CHONDRICHTHYES; OSTEICHTHYES; PLACODERMI. [R.H.De.]

Telephone An instrument containing a transmitter for converting the acoustic signals of a person's voice to electrical signals, a receiver for reconverting electrical signals to acoustic signals, and associated signaling devices (the dial) for communicating with other persons using similar instruments connected to a network. The term telephone also refers to the complicated system of transmission paths and switching points connected to this instrument. *See* TELEPHONE SERVICE.

The transmitter is a transducer that converts acoustic energy into electric energy. The carbon transmitter was the key to practical telephony because it amplified the power of the speech signal, making it possible to communicate over distances of many miles. Many of these transmitters are still in service, but they are gradually being replaced by designs based on the charged electret (a condenser microphone) or on electrodynamic principles. Both the electret and electrodynamic transmitters use transistors to provide needed power gain; they introduce less distortion than the carbon transmitter. *See* ELECTRET TRANSDUCER; MICROPHONE; TRANSDUCER; TRANSISTOR.

Transmitters have a frequency-response range from 250 to 5000 Hz. Even though normal human hearing has a much broader frequency response, speech heard on the telephone resembles closely that heard by a listener.

The heart of an electret transmitter is an electrical capacitor formed by the metal on the diaphragm, a conductive coating on top of the metalized lead frame, and the plastic and air between the metal layers. The diaphragm is made of a special plastic that can be given a permanent electrostatic charge (analogous to the magnetization of a permanent magnet). As sound waves entering the sound port cause pressure changes, the diaphragm moves closer to and farther away from the metalized lead frame. This changes the value of capacitance and produces a varying electric voltage which is the analog of the impinging sound-pressure wave. The signal is amplified by the internal amplifier chip to a level which is suitable for transmission on the telephone network.

The receiver transducer operates on the relatively low power used in the telephone circuit; it converts electric energy back into acoustic energy. Unlike a loudspeaker, the telephone receiver is designed for close coupling to the ear. As in the transmitter, careful design of the relationship of the acoustical and electrical elements produces a desired response-frequency characteristic.

There are two common types of receiver units with fixed coil windings, the ring armature receiver and the bipolar receiver. Moving-coil designs, similar to loudspeakers, are also used in some instances. Fixed-coil receivers are designed to have low acoustic impedance and high available power response over the frequency range 350–3500 Hz. Careful control of both the acoustic and electric design parameters is necessary to achieve the desired response and to avoid undesirable resonances. *See* ACOUSTIC IMPEDANCE.

Standard telephone sets typically include two cords: a line cord that connects the instrument to the building wiring and telephone network, and a handset cord that connects the telephone handset to the chassis. Cordless telephones use a two-way radio link between the handset and the base unit, which is similar to the chassis of the standard telephone; this replaces the handset cord. The base unit is connected through a normal line cord to the telephone network.

The cellular radio system is a form of mobile radio telephony. Cellular telephones use a two-way radio link to replace the line cord. The telephone communicates with one of a number of base stations spread in cells throughout the sevice area. As the telephone user changes location, the link is automatically switched from cell to cell to maintain a good connection. *See* MOBILE RADIO. [R.M.Ri.]

Telephone service The technology of providing many types of communications services via networks that transmit voice, data, image facsimile, and video by using both analog and digital encoding formats.

Telephone services involve three distinct sectors of components: (1) customer premises equipment (CPE), such as telephones, fax machines, personal and mainframe computers, and systems private branch exchanges (PBXs); (2) transmission systems, such as copper wires, coaxial cables, fiber-optic cables, satellites, point-to-point microwave routes, and wireless radio links, plus their associated components; and (3) switching systems that often can access associated databases, which can add new intelligent controls for the network's users. *See* COAXIAL CABLE; COMMUNICATIONS CABLE; COMMUNICATIONS SATELLITE; MICROWAVE; OPTICAL COMMUNICATIONS; OPTICAL FIBERS; PRIVATE BRANCH EXCHANGE; RADIO; SWITCHING SYSTEMS (COMMUNICATIONS); TELEPHONE.

Infrastructure. Made over a web of circuits known as a network, a connection often involves several different telephone companies or carriers. In the United States, there are more than 1300 local exchange companies (LECs) providing switched local service, plus more than 500 large and small interexchange companies (IECs) that provide switched long-distance services.

In addition, wireless mobile telephone services are provided on a city-by-city basis by cellular systems operated by two different companies in each metropolitan area. Each cellular system is connected to the wire networks of the local exchange companies and interexchange companies. *See* MOBILE RADIO.

Local exchange company operations of wired systems are divided geographically into 164 local access and transport areas (LATAs), each containing a number of cities and towns. Within a LATA, the telephone company operates many local switches, installed in facilities known as central offices or exchanges.

Each central office or exchange switch in connected to local telephone customer premises by a system of twisted-pair wires, coaxial cables, and fiber-optic lines called the loop plant. Direct current (dc) electricity that carries signals through the wires (or powers the lasers and photodetectors in the glass-fiber lines) is provided by a large 48-V stationary battery in the central office which is constantly recharged to maintain its power output. If a utility power outage occurs, the battery keeps the transmission system and the office operating for a number of hours, depending on the battery's size.

The transmission is usually analog to and from the customer site, especially for residences. However, in many systems a collection point between the customer and the switch, known as a subscriber loop carrier (SLC), provides a conversion interface to and from one or more digital cable facilities called T1 carriers (each with 24 channels) leading to the switch. In turn, most switches are interconnected by digital fiber-optic, coaxial, or copper-wire cables or by microwave transmission systems either directly or via intermediate facilities called tandem switches between local switches or between a group of central offices and a long-distance toll switch. *See* TELEPHONE SYSTEMS CONSTRUCTION.

Switching and transmission designs. Telephone switching machines used analog technology from 1889 to 1974, when the first all-digital switch was introduced, starting with long-distance or toll service and expanded later to central offices or local exchanges. Digital switching machines are comparable to digital computers in their components and functions. Unlike the analog electromechanical switches of the past, digital switches have no moving parts and can operate at much faster speeds. In addition, digital switches can be modified easily by use of operations systems—special software programs loaded into the switch's computer memory to provide new services or perform operational tasks such as billing, collecting and formatting traffic data from switches, monitoring the status of transmission and switching facilities, testing trunk lines between end offices, and identifying loop troubles. *See* DIGITAL COMPUTER.

In North America, digital switching and transmission are conducted within a hierarchy of multiplexing levels. The single digital telephone line, rated at 64 kilobits per second (kb/s), is known as a digital signal 0 (DS-0) level. The lowest digital network transmission level is DS-1, equivalent to 24 voice channels multiplexed by time-division multiplexing (TDM) to operate at 1.544 megabits per second (Mb/s). DS-1 is the most common digital service to customer premises. Two interim levels, now seldom used, are followed by DS-3, perhaps the most widely used high-speed level. DS-3 operates at 44.736 Mb/s, often rounded out to 45 Mb/s, the highest digital signal rate conventionally provided to customer premises by the telephone network. Of course, groups of DS-3 trunks can be connected to a customer facility if needed. Outside the United States, other digital multiplexing schemes are used. This results, for example, in a DS-1 level having 30 voice channels rather than 24 channels. *See* MULTIPLEXING AND MULTIPLE ACCESS.

A second network hierarchy appeared during the early 1990s and was gradually implemented in the world's industrial nations. Known in North America as SONET (synchronized optical network) and in the rest of the world as SDH (synchronized digital hierarchy), these standards move voice, data, and video information over a fiber network at any of eight digital transmission rates. These range from OC-1 at 51.84 Mb/s to OC-48 at 2.488 gigabits per second (Gb/s), and the hierarchy can be extended to more than 13 Gb/s. The OC designation stands for optical carrier.

Asynchronous transfer mode technology is based on cell-oriented switching and multiplexing. This is a packet-switching concept, but the packets are much shorter (always 53 bytes) and faster (for better response times) than are the packets in such applications as the global Internet and associated service networks which can have up to 4096 bytes of data in one packet. The asynchronous transfer mode cell-relay system moves cells through the network at speeds measured in megabits per second instead of kilobits. With its tremendous speed and capacity, asynchronous transfer mode technology permits simultaneous switching of data, video, voice, and image signals over cell-relay networks. *See* DATA COMMUNICATIONS; PACKET SWITCHING.

Out-of-band signaling systems. When the voice or communications information is encoded in a stream of bits, it becomes possible to use designated bits instead of analog tones for the supervisory signaling system. This simplifies the local switching equipment and allows the introduction of sophisticated data into the signaling, which significantly expands the potential range of telephone services.

Operations information now flows between switches as packet-switched signaling data via a connection that is independent of the channel being used for voice or data communications (a technique known as out-of-band signaling). Typically, a channel between two switching systems is known as a trunk. A trunk group between switches carries a number of channels whose combined signaling data are transmitted over a separate common channel as a signaling link operated at 56 kb/s. This technique is called common-channel interoffice signaling (CCIS).

In 1976, the first United States version of CCIS was introduced as a modification of an international standard, the CCITT No. 6 signaling system. The out-of-band signaling system was deployed in the long-distance (toll) network only, linking digital as well as analog switches via a network of packet-data switches called signal transfer points. Also known as Signaling System 6 (SS6), it helped to make possible numerous customer-controlled services, such as conferencing, call storage, and call forwarding.

A major advance in common-channel signaling was introduced with the CCITT's Signaling System 7 (SS7), which operates at up to 64 kb/s and carries more than 10 times as much information as SS6. In addition, Signaling System 7 is used in local exchange service areas as well as in domestic and international toll networks.

In addition to increasing network call setup efficiency, Signaling System 7 enables and enhances services such as ISDN applications; automatic call distributor (ACD); and local-area signaling services (LASS), known as caller identification. Other innovations include 800 or free-phone service, in which customers can place free long-distance calls to businesses and government offices; 900 services, in which customers pay for services from businesses; and enhanced 911 calls, in which customer names and addresses are automatically displayed in police, fire, or ambulance centers when calls are placed for emergency services. The Signaling System 7 software also can include numerous other custom calling services for residential and business customers such as call waiting and call forwarding.

Intelligent networks. The greatest potential for Signaling System 7 use is in emerging intelligent networks, both domestic and international. The intent is to provide customers with much greater control over a variety of network functions, yet to protect the network against misuse or disruption. Intelligent networks are evolving from the expanding use of digital switching and transmission, starting with the toll networks. The complexity of intelligent networks mandates the use of networked computers, programmed with advanced software.

An intelligent network allows the customer to setup and use a virtual private network as needed, and be charged only for the time that network is being used. A conventional private leased network, by contrast, reserves dedicated circuits on a full-time basis and charges for them whether they are used or not. A virtual private network enables a business to simultaneously reap the benefits of a dedicated network and the shared public-switched network by drawing on the infrastructure of intelligent networking.

Wireless. The rapid growth of cellular-service subscribers has led to congestion in some cellular systems. The solution is to introduce digital cellular systems, which can hande up to 10 times more calls in the same frequency range. However, in countries such as the United States, which already have an analog infrastructure, the FCC has mandated that any digital system must be compatible with the existing analog system. The initial digital designs, based on a technology called time-division multiple access (TDMA), provide a three-times growth factor. Another digital technology, based on code-division multiple access (CDMA), a spread-spectrum technique, could increase the growth factor to 10 or even 20. *See* RADIO SPECTRUM ALLOCATIONS; SPREAD SPECTRUM COMMUNICATION.

Personal communications service (PCS) is a sort of cellular system in which a pocket-size telephone is carried by the user. A series of small transmitter-receiver antennas operating at lower power than cellular antennas are installed throughout a city or community (mounted on lampposts and building walls, for example). All the antennas of the personal communications network (PCN) are linked to a master telephone switch that is connected to the main telephone network. [J.H.D.]

Telephone systems construction The construction of the transmission facilities portion (or outside plant) of a telephone system. A telephone system or network consists of one or more transmission paths, called channels or circuits, which have been specifically designed and constructed to carry a particular type of electrical information signal between two or more points. Station equipment, switching systems, and transmission facilities are the components of these transmission paths. Voice, data, video, and program signals, in either analog or digital form, are some of the types of information signals (known as traffic) carried over these paths, and their signal characteristics and requirements dictate the physical makeup of the system.

The telephone network has evolved to provide for the transmission requirements of human speech, and must also provide for the transmission of more complicated information signals. The primary objective in the design and construction of any telephone system is to meet these varying transmission requirements in the most economical way possible. *See* TELEPHONE; TELEPHONE SERVICE.

The telephone network is made up of a variety of transmission systems, each consisting of the transmission medium and its supporting structure. The ideal transmission facility should provide for the safe and satisfactory transmission of information signals under all types of conditions, and should be flexible enough to meet changing traffic requirements with a minimum amount of expense. Certain types of signals are better suited to certain types of transmission media because of bandwidth requirements and loss limits. Bandwidth is simply a measure of the information-carrying capacity of the medium; generally, the greater the bandwidth of a system, the more expensive it is to construct. Some common structures and systems are listed below. *See* COMMUNICATIONS SATELLITE; MOBILE RADIO; RADIO-WAVE PROPAGATION.

The most common structures used to support telephone systems are pole lines, underground conduit systems, and buried systems. The most common type of transmission facility found in telephone systems is metallic paired cable. Paired cable is composed of copper or aluminum conductors coated with wood-pulp or plastic insulation. These insulated conductors are then twisted together into color-coded cables, ranging in size from 6 to 4200 pairs. These cables are coated with a protective sheath made of lead, aluminum, or polyethylene. These sheaths provide for structural and moisture protection.

Paired cables can carry voice, program, video, and most data signals up to 3.2 megabits/s, although additional cable pairs may be required to meet the required bandwidth. Because of the high attenuation of paired cables, the maximum range of voice-frequency signals is approximately 3 mi (4.8 km). To reduce attenuation, lumped inductances, called load coils, are placed along the transmission line. For digital signals, repeaters are used to eliminate attenuation. *See* COMMUNICATIONS CABLE.

Fiber-optic transmission systems offer several advantages over other transmission systems. Ideally suited for digital transmission, the information-carrying capacity of glass silica fibers is unlimited, but due to the limitations of electronic terminating equipment, transmission bit rates do not currently exceed 274 megabits/s. Two optical fibers can carry 4032 voice signals simultaneously with very low attenuation. These systems utilize lasers or light-emitting diodes in converting the digital bit stream into an optical signal. *See* OPTICAL COMMUNICATIONS; OPTICAL FIBERS.

Coaxial cables offer wide bandwidths and can operate at very high frequencies. They are used in long-haul telephone transmission systems and as the transmission medium for most cable television systems. The cables contain 4 to 22 coaxial tubes. Each tube consists of a copper inner conductor that is kept centered within a cylindrical copper outer conductor by polyethylene-insulated disks. Coaxial tubes are spliced together with connectors that have been press-fitted onto the ends of the tube and then screwed together. The splice is then sealed with a moisture-protecting closure. *See* COAXIAL CABLE. [B.J.H.]

Telephoto lens A photographic lens system specially designed to give a large image of a distant object in a camera of relatively short focal length. A telephoto lens generally consists of a positive lens system and a negative lens system, separated by a considerable distance. *See* CAMERA; LENS (OPTICS). [M.J.H.]

Teleprocessing The exchange of information between computing devices achieved by sending data over telecommunications lines. Teleprocessing has become increasingly complex as computing has evolved from batch processing to tightly coupled networks of computers.

With any form of data transmission, two distinctions are useful. The first is between digital and analog communications, and the second is between baseband and broadband communications. A digital signal has a fixed number of discrete states; an analog signal has a continuous range of values. Computers use two-state digital or binary communications. It is frequently necessary to transmit a digital signal over an analog communications system. This is done by using a modem, or modulator-demodulator. *See* MODEM.

A baseband signal, either analog or digital, is transmitted at its original frequency. In broadband communications systems, a carrier signal is modulated or varied to carry the desired information. Of particular importance in telecommunications is the use of broadband techniques to frequency-multiplex multiple channels of information onto a single communications line. A voice-grade telephone is designed to respond to frequencies between 300 and 3100 Hz. Since a typical telephone line can respond to a much broader frequency range, multiple conversations can be stacked in 4000-Hz partitions. *See* MODULATION; MULTIPLEXING AND MULTIPLE ACCESS.

The rapid growth of computer communications, combined with the digitization of conventional voice services, will soon result in a national telecommunications infrastructure that is primarily digital rather than analog. Integrated services digital network (ISDN), which integrates voice and computer communications at modest speeds, is available in many communities. Asynchronous transfer mode (ATM), which integrates voice, video, and data communications at very high speeds, is widely used for long-distance transmissions and is being extended to the desktop. *See* INTEGRATED SERVICES DIGITAL NETWORK (ISDN).

Teleprocessing may be divided into two general areas: terminal-to-computer communications and computer-to-computer communications. In terminal-to-computer communications a small number of computers serve as the centralized hosts to a much larger number of relatively unintelligent and inexpensive remote input/output devices. Terminals on a time-shared computer and printers are common examples. *See* MULTIACCESS COMPUTER.

The rapid growth in microcomputers has combined with the favorable economics of distributed processing to make computer-to-computer communications increasingly important. The most common example of computer-to-computer communications is a computer network that links a number of computers, each of which has significant independent computational responsibilities and is recognized by the other computers in the network as an autonomous peer. *See* DISTRIBUTED SYSTEMS (COMPUTERS); MICROCOMPUTER.

Computer networks range from small local-area networks (LANs) that serve a few tens of users to metropolitan-area networks (MANs) and wide-area networks (WANs) that span the globe. All of these networks have four characteristics that distinguish them from each other: signaling technology, transmission media, topology, and access control. *See* LOCAL-AREA NETWORKS; WIDE-AREA NETWORKS.

The set of protocols or standards defining the interface between modules represents an architecture. The U.S. Department of Defense under the aegis of the Defense Advanced Research Project Agency (DARPA) developed a protocol suite commonly known as TCP/IP that is currently used on the Internet and comes the closest to providing a universal multivendor communications standard. Another important standard is the Open Systems Interconnection (OSI) model, under the leadership of the International Standards Organization (ISO). The OSI model contains seven levels with well-defined interfaces designed to ensure compatibility among devices and software from different vendors. While few vendors have implemented this standard in its entirety, it provides a model that is widely emulated. *See* DATA COMMUNICATIONS; DIGITAL COMPUTER; ELECTRICAL COMMUNICATIONS. [D.S.Ga.]

Telescope An instrument used to collect, measure, or analyze electromagnetic radiation from distant objects. A telescope overcomes the limitations of the eye by increasing the ability to see faint objects and discern fine details. In addition, when used in conjunction with modern detectors, a telescope can “see” light that is otherwise invisible. The wavelength of the light of interest can have a profound effect on the design of a telescope. *See* ELECTROMAGNETIC RADIATION; LIGHT.

For many applications, the Earth’s atmosphere limits the effectiveness of larger telescopes. The most obvious deleterious effect is image scintillation and motion, collectively known as poor seeing. Atmospheric turbulence produces an extremely rapid motion of the image resulting in a smearing. On the very best nights at ideal observing sites, the image of a star will be spread out over a 0.25-arcsecond seeing disk; on an average night, the seeing disk may be between 0.5 and 2.0 arcseconds.

The upper atmosphere glows faintly because of the constant influx of charged particles from the Sun. The combination of the finite size of the seeing disk of stars and the presence of airglow limits the telescope’s ability to see faint objects. One solution is placing a large telescope in orbit above the atmosphere. In practice, the effects of air and light pollution outweigh those of airglow at most observatories in the United States. *See* AIRGLOW.

There are basically three types of optical systems in use in astronomical telescopes: refracting systems whose main optical elements are lenses which focus light by refraction; reflecting systems, whose main imaging elements are mirrors which focus light by reflection; and catadioptric systems, whose main elements are a combination of a lens and a mirror. The most notable example of the last type is the Schmidt camera.

Astronomers seldom use large telescopes for visual observations. Instead, they record their data for future study. Modern developments in photoelectric imaging devices are supplanting photographic techniques for many applications. The great advantages of detectors such as charge-coupled devices is their high sensitivity, and the images can be read out in a computer-compatible format for immediate analysis. *See* CHARGE-COUPLED DEVICES.

Light received from most astronomical objects is made up of radiation of all wavelengths. The spectral characteristics of this radiation may be extracted by special instruments called spectrographs. *See* ASTRONOMICAL SPECTROSCOPY.

As collectors of radiation from a specific direction, telescopes may be classified as focusing and nonfocusing. Nonfocusing telescopes are used for radiation with energies of x-rays and above (x-ray, gamma-ray, cosmic-ray, and neutrino telescopes). Focusing telescopes, intended for nonvisible wavelengths, are similar to optical ones (solar, radio, infrared, and ultraviolet telescopes), but they differ in the details of construction. *See* CERENKOV RADIATION; COSMIC RAYS; GAMMA-RAY ASTRONOMY; INFRARED ASTRONOMY; NEUTRINO ASTRONOMY; RADIO TELESCOPE; SUN; ULTRAVIOLET ASTRONOMY; X-RAY TELESCOPE.

The 5-m (200-in.) Hale telescope at Palomar Mountain, California, was completed in 1950. The primary mirror is 5 m in diameter with a 1.02-m (40-in.) hole in the center.

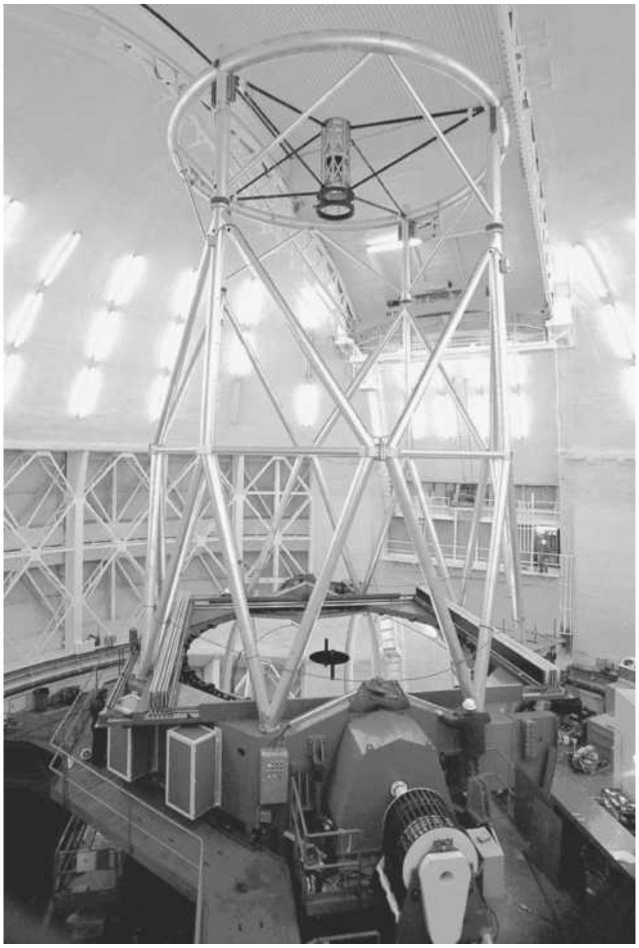
The 4-m (158-in.) Mayall reflector at the Kitt Peak National Observatory was dedicated in 1973. The prime focus has a field of view six times greater than that of the Hale reflector. An identical telescope was subsequently installed at Cerro Tololo Inter-American Observatory, in Chile.

The mirrors for these traditional large telescopes were all produced using the same general methodology. A large, thick glass mirror blank was first cast; then the top surface of the mirror was laboriously ground and polished to the requisite shape. The practical and economical limit to the size of traditional mirror designs was nearly reached by the 6-m (236-in.) telescope in the Caucasus Mountains, Russia. Newer telescopes have been designed and built that use either a number of mirrors mounted such that the light collection by them is brought to a common focus, or lightweight mirrors in computer-controlled mounts.

The Keck Telescope on Mauna Kea, Hawaii, completed in 1993, is the largest of the segmented mirror telescopes to be put into operation. The telescope itself is a fairly traditional design. However, its primary mirror is made up of 36 individual hexagonal segments mosaiced together to form a single 10-m (386-in.) mirror. Electronic sensors built into the edges of the segments monitor the relative positions of the segments, and feed the results to a computer-controlled actuator system.

In 1989, the European Southern Observatory put into operation their New Technology Telescope. The 3.58-m (141-in.) mirror was produced by a technique known as spin-casting, where molten glass is poured into a rotating mold.

Worldwide efforts are under way on a new generation of large, ground-based telescopes, using both the spin-casting method and the segmented method to produce large mirrors. The Gemini project of the National Optical Astronomy Observatories is building twin 8.1-m (319-in.) telescopes, Gemini North (see illustration) on Mauna Kea, Hawaii (1999), and Gemini South on Cerro Pachon in Chile (2000).



Gemini North telescope in its dome. (*Copyright Gemini Observatory/AURA/NOAO/NSF, all rights reserved*)

The Very Large Telescope (VLT), operated by the European Southern Observatory on Cerro Paranel, Chile, consists of four 8-m (315-in.) "unit" telescopes with spin-cast mirrors. The light from the four telescopes is combined to give the equivalent light-gathering power of a 16-m (630-in.) telescope. The last of the four telescopes began collecting scientific data in September 2000.

The ability of large telescopes to resolve fine detail is limited by a number of factors. Distortion due to the mirror's own weight causes problems in addition to those of atmospheric seeing. The Earth-orbiting Hubble Space Telescope, (HST) with an aperture of 2.4 m (94 in.), was designed to eliminate these problems. The telescope operates in ultraviolet as well as visible light, resulting in a great improvement in resolution not only by the elimination of the aforementioned terrestrial effects but by the reduced blurring by diffraction in the ultraviolet. *See* DIFFRACTION; RESOLVING POWER (OPTICS).

Soon after the telescope was launched in 1990, it was discovered that the optical system was plagued with spherical aberration, which severely limited its spatial resolution. After space-shuttle astronauts serviced and repaired the telescope in 1993, adding what amounted to eyeglasses for the scientific instruments, the telescope exceeded its prelaunch specifications for spatial resolution. Subsequent servicing missions replaced instruments with newer technology. *See* SPACE TELESCOPE, HUBBLE. [R.D.Ch.; W.M.S.]

Telestacea An order of the subclass Alcyonaria. Telestacea are typified by *Telesto*, which forms an erect branching colony by lateral budding from the body wall of an elongated primary or axial polyp. The stolon is bandlike or membranous. Sclerites are scattered singly, partly fused, or entirely fused to form a rigid tube. *See* ALCYONARIA. [K.At.]

Television The electrical transmission and reception of transient visual images. Like motion pictures, television consists of a series of successive images, which are registered on the brain as a continuous picture because of the persistence of vision. Each visual image impressed on the eye persists for a fraction of a second. In television in the United States, 30 complete pictures are transmitted each second, which with the use of interlaced scanning is fast enough to avoid evident flicker.

At the television transmitter, minute portions of a scene are sampled individually for brightness (and color for color television), and the information for each portion is transmitted consecutively. At the receiver, each portion is synchronized and reproduced in its proper position and with correct brightness (and color) to reproduce the original scene.

The scene is focused through a lens on a photoelectric screen of a camera tube. Each portion of the screen is changed by the photoelectrons to a degree depending upon the brightness of the particular portion of the scene. The screen is scanned by an electron beam just as a reader scans a page of printed type, character by character, line by line. When so scanned, an electric current flows with an instantaneous magnitude proportional to the brightness of the portion scanned. *See* TELEVISION CAMERA; TELEVISION CAMERA TUBE.

Variations in the current are transmitted to the receiver, where the process is reversed. An electron beam in the picture tube is varied in intensity (modulated) by the incoming signals as it scans the picture-tube screen in synchronism with the scanning at the transmitter. The photoelectric surface of the picture tube produces light in proportion to the intensity of the electron beam which strikes it. In this way the minute portions of the original scene are re-created in their proper positions, brightness, and (for color transmission) color values. *See* PICTURE TUBE; TELEVISION RECEIVER; TELEVISION TRANSMITTER.

In the Western Hemisphere and Japan, the NTSC (National Television System Committee) system is used, in which an individual picture (frame) is considered to be made up of 525 lines, each line containing several hundred picture elements. All these lines are scanned and the light values are sent to the receiver so that each second 30 pictures are received. The picture is blanked out at the end of each line while the scanning beam is directed to the next line. During these short intervals, synchronizing signals are transmitted to keep the scanning process at the receiver in step with that at the transmitter. To take full advantage of the persistence of vision, each frame is scanned twice, alternate lines being scanned in turn. This technique is called interlaced scanning. *See* TELEVISION SCANNING; TELEVISION STANDARDS.

The band of frequencies assigned to a television station for the transmission of synchronized picture and sound signals is called a television channel. In the United States a television channel is 6 MHz wide, with the visual carrier frequency 1.25 MHz above the lower edge of the band and the aural carrier 0.25 MHz below the upper edge of the band.

In the United States the sound portion of the program is transmitted by frequency modulation at a carrier frequency 4.5 MHz above the picture carrier. Maximum frequency deviation (bandwidth) of the sound signals is 25 kHz. *See* FREQUENCY MODULATION. [S.DeS.]

In television broadcasting, videotape recorders are used not only for delayed playback but also for program distribution and, especially, for storage of program segments during postproduction editing. In the latter case, the program tape that is actually broadcast can be several generations removed from that originally recorded at the television camera or telecine film reader. Three or four generations are typically encountered with dramatic programs; whereas, for commercials or productions involving complex special effects, as many as eight to ten rerecording generations are not uncommon. The quality of the image, especially as measured by the signal-to-noise ratio, degrades with each generation, since the recorder itself adds a noncoherent noise in each pass. To minimize the degradation from multiple generations, there has been a long-term effort to replace analog video recorders with digital technology. Digital communications has the advantage that noise does not accumulate in cascade links; thus, digital recorders will not accumulate noise through multiple generations of recording.

A digital system is also useful in the worldwide exchange of television programs, where standards conversions are necessary because of the large number of different scanning and color-encoding standards used in various countries. A single world wide digital studio standard was adopted in 1981, incorporating efforts to maximize commonality between equipments used in different standards, and to base the digital standards on separate luminance and color difference signals rather than on any given country's composite system. In 1986, specifications were completed for the digital recorder named D-1, which can retain good quality after more than 50 generations. [K.H.Po.]

High-definition television (HDTV) was originally conceived as a system for providing cinemalike viewing in the home. It was designed to provide much improved resolution with a wider aspect ratio of 16:9 (instead of 4:3 in standard television) and high-fidelity audio quality. High-definition television has twice the horizontal and twice the vertical resolution of standard television, with improved color resolution and multichannel high-fidelity sound. Digital processing offers greater accuracy and stability with a much better signal-to-noise ratio than analog processing can provide for video signals. *See* TELEVISION NETWORKS; TELEVISION STUDIO. [P.C.Ja.]

Television camera An electrooptical system used to pick up and convert a visual image or scene into an electrical signal called video. The video may be transmitted by cable or wireless means to a suitable receiver or monitor some distance from the actual scene. It may also be recorded on a video tape recorder for playback at a later time.

Television studio camera. (*Thomson Multimedia*)

A television camera may fall within one of several categories: studio (see illustration), telecine, or portable. It may also be one of several highly specialized cameras used for remote viewing of inaccessible places, such as the ocean bottom or the interior of nuclear power reactors. The camera may be capable of producing color or monochrome (black and white) pictures. Most modern cameras are entirely solid-state, including the light-sensitive element, which is composed of semiconductors called charge-coupled devices (CCDs). Inexpensive or special-purpose cameras, however, may use one or more vacuum tubes, called vidicon, with a light-sensitive surface in lieu of the charge-coupled devices. *See* CHARGE-COUPLED DEVICES.

Every camera shares certain essential elements: an optical system, one or more picture pickup devices, preamplifiers, scanning circuits, blanking and synchronizing circuits, video processing circuits, and control circuits. Color cameras also include some kind of color-encoding circuit.

Other functions that are necessary to obtain high-quality pictures include gamma correction, aperture correction, registration, and color balance. Gamma correction is required because the pickup devices do not respond linearly to increasing light levels. It allows the camera to capture detail in the dark areas of high-contrast scenes, essentially by "stretching" the video levels in those areas. Aperture correction provides several benefits mainly related to an even overall response to scenes with more or less detail. It also helps to improve the signal-to-noise ratio of the camera's output video. Registration must be adjusted on multiple-tube cameras to ensure that the separate red, blue, and green images are precisely aligned on one another; charge-coupled-device cameras are usually registered once, at the factory. Color balance must be properly set on color cameras and must be consistent from dark scenes to bright scenes, or there will be an objectionable tint to the camera output.

Studio cameras are equipped with several ancillary systems to enhance their operation. An electronic viewfinder (actually a small television monitor) shows the camera operator what the camera is seeing, making it possible to frame and focus the picture. The tally system consists of one or more red lights that illuminate when the camera's picture is "on the line" so that production and on-camera personnel know which camera is active. Generally an intercom system is built into the camera so that the director can communicate with the camera operator. The camera itself may be mounted upon a tripod, but more often it is on a dolly and pedestal, which allows the camera to be moved around on the studio floor and raised or lowered as desired. A pan head permits the camera to be rotated to the left or right and furnishes the actual mounting plate for the camera. The lens zoom and focus controls are mounted on a panning handle convenient to the operator.

Telecine cameras are used in conjunction with film or slide projectors to televise motion pictures and still images. Many of the usual controls are automatic so as to require less operator attention.

Portable cameras usually combine all of the basic elements into one package and may be used for a multitude of purposes. They have found their way into electronic news gathering for broadcast television, and into electronic field production, where they can be used for production of broadcast programs, commercials, and educational programs. The units often have built-in microphones, videocassette recorders, and batteries for completely self-contained operation.

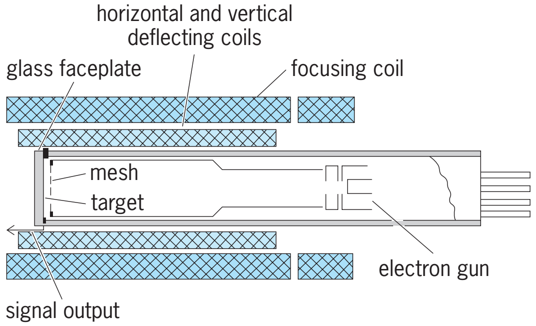
Cameras used in high-definition television (HDTV) are fundamentally similar in appearance and operation to previous cameras. In fact, some modern cameras are switchable to produce either a conventional output or an HDTV output. The conventional output has a 4:3 aspect ratio raster and the scan rates match the 525-horizontal-line, 59.94-Hz-vertical-field-rate NTSC standard in the United States. When switched to HDTV mode, the aspect ratio becomes 16:9 and the horizontal scan rate is usually increased to either 720 progressively scanned lines or 1080 interlace-scanned lines with a 60-Hz vertical field rate. *See* Television; Television receiver; Television standards; Television studio; Television transmitter. [E.F.A.]

Television camera tube An electron tube having a light-sensitive receptor that converts an optical image into an electrical television video signal. The tube is used in a television camera to generate a train of electrical pulses representing the light intensities present in an optical image focused on the tube. Each point of this image is interrogated in its proper turn by the tube, and an electrical impulse corresponding to the amount of light at that point of the optical image is generated by the tube. This signal represents the video or picture portion of a television signal. *See* Television camera.

Image orthicon. The image orthicon made broadcast television practical. It was used for more than 20 years as the primary studio and field camera tube for black and white and color television programming because of its high sensitivity and its ability to handle a wide range of scene contrast and to operate at very low light levels. It is one of the most complicated camera tubes. The image orthicon is divided into an image section, a scanning section, and a multiplier section, within a single vacuum envelope. The image isocon is a further development of the image orthicon.

Photoconductive tubes. These types have a photoconductor as the light-sensitive portion. The name vidicon was applied to the first photoconductive camera tube developed by RCA. It is loosely applied to all photoconductive camera tubes, although some manufacturers adopt their own brand names. The vidicon tube is a small tube that was first developed as a closed-circuit or industrial surveillance television camera tube. The development of new photoconductors has improved its performance to the point where it is now utilized in one form or another in most television cameras. Its small size and simplicity of operation make it well suited for use in systems to be operated by relatively unskilled people.

The vidicon is a simply constructed storage type of camera tube (see illustration). The signal output is developed directly from the target of the tube and is generated by a low-velocity scanning beam from an electron gun. The target generally consists of a transparent signal electrode deposited on the faceplate of the tube and a thin layer of photoconductive material, which is deposited over the electrode. The photoconductive layer serves two purposes. It is the light-sensitive element, and it forms the storage surface for the electrical charge pattern that corresponds to the light image falling on the signal electrode.



Cross section of a vidicon tube and its associated deflection and focusing coils.

Photoconductor properties determine to a large extent the performance of the different types of vidicon tubes. The first and still most widely used photoconductor is porous antimony trisulfide. The latest photoconductors are the lead oxide, selenium-arsenic-tellurium, cadmium selenide, zinc-cadmium telluride, and silicon diode arrays.

Silicon intensifier. The silicon intensifier camera tube utilizes a silicon diode target, but bombards it with a focused image of high-velocity electrons. Each high-energy electron can free thousands of electron carriers in the silicon wafer (compared to one carrier per photon of light on a silicon diode vidicon). This high amplification allows the camera to operate at light levels below that of the dark-adapted eye. The silicon intensifier tube is utilized for nighttime surveillance and other extremely low-light-level television uses in industrial, scientific, and military applications.

Solid-state imagers. These are solid-state devices in which the optical image is projected onto a large-scale integrated-circuit device which detects the light image and develops a television picture signal. Typical of these is the charge-coupled-device imager. The term charge-coupled device (CCD) refers to the action of the device which detects, stores, and then reads out an accumulated electrical charge representing the light on each portion of the image. The device detects light by absorbing it in a photoconductive substrate, such as silicon. The charge carriers generated by the light are accumulated in isolated wells on the surface of the silicon that are formed by voltages applied to an array of electrodes on top of an oxide insulator formed on the surface of the silicon. A practical CCD imager consists of a structure that forms several hundred thousand individual wells or pixels, and transfers the charges accumulated in these pixel wells out to an output amplifier in the proper sequence. *See* Charge-coupled devices. [R.G.N.]

Television networks Arrangements of communications channels, suitable for transmission of video and accompanying audio signals, which link together groups of television broadcasting stations or closed-circuit television users in different cities so that programs originating at one point can be fed simultaneously to all others.

In the United States, television network service is furnished by the long-distance or local-exchange carriers (hereafter identified as telephone companies) and satellite carriers, as well as by broadcaster-owned networks. The facilities, when provided by the telephone companies, consist of intercity channels, which interconnect the principal long-distance telephone offices in various cities, and local channels, which connect the telephone offices with the broadcasters' studios or other user locations in each city. In the terminating offices, the intercity and local channels are brought together in a television operating center (TOC) where means are provided for testing, monitoring, and connecting the channels in various patterns as required for service. *See* Telephone service.

The principal users of television network facilities are broadcast network organizations (broadcast networks). These may be national, regional, or local in scope, and may be regular or occasional in nature and may be commercial or noncommercial. Broadcast networks typically consist of a programming entity which simultaneously feeds content over the network interconnection facilities to commonly owned and operated stations, as well to other stations (affiliates) that have a contractual relationship with the broadcast network.

Geostationary satellite antenna footprints can be made to cover large areas of the Earth, thus making them ideal for point-to-multipoint transmissions. Direct broadcast satellite systems have been placed into operation in many developed nations. Their implementation in the United States is typical of other systems.

While all satellite television networks once used FM transmission, many operators now use digital video compression to transmit 4–10 signals over a single satellite transponder using quadrature phase-shift keying (QPSK) modulation. This changes the instantaneous amplitude of the two orthogonal carriers (I and Q) at a rate of about 38 Mbps. The received data require good forward error correction for perfect decompression to video and audio. Picture quality at four to six compressed video programs per satellite transponder is as good, or better, than FM-transmitted signals.

Over 96% of television households in the United States have access to cable television, and most of them receive all their television programming in analog format via cable. Programming usually includes the local broadcast stations and satellite services.

Because of the closed nature of cable television systems, all the frequencies between 50 and 750 MHz and higher can be used for distribution. The analog signals received at cable television headends are combined side by side on a frequency-division multiplex (FDM) basis for carriage in the cable systems. Digital satellite signals are decompressed in integrated receiver decoders, and the programs are passed through to the subscribers as analog signals. *See* MULTIPLEXING AND MULTIPLE ACCESS. [J.B.Gl.; C.M.Ha.]

Television receiver

The equipment used to receive the transmitted modulated radio-frequency signals and produce synchronized visual images and sound. The radio-frequency portion operates on the superheterodyne principle. *See* MODULATION; RADIO RECEIVER.

The first television receivers to be mass-produced were monochrome; that is, they provided pictures in black and white only. Later, color receivers, which produce pictures in full color as well as black and white, became available. Many television receivers now can receive stereophonic sound or alternate language in accordance with multichannel television sound standards. For basic discussion of a television system *see* TELEVISION; TELEVISION STANDARDS; STEREOPHONIC RADIO TRANSMISSION.

Early television receivers used vacuum-tube technology. Present-day receivers use solid-state technology with many functions integrated on a few chips. The only function still primarily implemented by using vacuum-tube technology is the display by the cathode-ray tube (CRT). *See* CATHODE-RAY TUBE; INTEGRATED CIRCUITS; VACUUM TUBE.

Since most broadcast television transmissions in the United States are horizontally polarized, the most basic type of television-receiving antenna is the horizontally mounted half-wave dipole. More complex antennas combine several dipole elements of various lengths, and passive reflectors may be used to achieve some degree of horizontal directivity, which increases the amplitude of the receiver signal and reduces interference from other stations. *See* ANTENNA (ELECTROMAGNETISM); POLARIZATION OF WAVES; YAGI-UDA ANTENNA.

The tuner of a television receiver selects the desired channel and converts the frequencies received to lower frequencies within the passband of the intermediate-frequency amplifier. The output from the tuner is applied to the intermediate-frequency (i-f) amplifier. The output of the intermediate-frequency amplifier consists of modulated radio-frequency signals, which when detected provide signals corresponding to the transmitted picture and sound information. *See* AMPLITUDE MODULATION; AMPLITUDE-MODULATION DETECTOR; FREQUENCY MODULATION.

Picture synchronizing information is obtained from the video signal by means of sync separation circuits. In general, sync separation circuits perform the following functions: (1) separation of the sync information from the picture information; (2) separation of the desired horizontal and vertical timing information by means of frequency selection; and (3) rejection of noise signals. *See* ELECTRICAL NOISE; TELEVISION SCANNING.

The display device for a monochrome television receiver is a cathode-ray tube, consisting of an evacuated bulb containing an electron gun and a phosphor screen, which emits light when excited by an electron beam. The intensity of the electron beam is controlled by the video signal, which is applied either to the grid or to the cathode of the electron gun. Television receivers designed to produce images in full color are necessarily more complex than those designed to produce monochrome images only. In monochrome systems, the video signal controls only the luminance of the various areas of the image. In color systems, it is necessary to control both the luminance and the chrominance of the picture elements. *See* PICTURE TUBE.

The chrominance of a color refers to those attributes which cause it to differ from a neutral (white or gray) color of the same luminance. In qualitative terms, chrominance may be regarded as those properties of a color that control the psychological sensations of hue and saturation. For color television purposes, chrominance is most frequently expressed quantitatively in terms of the amounts of two hypothetical, zero-luminance primary colors (usually designated I and Q), which must be added to or subtracted from a neutral color of a given luminance to produce the color in question. As a practical matter, color television receivers produce full-color images as additive combinations of red, green, and blue primary-color images, and it is necessary to process the luminance and chrominance information in a color signal in such a way as to make it usable by a practical reproducing device. *See* COLOR.

Color television broadcasts in the United States employ signal specifications that are fully compatible with those used for monochrome, making it possible for color programs to be received on monochrome receivers and monochrome programs to be received on color receivers. (Color pictures are produced, of course, only when color programs are viewed through color receivers.) Compatibility is achieved by encoding the color information at the transmitting end of a color television system in such a way that the transmitted signal consists essentially of a normal monochrome signal (conveying luminance information) supplemented by an additional modulated wave conveying chrominance information. Although it is added directly to the monochrome signal component before transmission, the color subcarrier signal does not cause objectionable interference, because of the use of the frequency interlace technique. Because the chrominance information involves two variables, the modulated subcarrier signal varies in both amplitude and phase, and it is necessary to employ synchronous detectors to recover the two variables. A phase reference for the special local oscillator, which provides the synchronized carriers in each color receiver, is transmitted in the form of so-called color synchronizing bursts. These are short samples of unmodulated subcarrier transmitted during the horizontal blanking periods after the horizontal sync pulses.

Special decoding circuits are necessary in a color receiver to process the luminance and chrominance information in a color signal so that it can be used for the control of a practical color cathode-ray tube utilizing red, green, and blue primary colors.

The great majority of color television receivers employ the shadow-mask color cathode-ray tube in which color images are produced in the form of closely intermingled red, green, and blue dots. The primary-color phosphor dots are excited by three separate electron beams, which are prevented from striking dots of the wrong color by the shadowing effect of an aperture mask located about $^1/_2$ in. (1.25 cm) behind the special phosphor screen. The beams in such a cathode-ray tube are deflected simultaneously by the fields produced by a single deflection yoke placed conventionally around the neck of the tube. New cathode-ray-tube designs and deflection yokes are self-converging and do not require auxiliary convergence deflection.

In addition to the same controls required for monochrome receivers (such as brightness and contrast), color receivers normally have controls for convergence, hue, and saturation. The convergence controls, considered servicing adjustments only, adjust the relative amplitudes and phases of the signal components that are added together to form the proper waveforms for the convergence yoke. The hue control usually adjusts the phase of the burst-controlled oscillator and alters all the colors in the image in a systematic manner comparable to the effect achieved when a color circle diagram is rotated in one direction or the other. The proper setting for the hue control is normally determined by observing skin tones of persons on the television screen. The saturation control, frequently labeled chroma or simply color, adjusts the gain of the chrominance circuits relative to the monochrome channel and controls the saturation or vividness of the reproduced colors. When this control is set too low, the colors are all pale or pastel, and when it is reduced to zero, the picture is seen in black and white only. [C.G.E.]

Television scanning The process used to convert a three-dimensional image intensity into a one-dimensional television signal waveform. The image information captured by a television camera conveys color intensity (in terms of red, green, and blue primary colors) at each spatial location, with horizontal and vertical coordinates, and at each time instance. Thus, the image intensity is multidimensional, since it involves two spatial dimensions and time. It needs to be converted to a unidimensional signal so that processing, storage, communications, and display can take place.

The television scene is sampled many times per second in order to create a sequence of images (called frames). Then, within each frame, sampling is done vertically to create scan lines. Scanning proceeds sequentially, left to right and top to bottom. In a television camera, an electron beam scans across an electrically photosensitive target upon which the image is focused. At the other end of the television chain, with raster scanned displays, an electronic beam scans and lights up the picture elements in proportion to the light intensity. While it is convenient to think of all the samples of a single frame occurring at a single time (similar to the simultaneous exposure of a single frame for film), the scanning in a camera and in a display results in every sample corresponding to a different instance in time, and successive lines occur later in time. *See* TELEVISION CAMERA TUBE; TELEVISION RECEIVER.

There are two types of scanning approaches: progressive (also called sequential) and interlaced. In progressive scanning, the television scene is first sampled in time to create frames, and within each frame all the raster lines are scanned from top to bottom. Therefore, all the vertically adjacent scan lines are also temporally adjacent and are highly correlated even in the presence of rapid motion in the scene. Film can be thought of as naturally progressively scanned, since all the lines were originally exposed simultaneously, so the correlation between adjacent lines is guaranteed. Almost all computer displays (except some low-end computers) are sequentially scanned. *See* ELECTRONIC DISPLAY.

In interlaced scanning, all the odd-numbered lines in the entire frame are scanned first, and then the even numbered lines. This process produces two distinct images per frame, representing two distinct samples of the image sequence at different points in time. The set of odd-numbered lines constitute the odd field, and the even-numbered lines make up the even field. All current television systems use interlaced scanning. One principal benefit of interlaced scanning is to reduce the scan rate (or the bandwidth). This is done with a relatively high field rate (a lower field rate would cause flicker), while maintaining a high total number of scan lines in a frame (lower number of lines per frame would reduce resolution on static images). Interlace cleverly preserves the high-detail visual information and, at the same time, avoids visible large-area flicker at the display due to temporal postfiltering by the human eye.

An agreement (not a standard) on high-definition formats has been reached and is in use, enabling the transition from analog to digital television. In early 2001, there were more than 150 stations broadcasting high-definition television. The format has 1920 active pixels per line and 1080 active (out of a total of 1125) lines in a frame. The frames may be interlaced or progressive and the frame rate is 29.97 Hz. Progressive frames at a rate of 23.976 Hz are also permitted to accommodate film material. An alternative progressive-only format that provides additional temporal resolution at the expense of some spatial resolution has also been approved and is currently in use. This format has 1280 active pixels per line and 720 active (out of a total of 750) lines per frame, and the frame rates permitted are 23.976 Hz, 29.97 Hz, or 59.94 Hz. Both high-definition formats have square pixels and a 16 × 9 aspect ratio. *See* DATA COMPRESSION; IMAGE PROCESSING; TELEVISION. [A.N.N.]

Television standards The accepted criteria for a television system, including the image aspect ratio, number of lines per frame, type of scanning, original video signal bandwidth, transmission format and bandwidth, reception, demodulation, decoding, and sound system. The implementation of high-definition television (HDTV), where the image resolution and audio fidelity are significantly higher than for conventional television, has required new standards. *See* TELEVISION.

In the early 1950s, the National Television Systems Committee (NTSC) was formed to set standards for a color television signal (in the United States) that would be fully compatible with the existing monochrome signal. Any color can be formed as a linear combination, that is, a weighted sum, of red (R), green (G), and blue (B). The NTSC standard started with three image signals—R, G, and B—and matrixed these three primary color image signals as linear combinations into one luminance signal (the conventional black-and-white video signal, often called the Y-signal) and two chrominance signals that control hue and saturation. The chrominance signals are termed the in-phase (I) signal and the quadrature (Q) signal. Although the luminance signal retained the original 4.2-MHz bandwidth, the characteristics of human color perception allowed the I-signal to be limited to 1.5 MHz and the Q-signal to only 0.5 MHz.

While NTSC color television standards are used in North America, South America, and Japan, the European International Radio Consultative Committee (CCIR) system is used in England, Germany, Italy, and Spain. The color system employed with CCIR television is called Phase Alternate Line (PAL). A modified CCIR television standard is used in France and Russia, where the color system is called SECAM (Sequential Couleur à Mémoire).

The next generation of television, HDTV, is not compatible with the previous television systems. HDTV relies on digital technology, making it more amenable with computer displays, while taking full advantage of the power and efficiency of digital signal processing (DSP). The desired characteristics of the HDTV system that would replace the NTSC system was expected to have a resolution that would approach the quality of a 35-mm film, that is, approximately twice the horizontal and twice the vertical resolution of conventional television, with a widescreen aspect ratio of 16:9. The target HDTV system standard was required to avoid interlace scanning artifacts, as well as chrominance artifacts and deliver digital multichannel audio. The end result was a 1996

FCC digital television (DTV) standard, and HDTV broadcasting commenced in the United States in 1998.

In Europe, a different transmission standard has been adopted. The European system is referred to as the Digital Video Broadcasting (DVB) standard.

The FCC expects everyone to be using new HDTV receivers by the year 2011, at which time NTSC broadcasting will cease, and all NTSC color television receivers will need to be replaced or modified with some type of converter to be able to decode and display HDTV images. [J.L.LoC.]

Television studio A facility designed for the production of television programs, which may be broadcast live concurrently with the production or recorded for later broadcast. A television studio consists of the studio room, wherein the actual program takes place, and various support rooms, which include the control room, the equipment room, and the property room.

The studio room is where the program action occurs and is analogous to a theatrical stage. Studio rooms may be of almost any size, depending on use, but invariably provide certain facilities, such as a flexible lighting and scenery system, one or more cameras, one or more microphones for sound pickup, and a communications system to allow coordination during the program. Most studios use a lighting grid suspended from a high ceiling that allows flexible placement of the various lighting fixtures. *See* MICROPHONE; SOUND-REPRODUCING SYSTEMS; TELEVISION CAMERA.

The studio control room is the nerve center of the television production facility. The control room usually has a bank of video monitors with screens which display the output of each camera, videotape recorder, or special-effects generator, as well as a previous monitor which shows the director what the next shot will look like and a line monitor which shows the scene currently on the air. The sound engineer operates an audio mixer console which has every microphone used in the studio connected to a separate input. Other sources, such as turntables, audio tape recorders, tape cartridge machines, compact disk players, and audio hard disk recorders (or audio servers), may also be connected to the audio mixer. *See* SOUND-RECORDING STUDIO. [E.F.A.]

Television transmitter An electronic device that converts audio and video signals into modulated radio-frequency (rf) energy which can be radiated from an antenna and received by a television receiver. The term can also refer to the entire television transmitting plant, consisting of the transmitter proper, associated visual and aural input and monitoring equipment, transmission line, the antenna with its tower or other support structure, and the building in which the equipment is housed. In the United States, both analog NTSC (National Television Systems Committee) and digital 8-VSB transmitters are in service. The digital transmitters are used for what is termed high-definition television (HDTV).

An analog television transmitter can be thought of as two separate transmitters integrated into a common cabinet. Video information is transmitted via a visual transmitter, while audio information is transmitted via an aural transmitter. Because video and audio have different characteristics, the two transmitters differ in terms of bandwidth, modulation technique, and output power level. Nevertheless, a common transmitting antenna is generally used, and the two transmitters feed this antenna via an rf diplexer or combiner.

A digital transmitter accepts a single encoded digital bit stream that may contain video, audio, and data. In the United States, the digital terrestrial transmission standard is known as 8-VSB, which is an eight-level, vestigal sideband format. The FCC has mandated that all U.S. television stations convert to difital and terminate analog transmissions.

Television stations are licensed to operate on a particular channel, but since it takes a very wide bandwidth to transmit a television picture, these channels are allocated over a broad range of frequencies. Channels 2 through 6 are low-band very-high-frequency (VHF) channels, while channels 7 through 13 are high-band VHF channels. Channels 14 through 69 are ultrahigh-frequency (UHF) channels. Each channel is 6 MHz wide. Because of the wide range of frequencies, television transmitters are designed to work in only one of the foregoing groups, and employ specific circuits which are most efficient for the channels involved. *See* RADIO SPECTRUM ALLOCATIONS.

The horizontal radiation pattern of most television transmitting antennas is circular, providing equal radiated signal strength to all points of the compass. Higher-gain antennas achieve greater power in the direction of the horizon by reducing the power radiated at vertical angles above and below the horizon. Since this could result in weaker signals at some receivers close to the transmitter, beam tilt and null fill are often used to lower the angle of maximum radiated power. Because television signals travel in a "line of sight," transmitting antennas are usually placed as high as possible above ground with respect to the surrounding service area. This allows viewers to orient their receiving antennas in one direction for the best reception from all of the stations. *See* ANTENNA (ELECTROMAGNETISM).

There are two broad classes of VHF analog visual television transmitter design philosophy. The classical approach modulates the visual carrier at a moderate power level, amplifies the carrier to rated output power by means of high-power linear amplifiers, and then filters this high-power carrier to obtain the required vestigial-sideband signal. The more contemporary approach, used by nearly all transmitter manufacturers, employs modulation at a very low power level of an intermediate-frequency (i-f) signal. The required vestigial-sideband filtering is imposed on this low-level signal, generally by means of a highly stable surface-acoustic-wave filter, whereupon the signal is upconverted to the carrier frequency and amplified by linear amplifiers to rated output power. *See* AMPLIFIER; SURFACE-ACOUSTIC-WAVE DEVICES; TELEVISION. [E.F.A.]

Tellurium A chemical element, Te, atomic number 52, and chemical atomic weight 127.60. There are eight stable isotopes of natural tellurium. Tellurium makes up approximately $10^{-9}\%$ of the Earth's igneous rock. It is found as the free element, sometimes associated with selenium. It is more often found as the telluride sylvanite (graphic tellurium), nagyagite (black tellurium), hessite, tetradymite, altaite, coloradoite, and other silver-gold tellurides, as well as the oxide, tellurium ocher. *See* PERIODIC TABLE.

There are two important allotropic modifications of elemental tellurium, the crystalline and the amorphous forms. The crystalline form has a silver-white color and metallic appearance. This form melts at 841.6°F (449.8°C) and boils at 2534°F (1390°C). It has a specific gravity of 6.25, and a hardness of 2.5 on Mohs scale. The amorphous form (brown) has a specific gravity of 6.015. Tellurium burns in air with a blue flame, forming tellurium dioxide, TeO_2. It reacts with halogens, but not sulfur or selenium, and forms, among other products, both the dinegative telluride anion (Te^{2-}), which resembles selenide, and the tetrapositive tellurium cation (Te^{4+}) which resembles platinum(IV).

Tellurium is used primarily as an additive to steel to increase its ductility, as a brightener in electroplating baths, as an additive to catalysts for the cracking of petroleum, as a coloring material for glasses, and as an additive to lead to increase its strength and corrosion resistance. *See* SELENIUM. [S.Ki.]

Telosporea A class of the subphylum Sporozoa. These protozoa are divided into two subclasses, the Gregarinia and Coccidia. All members of the group are either intra- or extracellular parasites, and the life cycles have both sexual and asexual phases. The spores lack a polar capsule and develop from an oocyst. The sporozoite is the usual infective stage which initiates the asexual phase in the life cycle. *See* COCCIDIA; GREGARINIA; PROTOZOA; SPOROZOA. [E.R.B./N.D.L.]

Temnopleuroida An order of Eichinacea with a camarodont lantern, smooth or sculptured test, tubercles imperforate or perforate (and usually crenulate), ambulacral plates of diademoid or echinoid type, and branchial slits which are usually shallow. There are three included families, Glyphocyphidae, Temnopleuridae, and Toxopneustidae. *See* ECHINACEA. [H.B.F.]

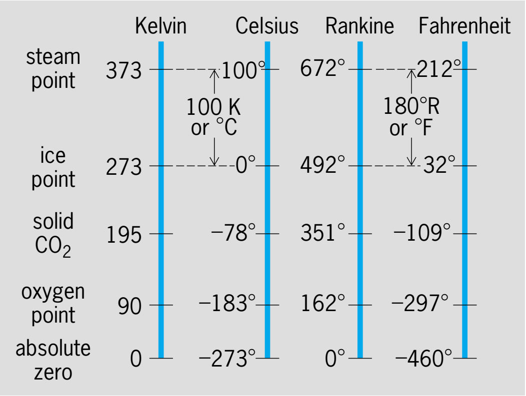
Temnospondyli The more common of the two major orders of the great extinct subclass Labyrinthodontia. Temnospondyls are differentiated from anthracosaurs by having the cheek suturally attached to the skull table. Their vertebral structure, in which the pleurocentra are seldom prominent and the intercentra are large, resembles that of some members of the rhipidistian crossopterygians, which include the ancestors of all amphibians. Terrestrial temnospondyls achieved their greatest diversity in the upper Carboniferous and lower Permian, during which time they were the most common land vertebrates. The last of the large aquatic temnospondyls occur in the Lower Jurassic of Australia. *See* AMPHIBIA; ANTHRACOSAURIA; CROSSOPTERYGII; LABYRINTHODONTIA. [R.L.C.]

Temperature A concept related to the flow of heat from one object or region of space to another. The term refers not only to the senses of hot and cold but to numerical scales and thermometers as well. Fundamental to the concept are the absolute scale and absolute zero and the relation of absolute temperatures to atomic and molecular motions.

Thermometers do not measure a special physical quantity. They measure length (as of a mercury column) or pressure or volume (with the gas thermometer at the National Institute of Standards and Technology) or electrical voltage (with a thermocouple). The basic fact is that if a mercury column has the same length when touching two different, separated objects when the objects are placed in contact, no heat will flow from one to the other. *See* THERMOMETER.

The numbers on the thermometer scales are merely historical choices; they are not scientifically fundamental. The most widely used scales are the Fahrenheit (°F) and the Celsius (°C). The centigrade scale with 0° assigned to ice water (ice point) and 100° assigned to water boiling under one atmosphere pressure (steam point) was formerly used, but it has been succeeded by the Celsius scale, defined in a different way than the centigrade scale. However, on the Celsius scale the temperatures of the ice and steam points differ by only a few hundredths of a degree from 0° and 100°, respectively. The illustration shows how the Celsius and Fahrenheit scales compare and how they fit onto the absolute scales. *See* ICE POINT.

In 1848 William Thomson (Lord Kelvin), following ideas of Sadi Carnot, stated the concept of an absolute scale of temperature in terms of measuring amounts of heat flowing between objects. Most important, Kelvin conceived of a body which would not give up any heat and which was at an absolute zero of temperature. Experiments have shown that absolute zero corresponds to −273.15°C or −459.7°F. Two absolute scales, shown in the illustration, are the Kelvin (K) and the Rankine (°R).



Comparisons of Kelvin, Celsius, Rankine, and Fahrenheit temperature scales. Temperatures are rounded off to nearest degree. (*After M. W. Zemansky, Temperatures Very Low and Very High, Van Nostrand, 1964*)

In practice, absolute temperatures are measured by using low-density helium gas and dilute paramagnetic crystals, the most nearly ideal of real materials. The measurement of a single temperature with a gas or magnetic thermometer is a major scientific event done at a national standards laboratory. Only a few temperatures have been measured, including the freezing point of gold (1337.91 K or 1948.57°F), and the boiling points of sulfur (717.85 K or 832.46°F), oxygen (90.18 K or −297.35°F), and helium (4.22 K or −452.07°F). Various types of thermometers (platinum, carbon, and doped germanium resistors; thermocouples) are calibrated at these temperatures and used to measure intermediate temperatures. *See* TEMPERATURE MEASUREMENT; THERMODYNAMIC PRINCIPLES. [R.A.Hu.]

Temperature adaptation The ability of animals to survive and function at widely different temperatures as a result of specific physiological adaptations. Temperature is an all-pervasive attribute of the environment that limits the activity, distribution, and survival of animals.

Changes in temperature influence biological systems, both by determining the rate of chemical reactions and by specifying equilibria. Because temperature exerts a greater effect upon the percentage of molecules that possess sufficient energy to react (that is, to exceed the activation energy) than upon the average kinetic energy of the system, modest reductions in temperature (for example, from 77 to 59°F or from 25 to 15°C, corresponding to only a 3% reduction in average kinetic energy) produce a marked depression (two- to threefold) in reaction rate. In addition, temperature specifies the equilibria between the formation and disruption of the noncovalent (electrostatic, hydrophobic, and hydrogen-bonding) interactions that stabilize both the higher levels of protein structure and macromolecular aggregations such as biological membranes. Maintenance of an appropriate structural flexibility is a requirement for both enzyme catalysis and membrane function, yet cold temperatures constrain while warm temperatures relax the conformational flexibility of both proteins and membrane lipids, thereby perturbing biological function. *See* CELL MEMBRANES; ENZYME.

Animals are classified into two broad groups depending on the factors that determine body temperature. For ectotherms, body temperature is determined by sources of heat external to the body; levels of resting metabolism (and heat production) are low, and mechanisms for retaining heat are limited. Such animals are frequently termed poikilothermic or cold-blooded, because the body temperature often conforms to the temperature of the environment. In contrast, endotherms produce more metabolic heat and possess specialized mechanisms for heat retention. Therefore, body temperature is elevated above ambient temperature; some endotherms (termed homeotherms or warm-blooded animals) maintain a relatively constant body temperature. There is no natural taxonomic division between ecto- and endotherms. Most invertebrates, fish, amphibians, and reptiles are ectotherms, while true homeothermy is restricted to birds and mammals. However, flying insects commonly elevate the temperature of their thoracic musculature prior to and during flight (to 96°F or 36°C), and several species of tuna retain metabolic heat in their locomotory musculature via a vascular countercurrent heat exchanger. *See* ADIPOSE TISSUE; HIBERNATION; THERMOREGULATION. [J.R.Ha.]

Temperature inversion The increase of air temperature with height; an atmospheric layer in which the upper portion is warmer than the lower. Such an increase is opposite, or inverse, to the usual decrease of temperature with height, or lapse rate, in the troposphere. However, above the tropopause, temperature increases with height throughout the stratosphere, decreases in the mesosphere, and increases again in the thermosphere. Thus inversion conditions prevail throughout much of the atmosphere much or all of the time, and are not unusual or abnormal. *See* AIR TEMPERATURE; ATMOSPHERE.

Inversions are created by radiative cooling of a lower layer, by subsidence heating of an upper layer, or by advection of warm air over cooler air or of cool air under warmer air. Outgoing radiation, especially at night, cools the Earth's surface, which in turn cools the lowermost air layers, creating a nocturnal surface inversion a few inches to several hundred feet thick.

Inversions effectively suppress vertical air movement, so that smokes and other atmospheric contaminants cannot rise out of the lower layer of air. California smog is trapped under an extensive subsidence inversion; surface radiation inversions, intensified by warm air advection aloft, can create serious pollution problems in valleys throughout the world; radiation and subsidence inversions, when horizontal air motion is sluggish, create widespread pollution potential, especially in autumn over North America and Europe. *See* AIR POLLUTION; SMOG. [A.Cou.]

Temperature measurement Measurement of the hotness of a body relative to a standard scale. The fundamental scale of temperature is the thermodynamic scale, which can be derived from any equation expressing the second law of thermodynamics. Efforts to approximate the thermodynamic scale as closely as possible depend on relating measurements of temperature-dependent physical properties of systems to thermodynamic relations expressed by statistical thermodynamic equations, thus in general linking temperature to the average kinetic energy of the measured system. Temperature-measuring devices, thermometers, are systems with properties that change with temperature in a simple, predictable, reproducible manner. *See* TEMPERATURE; THERMODYNAMIC PRINCIPLES.

In the establishment of a useful standard scale, assigned temperature values of thermodynamic equilibrium fixed points are agreed upon by an international body (General Conference of Weights and Measures), which updates the scale about once every 20 years. Thermometers for interpolating between fixed points and methods for realizing the fixed points are prescribed, providing a scheme for calibrating thermometers used in science and industry.

The scale now in use is the International Temperature Scale of 1990 (ITS-90). Its unit is the kelvin, K, arbitrarily defined as 1/273.16 of the thermodynamic temperature T of the triple point of water (where liquid, solid, and vapor coexist). For temperatures above 273.15 K, it is common to use International Celsius Temperatures, t_{90} (rather than International Kelvin Temperatures, T_{90}), having the unit degree Celsius, with symbol °C. The degree Celsius has the same magnitude as the kelvin. Temperatures, t_{90}, are defined as $t_{90}/^\circ\mathrm{C} = T_{90}/\mathrm{K} - 273.15$, that is, as differences from the ice-point temperature at 273.15 K. The ice point is the state in which the liquid and solid phases of water coexist at a pressure of 1 atm (101,325 pascals). [The Fahrenheit scale, with symbol °F, still in common use in the United States, is given by $t_F/^\circ\mathrm{F} = (t_{90}/^\circ\mathrm{C} \times 1.8) + 32$, or $t_F/^\circ\mathrm{F} = (T_{90}/\mathrm{K} \times 1.8) - 459.67$.] The ITS-90 is defined by 17 fixed points. *See* TRIPLE POINT.

Primary thermometers are devices which relate the thermodynamic temperature to statistical mechanical formulation. The fixed points of ITS-90 are all based on one or more types of gas thermometry or on spectral radiation pyrometry referenced to gas thermometry. Secondary thermometers are used as reference standards in the laboratory because primary thermometers are often too cumbersome. It is necessary to establish standard secondary thermometers referenced to one or more fixed points for interpolation between fixed points. Lower-order thermometers are used for most practical purposes and, when high accuracy is required, can usually be calibrated against reference standards maintained at laboratories, such as the U.S. National Institute of Standards and Technology, or against portable reference devices (sealed boiling or melting point cells). *See* GAS THERMOMETRY; LOW-TEMPERATURE THERMOMETRY; PYROMETER; THERMISTOR; THERMOCOUPLE; THERMOMETER. [B.W.M.]

Tempering The reheating of previously quenched alloy to a predetermined temperature below the critical range, holding the alloy for a specified time at that temperature, and then cooling it at a controlled rate, usually by immediate rapid quenching, to room temperature. The term is broadly applied to any process that toughens a material.

In alloys, if the composition is such that cooling produces a supersaturated solid solution, the resulting material is brittle. Heating the alloy to a temperature only high enough to allow the excess solute to precipitate out and then rapidly cooling the saturated solution fast enough to prevent further precipitation or grain growth result in a microstructure combining hardness and toughness.

With steel, the tempering must be carried out by slow heating to avoid steep temperature gradients, stress relief being one of the objectives. Properties produced by tempering depend on the temperature to which the steel is raised and on its alloy composition. For example, if hardness is to be retained, molybdenum or tungsten is used in the alloy. *See* HEAT TREATMENT (METALLURGY). [F.H.R.]

Temporary structure (engineering) A structure erected to aid in the construction of a permanent project. Temporary structures are used to facilitate the construction of buildings, bridges, tunnels, and other above- and below-ground facilities by providing access, support, and protection for the facility under construction, as well as assuring the safety of the workers and the public. Temporary structures either are dismantled and removed when the permanent works become self-supporting or completed, or are incorporated into the finished work. Temporary structures are also used in inspection, repair, and maintenance work.

The many types of temporary structures include cofferdams; earth-retaining structures; tunneling supports; underpinning; diaphragm/slurry walls; roadway decking; construction ramps, runways, and platforms; scaffolding; shoring; falsework; concrete formwork; bracing and guying; site protection structures such as sidewalk bridges, boards, and nets for protection against falling objects, barricades and fences, and signs; and unique structures that are specially conceived, designed, and erected to aid in a specific construction operation.

These temporary works have a primary influence on the quality, safety, speed, and profitability of all construction projects. More failures occur during construction than during the lifetimes of structures, and most of those construction failures involve temporary structures. However, codes and standards do not provide the same scrutiny as they do for permanent structures. Typical design and construction techniques and some industry practices are well established, but responsibilities and liabilities remain complex and present many contractual and legal pitfalls. [R.T.R.]

Tendon A cord connecting a muscle to another structure, often a bone. A tendon is a passive material, lengthening when the tension increases and shortening when it decreases. This characteristic contrasts with the active behavior of muscle. Away from its muscle, a tendon is a compact cord. At the muscle, it spreads into thin sheets called aponeuroses, which lie over and sometimes within the muscle belly. The large surface area of the aponeuroses allows the attachment of muscle fibers with a total cross-sectional area that is typically 50 times that of the tendon. *See* MUSCLE.

Tendons are living tissues that contain cells. In adult tendons, the cells occupy only a very small proportion of the volume and have a negligible effect on the mechanical properties. Like other connective tissues, tendon depends on the protein collagen for its strength and rigidity. The arrangement of the long, thin collagenous fibers is essentially longitudinal, but incorporates a characteristic waviness known as crimp. The fibers lie within a matrix of aqueous gel. Thus, tendon is a fiber-reinforced composite (like fiberglass), but its collagen is much less stiff than the glass and its matrix is very much less stiff than the resin. *See* Collagen; Composite material.

The function of tendons is to transmit force. They allow the force from the muscle to be applied in a restricted region. For example, the main muscles of the fingers are in the forearm, with tendons to the fingertips. If the hand had to accommodate these muscles, it would be too plump to be functional. Tendon extension can also be significant in the movement of a joint. For example, the tendon which flexes a human thumb joint is about 7 in. (170 mm) long. The maximum force from its muscle stretches this tendon about 0.1 in. (2.9 mm), which corresponds to rotation of the joint through an angle of about 21°. *See* Joint (anatomy).

Some tendons save energy by acting as springs. In humans, the Achilles tendon reduces the energy needed for running by about 35%. This tendon is stretched during the first half of each step, storing energy which is then returned during takeoff. This elastic energy transfer involves little energy loss, whereas the equivalent work done by muscles would require metabolic energy in both stages. *See* Connective tissue; Muscular system; Skeletal system. [R.F.K.]

Tenrec An insectivorous mammal indigenous to Madagascar. There are 30 species in 10 genera. These animals are nocturnally active and feed on insects, worms, and mollusks. All tenrecs are essentially primitive unspecialized mammals, with poor vision. The digits are clawed, and the first digit is not opposable to the others. The body of the tenrec is covered with a mixture of hair, spines, and bristles; the tail is rudimentary; and the toes may be separate or webbed, depending on the species. The female is prolific, and has litters of 12–20 young. *See* Insectivora; Mammalia. [C.B.C.]

Tensor analysis The systematic study of tensors which led to an extension and generalization of vectors, begun in 1900 by two Italian mathematicians. G. Ricci and T. Levi-Civita, following G. F. B. Riemann's proposal concerning a generalization of euclidean geometry. The principal aim of the tensor calculus (absolute differential calculus) is to construct relationships which are generally covariant in the sense that these relationships or laws remain valid in all coordinate systems. The differential equations for the geodesics in a Riemannian space are covariant expressions; they yield a description of the geodesics which is valid for all coordinate systems. On the other hand, Newton's equations of motion require a preferred coordinate system for their description, namely, one for which force is proportional to acceleration (an inertial frame of reference). Thus Albert Einstein was led to a study of Riemannian geometry and the tensor calculus in order to construct the general theory of relativity. *See* Calculus of vectors; Riemannian geometry. [H.La.]

Terbium Element number 65, terbium, Tb, is a very rare metallic element of the rare-earth group. Its atomic weight is 158.924, and the stable isotope ^{159}Tb makes up 100% of the naturally occurring element. *See* Periodic table.

The common oxide, Tb_4O_7, is brown and is obtained when its salts are ignited in air. Its salts are all trivalent and white in color and, when dissolved, give colorless solutions. The higher oxides slowly decompose when treated with dilute acid to give the trivalent ions in solution. Although the metal is attacked readily at high temperatures by air, the attack is extremely slow at room temperatures. The metal has a Néel point at about 229 K and a Curie point at about 220 K. For properties of the metal *see* Rare-earth elements. [F.H.Sp.]

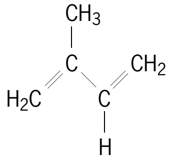
Terebratulida An order of articulated brachiopods consisting of a group of sessile, suspension-feeding, marine, benthic, epifaunal bivalves with representatives occurring from the Early Devonian Era. It is the most diverse and abundant group of living brachiopods, which probably exhibits maximum diversity in present-day seas.

The shells are biconvex and usually smooth, although some show radial ribbed ornamentation. The valves articulate about a hinge structure and posterior edges of the valves are not coincident with the hinge axis (nonstrophic condition). The shell is calcareous and punctate. A fleshy pedicle usually attaches the animal to the substrate, but in thecidine brachiopods the ventral valve is cemented to the substrate. The tentacular feeding organ (lophophore) occupies the mantle cavity as a looped structure (the ptycholophe) in the smaller forms or as a looped and coiled structure (the plectolophe) in the larger forms. In the smaller forms the lophophore is supported by a calcareous ridge, but in the larger forms by a calcareous loop.

Three suborders are recognized: Centronellida, Terebratulidina, and Terebratellidina. *See* Brachiopoda; Rhynchonelliformea. [M.A.J.]

Terpene A class of natural products having a structural relationship to isoprene, as shown below. Over 5000 structurally determined terpenes are known; many of these have also been synthesized in the laboratory. Historically terpenes have been isolated from green plants, but new compounds structurally related to isoprene continue to be isolated from other sources as well, so the class is also referred to as terpenoids, reflecting the biochemical origin without specification of the natural source. *See* Isoprene.

Isoprene unit



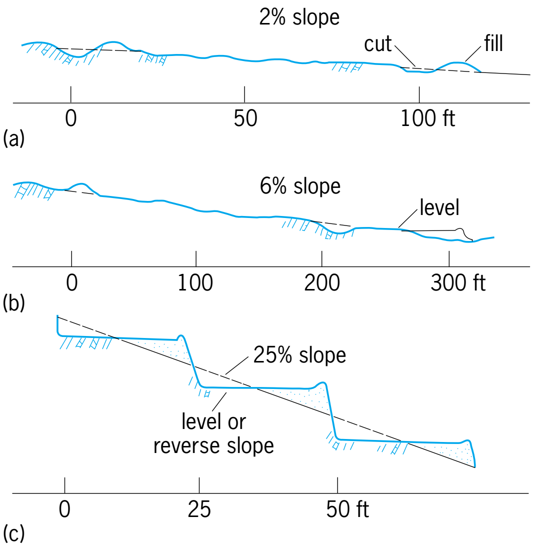
Isoprene

Terpenes are classified according to the number of isoprene units of which they are composed, as follows:

5	hemi	25	ses-
10	mono-	30	tri-
15	sesqui-	40	tetra-
20	di-	$(5)_n$	poly-

Although they may be named according to the systematic nomenclature and numbering systems set by the International Union of Pure and Applied Chemistry for all organic compounds, it is often easier to refer to terpenes by their common names, which usually reflect the botanical or zoological name of their source. [T.Hu.]

Terracing (agriculture) A method of shaping land to control erosion on slopes of rolling land used for cropping and other purposes. In early practice the land was shaped into a series of nearly level benches or steplike formations. Modern practice in terracing, however, consists of the construction of low-graded channels or levees to carry the excess rainfall from the land at nonerosive velocities. The physical principle involved is that, when water is spread in a shallow stream, its flow is retarded by the roughness of the bottom of the channel and its carrying, or erosive, power is reduced. Since direct impact of rainfall on bare land churns up the soil and the stirring effect keeps it in suspension in overland flow and rills, terracing does not prevent sheet erosion. It serves only to prevent destruction of agricultural land by gullying and must be supplemented by other erosion-control practices, such as grass rotation, cover crops, mulching,



Types of terraces. (*a*) Broadbase. (*b*) Conservation bench. (*c*) Bench. 1 ft = 0.3 m. (*After Soil and Water Conservation Engineering, 2d ed., The Ferguson Foundation Agricultural Engineering Series, John Wiley and Sons, Inc., 1966*)

contour farming, strip cropping, and increased organic matter content. *See* Erosion; Soil conservation.

The two major types of terraces are the bench and the broadbase (see illustration). The bench terrace is essentially a steepland terrace and consists of an almost vertical retaining wall, called a riser, or a steep vegetative slope to hold the nearly level surface of the soil for cultivation, orchards, vineyards, or landscaping. The broadbase terrace has the distinguishing characteristic of farmability; that is, crops can be grown on this terrace and worked with modern-day machinery. These terraces are constructed either to remove or retain water and, based on their primary function, are classified either as graded or level. *See* Land drainage (agriculture). [C.B.O.]

Terrain areas Subdivisions of the continental surfaces distinguished from one another on the basis of the form, roughness, and surface composition of the land. The pattern of landform differences is strongly reflected in the arrangement of such other features of the natural environment as climate, soils, and vegetation. These regional associations must be carefully considered in planning of activities as diverse as agriculture, transportation, city development, and military operations.

Eight classes of terrain are distinguished on the basis of steepness of slopes, local relief (the maximum local differences in elevation), cross-sectional form of valleys and divides, and nature of the surface material. Approximate definitions of terms used and percentage figures indicating the fraction of the world's land area occupied by each class are as follows; (1) flat plains: nearly level land, slight relief, 4%; (2) rolling and irregular plains: mostly gently sloping, low relief, 30%; (3) tablelands: upland plains broken at intervals by deep valleys or escarpments, moderate to high relief, 5%; (4) plains with hills or mountains: plains surmounted at intervals by hills or mountains of limited extent, 15%; (5) hills: mostly moderate to steeply sloping land of low to moderate relief, 8%; (6) low mountains: mostly steeply sloping, high relief, 14%; (7) high mountains: mostly steeply sloping, very high relief, 13%; and (8) ice caps: surface material, glacier ice, 11%. [E.H.Ha.]

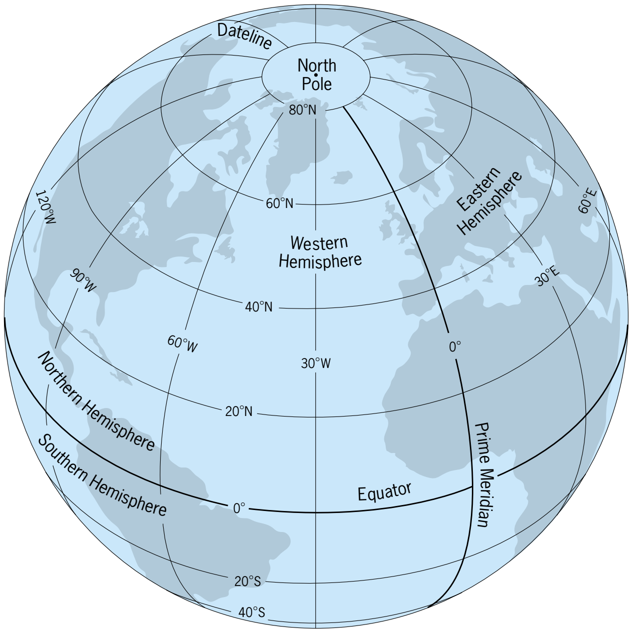
Terrestrial coordinate system The perpendicular intersection of two curves or two lines, one relatively horizontal and the other relatively vertical, is the basis for finding and describing terrestrial location. The Earth's graticule, consisting of an imaginary grid of east-to-west-bearing lines of latitude and north-to-south bearing lines of longitude, is derived from the Earth's shape and rotation, and is rooted in spherical geometry. Plane coordinate systems, equivalent to horizontal X and vertical Y coordinates, are based upon cartesian geometry and differ from the graticule in that they have no natural origin or beginning for their grids.

The Earth, which is essentially a sphere, rotates about an axis that defines the geographic North and South poles. The poles serve as the reference points on which the system of latitude and longitude is based (see illustration). *See* Latitude and longitude.

Latitude is arc distance (angular difference) from the Equator and is defined by a system of parallels, or lines that run east to west, each fully encompassing the Earth. The Equator is the parallel that bisects the Earth into the Northern and Southern hemispheres, and lies a constant 90° arc distance from both poles. As the only parallel to bisect the Earth, the Equator is considered a great circle. All other parallels are small circles (do not bisect the Earth), and are labeled by their arc distance north or south from the Equator and by the hemisphere in which they fall. Parallels are numbered from 0° at the Equator to 90° at the poles. For example, 42°S describes the parallel 42 degrees arc distance from the Equator in the Southern Hemisphere. For increased location precision, degrees of latitude and longitude are further subdivided into minutes (1° = 60′) and seconds (1′ = 60″). *See* Equator; Great circle, terrestrial.

Longitude is defined by a set of imaginary curves extending between the two poles, spanning the Earth. These curves, called meridians, always point to true geographical north (or south) and converge at the poles. In the present-day system of longitude, meridians are numbered by degrees east or west of the beginning meridian, called the Prime Meridian or the Greenwich Meridian, which passes through the Royal Observatory in Greenwich, England. The Prime Meridian was assigned a longitude of 0°.

Since the Earth is fundamentally a sphere, its circumference describes a circle containing 360°, the arc distance through which the Earth rotates in 24 hours. The arc distance from the Prime Meridian describes the location of any meridian (see illustration).



Earth's graticule. Meridians of longitude run from north to south, but are measured east or west of the Prime Meridian. Parallels run from east to west, but are measured north or south of the Equator.

The 180° meridian is commonly referred to as the International Dateline. Together, the Prime Meridian and the International Dateline describe a great circle that bisects the Earth, as do all other meridian circles. The west half of the Earth, located between the Prime Meridian and the International Dateline, comprises the Western Hemisphere, and the east half on the opposite side forms the Eastern Hemisphere. Meridians within the Western Hemisphere are labeled with a W, and meridians within the Eastern Hemisphere are labeled with an E. A complete description of longitude includes an angular measurement and a hemispheric label. For example, 78°W is the meridian 78° west of the Prime Meridian. Neither the 0° meridian (Prime) nor the 180° meridian (Dateline) is given a hemispheric suffix because they divide the two hemispheres, and therefore do not belong to either one.

Coordinate system alternatives to the graticule evolved in the early twentieth century because of the complexity of using spherical geometry in determining latitude, longitude, and direction. Plane (two-dimensional) or cartesian coordinate systems presume that a relatively nonspherical Earth exists in smaller areas. Plane coordinates are superimposed upon these small areas, with coordinates being determined by the equivalent of a grid composed of a number of parallel vertical lines (X) and a complementary set of parallel horizontal lines (Y).

The State Plane Coordinate system (SPC) is used only in the United States and partitions each state into zones. Each zone has its own coordinate system. The number of zones designated in each state is determined by the size of the state. Zone boundaries follow either meridians or parallels depending on the shape of the state. All measurements are made in feet.

The Universal Transverse Mercator (UTM) system is a worldwide coordinate system in which locations are expressed using metric units. The basis for the UTM system is the Universal Transverse Mercator map projection. This projection becomes vastly distorted in polar areas above 80°, and for this reason the UTM system is confined to extend from 84°N to 80°S. The UTM system partitions the Earth into 60 north-south elongated zones, each having a width of 6° of longitude. *See* MAP PROJECTIONS.

A number of other coordinate systems are in use today. Foremost among these are the U.S. Public Land Survey System, the Universal Polar Stereographic (UPS) system, and the World Geographic Reference (GEOREF) system. [S.Lav.]

Terrestrial ecosystem A community of organisms and their environment that occurs on the land masses of continents and islands. Terrestrial ecosystems are distinguished from aquatic ecosystems by the lower availability of water and the consequent importance of water as a limiting factor. Terrestrial ecosystems are characterized by greater temperature fluctuations on both a diurnal and seasonal basis than occur in aquatic ecosystems in similar climates. The availability of light is greater in terrestrial ecosystems than in aquatic ecosystems because the atmosphere is more transparent than water. Gases are more available in terrestrial ecosystems than in aquatic ecosystems. Those gases include carbon dioxide that serves as a substrate for photosynthesis, oxygen that serves as a substrate in aerobic respiration, and nitrogen that serves as a substrate for nitrogen fixation. Terrestrial environments are segmented into a subterranean portion from which most water and ions are obtained, and an atmospheric portion from which gases are obtained and where the physical energy of light is transformed into the organic energy of carbon-carbon bonds through the process of photosynthesis.

Terrestrial ecosystems occupy 55,660,000 mi^2 (144,150,000 km^2), or 28.2%, of Earth's surface. Although they are comparatively recent in the history of life (the first terrestrial organisms appeared in the Silurian Period, about 425 million years ago) and occupy a much smaller portion of Earth's surface than marine ecosystems, terrestrial ecosystems have been a major site of adaptive radiation of both plants and animals. Major plant taxa in terrestrial ecosystems are members of the division Magnoliophyta (flowering plants), of which there are about 275,000 species, and the division Pinophyta (conifers), of which there are about 500 species. Members of the division Bryophyta (mosses and liverworts), of which there are about 24,000 species, are also important in some terrestrial ecosystems. Major animal taxa in terrestrial ecosystems include the classes Insecta (insects) with about 900,000 species, Aves (birds) with 8500 species, and Mammalia (mammals) with approximately 4100 species. *See* ANIMAL SYSTEMATICS; PLANT TAXONOMY; TAXONOMY.

Organisms in terrestrial ecosystems have adaptations that allow them to obtain water when the entire body is no longer bathed in that fluid, means of transporting the water from limited sites of acquisition to the rest of the body, and means of preventing the evaporation of water from body surfaces. They also have traits that provide body support in the atmosphere, a much less buoyant medium than water, and other traits that render them capable of withstanding the extremes of temperature, wind, and humidity that characterize terrestrial ecosystems. Finally, the organisms in terrestrial ecosystems have evolved many methods of transporting gametes in environments where fluid flow is much less effective as a transport medium.

The organisms in terrestrial ecosystems are integrated into a functional unit by specific, dynamic relationships due to the coupled processes of energy and chemical flow. Those relationships can be summarized by schematic diagrams of trophic webs, which place organisms according to their feeding relationships. The base of the food web is occupied by green plants, which are the only organisms capable of utilizing the energy of the Sun and inorganic nutrients obtained from the soil to produce organic molecules. Terrestrial food webs can be broken into two segments based on the status of the plant material that enters them. Grazing food webs are associated with the consumption of living plant material by herbivores. Detritus food webs are associated with the consumption of dead plant material by detritivores. The relative importance of those two types of food webs varies considerably in different types of terrestrial ecosystems. Grazing food webs are more important in grasslands, where over half of net primary productivity may be consumed by herbivores. Detritus food webs are more important in forests, where less than 5% of net primary productivity may be consumed by herbivores. *See* FOOD WEB; SOIL ECOLOGY.

There is one type of extensive terrestrial ecosystem due solely to human activities and eight types that are natural ecosystems. Those natural ecosystems reflect the variation of precipitation and temperature over Earth's surface. The smallest land areas are occupied by tundra and temperate grassland ecosystems, and the largest land area is occupied by tropical forest. The most productive ecosystems are temperate and tropical forests, and the least productive are deserts and tundras. Cultivated lands, which together with grasslands and savannas utilized for grazing are referred to as agroecosystems, are of intermediate extent and productivity. Because of both their areal extent and their high average productivity, tropical forests are the most productive of all terrestrial ecosystems, contributing 45% of total estimated net primary productivity on land. *See* DESERT; ECOLOGICAL COMMUNITIES; ECOSYSTEM; FOREST AND FORESTRY; GRASSLAND ECOSYSTEM; SAVANNA; TUNDRA. [S.J.McN.]

Terrestrial radiation Electromagnetic radiation emitted from the Earth and its atmosphere. Terrestrial radiation, also called thermal infrared radiation or outgoing longwave radiation, is determined by the temperature and composition of the Earth's atmosphere and surface. The temperature structure of the Earth and the atmosphere is a result of numerous physical, chemical, and dynamic processes. In a one-dimensional context, the temperature structure is determined by the balance between radiative and convective processes.

The Earth's surface emits electromagnetic radiation according to the laws that govern a blackbody or a graybody. A blackbody absorbs the maximum radiation and at the same time emits that same amount of radiation so that thermodynamic equilibrium is achieved as to define a uniform temperature. A graybody is characterized by incomplete absorption and emission and is said to have emissivity less than unity. The thermal infrared emissivities from water and land surfaces are normally between 90 and 95%. It is usually assumed that the Earth's surfaces are approximately black in the analysis of infrared radiative transfer. Exceptions include snow and some sand surfaces whose emissivities are wavelength-dependent and could be less than 90%. Absorption and emission of radiation by atmospheric molecules are more complex and require a fundamental understanding of quantum mechanics. *See* ATMOSPHERE; BLACKBODY; GRAYBODY; HEAT BALANCE, TERRESTRIAL ATMOSPHERIC; HEAT RADIATION; RADIATIVE TRANSFER.

The radiant energy emitted from a number of temperatures covering the Earth and the atmosphere is measured as a function of wavenumber and wavelength. This energy is called Planck intensity (or radiance), and the units that are commonly used are denoted as watt per square meter per solid angle per wavenumber ($\mathrm{W/m^2 \cdot sr \cdot cm^{-1}}$). Terrestrial radiation originating from the Earth-atmosphere-ocean system, as well as solar radiation reflected and scattered back to space, is measured on a daily basis by meteorological satellites. Instruments on meteorological satellites measure visible, ultraviolet, infrared, and microwave radiation. *See* ABSORPTION OF ELECTROMAGNETIC RADIATION; ELECTROMAGNETIC RADIATION; METEOROLOGICAL SATELLITES; REFLECTION OF ELECTROMAGNETIC RADIATION; SCATTERING OF ELECTROMAGNETIC RADIATION.

Each spectral region provides meteorologists and other Earth system scientists with information about atmospheric ozone, water vapor, temperature, aerosols, clouds, precipitation, lightning, and many other parameters. Measuring atmospheric radiation allows the detection of sea and land temperature, snow and ice cover, and winds at the surface of the ocean. By tracking the movement of clouds and other atmospheric features, such as aerosols and water vapor, it is possible to obtain estimates of winds above the surface. *See* SATELLITE METEOROLOGY.

[K.N.L.; T.H.V.H.]

Terrestrial water The total inventory of water on the Earth. Water is unevenly distributed over the Earth's surface in oceans, rivers, and lakes. In addition, the world's water is distributed throughout the atmosphere and also occurs as soil moisture, groundwater, ice caps, and glaciers. *See* ATMOSPHERE; GLACIOLOGY; GROUND-WATER HYDROLOGY; HYDROLOGY; LAKE; SURFACE WATER. [R.L.N.]

Territoriality Behavior patterns in which an animal actively defends a space or some other resource. One major advantage of territoriality is that it gives the territory holder exclusive access to the defended resource, which is generally associated with feeding, breeding, or shelter from predators or climatic forces. Feeding and breeding territories can be mobile, such as when an animal defends a newly obtained food source or a temporarily receptive mate. Stationary territories often serve multiple functions and include access to food, a place to rear young, and a refuge site from predators and the elements.

Territoriality can be understood in terms of the benefits and costs accrued to territory holders. Benefits include time saved by foraging in a known area, energy acquired through feeding on territorial resources, reduction in time spent on the lookout for predators, or increase in number of mates attracted and offspring raised. Costs usually involve time and energy expended in patrolling and defending the territorial site, and increased risk of being captured by a predator when engaged in territorial defense.

Because territories usually include resources that are in limited supply, active defense is often necessary. Such defense frequently involves a graded series of behaviors called displays that include threatening gestures such as vocalizations, spreading of wings or gill covers, lifting and presentation of claws, head bobbing, tail and body beating, and finally, direct attack. Direct confrontation can usually be avoided by advertising the location of a territory in a way that allows potential intruders to recognize the boundaries and avoid interactions with the defender. Such advertising may involve odors that are spread with metabolic by-products, such as urine or feces in dogs, cats, or beavers, or produced specifically as territory markers, as in ants. Longer-lasting territorial marks can involve visual signals such as scrapes and rubs, as in deer and bear. *See* CHEMICAL ECOLOGY; ETHOLOGY; POPULATION ECOLOGY; REPRODUCTIVE BEHAVIOR. [G.S.H.]

Tertiary The older major subdivision (period) of the Cenozoic Era, extending from the Cretaceous (top of the Mesozoic Era) to the beginning of the Quaternary (younger Cenozoic Period). The term Tertiary corresponds to all the rocks and fossils formed during this period. Typical sedimentary rocks include widespread limestones, sandstones, mudstones, marls, and conglomerates deposited in both marine and terrestrial environments; igneous rocks include extrusive and intrusive volcanics as well as rocks formed deep in the Earth's crust (plutonic). *See* CRETACEOUS; FOSSIL; ROCK.

The Tertiary Period is characterized by a rapid expansion and diversification of marine and terrestrial life. In the marine realm, a major radiation of oceanic microplankton occurred following the terminal Cretaceous extinction events. This had its counterpart on land in the rapid diversification of multituberculates, marsupials, and insectivores—holdovers from the Mesozoic—and primates, rodents, and carnivores, among others, in the ecologic space vacated by the demise of the dinosaurs and other terrestrial forms. Shrubs and grasses and other flowering plants diversified in the middle Tertiary, as did marine mammals such as cetaceans (whales), which returned to the sea in the Eocene Epoch. The pinnipeds (walruses, sea lions, and seals) are derived from land carnivores, or fissipeds, and originated in the Neogene temperate waters of the North Atlantic and North Pacific. Indeed, the great diversification on land and in the sea of birds and, particularly, mammals has led to the informal designation of the Tertiary as the Age of Mammals in textbooks on historical geology.

The modern configuration of continents and oceans developed during the Cenozoic Era as a result of the continuing process known as plate tectonics. Mountain-building events (orogenies) and uplifts of large segments of the Earth's crust (epeirogenies) alternated with fluctuating transgressions and regressions of the seas over land. The middle to late Tertiary Alpine-Himalayan orogeny and the late Tertiary Cascadian orogeny led to the east-west and north-south mountain ranges, respectively, which are located in Eurasia and western North America. *See* CORDILLERAN BELT; MOUNTAIN SYSTEMS; OROGENY; PLATE TECTONICS. [W.A.Ber.]

Testis The organ of sperm production. In addition, the testis (testicle) is an organ of endocrine secretion in which male hormones (androgens) are elaborated. In the higher vertebrates (reptiles, birds, and mammals), the testes are paired and either ovoid or elongated in shape. In mammals, the testes are usually ovoid or round. In many species (for example, humans) they are suspended in a pouch (scrotum) outside the main body cavity; in other species they are found in such a pouch only at the reproductive season; in still others the testicles are permanently located in the abdomen (for example, in whales and bats).

Within a firm and thick capsule of connective tissue, the tunica albuginea, the testis contains a varying number of thin but very long seminiferous tubules which are the sites of sperm formation. Essentially, these tubules are simple loops which open with both their limbs into a network of fine, slitlike canals, the rete testis. From this the sperm drains through a few, narrow ducts, the ductuli efferentes, into the epididymis, where sperm mature and are stored.

The seminiferous tubules comprise most of the testis, and in different species vary greatly in complexity. Each tubule is surrounded by a layer of thin cells which is contractile and enables the tubules to wriggle slowly. The spaces between tubules are filled with connective tissue, blood vessels, an extensive network of very thin-walled lymph vessels, and secretory cells, the interstitial cells or cells of Leydig, which secrete male hormone.

The sperm cells, spermatozoa, develop in the wall of the seminiferous tubules, either periodically, as in most vertebrates, or continually, as in humans. Most of the cells in the tubules are potential spermatozoa (spermatogenic or germ cells). Nursing cells (Sertoli cells) are interspersed at regular intervals between them. The Sertoli cells support and surround the developing spermatogenic cells and provide a specialized environment, which is absolutely necessary for normal sperm development. *See* SPERM CELL.

Spermatogenesis in the testis is the result of a balance between proliferation and differentiation, and cell degeneration or apoptosis. Apoptosis of the spermatogenic cells is largely hormonally controlled, and specifically directed apoptosis occurs in conditions of testicular damage due to environmental insults such as heat, radiation, or chemical toxicants. Recovery of spermatogenesis is possible provided the stem cells are not depleted by these processes. *See* SPERMATOGENESIS. [M.P.H.; E.C.R.R.]

The functions of the testis are dependent on the secretion of gonadotropic hormones, the release of which from the pituitary gland is in turn regulated by the central nervous system. In mammals, male-hormone production resides in the Leydig cells, located in the intertubular tissue of the testes.

The principal androgenic hormone released by the testis into the bloodstream is testosterone. The testis is able to form cholesterol and to convert this via a number of pathways to testosterone. Testosterone may be further metabolized into estrogens in the testis. The production of estrogens in the male varies quite widely among species, from relatively low in humans to very high, for example in stallions and boars. Estrogens are important in the development and proper function of the ducts which drain the testis (the rete testis and ductuli efferentes), even in species with relatively low levels of estrogens. *See* ANDROGEN.

Testosterone synthesis is normally limited by the rate of pituitary gonadotrophin secretion: administration of the luteinizing hormone or of chorionic gonadotrophin results in increased testosterone synthesis and release within minutes. These hormones also stimulate growth and multiplication of Leydig cells. Hypophysectomy leads to cessation of androgen formation. *See* ADENOHYPOPHYSIS HORMONE; PITUITARY GLAND.

At the ambisexual stage of embryonic development, the testis promotes the growth of the paired Wolffian ducts and their differentiation into the epididymis, vasa deferentia, and seminal vesicles; the fetal testis also causes masculinization of the urogenital sinus, fusion of the labioscrotal folds in the midline, and development of the genital tubercle into a phallus. *See* EMBRYOLOGY.

Toward puberty, increased secretion of testosterone stimulates the growth of the penis, scrotum, and male accessory glands responsible for the formation of the seminal plasma, for example, the prostate and seminal vesicles. The hormone brings about the appearance of secondary sex characters, such as the male-type distribution of hair and body fat and lowered pitch of voice in man, the growth of the comb and wattles in birds, the clasping pads of amphibians, or the dorsal spine of certain fishes.

Unlike the ovary, the testis remains functional throughout life, with ongoing spermatogenic development. However, the efficiency of spermatogenesis falls away, and androgen levels begin to fall due to a declining Leydig cell activity. These events can lead to reduced fertility, and androgen insufficiency problems in later life in some men. *See* REPRODUCTIVE SYSTEM. [M.P.H.; H.R.L.]

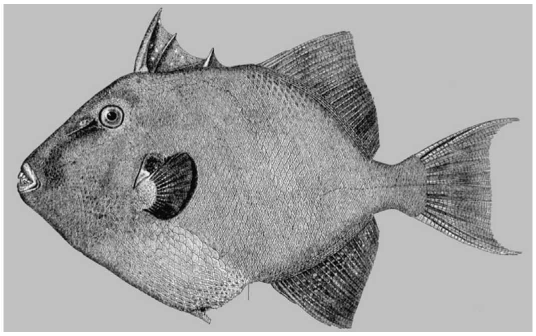
Tetanus An infectious disease, also known as lockjaw, which is caused by the toxin of *Clostridium tetani*. The bacterium may be isolated from fertile soil and the intestinal tract or fecal material of humans and other animals. Infection commonly follows dirt contamination of deep wounds or other injured tissues.

The incubation period of tetanus is usually 5–10 days, and the disease is characterized by convulsive tonic contraction of voluntary muscles. Prevention of tetanus rests on the proper, prompt surgical care of contaminated wounds and prophylactic use of antitoxin if the individual has not been protected by active immunization with toxoid. *See* IMMUNOLOGY. [L.S.McC.]

Tetrahedrite A mineral having the composition $(Cu,Fe,Zn,Ag)_{12}Sb_4S_{13}$. It is massive or granular. Its hardness is $3^1/_2$–4 on Mohs scale and the specific gravity varies from 4.6 to 5.1, depending on the composition. The luster is metallic and the color grayish black; thus, in some mining localities, this mineral is called gray copper.

Tetrahedrite is a widely distributed mineral, usually found in silver and copper veins. In some places it has sufficient silver to be a valuable ore, as at Freiberg, Germany, and silver mines of Peru, Bolivia, and Mexico. It is found in silver and copper mines in the western United States. [C.S.Hu.]

Tetraodontiformes An order of specialized teleost fishes, also called Plectognathi, that includes the triggerfishes (see illustration), puffers, trunkfishes, ocean sunfishes, and their allies. It is a group of diverse structure. The body is variably armored with bony plates or spines, encased in bone, prickly, thorny, or naked. Fin spines and some fins are variably well developed or wanting. Some species can inflate the body.



Gray triggerfish (*Batistes capriscus*). (*After G. B. Goode, Fishery Industries of the United States, sect. 1, 1884*)

Tetraodontiforms may be classified conservatively into 7 families, nearly 60 genera, and about 320 Recent species, but some specialists recognize more families and genera. Tetraodontiforms are largely reef and shore fishes of tropical or subtropical seas, but a few are pelagic, enter temperate waters, or ascend tropical rivers. Many are colorful inhabitants of coral reefs. Some are valued as food, but a few have a neurotoxic poison, tetrodotoxin, in the viscera that is sometimes fatal when eaten. *See* ACTINOPTERYGII. [R.M.B.]

Tetraphididae A subclass of the mosses (class Bryopsida) consisting of two families and three genera, especially characterized by growth from protonematal flaps, three-ranked leaves, and peristomes of four teeth made up of whole cells (rather than thickened parts of cells). The Tetraphididae include small acrocarpous mosses with peristome teeth in fours. The plants grow from buds produced on leaflike protonematal flaps. They are erect and simple or merely forked, with oblong-ovate leaves in three rows. The leaves usually have a single costa that ends near the apex. *See* BRYOPHYTA; BRYOPSIDA. [H.Cr.]

Tetraphyllidea An order of tapeworms of the subclass Cestoda. All species are intestinal parasites of elasmobranch fishes and are small in size, usually less than 2 in. (5 cm) in length. An outstanding feature of the order is the variation in the structure of the holdfast organ or scolex. All species are segmented and segments are usually shed from the body while sexually immature; these develop to sexual maturity as independent units in the host's intestine. Segment anatomy is very similar to that of Proteocephaloides. A complete life cycle is not known, but larval forms have been found in a variety of invertebrates and bony fishes. *See* CESTODA; PROTEOCEPHALOIDEA. [C.P.R.]

Tetrapoda The superclass of the subphylum Vertebrata whose members typically possess limbs in contrast to the superclass, the Pisces (fishes), whose members have fins. *See* PISCES (ZOOLOGY).

The animals making up the Tetrapoda typically live part or all of their lives on land, whereas the members of the Pisces live in water. The classes of the Tetrapoda are Amphibia, Reptilia, Aves, and Mammalia. The term Tetrapoda comes from Greek words meaning "four feet," but there are tetrapods that have only two limbs or none at all, such as some amphibians and reptiles. These forms have, however, evolved from four-footed ancestors. *See* AMPHIBIA; AVES; MAMMALIA; REPTILIA. [R.G.Z.]

Teuthoidea An order of the class Cephalopoda (subclass Coleoidea) commonly known as squids. They are characterized by 10 appendages (eight arms and two longer tentacles) around the mouth; an elongate, tapered, usually streamlined body; an internal, rod- or blade-like chitinous shell (gladius); and fins on the body. The two tentacles are strongly elastic, contractile, but not reactile into pockets as in cuttlefishes (Sepioidea). Two rows of suckers (infrequently four or six rows) occur on the arms on muscular stalks, with sucker rings that are chitinous, smooth, toothed, or modified as clawlike hooks. The muscular tentacles have terminal clubs with two rows, usually four, ranging up to many rows of suckers (and/or hooks in some families). Adults of the family Octopoteuthidae and genera *Gonatopsis* and *Lepidoteuthis* characteristically lose their tentacles. *See* SEPIOIDEA.

The Teuthoidea are divided into two suborders. The Myopsida, the nearshore, shallow-water squids, have a transparent skin (cornea) covering the two eyes, with a minute pore anteriorly, arms and tentacular clubs with suckers only, never hooks, and a single gonoduct in females, not paired. The Oegopsida, the oceanic squids, have no cornea over the eyes and no anterior pore, arms and tentacular clubs with suckers (and/or hooks in many families), and paired gonoducts in females (some exceptions).

Squids inhabit a wide variety of marine habitats, depending on the species, from very shallow grass flats, mangrove roots, lagoons, bays, and along coasts (myopsids) to the open ocean from the surface of the sea (*Ommastrephes*) to nearly 9600 ft (3000 m) in the deep sea (other oegopsids such as *Bathyteuthis*, *Neotheuthis*, and *Grimalditeuthis*). *See* CEPHALOPODA; COLEOIDA; SQUID. [C.F.E.R.]

Textile A material made mainly of natural or synthetic fibers. Modern textile products may be prepared from a number of combinations of fibers, yards, films, sheets, foams, furs, or leather. They are found in apparel, household and commercial furnishings, vehicles, and industrial products. *See* MANUFACTURED FIBER; NATURAL FIBER.

The term fabric may be defined as a thin, flexible material made of any combination of cloth, fiber, or polymer (film, sheet, or foams); cloth as a thin, flexible material made from yarns; yarn as a continuous strand of fibers; and fiber as a fine, rodlike object in which the length is greater than 100 times the diameter. The bulk of textile products are made from cloth.

The natural progression from raw material to finished product requires: the cultivation or manufacture of fibers; the twisting of fibers into yarns (spinning); the interlacing (weaving) or interlooping (knitting) of yarns into cloth; and the finishing of cloth prior to sale.

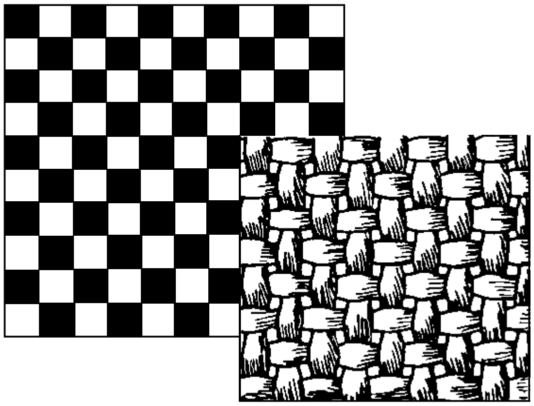


Fig. 1. Construction design for plain weave; filling yarns pass under and over alternate warp yarns, as shown at right. When fabric is closely constructed, there is no distinct pattern. (*After M. D. Potter and B. P. Corbman, Fiber to Fabric, 3d ed., McGraw-Hill, 1959*)

The conversion of staple fiber into yarn (spinning) requires the following steps: picking (sorting, cleaning, and blending), carding and combing (separating and aligning), drawing (reblending), drafting (reblended fibers are drawn out into a long strand), and spinning (drafted fibers are further attenuated and twisted into yarn).

The process of weaving allows a set of yarns running in the machine direction (warp) to be interlaced with another set of yarns running across the machine (filling or weft). The weaving process involves four functions: shedding (raising the warp yarns by means of the appropriate harnesses); picking (inserting the weft yarn); battening (pushing the weft into the cloth with a reed); and taking up and letting off (winding the woven cloth onto the cloth beam and releasing more warp yarn from the warp beam; Figs. 1 and 2).

Knit cloth is produced by interlocking one or more yarns through a series of loops. The lengthwise columns of loops are known as the wales, and the crosswise rows of loops are called courses. Filling (weft) knits (Fig. 3) are those in which the courses are composed of continuous yarns, while in warp knits (Fig. 4) the wale yarns are continuous.

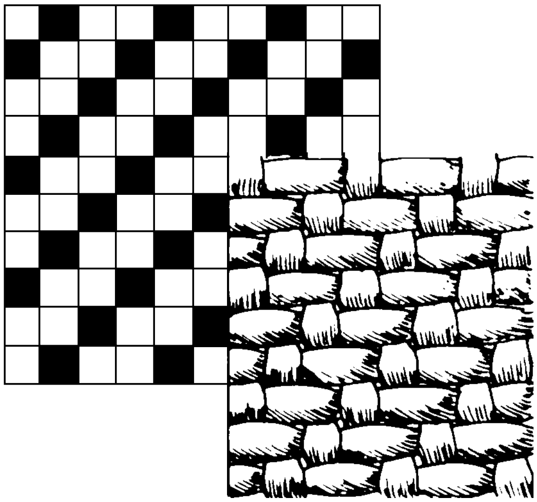

Fig. 2. Three-shaft twill. Two warp yarns are interlaced with one filling yarn. (*After M. D. Potter and B. P. Corbman, Fiber to Fabric, 3d ed., McGraw-Hill, 1959*)

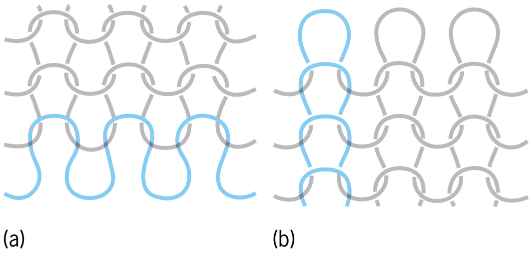

Fig. 3. Interlocking yarns of (*a*) course and (*b*) wale in a Jersey knit cloth. (*After B. P. Corbman, Fiber to Fabric, 5th ed., McGraw-Hill, 1975*)

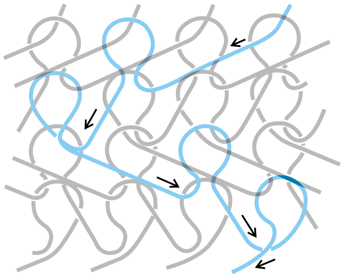

Fig. 4. Single-warp (one-bar) tricot knit. (*After B. P. Corbman, Fiber to Fabric, 5th ed., McGraw-Hill, 1975*)

Newly constructed knit or woven fabric must pass through various finishing processes to make it suitable for its intended purpose. Finishing enhances the appearance of fabric and also adds to its serviceability. Finishes can be solely mechanical, solely chemical, or a combination of the two. Those finishes, such as scouring and bleaching, which simply prepare the fabric for further use are known as general finishes. Functional finishes, such as durable press treatments, impart special characteristics to the cloth. For discussions of important finishing operations *see* Bleaching; Dyeing; Textile chemistry; Textile printing. [I.Bl.]

Textile chemistry The applied science of textile materials, consisting of the application of the principles of the many basic fields of chemistry to the understanding of textile materials and to their functional and esthetic modification into useful and desirable items. The study of textile chemistry begins with the knowledge of the textile fibers themselves. These are normally divided into three groups: natural, manufactured, and synthetic. *See* Manufactured fiber; Natural fiber; Textile.

Chemicals. The enormous number of chemicals used in textile processing may be divided broadly into two categories: those intended to remain on the fiber, and those intended to wet or clean the fiber or otherwise function in some related operation. The former includes primarily dyes and finishes. The latter group consists mainly of surface-active agents, commonly known as surfactants. *See* Surfactant.

Preparation. Preparation is a term applied to a group of essentially wet chemical processes having as their object the removal of all foreign matter from the fabric. This results in a clean, absorbent substrate, ready for the subsequent coloring and finishing operations.

The operations constituting preparation depend primarily on the fibers being handled. Synthetic fibers contain little or no natural impurities, so that the only materials that normally must be removed are the oils and lubricants or water-soluble sizes needed to facilitate earlier processing. This is generally accomplished by washing with water and a mild detergent capable of emulsifying the oils and waxes. On the other hand, natural fibers contain relatively high amounts of natural impurities, and in addition frequently are sized with materials presenting difficulties in removal. In the case of cotton, prolonged hot treatment with alkali, usually sodium hydroxide, and strong detergent is necessary to break down and remove the naturally occurring impurities. Special scours are necessary for cleaning such materials as wool and silk. The protein fibers are very sensitive to alkali and strong detergents; they are usually washed with mild soap or sulfated alcohols.

After other impurities are removed from the fiber, it is usually desirable to remove any coloring material. This process is known as bleaching. By far the major bleaching agent in use is hydrogen peroxide, which is efficient in color removal, while still being considered relatively controllable and safe for use. *See* Bleaching; Hydrogen peroxide.

Mercerization. Mercerization is a special process applied only to cotton. The fabric or yarn is treated with a strong sodium hydroxide solution while being held under tension. This process causes chemical and physical changes within the fiber itself, resulting in a substantial increase in luster and smoothness of the fabric, plus important improvements in dye affinity, stabilization, tensile strength, and chemical reactivity.

Coloring. Although many textiles reach the consumer in their natural color or as a bleached white, most textiles are colored in one way or another. Coloring may be accomplished either by dyeing or printing, and the coloring materials may be either dyes or pigments.

Dyeing essentially consists of immersing the entire fabric in the solution, so that the whole fabric becomes colored. On the other hand, printing may be considered as localized dyeing. In printing, a thickened solution of dyestuff or pigment is used. This thickened solution, or paste, is applied to specific areas of the fabric by means such as engraved rollers or partially porous screens. Application of steam or heat then causes the dyestuff to migrate from the dried paste into the interior of the fiber, but only in those specific areas where it has been originally applied. *See* Dye; Dyeing; Textile printing.

Finishing. Finishing includes a group of mechanical and chemical operations which give the fabric its ultimate feel and performance characteristics. Many desirable characteristics may be imparted to the fabric through the application of various chemical agents at this point.

Softeners are used to give a desirable hand or feel to the fabric. These chemicals are generally long fatty chains, with solubilizing groups which may be cationic, nonionic, or occasionally anionic in character. They are essentially surfactants constructed so as to contain a relatively high proportion of fatty material in the molecule. Conversely, certain types of polymeric material such as polyvinyl acetate or polymerized urea formaldehyde resins are used to impart a stiff or crisp hand to a fabric. *See* Polyvinyl resins; Urea-formaldehyde-type resins.

It is in finishing that the so-called proof finishes are applied, including fire-retardant and water-repellent finishes. A fire-retardant finish is a chemical or mixture containing a high proportion of phosphorus, nitrogen, chlorine, antimony, or bromine. A truly waterproof fabric may be made by coating with rubber or vinyl, but water-repellent fabrics are produced by treating with hydrophobic materials such as waxes, silicones, or metallic soaps.

Many other types of highly specialized treatments, such as antistatic, antibacterial, or soil-repellent finishes, may be applied to fit the fabric to a particular use. [D.H.A.]

Textile microbiology That branch of industrial microbiology concerned with textile materials. Most of the microorganisms on textiles—the fungi, actinomycetes, and bacteria—originate from air, soil, and water. Some of the microorganisms are harmful to either the fibers or the consumer. They may decompose the cellulose or protein in the fiber or affect the consumer's health. Since the minimum moisture content for microorganism development is 7%, dry storage is an effective prevention measure. Some of the microorganisms are useful, for example in the retting process, in which fibers are liberated from the stalks of such fiber plants as flax, hemp, and jute.

In principle, retting consists of a breaking down of pectic substances between the cell walls (middle lamellae) of the individual cells of the tissue surrounding the bundles. As a result, the bundles become separated from the surrounding tissue and can then easily be extracted mechanically. In water retting, the stalks are immersed in cold or warm, slowly renewed water, for from 4 days to several weeks. The active organism is *Clostridium felsineum* and related types, which break down the pectin to a mixture of organic acids (chiefly acetic and butyric), alcohols (butanol, ethanol, and methanol), carbon dioxide (CO_2), and hydrogen (H_2). In dew retting the stems are spread out in moist meadows; here the pectin decomposition is accomplished by molds and aerobic bacteria with the formation of CO_2 and H_2O. *See* INDUSTRIAL MICROBIOLOGY; TEXTILE CHEMISTRY. [A.N.J.H.]

Textile printing The localized application of color on fabrics. In printing textiles, a thick paste of dye or pigment is applied to the fabric by appropriate mechanical means to form a design. The olor is then fixed or transferred from the paste to the fiber itself, maintaining the sharpness and integrity of the design. In a multicolor design, each color must be applied separately and in proper position relative to all other colors. Printing is one of the most complex of all textile operations. *See* DYE.

A design may be applied in three major ways: raising the design in relief on a flat surface (block printing); cutting the design below a flat surface (intaglio or engraved printing); and cutting the design through a flat metal or paper sheet (stencil or screen printing). All three methods have been used for hand printing and reciprocating printing machines. In addition, these methods have been converted into rotary action by replacing blocks or plates with cylinders. Another method of printing utilizes individual computer-controlled nozzles for each color. The nozzles are used to paint a design on the fabric.

Each printing method requires a paste with special characteristics, frequently referred to as flow characteristics. The choice of thickener is dependent not only on the type of dyestuff, but on the type of printing machine on which the printing is to be done, and frequently also on the type of fixation to be used. Most natural thickening agents are based on combinations of starch and gum. The synthetic thickening agents used are generally extremely high-molecular-weight polymers capable of developing a very high viscosity at a relatively low concentration.

The first step is the preparation of print paste, which is made by dissolving the dyestuff and combining it with a solution of the appropriate thickening agent. The fabric is then printed by any of the standard methods and then dried in order to retain a sharp printed mark.

The next operation, steaming, may be likened to a dyeing operation. Before steaming, the bulk of the dyestuff is held in a dried film of thickening agent. During the steaming operation, the printed areas absorb moisture and form a very concentrated dyebath, from which dyeing of the fiber takes place. The thickening agent prevents the dyestuff from spreading outside the area originally printed, because the printed areas act as a concentrated dyebath that exists more in the form of a gel than a solution and restricts any tendency to bleed.

Printed goods are generally washed thoroughly to remove thickening agent, chemicals, and unfixed dyestuff. Drying of the washed goods is the final operation of printing. *See* TEXTILE CHEMISTRY. [D.H.A.]

Thaliacea A small class of pelagic Tunicata especially abundant in warmer seas. This class of animals contains three orders: the Salpida, Doliolida, and Pyrosomida. Oral and atrial apertures occur at opposite ends of the body. Members of the orders Salpida and Doliolida are transparent forms, partly or wholly ringed by muscular bands. The contractions of these bands produce currents used in propulsion, feeding, and respiration. The order Pyrosomida includes species which form tubular swimming colonies and which are often highly luminescent. *See* BIOLUMINESCENCE; TUNICATA. [D.P.A.]

Thallium A chemical element, Tl, atomic number 81, relative atomic weight of 204.37. The valence electron notation corresponding to its ground state term is $6s^2 6p^1$, which accounts for the maximum oxidation state of III in its compounds. Compounds of oxidation state I and apparent oxidation state II are also known. *See* PERIODIC TABLE.

Thallium occurs in the Earth's crust to the extent of 0.00006%, mainly as a minor constituent in iron, copper, sulfide, and selenide ores. Minerals of thallium are considered rare. Thallium compounds are extremely toxic to humans and other forms of life.

The insolubility of thallium(I) chloride, bromide, and iodide permits their preparation by direct precipitation from aqueous solution; the fluoride, on the other hand, is water-soluble. Thallium(I) chloride resembles silver chloride in its photosensitivity.

Thallium(I) oxide is a black powder which reacts with water to give a solution from which yellow thallium hydroxide can be crystallized. The hydroxide is a strong base and will take up carbon dioxide from the atmosphere.

Thallium also forms organometallic compounds of the following general classes, R_3Tl, R_2TlX, and $RTlX_2$, where R may be an alkyl or aryl group and X a halogen. *See* ORGANOMETALLIC COMPOUND. [E.M.L.]

Thallobionta One of the two commonly recognized subkingdoms of plants, encompassing the euglenoids and various classes of algae. In contrast to the more closely knit subkingdom Embryobionta, the Thallobionta (often also called Thallophyta) are diverse in pigmentation, food reserves, cell-wall structure, and flagellar structure. The Thallobionta are united more by the absence of certain specialized tissues or organs than by positive resemblances. They do not have the multicellular sex organs commonly found in most divisions of Embryobionta. Many of the Thallobionta are unicellular, and those which are multicellular seldom have much differentiation of tissues. None of them has tissues comparable to the xylem found in most divisions of the Embryobionta, and only some of the brown algae have tissues comparable to the phloem found in most divisions of the Embryobionta.

A large proportion of the Thallobionta are aquatic, and those which grow on dry land seldom reach appreciable size. The Thallobionta thus consist of all those plants which have not developed the special features that mark the progressive adaptation of the Embryobionta to life on dry land. *See* CHLOROPHYCOTA; CHRYSOPHYCEAE; EMBRYOBIONTA; EUGLENOPHYCEAE; PHAEOPHYCEAE; PLANT KINGDOM; RHODOPHYCEAE. [A.Cr.]

Theales An order of flowering plants, division Magnoliophyta (Angiospermae), in the subclass Dilleniidae of the class Magnoliopsida (dicotyledons). The order consists of 18 families and nearly 3500 species. The largest families are the Clusiaceae, sometimes called Guttiferae (about 1200 species), Theaceae (about 600 species), Dipterocarpaceae (about 600 species), and Ochnaceae (about 400 species). They are mostly woody plants, less often herbaceous, with simple or occasionally compound leaves. The perianth and stamens of the flowers are attached directly to the receptacle; the calyx is arranged in a tight spiral; and the petals are usually separate from each other (see illustration). The stamens are numerous and initiated in centrifugal sequence or, less often, are few and cyclic; the pollen is nearly always binucleate. The tea plant (*Thea sinensis*), *Camellia* (in the

Franklin tree (*Franklinia alatamaha*) flowers, a characteristic member of the family Theaceae in the order Theales, named in honor of Benjamin Franklin. (*Photograph by A. W. Ambler, from National Audubon Society*)

Theaceae), and St.-John's-wort (*Hypericum*, in the Clusiaceae) are familiar members of the Theales. *See* DILLENIIDAE; FLOWER; MAGNOLIOPHYTA; PLANT KINGDOM; TEA. [A.Cr.; T.M.Ba.]

Thecanephria An order of Pogonophora, a group of elongate, tentaculated, tube-dwelling, sedentary, nonparasitic marine worms lacking a digestive system. In this order the "coelomic" space in the anterior tentacular region is horse-shoe-shaped, and the excretory (osmoregulatory) portion of its ducts come close together medially near the median, adneural blood vessel. The species in this order are multitentaculate.

The order includes four families: Polybrachiidae (with seven genera), Sclerolinidae (one genus), Lamellisabellidae (two genera), and Spirobrachiidae (one genus). *See* ATHECANEPHRIA; POGONOPHORA. [E.B.Cu.]

Thelodontida Sometimes called Coelolepida, this is an extinct group of Agnatha or jawless vertebrates known from the Lower Silurian to Middle Devonian of Europe, Asia, Australia, and North America. Since they had no hard skeleton, their structure and relationships are poorly known. Well-preserved specimens of *Logania* suggest a relationship to Heterostraci in their widely spaced, lateral eyes, nearly terminal mouth, pectoral flaps at the posterior end of the head, and hypocercal tail with a downwardly directed main lobe. *Phlebolepis* resembles Anaspida in general form but lacks the dorsal nostril of that group. *See* AGNATHA; HETEROSTRACI; OSTEOSTRACI; PTERASPIDOMORPHA. [R.H.De.]

Theorem A proposition arrived at by the methods of logical deduction from a set of basic postulates or axioms accepted as primitive and therefore not subject to deductive proof. So long as a theorem is part of a purely formal system, it is not meaningful to speak about the "truth" of a theorem but only about its "correctness." It becomes true when it, or its consequences, can be shown to be in accord with observable facts. *See* LOGIC. [P.W.Br./H.Ma.]

Theoretical ecology The use of models to explain patterns, suggest experiments, or make predictions in ecology. Because ecological systems are idiosyncratic, extremely complex, and variable, ecological theory faces special challenges. Unlike physics or genetics, which use fundamental laws of gravity or of inheritance, ecology has no widely accepted first-principle laws. Instead, different theories must be invoked for different questions, and the theoretical approaches are enormously varied. A central problem in ecological theory is determining what type of model to use and what to leave out of a model. The traditional approaches have relied on analytical models based on differential or difference equations; but recently the use of computer simulation has greatly increased. *See* ECOLOGICAL MODELING; ECOLOGY; ECOLOGY, APPLIED; SIMULATION.

The nature of ecological theory varies depending on the level of ecological organization on which the theory focuses. The primary levels of ecological organization are (1) physiological and biomechanical, (2) evolutionary (especially applied to behavior), (3) population, and (4) community.

At the physiological and biomechanical level, the goals of ecological theory are to understand why particular structures are present and how they work. The approaches of fluid dynamics and even civil engineering have been applied to understanding the structures of organisms, ranging from structures that allow marine organisms to feed, to physical constraints on the stems of plants.

At the behavioral evolutionary level, the goals of ecological theory are to explain and predict the different choices that individual organisms make. Underlying much of this theory is an assumption of optimality: the theories assume that evolution produces an optimal behavior, and they attempt to determine the characteristics of the optimal behavior so it can be compared with observed behavior. One area with well-developed theory is foraging behavior (where and how animals choose to feed). Another example is the use of game theory to understand the evolution of behaviors that are apparently not optimal for an individual but may instead be better for a group. *See* BEHAVIORAL ECOLOGY; GAME THEORY; OPTIMIZATION.

The population level has the longest history of ecological theory and perhaps the broadest application. The simplest models of single-species populations ignore differences among individuals and assume that the birth rates and death rates are proportional to the number of individuals in the population. If this is the case, the rate of growth is exponential, a result that goes back at least as far as Malthus's work in the 1700s. As Malthus recognized, this result produces a dilemma: exponential growth cannot continue unabated. Thus, one of the central goals of population ecology theory is to determine the forces and ecological factors that prevent exponential growth and to understand the consequences for the dynamics of ecological populations. *See* ECOLOGICAL METHODS; POPULATION ECOLOGY.

Modifications and extensions of theoretical approaches like the logistic model (which uses differential equations to explain the stability of populations) have also been used to guide the management of renewable natural resources. Here, the most basic concept is that of the maximum sustainable yield, which is the greatest level of harvest at which a population can continue to persist. *See* ADAPTIVE MANAGEMENT; MATHEMATICAL ECOLOGY.

The primary goal of ecological theory at the community level is to understand diversity at local and regional scales. Recent work has emphasized that a great deal of diversity in communities may depend on trade-offs. For example, a trade-off between competitive prowess and colonization ability is capable of explaining why so many plants persist in North American prairies. Another major concept in community theory is the role of disturbance. Understanding how disturbances (such as fires, hurricanes, or wind storms) impacts communities is crucial because humans typically alter disturbance. *See* BIODIVERSITY; ECOLOGICAL COMMUNITIES. [A.Has.]

Theoretical physics The description of natural phenomena in mathematical form. It is impossible to separate theoretical physics from experimental physics, since a complete understanding of nature can be obtained only by the application of both theory and experiment. There are two main purposes of theoretical physics: the discovery of the fundamental laws of nature and the derivation of conclusions from these fundamental laws.

Physicists aim to reduce the number of laws to a minimum to have as far as possible a unified theory. When the laws are known, it is possible from any given initial conditions of a physical system to derive the subsequent events in the system. Sometimes, especially in quantum theory, only the probability of various events can be predicted. *See* DETERMINISM; QUANTUM MECHANICS.

The conclusions to be derived from the fundamental laws of nature may be of several different types.

1. Conclusions may be derived in order to test a given theory, particularly a new theory. An example is the derivation of the spectrum of the hydrogen atom from quantum mechanics; the verification of the predictions by accurate measurements is a good test of quantum mechanics. On rather rare occasions an experiment has been found to contradict the predictions of an existing theory, and this has then led to the discovery of important new physical laws. An example is the Michelson-Morley experiment on the constancy of the velocity of light, an experiment which led to special relativity theory. *See* ATOMIC STRUCTURE AND SPECTRA; LIGHT; RELATIVITY.
2. Theory may be required for experiments designed to determine physical constants. Most fundamental physical constants cannot be accurately measured directly. Elaborate theories may be required to deduce the constant from indirect experiments. *See* FUNDAMENTAL CONSTANTS.
3. Predictions of physical phenomena may be made in order to gain understanding of the structure of the physical world. In this category fall theories of the structure of the atom leading to an understanding of the periodic system of elements, or of the structure of the nucleus in which various models are tested (for example, shell model or collective model). In the same category fall applications of theoretical physics to other sciences, for example, to chemistry (theory of the chemical bond and of the rate of chemical reactions), astronomy (theory of planetary motion, internal constitution, and energy production of stars), or biology.
4. Engineering applications may be drawn from fundamental laws. All of engineering may be considered an application of physics, and much of it is an application of mathematical physics, such as elasticity theory, aerodynamics, electricity, and magnetism. The generation and propagation of radio waves of all frequencies are examples of application of theoretical physics to direct practice. *See* AERODYNAMICS; ELASTICITY; ELECTRICITY; MAGNETISM; RADIO-WAVE PROPAGATION.

Apart from the classification of the fields of theoretical physics according to purpose, a classification can also be made according to content. Here one may perhaps distinguish three classification principles: type of force, scale of physical phenomena, and type of phenomena. *See* MATHEMATICAL PHYSICS; PHYSICS.

[H.A.Be.]

Therapsida

An order of Reptilia, subclass Synapsida, often called advanced mammallike reptiles, that flourished from the middle Permian through the Late Triassic. The group is highly diverse and subdivided into six suborders. Two of these, Eotitanosuchia and Dinocephalia, include relatively primitive mid-Permian carnivores and herbivores. A third, the Dicynodontia, made up of small to large herbivores, was abundant in the late Permian. Dicynodonts were associated with two carnivorous suborders, the Therocephalia and Gorgonopsia, which are morphologically intermediate between Eotitanosuchia and the cynodonts. Although these five developing lines are distinct, the skulls and skeletons in each became increasingly mammallike.

The trend continued among the highly diverse Cynodontia. This suborder includes a variety of carnivores, omnivores, and herbivores. The most highly derived herbivorous cynodonts were the tritylodonts of the Late Triassic and Early Jurassic. They were very mammallike.

Climatic changes during the Triassic rather than direct competition largely accounted for the decline of the therapsids and the rapid expansion of the Archosauria. Only the very mammallike therapsids, the herbivorous tritylodonts, and the minute derived first mammals survived into the Early Jurassic. *See* ARCHOSAURIA; MAMMALIA; REPTILIA; SYNAPSIDA.

[E.C.O.]

Theria

One of the four subclasses of the class Mammalia, including all living mammals except the monotremes. The Theria were by far the most successful of the several mammalian stocks that arose from the mammallike reptiles in the Triassic. The subclass is divided into three infraclasses: Pantotheria (no living survivors), Metatheria (marsupials), and Eutheria (placentals). Therian mammals are characterized by the distinctive structural history of the molar teeth. The fossil record shows that all the extremely varied therian molar types were derived from a common tribosphenic type in which three main cusps, arranged in a triangle on the upper molar, are opposed to a reversed triangle and basinlike heel on the lower molar. *See* MAMMALIA; THERAPSIDA.

[D.D.D./F.S.S.]

Thermal analysis

A group of analytical techniques developed to continuously monitor physical or chemical changes of a sample which occur as the temperature of a sample is increased or decreased. Thermogravimetry, differential thermal analysis, and differential scanning calorimetry are the three principal thermoanalytical methods. *See* ANALYTICAL CHEMISTRY; COMPUTER; THERMOCHEMISTRY.

The occurrence of physical or chemical changes upon heating a sample may be explained from either a kinetic or thermodynamic viewpoint. Kinetically the rate of a process may be increased by raising the temperature as shown by the Arrhenius equation (1), where A, E_a, and R represent the preexponential

$$\text{Rate} = Ae^{-E_a/RT} \tag{1}$$

factor, activation energy, and the gas law constant, respectively. At some point the rate becomes significant and readily observable. Similarly an increase in temperature can change the Gibbs free energy [Eq. (2), where ΔG° is the Gibbs free energy, ΔH°

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ \tag{2}$$

is the reaction enthalpy, and ΔS° is the entropy change for the process] to a more favorable (that is, more negative) value. In particular, ΔG° will become more negative if ΔS° is positive and the temperature is increased. In many cases a combination of these factors causes the observed physiochemical process. *See* CHEMICAL THERMODYNAMICS; KINETICS (CLASSICAL MECHANICS).

Thermogravimetry involves measuring the changes in mass of a substance, typically a solid, as it is heated. Specially designed thermobalances are required to continuously monitor sample mass during the heating process. Modern balances have a capacity of 1–1500 milligrams and can accurately detect mass changes of 0.1 microgram.

Any type of physiochemical process which involves a change in sample mass may be observed by using thermogravimetry. Mass losses are observed for dehydration, decomposition, desorption, vaporization, sublimation, pyrolysis, and chemical reactions with gaseous products. Mass increases are noted with adsorption, absorption, and chemical reactions of the sample with the atmosphere in the oven, such as the oxidation of metals.

Quantitative gravimetric analyses may be performed due to the precise measure of the mass change obtained. Rates of mass change have been used to evaluate the kinetics of a process and to estimate activation energies. Fine details of these thermograms may also be used to deduce reaction intermediates and reaction mechanisms.

Primary applications of thermogravimetry are to deduce stabilities of compounds and mixtures of elevated temperatures and to determine appropriate drying temperatures for compounds and mixtures. Evaluation of polymers, food products, and pharmaceuticals is a major application of thermogravimetry.

Differential thermal analysis involves the monitoring of the temperature difference T_D between a sample and inert reference material (such as aluminum oxide) as they are simultaneously heated, or cooled, at a predetermined rate. Multijunction thermocouples and thermistors are the most common temperature sensors used for this purpose; they are arranged in an oven. As enthalpic changes occur, T_D will be positive if the process is exothermic and negative if it is endothermic.

More physical and chemical processes may be observed using differential thermal analysis as compared to thermogravimetry. Endothermic physical processes include crystalline transitions, fusion, vaporization, sublimation, desorption, and adsorption. Endothermic physical processes include crystalline transitions, fusion, vaporization, sublimation, desorption, and adsorption. Endothermic chemical processes include dehydration, decomposition, gaseous reduction, redox reactions, and solid-state metathesis. Exothermic processes include adsorption, chemisorption, decomposition, oxidation, redox reactions, and solid-state metathesis reactions. Both solids and liquids can be studied by differential thermal analysis. Hermetically sealed capsules are often used for liquids and some solids. Other samples are studied in open or crimped pans.

Analytical applications of this technique include the identification, characterization, and quantitation of a wide variety of materials, including polymers, pharmaceuticals, metals, clays, minerals, and inorganic and organic compounds. Characteristic thermograms can be used to determine purity, heats of reaction, thermal stability, phase diagrams, catalytic properties, and radiation damage.

In differential scanning calorimetry a sample and a reference are individually heated, by separately controlled resistance heaters, at a predetermined rate. Enthalpic (heat-generating or -absorbing) processes are detected as differences in electrical energy supplied to either the sample or the reference material to maintain this heating rate. This difference in electrical energy, in milliwatts per second, of the heat flow into or out of the sample is due to the occurrence of a physical or chemical process. Modulated differential scanning calorimetry is a new method that superimposes a sine wave on the heating ramp. A significant increase in sensitivity is often observed with modulated differential scanning calorimetry.

Analytical uses of differential scanning calorimetry are very similar to those of differential thermal analysis. Usually one calibration standard is sufficient to calibrate the entire operating range of the instrument. Differential scanning calorimetry instruments are highly sensitive and may measure heat flows as small as 1 nanowatt. Differential scanning calorimetry is very useful in determining heat capacities of substances over large temperature ranges. Such evaluation has become important in polymer and biochemical studies. Small (approximately 1–10 mg) samples are used in most cases, although some instruments have been developed which use up to 1 ml of a liquid sample. *See* CALORIMETRY. [N.D.J.]

Thermal conduction in solids Thermal conduction in a solid is generally measured by stating the thermal conductivity K, which is the ratio of the steady-state heat flow (heat transfer per unit area per unit time) along a long rod to the temperature gradient along the rod. Thermal conductivity varies widely among different types of solids, and depends markedly on temperature and on the purity and physical state of the solids, particularly at low temperatures.

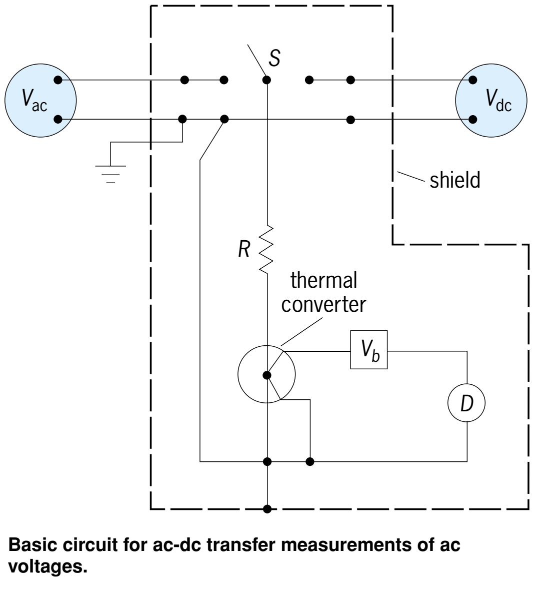
From the kinetic theory of gases the thermal conductivity can be written as $K =$ (constant) Svl, where S is the specific heat per unit volume, v is the average particle velocity, and l is the mean free path. In solids, thermal conduction results from conduction by lattice vibrations and from conduction by electrons. In insulating materials, the conduction is by lattice waves; in pure metals, the lattice contribution is negligible and the heat conduction is primarily due to electrons. In many alloys, impure metals, and semiconductors, both conduction mechanisms contribute. *See* CONDUCTION (HEAT); KINETIC THEORY OF MATTER; LATTICE VIBRATIONS; SPECIFIC HEAT.

In superconductors at temperatures below the critical temperature, the electronic conduction is reduced; at sufficiently low temperatures, the thermal conductivity becomes entirely due to lattice waves and is similar to the form of the thermal conductivity of an insulating material. *See* SUPERCONDUCTIVITY. [K.A.McC.]

Thermal converters Devices consisting of a conductor heated by an electric current, with one or more hot junctions of a thermocouple attached to it, so that the output emf responds to the temperature rise, and hence the current. Thermal converters are used with external resistors for alternating-current (ac) and voltage measurements over wide ranges and generally form the basis for calibration of ac voltmeters and the ac ranges of instruments providing known voltages and currents.

In the most common form, the conductor is a thin straight wire less than 0.4 in. (1 cm) long, in an evacuated glass bulb, with a single thermocouple junction fastened to the midpoint by a tiny electrically insulating bead. Thermal inertia keeps the temperature of the heater wire constant at frequencies above a few hertz, so that the constant-output emf is a true measure of the root-mean-square (rms) heating value of the current. The reactance of the short wire is so small that the emf can be independent of frequency up to 10 MHz or more. An emf of 10 mV can be obtained at a rated current less than 5 mA, so that resistors of reasonable power dissipation, in series or in shunt with the heater, can provide voltage ranges up to 1000 V and current ranges up to 20 A. However, the flow of heat energy cannot be controlled precisely, so the temperature, and hence the emf, generally changes with time and other factors. Thus an ordinary thermocouple instrument, consisting of a thermal converter and a millivoltmeter to measure the emf, is accurate only to about 1–3%. *See* THERMOCOUPLE; VOLTMETER.

To overcome this, a thermal converter is normally used as an ac-dc transfer instrument (ac-dc comparator) to measure an unknown alternating current or voltage by comparison with a known nearly equal dc quantity (see illustration). By replacing the millivoltmeter with an adjustable, stable, opposing voltage V_b in series with a microvoltmeter D, very small changes in emf can be detected. The switch S is connected to the unknown ac voltage V_{ac}, and V_b is adjusted for a null (zero) reading of D. Then S is immediately connected to the dc voltage V_{dc}, which is



Basic circuit for ac-dc transfer measurements of ac voltages.

adjusted to give a null again, without changing V_b. Thus $V_{ac} = V_{dc}(1 + d)$, where d is the ac-dc difference of the transfer instrument, which can be as small as a few parts per million (ppm).

In many commercial instruments, all of the components are conveniently packaged in the shield, shown with a broken line, and several ranges are available by taps on R. Accuracies of 0.001% are attainable at audio frequencies. *See* Electrical measurement. [F.L.H.; J.R.K.]

Thermal ecology The examination of the independent and interactive biotic and abiotic components of naturally heated environments. Geothermal habitats are present from sea level to the tops of volcanoes and occur as fumaroles, geysers, and hot springs. Hot springs typically possess source pools with overflow, or thermal, streams (rheotherms) or without such streams (limnotherms). Hot spring habitats have existed since life began on Earth, permitting the gradual introduction and evolution of species and communities adapted to each other and to high temperatures. Other geothermal habitats do not have distinct communities.

Hot-spring pools and streams, typified by temperatures higher than the mean annual temperature of the air at the same locality and by benthic mats of various colors, are found on all continents except Antarctica. They are located in regions of geologic activity where meteoric water circulates deep enough to become heated. The greatest densities occur in Yellowstone National Park (Northwest United States), Iceland, and New Zealand. Source waters range from 40°C (104°F) to boiling (around 100°C or 212°F depending on elevation), and may even be superheated at the point of emergence. Few hot springs have pH 5–6; most are either acidic (pH 2–4) or alkaline (pH 7–9). [C.Wi.]

Thermal expansion Solids, liquids, and gases all exhibit dimensional changes for changes in temperature while pressure is held constant. The molecular mechanisms at work and the methods of data presentation are quite different for the three cases.

The temperature coefficient of linear expansion α_l is defined by Eq. (1), where l is the length of the specimen, t is the temperature, and p is the pressure.

$$\alpha_l = \frac{1}{l}\left(\frac{\partial l}{\partial t}\right)_{p=\text{const}} \qquad (1)$$

For each solid there is a Debye characteristic temperature Θ, below which α_l is strongly dependent upon temperature and above which α_l is practically constant. Many common substances are near or above Θ at room temperature and follow approximate equation (2), where l_0 is the length at 0°C and t is the temperature in °C.

$$l = l_0(1 + \alpha_l t) \qquad (2)$$

The total change in length from absolute zero to the melting point has a range of approximately 2% for most substances.

So-called perfect gases follow the relation in Eq. (3), where p is absolute pressure, v is specific volume, T is absolute temperature, and R is the so-called gas constant.

$$\frac{pv}{T} = \frac{R}{\text{molecular weight}} \qquad (3)$$

Real gases often follow this equation closely. *See* Gas constant.

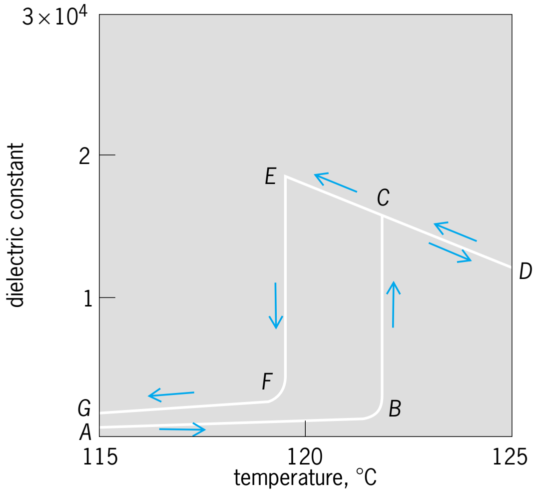
The coefficient of cubic expansion α_v is defined by Eq. (4), and for a perfect gas this is found to be $1/T$.

$$\alpha_v = \frac{1}{v}\left(\frac{\partial v}{\partial t}\right)_{p=\text{const}} \qquad (4)$$

The behavior of real gases is largely accounted for by the van der Waals equation. *See* Gas; Kinetic theory of matter.

For liquids, α_v is somewhat a function of pressure but is largely determined by temperature. Though α_v may often be taken as constant over a sizable range of temperature (as in the liquid expansion thermometer), generally some variation must be accounted for. For example, water contracts with temperature rise from 32 to 39°F (0 to 4°C), above which it expands at an increasing rate. *See* Thermometer. [R.A.Bu.]

Thermal hysteresis A phenomenon in which a physical quantity depends not only on the temperature but also on the preceding thermal history. It is usual to compare the behavior of the physical quantity while heating and the behavior while cooling through the same temperature range. The illustration shows the thermal hysteresis which has been observed in the behavior of the dielectric constant of single crystals of barium titanate. On heating, the dielectric constant was observed to follow the path *ABCD*, and on cooling the path *DCEFG*. *See* Dielectric constant; Ferroelectrics.



Plot of dielectric constant versus temperature for a single crystal of barium titanate. (*After M. E. Drougard and D. R. Young, Phys. Rev., 95:1152–1153, 1954*)

Perhaps the most common example of thermal hysteresis involves a phase change such as solidification from the liquid phase. In many cases these liquids can be dramatically supercooled. Elaborate precautions to eliminate impurities and outside disturbances can be instrumental in supercooling 60 to 80°C. On raising the temperature after freezing, however, the system follows a completely different path, with melting coming at the prescribed temperature for the phase change. *See* Crystal; Nucleation; Phase transitions. [H.B.H.; R.K.Mac.C.]

Thermal neutrons Neutrons whose energy distribution is governed primarily by the kinetic energy distribution of molecules of the material in which the neutrons are found. *See* Neutron.

The molecules of the material usually have a kinetic energy distribution very close to a Maxwell-Boltzmann distribution. This distribution shows a peak at an energy equal to half the product of the temperature and the Boltzmann constant. At high energies it decreases exponentially, and at low energies it is proportional to the square root of the energy. When the material is large and very weakly absorbing, the neutron energy distribution closely approaches this maxwellian. *See* Boltzmann statistics; Kinetic theory of matter.

The most common way of generating thermal neutrons is to allow neutrons from a source—reactor, accelerator, or spontaneous fission neutron emitter—to diffuse outward through a large block or tank of very weakly absorbing moderator. *See* Reactor physics. [B.I.S.]

Thermal stress Mechanical stress induced in a body when some or all of its parts are not free to expand or contract in response to changes in temperature. In most continuous bodies, thermal expansion or contraction cannot occur freely in all directions because of geometry, external constraints, or the existence of temperature gradients, and so stresses are produced. Such stresses caused by a temperature change are known as thermal stresses.

Problems of thermal stress arise in many practical design problems, such as those encountered in the design of steam and gas turbines, diesel engines, jet engines, rocket motors, and nuclear reactors. The high aerodynamic heating rates associated with high-speed flight present even more severe thermal-stress problems for the design of spacecraft and missiles. *See* STRESS AND STRAIN. [S.-Y.C.]

Thermal wind The difference in the geostrophic wind between two heights in the atmosphere over a given position on Earth. It approximates the variation of the actual winds with height for large-scale and slowly changing motions of the atmosphere. Such structure in the wind field is of fundamental importance to the description of the atmosphere and to processes causing its day-to-day changes. The thermal wind embodies a basic relationship between vertical fluctuations of the horizontal wind and horizontal temperature gradients in the atmosphere. This relationship arises from the combination of the geostrophic wind law, the hydrostatic equation, and the gas law.

The geostrophic wind law applies directly to steady, straight, and unaccelerated horizontal motion and is a good approximation for large-scale and slowly changing motions in the atmosphere. The hydrostatic equation combined with the gas law relates the atmospheric pressure and temperature fields. The relationship is accurate for most atmospheric situations but not for small-scale and rapidly changing conditions such as in turbulence and thunderstorms. The equation gives the change of pressure in the vertical direction as a function of pressure and temperature. The key conclusion is that at a given level in the atmosphere the pressure change (decrease) with height is more rapid in cold air than in warm air. *See* ATMOSPHERE; GEOSTROPHIC WIND; HYDROSTATICS; TROPOSPHERE. [D.D.H.]

Thermionic emission The emission of electrons into vacuum by a heated electronic conductor. In its broadest meaning, thermionic emission includes the emission of ions, but this process is quite different from that normally understood by the term. Thermionic emitters are used as cathodes in electron tubes and hence are of great technical and scientific importance. Although in principle all conductors are thermionic emitters, only a few materials satisfy the requirements set by practical applications. Of the metals, tungsten is an important practical thermionic emitter; in most electron tubes, however, the oxide-coated cathode is used to great advantage. For a detailed discussion of practical thermionic emitters. *See* VACUUM TUBE.

The thermionic emission of a material may be measured by using the material as the cathode in a vacuum tube and collecting the emitted electrons on a positive anode. If the anode is sufficiently positive relative to the cathode, space charge (a concentration of electrons near the cathode) can be avoided and all electrons emitted can be collected; the saturation thermionic current is then measured. *See* SCHOTTKY EFFECT.

The emission current density J increases rapidly with increasing temperature; this is illustrated by the following approximate values for tungsten:

T(K)	1000	2000	2500	3000
J(amperes/cm^2)	10^{-15}	10^{-3}	0.3	15

The temperature dependence of J is given by the Richards (or Dushman-Richardson) equation below. Here A is a constant, k is Boltzmann's constant ($=1.38 \times 10^{-23}$ joule/degree), and ϕ is the work function of the emitter. The work function has the dimensions of energy and is a few electronvolts for thermionic emitters. *See* WORK FUNCTION (ELECTRONICS). [A.J.D.]

$$J = AT^2 e^{-(\phi - kT)}$$

Thermionic power generator A device for converting heat into electricity through the use of thermionic emission and no working fluid other than electric charges. An elementary thermionic generator, or thermionic converter, consists of a hot metal surface (emitter) separated from a cooler electrode (collector) by an insulator seal (see illustration). The interelectrode gap is usually a fraction of a millimeter in width. The hermetic enclosure contains a small amount of an easily ionizable gas, such as cesium vapor maintained by a liquid-cesium reservoir. In some experimental devices, the enclosure may be evacuated.

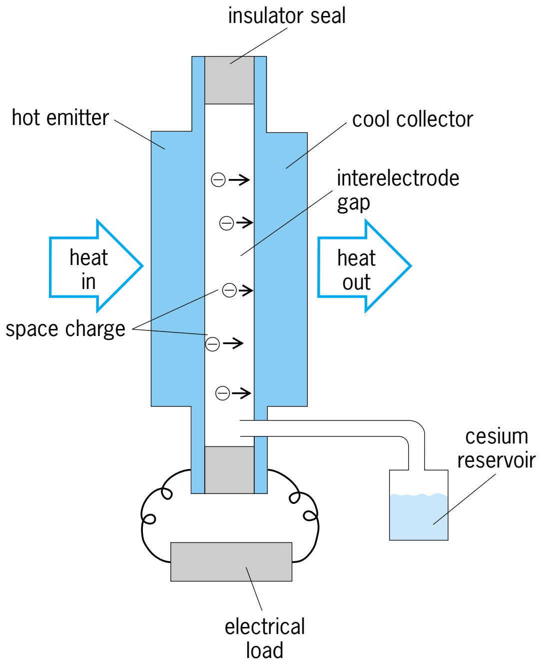


Diagram of thermionic converter.

Electrons evaporated from the emitter cross the interelectrode gap, condense on the collector, and are returned to the emitter via the external electrical load circuit. The thermionic generator is essentially a heat engine utilizing an electron gas as the working fluid. The temperature difference between the emitter and the collector drives the electron current.

Thermionic generators are characterized by high operating temperatures [typically emitter temperatures between 1600 and 2500 K (2420 and 4040°F) and collector temperatures ranging from 800 to 1100 K (980 to 1520°F)]; low output voltage (approximately 0.5 V per converter); high current density (around 5–10 A/cm^2); and high conversion efficiency (about 10–15%). These characteristics, especially the relatively high heat-rejection temperature, make the thermionic generator attractive for producing electric power in space with nuclear-reactor or radioisotope energy sources. The high electrode temperatures make thermionic generators also attractive as topping units for steam power plants, and for the cogeneration of electricity in combination with heat for intermediate-temperature industrial processes. Topping units increase the overall system efficiency. *See* COGENERATION; NUCLEAR BATTERY. [E.P.G.Y.; G.N.H.]

Thermionic tube An electron tube that relies upon thermally emitted electrons from a heated cathode for tube current.

Thermionic emission of electrons means emission by heat. In practical form an electrode, called the cathode because it forms the negative electrode of the tube, is heated until it emits electrons. The cathode may be either a directly heated filament or an indirectly heated surface. With a filamentary cathode, heating current is passed through the wire, which either emits electrons directly or is covered with a material that readily emits electrons. Indirectly heated cathodes have a filament, commonly called the heater, located within the cathode electrode to bring the surface of the cathode to emitting temperature. The majority of all vacuum tubes are thermionic tubes. *See* ELECTRON TUBE; GAS TUBE; THERMIONIC EMISSION; VACUUM TUBE. [L.S.N.]

Thermistor An electrical resistor with a relatively large negative temperature coefficient of resistance. Thermistors are useful for measuring temperature and gas flow or wind velocity. Often they are employed as bolometer elements to measure radio-frequency, microwave, and optical power. They also are used as electrical circuit components for temperature compensation, voltage regulation, circuit protection, time delay, and volume control. Thermistors are semiconducting ceramics composed of mixtures of several metal oxides. Metal electrodes or wires are attached to the ceramic material so that the thermistor resistance can be measured conveniently. *See* BOLOMETER; ELECTRICAL RESISTIVITY; VOLTAGE REGULATOR; VOLUME CONTROL SYSTEMS.

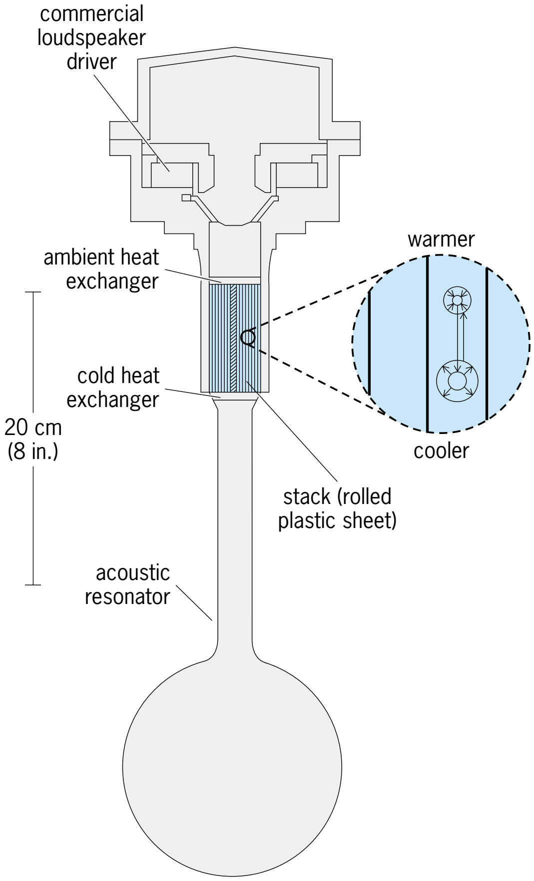
At room temperature the resistance of a thermistor may typically change by several percent for a variation of 1° of temperature, but the resistance does not change linearly with temperature. The temperature coefficient of resistance of a thermistor is approximately equal to a constant divided by the square of the temperature in kelvins. The constant is equal to several thousand kelvins and is specified for a given thermistor and the temperature range of intended use.

The resistance and heat capacity of a thermistor depend upon the material composition, the physical dimensions, and the environment provided by the thermistor enclosure. Thermistors range in form from small beads and flakes less than 10^{-3} in. (25 micrometers) thick to disks, rods, and washers with inch dimensions. The small beads are often coated with glass to prevent changes in composition or encased in glass probes or cartridges to prevent damage. Beads are available with room-temperature resistances ranging from less than 100 Ω to tens of megohms, with heat capacities as low as tens of microwatts per degree celsius, and with time constants of less than a second. Large disks and washers have heat capacities as high as a few watts per degree Celsius and time constants of minutes. *See* ELECTRIC POWER MEASUREMENT; FLOW MEASUREMENT; LEVEL MEASUREMENT; MICROWAVE POWER MEASUREMENT; TEMPERATURE MEASUREMENT; TIME CONSTANT. [R.Pow.]

Thermoacoustics The study of phenomena that involve both thermodynamics and acoustics. A sound wave in a gas is usually regarded as consisting of coupled pressure and displacement oscillations, but temperature oscillations accompany the pressure oscillations. When there are spatial gradients in the oscillating temperature, oscillating heat flow also occurs. The combination of these four oscillations produces a rich variety of thermoacoustic effects. *See* ACOUSTICS; OSCILLATION; SOUND; THERMODYNAMIC PRINCIPLES.

Although the oscillating heat transfer at solid boundaries does contribute significantly to the dissipation of sound in enclosures such as buildings, thermoacoustic effects are usually too small to be obviously noticeable in everyday life. However, thermoacoustic effects in intense sound waves inside suitable cavities can be harnessed to produce extremely powerful pulsating combustion, thermoacoustic refrigerators, and thermoacoustic engines.

Pulsating combustion. Oscillations can occur whenever combustion takes place in a cavity. In industrial equipment and residential appliances, these oscillations are sometimes encouraged in order to stir or pump the combustion ingredients, while in rocket engines such oscillations must usually be suppressed because they can damage the rocket structure. The oscillations occur spontaneously if the combustion progresses more rapidly or efficiently during the compression phase of the pressure oscillation than during the rarefaction (expansion) phase—the Rayleigh criterion. *See* COMBUSTION; GAS DYNAMICS.



An early standing-wave thermoacoustic refrigerator that cooled to −60°C (−76°F). Heat is carried up the temperature gradient in the stack. At the right is a magnified view of the oscillating motion of a typical parcel of gas. The volume of the parcel depends on its pressure and temperature. (*After T. J. Hofler, Thermoacoustic Refrigerator Design and Performance, Ph.D. thesis, University of California at San Diego, 1996*)

Thermoacoustic refrigerators. Thermoacoustic refrigerators use acoustic power to pump heat from a low temperature to ambient temperature (see illustration). The heat-pumping mechanism takes place in the pores of a structure called a stack. As a typical parcel of the gas oscillates along a pore, it experiences changes in temperature. Most of the temperature change comes from adiabatic compression and expansion of the gas by the sound pressure, and the rest is a consequence of the local temperature of the solid wall of the pore. A thermodynamic cycle results from the coupled pressure, temperature, position, and heat oscillations. The overall effect, much as in a bucket brigade, is the net transport of heat from the cold heat exchanger to room temperature. *See* ADIABATIC PROCESS; SOUND PRESSURE; THERMODYNAMIC CYCLE; THERMODYNAMIC PROCESSES.

Thermoacoustic engines. While standing-wave thermoacoustic systems have matured only recently, Stirling engines and refrigerators have a long, rich history. New insights have resulted from applying thermoacoustics to Stirling systems, treating them as traveling-wave thermoacoustic systems in which the extrema in pressure and gas motion are approximately 90° out of phase in time. In the thermoacoustic-Stirling engine, the thermodynamic cycle is accomplished in a traveling-wave acoustic network, and acoustic power is produced from heat with an efficiency of 30%. [G.Swi.]

Thermochemistry A branch of physical chemistry concerned with the absorption or evolution of heat that accompanies chemical reactions. Closely related topics are the latent heat associated with a change in phase (crystal, liquid, gas), the chemical composition of reacting systems at equilibrium, and the electrical potentials of galvanic cells. Thermodynamics provides the link among these phenomena.

A knowledge of such heat effects is important to the chemical engineer for the design and operation of chemical reactors, the determination of the heating values of fuels, the design and operation of refrigerators, the selection of heat storage systems, and the assessment of chemical hazards. Thermochemical information is used by the physiologist and biochemist to study the energetics of living organisms and to determine the calorific values of foods. Thermochemical data give the chemist an insight to the energies of, and interactions among, molecules. *See* CHEMICAL THERMODYNAMICS.

A calorimeter is an instrument for measuring the heat added to or removed from a process. There are many designs, but the following parts can generally be identified: the vessel in which the process is confined, the thermometer which measures its temperature, and the surrounding environment called the jacket. The heat associated with the process is calculated by the equation below, where T is the temperature. The quantity C, the

$$q = C[(T(\text{final}) - T(\text{initial})] - q_{\text{ex}} - w$$

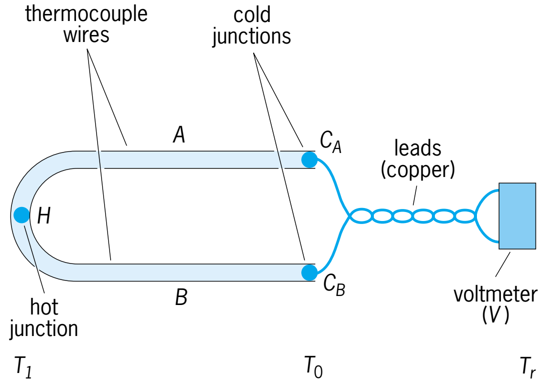
energy equivalent of the calorimeter, is obtained from a separate calibration experiment. The work transferred to the process, w, is generally in the form of an electric current (as supplied to a heater, for example) or as mechanical work (as supplied to a stirrer, for example) and can be calculated from appropriate auxiliary measurements. The quantity q_{ex} is the heat exchanged between the container and its jacket during the experiment. It is calculated from the temperature gradients in the system and the measured thermal conductivities of its parts.

Two principal types of calorimeters are used to measure heats of chemical reactions. In a batch calorimeter, known quantities of reactants are placed in the vessel and the initial temperature is measured. The reaction is allowed to occur and then the final equilibrium temperature is measured. If necessary, the final contents are analyzed to determine the amount of reaction which occurred.

In a flow calorimeter, the reactants are directed to the reaction vessel in two or more steady streams. The reaction takes place quickly and the products emerge in a steady stream. The rate of heat production is calculated from the temperatures, flow velocities, and heat capacities of the incoming and outgoing streams, and the rates of work production and heat transfer to the jacket. Dividing this result by the rate of reaction gives the heat of reaction. *See* CALORIMETRY.

In the past, thermochemical quantities usually have been given in units of calories. A calorie is defined as the amount of heat needed to raise the temperature of 1 gram of water 1°C. However, since this depends on the initial temperature of the water, various calories have been defined, for example, the 15° calorie, the 20° calorie, and the mean calorie (average from 0 to 100°C). In addition, a number of dry calories have been defined. Those still used are the thermochemical calorie (exactly 4.184 joules) and the International Steam Table calorie (exactly 4.1868 J). [R.C.W.]

Thermocouple A device in which the temperature difference between the ends of a pair of dissimilar metal wires is deduced from a measurement of the difference in the thermoelectric potentials developed along the wires. The presence of a temperature gradient in a metal or alloy leads to an electric potential gradient being set up along the temperature gradient. This thermoelectric potential gradient is proportional to the temperature gradient and varies from metal to metal. It is the fact that the thermoelectric emf is different in different metals and alloys for the same temperature gradient that allows the effect to be used for the measurement of temperature.



Basic circuit of a thermocouple.

The basic circuit of a thermocouple is shown in the illustration. The thermocouple wires, made of different metals or alloys A and B, are joined together at one end H, called the hot (or measuring) junction, at a temperature T_1. The other ends, C_A and C_B (the cold or reference junctions), are maintained at a constant reference temperature T_0, usually but not necessarily 32°F (0°C). From the cold junctions, wires, usually of copper, lead to a voltmeter V at room temperature T_r. Due to the thermoelectric potential gradients being different along the wires A and B, there exists a potential difference between C_A and C_B. This can be measured by the voltmeter, provided that C_A and C_B are at the same temperature and that the lead wires between C_A and V and C_B and V are identical (or that V is at the temperature T_0, which is unusual). Such a thermocouple will produce a thermoelectric emf between C_A and C_B which depends only upon the temperature difference $T_1 - T_0$. *See* TEMPERATURE MEASUREMENT; THERMOELECTRICITY.

Letter designations and compositions for standardized thermocouples*

Type designation	Materials
B	Platinum-30% rhodium/platinum-6% rhodium
E	Nickel-chromium alloy/a copper-nickel alloy
J	Iron/another slightly different copper-nickel alloy
K	Nickel-chromium alloy/nickel-aluminum alloy
R	Platinum-13% rhodium/platinum
S	Platinum-10% rhodium/platinum
T	Copper/a copper-nickel alloy

*After T. J. Quinn, *Temperature*, Academic Press, 1983.

A large number of pure metal and alloy combinations have been studied as thermocouples, and the seven most widely used are listed in the table. The thermocouples in the table together cover the temperature range from about −420°F (−250°C or 20 K) to about 3300°F (1800°C). The most accurate and reproducible are the platinum/rhodium thermocouples, types R and S, while the most widely used industrial thermocouples are probably types K, T, and E. [T.J.Q.]

Thermodynamic cycle A procedure or arrangement in which one form of energy, such as heat at an elevated temperature from combustion of a fuel, is in part converted to another form, such as mechanical energy on a shaft, and the remainder is rejected to a lower-temperature sink as low-grade heat.

A thermodynamic cycle requires, in addition to the supply of incoming energy, (1) a working substance, usually a gas or vapor; (2) a mechanism in which the processes or phases can be carried through sequentially; and (3) a thermodynamic sink to which the residual heat can be rejected. The cycle itself is a repetitive series of operations.

There is a basic pattern of processes common to power-producing cycles. There is a compression process wherein the working substance undergoes an increase in pressure and therefore density. There is an addition of thermal energy from a source such as a fossil fuel, a fissile fuel, or solar radiation. There is an expansion process during which work is done by the system on the surroundings. There is a rejection process where thermal energy is transferred to the surroundings. The algebraic sum of the energy additions and abstractions is such that some of the thermal energy is converted into mechanical work. *See* HEAT.

The basic processes of the cycle, either open or closed, are heat addition, heat rejection, expansion, and compression. These processes are always present in a cycle even though there may be differences in working substance, the individual processes, pressure ranges, temperature ranges, mechanisms, and heat transfer arrangements.

Many cyclic arrangements, using various combinations of phases but all seeking to convert heat into work, have been proposed by many investigators whose names are attached to their proposals, for example, the Diesel, Otto, Rankine, Brayton, Stirling, Ericsson, and Atkinson cycles. All proposals are not equally efficient in the conversion of heat into work. However, they may offer other advantages which have led to their practical development for various applications. *See* BRAYTON CYCLE; CARNOT CYCLE; DIESEL CYCLE; OTTO CYCLE; STIRLING ENGINE; THERMODYNAMIC PROCESSES. [T.Ba.]

Thermodynamic principles Laws governing the transformation of energy. Thermodynamics is the science of the transformation of energy. It differs from the dynamics of Newton by taking into account the concept of temperature, which is outside the scope of classical mechanics. In practice, thermodynamics is useful for assessing the efficiencies of heat engines (devices that transform heat into work) and refrigerators (devices that use external sources of work to transfer heat from a hot system to cooler sinks), and for discussing the spontaneity of chemical reactions (their tendency to occur naturally) and the work that they can be used to generate.

The subject of thermodynamics is founded on four generalizations of experience, which are called the laws of thermodynamics. Each law embodies a particular constraint on the properties of the world. The connection between phenomenological thermodynamics and the properties of the constituent particles of a system is established by statistical thermodynamics, also called statistical mechanics. Classical thermodynamics consists of a collection of mathematical relations between observables, and as such is independent of any underlying model of matter (in terms, for instance, of atoms). However, interpretations in terms of the statistical behavior of large assemblies of particles greatly enriches the understanding of the relations established by thermodynamics. *See* STATISTICAL MECHANICS.

Zeroth law of thermodynamics. The zeroth law of thermodynamics establishes the existence of a property called temperature. This law is based on the observation that if a system A is in thermal equilibrium with a system B (that is, no change in the properties of B take places when the two are in contact), and if system B is in thermal equilibrium with a system C, then it is invariably the case that A will be found to be in equilibrium with C if the two systems are placed in mutual contact. This law suggests that a numerical scale can be established for the common property, and if A, B, and C have the same numerical values of this property, then they will be in mutual thermal equilibrium if they were placed in contact. This property is now called the temperature. *See* TEMPERATURE.

First law of thermodynamics. The first law of thermodynamics establishes the existence of a property called the internal energy of a system. It also brings into the discussion the concept of heat.

The first law is based on the observation that a change in the state of a system can be brought about by a variety of techniques. Indeed, if attention is confined to an adiabatic system, one that is thermally insulated from its surroundings, then the work of J. P. Joule shows that same change of state is brought about by a given quantity of work regardless of the manner in which the work is done. This observation suggests that, just as the height through which a mountaineer climbs can be calculated from the difference in altitudes regardless of the path the climber takes between two fixed points, so the work, w, can be calculated from the difference between the final and initial properties of a system. The relevant property is called the internal energy, U. However, if the transformation of the system is taken along a path that is not adiabatic, a different quantity of work may be required. The difference between the work of adiabatic change and the work of nonadiabatic change is called heat, q. In general, Eq. (1) is satisfied, where ΔU is the change in internal energy

$$\Delta U = w + q \tag{1}$$

between the final and initial states of the system. *See* ADIABATIC PROCESS; ENERGY; HEAT.

The implication of this argument is that there are two modes of transferring energy between a system and its surroundings. One is by doing work; the other is by heating the system. Work and heat are modes of transferring energy. They are not forms of energy in their own right. Work is a mode of transfer that is equivalent (if not the case in actuality) to raising a weight in the surroundings. Heat is a mode of transfer that arises from a difference in temperature between the system and its surroundings. What is commonly called heat is more correctly called the thermal motion of the molecules of a system.

The first law of thermodynamics states that the internal energy of an isolated system is conserved. That is, for a system to which no energy can be transferred by the agency of work or of heat, the internal energy remains constant. This law is a cousin of the law of the conservation of energy in mechanics, but it is richer, for it implies the equivalence of heat and work for bringing about changes in the internal energy of a system (and heat is foreign to classical mechanics).

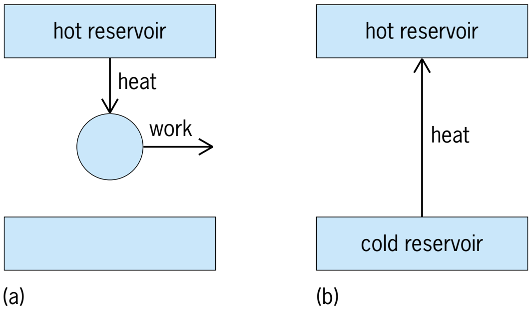
Second law of thermodynamics. The second law of thermodynamics deals with the distinction between spontaneous and nonspontaneous processes. A process is spontaneous if it occurs without needing to be driven. In other words, spontaneous changes are natural changes, like the cooling of hot metal and the free expansion of a gas. Many conceivable changes occur with the conservation of energy globally, and hence are not in conflict with the first law; but many of those changes turn out to be nonspontaneous, and hence occur only if they are driven.

The second law was formulated by Lord Kelvin and by R. Clausius in a manner relating to observation: "no cyclic engine operates without a heat sink" and "heat does not transfer spontaneously from a cool to a hotter body," respectively (see illustration). The two statements are logically equivalent in the sense that failure of one implies failure of the other. However, both may be absorbed into a single statement: the entropy of an isolated system increases when a spontaneous change occurs. The property of entropy is introduced to formulate the law quantitatively in exactly the same way that the properties of temperature and internal energy are introduced to render the zeroth and first laws quantitative and precise.

The entropy, S, of a system is a measure of the quality of the energy that it stores. The formal definition is based on Eq. (2),

$$dS = \frac{dq_{\text{reversible}}}{T} \tag{2}$$

where dS is the change in entropy of a system, dq is the energy transferred to the system as heat, T is the temperature, and the subscript "reversible" signifies that the transfer must be carried out reversibly (without entropy production other than in the



Representation of the statements of the second law of thermodynamics by (*a*) Lord Kelvin and (*b*) R. Clausius. In each case, the law states that the device shown cannot operate as shown.

system). When a given quantity of energy is transferred as heat, the change in entropy is large if the transfer occurs at a low temperature and small if the temperature is high.

This definition of entropy is illuminated by L. Boltzmann's interpretation of entropy as a measure of the disorder of a system. The connection can be appreciated qualitatively at least by noting that if the temperature is high, the transfer of a given quantity of energy as heat stimulates a relatively small additional disorder in the thermal motion of the molecules of a system; in contrast, if the temperature is low, the same transfer could stimulate a relatively large additional disorder.

The illumination of the second law brought about by the association of entropy and disorder is that in an isolated system the only changes that may occur are those in which there is no increase in order. Thus, energy and matter tend to disperse in disorder (that is, entropy tends to increase), and this dispersal is the driving force of spontaneous change. *See* ENTROPY; TIME, ARROW OF.

Third law of thermodynamics. The practical significance of the second law is that it limits the extent to which the internal energy may be extracted from a system as work. In order for a process to generate work, it must be spontaneous. For the process to be spontaneous, it is necessary to discard some energy as heat in a sink of lower temperature. In other words, nature in effect exacts a tax on the extraction of energy as work. There is therefore a fundamental limit on the efficiency of engines that convert heat into work.

The quantitative limit on the efficiency, ϵ, which is defined as the work produced divided by the heat absorbed from the hot source, was first derived by S. Carnot. He found that, regardless of the details of the construction of the engine, the maximum efficiency (that is, the work obtained after payment of the minimum allowable tax to ensure spontaneity) is given by Eq. (3), where

$$\epsilon = 1 - \frac{T_{\text{cold}}}{T_{\text{hot}}} \tag{3}$$

T_{hot} is the temperature of the hot source and T_{cold} is the temperature of the cold sink. The greatest efficiencies are obtained with the coldest sinks and the hottest sources, and these are the design requirements of modern power plants. *See* CARNOT CYCLE.

Perfect efficiency ($\epsilon = 1$) would be obtained if the cold sink were at absolute zero ($T_{\text{cold}} = 0$). However, the third law of thermodynamics, which is another summary of observations, asserts that absolute zero is unattainable in a finite number of steps for any process. Therefore, heat can never be completely converted into work in a heat engine. The implication of the third law in this form is that the entropy change accompanying any process approaches zero as the temperature approaches zero. That implication in turn implies that all substances tend toward the same entropy as the temperature is reduced to zero. It is therefore sensible to take the entropy of all perfect crystalline substances (substances in which there is no residual disorder arising from the location of atoms) as equal to zero. A common short statement of the third law is therefore that all perfect crystalline substances have zero entropy at absolute zero ($T = 0$). This statement is consistent with the interpretation of entropy as a measure of disorder, since at absolute zero all thermal motion has been quenched. *See* ABSOLUTE ZERO. [P.W.A.]

Thermodynamic processes

Changes of any property of an aggregation of matter and energy, accompanied by thermal effects.

Systems and processes. To evaluate the results of a process, it is necessary to know the participants that undergo the process, and their mass and energy. A region, or a system, is selected for study, and its contents determined. This region may have both mass and energy entering or leaving during a particular change of conditions, and these mass and energy transfers may result in changes both within the system and within the surroundings which envelop the system.

To establish the exact path of a process, the initial state of the system must be determined, specifying the values of variables such as temperature, pressure, volume, and quantity of material. The number of properties required to specify the state of a system depends upon the complexity of the system. Whenever a system changes from one state to another, a process occurs.

The path of a change of state is the locus of the whole series of states through which the system passes when going from an initial to a final state. For example, suppose a gas expands to twice its volume and that its initial and final temperatures are the same. An extremely large number of paths connect these initial and final states. The detailed path must be specified if the heat or work is to be a known quantity; however, changes in the thermodynamic properties depend only on the initial and final states and not upon the path. A quantity whose change is fixed by the end states and is independent of the path is a point function or a property.

Pressure-volume-temperature diagram. Whereas the state of a system is a point function, the change of state of a system, or a process, is a path function. Various processes or methods of change of a system from one state to another may be depicted graphically as a path on a plot using thermodynamic properties as coordinates.

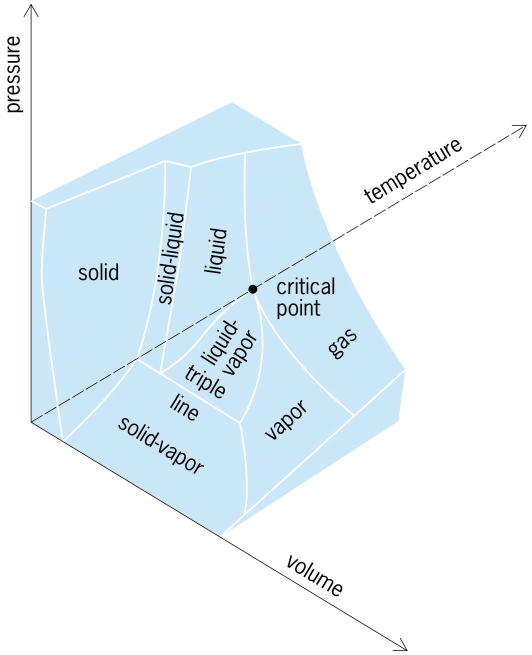


Fig. 1. Portion of pressure-volume-temperature (*P-V-T*) surface for a typical substance.

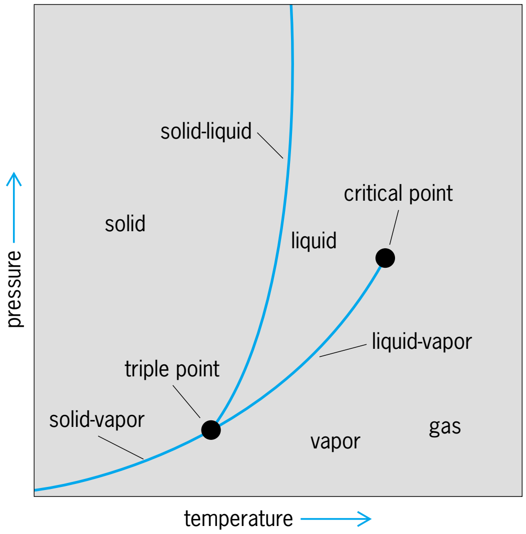

Fig. 2. **Portion of equilibrium surface projected on pressure-temperature (*P-T*) plane.**

The variable properties most frequently and conveniently measured are pressure, volume, and temperature. If any two of these are held fixed (independent variables), the third is determined (dependent variable). To depict the relationship among these physical properties of the particular working substance, these three variables may be used as the coordinates of a three-dimensional space. The resulting surface is a graphic presentation of the equation of state for this working substance, and all possible equilibrium states of the substance lie on this *P-V-T* surface.

Because a *P-V-T* surface represents all equilibrium conditions of the working substance, any line on the surface represents a possible reversible process, or a succession of equilibrium states.

The portion of the *P-V-T* surface shown in Fig. 1 typifies most real substances; it is characterized by contraction of the substance on freezing. Going from the liquid surface to the liquid-solid surface onto the solid surface involves a decrease in both temperature and volume. Water is one of the few exceptions to this condition; it expands upon freezing, and its resultant *P-V-T* surface is somewhat modified where the solid and liquid phases abut.

One can project the three-dimensional surface onto the *P-T* plane as in Fig. 2. The triple point is the point where the three phases are in equilibrium. When the temperature exceeds the critical temperature (at the critical point), only the gaseous phase is possible.

Temperature-entropy diagram. Energy quantities may be depicted as the product of two factors: an intensive property and an extensive one. Examples of intensive properties are pressure, temperature, and magnetic field; extensive ones are volume, magnetization, and mass. Thus, in differential form, work is the product of a pressure exerted against an area which sweeps through an infinitesimal volume, as in Eq. (1). As a gas expands,

$$dW = P\,dV \tag{1}$$

it is doing work on its environment. However, a number of different kinds of work are known. For example, one could have work of polarization of a dielectric, of magnetization, of stretching a wire, or of making new surface area. In all cases, the infinitesimal work is given by Eq. (2), where X is a generalized applied force

$$dW = X\,dx \tag{2}$$

which is an intensive quantity, and dx is a generalized displacement of the system and is thus extensive.

By extending this approach, one can depict transferred heat as the product of an intensive property, temperature, and a distributed or extensive property defined as entropy, for which the symbol is S. *See* ENTROPY.

Reversible and irreversible processes. Not all energy contained in or associated with a mass can be converted into useful work. Under ideal conditions only a fraction of the total energy present can be converted into work. The ideal conversions which retain the maximum available useful energy are reversible processes.

Characteristics of a reversible process are that the working substance is always in thermodynamic equilibrium and the process involves no dissipative effects such as viscosity, friction, inelasticity, electrical resistance, or magnetic hysteresis. Thus, reversible processes proceed quasistatically so that the system passes through a series of states of thermodynamic equilibrium, both internally and with its surroundings. This series of states may be traversed just as well in one direction as in the other.

Actual changes of a system deviate from the idealized situation of a quasistatic process devoid of dissipative effects. The extent of the deviation from ideality is correspondingly the extent of the irreversibility of the process. *See* THERMODYNAMIC PRINCIPLES.

[P.E.Bl.; W.A.S.]

Thermoelectric power generator

A solid-state heat engine which employs the electron gas as a working fluid. It directly converts heat energy into electrical energy using the Seebeck effect. This phenomenon can be demonstrated using a thermocouple which comprises two legs (thermoelements) of dissimilar conducting materials joined at one end to form a junction. If this junction is maintained at a temperature which differs from ambient, a voltage is generated across the open ends of the thermoelements. When the circuit is completed with a load, a current flows in the circuit and power is generated. In practice the thermocouples are fabricated generally from *n*- and *p*-type semiconductors, and several hundred are connected electrically in series to form a module which is the active component of a thermoelectric generator. Provided a temperature difference is maintained across the device, it will generate electrical power. Heat is provided from a variety of sources depending on the application, and they include burning fossil fuels in terrestrial and military applications, decaying long-life isotopes in medical and deep-space applications, and waste heat. The performance of the thermoelectric generator, in terms of efficiency, output power, and economic viability, depends upon its temperature regime of operation; the materials used in the module construction; its electrical, thermal, and geometrical design; and the generator load. The power output spectrum of thermoelectric generators spans 14 orders of magnitude and ranges from nanowatt generators fabricated using integrated circuit technology to the nuclear-reactor-powered 100-kW SP-100 generator intended to provide electrical power to orbiting space stations. *See* NUCLEAR BATTERY; RADIOACTIVITY AND RADIATION APPLICATIONS; SEEBECK EFFECT; SPACE POWER SYSTEMS; SPACE PROBE; THERMOCOUPLE; THERMOELECTRICITY.

Historically the use of thermoelectric generators has been restricted to specialized applications where combinations of their desirable properties, such as the absence of moving parts, reliability, and silent operation, has outweighed their low overall conversion efficiency, typically 5%. In these applications, fuel cost or weight is a major consideration, and improving the conversion efficiency is the main research target. Improving the figure of merit has been regarded as the most important factor in increasing the conversion efficiency of a thermoelectric generator.

Selection of thermocouple material depends upon the generator's temperature regime of operation. The figures of merit of established thermoelectric materials reach maxima at different temperatures, and semiconductor compounds or alloys based on bismuth telluride, lead telluride, and silicon germanium cover the temperature ranges up to 150°C (300°F), 650°C (1200°F), and 1000°C (1830°F) respectively, with the best materials capable of generating electrical power with an efficiency of around

20%. Material research is focused on improving the figure of merit and to a lesser, though an increasing, extent, the electrical power factor.

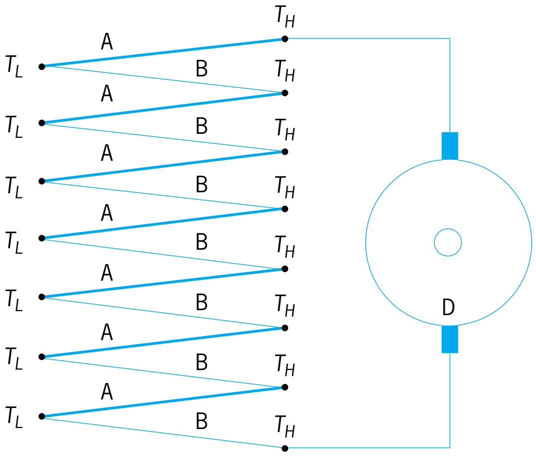
The emergence of thermoelectrics as a technology for application in waste heat recovery has resulted in a successful search for materials with high electrical power factors and cheap materials. The rare-earth ytterbium-aluminum compound $YbAl_3$ has a power factor almost three times that of bismuth telluride, the established material for low-temperature application, while magnesium tin (MgSn) has almost the same performance as lead telluride but is available at less than a quarter of the cost. [D.M.Row.]

Thermoelectricity The direct conversion of heat into electrical energy, or the reverse, in solid or liquid conductors by means of three interrelated phenomena—the Seebeck effect, the Peltier effect, and the Thomson effect—including the influence of magnetic fields upon each. The Seebeck effect concerns the electromotive force (emf) generated in a circuit composed of two different conductors whose junctions are maintained at different temperatures. The Peltier effect refers to the reversible heat generated at the junction between two different conductors when a current passes through the junction. The Thomson effect involves the reversible generation of heat in a single current-carrying conductor along which a temperature gradient is maintained. Specifically excluded from the definition of thermoelectricity are the phenomena of Joule heating and thermionic emission. *See* Electromotive force (emf); Joule's law; Peltier effect; Seebeck effect; Thermionic emission; Thomson effect.

The three thermoelectric effects are described in terms of three coefficients: the absolute thermoelectric power (or thermopower) S, the Peltier coefficient Π, and the Thomson coefficient μ, each of which is defined for a homogeneous conductor at a given temperature. These coefficients are connected by the Kelvin relations, which convert complete information about one into complete information about all three. It is therefore necessary to measure only one of the three coefficients; usally the thermopower S is chosen.

The most important practical application of thermoelectric phenomena is in the accurate measurement of temperature. The phenomenon involved is the Seebeck effect. Of less importance are the direct generation of electrical power by application of heat (also involving the Seebeck effect) and thermoelectric cooling and heating (involving the Peltier effect).

A basic system suitable for all four applications is shown schematically in the illustration. Several thermocouples are connected in series to form a thermopile, a device with increased output (for power generation or cooling and heating) or sensitivity (for temperature measurement) relative to a single thermocouple. The junctions forming one end of the thermopile are all at the same low temperature T_L, and the junctions forming the other end are at the high temperature T_H. The thermopile is connected to a device D which is different for each application. For temperature measurement, the temperature T_L is fixed, for example, by means of a bath; the temperature T_H becomes the running temperature T, which is to be measured; and the device is a potentiometer for measuring the thermoelectric emf generated by the thermopile. For power generation, the temperature T_L is fixed by connection to a heat sink; the temperature T_H is fixed at a value determined by the output of the heat source and the thermal conductance of the thermopile; and the device is whatever is to be run by the electricity that is generated. For heating or cooling, the device is a current generator that passes current through the thermopile. If the current flows in the proper direction, the junctions at T_H will heat up, and those at T_L will cool down. If T_H is fixed by connection to a heat sink, thermoelectric cooling will be provided by T_L. Alternatively, if T_L is fixed, thermoelectric heating will be provided at T_H. Such a system has the advantage that at any given location it can be converted from a cooler to a heater merely by reversing the direction of the current.



Thermopile, a battery of thermocouples connected in series. *D* is a device appropriate to the particular application; *A* and *B* are the two different conductors.

Thermoelectric power generators, heaters, or coolers made from even the best presently available materials have the disadvantages of relatively low efficiencies and concomitant high cost per unit of output. Their use has therefore been largely restricted to situations in which these disadvantages are outweighed by such advantages as small size, low maintenance due to lack of moving parts, quiet and vibration-free performance, light weight, and long life. *See* Thermoelectric power generator. [J.B.]

Thermoluminescence The emission of light when certain solids are warmed, generally to a temperature lower than that needed to provoke visible incandescence. Two characteristics of thermoluminescence distinguish it from incandescence. First, the intensity of thermoluminescent emission does not remain constant at constant temperature, but decreases with time and eventually ceases altogether. Second, the spectrum of the thermoluminescence is highly dependent on the composition of the material and is only slightly affected by the temperature of heating. If a thermoluminescent material emits both thermoluminescence and incandescent light at some temperature of observation, the transient light emission is the thermoluminescence and the remaining steady-state emission is the incandescence. The transient nature of the thermoluminescent emission suggests that heating merely triggers the release of stored energy previously imparted to the material. Supporting this interpretation is the fact that after the thermoluminescence has been reduced to zero by heating, the sample can be made thermoluminescent again by exposure to one of a number of energy sources: x-rays and gamma rays, electron beams, nuclear particles, ultraviolet light, and, in some cases, even short-wave visible light (violet and blue). A thermoluminescent material, therefore, has a memory of its earlier exposure to an energizing source, and this memory is utilized in a number of applications. Many natural minerals are thermoluminescent, but the most efficient materials of this type are specially formulated synthetic solids (phosphors). *See* Luminescence.

In addition to special sites capable of emitting light (luminescent centers), thermoluminescent phosphors have centers that can trap electrons or holes when these are produced in the solid by ionizing radiation. The luminescent center itself is often the hole trap, and the electron is trapped at another center, although the reverse situation can also occur. In the former case, if the temperature is low and the energy required to release an electron from a trap (the trap depth) is large, electrons will remain trapped and no luminescence will occur. If, however, the temperature of the phosphor is progressively raised, electrons will receive increasing amounts of thermal energy and will have an increased probability of escape from the traps. Freed electrons may then go over to luminescent centers and recombine with holes trapped at or near these centers. The energy liberated by the recombination can excite the luminescent centers, causing them to emit light. *See* Hole states in solids; Traps in solids.

Radiation dosimeters based on thermoluminescence are widely used for monitoring integrated radiation exposure in nuclear power plants, hospitals, and other installations where high-energy radiations are likely to be encountered. The key elements of the dosimeters, thermoluminescent phosphors with deep traps, can store some of the energy absorbed from these radiations for very long periods of time at normal temperatures and release it as luminescence on demand when appropriately heated. The brightness (or light sum) of the luminescence is a measure of the original radiation dose. *See* Dosimeter. [J.H.S.]

Thermomagnetic effects Electrical and thermal phenomena occurring when a conductor or semiconductor which is carrying a thermal current (that is, is in a temperature gradient) is placed in a magnetic field. *See* Semiconductor.

Let the temperature gradient be transverse to the magnetic field H_z, for example, along x. Then the following transverse-transverse effects are observed:

1. Ettingshausen-Nernst effect, an electric field along y.
2. Righi-Leduc effect, a temperature gradient along y.
3. An electric potential change along x, amounting to a change of thermoelectric power.
4. A temperature gradient change along x, amounting to a change of thermal resistance.

Let the temperature gradient be along H. Then changes in thermoelectric power and in thermal conductivity are observed in the direction of H.

For related phenomena *see* Hall effect; Magnetoresistance. [E.A.; F.Ke.]

Thermometer An instrument that measures temperature. Although this broad definition includes all temperature-measuring devices, they are not all called thermometers. Other names have been generally adopted. For a discussion of two such devices *see* Pyrometer; Thermocouple. For a general discussion of temperature measurement; Temperature measurement.

Liquid-in-glass thermometer. This thermometer consists of a liquid-filled glass bulb and a connecting partially filled capillary tube. When the temperature of the thermometer increases, the differential expansion between the glass and the liquid causes the liquid to rise in the capillary. A variety of liquids, such as mercury, alcohol, toluene, and pentane, and a number of different glasses are used in thermometer construction, so that various designs cover diverse ranges between about −300°F and +1200°F (−184°C and +649°C).

Bimetallic thermometer. In this thermometer the differential expansion of thin dissimilar metals, bonded together into a narrow strip and coiled into the shape of a helix or spiral, is used to actuate a pointer. In some designs the pointer is replaced with low-voltage contacts to control, through relays, operations which depend upon temperature, such as furnace controls.

Filled-system thermometer. This type of thermometer has a bourdon tube connected by a capillary tube to a hollow bulb. When the system is designed for and filled with a gas (usually nitrogen or helium) the pressure in the system substantially follows the gas law, and a temperature indication is obtained from the bourdon tube. The temperature-pressure-motion relationship is nearly linear. Atmospheric pressure effects are minimized by filling the system to a high pressure. When the system is designed for and filled with a liquid, the volume change of the liquid actuates the bourdon tube.

Vapor-pressure thermal system. This filled-system thermometer utilizes the vapor pressure of certain stable liquids to measure temperature. The useful portion of any liquid-vapor pressure curve is between approximately 15 psia (100 kilopascals absolute) and the critical pressure, that is, the vapor pressure at the critical temperature, which is the highest temperature for a particular liquid-vapor system. A nonlinear relationship exists between the temperature and the vapor pressure, so the motion of the bourdon tube is greater at the upper end of the vapor-pressure curve. Therefore, these thermal systems are normally used near the upper end of their range, and an accuracy of 1% or better can be expected.

Resistance thermometer. In this type of thermometer the change in resistance of conductors or semiconductors with temperature change is used to measure temperature. Usually, the temperature-sensitive resistance element is incorporated in a bridge network which has a reasonably constant power supply. Although a deflection circuit is occasionally used, almost all instruments of this class use a null-balance system, in which the resistance change is balanced and measured by adjusting at least one other resistance in the bridge. Metals commonly used as the sensitive element in resistance thermometers are platinum, nickel, and copper.

Thermistor. This device is made of a solid semiconductor with a high temperature coefficient of resistance. The thermistor has a high resistance, in comparison with metallic resistors, and is used as one element in a resistance bridge. Since thermistors are more sensitive to temperature changes than metallic resistors, accurate readings of small changes are possible. *See* Thermistor. [H.S.B.]

Thermonuclear reaction A nuclear fusion reaction which occurs between various nuclei of the light elements when they are constituents of a gas at very high temperatures. Thermonuclear reactions, the source of energy generation in the Sun and the stable stars, are utilized in the fusion bomb. *See* Hydrogen bomb; Nuclear fusion; Stellar evolution; Sun.

Thermonuclear reactions occur most readily between isotopes of hydrogen (deuterium and tritium) and less readily among a few other nuclei of higher atomic number. At the temperatures and densities required to produce an appreciable rate of thermonuclear reactions, all matter is completely ionized; that is, it exists only in the plasma state. Thermonuclearer fusion reactions may then occur within such an ionized gas when the agitation energy of the stripped nuclei is sufficient to overcome their mutual electrostatic repulsions, allowing the colliding nuclei to approach each other closely enough to react. For this reason, reactions tend to occur much more readily between energy-rich nuclei of low atomic number (small charge) and particularly between those nuclei of the hot gas which have the greatest relative kinetic energy. This latter fact leads to the result that, at the lower fringe of temperatures where thermonuclear reactions may take place, the rate of reactions varies exceedingly rapidly with temperature. *See* Carbon-nitrogen-oxygen cycles; Kinetic theory of matter; Magnetohydrodynamics; Nuclear reaction; Pinch effect; Proton-proton chain. [R.F.P.]

Thermoregulation The processes by which many animals actively maintain the temperature of part or all of their body within a specified range in order to stabilize or optimize temperature-sensitive physiological processes. Body temperatures of normally active animals may range from 32 to 115°F (0 to 46°C) or more, but the tolerable range for any one species is much narrower.

Animals are commonly classified as warm-blooded or cold-blooded. When the temperature of the environment varies, the body temperature of a warm-blooded or homeothermic animal remains high and constant, while that of a cold-blooded or poikilothermic animal is low and variable. However, supposedly cold-blooded reptiles and insects, when active, may regulate body temperatures within 2–4°F (1–2°C) of a species-specific value. Supposedly warm-blooded mammals and birds may allow their temperature to drop to 37–68°F (5–20°C) during hibernation or torpor. Further, optimal temperature varies with organ, time of day, and circumstance. Thus, this classification is often misleading.

A better classification is based on the principal source of heat used for thermoregulation. Endotherms (birds, mammals) use heat generated from food energy. Ectotherms (invertebrates, fish, amphibians, reptiles) use heat from environmental sources. This classification also has limitations, however. For example, endotherms routinely use external heat sources to minimize the food cost of thermoregulation, and some ectotherms use food energy for thermoregulation. *See* PHYSIOLOGICAL ECOLOGY (ANIMAL).

Behavior is the most obviously active form of thermoregulation. Most animals are mobile, sensitive to their environment, and capable of complex behaviors. The simplest thermoregulatory behavior consists of moving to a favorable location. Operative temperature may also be altered by changing posture in one place. Lizards face the sun to minimize the area exposed to solar heating, or orient broadside to maximize it, and some ground squirrels use their tail as a sunshade. Some reptiles and amphibians also expand or contract pigmented cells in their skin to increase or decrease solar heating. *See* CHROMATOPHORE.

Evaporation is an effective means of cooling the body. Evaporation from the respiratory mucous membranes is the most common mechanism. Evaporation from the mucous membranes cools the nose during inhalation. During exhalation, water vapor condenses on the cool nasal membranes and is recovered. Evaporation can be greatly increased by exhaling from the mouth to prevent condensation. Additional increases in evaporation result from panting, that is, rapid breathing at the resonant frequency of the respiratory system. Evaporation from the eyes and the mucous membranes of the mouth and tongue is another source of cooling. Water is also evaporated from the skin of all animals, and can be varied for thermoregulation. Some desert frogs control evaporation by spreading an oily material on the skin. Reptiles, birds, and mammals have relatively impermeable skins, but evaporation can be increased by various means. The sweat glands in the skin of mammals are particularly effective and are one of the few purely thermoregulatory organs known. *See* SKIN.

Changes in circulation can be used to regulate heat flow. Countercurrent heat exchange is used to regulate heat flow to particular parts of the body while maintaining oxygen supply. Large vessels may be divided into intermingled masses of small vessels to maximize heat exchange, forming an organ called a rete. However, retes can be bypassed by alternative circulation paths to regulate heat flow. Many animals living in warm environments have a rete that regulates brain temperature by cooling the arterial blood supply to the brain with blood draining from the nasal membranes, eyes, ears, or horns. *See* CARDIOVASCULAR SYSTEM; COUNTERCURRENT EXCHANGE (BIOLOGY).

Heat exchange with the environment is limited by the fur of mammals, feathers of birds, and furlike scales or setae of insects. Erection or compression of this insulation varies heat flow. Insulation thickness varies over the body to exploit variations in local operative temperature. Thermal windows are thinly insulated areas that are either shaded (abdomen of mammals, axilla of birds and mammals) or of small size (ears, face, legs) so that solar heating is minimized.

The oxidation of foodstuffs within the metabolic pathways of the body releases as much heat as if it were burned. Basal metabolism is the energy use rate of a fasting animal at rest. Activity, digestion, and thermoregulation increase metabolism above the basal rate. Endothermy is the utilization of metabolic heat for thermoregulation. Birds and mammals are typical examples, but significant endothermy also occurs in large salt-water fish, large reptiles, and large flying insects. Endotherms regulate only the temperature of the body core, that is, the brain, heart, and lungs. The heat production of these metabolically active organs is often supplemented with heat produced in muscles. Heat produced as a by-product of activity may substitute partially for thermoregulatory heat production, and imposes no thermoregulatory energy cost. In contrast, shivering produces heat only for thermoregulation and results in an extra cost. Some animals have specialized heater organs for nonshivering thermogenesis, which is more efficient than shivering. Brown adipose tissue is a fatty tissue with a high density of mitochondria. It is found in the thorax of mammals, especially newborns and hibernators, and it warms the body core efficiently. *See* ADIPOSE TISSUE; METABOLISM.

The variety of mechanisms used in thermoregulation indicates a corresponding complexity in neural control. Temperature sensors distributed over the skin respond nearly immediately to changes in the environment and provide the major input. Nearly all parts of the central nervous system also respond to local thermal stimulation. These peripheral and central thermal inputs are integrated at a series of centers beginning in the spinal cord. This series clearly extends to the cerebral cortex, as a learning period is required before behavioral thermoregulation reaches maximum precision. Various components respond to the rate of temperature change as well as the difference between preferred and actual temperature. The neuroendocrine system then regulates metabolic heat production, the sympathetic nervous system controls blood flow, and the cerebral cortex controls behavioral thermoregulation. *See* ENDOCRINE SYSTEM (VERTEBRATE); HOMEOSTASIS; NERVOUS SYSTEM (VERTEBRATE). [G.Ba.]

Thermosbaenacea A small order of the superorder Peracarida in the superclass Crustacea. In thermosbaenaceans, the carapace, which may cover part of the cephalic region and one to several thoracic somites, is fused only to the first thoracic somite. The carapace of females is expanded to provide a dorsally positioned brood pouch where embryos hatch as subadults. Eyes are reduced or absent. The abdomen consists of six somites and a telson; however, in *Thermosbaena*, at least, the telson and sixth somite are fused to form a pleotelson. The first pair of thoracic appendages are modified as maxillipeds, and may be sexually dimorphic; the remaining five to seven pairs provide the animals with locomotion. Sexes are separate. Thermosbaenaceans have been found principally in thermal, but occasionally in cool, fresh- or brackish-water, lakes, springs, and interstitial coastal areas, and also in cave pools, in a geographic band stretching from the Mediterranean to the Caribbean and Gulf of Mexico. *See* PERACARIDA. [P.A.McL.]

Thermosphere A rarefied portion of the atmosphere, lying in a spherical shell between 50 and 300 mi (80 and 500 km) above the Earth's surface, where the temperature increases dramatically with altitude. The thermosphere responds to the variable outputs of the Sun, the ultraviolet radiation at wavelengths less than 200 nanometers, and the solar wind plasma that flows outward from the Sun and interacts with the Earth's geomagnetic field. This interaction energizes the plasma, accelerates charged particles into the thermosphere, and produces the aurora borealis and aurora australis, which are nearly circular-shaped regions of luminosity that surround the magnetic north and south poles respectively. Embedded within the thermosphere is the ionosphere, a weakly ionized plasma. *See* IONOSPHERE; MAGNETOSPHERE; PLASMA PHYSICS; SOLAR WIND.

In the thermosphere, these molecular species are subjected to intense solar ultraviolet radiation and photodissociation that gradually turns the molecular species into the atomic species oxygen, nitrogen, and hydrogen. Up to above 60 mi (100 km), atmospheric turbulence keeps the atmosphere well mixed, with the molecular concentrations dominating in the lower atmosphere. Above 60 mi, solar ultraviolet radiation most strongly dissociates molecular oxygen, and there is less mixing from atmospheric turbulence. The result is a transition area where molecular diffusion dominates and atmospheric species settle according to their molecular and atomic weights. Above 60 mi, atomic oxygen is the dominant species. *See* ATMOSPHERE.

About 60% of the solar ultraviolet energy absorbed in the thermosphere and ionosphere heats the ambient neutral gas and ionospheric plasma; 20% is radiated out of the thermosphere as airglow from excited atoms and molecules; and 20% is stored as chemical energy of the dissociated oxygen and nitrogen molecules, which is released later when recombination of the atomic species occurs. Most of the neutral gas heating that establishes the basic temperature structure of the thermosphere is derived from excess energy released by the products of ion-neutral and neutral chemical reactions occurring in the thermosphere and ionosphere. *See* Airglow; Ultraviolet radiation.

The average vertical temperature profile is determined by a balance of local solar heating by the downward conduction of molecular thermal product to the region of minimum temperature near 50 mi (80 km). For heat to be conducted downward within the thermosphere, the temperature of the thermosphere must increase with altitude. The global mean temperature increases from about 200 K (−100°F) near 50 mi to 700–1400 K (800–2100°F) above 180 mi (300 km), depending upon the intensity of solar ultraviolet radiation reaching the Earth. Above 180 mi, molecular thermal conduction occurs so fast that vertical temperature differences are largely eliminated; the isothermal temperature in the upper thermosphere is called the exosphere temperature.

As the Earth rotates, absorption of solar energy in the thermosphere undergoes a daily variation. Dayside heating causes the atmosphere to expand, and the loss of heat at night causes it to contract. This heating pattern creates pressure differences that drive a global circulation, transporting heat from the warm dayside to the cool nightside. [R.G.R.]

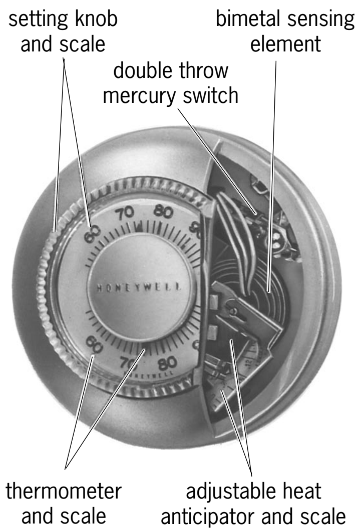
Thermostat An instrument which directly or indirectly controls one or more sources of heating and cooling to maintain a desired temperature. To perform this function a thermostat must have a sensing element and a transducer. The sensing element measures changes in the temperature and produces a desired effect on the transducer. The transducer converts the effect produced by the sensing element into a suitable control of the device or devices which affect the temperature.

The most commonly used principles for sensing changes in temperature are (1) unequal rate of expansion of two dissimilar metals bonded together (bimetals), (2) unequal expansion of two dissimilar metals (rod and tube), (3) liquid expansion (sealed diaphragm and remote bulb or sealed bellows with or without a remote bulb), (4) saturation pressure of a liquid-vapor system (bellows), and (5) temperature-sensitive resistance element.

The most commonly used transducers are (1) switches that make or break an electric circuit, (2) potentiometer with a wiper that is moved by the sensing element, (3) electronic amplifier, and (4) pneumatic actuator.

The most common thermostat application is for room temperature control. The illustration shows a typical on-off heating-cooling room thermostat. In a typical application the thermostat controls a gas valve, oil burner control, electric heat control, cooling compressor control, or damper actuator.

Thermostats are also used extensively in safety and limit application. Thermostats are generally of the following types: insertion types that are mounted on ducts with the sensing element extending into a duct; immersion types that control a liquid in a pipe or tank with the sensing element extending into the liquid; and surface types in which the sensing element is mounted on a pipe or similar surface. *See* Comfort heating; Furnace; Oil burner. [N.R.]



Typical heat-cool thermostat. (*Honeywell Inc.*)

Thermotherapy The treatment of disease by the local or general application of heat. The following discussion is limited to the local application of heat as an adjunct to therapeutic management of musculoskeletal and joint diseases. The most commonly used methods for this form of treatment include hot packs, hydrotherapy, radiant heat, shortwave diathermy, microwave diathermy, ultrasound, and laser therapy.

The reason so many different methods are employed is that each modality heats selectively different anatomical structures, and thus the modality selected for a given treatment is based on the temperature distribution produced in the tissues. For vigorous heat application to a given site, the location of the peak temperature produced by the modality must coincide with the site so that maximally tolerated tissue temperatures can be obtained there without burning elsewhere. Customarily, the modalities are divided into those that heat superficial tissues and those that heat deep-seated tissues. Hot packs, hydrotherapy, and radiant heat are used to heat superficial tissues. Photons of ultraviolet radiation, x-rays, and radium penetrate deeper into the tissues and produce photochemical reactions long before the temperature increases significantly. Other forms of energy used for heating deep-seated tissues include shortwave, microwave, and ultrasound. *See* Electromagnetic radiation; Microwave; Ultrasonics.

The therapeutic effects produced by heating selectively by ultrasound include an increase in the extensibility of collagen tissues. Disease or injury, such as arthritis, burns, scarring, or long-term immobilization in a cast, may cause shortening of collagen tissue producing severe limitation of the range of motion at a joint. This application of heat (mostly ultrasound) is often used in conjunction with physical therapy. Heat applied by using shortwaves and microwaves may reduce muscle spasms secondary to musculoskeletal pathology. Selective heating of muscle with microwave radiation has been used to accelerate absorption of hematomas and to prepare for stretching of the contracted and stiffened muscle. Heat therapy in the form of hyperthermia has been used as an effective adjunct to cancer therapy in combination with ionizing radiation in the form of x-rays or radium therapy.

The most commonly used laser in physical therapy is the helium-neon laser. The depth of penetration and the heating effect are similar to infrared light. However, the major difference between laser light and diffuse light of the same wavelength is that with laser light, any desirable intensity can be easily produced. *See* Laser photobiology. [J.F.Le.]

Thévenin's theorem (electric networks) This theorem, from electric circuit theory, is also known as the Helmholtz or Helmholtz-Thévenin theorem, since H. Helmholtz stated it in an earlier form prior to M. L. Thévenin. Closely related is the Norton theorem, which will also be discussed. Laplace transform notation will be used. *See* Laplace transform.

Thévenin's theorem states that at a pair of terminals a network composed of lumped, linear circuit elements may, for purposes of analysis of external circuit or terminal behavior, be replaced by a voltage source $V(s)$ in series with a single impedance $Z(s)$. The source $V(s)$ is the Laplace transform of the voltage across the pair of terminals when they are open-circuited; $Z(s)$ is the transform impedance at the two terminals with all independent sources set to zero (Fig. 1).

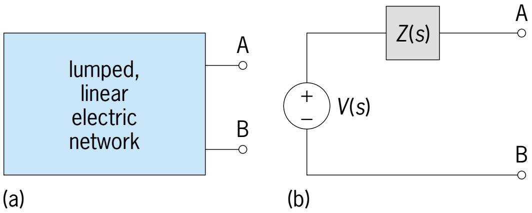


Fig. 1. Network and its Thévenin equivalent. (*a*) Original network. (*b*) Thévenin equivalent circuit.

Norton's theorem states that a second equivalent network consists of a current source $I(s)$ in parallel with an impedance $Z(s)$. The impedance $Z(s)$ is identical with the Thévenin impedance, and $I(s)$ is the Laplace transform of the current between the two terminals when they are short-circuited (Fig. 2).

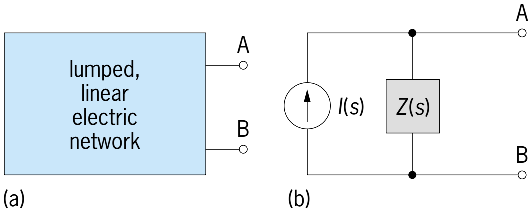

Fig. 2. Network and its Norton equivalent. (*a*) Original network. (*b*) Norton equivalent circuit.

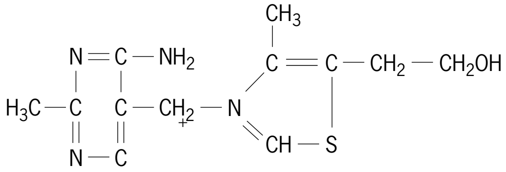
Thévenin's and Norton's equivalent networks are related by the equation $V(s) = Z(s) \cdot I(s)$.

These theorems are useful for the study of the behavior of a load connected to a (possibly complex) system that is supplying electric power to that load. *See* Superposition theorem (electric networks). [E.C.Jo.]

Thiamine A water-soluble vitamin found in many foods; pork, liver, and whole grains are particularly rich sources. It is also known as vitamin B_1 or aneurin. The structural formula of thiamine is shown below.



Thiamine deficiency is known as beriberi in humans and polyneuritis in birds. Muscle and nerve tissues are affected by the deficiency, and poor growth is observed. People with beriberi are irritable, depressed, and weak. They often die of cardiac failure. Wernicke's disease observed in alcoholics is associated with a thiamine deficiency. This disease is characterized by brain lesions, liver disease, and partial paralysis, particularly of the motor nerves of the eye. As is the case in all B vitamin diseases, thiamine deficiency is usually accompanied by deficiencies of other vitamins. [S.N.G.]

Thick-film sensor A sensor that is based on a thick-film circuit. Thick-film circuits are formed by the deposition of layers of special pastes onto an insulating substrate. The pastes are usually referred to as inks, although there is little resemblance to conventional ink. The printed pattern is fired in a manner akin to the production of pottery, to produce electrical pathways of a controlled resistance. Parts of a thick-film circuit can be made sensitive to strain or temperature. The thick-film pattern can include mounting positions for the insertion of conventional silicon devices, in which case the assembly is known as a thick-film hybrid. The process is relatively cheap, especially if large numbers of devices are produced, and the use of hybrid construction allows the sensor housing to include sophisticated signal conditioning circuits. These factors indicate that thick-film technology is likely to play an increasing role in sensor design.

The three main categories of thick-film inks are conductors, dielectrics (insulators), and resistors. Conductors are used for interconnections, such as the wiring of bridge circuits. Dielectrics are used for coating conducting surfaces (such as steel) prior to laying down thick-film patterns, for constructing thick-film capacitors, and for insulating cross-over points, where one conducting path traverses another. Resistor inks are the most interesting from the point of view of sensor design, since many thick-film materials are markedly piezoresistive. The piezoresistive properties of thick-film resistor inks can be used to form strain sensors. This approach is commonly used to manufacture pressure sensors and is exploited to produce accelerometers. *See* Accelerometer; Pressure transducer; Strain gage.

Piezoresistive sensors. Piezoresistive sensors are formed by placing stress-sensitive resistors on highly stressed parts of a suitable mechanical structure. The piezoresistive transducers are usually attached to cantilevers, or other beam configurations, and are connected in a Wheatstone bridge circuit. The beam may carry a seismic mass to form an accelerometer or may deform in response to an externally applied force. The stress variations in the transducer are converted into an electrical output, which is proportional to strain, by the piezoresistive effect. *See* Wheatstone bridge.

Temperature sensors. The linear temperature coefficient of resistance possessed by certain platinum-containing conductive inks has allowed thermistors to be printed onto suitable substrates using thick-film fabrication techniques. Thick-film thermistors are very inexpensive and physically small, and have the further advantage of being more intimately bonded to the substrate than a discrete component. It has been shown that thick-film thermistors can have as good, if not better, performance than a comparable discrete component. *See* Thermistor.

Chemical sensors. Thick-film materials have been used for a number of chemical sensing applications, including the measurement of gas and liquid composition, acidity (pH), and humidity. A classification based on two categories seems to cover most devices: impedance-based transducers, in which the measurand causes a variation of resistance, capacitance, and so forth; and electrochemical systems, in which the sensed quantity causes a change in electrochemical potential or current. *See* Electrical impedance; Electrochemistry. [J.D.T.]

Thickening The production of a concentrated slurry from a dilute suspension of solid particles in a liquid. In practice, a thickener also usually generates a clear liquid; therefore clarification is generally a concurrent process. Thickening and clarification are outcomes of sedimentation, and both are representative of a group of industrial processes termed mechanical separations. Although thickening may be carried out either batchwise or continuously, the latter method is more common. *See* Clarification; Sedimentation (industry).

Thickeners are especially useful when large volumes of dilute slurries must be treated, as in manufacture of cement, production of magnesium from seawater, treatment of sewage, purification of water, treatment of coal, and dressing of metallurgical ores. [V.W.U.]

Thigmotrichida A restricted group of forms constituting an order of the Holotrichia and generally found in association with mollusks from both fresh and salt water. Some are mouthless. Those species with a cytostome are generally equipped with a buccal ciliature which indicates an advance over the primitive hymenostome arrangement. *See* HOLOTRICHIA; HYMENOSTOMATIDA. [J.O.C.]

Thinner A material used in paints and varnishes to adjust the consistency for application. Thinners are usually solvents for the vehicle used in the coating and are expected to evaporate after application. Water is used as a thinner in emulsion paints and in certain water-soluble paints such as watercolors and calcimines. Petroleum fractions are most commonly used for oil and resin coatings. Stronger solvents contain substantial amounts of aromatic hydrocarbons and may be derived from petroleum or coal tar.

Since numerous coating resins are not sufficiently soluble in hydrocarbons, other materials or mixtures must be used. These include alcohols such as denatured ethyl or isopropyl alcohols for shellac, esters such as amyl acetate for nitrocellulose, and ketones and other compounds for acrylic and vinyl resins. Chlorinated hydrocarbons are used for some materials which are otherwise hard to dissolve, but toxicity limits their usefulness. *See* PAINT; SOLVENT; SURFACE COATING; TURPENTINE; VARNISH. [C.R.Ma; C.W.Si.]

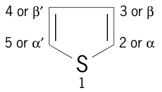
Thiocyanate A compound containing the —SCN group, typically a salt or ester of thiocyanic acid (HSCN). Thiocyanates are bonded through the sulfur(s) and have the structure $\mathrm{R{-}S{-}C{\equiv}N}$. They are isomeric with the isothiocyanates, $\mathrm{R{-}N{=}C{\equiv}S}$, which are the sulfur analogs of isocyanates (—NCO). The thiocyanates may be viewed as structural analogs of the cyanates (—OCN), where the oxygen (O) atom is replaced by a sulfur atom.

The principal commercial derivatives of thiocyanic acid are ammonium and sodium thiocyanates. Thiocyanates and isothiocyanates have been used as insecticides and herbicides. Specifically, ammonium thiocyanate is used as an intermediate in the manufacture of herbicides and as a stabilizing agent in photography. Sodium and potassium thiocyanates are used in the manufacture of textiles and the preparation of organic thiocyanates.

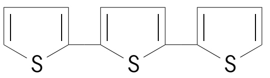
In living systems, thiocyanates are the product of the detoxification of cyanide ion (CN—) by the action of 3-mercaptopyruvate sulfur transferase. In addition, thiocyanates can interfere with thyroxine synthesis in the thyroid gland and are part of a class known as goitrogenic compounds. *See* CYANIDE; SULFUR; THYROXINE. [T.J.Me.]

Thiophene An organic heterocyclic compound containing a diunsaturated ring of four carbon atoms and one sulfur atom. *See* HETEROCYCLIC COMPOUNDS.

Thiophene (**1**), methylthiophenes, and other alkylthiophenes are found in relatively small amounts in coal tar and petroleum. Thiophene accompanies benzene in the fractional distillation of coal tar. 2,5-Dithienylthiophene (**2**) has been found in the marigold plant. Biotin, a water-soluble vitamin, is a tetrahydrothiophene derivative.



(1)



(2)

The parent compound (**1**) is nearly insoluble in water, with mp −38.2°C (−36.8°F), bp 84.2°C (183.6°F), and specific gravity (20/4) 1.0644. Thiophene is considered to be an aromatic compound. Thiophenes are stable to alkali and other nucleophilic agents, and are relatively resistant to disruption by acid. *See* AROMATIC HYDROCARBON; ORGANOSULFUR COMPOUND. [W.J.Ge.; M.St.]

Thiosulfate A salt containing the negative ion $S_2O_3^{2-}$. This species is an important reducing agent and may be viewed as a structural analog of the sulfate ion (SO_4^{2-}) where one of the oxygen (O) atoms has been replaced by a sulfur (S) atom. The sulfur atoms of the thiosulfate ion are not equivalent. Thiosulfate is tetrahedral, and the central sulfur is in the formal oxidation state 6+ and the terminal sulfur is in the formal oxidation state 2−.

Principal uses of thiosulfates include agricultural, photographic, and analytical applications. Ammonium thiosulfate [$(NH_4)_2S_2O_3$] is exploited for both the nitrogen and sulfur content, and it is combined with other nitrogen fertilizers such as urea. Thiosulfate ion is an excellent complexing agent for silver ions (bound through sulfur). The sodium salt and the ammonium salt are well known as the fixing agent "hypo" used in photography. The aqueous thiosulfate ion functions as a scavenger for unreacted solid silver bromide on exposed film and therefore prevents further reaction with light. In nature, thiosulfate is converted into hydrogen sulfide (H_2S) via enzymatic reduction. Hydrogen sulfide, in turn, is converted into the thiol group of cysteine by the reaction with *O*-acetylserine. *See* COORDINATION COMPLEXES; OXIDATION-REDUCTION; PHOTOGRAPHIC MATERIALS; SULFUR. [T.J.Me.]

Thirst and sodium appetite The sensations caused by dehydration, the continuing loss of fluid through the skin and lungs and in the urine and feces while there is no water intake into the body. Thirst becomes more and more insistent as dehydration worsens. Water and electrolytes are needed to replace losses, and an adequate intake of sodium as well as water is important for maintaining blood volume. Normally, the amounts of water drunk and taken in food are more than enough to maintain hydration of the body, and the usual mixed diet provides all the electrolytes required.

Deficit-induced drinking occurs when a deficit of fluid in one or both of the major fluid compartments of the body serves as a signal to increase drinking. Cellular dehydration, detected by osmoreceptors, causes thirst and vasopressin release. Hypovolemia (low blood volume), detected by volume receptors in the heart and large veins and the arterial baroreceptors, causes immediate thirst, a delayed increase in sodium appetite, activation of the renin-angiotensin system, and increased mineralocorticoid and vasopressin secretion. Increases or decreases in amounts drunk in disease may result from normal or abnormal functioning of mechanisms of thirst or sodium appetite.

Cellular dehydration. Observations using a variety of osmotic challenges have established that hyperosmotic solutions of solutes that are excluded from cells cause more drinking than equiosmolar amounts of solutes that penetrate cells. Thus, the osmotic shift of water out of the cells caused by the excluded solutes provides the critical stimulus to drinking. Continuing water loss in the absence of intake is perhaps a more significant cause of cellular dehydration than administration of an osmotic load, but the same mechanisms apply. *See* OSMOSIS.

Sharing in the overall cellular dehydration are osmoreceptors which initiate the responses of thirst and renal conservation of water. Osmoreceptors are mainly located in the hypothalamus. The nervous tissue in the hypothalamus surrounding the anterior third cerebral ventricle and, in particular, the vascular organ of the lamina terminalis also respond to osmotic stimuli. Osmoreceptors initiating thirst work in conjunction with osmoreceptors initiating antidiuretic hormone (ADH) release to restore the cellular water to its prehydration level. In addition to reducing urine loss, ADH may lower the threshold to the onset of drinking in response to cellular dehydration and other thirst stimuli. The cellular dehydration system is very sensitive, responding to changes in effective osmolality of 1–2%.

Hypovolemia. The cells of the body are bathed by sodium-rich extracellular fluid that corresponds to the aquatic environment of the unicellular organism. Loss of sodium from the extracellular fluid is inevitably accompanied by loss of water, resulting in hypovolemia with thirst followed by a delayed increase in sodium appetite. If not corrected, continuing severe sodium loss eventually leads to circulatory collapse.

Stretch receptors in the walls of blood vessels entering and leaving the heart and in the heart itself are thought to initiate hypovolemic drinking. Volume receptors in the venoatrial junctions and receptors that register atrial and ventricular pressure respond to the underfilling of the circulation with a reduction in inhibitory nerve impulses to the thirst centers, which results in increased drinking. Angiotensin II and other hormones (such as aldosterone and ADH) are also involved in this response. Arterial baroreceptors function in much the same way as the volume receptors on the low-pressure side of the circulation, exerting continuous inhibitory tone on thirst neurons. A fall in blood pressure causes increased drinking, whereas an acute rise in blood pressure inhibits drinking. The anterior third cerebral ventricle region, which is implicated in angiotensin-induced drinking, plays a crucial role in hypovolemic drinking, body fluid homeostasis, and blood pressure control.

Renin-angiotensin systems. It is believed that drinking caused by hypovolemic stimuli partly depends on the kidneys. The renal thirst factor is the proteolytic enzyme renin, which is secreted into the circulation by the kidney in response to hypovolemia. Renin cleaves an inactive decapeptide, angiotensin I, from angiotensinogen, an α_2-globulin that is synthesized in the liver and released into the circulation. Angiotensin I is converted to the physiologically active octapeptide angiotensin II during the passage of blood through the lungs. Angiotensin II is an exceptionally powerful stimulus of drinking behavior in many animals when administered systemically or into the brain. Increased activation of the renin-angiotensin system may sometimes account for pathologically increased thirst in humans. Angiotensin II also produces (1) a rise in arterial blood pressure, release of norepinephrine from sympathetic nerve endings, and secretion of adrenomedullary hormones; and (2) water and sodium retention by causing release of ADH from the posterior pituitary and stimulation of renal tubular transport of sodium through direct action on the kidney and indirectly through increased aldosterone secretion from the adrenal cortex. *See* ALDOSTERONE; KIDNEY.

Neuropharmacology. Many substances released by neurons, and in some cases by neuroglial cells, affect drinking behavior when injected into the brain and may interact with the brain and modify angiotensin-induced drinking. Substances may stimulate or inhibit drinking, or both, depending on the species and the conditions of the experiment. Acetylcholine is a particularly powerful stimulus to drinking in rats, and no inhibitory effects on drinking have been described. Histamine also seems to be mainly stimulatory. However, a lengthening list of neuroactive substances, including norepinephrine, serotonin, nitric oxide, opioids, bombesin-like peptides, tachykinins, and neuropeptide Y, may either stimulate or inhibit drinking with varying degrees of effectiveness, depending on the species or the site of injection in the brain. Natriuretic peptides, prostaglandins, and gamma-amino butyric acid seem to be exclusively inhibitory. *See* ACETYLCHOLINE; NEUROBIOLOGY; SYNAPTIC TRANSMISSION.

Many hormones also affect water or sodium intake. Relaxin stimulates water intake, and ADH (or vasopressin) lowers the threshold to thirst in some species. Vasopressin injected into the third cerebral ventricle may stimulate water intake, suggesting a possible role for vasopressinergic neurons. Increased sodium appetite in pregnancy and lactation depends partly on the conjoint action of progesterone, estrogen, adrenocorticotrophic hormone (ACTH), cortisol, corticosterone, prolactin, and oxytocin. Aldosterone and other mineralocorticoids, the stress hormones of the hypothalamo-pituitary-adrenocortical axis, corticotrophin, ACTH, and the glucocorticoids also stimulate sodium intake. *See* ENDOCRINE MECHANISMS; NEUROHYPOPHYSIS HORMONE.

The effect of many of these substances on drinking behavior shows both species and anatomical diversity. The multiplicity of effects of many of these substances makes it impossible to generalize on their role in natural thirst, but none of these substances seems to be as consistent and as universal a stimulus of increased thirst and sodium appetite as angiotensin. [J.T.F.]

Thomson effect A phenomenon discovered in 1854 by William Thomson, later Lord Kelvin. He found that there occurs a reversible transverse heat flow into or out of a conductor of a particular metal, the direction depending upon whether a longitudinal electric current flows from colder to warmer metal or from warmer to colder. Any temperature gradient previously existing in the conductor is thus modified if a current is turned on. The Thomson effect does not occur in a current-carrying conductor which is initially at uniform temperature. *See* THERMOELECTRICITY. [J.W.St.]

Thoracica The major order of the crustacean subclass Cirripedia. The adult animals are permanently attached. The mantle is usually reinforced by calcareous plates. Six pairs of biramous cirri are present, and the abdomen is absent or represented by caudal appendages. Antennules are present in the adult, and cement glands are strongly developed. Most species are hermaphroditic. Thoracica are subdivided into three suborders: Lepadomorpha, stalked or goose barnacles; Balanomorpha, the common acorn barnacles; and Verrucomorpha, a rare group of asymmetric barnacles. *See* BALANOMORPHA; BARNACLE; CIRRIPEDIA; LEPADOMORPHA; VERRUCOMORPHA. [H.G.St.]

Thorianite A radioactive mineral with the idealized composition ThO_2 (thorium dioxide) and isostructural with uraninite (pitchblende). Rare earths and uranium are often present in variable amounts, together with small amounts of radiogenic lead. Thorianite usually occurs as worn cubic crystals. The hardness is about 7 on Mohs scale, and the specific gravity is 9.7–9.8. The color is brownish black to reddish brown, and the luster usually is resinous. Thorianite is a primary mineral found chiefly in pegmatites. It is best known as a detrital mineral. It has been obtained commercially from detrital deposits and pegmatites in Madagascar and Ceylon. *See* NUCLEAR FUELS; PEGMATITE; RADIOACTIVE MINERALS; RARE-EARTH ELEMENTS; THORIUM; URANINITE; URANIUM. [C.Fr.]

Thorite A mineral, thorium silicate. The idealized chemical formula of thorite is $ThSiO_4$. All natural material departs widely from this composition owing to the partial substitution of uranium, rare earths, calcium, and iron for thorium. The specific gravity ranges between about 4.3 and 5.4. The hardness on Mohs scale is about $4^1/_2$. The color commonly is brownish yellow to brownish black and black.

Vein deposits containing thorite occur in Colorado, Idaho, and Montana. A vein deposit of monazite containing thorium is mined at Steenkampskraal near Van Rhynsdorp, Cape Province, South Africa. *See* METAMICT STATE; RADIOACTIVE MINERALS; SILICATE MINERALS; THORIUM. [C.Fr.]

Thorium A chemical element, Th, atomic number 90. Thorium is a member of the actinide series of elements. It is radioactive with a half-life of about 1.4×10^{10} years. *See* PERIODIC TABLE.

Thorium oxide compounds are used in the production of incandescent gas mantles. Thorium oxide has also been incorporated in tungsten metal, which is used for electric light filaments. It is employed in catalysts for the promotion of certain organic chemical reactions and has special uses as a high-temperature ceramic material. The metal or its oxide is employed in some electronic tubes, photocells, and special welding electrodes. Thorium has important applications as an alloying agent in some structural metals. Perhaps the major use for thorium metal, outside the nuclear field, is in magnesium technology. Thorium can be converted in a nuclear reactor to uranium-233, an atomic fuel. The energy available from the world's supply of thorium has been estimated as greater than the energy available from all of the world's uranium, coal, and oil combined.

Monazite, the most common and commercially most important thorium-bearing mineral, is widely distributed in nature. Monazite is chiefly obtained as a sand, which is separated from other sands by physical or mechanical means. *See* Monazite.

Thorium has an atomic weight of 232. The temperature at which pure thorium melts is not known with certainty; it is thought to be about 1750°C (3182°F). Good-quality thorium metal is relatively soft and ductile. It can be shaped readily by any of the ordinary metal-forming operations. The massive metal is silvery in color, but it tarnishes on long exposure to the atmosphere; finely divided thorium has a tendency to be pyrophoric in air.

All of the nonmetallic elements, except the rare gases, form binary compounds with thorium. With minor exceptions, thorium exhibits a valence of 4+ in all of its salts. Chemically, it has some resemblance to zirconium and hafnium. The most common soluble compound of thorium is the nitrate which, as generally prepared, appears to have the formula $Th(NO_3)_4 \cdot 4H_2O$. The common oxide of thorium is ThO_2, thoria. Thorium combines with halogens to form a variety of salts. Thorium sulfate can be obtained in the anhydrous form or as a number of hydrates. Thorium carbonates, phosphates, iodates, chlorates, chromates, molybdates, and other inorganic salts of thorium are well known. Thorium also forms salts with many organic acids, of which the water-insoluble oxalate, $Th(C_2O_4)_2 \cdot 6H_2O$, is important in preparing pure compounds of thorium. *See* Actinide elements; Radioactivity. [H.A.W.]

Throat The region that includes the pharynx, the larynx, and related structures. Both the nasal passages and the oral cavity open into the pharynx, which also contains the openings of the Eustachian tubes from the ears. The lower portion of the pharynx leads into the esophagus and the trachea or windpipe. The rather funnel-shaped pharynx is suspended from the base of the skull and the jaws; it is surrounded by three constrictor muscles that function primarily in swallowing. *See* Ear; Pharynx.

The larynx, or voice box, is marked externally by the shield-shaped thyroid cartilage which forms the Adam's apple. The larynx contains the vocal cords that act as sphincters for air regulation and permit phonation. The lower end of the larynx is continuous with the trachea, a tube composed of cartilaginous rings and supporting tissues. *See* Larynx.

The term throat is also used in a general sense to denote the front (ventral side) of the neck. [T.S.P.]

Thrombosis The process of forming a thrombus, which is a solid mass or plug in the living heart or vessels composed of the constituents of the blood. Thrombosis usually occurs in a diseased blood vessel, as a result of arteriosclerosis. The consequences of thrombosis include local obstruction causing both tissue death and hemorrhage. Thrombosis is a significant factor in the death of an individual affected by arteriosclerotic cardiovascular disease, malignancy, and infection. *See* Hemorrhage; Infarction.

Thrombosis is usually initiated by vascular damage and consequent platelet adhesion and clumping. The process is initiated when platelets specifically adhere to the subendothelial collagen at the points of damage to the endothelium. At the same time that the platelets begin to aggregate and release products that will further promote thrombus formation, the protein factors of the blood, which help to form the insoluble meshwork of the thrombus, become activated. This latter process is known as blood coagulation. The proteins of the coagulation system, through a series of cascading reactions, eventually reach a final common pathway to form fibrin, the insoluble protein that forms the scaffolding of the thrombus. As blood flows by the thrombus, more platelets and fibrin are deposited. Red blood cells and white blood cells become entrapped in the thrombus and are integrated into its structure. *See* Fibrinogen.

Once a thrombus forms, it can have one of four fates. (1) It may be digested, destroyed, and removed by proteolytic enzymes of the plasminogen-plasmin system. (2) It may continue to propagate itself and eventually occlude the vessel. (3) It may give rise to an embolus. Emboli may cause tissue damage at sites distant from the origin of the thrombus. (4) It may undergo a process known as organization. Organization helps stabilize the thrombus, and it may result in incorporation of a contracted fibrous mass into the vessel wall. *See* Embolism.

Maintaining good blood flow (especially in the veins) helps prevent thrombosis. Treating hypertension and hypercholesterolemia retards atherosclerosis, which is a major cause of arterial thrombosis. Agents that interfere with platelet function, such as aspirin and fish oils, may help avoid thrombotic episodes. Anticoagulants prevent the formation of fibrin and may also be used to prevent thrombosis. If treatment can be given in the early stages of thrombosis, fibrinolytic therapy, utilizing agents that will help form plasmin, can minimize the tissue damage caused by thrombosis. *See* Arteriosclerosis; Circulation disorders; Phlebitis. [I.N.; R.A.V.]

Thrust The force that propels an aerospace vehicle or marine craft. Thrust is a vector quantity. Its magnitude is usually given in newtons (N) in International System (SI) units or pounds-force (lbf) in U.S. Customary Units. A newton is defined as 1 kilogram mass times an acceleration of 1 meter per second squared. One newton equals approximately 0.2248 lbf. *See* Force; Units of measurement.

The thrust power of a vehicle is the thrust times the velocity of the vehicle. It is expressed in joules (J) per second or watts (W) in SI units. In U.S. Customary Units thrust power is expressed in foot-pounds per second, which can be converted to horsepower by dividing by 550. *See* Jet propulsion; Power; Ramjet; Reciprocating aircraft engine; Rocket; Turbojet. [J.P.L.]

Thulium A chemical element, Tm, atomic number 69, atomic weight 168.934. It is a rare metallic element belonging to the rare-earth group. The stable isotope ^{169}Tm makes up 100% of the naturally occurring element. *See* Periodic table.

The salts of thulium possess a pale green color and the solutions have a slight greenish tint. The metal has a high vapor pressure at the melting point. When ^{169}Tm is irradiated in a nuclear reactor, $_{170}$Tm is formed. The isotope then emits strongly an 84-keV x-ray, and this material is useful in making small portable x-ray units for medical use. *See* Rare-earth elements. [F.H.Sp.]

Thunder The acoustic radiation produced by thermal lightning channel processes. The lightning return stroke is a high surge of electric current that has a very short duration, depositing approximately 95% of its electrical energy during the first 20 microseconds. Spectroscopic studies have shown that the lightning channel is heated to temperatures in the 20,000–30,000 K (36,000–54,000°F) range by this process. The pressure of the hot channel exceeds 10 atm ($>10^6$ pascals). The hot, high-pressure channel expands supersonically and forms a shock wave as it pushes against the surrounding air. Because of the momentum gained in expanding, the shock wave overshoots, causing the pressure in the core of the channel to go below atmospheric pressure temporarily. The outward-propagating wave separates from the core of the channel, forming an N-shaped wave that eventually decays into an acoustic wavelet. *See* SHOCK WAVE; STORM ELECTRICITY.

The sound that is eventually heard or detected, thunder, is the sum of many individual acoustic pulses, each a remnant of a shock wave, that have propagated to the point of observation from the generating channel segments. The first sounds arrive from the nearest part of the lightning channel and the last sounds from the most distant parts.

The higher the source of the sound, the farther it can be heard. Frequently, the thunder that is heard originates in the cloud and not in the visible channel. On some occasions, the observer may hear no thunder at all; this is more frequent at night when lightning can be seen over long distances and thunder can be heard only over a limited range (∼10 km or 6 mi). *See* LIGHTNING; THUNDERSTORM. [A.A.F.]

Thunderstorm A convective storm accompanied by lightning and thunder and a variety of weather such as locally heavy rainshowers, hail, high winds, sudden temperature changes, and occasionally tornadoes. The characteristic cloud is the cumulonimbus or thunderhead, a towering cloud, generally with an anvil-shaped top. A host of accessory clouds, some attached and some detached from the main cloud, are often observed in conjunction with cumulonimbus. *See* LIGHTNING; THUNDER.

Thunderstorms are manifestations of convective overturning of deep layers in the atmosphere and occur in environments in which the decrease of temperature with height (lapse rate) is sufficiently large to be conditionally unstable and the air at low levels is moist. In such an atmosphere, a rising air parcel, given sufficient lift, becomes saturated and cools less rapidly than it would if it remained unsaturated because the released latent heat of condensation partly counteracts the expansional cooling. The rising parcel reaches levels where it is warmer (by perhaps as much as 18°F or 10°C over continents) and less dense than its surroundings, and buoyancy forces accelerate the parcel upward. The rising parcel is decelerated and its vertical ascent arrested at altitudes where the lapse rate is stable, and the parcel becomes denser than its environment. The forecasting of thunderstorms thus hinges on the identification of regions where the lapse rate is unstable, low-level air parcels contain adequate moisture, and surface heating or uplift of the air is expected to be sufficient to initiate convection. *See* CONVECTIVE INSTABILITY; FRONT.

Thunderstorms are most frequent in the tropics, and rare poleward of 60° latitude. Thunderstorms are most common during late afternoon because of the diurnal influence of surface heating.

Radar is used to detect thunderstorms at ranges up to 250 mi (400 km) from the observing site. Much of present-day knowledge of thunderstorm structure has been deduced from radar studies, supplemented by visual observations from the ground and satellites, and in-place measurements from aircraft, surface observing stations, and weather balloons. *See* METEOROLOGICAL INSTRUMENTATION; RADAR METEOROLOGY; SATELLITE METEOROLOGY.

Thunderstorms are considered severe when they produce winds greater than 58 mi/h (26 m/s or 50 knots), hail larger than 3/4 in. (19 mm) in diameter, or tornadoes. While thunderstorms are generally beneficial because of their needed rains (except for occasional flash floods), severe storms have the capacity of inflicting utter devastation over narrow swaths of the countryside. Severe storms are most frequently supercells which form in environments with high convective instability and moderate-to-large vertical wind shears. The supercell may be an isolated storm or part of a squall line. *See* HAIL; SQUALL; SQUALL LINE; TORNADO. [R.D.J.]

Thyme Any of a large and diverse group of plants in the genus Thymus utilized for their essential oil and leaves in both cooking and medicine. Hundreds of different forms, or ecotypes, of thyme are found in the Mediterranean area, where thyme occurs as a wild plant. *Thymus vulgaris*, generally considered to be the true thyme, is the most widely used and cultivated species. Both “French” and “German” thyme are varieties of this species. Most types of thyme are low-growing perennials, typically having small smooth-edged leaves that are closely spaced on stems that become woody with age.

Wild European thyme, the source of much imported material, is usually harvested only once a year, while cultivated plants in the United States are harvested mechanically up to three times a year. As with most herbs, both stems and leaves are harvested and then dehydrated. Dried stems and leaves are separated mechanically. Thyme oil is extracted from fresh material. Thyme is a widely used herb, both alone and in blends such as “fine herbs.” Thyme oil is used for flavoring medicines and has strong bactericidal properties. *See* SPICE AND FLAVORING. [S.Kir.]

Thymosin A polypeptide hormone synthesized and secreted by the endodermally derived reticular cells of the thymus gland. Thymosin exerts its actions in several loci: (1) in the thymus gland, either on precursor stem cells derived from fetal liver or from bone marrow, or on immature thymocytes, and (2) in peripheral sites, on either thymic-derived lymphoid cells or on precursor stem cells. The precursor stem cells, which are immunologically incompetent whether in the thymus or in peripheral sites, have been designated as predetermined T cells or T_0 cells, and mature through stages termed T_1 and T_2, each reflecting varying degrees of immunological competence. Thymosin promotes or accelerates the maturation of T_0 cells to T_1 cells as well as to the final stage of a T_2. In addition to this maturation influence, the hormone also increases the number of total lymphoid cells by accelerating the rate of proliferation of both immature and mature lymphocytes. *See* IMMUNITY; THYMUS GLAND. [A.W.]

Thymus gland An important central lymphoid organ in the neck or upper thorax of all vertebrates from elasmobranchs to mammals. The thymus gland is most prominent during early life. In many laboratory species of mammals and in humans it reaches its greatest relative weight at the time of birth, but its absolute weight continues to increase until the onset of puberty. Thereafter, it begins to undergo an involution and progressively decreases in size throughout adult life.

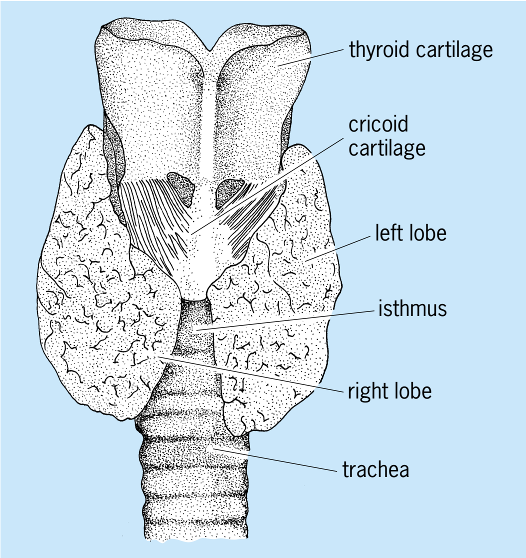
The thymic stem cells generate a large population of small lymphocytes (thymocytes) through a series of mitotic divisions. Simultaneously these dividing lymphocytes show evidence of cellular differentiation within the special thymic environment. During this division and maturation phase the developing thymocytes undergo an intrathymic migration from the peripheral cortical area to the medullary core of the organ. Some thymocytes degenerate within the organ, but many enter the circulating blood and lymph systems at various stages of maturity. A small percentage of the T lymphocyte population (5–10%) within the thymus is antigenically competent and capable of recognizing antigenic determinents on foreign cells or substances. Some of the T lymphocytes have the capacity to lyse the foreign tissue cells, while others are involved in recognizing the “foreignness” of the antigens and assisting a second sub-population of bone-marrow-derived lymphocytes (B lymphocytes) to respond to the antigen by producing a specific antibody. These two types of immunocompetent T lymphocytes are called killer cells and helper cells, respectively. They are involved in both tissue transplantation and humoral antibody responses. On the other hand, the vast majority of the thymic lymphocytes are immunologically incompetent (90–95%). Some thymocytes are thought to give rise to the smaller pool of immunocompetent T lymphocytes, but many emigrate into the circulating blood. *See* CELLULAR IMMUNOLOGY; LYMPHATIC SYSTEM; THYMOSIN. [C.E.S.]

Thyrocalcitonin A hormone, the only known secretory product of the parenchymal or C cells of the mammalian thyroid and of the ultimobranchial glands of lower forms.

In conjunction with the parathyroid hormone, thyrocalcitonin is of prime importance in regulating calcium and phosphate metabolism. Its major function is to protect the organism from the dangerous consequences of elevated blood calcium. Its sole known effect is that of inhibiting the resorption of bone. It thus produces a fall in the concentration of calcium and phosphate in the blood plasma because these two minerals are the major constituents of bone mineral and are released into the bloodstream in ionic form when bone is resorbed. *See* BONE; CALCIUM METABOLISM; PARATHYROID GLAND; PARATHYROID HORMONE.

Thyrocalcitonin also causes an increased excretion of phosphate in the urine under certain circumstances, but a question remains as to whether this is a direct effect of the hormone upon the kidney or an indirect consequence of the fall in blood calcium which occurs when the hormone inhibits bone resorption. *See* PHOSPHATE METABOLISM; THYROID GLAND. [H.Ras.]

Thyroid gland An endocrine gland found in all vertebrates that produces, stores, and secretes the thyroid hormones. In humans, the gland is located in front of, and on either side of, the trachea (see illustration). Thyrocalcitonin, one hormone of the thyroid gland, assists in regulating serum calcium by reducing its levels. The iodine-containing hormones thyroxine and triiodothyronine regulate metabolic rate in warm-blooded animals and are essential for normal growth and development. To produce these, the thyroid gland accumulates inorganic iodides from the bloodstream and unites them with the amino acid tyrosine. This activity is regulated by thyrotropic hormone from the anterior lobe of the pituitary gland. *See* THYROID HORMONE; THYROXINE. [G.C.Ke.]



Ventral view of human thyroid gland shown in relation to trachea and larynx. (*After C. K. Weichert, Elements of Chordate Anatomy, 3d ed., McGraw-Hill, 1967*)

Thyroid gland disorders Disorders of the thyroid gland may be classified according to anatomical and functional characteristics. Those thyroid disorders that are primarily anatomical include goiter and neoplasia; those that are primarily functional result in either hyperthyroidism or hypothyroidism.

Thyroid gland enlargement, or goiter, is the most common disorder. Its classification is based upon both the anatomy and function of the gland. An enlarged but normally functioning thyroid gland is termed a nontoxic goiter. This condition affects hundreds of millions of people throughout the world in areas where the diet is deficient in iodine. In other areas it may be caused by subtle disorders in the biosynthesis of thyroid hormone. In both cases, there is compensatory enlargement of the gland that can be diffuse and symmetrical or can produce a multinodular goiter. The multinodular goiter can grow independently from pituitary gland control and produce excess thyroid hormone, causing hyperthyroidism. However, hyperthyroidism is most often the result of Graves' disease. Thyroid enlargement can also be caused by Hashimoto's thyroiditis, in which the individual's immune system develops abnormal antibodies that react with proteins in the thyroid gland. This autoimmunity can make the gland enlarge or become underactive. *See* AUTOIMMUNITY.

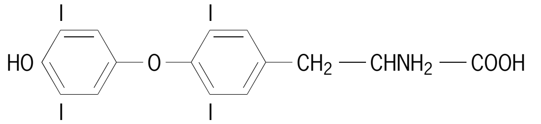
Tumors of the thyroid account for a small fraction of human neoplasms and an even smaller fraction of deaths due to cancer. The vast majority of thyroid neoplasms are follicular adenomas, which are benign; however, some thyroid neoplasms are malignant. Rarely, tumors arising elsewhere in the body can metastasize to the thyroid gland.

Hyperthyroidism is the clinical condition that results from excessive levels of the circulating thyroid hormones thyroxine and triiodothyronine, which are secreted by the thyroid gland. Signs and symptoms include weight loss, tachycardia (increased heart rate), heat intolerance, sweating, and tremor. Graves' disease, the most common form of hyperthyroidism, is mediated by an abnormal antibody directed to the thyroid-stimulating hormone (TSH) receptor on the surface of the thyroid cell, which stimulates secretion of thyroid hormone. Unique to Graves' disease is the associated protrusion of the eyes (exophthalmos).

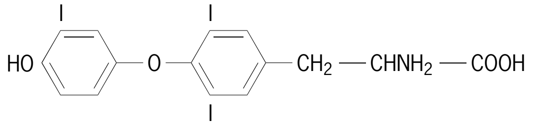
Hypothyroidism is the clinical state that results from subnormal levels of circulating thyroid hormones. Manifestations in infancy and childhood include growth retardation and reduced intelligence; in adults, cold intolerance, dry skin, weight gain, constipation, and fatigue predominate. Individuals with hypothyroidism often have a slow pulse (bradycardia), puffy dry skin, thin hair, and delayed reflexes. In its most extreme form, hypothyroidism can lead to coma and death if untreated. *See* THYROID GLAND; THYROID HORMONE. [L.J.DeG.; D.A.E.]

Thyroid hormone Any of the chemical messengers produced by the thyroid gland, including thyrocalcitonin, a polypeptide, and thyroxine and triiodothyronine, which are iodinated thyronines. *See* HORMONE; THYROCALCITONIN; THYROID GLAND; THYROXINE. [H.Ras.]

Thyroxine A hormone secreted by the thyroid gland. Thyroxine (structure **1**) is quite similar chemically and in biological activity to triiodothyronine (**2**). Both are derivatives of the amino acid tyrosine and are unique in being the only iodine-containing compounds of importance in the economy of all higher forms of animal life. The thyroid gland avidly accumulates the small amount of iodine in the diet. This iodine is oxidized to iodide ion in the gland and then reacts with tryosine to form mono- and diiodotyrosine. These latter are then coupled to form either thyroxine or triiodothyronine. *See* THYROID GLAND.



(1)



(2)

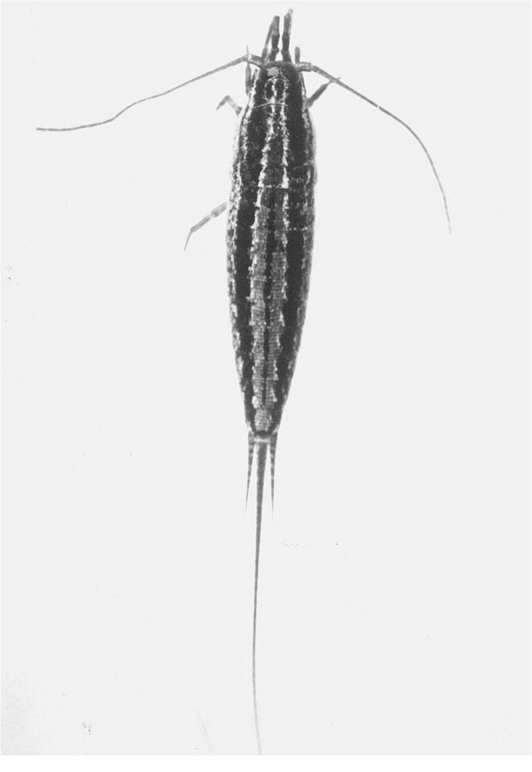
The maintenance of a normal level of thyroxine is critically important for normal growth and development as well as for proper bodily function in the adult. Its absence leads to delayed or arrested development. It is one of the few hormones with general effects upon all tissues. Its lack leads to a decrease in the general metabolism of all cells, most characteristically measured as a decrease in nucleic acid and protein synthesis, and a slowing down of all major metabolic processes. *See* THYROID GLAND DISORDERS. [H.Ras.]

Thysanoptera An order of small, slender insects, commonly called thrips, having exopterygote development, sucking mouthparts, and highly modified wings. The order is a relatively small one, but individuals are often very numerous in favorable environments. *See* THRIP.

The mouthparts are conical and used for scraping, piercing, and sucking. The wings are exceptionally narrow, with few or no veins, and are bordered by long hairs. The tarsi terminate in an inflatable membranous bladder, which has remarkable adhesive properties.

The eggs of thrips are laid on the surface of twigs (suborder Tubulifera) or in small cuts made by the ovipositor (suborder Terebrantia). There are usually four nymphal stages, the last of these being quiescent and pupalike. There are from one to several generations produced in a single year. *See* INSECTA. [F.M.C.]

Thysanura Primarily wingless insects, with soft, fusiform bodies from 0.12 to 0.80 in. (3 to 20 mm) long, often covered with scales forming diverse patterns (see illustration). These insects are considered by some authors to constitute two orders: the true Thysanura (silverfish and allies) and the Microcoryphia (machilids). The mouthparts are free. The mandibles are monocondylous in the machilids, and scraping in function; they are dicondylous—as in all winged insects—in the silverfish, in which they are of the chewing type. Machilids have large compound eyes, but silverfish have simple ommatidia, or lack eyes altogether. Many machilids have coxae with styliform appendages. Tarsi are from two- to five-segmented; there are two or three claws. Abdominal ventral plates are entire, or subdivided into a central sternum and posterolateral coxites. Abdominal styli are present in varied numbers. The females have well-developed ovipositors, and the males have a penis and often one or rarely two pairs of parameres. There are cerci and a median caudal filament.



***Machilinus* sp. (Microcoryphia).**

These primitive insects, fossils of which are known as far back as the Devonian (primitive machilids, the Monura), are worldwide in distribution. Machilids are more numerous in temperate climates, the silverfish in the tropics and subtropics. *See* APTERYGOTA; INSECTA. [P.W.W.]

Tick paralysis A loss of muscle function or sensation in humans or certain animals following the prolonged feeding of female ticks. Paralysis, of Landry's type, usually begins in the legs and spreads upward to involve the arms and other parts of the body. Evidence suggests that paralysis is due to a neurotoxin formed by the feeding ticks rather than the result of infection with microorganisms. *See* IXODIDES.

The disease has been reported in North America, Australia, South Africa, and occasionally in some European countries and is caused by appropriate species of indigenous ticks. In Australia, *Ixodes holocyclus* causes frequent cases in dogs, and occasional cases in humans, and paralysis has been known to progress even after removal of ticks. *Ixodes cubicundus* is associated with the disease in South Africa. [C.B.P.]

Tidal bore A part of a tidal rise in a river which is so rapid that water advances as a wall often several feet high. The phenomenon is favored by a substantial tidal range and a channel which shoals and narrows rapidly upstream, but the conditions are so critical that it is not common. Although the bore is a very striking feature, the tide continues to rise after the passage of the bore. Bores may be eliminated by changing channel depth or shape. *See* RIVER TIDES; TIDE.

In North America three bores have been observed: at the head of the Bay of Fundy (see illustration), at the head of the Gulf of California, and at the head of Cook Inlet, Alaska. The largest known bore occurs in the Tsientang Kiang, China. At spring tides this bore is a wall of water 15 ft (4.5 m) high moving upstream at 25 ft/s (7.5 m/s). [B.K.]

Tidal bore of the Petitcodiac River, Bay of Fundy, New Brunswick, Canada. Rise of water is about 4 ft (1.2 m). (*New Brunswick Travel Bureau*)

Tidal datum A reference elevation of the sea surface from which vertical measurements are made, such as depths of the ocean and heights of the land. The intersection of the elevation of a tidal datum with the sloping shore forms a line used as a horizontal boundary. In turn, this line is also a reference from which horizontal measurements are made for the construction of additional coastal and marine boundaries.

Since the sea surface moves up and down from infinitely small amounts to hundreds of feet over periods of less than a second to millions of years, it is necessary to stop the vertical motion in order to have a practical reference. This is accomplished by hydraulic filtering, numerical averaging, and segment definition of the record obtained from a tide gage affixed to the adjacent shore. Waves of periods up through wind waves are effectively damped by a restricting hole in the measurement well. Recorded hourly heights are averaged to determine the mean of the higher (or only) high tide of each tidal day (24.84 h), all the high tides, all the hourly heights, all the low tides, and the lower (or only) low tide. The length of the averaging segment is a specific 19 year, which averages all the tidal cycles through the regression of the Moon's nodes and the metonic cycle. [The metonic cycle is a time period of 235 lunar months (19 years); after this period the phases of the Moon occur on the same days of the same months.] But most of all, the 19-year segment is meaningful in terms of measurement capability, averaging meteorological events, and for engineering and legal interests. However, the 19-year segment must be specified and updated because of sea-level changes occurring over decades. The present tidal datum epoch is 1983 through 2001.

Tidal datums are legal entities. Because of variations in gravity, semistationary meteorological conditions, semipermanent ocean currents, changes in tidal characteristics, ocean density differences, and so forth, the sea surface (at any datum elevation) does not conform to a mathematically defined spheroid. *See* Geodesy; Tide. [S.D.H.]

Tidal power Tidal-electric power is obtained by utilizing the recurring rise and fall of coastal waters. Marginal marine basins are enclosed with dams, making it possible to create differences in the water level between the ocean and the basins. The oscillatory flow of water filling or emptying the basins is used to drive hydraulic turbines which propel electric generators.

Large amounts of electric power could be developed in the world's coastal regions having tides of sufficient range, although even if fully developed this would amount to only a small percentage of the world's potential water (hydroelectric) power. *See* Electric power generation; Tide. [G.G.A.]

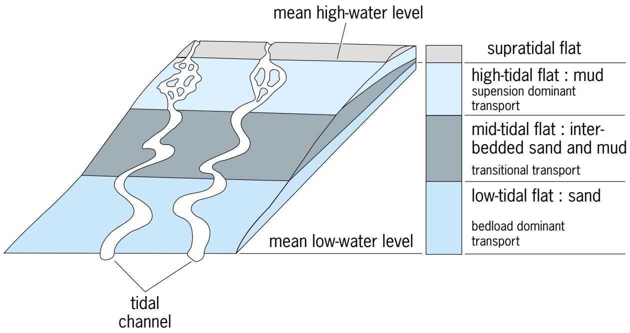
Tidalites Sediments of varied composition deposited by tidal processes in subtidal, intertidal, and supratidal environments. Tides along modern coastlines produce flood and ebb currents which advance and retreat between high- and low-water levels and also operate in subtidal environments. These currents are largely responsible for the formation of tidalites. *See* Tide.

The tidal flat, including the supratidal and intertidal zones, is the best understood of the tidal environments. In these zones both terrigenous and nonterrigenous tidal flats occur, the former often incised by tidal channels.

Terrigenous tidal flats consist of an intertidal zone that is subdivided into a low, mid, and high tidal flat (see illustration). Each of the specific tidal processes operate to produce sediments with characteristic textures and sedimentary structures. On extensive tidal flats, fine-grained sediments accumulate from suspension near high-water line, and coarser sandy sediments are deposited by bed-load processes around low-water level. On mid flats, interbedded sands and muds are developed under conditions of alternating bed-load and suspension sedimentation (see illustration). The supratidal flat receives limited quantities of marine sediment, and instead comprises salt marshes and mangrove swamps in humid climates, with sabkhas, consisting of evaporite minerals such as gypsum and halite, commonly developed under arid conditions.

Nonterrigenous tidal flats do not receive terrigenous clastic sediment. Instead, sediment which accumulates on these tidal flats consists predominantly of calcium carbonate produced within the basin. Various organisms which live mainly below low-water level form calcium carbonate in their life cycle, and upon death this hard framework breaks down to produce clay, silt, and sand-size carbonate particles. These are available for reworking both within the subtidal zone and onto the tidal flats.

Sedimentation below low-water level and under the influence of tides is occurring today in shallow shelf seas. The best understood is the North Sea, where sand transport by tidal currents is taking place down to depths of 150 ft (50 m). Echo sounding has shown that the sands form linear bodies up to 90 ft (30 m) high. They are asymmetric in cross section and, as revealed by seismic profiling, are structured internally by giant cross-strata.



Tidal-flat sedimentation model for the North Sea coasts of Germany and the Netherlands. (*After G. de V. Klein, Clastic Tidal Facies, Continuing Educational Publication Company, 1977*)

The recognition of tidalites in the geological record requires evidence of a marine environment, ebb and flood current flow, and exposure of the depositional surface during low-water stage for intertidalites. *See* Depositional systems and environments; Sedimentology. [K.A.Eri.]

Tide Stresses exerted in a body by the gravitational action of another, and related phenomena resulting from these stresses. Every body in the universe raises tides, to some extent, on every other. This article deals only with tides on the Earth, since these are fundamentally the same as tides on all bodies, and more specifically with variations of sea level, whatever their origin. *See* Gravitation; Sea-level fluctuations.

The tide-generating forces arise from the gravitational action of Sun and Moon, the effect of the Moon being about twice as effective as that of the Sun in producing tides. The tidal effects of all other bodies on the Earth are negligible. The tidal forces act to generate stresses in all parts of the Earth and give rise to relative movements of the matter of the solid Earth, ocean, and atmosphere. In the ocean the tidal forces act to generate alternating tidal currents and displacements of the sea surface.

If the Moon attracted every point within the Earth with equal force, there would be no tide. It is the small difference in direction and magnitude of the lunar attractive force, from one point of the Earth's mass to another, which gives rise to the tidal stresses. The tide-generating force is proportional to the mass of the disturbing body (Moon) and to the inverse cube of its distance. This inverse cube law accounts for the fact that the Moon is 2.17 times as important, insofar as tides are concerned, as the Sun, although the latter's direct gravitational pull on the Earth, which is governed by an inverse-square law, is about 180 times the Moon's pull.

At most places in the ocean and along the coasts, sea level rises and falls in a regular manner. The highest level usually occurs twice in any lunar day, the times bearing a constant relationship with the Moon's meridional passage. The time between the Moon's meridional passage and the next high tide is called the lunitidal interval. The difference in level between successive high and low tides, called the range of the tide, is generally greatest near the time of full or new Moon, and smaller near the times of quadrature. The range of the tide usually exhibits a secondary variation, being greater near the time of perigee (when the Moon is closest to the Earth) and smaller at apogee (when the Moon is farthest away).

The above situation is observed at places where the tide is predominantly semidiurnal. At many other places, it is observed that one of the two maxima in any lunar day is higher than the other. This effect is known as the diurnal inequality and represents the presence of an appreciable diurnal variation. At these places, the tide is said to be of the "mixed" type. At a few places, the diurnal tide actually predominates, there generally being only one high and low tide during the lunar day.

The range of the ocean tide varies between wide limits. The highest range is encountered in the Bay of Fundy, where values exceeding 50 ft (15 m) have been observed. In some places in the Mediterranean, South Pacific, and Arctic, the tidal range never exceeds 2 ft (0.6 m).

Owing to the rotation of the Earth, there is a gyroscopic, or Coriolis, force acting perpendicularly to the motion of any water particle in motion. In the Northern Hemisphere this force is to the right of the current vector. The horizontal, or tractive, component of the tidal force generally rotates in the clockwise sense in the Northern Hemisphere. As a result of both these influences the tidal currents in the open ocean generally rotate in the clockwise sense in the Northern Hemisphere, and in the counterclockwise sense in the Southern Hemisphere. *See* CORIOLIS ACCELERATION; EARTH TIDES. [G.W.G.]

Tie rod A tie rod or tie bar, usually circular in cross section, is used in structural parts of machines to tie together or brace connected members, or in moving parts of machines or mechanisms it may connect arms or parts to transmit motion. In the first use the rod ends are usually a threaded fastening, while in the latter they are usually forged into an eye for a pin connection. [P.H.B.]

Tile As a structural material, a burned clay product in which the coring exceeds 25% of the gross volume; as a facing material, any thin, usually flat, square product. Structural tile used for load bearing may or may not be glazed; it may be cored horizontally or vertically. Two principal grades are manufactured: one for exposed masonry construction, and the other for unexposed construction.

As a facing, clay products are formed into thin flat, curved, or embossed pieces, which are then glazed and burned. Commonly used on surfaces subject to water splash or that require frequent cleaning, such vitreous glazed wall tile is fireproof. Unglazed tile is laid as bathroom floor. By extension, any material formed into a size comparable to clay file is called tile. Among the materials formed into tile are asphalt, cork, linoleum, vinyl, and porcelain. [F.H.R.]

Till The generic term for sediment deposited directly from glacier ice. Till is characteristically nonsorted and nonstratified and is deposited by lodgement or melt-out beneath a glacier or by melt-out on the surface of a glacier. The texture of till varies greatly and all tills are characterized by a wide range, of particle sizes. Till contains a variety of rock and mineral fragments which reflect the source material over which the glacier flowed. The particles in the deposit usually show a preferred orientation related to the nature and direction of the ice flow. The overall character of the fill reflects the source material, position and distance of transport, nature and position of deposition, and postdepositional changes. [W.H.J.]

Tillodontia An extinct order of early Cenozoic (about 65 to 40 million years ago) quadrupedal eutherian land mammals, represented by nine known genera, from the late Paleocene to middle Eocene of North America (*Esthonyx* [*Azygonyx*], *Megalesthonyx*, *Trogosus*, and *Tillodon*), early Paleocene to late Eocene of China (*Lofochaius*, *Meiostylodon*, *Adapidium*, *Trogosus* [*Kuanchuanius*]), middle Eocene of Pakistan (*Basalina*), and the early Eocene of Europe (*Plesiesthonyx*). The tillodonts left no known descendants and were probably most closely related to the extinct order Pantodonta (another group of extinct ungulatelike mammals from the Paleocene and Eocene that in turn may be related to the early eutherian mammals known as arctocyonids).

Tillodonts were medium- to large-sized mammals (their skulls range in length from 5 to 37 cm or 2 to 15 in.) that probably fed primarily on roots and tubers in warm temperate to subtropical habitats. Tillodonts were most common in the early Eocene faunas of North America. They developed large second incisors that became rodentlike, relatively long snouts, massive skeletons, and moderately large claws. *See* ARCHAIC UNGULATE; MAMMALIA; TOOTH. [R.M.Scho.]

Time The dimension of the physical universe which orders the sequence of events at a given place; also, a designated instant in this sequence, such as the time of day, technically known as an epoch, or sometimes as an instant.

Measurement. Time measurement consists of counting the repetitions of any recurring phenomenon and possibly subdividing the interval between repetitions. Two aspects to be considered in the measurement of time are frequency, or the rate at which the recurring phenomena occur, and epoch, or the designation to be applied to each instant.

Time units are the intervals between successive recurrences of phenomena, such as the period of rotation of the Earth or a specified number of periods of radiation derived from an atomic energy-level transition. Other units are arbitrary multiples and subdivisions of these intervals, such as the hour being 1/24 of a day, and the minute being 1/60 of an hour. *See* DAY; MONTH; TIME-INTERVAL MEASUREMENT; YEAR.

Time bases. Several phenomena are used as bases with which to determine time. The phenomenon traditionally used has been the rotation of the Earth, where the counting is by days. Days are measured by observing the meridian passages of stars and are subdivided with the aid of precision clocks. The day, however, is subject to variations in duration. Thus, when a more uniform time scale is required, other bases for time must be used.

The angle measured along the celestial equator between the observer's local meridian and the vernal equinox, known as the hour angle of the vernal equinox, is the measure of sidereal time. It is reckoned from 0 to 24 hours, each hour being subdivided into 60 sidereal minutes and the minutes into 60 sidereal seconds. Sidereal clocks are used for convenience in most astronomical observatories because a star or other object outside the solar system comes to the same place in the sky at virtually the same sidereal time.

The hour angle of the Sun is the apparent solar time. The only true indicator of local apparent solar time is a sundial. Mean solar time has been devised to eliminate the irregularities in apparent solar time that arise from the obliquity of the ecliptic and the varying speed of the Earth in its orbit around the Sun. It is the hour angle of a fictitious point moving uniformly along the celestial equator at the same rate as the average rate of the Sun along the ecliptic. Both sidereal and solar time depend on the rotation of the Earth for their time base.

The mean solar time determined for the meridian of 0° longitude from the rotation of the Earth by using astronomical observations is referred to as UT1. Observations are made at a number of observatories around the world. The International Earth Rotation Service (IERS) receives these data and maintains a UT1 time scale. *See* EARTH ROTATION AND ORBITAL MOTION.

Because the Earth has a nonuniform rate of rotation and since a uniform time scale is required for many timing applications, a different definition of a second was adopted in 1967. The international agreement calls for the second to be defined as 9,192,631,770 periods of the radiation derived from an energy-level transition in the cesium atom. This second is referred to as the international or SI (International System) second and is independent of astronomical observations. International Atomic Time (TAI) is maintained by the International Bureau of Weights and Measures (BIPM) from data contributed by time-keeping laboratories around the world. *See* ATOMIC TIME.

Coordinated Universal Time (UTC) uses the SI second as its time base. However, the designation of the epoch may be changed at certain times so that UTC does not differ from UT1 by more than 0.9 s. UTC forms the basis for civil time in most countries and may sometimes be referred to as Greenwich mean time. The adjustments to UTC to bring this time scale into closer accord with UT1 consist of the insertion or deletion of integral seconds. These "leap seconds" may be applied at 23 h 59 m 59 s of June 30 or December 31 of each year according to decisions made by the IERS. UTC differs from TAI by an integral number of atomic seconds.

Civil and standard times. Because rotational time scales are defined as hour angles, at any instant they vary from place to place on the Earth. Persons traveling westward around the Earth must advance their time 1 day, and those traveling eastward must retard their time 1 day in order to be in agreement with their neighbors when they return home. The International Date Line is the name given to a line where the change of date is made. It follows approximately the 180th meridian but avoids inhabited land. To avoid the inconvenience of the continuous change of mean solar time with longitude, zone time or civil time is generally used. The Earth is divided into 24 time zones, each approximately 15° wide and centered on standard longitudes of 0°, 15°, 30°, and so on. Within each of these zones the time kept is the mean solar time of the standard meridian. *See* International Date Line.

Many countries, including the United States, advance their time 1 hour, particularly during the summer months, into "daylight saving time." [D.D.McC.]

Time, arrow of

The uniform and unique direction associated with the apparent inevitable flow of time into the future. There appears to be a fundamental asymmetry in the universe. Herein lies a paradox, for all the laws of physics, whether they are the equations of classical mechanics, classical electromagnetism, general relativity, or quantum mechanics, are time reversible in that they admit solutions in either direction of time. This reversibility raises the question of how these fundamentally time-symmetrical equations can result in the perceived asymmetry of temporally ordered events.

The symmetry breaking of temporal order has not yet been fully explained. There are certain indications that an intrinsic asymmetry exists in temporal evolution. Thus it may be that the fundamental laws of physics are not really time symmetric and that the currently known laws are only symmetrized approximations to the truth. Indeed, the decay of the K^0 meson is not time reversible. However, it is not clear how such a rare and exotic instance of time asymmetry could emerge into the world of essentially macroscopic, electromagnetic phenomena as an everyday observable. *See* Time reversal invariance.

Another, more ubiquitous example of a fundamentally time-asymmetric process is the expansion of the universe. It has been speculated that this expansion is the true basis of time asymmetry. *See* Big bang theory; Cosmology.

Alternatively, even a time-symmetrical universe will have a statistical behavior in which configurations of molecules and localizations of energy have significant probabilities of recurring only after enormously long time intervals. Indeed, such time intervals are longer than the times required for the ceaseless expansion of the universe and the evolution of its component particles. Time's arrow is destined, either by the nature of space-time or the statistics of large assemblies, to fly into the future. *See* Statistical mechanics. [P.W.A.]

Time constant

A characteristic time that governs the approach of an exponential function to a steady-state value. When a physical quantity is varying as a decreasing exponential function of time as in Eq. (1), or as an increasing exponential function as in Eq. (2), the approach to the steady-state value achieved after a long time is governed by a characteristic time T as given in Eq. (3). This time T is called the time constant.

$$f(t) = e^{-kt} \tag{1}$$

$$f(t) = 1 - e^{-kt} \tag{2}$$

$$t = \frac{1}{k} = T \tag{3}$$

When time t is zero, $f(t)$ in Eq. (1) has the magnitude 1, and when t equals T the magnirude is $1/e$. Here e is the transcendental number whose value is approximately 2.71828, and the change in magnitude is $1 - (1/e) = 0.63212$. The function has moved 63.2% of the way to its final value. The same factor also holds for Eq. (2). *See* e (mathematics).

The initial rate of change of both the increasing and decreasing functions is equal to the maximum amplitude of the function divided by the time constant.

The concept of time constant is useful when evaluating the presence of transient phenomena. [R.L.R.]

Time-interval measurement

A determination of the duration between two instants of time (epochs). Time intervals are measured with high precision with a digital display counter. An electronic oscillator generates pulses; the count begins with a start signal and ends with a second signal. Two atomic clocks can be compared in epoch to 1 picosecond (1 ps $= 10^{-12}$ s) by electronic interpolation. *See* Atomic clock; Digital counter; Oscillator; Oscilloscope.

Rapid motions can be studied at short intervals by means of a large variety of high-speed cameras, including stroboscopic, rotating film-drum, rotating mirror, streak, and image converter cameras. An electronic streak camera can separate two pulses 1 ps apart. *See* Photography; Stroboscopic photography.

Ultrashort laser pulses are used to study rapid processes caused by the interaction of photons with an atom or molecule. Pulses as short as three wavelengths of 620-nm light, with $\tau =$ 6 femtoseconds (1 fs $= 10^{-15}$ s), have been formed. *See* Laser; Laser photochemistry; Optical pulses; Ultrafast molecular processes.

Radioactive decay is used to measure long time intervals, to about 5×10^9 years, concerning human history, the Earth, and the solar system. *See* Geochronometry; Radiocarbon dating. [W.M.]

Time-of-flight spectrometer

Any of a general class of instruments in which the speed of a particle is determined directly by measuring the time that it takes to travel a measured distance. By knowing the particle's mass, its energy can be calculated. If the particles are uncharged (for example, neutrons), difficulties arise because standard methods of measurement (such as deflection in electric and magnetic fields) are not possible. The time-of-flight method is a powerful alternative, suitable for both uncharged and charged particles.

The time intervals are best measured by counting the number of oscillations of a stable oscillator that occur between the instants that the particle begins and ends its journey. Oscillators operating at 100 MHz are in common use. *See* Mass spectroscope; Neutron spectrometry; Time-interval measurement. [F.W.K.F.]

Time-projection chamber

An advanced particle detector for the study of ultra-high-energy collisions of positrons and electrons. The underlying physics of the scattering process can be studied through precise measurements of the momenta, directions, particle species, and correlations of the collision products. The time-projection chamber (TPC) provides a unique combination of capabilities for these studies and other problems in elementary particle physics by offering particle identification over a wide momentum range, and by offering high resolution of intrinsically three-dimensional spatial information for accurate event reconstruction.

The time-projection chamber concept is based on the maximum utilization of ionization information, which is deposited by high-energy charged particles traversing a gas. The ionization trail, a precise image of the particle trajectory, also contains information about the particle velocity. A strong, uniform magnetic field and a uniform electric field are generated within the time-projection chamber active volume in an exactly parallel orientation. The parallel configuration of the fields permits electrons, products of the ionization processes, to drift through the time-projection chamber gas over great distances without distortion; the parallel configuration offers a further advantage in that the diffusion of the electrons during drift can be greatly suppressed by the magnetic field, thus preserving the quality of track information. *See* Particle detector. [D.R.N.]

Time reversal invariance A symmetry of the fundamental (microscopic) equations of motion of a system; if it holds, the time reversal of any motion of the system is also a motion of the system. With one exception (K_L meson decay), all observations are consistent with time reversal invariance (T invariance).

Time reversal invariance is not evident from casual observation of everyday phenomena. If a movie is taken of a phenomenon, the corresponding time-reversed motion can be exhibited by running the movie backward. The result is usually strange. For instance, water in the ground is not ordinarily observed to collect itself into drops and shoot up into the air. However, if the system is sufficiently well observed, the direction of time is not obvious. For instance, a movie which showed the motion of the planets would look just as right run backward or forward. The apparent irreversibility of everyday phenomena results from the combination of imprecise observation and starting from an improbable situation (a state of low entropy, to use the terminology of statistical mechanics). *See* Entropy; Statistical mechanics; Time, arrow of.

If time reversal invariance holds, no particle (a physical system with a definite mass and spin) can have an electric dipole moment. A polar body, for example, a water (H_2O) molecule, has an electric dipole moment, but its energy and spin eigenstates (which are particles) do not. No particle has been observed to have an electric dipole moment; for instance, the present experimental upper limit on the electric moment of the neutron is approximately 10^{-25} cm times e, where e is the charge of the proton. Even smaller upper limits have been reported for the electric moment of some nuclei. *See* Dipole moment; Neutron; Polar molecule; Spin (quantum mechanics).

Another test of time reversal invariance is to compare the cross sections for reactions which are inverse to one another. The present experimental upper limit on the relative size of the time reversal invariance-violating amplitude of such reactions is approximately 3×10^{-3}; unfortunately, this is far larger than any expected violation. *See* Nuclear reaction.

If time reversibility holds, then by the CPT theorem CP invariance must hold, that is, invariance of the fundamental equations under the combined operations of charge conjugation C and space inversion P. Conversely, violation of CP invariance implies violation of T (time reversal invariance). In 1964, CP violation was observed in the decay of the long-lived neutral K meson, the K_L. For many years, no other evidence for T or CP violation was seen. From this it was deduced that the interactions which violate CP are very weak and are evident in K_L decay only because there are two neutral K mesons that have practically the same mass and are therefore easily mixed. *See* CPT theorem; Meson.

Within the current understanding of particle physics, namely the so-called standard model, CP violation comes from the Kobayashi-Maskawa matrix of coefficients that relate the quark weak i-spin eigenstates with the quark mass eigenstates. It turns out that because the number of flavors is greater than four, the Kobayashi-Maskawa matrix can be nonreal, resulting in nonconservation of CP and T. *See* Electroweak interaction; Flavor; Quarks; Standard model; Weak nuclear interactions.

It is also possible that CP violation comes from yet unknown interactions. More is being learned from observations since 2001 of CP violation in the decay of the neutral B mesons at the so-called B factories, particle accelerators built for the purpose of copiously producing B mesons. Initial results are consistent with the standard model. *See* Elementary particle; Particle accelerator; Symmetry laws (physics). [C.J.G.]

Timothy A plant, *Phleum pratense*, of the order Cyperales, long the most important hay grass for the cooler temperate humid regions. It is easily established and managed, produces seed abundantly, and grows well in mixtures with alfalfa and clover. It is a short-lived perennial, makes a loose sod, and has moderately leafy stems and a dense cylindrical inflorescence. Timothy-legume mixtures still predominate in hay and pasture seedings for crop rotations in the northern half of the United States. *See* Grass. [H.B.S.]

Tin A chemical element, symbol Sn, atomic number 50, atomic weight 118.69. Tin forms tin(II) or stannous (Sn^{2+}), and tin(IV) or stannic (Sn^{4+}) compounds, as well as complex salts of the stannite (M_2SnX_4) and stannate (M_2SnX_6) types. *See* Periodic table.

Tin melts at a low temperature, is highly fluid when molten, and has a high boiling point. It is soft and pliable and is corrosion-resistant to many media. An important use of tin has been for tin-coated steel containers (tin cans) used for preserving foods and beverages. Other important uses are solder alloys, bearing metals, bronzes, pewter, and miscellaneous industrial alloys. Tin chemicals, both inorganic and organic, find extensive use in the electroplating, ceramic, plastic, and agricultural industries.

The most important tin-bearing mineral is cassiterite, SnO_2. No high-grade deposits of this mineral are known. The bulk of the world's tin ore is obtained from low-grade alluvial deposits. *See* Cassiterite.

Two allotropic forms of tin exist: white (β) and gray (α) tin. Tin reacts with both strong acids and strong bases, but it is relatively resistant to solutions that are nearly neutral. In a wide variety of corrosive conditions, hydrogen gas is not evolved from tin and the rate of corrosion becomes controlled by the supply of oxygen or other oxidizing agents. In their absence, corrosion is negligible. A thin film of stannic oxide forms on tin upon exposure to air and provides surface protection. Salts that have an acid reaction in solution, such as aluminum chloride and ferric chloride, attack tin in the presence of oxidizers or air. Most nonaqueous liquids, such as oils, alcohols, or chlorinated hydrocarbons, have slight or no obvious effect on tin. Tin metal and the simple inorganic salts of tin are nontoxic. Some forms of organotin compounds, on the other hand, are toxic. Some important physical constants for tin are shown in the table.

Stannous oxide, SnO, is a blue-black, crystalline product which is soluble in common acids and strong alkalies. It is used in making stannous salts for plating and glass manufacture. Stannic oxide, SnO_2, is a white powder, insoluble in acids and alkalies.

Properties of tin

Property	Value
Melting point, °C	231.9
Boiling point, °C	2270
Specific gravity, α form (gray tin)	5.77
β form (white tin)	7.29
Specific heat, cal/g*, white tin at 25°C	0.053
Gray tin at 10°C	0.049

*1 cal = 4.184 joules.

It is an excellent glaze opacifier, a component of pink, yellow, and maroon ceramic stains and of dielectric and refractory bodies. It is an important polishing agent for marble and decorative stones.

Stannous chloride, $SnCl_2$, is the major ingredient in the acid electrotinning electrolyte and is an intermediate for tin chemicals. Stannic chloride, $SnCl_4$, in the pentahydrate form is a white solid. It is used in the preparation of organotin compounds and chemicals to weight silk and to stabilize perfume and colors in soap. Stannous fluoride, SnF_2, a white water-soluble compound, is a toothpaste additive.

Organotin compounds are those compounds in which at least one tin-carbon bond exists, the tin usually being present in the + IV oxidation state. Organotin compounds that find applications in industry are the compounds with the general formula R_4Sn, R_3SnX, R_2SnX_2, and $RSnX_3$. R is an organic group, often methyl, butyl, octyl, or phenyl, while X is an inorganic substituent, commonly chloride, fluoride, oxide, hydroxide, carboxylate, or thiolate. *See* Tin alloys. [J.B.Lo.]

Tin alloys Solid solutions of tin and some other metal or metals. Alloys cover a wide composition range and many applications because tin alloys readily with nearly all metals. *See* Tin; Tin metallurgy.

Soft solders constitute one of the most widely used and indispensable series of tin-containing alloys. Common solder is an alloy of tin and lead, usually containing 20–70% tin. *See* Soldering.

Bronzes form an important group of structural metals. Of the true copper-tin bronzes, up to 10% tin is used in wrought phosphor bronzes, and from 5 to 10% tin in the most common cast bronzes. Many brasses, which are basically copper-zinc alloys, contain 0.75–1.0% tin for additional corrosion resistance. *See* Copper alloys.

Other useful tin alloys include babbitt metal (tin containing 4–8% each copper and antimony), an alloy with bearing applications; pewter; a tin-base alloy containing small quantifies of antimony and copper; and type metals, which are lead-base alloys containing 3–15% tin. *See* Alloy. [B.W.G.]

Tin metallurgy The extraction of tin from its ores and its subsequent refining and preparation for use. Most tin concentrates are primarily cassiterite (SnO_2), the naturally occurring oxide of tin. These are comparatively easy to reduce by using carbon at high temperatures. However, this operation differs from the smelting of most common metals because retreatment of the slag is necessary to obtain efficient metal recovery. *See* Cassiterite.

In primary smelting, carbon monoxide (CO) formed during heat-up reacts with the solid cassiterite particles to produce tin (Sn) and carbon dioxide (CO_2). As the temperature increases, silica (present in nearly all concentrates) also reacts under reducing conditions with the SnO_2 to give stannous silicate. Iron, also present as an impurity in all concentrates, reacts with the silica to form ferrous silicate ($FeSiO_3$). These silicates fuse with the added fluxes to form a liquid slag, at which point unreacted carbon from the fuel becomes the predominant reductant in reducing both stannous silicate to tin and ferrous silicate to iron. The metallic iron then reduces tin from stannous silicate, as shown in the reaction below.

$$SnSiO_3 + Fe \rightleftharpoons FeSiO_3 + Sn$$

Secondary tin from metal scrap amounts to about one-quarter of the total tin consumed in the United States. Most of this comes from tin-bearing alloys, and secondary smelters rework them into alloys and chemicals. However, additional tin of high purity is recovered from the detinning of tinplate scrap. *See* Electrochemical process; Electrometallurgy; Heat treatment (metallurgy); Pyrometallurgy, nonferrous; Tin. [D.May.]

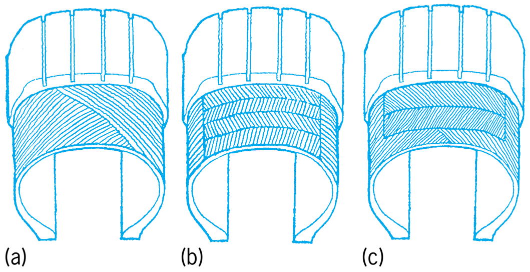
Tintinnida An order of the Spirotrichia whose members are conical or trumpet-shaped pelagic forms bearing shells (loricae). These protozoa are planktonic ciliates and are especially abundant in oceans, notably the Pacific. The lorica is composed of a resistant organic compound in which various foreign mineral grains are embedded; its shape may range from trumpet- or bell-form to cylindrical or subspherical.

Fossil tintinnids, representing practically the only fossilized species of ciliate protozoa known to science, are identified on the basis of the shape of the lorica in cross section as seen in randomly oriented thin sections of the rocks in which they are found. Twelve genera of fossil tintinnids have been described from limestones and cherts of the Jurassic and Cretaceous. *See* Ciliophora; Spirotrichia. [J.O.C.; D.J.J.]

Tire A continuous pneumatic rubber and fabric cushion encircling and fitting onto the rim of a wheel. In modern tire building, chemicals are compounded into the rubber to help it withstand wear, heat, and aging and to produce desired changes in its characteristics. Fabric (rayon, nylon, or polyester) is used to give the tire body strength and resilience. In belted tires, additional layers of fabric (rayon, fiber glass, finely drawn steel, or aramid) are placed just under the tread rubber to increase mileage and handling. Steel wire is used in the bead that holds the tire to the rim.

A tire is made up of two basic parts: the tread, or road-contacting part, which must provide traction and resist wear and abrasion, and the body or carcass, consisting of rubberized fabric that gives the tire strength and flexibility. In compounding the rubber, large amounts of carbon black are mixed with it to improve abrasion resistance. Other substances, such as sulfur, are added to enable satisfactory processing and vulcanization. *See* Rubber.

There are three types of tires: bias, belted bias, and radial (see illustration). For bias tires, cords in the piles extend diagonally across the tire from bead to bead. The cords run in opposite directions in each successive ply, resulting in a crisscross pattern. For belted bias tires, plies are placed in a manner similar to that used in the bias-ply tire, with belts of material placed circumferentially around the tire between the plies and the tread rubber. For radial tires, cords in the plies extend transversely from bead to bead, substantially perpendicular to the direction of travel. Belts are placed circumferentially around the tire. [D.B.H.]



Tire construction. (*a*) Bias-ply. (*b*) Radial-ply. (*c*) Belted bias-ply. (*Goodyear Tire and Rubber Co.*)

Tissue An aggregation of cells more or less similar morphologically and functionally. The animal body is composed of four primary tissues, namely, epithelium, connective tissue (including bone, cartilage, and blood), muscle, and nervous tissue. The process of differentiation and maturation of tissues is called histogenesis. *See* Histology. [C.B.C.]

Tissue culture The branch of biology in which tissues or cells of higher animals and plants are grown artificially in a controlled environment. Tissue culture is possible when cells are attached to a solid substrate, such as glass or cellophane, and if the necessary complex nutrient medium is provided. All cultures are now also grown in liquid suspension. Tissue cultures are used in the study of cell growth, multiplication, and differentiation, as well as in cancer research, hereditary mechanisms, radiation biology, all hybridization, and virus studies. *See* MICROBIOLOGICAL METHODS. [T.T.P.]

Tissue typing A procedure involving a test or a series of tests to determine the compatibility of tissues from a prospective donor and a recipient prior to transplantation. The immunological response of a recipient to a transplant from a donor is directed against many cell-surface histocompatibility antigens controlled by genes at many different loci. However, one of these loci, the major histocompatibility complex (MHC), controls antigens that evoke the strongest immunological response. The human MHC is known as the HLA system, which stands for the first (A) human leukocyte blood group system discovered. *See* CELLULAR IMMUNOLOGY; HISTOCOMPATIBILITY.

The success of transplantation is greatly dependent on the degree of histocompatibility (identity) between the donor and recipient, which is determined by the HLA complex. When the donor and recipient have a low degree of histocompatibility, the organ is said to be mismatched, and the recipient mounts an immune response against the donor antigen. By laboratory testing, the degree of antigenic similarity between the donor and the recipient and the degree of preexisting recipient sensitization to donor antigens (and therefore preformed antibodies) can be determined. This is known as cross-matching.

Phenotyping of HLA-A, -B, and -C (ABC typing) of an individual is determined by reacting that individual's lymphocytes with a large panel of antisera directed against specific HLA antigens. The procedure is known as complement-mediated cytotoxicity assay. The person's lymphocytes are incubated with the different antisera and complement is added. Killing of the cells being tested indicates that they express the HLA antigens recognized by the particular antiserum being used. Killing of potential donor lymphocytes in the complement-mediated cytotoxicity assay is a contraindication to transplantation of tissue from that donor. *See* COMPLEMENT; HYPERSENSITIVITY; IMMUNOASSAY.

In addition to its important role in organ transplantation, determination of the HLA phenotype is useful in paternity testing, forensic medicine, and the investigation of HLA-disease associations. *See* TRANSPLANTATION BIOLOGY. [M.W.Fl.; T.Moh.]

Titanite A calcium, titanium silicate, $CaTiOSiO_4$, of high titanium content. Titanite is also known as sphene. Titanite is an orthosilicate (nesosilicate) with a hardness of 5–5$^1/_2$ on the Mohs scale, a distinct cleavage, a specific gravity of 3.4–3.55, and an adamantine to resinous luster. It commonly occurs as distinct wedge-shaped crystals that are usually brown in hand specimens. Titanite may also be gray, green, yellow, or black. *See* CRYSTAL STRUCTURE; HARDNESS SCALES.

Titanite is a common accessory mineral in many igneous and metamorphic rocks. It may be the principal titanium-bearing silicate mineral. It occurs in abundance in the Magnet Cove, igneous complex in Arkansas and in the intrusive alkalic-rocks of the Kola Penninsula, Russia.

The composition of titanite may diverge from pure $CaTiSiO_4$ because of a variety of chemical substitutions. Calcium ions (Ca^{2+}) can be partially replaced by strontium ions (Sr^{2+}) and rare-earth ions such as thorium (Th^{4+}) and uranium (U^{4+}). Because titanite commonly contains radioactive elements, it has been used for both uranium-lead and fission track methods of dating. *See* DATING METHODS; IGNEOUS ROCKS; METAMORPHIC ROCKS; SILICATE MINERALS; TITANIUM. [J.C.D.]

Titanium A chemical element, Ti, atomic number 22, and atomic weight 47.90. It occurs in the fourth group of the periodic table, and its chemistry shows many similarities to that of silicon and zirconium. On the other hand, as a first-row transition element, titanium has an aqueous solution chemistry, especially of the lower oxidation states, showing some resemblances to that of vanadium and chromium. *See* PERIODIC TABLE; TRANSITION ELEMENTS.

The catalytic activity of titanium complexes forms the basis of the well-known Ziegler process for the polymerization of ethylene. This type of polymerization is of great industrial interest since, with its use, high-molecular-weight polymers can be formed. In some cases, desirable special properties can be obtained by forming isotactic polymers, or polymers in which there is a uniform stereochemical relationship along the chain. *See* POLYOLEFIN RESINS.

The dioxide of titanium, TiO_2, occurs most commonly in a black or brown tetragonal form known as rutile. Less prominent naturally occurring forms are anatase and brookite (rhombohedral). Both rutile and anatase are white when pure. The dioxide may be fused with other metal oxides to yield titanates, for example, K_2TiO_3, $ZnTiO_3$, $PbTiO_3$, and $BaTiO_3$. The black basic oxide, $FeTiO_3$, occurs naturally as the mineral ilmenite; this is a principal commercial source of titanium.

Titanium dioxide is widely used as a white pigment for exterior paints because of its chemical inertness, superior covering power, opacity to damaging ultraviolet light, and self-cleaning ability. The dioxide has also been used as a whitening or opacifying agent in numerous situations, for example as a filler in paper, a coloring agent for rubber and leather products, a pigment in ink, and a component of ceramics. It has found important use as an opacifying agent in porcelain enamels, giving a finish coat of great brilliance, hardness, and acid resistance. Rutile has also been found as brilliant, diamondlike crystals, and some artificial production of it in this form has been achieved. Because of its high dielectric constant, it has found some use in dielectrics.

The alkaline-earth titanates show some remarkable properties. The dielectric constants range from 13 for $MgTiO_3$ to several thousand for solid solutions of $SrTiO_3$ in $BaTiO_3$. Barium titanate itself has a dielectric constant of 10,000 near 120°C (248°F), its Curie point; it has a low dielectric hysteresis. These properties are associated with a stable polarized state of the material analogous to the magnetic condition of a permanent magnet, and such substances are known as ferroelectrics. In addition to the ability to retain a charged condition, barium titanate is piezoelectric and may be used as a transducer for the interconversion of sound and electrical energy. Ceramic transducers containing barium titanate compare favorably with Rochelle salt and quartz, with respect to thermal stability in the first case, and with respect to the strength of the effect and the ability to form the ceramic in various shapes, in the second case. The compound has been used both as a generator for ultrasonic vibrations and as a sound detector. *See* PIEZOELECTRICITY. [A.W.A.]

In addition to important uses in applications such as structural materials, pigments, and industrial catalysis, titanium has a rich coordination chemistry. The formal oxidation of titanium in molecules and ions ranges from −II to +IV. The lower oxidation states of −II and −I occur only in a few complexes containing strongly electron-withdrawing carbon monoxide ligands.

The lower oxidation states of titanium are all strongly reducing. Thus, unless specific precautions are taken, titanium complexes are typically oxidized rapidly to the +IV state. Moreover, many titanium complexes are extremely susceptible to hydrolysis. Consequently, the handling of titanium complexes normally requires oxygen- and water-free conditions. *See* COORDINATION CHEMISTRY. [L.K.W.]

Titanium metallurgy The winning of metallic titanium (Ti) from its ores followed by alloying and processing into forms and shapes that can be used for structural purposes.

All commercial titanium metal is produced from titanium tetrachloride ($TiCl_4$), an intermediate compound produced during the chlorination process for titantium oxide pigment. The process involves chlorination of ore concentrates; reacting TiO_2 with chlorine gas (Cl_2) and coke (carbon; C) in a fluidized-bed reactor forms impure titanium tetrachloride. For the production of acceptable metal, purification of the raw tetrachloride is required to remove other metal chlorides that would contaminate the virgin titanium.

The purified titanium tetrachloride is delivered as a liquid to the reactor vessel. In these vessels, constructed of carbon or stainless steel, the titanium tetrachloride is reacted with either magnesium (Mg) or sodium (Na) to form the pure metal called sponge, because of its porous cellular form. To avoid contamination by oxygen or nitrogen, the reaction is carried out in an argon atmosphere. The sponge, removed from the reactor pot by boring, is cleaned by acid leaching.

A mass of sponge, alloy additions, and scrap are mixed, then compressed into compacts and welded together to form a sponge electrode. This is melted by an electric arc into a water-cooled copper crucible in a vacuum or an atmosphere of purified argon. The arc progressively consumes the sponge electrode to form an ingot. Ingots up to 30,000 lb (13,600 kg) are routinely produced by using this consolidation method.

The conversion of the titanium ingot into mill products, such as forging billet, plate, sheet, and tubing, is accomplished for the most part on conventional metalworking equipment. Mills designed to roll and shape stainless or alloy steel are used with only slight modifications. For this reason titanium and its structural alloys are produced in most of the same forms and shapes as stainless steel. *See* METAL FORMING; STAINLESS STEEL.

Pure titanium is soft, weak, and extremely ductile. However, through appropriate additions of other elements, the titanium metal base is converted to an engineering material having unique characteristics, including high strength and stiffness, corrosion resistance, and usable ductility. The type and quantity of alloy addition determine the mechanical and, to some extent, the physical properties. Some common titanium alloy additions include aluminum, oxygen, nitrogen, carbon, molybdenum, chromium, iron, nickel, zirconium, and tin. *See* ALLOY; METALLURGY; TITANIUM. [W.W.Mi.; S.R.Se.]

Titration A quantitative analytical process that is basically volumetric. However, in high-precision titrimetry the titrant solution is sometimes delivered from a weight buret, so that the volumetric aspect is indirect. Generally, a standard solution, that is, one containing a known concentration of substance X (titrant), is progressively added to a measured volume of a solution of a substance Y (titrand) that will react with the titrant. The addition is continued until the end point is reached.

Ideally, this is the same as the equivalence point, at which an excess of neither X nor Y remains. If the stoichiometry or exact ratio in which X and Y react is known, it is possible to calculate the amount of Y in the unknown solution. *See* VOLUMETRIC ANALYSIS.

The normal requirements for the performance of a titration are: a standard titrant solution; calibrated volumetric apparatus, including burets, pipets, and volumetric flasks; and some means of detecting the end point. *See* BURET; PIPET; VOLUMETRIC FLASK.

Classification by chemical reaction. For the purposes of titrimetry, chemical reactions can be placed in three general categories: acid-base or neutralization, combination, and oxidation-reduction.

Acid-base titrations involve neutralization of an acid by titration with a base, or vice versa. However, the process is often nonspecific; in the titration of a mixture of nitric and hydrochloric acids, only the total acidity can be found without recourse to additional measurements. A salt derived from a strong base and a very weak acid can often be titrated just as if it were a base. *See* ACID AND BASE.

In titrimetry, attention is usually focused upon the combination of an ion in the titrant with one of the opposite sign in the titrand solution. Sometimes the combination may involve more than two species, some of which may be nonionic. The combinations may result in precipitation or formation of a complex. *See* COORDINATION COMPLEXES; PRECIPITATION (CHEMISTRY).

In so-called redox titrations the titrant is usually an oxidizing agent, and is used to determine a substance that can be oxidized and hence can act as a reducing agent. *See* OXIDATION-REDUCTION.

Coulometric titration. The passage of a uniform current for a measured period of time can be used to generate a known amount of a product such as a titrant. This fact is the basis of the technique known as coulometric titration. An obvious requirement is that generation shall proceed with a fixed, preferably 100%, current efficiency. The uniform current is then analogous to the concentration of an ordinary titrant solution, while the total time of passage is analogous to the volume of such a solution that would be needed to reach the end point. *See* ELECTROLYSIS.

Classification by end-point techniques. The precision and accuracy with which the end point can be detected is a vital factor in all titrations. Because of its simplicity and versatility, chemical indication is quite common, especially in acid-base titrimetry.

Indicators. An acid-base indicator is a weak acid or a weak base that changes color when it is transformed from the molecular to the ionized form, or vice versa. The color change is normally intense, so that only a low concentration of indicator is needed. The working range, or visual color change, of a typical acid-base indicator is spread over about a hundredfold (∼2 pH units) change in hydrogen ion concentration. Available indicators have individual working ranges that together cover the entire range of hydrogen ion concentration likely to be encountered in general acid-base titration. *See* ACID-BASE INDICATOR; HYDROGEN ION; PH.

Sometimes no suitable chemical indicator can be found for a desired titration. Possibly the concentrations involved may be so low that chemical indication functions poorly. Other situations might be the need for high precision or for the automatic arrest of the titration. Recourse is then made to some physical method of end-point detection.

Potentiometric titration. If a pH meter is used, its associated electrodes are first standardized by use of a buffer solution of known pH. By suitable choice of electrodes, potentiometric methods can also be applied to combination titrations and to oxidation-reduction titrations. The advent of modern ion-selective electrodes has greatly extended the scope of potentiometric titration and of other branches of titrimetry. *See* ELECTRODE POTENTIAL; ION-SELECTIVE MEMBRANES AND ELECTRODES.

Conductometric titration. Conductometric titration is sometimes successful when chemical indication fails. The underlying principles of conductometric titration are that the solvent and any molecular species in solution exhibit only negligible conductance; that the conductance of a dilute solution rises as the concentration of ions is increased; and that at a given concentration the hydrogen ion and the hydroxyl ion are much better conductors than any of the other ions. *See* ELECTROLYTIC CONDUCTANCE.

Spectrophotometric titration. The spectrophotometer is an optical device that responds only to radiation within a selected very narrow band of wavelengths in the visual, ultraviolet, or infrared regions of the spectrum. The response can be made both quantitative and linearly related to the concentration of a species that absorbs radiation within this band. Titrations at wavelengths within the visual region are by far the most common. *See* SPECTROPHOTOMETRIC ANALYSIS.

Amperometric titration. By use of a dropping-mercury or other suitable microelectrode, it is possible to find a region of applied electromotive force (emf) in which the current is proportional to the concentration of one or both of the reactants in a titration.

Biamperometric titration is a closely related technique. An emf that is usually small is applied across two identical microelectrodes that dip into the titrand solution. This arrangement, which involves no liquid-liquid junctions, is valuable in nonaqueous titrations, but also finds much use in aqueous titrimetry. *See* Polarographic analysis.

Thermometric or enthalpimetric titration. Many chemical reactions proceed with the evolution of heat. If one of these is used as the basis of a titration, the temperature first rises progressively and then remains unchanged as the titration is continued past the end point. If the reaction is endothermic, the temperature falls instead of rising. Thermometric titration is applicable to all classes of reactions. *See* Thermochemistry.

Nonaqueous titration. This technique is used to perform titrations that give poor or no end points in water. Although applicable in principle to all classes of reactions, acid-base applications have greatly exceeded all others. Nonaqueous titrations in which the solvent is a molten salt or salt mixture are also possible.

Automatic titration. Automation is particularly valuable in routine titrations, which are usually performed repeatedly. One approach is to record the titration curve and to interpret it later. Another method is to stop titrant addition or generation automatically at, or very near to, the end point. Although a constant-delivery device is desirable, an ordinary buret with an electromagnetically controlled valve is often used.

Microcomputer control permits such refinements as the continuous adjustment of the titrant flow rate during the titration. In some cases, it is possible to automate an entire analysis, from the measurement of the sample to the final washout of the titration vessel and the printout of the result of the analysis. *See* Analytical chemistry. [J.T.St.]

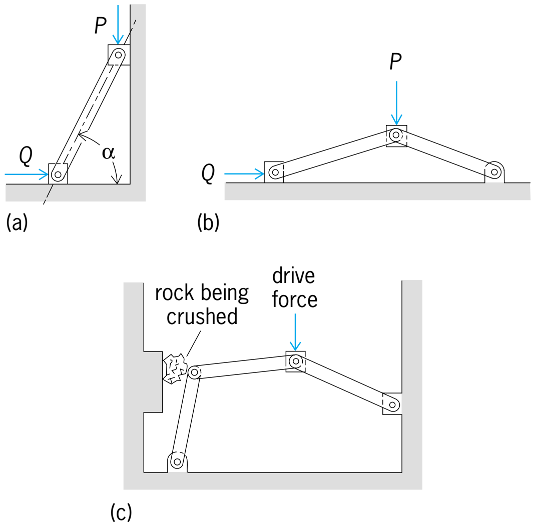
Tobacco The plant genus *Nicotiana*, certain species in the genus, and dried leaves of these plants are all called tobacco. Most often tobacco means a leaf product containing 1–3% of the alkaloid nicotine, which produces a narcotic effect when smoked, chewed, or snuffed. The plant *N. rustica* provides tobacco in parts of Europe, but the tobacco of world commerce is *N. tabacum*. Tobacco is American in origin. *See* Solanales. [G.S.T.]

Todorokite A hydrated manganese oxide mineral containing calcium, barium, potassium, sodium, and sometimes magnesium, general formula $(Na,Ca,K,Ba,Sr)_{0.3\text{–}0.7}(Mn,Mg,Al)_6O_{12} \cdot 3.2\text{–}4.5\,H_2O$. Todorokite is a major constituent of manganese nodules, which occur in large quantities ($>10^{12}$ tons) on the ocean floors. It has been shown to host some of the copper, nickel, and cobalt that occur in some manganese nodules in quantities of up to several weight percent. First described in 1934, todorokite is named for its occurrence at the Todoroki mine, Hokkaido, Japan. Terrestrial todorokite has also been found in deposits in Cuba, Portugal, Austria, France, United States, Brazil, and South Africa.

Todorokite is black to brown and is commonly very fine grained. It occurs as massive samples or as fibrous aggregates. Its hardness on the Mohs scale is low (1.5–2.5), and its reported specific gravity ranges from approximately 3.1 to 3.8.

The basic todorokite structure consists of triple chains of manganese-oxygen octahedra that are linked at roughly right angles to form a tunnel structure. This [3 × 3] structure can accommodate large cations and water in the tunnel sites. *See* Crystal; Manganese nodules. [S.T.]

Toggle Any of a wide variety of mechanisms, many used to open or close electrical contacts abruptly and all characterized by the control of a large force by a small one. The basic action of a toggle mechanism is shown in illustration *a*. When $\alpha = 90^\circ$ the forces *P* and *Q* are independent of each other. Again, when $\alpha = 0^\circ$ the forces are isolated, force *Q* being sustained entirely by the frame, and force *P* serving only to hold the link in position. At $\alpha = 45^\circ$ from the symmetry $|P| = |Q|$, the mechanism serves to transfer the direction of forces to achieve equilibrium. *See* Coupling.



Toggle mechanism. (*a*) Simple structure. (*b*) Traditional configuration. (*c*) Typical application.

Because the simple configuration of illus. *a* requires low-friction sliders, it is impractical. A more useful structure replaces the vertical slider with a second link pinned to the frame (illus. *b*), in which case input *P* sets up forces in both links. A further modification (illustration *c*) replaces the other slider with a link. *See* Four-bar linkage; Linkage (mechanism). [F.H.R.]

Tolerance Amount of variation permitted or “tolerated” in the size of a machine part. Manufacturing variables make it impossible to produce a part of exact dimensions; hence the designer must be satisfied with manufactured parts that are between a maximum size and a minimum size. Tolerance is the difference between maximum and minimum limits of a basic dimension. For instance, in a shaft and hole fit, when the hole is a minimum size and the shaft is a maximum, the clearance will be the smallest, and when the hole is the maximum size and the shaft the minimum, the clearance will be the largest.

If the initial dimension placed on the drawing represents the size of the part that would be used if it could be made exactly to size, then a consideration of the operating conditions of the pair of mating surfaces shows that a variation in one direction from the ideal would be more dangerous than a variation in the opposite direction. The dimensional tolerance should be in the less dangerous direction. This method of stating tolerance is called unilateral tolerance and has largely displaced bilateral tolerance, in which variations are given from a basic line in plus and minus values. [P.H.B.]

Tomato An important vegetable, belonging to the genus *Lycopersicon*, especially *L. esculentum*, that is grown for its edible fruit. The tomato was first domesticated in Mexico, and was introduced to Europe in the mid-sixteenth century. It has been grown in the United States since colonial days, but it became an important vegetable there only in the past century.

The genus *Lycopersicon* (Greek, “wolf peach”) is a member of the Solanaceae, the nightshade family. *Lycopersicon esculentum*, the familiar tomato, can be hybridized with each of the eight other species of *Lycopersicon*. Tomato breeders have transferred many genes, particularly for disease resistance, from wild *Lycopersicon* species to the tomato. *See* Breeding (plant).

The tomato is a herbaceous perennial, but is usually grown as an annual in temperate regions since it is killed by frost. Cultivated tomatoes are self-fertile. The fruit is a berry with 2 to 12 locules containing many seeds. Most tomato varieties have red fruit, due to the red carotenoid lycopene. Different single genes are known to produce various shades of yellow, orange, or green fruit. There is no basis for the common belief that yellow-fruited tomatoes are low in acidity.

Tomatoes prefer warm weather. Cool temperature, 10°C (50°F) and below, delays seed germination, inhibits vegetative development, reduces fruit set, and impairs fruit ripening. High temperature, above 35°C (95°F), reduces fruit set and inhibits development of normal fruit color. The tomato plant is day-neutral, flowering when grown with either short or long days. This makes it possible to grow tomatoes outdoors during the short days of winter in frost-free areas as well as in more northern areas during the long days of summer.

The tomato is the most important processed vegetable, constituting over 23 lb (10.4 kg) of the 54 lb (24.3 kg) of processed vegetables the average American consumes each year. Tomatoes for processing are harvested when red ripe and are soon sent to a nearby cannery. Tomatoes for fresh market, however, are often harvested at an earlier stage of maturity when they are still firm and better able to tolerate shipment to distant markets. Most tomatoes for fresh market are harvested by hand, but almost all of the processing tomatoes in California are harvested mechanically. *See* AGRICULTURAL MACHINERY.

The tomato is highly esteemed as a source of vitamin C, and one medium-sized tomato provides about half of the required daily allowance for adults. Tomatoes are also a significant source of vitamin A and are a good source of protein, but most of it is in the seeds. Tomato juice contains 19 amino acids, principally glutamic acid. *See* ASCORBIC ACID; VITAMIN A.

The tomato has been a favored organism for genetic studies. Over a thousand genes are known for the tomato, and several hundred of these have been located on their respective chromosomes. *See* AGRICULTURAL SCIENCE (PLANT); FOOD MANUFACTURING; PLANT PHYSIOLOGY. [R.W.R.]

Tommot fauna The first diverse assemblages of unquestionable animal fossils at the Proterozoic-Phanerozoic transition, which marks the change from a predominantly microbial biosphere to a modern type of biosphere abundant with multicellular life. The name derives from the Early Cambrian Tommotian Stage in Siberia, where the significance of this fauna of early skeletal fossils was first realized. However, the concept goes beyond the geographical and temporal boundaries of the Tommotian Stage. It can be traced back to the low-diversity assemblages of skeletal animal fossils appearing near the end of the Neoproterozoic. *See* CAMBRIAN; FOSSIL.

Traditionally, the fauna was considered to predate the earliest trilobites; however, recent stratigraphic studies suggest that at least some of the Tommotian Stage correlates with trilobite-carrying beds elsewhere. A number of the characteristic Tommotian taxa are now also known to continue into post-Tommotian strata. The Tommot fauna is known to have radiated from all continents, but it is particularly diverse and abundant on the Siberian Platform in Russia, in Australia, and in the belt of phosphorite-rich deposits that extends from the South China Platform through Mongolia, Kazakhstan, the Himalayas, and Iran. *See* TRILOBITA.

The Tommot fauna has been instrumental in forming our understanding of the Cambrian explosion (dramatic evolutionary radiation of animals beginning about 545 million years ago), because its preservation is generally not dependent on extraordinary conditions and is therefore less spotty. Also, fossilized embryos of Tommot animals make it possible to understand the complete life cycles of some of the most basal members of the metazoan evolutionary tree. *See* ANIMAL EVOLUTION.

Characteristic morphologic features of the Tommot fauna include mineralized tubes, spicules (knoblike supporting structures), sclerites (hardened plates), and shells, often belonging to animals of unknown affinities. The minerals involved are opal (a hydrated gel of silica), apatite (calcium phosphate), and aragonite/calcite (calcium carbonate)—the same minerals that are common in animal skeletons today. [S.Be.]

Ton of refrigeration A rate of cooling that is equivalent to the removal of heat at 200 Btu/min (200 kilojoules/min), 12,000 Btu/h (13 megajoules/h), or 288,000 Btu/day (300 MJ/day). This unit of measure stems from the original use of ice for refrigeration. One pound of ice, in melting at 32°F (0°C), absorbs as latent heat approximately 144 Btu/lb (335 J/kg), and 1 ton (0.9 metric ton) of ice, in melting in 24 h, absorbs 288,000 Btu/day (300 MJ/day). In Europe, where the metric system is used, the equivalent cooling unit is the frigorie, which is a kilogram calorie, or 3.96 Btu. Thus 3000 frigories/h is approximately 1 ton of refrigeration. A standard ton of refrigeration is one developed at standard rating conditions of 5°F (−15°C) evaporator and 86°F (30°C) condenser temperatures, with 9°F (−13°C) liquid subcooling and 9°F (−13°C) suction superheat. *See* REFRIGERATION. [C.F.K.]

Tone (music and acoustics) Physically, a sound that is composed of discrete frequency (or sine-wave) components; psychologically, an auditory sensation that is characterized foremost by its pitch or pitches.

The physical definition distinguishes a tone from a noise, wherein the components form a continuum of frequencies. Tones may be pure, consisting of a single frequency, or they may be complex. Complex tones, in turn, may be periodic or not periodic. Periodic complex tones repeat themselves at rapid regular intervals. They have frequency components that are harmonics—discrete frequencies that are integer multiples of a fundamental frequency. For example, the tone of an oboe consists of a fundamental frequency of 440 hertz, a second harmonic component with a frequency of 880 Hz, a third harmonic at 1320 Hz, and so on. In general, musical instruments that generate continuous sounds—the bowed strings, the brasses, and the woodwinds—create such periodic tones. Tones that are not periodic (aperiodic) have frequency components that do not fit a harmonic series. Percussive instruments such as kettledrums and bells make such aperiodic tones. *See* HARMONIC (PERIODIC PHENOMENA); MUSICAL ACOUSTICS; MUSICAL INSTRUMENTS; PERIODIC MOTION.

Pitch is a sensation of highness or lowness that is the basic element of melody. Periodic complex tones tend to have a single pitch, which listeners will match by a pure tone having a frequency equal to the fundamental frequency of the periodic complex tone. Aperiodic complex tones tend to have multiple pitches. A second psychological attribute of complex tones is tone color or timbre. Tone color is often represented by descriptive adjectives. The adjectives may be linked to the physical spectrum. Thus, a tone with strong harmonics above 1000 Hz may be called "bright." A tone with no harmonics at all above 1000 Hz may be called "dull" or "stuffy." *See* PITCH; PSYCHOACOUSTICS; SOUND. [W.M.Ha.]

Tongue An organ located at the base of the oral cavity and found in all vertebrate animals. It is best developed in terrestrial vertebrates, where it takes on the functions of food procurement, food transport, and acquisition of chemosensory signals. The tongue generally is not a significant independent organ in fish, and it is secondarily reduced in organisms that feed aquatically, such as crocodilians and some turtles.

Within terrestrial vertebrates, there is considerable variability in the specific structure of the tongue, the degree of participation of the hyoid skeleton (that is, a complex of bones at the base of the tongue which supports the tongue and its muscles), and the mechanisms of movement. In birds the tongue is merely a thickened epithelium that overlies the hyoid apparatus. Movement is produced by moving various hyoid elements. In most amphibians, including both frogs and salamanders, the hyoid provides extensive support, but considerable intrinsic tongue musculature exists. In squamate reptiles (lizards and snakes) and mammals the tongue is largely independent of the hyoid apparatus and is composed entirely of muscle. The musculature is tightly packed in the tongue and is generally arranged in three mutually perpendicular planes. In the mammalian tongue the musculature is arranged into longitudinal, transverse, and vertical bundles. Organs composed entirely of muscle and lacking independent skeletal systems, termed muscular hydrostats, are widespread. One of the primary advantages of a muscular hydrostat is that bending is not restricted to movement at joints, and the highly subdivided muscular and neural systems seen in mammalian tongues in particular produce movements that are remarkably specific, complex, and diverse.

While muscular-hydrostatic movements characterize the tongue of most mammals and many lizards and snakes, many of the most spectacular tongue projectors, such as chameleon lizards and plethodontid salamanders, do not use this mechanism in protrusion. These organisms have developed separate mechanisms in which the muscular tongue is projected ballistically from the body. In both, a muscle squeezes a process of the hyoid apparatus to generate the projectile force. *See* TASTE. [K.K.S.]

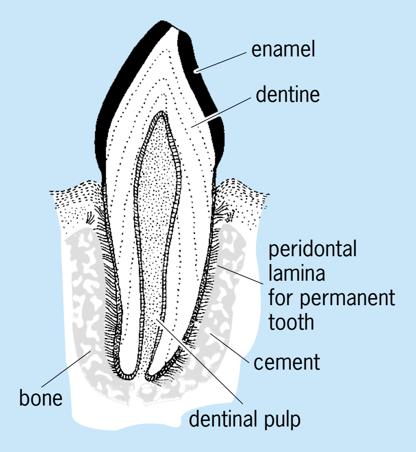
Tonsil Localized aggregation of diffuse and nodular lymphoid tissue found in the region where the nasal and oral cavities open into the pharynx. The tonsils are important sources of blood lymphocytes. They often become inflamed and enlarged, necessitating surgical removal. *See* TONSILLITIS.

The two palatine (faucial) tonsils are almond-shaped bodies measuring 1 by 0.5 in. (2.5 by 1.2 cm) and are embedded between folds of tissue connecting the pharynx and posterior part of the tongue with the soft palate. These are the structures commonly known as the tonsils. The lingual tonsil occupies the posterior part of the tongue surface. It is really a collection of 35–100 separate tonsillar units, each having a single crypt surrounded by lymphoid tissue. Each tonsil forms a smooth swelling about 0.08–0.16 in. (2–4 mm) in diameter. The pharyngeal tonsil (called adenoids when enlarged) occupies the roof of the nasal part of the pharynx. This tonsil may enlarge to block the nasal passage, forcing mouth breathing. *See* LYMPHATIC SYSTEM. [T.Sn.]

Tonsillitis An inflammation of the tonsil. Tonsillitis is a nonspecific term usually referring to bacterial or viral infection involving all or part of Waldeyer's ring, a collection of lymphatic tissue encircling the pharynx. It consists primarily of the tonsils (palatine tonsils), adenoids (pharyngeal tonsils), and lingual tonsils.

The complication of tonsillitis depend on which tonsil is involved. Recurrent adenoiditis with adenoid hypertrophy is frequently associated with recurrent otitis media, middle-ear fluid, and at times nasal obstruction with mouth breathing and snoring. Acute palatine tonsillitis may be complicated by peritonsillar abscess which may develop lateral to the tonsillar capsule. Removal of the adenoids is considered when there is residual middle-ear fluid. Palatine tonsils must be removed after peritonsillar abscess, but otherwise their removal depends upon the frequency of recurrent attacks of bacterial pharyngotonsillitis in relation to the patient's age. *See* TONSIL. [J.A.D.]

Tooth One of the structures found in the mouth of most vertebrates which, in their most primitive form, were conical and were usually used for seizing, cutting up, or chewing food, or for all three of these purposes. The basic tissues that make up the vertebrate tooth are enamel, dentin, cementum, and pulp (see illustration).



Structure of a tooth.

Enamel is the hardest tissue in the body because of the very high concentration, about 96%, of mineral salts. The remaining 4% is water and organic matter. The enamel has no nerve supply, although it is nourished to a very slight degree from the dentin it surrounds. The fine, microscopic hexagonal rods (prisms) of apatite which make up the enamel are held together by a cementing substance.

Dentin, a very bonelike tissue, makes up the bulk of a tooth, consisting of 70% of such inorganic material as calcium and phosphorus, and 30% of water and organic matter, principally collagen. The rich nerve supply makes dentin a highly sensitive tissue; this sensitivity serves no obvious physiological function.

Cement is a calcified tissue, a type of modified bone less hard than dentin, which fastens the roots of teeth to the alveolus, the bony socket into which the tooth is implanted. A miscellaneous tissue, consisting of nerves, fibrous tissue, lymph, and blood vessels, known as the pulp, occupies the cavity of the tooth surrounded by dentin.

The dentition of therian mammals, at least primitively, consists of four different kinds of teeth. The incisors (I) are usually used for nipping and grasping; the canines (C) serve for stabbing or piercing; the premolars (Pm) grasp, slice, or function as additional molars; and the molars (M) do the chewing, cutting, and grinding of the food. Primitively the placentals have 40 teeth and the marsupials 50.

In therian mammals, probably because of the intricacies and vital importance of tooth occlusion, only part of the first (or "milk") dentition is replaced. This second, or permanent, dentition is made up of incisors, canines, and premolars; as a rule only one premolar is replaced in marsupials. Although the molars erupt late in development and are permanent, that is, not replaced, they are part of the first, or deciduous, dentition. *See* TOOTH DISORDERS. [F.S.S.]

Tooth disorders Diseases and disturbances of the teeth and associated structures, including abnormal formation and growth of the teeth and jaws, tooth decay, inflammation of the tissues housing the roots of the teeth, and various diseases of the jaw bones.

Defective formation of dentin and enamel are referred to respectively as dentinogenesis and amelogenesis imperfecta, and may be caused by febrile illness during the period of tooth formation, or by faulty calcium or phosphorus metabolism, such as occurs in rickets. Some or all of the teeth may fail to form completely, or extra or supernumerary teeth may be present.

In most societies, dental decay, or caries, is one of the most important and common tooth disorders. Decay occurring during the adolescent years is caused by a class of microorganisms referred to as the cariogenic streptococci, of which *Streptococcus mutans* is a predominant member. However, a susceptible host and a cariogenic diet containing sucrose are also essential factors. Although the mechanism by which bacteria cause decay is not completely understood, most experts believe that cariogenic organisms, by using sucrose, and to a lesser extent other sugars, produce polymers which bind the organisms to the tooth surface and acids which cause demineralization resulting in cavity formation. Fluoride administration, either in the drinking water or by other routes, effectively reduces dental decay about 50–70%. The mechanism by which fluoride causes decreased decay rates is not understood.

Whereas dental decay is the principal cause of tooth loss in young individuals, inflammatory disease of the tissues surrounding the teeth, referred to as periodontal disease, causes most of the tooth loss in adults. *See* PERIODONTAL DISEASE.

Diseases of the jaws may affect the teeth. The most common jaw disorders fall into four categories: (1) inflammation of the jawbone caused by infections such as osteomyelitis; (2) cysts associated with the teeth as well as those located in bone sutures of the jaws; (3) benign and malignant tumors of the jaws; and (4) systemic diseases such as generalized skeletal abnormalities produced by endocrine disfunction in which the jaws are affected. *See* DENTISTRY; TOOTH. [R.C.P.]

Topaz A mineral best known for its use as a gemstone. Crystals are usually colorless but may be red, yellow, green, blue, or brown. The wine-yellow variety is the one usually cut and most highly prized as a gem. Corundum of similar color sometimes goes under the name of Oriental topaz. Citrine, a yellow variety of quartz, is the most common substitute and may be sold as quartz topaz.

Topaz is a nesosilicate with chemical composition $Al_2SiO_4(F,OH)_2$. The mineral crystallizes in the orthorhombic system and is commonly found in well-developed prismatic crystals with pyramidal terminations. It has a perfect basal cleavage which enables it to be distinguished from minerals otherwise similar in appearance. Hardness is 8 on Mohs scale; specific gravity is 3.4–3.6. *See* HARDNESS SCALES.

Fine yellow and blue crystals have come from Siberia and much of the wine-yellow gem material from Minas Gerais, Brazil. In the United States topaz has been found near Florissant, Colorado; in Thomas Range, Utah; in San Diego County, California; and near Topsham, Maine. *See* GEM; SILICATE MINERALS. [C.S.Hu.]

Topographic surveying and mapping The measurement of surface features and configuration of an area or a region, and the graphic expression of those features. Surveying is the art and science of measurement of points on, above, or under the surface of the Earth. Topographic maps show the natural and cultural features of a piece of land. The natural features include configuration (relief), hydrography, and vegetation. The cultural features include roads, buildings, bridges, political boundaries, and the sectional breakdown of the land. Topographic maps are used by a wide variety of people, such as engineers designing a new road; backpackers finding their way into remote areas; scientists describing soil or vegetation types, wildlife habitat, or hydrology; and military personnel planning field operations. *See* CARTOGRAPHY; MAP PROJECTIONS; MAP REPRODUCTION.

Topographic maps that show natural and cultural features only in plan view are called planimetric maps, while maps that show relief are called hypsometric maps. Contour lines join points along a line of the same elevation across the ground. Contours show not only the elevation of the ground but also the geomorphic shape of features. *See* CONTOUR.

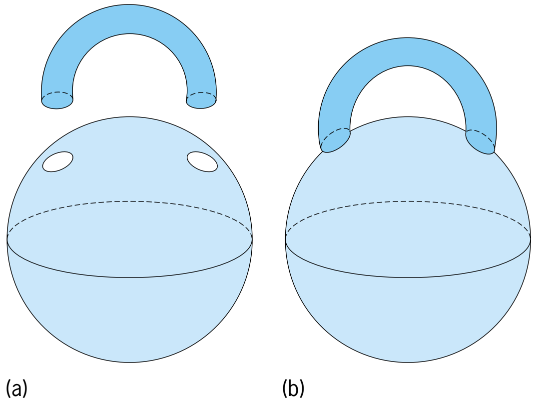
A digital terrain model (DTM) is a computer-generated grid laid over the topographic information, which can then be rotated, tilted, and vertically exaggerated to give a three-dimensional view of the ground from different perspectives, including oblique representations. This technology is an excellent presentation tool: it utilizes the advances that have been made in computer mapping and drafting software.

Prior to starting collection of data, a network of known horizontal and vertical control points must be established. The network also allows measurements made from several different locations in the same coordinate system to fit together into the same reference datum (the basis for the coordinate system). Field methods that are used to make measurements include ground surveys, geographic positioning systems, and hydrographic surveys. Photogrammetry and remote sensing techniques involve the use of photography to obtain reliable measurements. Photographs can be taken from airplanes, helicopters, and even satellites; thus the term remote sensing is applied to this technology. *See* AERIAL PHOTOGRAPH; HYDROGRAPHY; PHOTOGRAMMETRY; REMOTE SENSING; SURVEYING INSTRUMENTS. [C.Br.]

Topology The branch of mathematics that studies the qualitative properties of spaces, as opposed to the more delicate and refined geometric or analytic properties. While there are earlier results that belong to the field, the beginning of the subject as a separate branch of mathematics dates to the work of H. Poincaré during 1895–1904. The ideas and results of topology have a central place in mathematics, with connections to almost all the other areas of the subject.

The difference between topological and geometric properties is illustrated by the example of a space with three separate pieces. The exact shapes of the pieces constitute a geometric property of the space, and the study of these shapes is in the domain of differential geometry, but the fact that the space has three separate pieces is a qualitative or topological property. As another example, if a round sphere is deformed to be pear-shaped (or even more irregularly shaped, like the surface of the Earth), then the geometric notions of distance, straight line, and angle are changed, but the topological properties of the surface are left unchanged. However, if a handle is added by cutting two holes in the sphere and connecting them by a curved pipe, then the topology of the surface is changed (see illustration).

Four major areas of topology are algebraic topology, homotopy theory, general topology, and manifold theory. Algebraic topology, the first area of modern topology to be developed, is concerned with associating algebraic invariants to geometric spaces in order to measure higher-dimensional analogs of the number of pieces of a space or the number of handles of a surface. (An algebraic invariant of a space is an algebraic object associated to the space that remains unchanged if the space is replaced by a homeomorphic space. By an algebraic object is meant either an algebraic structure, such as a group, ring, or field, or an element of an algebraic structure.) Algebraic topology has tremendous influence on other branches of mathematics, both direct (application of the invariants of algebraic topology to problems from other areas of mathematics and physics)



Process of adding a handle to a 2-sphere. (*a*) Cutting of holes in sphere. (*b*) Connecting of holes by a curved pipe.

and indirect (application in other contexts of ideas arising from algebraic topology).

As algebraic topology developed, it became clear that if one function could be continuously deformed to another (that is, if they were homotopic), then these two functions behaved in the same way as far as the invariants of algebraic topology were concerned. This led naturally to the study of invariants that remain unchanged as the maps are deformed by homotopies, that is, homotopy invariants. This study, which is an offshoot of algebraic topology, is called homotopy theory. Some of the most interesting homotopy invariants are the higher homotopy groups. These proved extremely difficult to compute, even for spaces as simple as the sphere, and are the subject of much investigation.

Early in the development of topology it was realized that the foundations of the subject needed attention. General or point-set topology studies the relationships between the basic topological properties that spaces may possess.

Before abstract topological spaces were defined, there were numerous examples of spaces arising from geometric and analytic problems. The most important of these is a class of spaces known as manifolds. Both because of their ubiquitous appearance throughout mathematics and because they possess extraordinarily rich topological properties, manifolds became one of the central objects of study in topology. The basic theme in manifold theory is to find sufficient algebraic invariants to classify, that is, to list comprehensively, all manifolds, and to give methods for evaluating these invariants in geometric cases. *See* MANIFOLD (MATHEMATICS). [J.W.Mor.]

Torbanite A variety of coat that resembles a carbonaceous shale in outward appearance. It is fine-grained, brown to black, and tough, and breaks with a conchoidal or subconchoidal fracture. Torbanite is synonymous with boghead coal and is related to cannel coal. It is derived from colonial algae identified with the modern species of *Botryococcus braunii* and antecedent forms. High-assay torbanite yields paraffinic oil, whereas low-assay material yields asphaltic oil. *See* COAL. [I.A.B.]

Torch A gas-mixing and burning tool that produces a hot flame for the welding or cutting of metal. The torch usually delivers acetylene and commercially pure oxygen producing a flame temperature of 5000–6000°F (2750–3300°C), sufficient to melt the metal locally. The torch thoroughly mixes the two gases and permits adjustment and regulation of the flame. Acetylene can produce a higher flame temperature than other fuel gases. *See* ACETYLENE; WELDING AND CUTTING OF METALS.

Torches are of two types: low-pressure and high-pressure. In a low-pressure, or injector, torch, acetylene enters a mixing chamber, where it meets a jet of high-pressure oxygen. The amount of acetylene drawn into the flame is controlled by the velocity of this oxygen jet. In a high-pressure torch both gases are delivered under pressure.

A welding torch mixes the fuel and gas internally and well ahead of the flame. For cutting, the torch delivers an additional jet of pure oxygen to the center of the flame. The oxyacetylene flame produced by the internally mixed gases raises the metal to its ignition temperature. The central oxygen jet oxidizes the metal, the oxide being blown away by the velocity of the gas jet to leave a narrow slit or kerf. [F.H.R.]

Tornado A violently rotating, tall, narrow column of air (vortex), typically about 300 ft (100 m) in diameter, that extends to the ground from a cumulonimbus cloud. The vast majority of tornadoes rotate cyclonically (counterclockwise in the Northern Hemisphere). Of all atmospheric storms, tornadoes are the most violent. *See* CLOUD; CYCLONE.

Tornadoes are made visible by a generally sharp-edged, funnel-shaped cloud pendant from the cloud base, and a swirling cloud of dust and debris rising from the ground (see illustration). The funnel consists of small waterdroplets that form as moist air entering the tornado's partial vacuum expands and cools. The condensation funnel may not extend all the way to the ground and may be obscured by dust. Many condensation funnels exist aloft without tangible signs that the vortex is in contact with the ground; these are known as funnel clouds. Tornado funnels assume various forms: a slender smooth rope, a cone (often truncated by the ground), a thick turbulent black cloud on the ground, or multiple funnels (vortices) that revolve around the axis of the overall tornado.

The Cordell, Oklahoma, tornado of May 22, 1981, in its decay stage. (*National Severe Storms Laboratory/University of Mississippi Tornado Intercept Project*)

Many tornadoes evolve as follows: The tornado begins outside the precipitation region as a dust whirl on the ground and a short funnel pendant from a wall cloud on the southwest side of the thunderstorm; it intensifies as the funnel lengthens downward, and attains its greatest power as the funnel reaches its greatest width and is almost vertical; then it shrinks and becomes more tilted, and finally becomes contorted and ropelike as it decays. A downdraft and curtain of rain and large hail gradually spiral from the northeast cyclonically around the tornado, which often ends its life in rain. *See* HAIL; PRECIPITATION (METEOROLOGY); THUNDERSTORM.

Most tornadoes and practically all violent ones develop from a larger-scale circulation, the mesocyclone, which is 2–6 mi (3–9 km) in diameter and forms in a particularly virulent variety of thunderstorm, the supercell. The mesocyclone forms first at midaltitudes of the storm and in time develops at low levels and may extend to high altitudes as well. The tornado forms on the southwest side (Northern Hemisphere) of the storm's main updraft, close to the downdraft, after the development of the mesocyclone at low levels. Some supercells develop up to six mesocyclones and tornadoes repeatedly over great distances at roughly 45-min intervals. Tornadoes associated with supercells are generally of the stronger variety and have larger parent cyclones. Hurricanes during and after landfall may spawn numerous tornadoes from small supercells located in their rainbands. *See* HURRICANE.

Tornadoes are classified as weak, strong, or violent, or from F0 to F5 on the Fujita (F) scale of damage intensity. Sixty-two percent of tornadoes are weak (F0 to F1). These tornadoes have maximum windspeeds less than about 50 m/s (110 mi/h) and inflict only minor damage, such as peeling back roofs, overturning mobile homes, and pushing cars into ditches. Thirty-six percent of tornadoes are strong (F2 to F3) with maximum windspeeds estimated to be 50–90 m/s (110–200 mi/h). Strong tornadoes extensively damage the roofs and walls of houses but leave some walls partially standing. They demolish mobile homes, and lift and throw cars. The remaining 2% are violent (F4 to F5), with windspeeds in excess of about 90 m/s (200 mi/h). They level houses to their foundations, strew heavy debris over hundreds of yards, and make missiles out of heavy objects such as roof sections, vehicles, utility poles, and large, nearly empty storage tanks. *See* WIND.

Tornadoes occur most often at latitudes between 20° and 60°, and they are relatively frequent in the United States, Russia, Europe, Japan, India, South Africa, Argentina, New Zealand, and parts of Australia. Violent tornadoes are confined mainly to the United States, east of the Rocky Mountains.

Essentially, there are five atmospheric conditions that set the stage for wide-spread tornado development: (1) a surface-based layer, at least 3000 ft (1 km) deep, of warm, moist air, overlain by dry air at midlevels; (2) an inversion separating the two layers, preventing deep convection until the potential for explosive overturning is established; (3) rapid decrease of temperature with height above the inversion; (4) a combination of mechanisms, such as surface heating and lifting of the air mass by a front or upper-level disturbance, to eliminate the inversion locally; (5) pronounced vertical wind shear (variation of the horizontal wind with height). Specifically, storm-relative winds in the lowest 6000 ft (2 km) should exceed 20 knots (10 m/s) and veer (turn anticyclonically) with height at a rate of more than 10°/1000 ft (30°/km). Such conditions are prevalent in the vicinity of the jet stream and the low-level jet.

The first three conditions above indicate that the atmosphere is in a highly metastable state. There is a strong potential for thunderstorms with intense updrafts and downdrafts. The fourth condition is the existence of a trigger to release the instability and initiate the thunderstorms. The fifth is the ingredient for updraft rotation. *See* AIR MASS; FRONT; JET STREAM; TEMPERATURE INVERSION. [R.D.J.]

Torque The product of a force and its perpendicular distance to a point of turning; also called the moment of the force. Torque produces torsion and tends to produce rotation. Torque arises from a force or forces acting tangentially to a cylinder or from any force or force system acting about a point. A couple, consisting of two equal, parallel, and oppositely directed forces, produces a torque or moment about the central point. A prime mover such as a turbine exerts a twisting effort on its output shaft, measured as torque. In structures, torque appears as the sum of moments of torsional shear forces acting on a transverse section of a shaft or beam. *See* COUPLE; TORSION. [N.S.F.]

Torque converter A device for changing the torque-speed ratio or mechanical advantage between an input shaft and an output shaft. A pair of gears is a mechanical torque converter. A hydraulic torque converter is an automatically and continuously variable torque converter, in contrast to a gear shift, whose torque ratio is changed in steps by an external control. *See* AUTOMOTIVE TRANSMISSION; GEAR DRIVE.

A mechanical torque converter transmits power with only incidental losses; thus, the power, which is the product of torque T and rotational speed N, at input I is substantially equal to the power at output O of a mechanical torque converter, or $T_I N_I = kT_O N_O$, where k is the efficiency of the gear train. This equal-power characteristic is in contrast to that of a fluid coupling in which input and output torques are equal during steady-state operations. *See* FLUID COUPLING.

In a hydraulic torque converter, efficiency depends intimately on the angles at which the fluid enters and leaves the blades of the several parts. Because these angles change appreciably over the operating range, k varies, being by definition zero when the output is stalled, although output torque at stall may be three times engine torque for a single-stage converter and five times engine torque for a three-stage converter. Depending on its input absorption characteristics, the hydraulic torque converter tends to pull down the engine speed toward the speed at which the engine develops maximum torque when the load pulls down the converter output speed toward stall. [H.J.Wir.]

Torricelli's theorem The speed of efflux of a liquid from an opening in a reservoir equals the speed that the liquid would acquire if allowed to fall from rest from the surface of the reservoir to the opening.

Torricelli, a student of Galileo, observed this relationship in 1643. In equation form, $v^2 = 2gh$, in which v is the speed of efflux, h the head (or elevation difference between reservoir surface and center line of opening if in a vertical plane), and g the acceleration due to gravity. (The equation is the same as that for a solid particle dropped a distance h in a vacuum.) The relationship can be derived from the energy equation for flow along a streamline, if energy losses are neglected. *See* FLOW MEASUREMENT. [V.L.S.]

Torsion A straining action produced by couples that act normal to the axis of a member. Torsion is identified by a twisting deformation.

In practice, torsion is often accompanied by bending or axial thrust as in the case of line shafting driving gears or pulleys, or propeller shafts for ship propulsion. Other important examples include springs and machine mechanisms usually having circular sections, either solid or tubular. Members with noncircular sections are of interest in special applications, such as structural members subjected to unsymmetrical bending loads that twist and buckle beams. *See* SPRING (MACHINES); TORSION BAR.

When subjected only to torque, the member is in pure torsion, which produces pure shear stresses. The shear properties of materials are determined by a torsion test. *See* SHEAR; TORQUE. [J.B.S.]

Torsion bar A spring flexed by twisting about its axis. Design of a torsion bar spring is primarily based on the relationships between the torque applied in twisting the spring, the angle through which the torsion bar twists, and the physical dimensions and material (modulus of elasticity in shear) from which the torsion bar is made. The illustration shows the elements of a simple

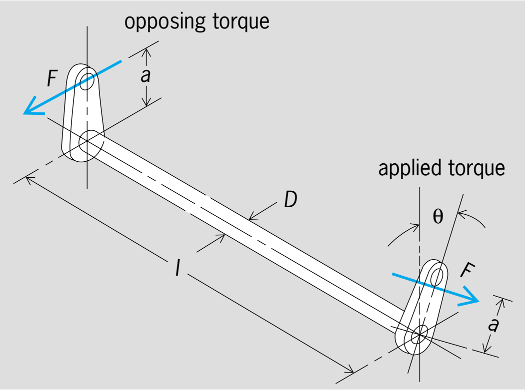


Diagram of torsion bar.

torsion bar and the important dimensions involved in its design. The equation below relates these dimensions. Here θ is angle

$$\theta = \frac{32Fal}{\pi D^4 G}$$

of twist in radians, F is force in pounds, a is radius arm of force in inches, l is length of torsion bar in inches, D is diameter of torsion bar in inches, and G is modulus of elasticity in shear in pounds per square inch.

Torsion bar springs are found in the spring suspension of truck and passenger car wheels, in production machines where space limitations are critical, and in high-speed mechanisms where inertia forces must be minimized. *See* SPRING (MACHINES). [L.S.L.]

Torus A surface obtained by rotating a circle about a line that lies in its plane, but which has no points in common (see illustration). It is a two-dimensional manifold of genius 1 and connectivity 3. *See* MANIFOLD (MATHEMATICS); TOPOLOGY. [L.M.Bl.]

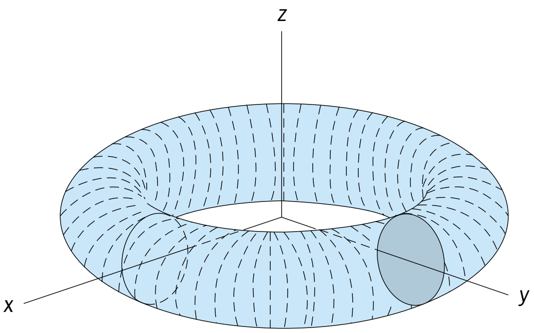

Diagram of a torus.

Tourette's syndrome A neurobehavioral disorder characterized by frequent, recurrent motor and vocal tics. The motor tics include brief, rapid, and darting movements of almost any muscle group, and can include eye blinking, eye rolling or deviations, nose wrinkling, facial grimacing, and head shaking. Some motor tics are more complex, are slow, and appear purposeful such as head turning, shoulder shrugging, touching, hopping, or twirling. Vocal tics are brief guttural sounds such as recurrent sniffing, throat clearing, coughing, and grunting or barking sounds. Complex vocal tics can be more meaningful and include verbal expressions. Tourette's syndrome has been described in nearly every country and ethnic group, with an estimated prevalence of one or two occurrences per 2000 people.

The motor and vocal tics begin in childhood, often worsen during adolescence, and tend to improve during the twenties and thirties. Symptoms increase with stress and excitement and decrease with activities that require focused effort. While the motor and vocal tics are involuntary, they can be suppressed for brief periods of time, giving the false impression that the movements and sounds are voluntary.

The pattern of inheritance is consistent with a single autosomal dominant gene whose expression is variable and dependent on the sex of the person. Tic symptoms can vary from transient tics to Tourette's syndrome and can include obsessive-compulsive symptoms. The complexity of symptoms is likely related to the various brain regions implicated in the development of Tourette's syndrome. Treatment can be targeted toward suppressing tics and the specific associated behavioral problems. Methods for tic suppression include medications that affect the brain by blocking the neurotransmitter dopamine at the site of nerve-to-nerve connections. *See* BRAIN; HUMAN GENETICS; NERVOUS SYSTEM DISORDERS. [J.T.W.; M.A.Ri.]

Tourmaline A cyclosilicate mineral family with (BO_3) triangular groups and a complex chemical composition. The general formula can be written $XY_3Al_6(OH)_4(BO_3)_3(Si_6O_{18})$, in which X = Na, Ca, and Y = Al, Fe^{3+}, Li, Mg, Mn^{2+}. The more common tourmalines are dravite (X,Y = Na,Mg), schorl (X,Y = Na,Fe), uvite (X,Y = Ca,Mg), and elbaite (X,Y = Na,Li). Fluorine commonly substitutes in the hydroxyl position. Tourmaline is a hard ($7\frac{1}{2}$ on Mohs scale), varicolored mineral which can be an important semiprecious gemstone. *See* GEM; SILICATE MINERALS.

The tourmaline crystal is polar; thus it is piezoelectric; that is, if pressure is exerted at one end, opposite electrical charges will occur at opposite poles. It is also pyroelectric, with the electrical charges developed at the ends of the polar axis on a change in temperature. Because of its piezoelectric property, tourmaline can be cut into gages to measure transient pressures. *See* PIEZOELECTRICITY; PYROELECTRICITY. [P.B.M.]

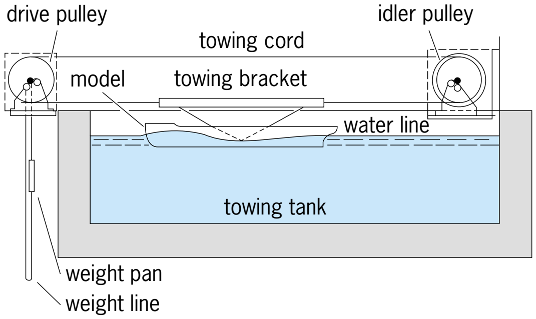
Tower A concrete, metal, or timber structure that is relatively high for its length and width. Towers are constructed for many purposes, including the support of electric power transmission lines, radio and television antennas, and rockets and missiles prior to launching.

Transmission towers are rectangular in plan and are not steadied by guy wires. A transmission tower is subjected to a number of forces; its own weight, the pull of the cables at the top of the tower, the effect of wind and ice on the cable, and the effect of wind on the tower itself.

Radio and television towers are either guyed or freestanding. Freestanding towers are usually rectangular in plan. In addition to their own weight, freestanding towers support the weight of the antenna and accessories and the weight of ice, unless a deicing circuit is installed. Wind forces must also be carefully considered. Guyed towers are usually triangular in plan, with the main structural members, or legs, at the vertexes of the triangle. The legs are usually solid round steel bars. *See* ANTENNA (ELECTROMAGNETISM); TRANSMISSION LINES. [C.M.A.]

Towing tank A tank of water used to determine the hydrodynamic performance of waterborne bodies such as ships and submarines, as well as torpedoes and other underwater forms. In the narrow sense, towing tanks are considered to be experimental facilities used to measure the forces, such as drag, on ship models and in turn to predict the performance of the full-scale prototype. In general, towing tanks are rectangular in planform with a uniform cross section. Different section shapes are used, ranging from rectangular to semicircular.

The principal measurements made in a towing tank are force measurements, particularly drag or resistance of a towed ship model or other body. One of two principal systems for towing a model is used in most towing tanks. The simpler system consists of a gravity dynamometer and an endless cable attached to the model. A weight provides a constant towing force (see illustration). The time to traverse a fixed distance is measured when the model reaches a constant speed, thus establishing the



Tank with model towed by falling weight.

speed-resistance relationship for the model. This dynamometer is simple and capable of high accuracy, but is limited to the measurement of the drag force of waterborne bodies. It is used in the smaller towing tanks in which the models are generally under 6 ft (1.8 m) in length.

In larger towing tanks the model is towed by a towing carriage mounted on rails at the side of the towing tank or suspended from an overhead track system. Speed can be controlled and measured precisely on these carriages. Most carriages are equipped with a drag dynamometer as a permanent component. [J.B.H.]

Townsend discharge A particular part of the voltage-current characteristic curve for a gaseous discharge device named for J. S. Townsend, who studied it about 1900. It is that part for low current where the discharge cannot be maintained by the field alone. Thus, if the agents producing the initial ionization were removed, conduction would cease. *See* ELECTRICAL CONDUCTION IN GASES. [G.H.M.]

Toxic shock syndrome A serious, sometimes life-threatening disease usually caused by a toxin produced by some strains of the bacterium *Staphylococcus aureus*. The signs and symptoms are fever, abnormally low blood pressure, nausea and vomiting, diarrhea, muscle tenderness, and a reddish rash, followed by peeling of the skin.

Toxic shock syndrome was first reported in 1978 in seven pediatric patients. However, in 1980 hundreds of cases were reported among young women without apparent staphylococcal infections. Epidemiologists observed that the illness occurred predominantly in young women who were menstruating and were using tampons, especially those that contained so-called superabsorbent synthetic materials. A toxin [toxic shock syndrome toxin number 1 (TSST-1)] that occurs in some strains of staphylococci was later identified. These bacteria are known to proliferate in the presence of foreign particles in human infections, and it has been postulated that the tampons acted as foreign particles, allowing toxin-producing staphylococci to multiply in the vagina.

Several hundred cases of toxic shock syndrome not associated with menstruation have been reported. In these cases, which occurred in males as well as females, there was almost always an overt staphylococcal infection. Susceptibility may depend on lack of antibodies to the toxin that occur in most adults.

The toxin has been shown to occur in only about 1% of the staphylococcal strains studied. Moreover, there is some evidence that the syndrome may be caused also by other staphylococcal toxins, particularly enterotoxins. Cases of toxic shock syndrome that were caused by streptococci have been reported. A toxin distinct from TSST-1 appears involved. Persons with the symptoms of toxic shock syndrome should receive immediate medical care to reduce the chance of death. *See* STAPHYLOCOCCUS; TOXIN. [J.O.Co.]

Toxicology The study of the adverse effects of chemical and physical agents on living organisms. Toxicology has also been referred to as the science of poisons. *See* ENVIRONMENTAL TOXICOLOGY; POISON.

The most important factor that influences the toxic effect of a specific chemical is the dose. All chemicals, including essential substances such as oxygen and water, produce toxic effects when administered in large enough doses. Another significant factor is the route of exposure. Living organisms may be exposed to a chemical by inhalation (into the lungs), ingestion (into the stomach), penetration through the skin, or, in special circumstances, injection into the body. In general, substances are absorbed into the body most efficiently through the lungs so that inhalation is often the most serious route of exposure.

A third factor is the fate of the chemical after the organism is exposed. The chemical may not be absorbed at all, limiting its possible adverse effects to the site of exposure. If it is absorbed, then it may travel throughout the body and has the potential to cause toxic effects at one or more sites remote from the site of entry. The remote sites where these adverse effects occur are called target organs.

Another significant variable is the time course of the exposure. A quantity of chemical administered at one time may have an effect even though the same quantity administered in small doses over time has no effect.

In view of the importance of timing in producing adverse effects, toxicologists distinguish between two broad classes of toxicity, acute and chronic. Acute toxicity refers to effects that occur shortly after a single exposure or small number of closely spaced exposures. Chronic toxicity refers to delayed effects that occur after long-term repeated exposures.

Traditionally, the effect of most concern for acute toxicants (such as cyanide) is death. Acute toxicity is generally measured by using an assay to determine the lethal dose; rodents are given single doses and the number that have died 14 days later is recorded. The data are plotted for each dose, and the dose that is lethal for 50% of the animals (lethal dose 50 or LD_{50}) is used as the criterion for acute toxicity. *See* LETHAL DOSE 50.

Some synthetic chemicals, such as polychlorinated biphenyls (PCBs) and dichlorodiphenyltrichloroethane (DDT), exhibit their effects only after a number of repeated exposures and are considered chronic hazards, with cancer and reproductive effects being of greatest concern. To determine the dose at which chronic effects occur, rodents are exposed to daily doses of the chemical under study for long periods of time—from a few months to a lifetime. The highest dose at which no effects can be observed, the no observed effect level (NOEL), is used as a measure of chronic toxicity. *See* MUTAGENS AND CARCINOGENS. [M.Kam.; R.W.L.]

Toxin Properly, a poisonous protein, especially of bacterial origin. However, nonproteinaceous poisons, such as fungal aflatoxins and plant alkaloids, are often called toxins. *See* AFLATOXIN; ALKALOID.

Bacterial exotoxins are proteins of disease-causing bacteria that are usually secreted and have deleterious effects. Several hundred are known. In some extreme cases a single toxin accounts for the principal symptoms of a disease, such as diphtheria, tetanus, and cholera. Bacteria that cause local infections with pus often produce many toxins that affect the tissues around the infection site or are distributed to remote organs by the blood. *See* CHOLERA; DIPHTHERIA; STAPHYLOCOCCUS; TETANUS.

Toxins may assist the parent bacteria to combat host defense systems, to increase the supply of certain nutrients such as iron, to invade cells or tissues, or to spread between hosts. Sometimes the damage suffered by the host organism has no obvious benefit to the bacteria. For example, botulinal neurotoxin in spoiled food may kill the person or animal that eats it long after the parent bacteria have died. In such situations it is assumed that the bacteria benefit from the toxin in some other habitat and that the damage to vertebrates is accidental. *See* FOOD POISONING.

Certain bacterial and plant toxins have the unusual ability to catalyze chemical reactions inside animal cells. Such toxins are always composed of two functionally distinct parts termed A and B, and they are often called A-B toxins. The B part binds to receptor molecules on the animal cell surface and positions the toxin upon the cell membrane. Subsequently, the enzymically active A portion of the toxin crosses the animal cell membrane and catalyzes some intracellular chemical reaction that disrupts the cell physiology or causes cell death. *See* IMMUNOLOGIC CYTOTOXICITY.

A large group of toxins breach the normal barrier to free movement of molecules across cell membranes. In sufficient concentration such cytolytic toxins cause cytolysis, a process by which soluble molecules leak out of cells, but in lower concentration they may cause less obvious damage to the cell's plasma membrane or to its internal membranes. *See* CELL MEMBRANES; CELL PERMEABILITY.

Tetanus and botulinal neurotoxins block the transmission of nerve impulses across synapses. Tetanus toxin blockage results in spastic paralysis, in which opposing muscles contract simultaneously. The botulinal neurotoxins principally paralyze neuromuscular junctions and cause flaccid paralysis.

Gram-negative bacteria, such as *Salmonella* and *Hemophilus*, have a toxic component in their cell walls known as endotoxin or lipopolysaccharide. Among other detrimental effects, endotoxins cause white blood cells to produce interleukin-1, a hormone responsible for fever, malaise, headache, muscle aches, and other nonspecific consequences of infection. The exotoxins of toxic shock syndrome and of scarlet fever induce interleukin-1 and also tumor necrosis factor, which has similar effects. *See* ENDOTOXIN; FEVER; SCARLET FEVER; TOXIC SHOCK SYNDROME.

Toxoids are toxins that have been exposed to formaldehyde or other chemicals that destroy their toxicities without impairing immunogenicity. When injected into humans, toxoids elicit specific antibodies known as antitoxins that neutralize circulating toxins. Such immunization (vaccination) is very effective for systemic toxinoses, such as diphtheria and tetanus. *See* ANTIBODY; IMMUNITY; VACCINATION. [D.M.Gi.]

Toxin-antitoxin reaction A term used in serology to denote the combination of a toxic antigen with its corresponding antitoxin. If the antitoxin is derived from any species other than the horse, precipitation occurs over a wide range of reactant ratios, 20 × or more, as in other antigen-antibody reactions. With horse antitoxin, flocculation occurs only if toxin and antitoxin are near equivalence, a twofold excess of either reactant giving soluble complexes. In most instances, the reaction results in partial or complete neutralization of the toxic activity of the antigen. *See* ANTIBODY; ANTIGEN; ANTITOXIN; NEUTRALIZATION REACTION (IMMUNOLOGY); SEROLOGY. [H.P.T.]

Toxoplasmea A class of the subphylum Sporozoa. The organisms are small and crescent-shaped. They move by body flection or gliding and have no flagella or pseudopodia. Characteristic structures are the two-layered pellicle and underlying longitudinal microtubules, micropyle, a conoid, paired organelles, and micronemes.

The most distinguishing characteristic of the Toxoplasmea is the unique means of reproduction. Electron microscope studies indicate that endodyogeny is the sole method. Endodyogeny is an internal budding wherein two daughter cells are produced within a mother cell which is destroyed in the process.

Only two stages are known in the life cycle most animals. One stage, the proliferative form or trophozoite, occurs singly or in groups within host cells. The other stage, the so-called cysts, consists of a large number of organisms which, with minor differences, are structurally similar to the proliferative forms. *See* SPOROZOA; TOXOPLASMIDA. [H.G.Sh.]

Toxoplasmida An order of the class Toxoplasmea. Four genera, *Toxoplasma*, *Besnoitia*, *Sarcocystis*, and *Encephalitozoon*, make up the order. The organisms are parasites of vertebrates. *Toxoplasma* is often found encysted in nerve tissue, *Besnoitia* in connective tissue, and *Sarcocystis* in muscle. Very little is known about *Encephalitozoon*, but the parasite has been found in the brain of rabbits. *See* TOXOPLASMIDA; TOXOPLASMOSIS. [H.G.Sh.]

Trace fossils Fossilized evidence of animal behavior, also known as ichnofossils, biogenic sedimentary structures, bioerosion structures, or lebensspuren. The fossils include burrows, trails, and trackways created by animals in unconsolidated sediment (see illustration), as well as borings, gnawings, raspings, and scrapings excavated by organisms in harder materials, such as rock, shell, bone, or wood. Some workers also consider coprolites (fossilized feces), regurgitation pellets, burrow excavation pellets, rhizoliths (plant root penetration structures), and algal stromatolites to be trace fossils. *See* STROMATOLITE.

Agrichnial farming traces (burrows produced in order to farm or trap food inside the sediment) of unknown organisms, including a double-spiral tunnel (*Spirorhaphe*) and a meshlike network of tunnels (*Paleodictyon*). Tertiary, Austria. (*Photograph by W. Häntzschel*)

Trace fossils are important in paleontology and paleoecology, because they provide information about the presence of unpreserved soft-bodied members of the original communities, life habits of fossil organisms, evolution of certain behavior patterns through geologic time, and biostratigraphy of otherwise unfossiliferous deposits. Trace fossils also are useful in sedimentology and paleoenvironmental studies, because they are sedimentary structures that are preserved in place and are very rarely reworked and transported, as body fossils of animals and plants commonly are. This fact allows trace fossils to be regarded as reliable indicators of original conditions in the sedimentary environment. The production of trace fossils involves disruption of original stratification and sometimes results in alteration of sediment texture or composition. *See* FOSSIL; PALEOECOLOGY; PALEONTOLOGY; SEDIMENTOLOGY.

Trace fossils occur in sedimentary deposits of all ages from the late Precambrian to the Recent. Host rocks include limestone, sandstone, siltstone, shale, coal, and other sedimentary rocks. These deposits represent sedimentation in a broad spectrum of settings, ranging from subaerial (such as eolian dunes and soil horizons) to subaqueous (such as rivers, lakes, swamps, tidal flats, beaches, continental shelves, and the deep-sea floor). *See* DEPOSITIONAL SYSTEMS AND ENVIRONMENTS.

Organisms may produce fossilizable traces on the sediment surface (epigenic structures) or within the sediment (endogenic structures). Trace fossils may be preserved in full three-dimensional relief (either wholly contained within a rock or weathered out as a separate piece) or in partial relief (either as a depression or as a raised structure on a bedding plane). Simply because a trace fossil is preserved on a bedding plane does not indicate that it originally was an epigenic trace. Diagenetic alteration of sediment commonly enhances the preservation of trace fossils by differential cementation or selective mineralization. In some cases, trace fossils have been preferentially replaced by chert, dolomite, pyrite, glauconite, apatite, siderite, or other minerals. *See* DIAGENESIS.

The study of trace fossils is known as ichnology. The prefix "ichno-" (as in ichnofossil and ichnotaxonomy) and the suffix "-ichnia" (as in epichnia and hypichnia) commonly are employed to designate subjects relating to trace fossils. The suffix "-ichnus" commonly is attached to the ichnogenus name of many trace fossils (as in *Dimorphichnus* and *Teichichnus*). [A.A.E.]

Trachylina An order of jellyfish of the class Hydrozoa of the phylum Coelenterata. These jellyfish are of moderate size. They differ from other hydrozoan jellyfish in having balancing organs which develop partly from the digestive epithelium and in having only a small polyp stage or none at all. Many authorities recognize three distinct orders of trachylines—Limnomedusae, Trachymedusae, and Narcomedusae—and in this case the older term Trachylina is abandoned. *See* HYDROZOA. [S.Cr.]

Trachyte A light-colored, aphanitic (very finely crystalline) rock of volcanic origin, composed largely of alkali feldspar with minor amounts of dark-colored (mafic) minerals (biotite, hornblende, or pyroxene). If sodic plagioclase (oligoclase or andesine) exceeds the quantity of alkali feldspar, the rock is called latite. Trachyte and latite are chemically equivalent to syenite and monzonite, respectively. *See* LATITE; MONZONITE; SYENITE.

Streaked, banded, and fluidal structures due to flowage of the solidifying lava are commonly visible in many trachytes and may be detected by a parallel arrangement of tabular feldspar phenocrysts. A distinctive microscopic feature is trachytic texture in which the tiny, lath-shaped sanidine crystals of the rock matrix are in parallel arrangement and closely packed.

Trachyte is not an abundant rock, but it is widespread. It occurs as flows, tuffs, or small intrusives (dikes and sills). It may be associated with alkali rhyolite, latite, or phonolite. *See* IGNEOUS ROCKS; MAGMA; SPILITE. [C.A.C.]

Tractor A wheeled, self-propelled vehicle for hauling other vehicles or equipment and for operating the towed implements; also, a crawler which runs on an endless, self-laid track and performs similar functions.

A farm tractor is a multipurpose power unit. It has a drawbar for drawing tillage tools and a power takeoff device for driving implements or operating a belt pulley. The acreage to be worked, type of crops grown, and the terrain all impose their requirements on tractor design. Accordingly, models vary in such details as power generated, weight, ground clearance, turning radius, and facilities for operating equipment. All models can, however, be grouped under four general types: four-wheel, row-crop or high-wheel, tricycle, and crawler.

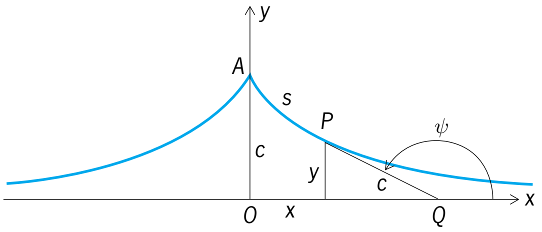
Tractors are rated by the horsepower they deliver at the drawbar and at the belt. On small models, the drawbar and belt horsepower may run as low as 10 (7.5 kW); on large models the drawbar horsepower runs as high as 132 (98 kW), while belt horsepower reaches about 144 (107 kW).

The major components are engine, clutch, and transmission. These components are intimately related and designed to work in conjunction with each other to accomplish specific work. Tractor engines are relatively low-speed; their maximum horsepower is generated at crankshaft speeds in the neighborhood of 2000 rpm. These engines have one, two, three, four, six, or eight cylinders and operate on gasoline, kerosine, liquid petroleum gas, or diesel fuel. They are of the spark-ignition or diesel type, operating on the four-stroke-cycle principle, and are cooled by water or air.

Power is transmitted to the rear wheels or to all four wheels. Drive to the front wheels is mechanical or hydrostatic, its purpose being to increase drawbar pull at the will of the operator. Transmissions have 3, 4, 5, 6, 8, 10, or 12 forward speeds and one or two reverse gears. Clutchless hydraulic transmissions are also used, making it possible to shift gears while in motion. Vehicle speeds are low, ranging from slightly more than 1 mi/h (1.6 km/s) to about 18 mi/h (13 km/h) in high gear. *See* CLUTCH; TORQUE CONVERTER.

The basic design of an industrial tractor for hauling and for operating construction equipment departs little from that of a farm tractor, and differences in design of models fit the vehicle to its intended work. Because high ground clearance is not needed for industrial work, the tractor is commonly built with a lower center of gravity and is capable of traveling a few miles per hour faster than a farm tractor. If its use is confined to hauling, it may not be equipped with hydraulic power. If it is to be used for operating a scraper, backhoe, or front-end loader, its structure may be heavier and more rugged. *See* BULK-HANDLING MACHINES. [P.H.S.]

Tractrix A plane curve for which the length of any tangent between the curve and a fixed line is constant *c* (see illustration).



Tractrix (upper half).

If the *x* axis is the fixed line, its differential equation is Eq. (1). With ψ, the inclination of the tangent, as parameter, this yields equations (2). The tractrix has the *x* axis as asymptote and cusps at $(0, \pm c)$. The arc *AP*, measured from a cusp, is as in Eq. (3).

$$(dy/dx)^2 = y^2/(c^2 - y^2) \tag{1}$$

$$x = c \log \tan {}^1\!/_2|\psi| + c \cos \psi \tag{2}$$

$$y = c \sin \psi$$

$$s = -c \log \sin \psi = c \log \frac{c}{y} \tag{3}$$

[L.Br.]

Traffic-control systems Systems that act to control the movement of people, goods, and vehicles in order to ensure their safe, orderly, and expeditious flow throughout the transportation system. Each of the five areas of transportation—roadways, airports and airways, railways, coastal and inland waterways, and pipelines—have unique systems of control.

Roadway traffic-control systems are intended to improve safety, increase the operational efficiency and capacity of the roadway, and contribute to the traveler's comfort and convenience. They range from simple control at isolated intersections using signs and markings, to sophisticated traffic-control centers which have the ability to react to changes in the traffic environment. Traffic-control systems are used at roadway intersections, on highways and freeways, at ramp entrances to freeways, and in monitoring and controlling wider-area transportation networks. Intelligent roadway traffic control, now known as intelligent transportation systems (ITS), is a very sophisticated form of traffic control for roadway and other areas. *See* HIGHWAY ENGINEERING.

The U.S. federal government has designated airspace as either uncontrolled or controlled. In uncontrolled airspace, pilots may conduct flights without specific authorization. In controlled airspace, pilots may be required to maintain communications with the appropriate air-traffic control facility to receive authorization and instruction on traversing, taking off from, or landing, in that controlled area. Air-traffic control systems for controlled areas may be divided loosely into en route and terminal systems. *See* AIR NAVIGATION; AIR-TRAFFIC CONTROL; AIR TRANSPORTATION.

Railroads operate high-speed freight and passenger services essentially over an exclusive right of way. Railroads use both semaphore and light signals for traffic control. Semaphores convey visual messages to train operators according to predetermined rules indicating how the train is to be operated in specified areas. Automatic block signaling prevents rear-end and head-on collisions on signal tracks. In this system, track sections are divided into blocks. Only one train is permitted to occupy a block at any time. Blocks are monitored by automatic circuitry that controls traffic signals, indicating the appropriate clear or stop signals to following or approaching trains. Similar block systems are used for subway systems. Centralized traffic-control systems may control hundreds of miles of track signals and switches. A dispatcher at a central location monitors the location of trains by means of visual displays of colored lights on a large track diagram, and can operate the switches and signals at key points from the central control console. *See* RAILROAD CONTROL SYSTEMS; RAILROAD ENGINEERING.

Vessel traffic control consists largely of marine aides that function more for informational, advisory, and guidance purposes than as positive traffic-control devices. Lighted or unlighted buoys indicate navigable areas in coastal waters and within waterways. Lightships and lighthouses with fog signals and radio beacons are placed as markers at prominent points during periods of limited visibility. Radar devices have become common, even on smaller ships. Navigation systems often employ the Differential Global Positioning System. The Vessel Traffic Service (VTS) is available in selected areas. Services may range from the provision of single advisory messages to extensive management of traffic communication and radar services. *See* BUOY; LIGHTHOUSE; MARINE NAVIGATION; NAVIGATION.

The 450,000 mi (750,000 km) of pipelines in the United States are a major part of the nation's transportation network, carrying about 25% of all intercity freight-ton mileage. The primary goods moved through pipelines are oil and oil by-products, natural gas, and fertilizers. The movement of goods in pipelines is controlled by systems of valves, pumps, and compressors. *See* PIPELINE; TRANSPORTATION ENGINEERING. [J.Cos.; D.C.N.]

Trajectory The curve described by a body moving through space, as of a meteor through the atmosphere, a planet around the Sun, a projectile fired from a gun, or a rocket in flight. In general, the trajectory of a body in a gravitational field is a conic section—ellipse, hyperbola, or parabola—depending on the energy of motion. The trajectory of a shell or rocket fired from the ground is a portion of an ellipse with the Earth's center as one focus; however, if the altitude reached is not great, the effect of gravity is essentially constant, and the parabola is a good approximation. *See* BALLISTICS. [J.P.H.]

Tranquilizer A psychopharmacologic drug that tends to have a calming effect, and is unique in inducing drowsiness without impairing ready arousal and in restraining hyperactivity without inducing coma or arrest of respiratory muscles.

According to basic chemical structure, five categories of tranquilizers can be delineated: (1) phenothiazines (for example, chlorpromazine) and rauwolfia derivatives (for example, reserpine) are major or antipsychotic tranquilizers; (2) propanediols (for example, meprobamate, or Miltown), (3) diphenylmethanes (for example, benactyzine), (4) chlordiazepoxide and derivatives (for example, Librium and Valium), and (5) a miscellaneous group used generally for nighttime sedation (for example, ectylurea, glutethimide, and methylparafynol) are termed minor or sedative antianxiety tranquilizers. The antipsychotic tranquilizers in greatest use are phenothiazines, of which there are many derivatives and trade names. The sedative antianxiety agents are generally used in crisis situations or in neurotic episodes of intense anxiety or panic. Their effectiveness is more difficult to establish and is less specific than that of drugs for the treatment of psychosis. In high dosages such drugs have an addiction liability and can produce convulsions on withdrawals. [D.X.F.]

Transamination The transfer of an amino group from one molecule to another without the intermediate formation of ammonia. Enzymatic reactions of this type play a prominent role in the formation and ultimate breakdown of amino acids by living organisms. Enzymes that catalyze such reactions are widely distributed and are termed transaminases, or amino-transferases. Perhaps the most prominent transamination reactions in higher animals are those in which glutamate is formed from α-ketoglutarate and other amino acids. *See* PROTEIN METABOLISM. [E.E.S.]

Transducer A device that converts variations in one energy form into corresponding variations in another, usually electrical form. Measurement transducers or input transducers may exploit a wide range of physical, chemical, or biological effects to achieve transduction, and their design principles usually revolve around high sensitivity and minimum disturbance to the measurand, that is, the quantity to be measured. Output transducers or actuators are designed to achieve some end effect, for example, opening of a valve or deflection of a control surface on an aircraft. Actuators, therefore, normally operate at high power levels. The term sensor is often used instead of transducer, but strictly a sensor does not involve energy transformation; the term should be reserved for devices such as a thermistor, which is not energy-changing but simply changes its intrinsic electrical resistance in response to changes in temperature.

Both input and output transducers, together with the instrumentation to which they are connected, may be called upon to respond to both slowly varying or dynamic signals. This means that the transducer, together with its instrumentation system, must be designed to meet such a specification. Some prior knowledge is therefore required of the type of signal to be transduced, and the bandwidth of the transducer and instrumentation system must be suitably matched to this signal.

Transducers are often described in terms of their sensitivity to input signals (responsivity). This is simply defined as the ratio of the output signal to the corresponding input signal. Once again, the responsivity of a transducer must be matched to the expected levels of signal to be transduced. *See* SENSITIVITY (ENGINEERING).

The measurement of force is very often accomplished by allowing an elastic member (spring or cantilever beam) to deflect and then measuring the deflection by using some form of displacement transducer. Transducers designed to measure acceleration are frequently based on the simple equation below, where

$$f = ma$$

f is force, m is mass, and a is acceleration. Thus, if the force due to the movement of a known mass can be measured, it is possible to derive the acceleration. Very often, the measurement technique employed uses piezoelectric, magnetostrictive, or mechanoresistive materials. Acceleration transducers or accelerometers are frequently employed for the measurement of vibration. *See* ACCELEROMETER; FORCE; MAGNETOSTRICTION.

Transducers for a wide range of chemical species are available, but probably the most widely applied is the pH transducer for the measurement of hydrogen-ion concentration. The traditional method has relied on a glass membrane electrode used to make up an electrochemical cell. *See* HYDROGEN ION; ION-SELECTIVE MEMBRANES AND ELECTRODES; PH.

Measurements of the partial pressure of oxygen (pO_2) may be accomplished by the use of a Clark oxygen cell, which comprises a gas-permeable membrane controlling the rate of arrival of oxygen molecules at a noble-metal cathode that is held at 600–800 mV potential with respect to the anode. The ensuing reduction process gives rise to a cathode current from which oxygen concentration can be derived.

Other electrochemical transducers are used in such applications as voltametry, polarography, and amperometry. Chemical transduction is also possible by adsorbing a species onto a surface and detecting its presence by mass change, electrical property change, color change, and so on. *See* ELECTROCHEMICAL TECHNIQUES; POLAROGRAPHIC ANALYSIS; TITRATION.

Measurements of the partial pressure of oxygen and the partial pressure of carbon dioxide (pCO_2) are also of particular importance in the context of blood gas analysis in medicine, and by using the Clark cell they can be performed without removing the blood from the body and noninvasively, that is, without puncturing the skin.

There have been remarkable advances in the area of biological transducers or biosensors. Examples are the ion-selective field-effect transducer (ISFET), the insulated-gate field-effect transducer (IGFET), and the chemically sensitive field-effect transducer (CHEMFET).

A smart transducer or smart sensor is a device that not only undertakes measurement but also can adapt to the environment in which it is placed. Such adaptation may range from simple changes in the characteristics of the transducer in response to changes in temperature, to more complex procedures such as adaptation of the transducer's performance to conform to overall system requirements. In integrated transducers, much of the signal processing that might previously be done remotely is brought into the transducer packaging.

The development of inexpensive fiber-optic materials for communications has led to an examination of the potential for using these devices as the basis for transduction. Two major types of devices have resulted: fiber-optic transducers for physical variables and similar devices devoted to chemical and biological determinations. The advantages of the all-optical transducer are its lack of susceptibility to electrical interference and its intrinsic safety. Small deformations of an optical-fiber waveguide cause a change in the light transmission of the fiber, and this has been exploited to produce force and pressure transducers. Alternatively, miniature transducers based on color chemistry can be fabricated at the end of a fiber and the color change can be sensed remotely. Devices of this type have been developed for measuring pH, the partial pressures of oxygen and carbon dioxide, and glucose. *See* FIBER-OPTIC SENSOR.

The most important recent technological development in the area of transducers, sensors, and actuators is micro-electromechanical systems (MEMS). There are a wide variety of MEMS devices, mostly fabricated in silicon. *See* MICRO-ELECTRO-MECHANICAL SYSTEMS (MEMS). [P.A.P.]

Transduction (bacteria) A mechanism for the transfer of genetic material between cells. The material is transferred by virus particles called bacteriophages (in the case of bacteria), or phages. The transfer method differentiates transduction from transformation. In transformation the genetic material (deoxyribonucleic acid) is extracted from the cell by chemical means or released by lysis. *See* BACTERIAL GENETICS; BACTERIOPHAGE; DEOXYRIBONUCLEIC ACID (DNA); TRANSFORMATION (BACTERIA).

The transduction mechanism has two features to distinguish it from the more usual mechanism of gene recombination, the sexual process. The most striking feature is the transfer of genetic material from cell to cell by viruses. The second feature is the fact that only a small part of the total genetic material of any one bacterial cell is carried by any particular transducing particle. However, in general transduction, all of the genetic material is distributed among different particles.

Transduction is not accomplished by all bacteriophages. It is done by some that are classified as "temperate." When such temperate bacteriophages infect sensitive bacteria, some of the bacteria respond by producing more bacteriophage particles. These bacteria donate the transducing material. Other bacteria respond to the infection by becoming more or less permanent carriers of the bacteriophage, in a kind of symbiotic relationship; these are called lysogenic bacteria. Bacteria in this latter class survive the infection, and it is among these that transduced cells are found. The proportion of bacteria in any culture that responds to infection in either manner can be influenced by the particular environment at the time of infection. *See* LYSOGENY.

Certain phages carry out a more restricted kind of transduction. They carry only a specific section of bacterial genetic material; they transduce only a few genes. Retroviruses carry out specific or restricted transduction. It has long been known that these viruses can cause the formation of tumors (oncogenesis) in animals. It is now known that these viruses exchange a small portion of their genome for a mutant cellular gene that has a role in gene regulation or replication. These viruses carrying mutant genes infect cells, causing them to be transformed into tumor cells. *See* ANIMAL VIRUS; RETROVIRUS. [N.D.Z.]

Transfer cells Plant cells characterized by the elaboration of an unlignifed, secondary cell wall to form fingerlike projections or wall ingrowths which protrude into the cytoplasm of the cell. These ingrowths are enveloped by plasma membrane, forming a wall-membrane apparatus which increases the surface-volume ratio of the cell.

The location of transfer cells within the plant provides circumstantial evidence for their involvement in solute transport. They are situated at many sites in the plant where secretion or absorption takes place. Transfer cells are most frequently associated with the conducting elements of the xylem and phloem, where they may play a role in either loading or unloading solutes from these cells. Four main categories of secretion or absorption involving transfer cells are generally recognized: (1) absorption of solutes from the external environment; (2) secretion of solutes to the external environment; (3) absorption of solutes from internal, extracytoplasmic compartments; and (4) secretion of solutes into internal, extracytoplasmic compartments. *See* PHLOEM; SECRETORY STRUCTURES (PLANT); XYLEM. [R.L.Pe.]

Transform fault One of the three fundamental types of boundaries between the mobile lithospheric plates that cover the surface of the Earth. Whereas spreading centers mark sites where crust is created between diverging plates, and subduction zones are where crust is destroyed between convergent plates, transform faults separate plates that are sliding past each other with neither creation nor destruction of crust. The primary tectonic feature of all transform faults is a strike-slip fault zone, a generally vertical fracture parallel to the relative motion between the two plates that it separates. Strike-slip fault zones are described as right-lateral if the far side is moving right relative to the near side or left-lateral if it is moving to the left. Not all such fault zones are plate-bounding transform faults. Small-scale strike-slip faulting is a common secondary feature of many subduction zones, especially where plate convergence is oblique, and of some spreading centers, especially those with propagating rifts; it also occurs locally deep in plate interiors. The distinguishing characteristic of a transform fault is that both ends extend to a junction with another type of plate boundary. At these junctions the divergent or convergent motion along the other boundaries is transformed into purely lateral slip. *See* EARTH CRUST; PLATE TECTONICS; SUBDUCTION ZONES.

Transform faults are most readily classified by the types of plate boundary intersected at their ends, the variety of lithosphere (oceanic or continental) they separate, and by whether they are isolated or are part of a multifault system. The common oceanic type is the ridge-ridge transform, linking two literally offset axes of a spreading center. Also common are transform faults that link the end of a spreading center to a triple junction, the meeting place of three plates and three plate boundaries. *See* LITHOSPHERE; MID-OCEANIC RIDGE.

Other types are long trench-trench transforms at the northern and southern margins of the Caribbean plate, and the combined San Andreas/Gulf of California transform, which separates the North American and Pacific plates for 1500 mi (2400 km) between triple junctions at Cape Mendocino (California) and the mouth of the Gulf of California. Strike-slip faulting in the Gulf of California (and on the northern Caribbean plate boundary) occurs along several parallel zones linked by short spreading centers, and the overall structure is more properly called a transform fault system; similar fault patterns are found at many ridge-ridge transforms. Along a few strike-slip fault zones, lithospheric plates slide quietly and almost continuously past each other by the process called aseismic creep. Much more often, frictional resistance to the sliding in the brittle crust causes the accumulation of shear stresses that are episodically or periodically relieved by sudden shifts of crustal blocks, creating earthquakes. The largest lateral shifts (slips) of the ground surface along major continental transform faults have been associated with some of the largest earthquakes on record; in 1906 the Pacific plate alongside 270 mi (450 km) of the San Andreas Fault suddenly moved an average of 15 ft (4.5 m) northwest relative to the North American plate on the other side, and the resulting magnitude-8.2 earthquake destroyed much of San Francisco. The average slip in this single event was equivalent to about 150–250 years of Pacific–North American plate motion. *See* EARTHQUAKE; FAULT AND FAULT STRUCTURES; SEISMOLOGY. [P.Lo.]

Transformation (bacteria)

Transformation (bacteria) The addition of deoxyribonucleic acid (DNA) to living cells, thereby changing their genetic composition and properties. The recipient bacteria are usually closely related to the donor strain. The process may occur in natural conditions, for example, in a host animal infected with two parasitic strains, and indeed it might play a part in the rapid evolution of pathogenic bacteria. There are several species of bacteria in which transformation has been achieved in the laboratory.

That bacterial transformation is true genetic transmission on a small scale, rather than controlled mutation, is demonstrated by the following characteristics: (1) A specific trait is introduced, coming always from donors bearing the trait. (2) The trait is transferred by determinant, genelike material far less complex than whole cells or nuclei, and this material, DNA, is known to be present in gene-carrying chromosomes. (3) The trait is inherited by the progeny of the changed bacteria. (4) The progeny produce, when they grow, increased amounts of DNA carrying the specific property. (5) The traits are transferred as units exactly in the patterns in which they appear or in which they are induced by mutation. (6) The DNA transmits the full potentialities of the donor strain, whether these are in an expressed or in a latent state. (7) The traits are often attributable to the presence of a specific gene-determined enzyme protein. (8) Certain groups of determinants may occur "linked" within DNA molecules, just as genes may be linked, and if so, heat denaturation, radiation, or enzyme action will inactivate or separate them just to the extent that they can damage or break apart the DNA molecules. (9) Linked determinants, while transforming a new cell, may become exchanged (recombined) between themselves and their unmarked or unselective alternate forms in such a way that they bring about genetic variation, and in a pattern indicating the existence of larger organized genetic units. *See* BACTERIAL GENETICS; GENE.

Through the application of a number of procedures prior to adding the DNA, transformation was extended first to many different bacterial species and then to eukaryotic cells. Today almost any cell type can be transformed. In some cases, tissues can be injected directly with naked DNA and transformed. However, unlike with bacteria, the naked DNA adds almost anywhere in the genome rather than recombining with its indigenous homolog. However, with special highly selective procedures, homologous recombination can be obtained. By treating embryonic stem cells and adding them to embryos that then go to term, specific and nonspecific transgenic animals can be obtained (for example, mice). *See* GENETIC ENGINEERING.

When the source of the DNA is some entity capable of independent replication, such as a virus or plasmid, the phenomenon is called transfection. If foreign DNA is then inserted into these entities, the result is recombinant DNA that can lead to transduction. *See* MOLECULAR BIOLOGY; TRANSDUCTION (BACTERIA). [R.D.H.; N.D.Z.]

Transformer

Transformer An electrical component used to transfer electric energy from one alternating-current (ac) circuit to another by magnetic coupling. Essentially it consists of two or more multiturn coils of insulated conducting material, so arranged that any magnetic flux linking one coil will link the others also. That is to say, mutual inductance exists between the coils. The mutual magnetic field acts to transfer energy from one input coil or primary winding to the other coils, which are called secondary windings. Under steady-state conditions, only one winding can serve as a primary. *See* COUPLED CIRCUITS; INDUCTANCE.

The transformer accomplishes one or more of the following effects between two circuits: (1) a developed voltage of different magnitude, (2) a developed current of different magnitude, (3) a difference in phase angle, (4) a difference in impedance level, and (5) a difference in voltage insulation level, either between the two circuits or to ground.

Transformers are used to meet a wide range of requirements. Pole-type distribution transformers supply relatively small amounts of power to residences. Power transformers are used at generating stations to step up the generated voltage to high levels for transmission. The transmission voltages are then stepped down by transformers at the substations for local distribution. Instrument transformers are used to measure voltages and currents accurately. Audio- and video-frequency transformers must function over a broad band of frequencies. Radio-frequency transformers transfer energy in narrow frequency bands from one circuit to another. *See* INSTRUMENT TRANSFORMER.

Power transformers. Power transformers, as a class, may be defined as those designed to operate at power-system frequencies: 60 Hz in the United States and Canada, and 50 Hz in much of the rest of the world. The largest power transformers connect generators to the power grid. Since a generator, together with its driving turbine and prime energy source, is called a generating unit, such transformers are called unit transformers. The classification "distribution transformers" refers to those supplying power to the ultimate consumers. They are designed for lower power and output-voltage ratings than the other transformers in the system.

Typical configurations for single-phase transformers are shown in Fig. 1. The arrangement in Fig. 1*a* is called a shell-form transformer, while that in Fig. 1*b* is called a core-form transformer. Each of the rectangles labeled "windings" in this figure represents at least two coils. The coils may be concentric, or interleaved. In the shell form, all of the windings are on the center leg. In the core form, half of the turns of the primary winding and half of those of the secondary are on each leg. The two halves of a given winding may be connected in series or in parallel.

Power transformers operate on the basis of two fundamental physical laws: Faraday's voltage law and Ampère's law. Faraday's

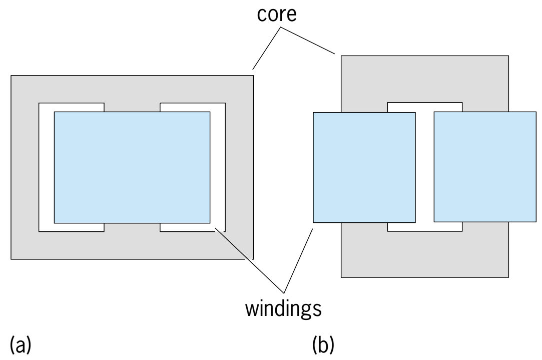


Fig. 1. Location of windings in single-phase cores. (*a*) Shell form. (*b*) Core form.

law states that the voltage induced in a winding by a magnetic flux linking that winding is proportional to the number of turns and the time rate of change of the flux; that is, Eq. (1) holds,

$$e_i = N_i \frac{d\phi_i}{dt} \qquad \text{volts} \tag{1}$$

where e_i is the voltage induced in a coil of N_i turns which is threaded by a flux of ϕ_i webers changing at a rate of $d\phi_i/dt$ webers per second. The ratio of the voltages induced in two windings of a transformer by the core flux is, then, given by Eq. (2).

$$\frac{e_1}{e_2} = \frac{N_1}{N_2}\frac{d\phi_{\text{core}}/dt}{d\phi_{\text{core}}/dt} = \frac{N_1}{N_2} \tag{2}$$

In other words, the voltages induced in the windings are proportional to the numbers of turns in the windings. This is the basic law of the transformer. A high-voltage winding will have many turns, and a low-voltage winding only a few. The N_1/N_2 ratio is usually called the turns ratio or transformation ratio and is designated by the symbol a, so that Eq. (3) holds.

$$\frac{e_1}{e_2} = a \tag{3}$$

See Faraday's law of induction.

Since the flux must change to induce a voltage, steady-state voltages can be obtained only by a cyclically varying flux. This means that alternating voltages and fluxes are required for normal transformer operation, and that is the fundamental reason for ac operation of power systems. Devices operated on ac have fewer losses when the voltages and fluxes are sinusoidal in form, and sinusoidal fluxes and terminal voltages will be assumed in this discussion. *See* Alternating-current circuit theory.

Figure 2 shows the elements of a two-winding, shell-form transformer. The center leg of the core carries the full mutual flux, and each of the outside legs carries half of it. Thus the cross-sectional area of each outside leg is half of that of the center leg.

Efficiency is defined by Eq. (4). The output power is equal to

$$\eta = \frac{\text{output power}}{\text{input power}} \tag{4}$$

the input power, less the internal losses of the transformer. These losses include the ohmic (I^2R) loss in the windings, called copper loss and the core loss, called the no-load loss. The input power is thus the sum of the output power and the copper and core losses. Typical efficiency for a 20,000-kVA power transformer at full load is 99.4%, while that of a 5-kVA transformer is 94%.

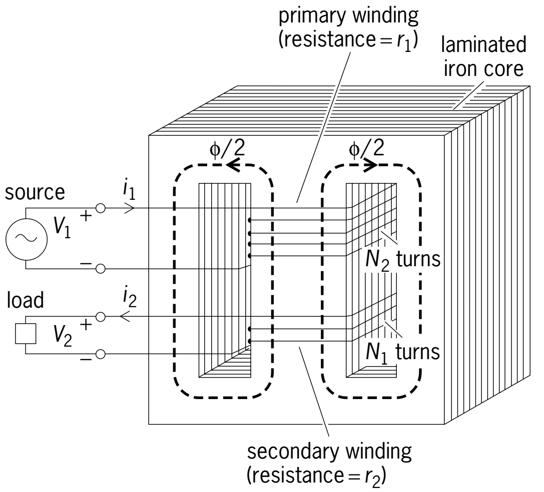

Fig. 2. Elements of a transformer.

Transformer losses in the windings and core generate heat, which must be removed to prevent deterioration of the insulation and the magnetic properties of the core. Most power transformers are contained in a tank of oil. The oil is especially formulated to provide good electrical insulation, and also serves to carry heat away from the core and windings by convection. Transformers which are designed to operate in air are called "dry-type" transformers. [G.McP.]

Audio- and radio-frequency transformers. Audio or video (broad-frequency-band) transformers are used to transfer complex signals containing energy at a large number of frequencies from one circuit to another. Radio-frequency (rf) and intermediate-frequency (i-f) transformers are used to transfer energy in narrow frequency bands from one circuit to another. Audio and video transformers are required to respond uniformly to signal voltages over a frequency range three to five or more decades wide (for example, from 10 to 100,000 Hz), and consequently must be designed so that very nearly all of the magnetic flux threading through one coil also passes through the other.

Audio and video transformers have two resonances (caused by existing stray and circuit capacitances) just as many tuned transformers do. One resonance point is near the low-signal-frequency limit; the other is near the high limit. As the coefficient of coupling in a transformer is reduced appreciably below unity by removal of core material and separation of the windings, tuning capacitors are added to provide efficient transfer of energy. The two resonant frequencies combine to one when the coupling is reduced to the value known as critical coupling, then stay relatively fixed as the coupling is further reduced.

The rF and i-f transformers use two or more inductors, loosely coupled together, to limit the band of operating frequencies. Efficient transfer of energy is obtained by resonating one or more of the inductors. By using higher than critical coupling, a wider bandwidth than that from the individual tuned circuits is obtained, while the attenuation of side frequencies is as rapid as with the individual circuits isolated from one another. [K.A.P.]

Transfusion The administration of blood or its components as a part of a medical treatment. There are certain fairly well-delineated indications for the use of some form of transfusion. Hemorrhage, severe burns, and certain forms of shock are perhaps the most important conditions for which blood transfusion is utilized. Other disorders in which hemotherapy may be indicated include hemophilia, leukemia, certain anemias, and rare hereditary or familial disorders in which some portion of the blood is lacking or deficient. *See* Hematologic disorders.

In order for a recipient to accept a blood transfusion, the donor blood cells must be immunologically compatible with the recipient. That is, the recipient must recognize certain molecules (antigens) on donor blood cells as "self" and not foreign. The three main antigen systems on blood cells are the ABO, Rh, and HLA. *See* Blood groups; Rh Incompatibility.

Donated blood is tested for blood groups, blood-group antibodies, and laboratory evidence of syphilis, hepatitis B, AIDS, human T-cell lymphotrophic virus type I (HTLV-I, which is associated with adult T-cell leukemia), and hepatitis C. As a result, blood transfusions have become safer. However, persons who may have been exposed to AIDS should not donate blood, because it has been found that blood may test negative for AIDS and yet still be capable of transmitting AIDS to recipients. This situation can arise because there is a period of time during which a recently infected individual has not yet made sufficient antibody to test positive. Because of the concern that AIDS can be transmitted by blood transfusion, patients sometimes request donations from specific family members and friends. In general, such directed donations are statistically no safer than volunteer blood donation. More patients are donating their own blood (autologous blood) before elective surgery, for their own use during and after the surgery. Autologous blood is the safest blood for transfusion. *See* Acquired immune deficiency syndrome (AIDS).

Shortly before transfusion, the blood of the donor and recipient is tested once again to make sure that the blood groups are compatible. In an emergency, these tests are abbreviated, or type O red blood cells which can be transfused safely to any individual, are used. Transfusion of blood and blood components is essential to support many patients undergoing surgery, treatment for cancer, or organ transplantation, as well as premature infants.

In addition to transmission of infections, adverse effects of blood transfusion are due to immune reactions between donor and recipient. Fever, the most frequent reaction, is caused by reaction of recipient antibody against donor white blood cells. Hives are due to allergic reactions to substances in donor plasma. Destruction of donor red cells (hemolytic reaction) occurs if the wrong type of blood is inadvertently given, or if recipient antibody is not detected prior to transfusion. *See* Blood. [P.To.]

Transistor A solid-state device involved in amplifying small electrical signals and in processing of digital information. Transistors act as the key element in amplification, detection, and switching of electrical voltages and currents. They are the active electronic component in all electronic systems which convert battery power to signal power. Almost every type of transistor is produced in some form of semiconductor, often single-crystal materials, with silicon being the most prevalent. There are several different types of transistors, classified by how the internal mobile charges (electrons and holes) function. The main categories are bipolar junction transistors (BJTs) and field-effect transistors (FETs).

Single-crystal semiconductors, such as silicon from column 14 of the periodic table of chemical elements, can be produced with two different conduction species, majority and minority carriers. When made with, for example, 1 part per million of phosphorus (from column 15), the silicon is called *n*-type because it adds conduction electrons (negative charge) to form the majority carrier. When doped with boron (from column 13), it is called *p*-type because it has added positive mobile carriers called holes. For *n*-type doping, electrons are the majority carrier while holes become the minority carrier. For *p*-type doping holes are in larger numbers, hence they are the majority carriers, while electrons are the minority carriers. All transistors are made up of regions of *n*-type and *p*-type semiconducting material. *See* Semiconductor; Single crystal.

The bipolar transistor has two conducting species, electrons and holes. Field-effect transistors can be called unipolar because their main conduction is by one carrier type, the majority carrier. Therefore, field-effect transistors are either *n*-channel (majority electrons) or *p*-channel (majority holes). For the bipolar transistor, there are two forms, n^+pn and p^+np, depending on which carrier is majority and which is the minority in a given region. As a result the bipolar transistor conducts by majority as well as by minority carriers. The n^+pn version is by far the most used as it has several distinct performance advantages, as does the *n*-channel for the field-effect transistors. (The n^+ indicates that the region is more heavily doped than the other two regions.)

Bipolar transistors. Bipolar transistors have additional categories: the homojunction for one type of semiconductor (all silicon), and heterojunction for more than one (particularly silicon and silicon-germanium, $Si/Si_{1-x}Ge_x/Si$). At present the silicon homojunction, usually called the BJT, is by far the most common. However, the highest performance (frequency and speed) is a result of the heterojunction bipolar transistor (HBT).

Bipolar transistors are manufactured in several different forms, each appropriate for a particular application. They are used at high frequencies, for switching circuits, in high-power applications, and under extreme environmental stress. The bipolar junction transistor may appear in discrete form as an individually encapsulated component, in monolithic form (made in and from a common material) in integrated circuits, or as a so-called chip in a thick-film or thin-film hybrid integrated circuit. In the *pn*-junction isolated integrated-circuit n^+pn bipolar transistor, an n^+ subcollector, or buried layer, serves as a low-resistance contact which is made on the top surface (Fig. 1). *See* Integrated circuits; Junction transistor.

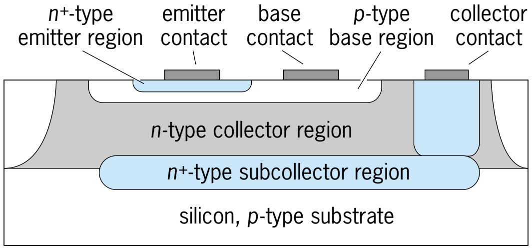

Fig. 1. Isolated n^+pn bipolar junction transistor for integrated-circuit operation.

Field-effect transistors. Majority-carrier field-effect transistors are classified as metal-oxide-semiconductor field-effect transistor (MOSFET), junction "gate" field-effect transistor (JFET), and metal "gate" on semiconductor field-effect transistor (MESFET) devices. MOSFETs are the most used in almost all computers and system applications. However, the MESFET has high-frequency applications in gallium arsenide (GaAs), and the silicon JFET has low-electrical noise performance for audio components and instruments. In general, the *n*-channel field-effect transistors are preferred because of larger electron mobilities, which translate into higher speed and frequency of operation.

An *n*-channel MOSFET (Fig. 2) has a so-called source, which supplies electrons to the channel. These electrons travel through the channel and are removed by a drain electrode into the external circuit. A gate electrode is used to produce the channel or to remove the channel; hence it acts like a gate for the electrons, either providing a channel for them to flow from the source to the drain or blocking their flow (no channel). With a large enough voltage on the gate, the channel is formed, while at a low gate voltage it is not formed and blocks the electron flow to the drain. This type of MOSFET is called enhancement mode because the gate must have sufficiently large voltages to create a channel through which the electrons can flow. Another way of saying the same idea is that the device is normally "off" in an nonconducting state until the gate enhances the channel.

In the JFET (Fig. 3), a conducting majority-carrier *n* channel exists between the source and drain. When a negative voltage is applied to the p^+ gate, the depletion regions widen with reverse

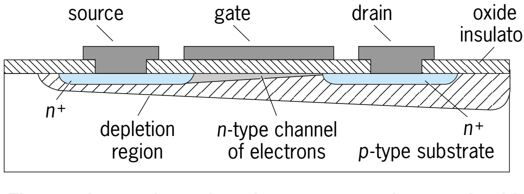

Fig. 2. An *n*-channel enhancement-mode metal-oxide-semiconductor field-effect transistor (MOSFET).

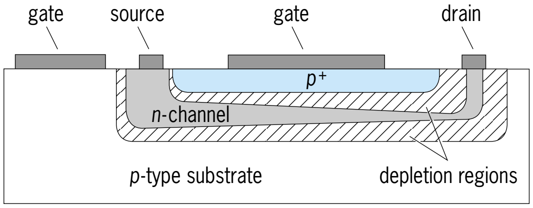

Fig. 3. An *n*-channel junction field-effect transistor (JFET).

bias and begin to restrict the flow of electrons between the source and drain. At a large enough negative gate voltage (symbolized V_P), the channel pinches off.

The MESFET is quite similar to the JFET in its mode of operation. A conduction channel is reduced and finally pinched off by a metal Schottky barrier placed directly on the semiconductor. Metal on gallium arsenide is extensively used for high-frequency communications because of the large mobility of electrons, good gain, and low noise characteristics. Its cross section is similar to that of the JFET (Fig. 3), with a metal used as the gate. *See* Schottky barrier diode. [G.W.N.]

Transit (astronomy) The apparent passage of a celestial body across the apparent disk of a larger body, such as a planet across its parent star or of a satellite across its parent planet; also, the apparent passage of a celestial object or reference point across an adopted line of reference in a celestial coordinate system. Classically, the observed data were instants of internal and external tangency of the disks (contacts) at ingress and egress of the smaller body. In the modern era, data may also include the differential brightness of the two disks and the duration of any change of brightness.

Mercury and Venus are the only planets whose orbits lie between the Earth and the Sun and thus can be seen from Earth to cross the disk of the Sun. The conditions are that the planet is in inferior conjunction at the same time that it passes one of the two nodes of its orbit, thus putting it essentially in a straight line between the Earth and the Sun. Historically, transits of Mercury were observed for the purpose of getting precise positions of the planet to improve knowledge of its orbit, and transits of Venus to determine the solar parallax. In a century, there are 13 or 14 transits of Mercury. The size, shape, and orientation of the orbit of Venus causes transits to be very rare. Transits usually occur in pairs separated by 8 years, with 105.5 or 121.5 years between pairs. A pair occurs on June 8, 2004, and June 6, 2012. *See* Mercury (planet); Planet; Venus.

Transits of the galilean satellites of Jupiter are used mainly to estimate the albedo (reflectivity) of the satellites relative to that of Jupiter. As each satellite passes in front of the planet, it casts its shadow on the planet's disk and causes the phenomenon of shadow-transit. *See* Jupiter; Satellite (astronomy).

Until the close of the twentieth century, passages of stars and other celestial bodies across the local meridian were observed extensively for determining precise coordinates of the stars and planets, accurate time, or the position of the observer. The instrument commonly used is often called a transit circle. This type of observation has been almost completely superseded by interferometric methods from Earth's surface and orbiting satellites, and by other astrometric observations from spacecraft. *See* Astronomical coordinate systems; Astronomical transit instrument.

The search for planets around solarlike stars other than the Sun yielded the first positive results in 1995. The most recently developed of several techniques is to detect photometrically the minute decrease in brightness of a star as an orbiting planet crosses its face. This can occur only if the planet's orbital plane lies edge-on to the Earth. The first planetary companion detected this way was reported in 1999, orbiting the star HD 209458 in Pegasus. Even though that companion was larger than Jupiter, the technique is considered the most mature for detecting Earth-class extrasolar planets, that is, those that are 0.5–10 times the size of Earth. [A.D.F.]

Transition elements In broad definition, the elements of atomic numbers 21–31, 39–49, and 71–81, inclusive. A more restricted classification of the transition elements, preferred by many chemists, is limited to elements with atomic numbers 22–28, 40–46, and 72–78, inclusive. All of the elements in this classification have one or more electrons present in an unfilled *d* subshell in at least one well-known oxidation state.

All the transition elements are metals and, in general, are characterized by high densities, high melting points, and low vapor pressures. Within a given subgroup, these properties tend to increase with increasing atomic weight. Facility in the formation of metallic bonds is demonstrated also by the existence of a wide variety of alloys between different transition metals.

The transition elements include most metals of major economic importance, such as the relatively abundant iron, nickel, and zinc, on one hand, and the rarer coinage metals, copper, silver, and gold, on the other. Also included are the rare and relatively unfamiliar element, rhenium, and technetium, which is not found naturally in the terrestrial environment, but is available in small amounts as a product of nuclear fission.

In their compounds, the transition elements tend to exhibit multiple valency, the maximum valence increasing from +3 at the beginning of a series (Sc, Y, Lu) to + 8 at the fifth member (Mn, Re). One of the most characteristic features of the transition elements is the ease with which most of them form stable complex ions. Features which contribute to this ability are favorably high charge-to-radius ratios and the availability of unfilled *d* orbitals which may be used in bonding.

Most of the ions and compounds of the transition metals are colored, and many of them are paramagnetic. Both color and paramagnetism are related to the presence of unpaired electrons in the *d* subshell. Because of their ability to accept electrons in unoccupied *d* orbitals, transition elements and their compounds frequently exhibit catalytic properties.

Broadly speaking, the properties of the transition elements are intermediate between those of the so-called representative elements, in which the subshells are completely occupied by electrons (alkali metals, halogen elements), and those of the inner or *f* transition elements, in which the subshell orbitals play a much less significant role in influencing chemical properties (rare-earth elements, actinide elements). *See* Actinide elements; Atomic structure and spectra; Rare-earth elements. [B.B.Cu.]

Transition point The point at which a substance changes from one state of aggregation to another. This general definition would include the melting point (transition from solid to liquid), boiling point (liquid to gas), or sublimation point (solid to gas); but in practice the term transition point is usually restricted to the transition from one solid phase to another, that is, to the temperature (for a fixed pressure, usually 1 atm or 10^5 pascals) at which a substance changes from one crystal structure to another.

Another kind of transition point is the culmination of a gradual change (for example, the loss of ferromagnetism in iron or nickel) at the lambda point, or Curie point. This behavior is typical of second-order transitions. *See* Boiling point; Melting point; Phase equilibrium; Sublimation; Triple point. [R.L.S.]

Transition radiation detectors Detectors of energetic charged particles that make use of radiation emitted as the particle crosses boundaries between regions with different indices of refraction. An energetic charged particle moving through matter momentarily polarizes the material nearby. If the particle crosses a boundary where the index of refraction changes, the change in polarization gives rise to the emission of electromagnetic transition radiation. About one photon is emitted for every 100 boundaries crossed, for transitions between air and matter of ordinary density. Transition radiation is emitted even if the velocity of the particle is less than the light velocity of a given wavelength, in contrast to Cerenkov radiation. Consequently, this radiation can take place in the x-ray region of the spectrum where there is no Cerenkov radiation, because the index of refraction is less than one. *See* Cerenkov radiation; Particle detector; Refraction of waves. [W.J.W.]

Translucent medium A medium which transmits rays of light so diffused that objects cannot be seen distinctly; that is, the medium is only partially transparent. Familiar examples are various forms of glass which admit considerable light but impede vision. Inasmuch as the term translucent seems to imply seeing, usage of the term is ordinarily limited to the visible region of the spectrum. [M.G.M.]

Transmission lines A system of conductors suitable for conducting electric power or signals between two or more termini. Transmission lines take many forms in practice and have application in many disciplines. For example, they traverse the countryside, carrying telephone signals and electric power. The same transmission lines, with similar functions, may be hidden above false ceilings in urban buildings. With the need to reliably and securely transmit ever larger amounts of data, the required frequency of operation has increased from the high-frequency microwave range to the still higher frequency of light. Optical fibers are installed in data-intensive buildings and form a nationwide network. Increasing demand also requires that transmission lines handle greater values of electric power.

Transmission lines can, in some cases, be analyzed by using a fairly simple model that consists of distributed linear electrical components. Models of this type, with some permutations, can also be used to describe wave propagation in integrated circuits and along nerve fibers in animals. The study of hollow metal waveguides or optical fibers is usually based upon an analysis starting from Maxwell's equations rather than employing transmission-line models. Fundamentals and definitions that can initially be obtained from a circuit model of a transmission line carry over to waveguides, where the analysis is more complicated. *See* OPTICAL FIBERS; WAVEGUIDE.

Coaxial cables and strip lines. Two particular types of transmission lines for communication that have received considerable attention are the coaxial cable and the strip line. The coaxial cable is a flexible transmission line and typically is used to connect two electronic instruments together. In the coaxial cable, a dielectric separates a center conducting wire from a concentric conducting sleeve. The strip line is used in integrated circuits to connect, say, two transistor circuits together. A strip line also has a dielectric that separates the top conducting element from the base, which may be an electrical ground plane in the circuit. *See* COAXIAL CABLE; INTEGRATED CIRCUITS.

Circuit model. These transmission lines can be most easily analyzed in terms of electrical circuit elements consisting of distributed linear inductors and capacitors. The values of these elements are in terms of the physical dimensions of the coaxial cable and the strip line, and the permittivity of the dielectric. Each of the elements is interpreted to be measured in terms of a unit length of the element. An equivalent circuit represents either the coaxial cable or the strip line as well as other transmission lines such as two parallel wires. *See* ALTERNATING-CURRENT CIRCUIT THEORY; CAPACITANCE; CAPACITOR; INDUCTANCE; INDUCTOR; PERMITTIVITY.

Losses are incorporated into the transmission-line model with the addition of a distributed resistance in series with the inductor and a distributed conductance in parallel with the capacitor. Additional distributed circuit elements can be incorporated into the model in order to describe additional effects. For example, the linear capacitors could be replaced with reverse-biased varactor diodes and the propagation of nonlinear solitons could be studied. *See* CONDUCTANCE; ELECTRICAL RESISTANCE; SOLITON; VARACTOR. [K.E.Lo.]

Power transmission lines. Electric power generating stations and load consumption centers are connected by a network of power transmission lines, mostly overhead lines. Power transmitted is generally in the form of three-phase alternating current (ac) at 60 or 50 Hz. In a few instances, where a clear technical or economic advantage exists, direct-current (dc) systems may be used. As the distances over which the power must be transmitted become great and as the amount of power transmitted increases, the power lost in the transmission lines becomes an important component of the production cost of electricity, and it becomes advantageous to increase the transmission voltage. This basic consideration has led to electric power networks which use higher voltages for long-distance bulk power transfers, with several layers of underlying regional networks at progressively lower voltages which extend over shorter distances. The most common transmission voltages in use are 765, 500, 400, 220 kV, and so forth. Voltages below 69 kV are termed subtransmission or distribution voltages, and at these and lower voltages the networks may have fewer alternative supply paths (loops) or may be entirely radial in structure. *See* ALTERNATING CURRENT; DIRECT CURRENT; DIRECT-CURRENT TRANSMISSION; ELECTRIC DISTRIBUTION SYSTEMS; ELECTRIC POWER TRANSMISSION. [A.G.Ph.]

Transmutation The nuclear change of one element into another, either naturally, in radioactive elements, or artificially, by bombarding an element with electrons, deuterons, or α-particles in particle accelerators or with neutrons in atomic piles.

Natural transmutation was first explained by Marie Curie about 1900 as the result of the decay of radioactive elements into others of lower atomic weight. Ernest Rutherford produced the first artificial transmutation (nitrogen into oxygen and hydrogen) in 1919. Artificial transmutation is the method of origin of the heavier, artificial transuranium elements, and also of hundreds of radioactive isotopes of most of the chemical elements in the periodic table. *See* NUCLEAR REACTION; PERIODIC TABLE. [F.H.R.]

Transonic flight In aerodynamics, flight of a vehicle at speeds near the speed of sound. When the velocity of an airplane approaches the speed of sound (roughly 660 mi/h or 1056 km/h at 35,000 ft or 10.7 km altitude), the flight characteristics become radically different from those at subsonic speeds. The drag increases greatly, the lift at a given altitude decreases, the moments acting on the airplane change abruptly, and the vehicle may shake or buffet. Such phenomena usually persist to flight velocities somewhat above the speed of sound. These flight characteristics, as well as the speeds at which they occur, are usually referred to as transonic. The extent of the speed range of these changes depends on the form of the airplane; for configurations designed for subsonic flight they may occur at velocities of 70–110% of the speed of sound (Mach numbers of 0.7–1.1); for airplanes intended for transonic or supersonic flight they may be present only at Mach numbers of 0.95–1.05. *See* MACH NUMBER.

The transonic flight characteristics result from the development of shock waves about the airplane. Because of the accelerations of airflow over the various surfaces, the local velocities become supersonic while the airplane itself is still subsonic. (The flight speed at which such local supersonic flows first occur is called the critical speed.) Shock waves are associated with deceleration of these local supersonic flows to subsonic flight velocities. Such shock waves cause abrupt streamwise increases of pressure on the airplane surfaces. These gradients may cause a reversal and separation of the flow in the boundary layer on the wing surface in roughly the same manner as do similar pressure changes at lower subcritical speeds. *See* AERODYNAMIC FORCE; AERODYNAMIC WAVE DRAG; BOUNDARY-LAYER FLOW; SCHLIEREN PHOTOGRAPHY; SHOCK WAVE.

As for boundary-layer separation at lower speeds, the flow breakdown in this case leads to increases of drag, losses of lift, and changes of aerodynamic moments. The unsteady nature of the separated flow results in an irregular change of the aerodynamic forces acting on the airplane with resultant buffeting and shaking. As the Mach number is increased, the shock waves move aft so that at Mach numbers of about 1.0 or greater, depending on the configurations, they reach the trailing edges of the surfaces. With the shocks in these positions, the associated pressure gradients have relatively little effect on the boundary layer, and the shock-induced separation is greatly reduced. *See* SUBSONIC FLIGHT; SUPERSONIC FLIGHT. [R.T.Wh.]

Transplantation biology The science of transferring a graft from one part of the body to another or from one individual to another. The graft may consist of an organ, tissue, or cells. If donor and recipient are the same individual, the graft is autologous. If donor and recipient are genetically identical (monozygotic), it is syngeneic. If donor and recipient are any other same-species individuals, the graft is allogeneic. If the donor and recipient are of different species, it is called xenogeneic.

In theory, virtually any tissue or organ can be transplanted. The principal technical problems have been defined and, in general, overcome. Remaining major problems concern the safety of methods used to prevent graft rejection and the procurement of adequate numbers of donor organs.

Living volunteers can donate one of a pair of organs, such as a kidney, only one of which is necessary for normal life. Volunteer donors may also be employed for large unpaired organs such as small bowel, liver, or pancreas, segments of which can be removed without impairment of function. Living donors can also provide tissues capable of regeneration; these include blood, bone marrow, and the superficial layers of the skin. In the case of a vital, unpaired organ, such as the heart, the use of cadaver donors is obligatory. In practice, with the exception of blood and bone marrow, the great majority of transplanted organs are cadaveric in origin, a necessity that presents difficult logistic problems.

Autografts are used for an increasing number of purposes. Skin autografts are important in the treatment of full-thickness skin loss due to extensive burns or other injuries. Provided that the grafts comprise only the superficial levels of the skin, the donor sites reepithelialize spontaneously within a week or two. The saphenous vein of the ankle is frequently transplanted to the heart to bypass coronary arteries obstructed by atherosclerosis. Autologous hematopoietic stem cell transplantation is sometimes used to restore blood cells to cancer patients who receive forms of chemotherapy that are lethal to their bone marrow.

The most serious problem restricting the use of allografts is immunological. Because cells in the donor graft express on their surface a number of genetically determined transplantation antigens that are not present in the recipient, allografts provoke a defensive reaction analogous to that evoked by pathogenic microorganisms. As a consequence, after a transient initial period of apparent well-being, graft function progressively deteriorates and the donor tissue is eventually destroyed. The host response, known as allograft rejection, involves a large number of immunological agents, including cytotoxic antibodies and effector lymphocytes of various types. There are a few special exemptions from rejection that apply to certain sites in the body or to certain types of graft. For example, the use of corneal allografts in restoring sight to individuals with corneal opacification succeeds because of the absence of blood vessels in the host tissue.

Successful transplantation of allografts such as kidneys and hearts currently requires suppressing the recipient's immune response to the graft without seriously impairing the immunological defense against infection. Treatment of individuals with so-called immunosuppressive drugs and other agents prevents allograft rejection for prolonged periods, if not indefinitely. Under cover of nonspecific immunosuppression, the recipient's immune system appears to undergo an adaptation to the presence of the graft, allowing the dosage of the drugs to be reduced. However, in almost all successfully transplanted individuals, drug therapy at some low dose is required indefinitely. *See* IMMUNOSUPPRESSION.

An individual's response against an allograft is directed against a large number of cell-surface transplantation antigens controlled by allelic genes at many different loci. However, in all species, one of these loci, the major histocompatibility complex (MHC), transcends all the other histocompatibility loci in terms of its genetic complexity and the strength of the antigenic response it controls. In humans, the MHC, known as the HLA (human leukocyte antigen) complex, is on the sixth chromosome; its principal loci are designated A, B, C, DR, and DQ. The allelic products of the HLA genes can be detected by serology, polymerase chain reaction technology, or microcytotoxicity assays. The ABO red cell antigens are also important because they are expressed on all tissues. *See* BLOOD GROUPS; HISTOCOMPATIBILITY.

In kidney transplants between closely related family members, the degree of HLA antigen matching can be determined very precisely, and there is a very good correlation between the number of shared HLA antigens and the survival of the graft. With grafts from unrelated donors, HLA matching is more difficult and can delay transplantation, but it may be beneficial. HLA matching is not as clearly beneficial in the case of most other solid organ grafts, and no attempt is made to HLA-match heart, lung, liver, and pancreas grafts. With few exceptions, however, most donors and recipients are matched for the expression of ABO blood group antigens.

Bone marrow transplantation presents a unique problem in its requirements for HLA matching and for immunosuppression in advance of grafting. In addition to the possibility of rejection of the graft by the recipient, by virtue of immunologically competent cells still present in the recipient, bone marrow grafts can react against the transplantation antigens of their hosts. These are known as graft-versus-host reactions, and they can be fatal. *See* IMMUNOLOGY.

The immunological events that lead to the rejection of xenografts are different from and less well understood than those responsible for allograft rejection. The small number of xenografts attempted to date have failed. In particular, xenografts are susceptible to hyperacute rejection by humans. This is due to the presence of certain glycoproteins in blood vessels of many species that are recognized by antibodies present in the blood of all humans. [J.P.Mo.; R.E.Bi.; D.L.Gr.; A.A.R.]

Transport processes The processes whereby mass, energy, or momentum are transported from one region of a material to another under the influence of composition, temperature, or velocity gradients. If a sample of a material in which the chemical composition, the temperature, or the velocity vary from point to point is isolated from its surroundings, the transport processes act so as to eventually render these quantities uniform throughout the material. The nonuni-form state required to generate these transport processes causes them to be known also as nonequilibrium processes. Associated with gradients of composition, temperature, and velocity in a material are the transport processes of diffusion, thermal conduction, and viscosity, respectively. *See* DIFFUSION IN GASES AND LIQUIDS; DIFFUSION IN SOLIDS; THERMAL CONDUCTION IN SOLIDS; VISCOSITY. [W.A.W.]

Transportation engineering That branch of engineering related to the movements of goods and people by highway, rail, air, water, and pipeline. Special categories include urban and intermodal transportation.

Engineering for highway transportation involves planning, construction, and operation of highway systems, urban streets, roads, and bridges, as well as parking facilities. Important aspects of highway engineering include (1) overall planning of routes, financing, environmental impact evaluation, and value engineering to compare alternatives; (2) traffic engineering, which plans for the volumes of traffic to be handled, the methods to accommodate these flows, the lighting and signing of highways, and general layout; (3) pavement and roadway engineering, which involves setting of alignments, planning the cuts and fills to construct the roadway, designing the base course and pavement, and selecting the drainage system; and (4) bridge engineering, which involves the design of highway bridges, retaining walls, tunnels, and other structures. *See* HIGHWAY ENGINEERING; TRAFFIC-CONTROL SYSTEMS; VALUE ENGINEERING.

Engineering for railway transportation involves planning, construction, and operation of terminals, switchyards, loading/unloading facilities, trackage, bridges, tunnels, and traffic-control systems for freight and passenger service. For freight operations, there is an emphasis on developing more efficient systems for loading, unloading, shifting cars, and operating trains. Facilities include large marshaling yards where electronic equipment is used to control the movement of railroad cars. Also, there is a trend to developing more automated systems on trackage whereby signals and switches are set automatically by electronic devices. To accommodate transportation of containers, tunnels on older lines are being enlarged to provide for double-stack container cars. *See* RAILROAD ENGINEERING; TUNNEL.

Engineering for air transportation encompasses the planning, design, and construction of terminals, runways, and navigation aids to provide for passenger and freight service. High-capacity, long-range, fuel-efficient aircraft, such as the 440-seat Boeing 777 with a range of 7200 mi (12,000 km), are desirable. Wider use of composites and the substitution of electronic controls for mechanical devices reduce weight to improve fuel economy. Smaller planes are more efficient for shorter runs. *See* AIR NAVIGATION; AIR-TRAFFIC CONTROL; AIR TRANSPORTATION; COMPOSITE MATERIAL.

Engineering for water transportation entails the design and construction of a vast array of facilities such as canals, locks and dams, and port facilities. The transportation system ranges from shipping by barge and tugboat on inland waterways to shipping by oceangoing vessels. Although there is some transportation of passengers, such as on ferries and cruise ships, water transportation is largely devoted to freight. *See* CANAL; DAM; RIVER ENGINEERING.

Pipeline engineering embraces the design and construction of pipelines, pumping stations, and storage facilities. Pipelines are used to transport liquids such as water, gas, and petroleum products over great distances. Also, products such as pulverized coal and iron ore can be transported in a water slurry. *See* PIPELINE; STORAGE TANK.

Engineering for urban transportation concerns the design and construction of light rail systems, subways, and people-movers, as well as facilities for traditional bus systems. To enhance public acceptance of new and expanded systems, increased use is being made of computer-aided design (CAD) to visulaize alternatives for stations and facilities. Also, animated video systems are used for interactive visualization of plans. *See* COMPUTER-AIDED ENGINEERING; HARBORS AND PORTS; SUBWAY ENGINEERING.

Intermodal transportation, often referred to as containerization, entails the use of special containers to ship goods by truck, rail, or ocean vessel. Engineers must design and construct intermodal facilities for efficient operations. The containers are fabricated from steel or aluminum, and they are designed to withstand the forces from handling. The ships are constructed with a cellular grid of compartments for containers below deck, and they can accommodate one or two layers on deck as well. Advantages include savings in labor costs, less pilferage, and lower insurance costs. *See* HOISTING MACHINES; MARINE CONTAINERS; MERCHANT SHIP.

The environment and energy consumption are taken into major consideration when planning, designing, and constructing transportation facilities. Efforts to curb energy use arise from a variety of concerns, including security issues and environmental implications. Efforts to relieve congestion in urban areas through incentives to make greater use of car pooling, such as special freeway lanes, and encouraging greater use of mass transit, deserve further emphasis. [R.L.Broc.]

Transposons Types of transposable elements which comprise large discrete segments of deoxyribonucleic acid (DNA) capable of moving from one chromosome site to a new location. In bacteria, the transposable elements can be grouped into two classes, the insertion sequences and the transposons. The ability of transposable elements to insert into plasmid or bacterial virus (bacteriophage) which is transmissible from one organism to another allows for their rapid spread. *See* BACTERIOPHAGE; PLASMID.

The insertion sequences were first identified by their ability to induce unusual mutations in the structural gene for a protein involved in sugar metabolism. These insertion sequences are relatively small (about 500–1500 nucleotide pairs) and can only be followed by their ability to induce these mutations. Most bacterial chromosomes contain several copies of such insertion sequence elements.

The transposons are larger segments of DNA (2000–10,000 base pairs) that encode several proteins, usually one or two required for the movement of the element and often an additional protein that imparts a selective advantage to the host containing a copy of that element. The structure of many transposons suggests they may have evolved from the simpler insertion sequence elements.

All transposable elements, both the simple insertion sequence elements and the more complex transposons, have a similar structure and genetic organization. The ends of the element represent recognition sites and define the segment of DNA undergoing transposition. A short sequence present at one end of the element is repeated in an inverted fashion at the other end. These terminal inverted repeats are characteristic for each element.

Members of a widespread group of transposons, the Tn3 family, all have a similar structure and appear to move by a similar mechanism. Transposase, one protein encoded by the element, promotes the formation of intermediates called cointegrates, in which the element has been duplicated by replication. A second element-encoded protein, resolvase, completes the process by converting the cointegrates into the end products of transposition, a transposon inserted into a new site. A third protein encoded by the Tn3 element imparts resistance to the antibiotic ampicillin.

Transposons are known that encode resistances to almost all antibiotics as well as many toxic metals and chemicals. In addition, some transposons have acquired the ability to direct the synthesis of proteins that metabolize carbohydrates, petroleum, and pesticides. Other transposable elements produce enterotoxins that cause travelers to become ill from drinking water contaminated with bacteria carrying the element. The broad spectrum of activities encoded by the transposable elements demonstrates the strong selective advantage that has accompanied their evolution.

Transposable elements are not restricted to prokaryotes. Yeast as well as higher eukaryotes have DNA segments that move and cause mutations. The eukaryotic elements have much in common with their prokaryotic counterparts: the termini of the elements are composed of inverted repeats, and many of the larger elements are composed of two small insertion sequence-like regions flanking a unique central region. One class of eukaryotic virus, the ribonucleic acid (RNA) retrovirus, also has this structure and is thought to integrate into the host chromosome through a transpositionlike mechanism. *See* ANTIBIOTIC; GENE; GENE ACTION; RETROVIRUS; VIRUS. [R.Re.]

Transuranium elements Those synthetic elements with atomic numbers larger than that of uranium (atomic number 92). They are the members of the actinide series, from neptunium (atomic number 93) through lawrencium (atomic number 103), and the transactinide elements (with higher atomic numbers than 103). Of these elements, plutonium, an explosive ingredient for nuclear weapons and a fuel for nuclear power because it is fissionable, has been prepared on the largest (ton) scale, while some of the others have been produced in kilograms (neptunium, americium, curium) and in much smaller quantities (berkelium, californium, and einsteinium).

The concept of atomic weight in the sense applied to naturally occurring elements is not applicable to the transuranium elements, since the isotopic composition of any given sample depends on its source. In most cases the use of the mass number of the longest-lived isotope in combination with an evaluation of its availability has been adequate. Good choices at present are neptunium, 237; plutonium, 242; americium, 243; curium, 248; berkelium, 249; californium, 249; einsteinium, 254; fermium, 257; mendelevium, 258; nobelium, 259; lawrencium, 260; rutherfordium, 261; dubnium, 262; and seaborgium, 263. The actinide elements are chemically similar and have a strong chemical resemblance to the lanthanide, or rare-earth, elements (atomic numbers 57–71). The transactinide elements, with atomic numbers 104–118, appear in an expanded periodic table under the row of elements beginning with hafnium, number 72, and ending with radon, number 86. This arrangement allows prediction of the chemical properties of these elements and suggests that they will have a chemical analogy with the elements which appear immediately above them in the periodic table.

The transuranium elements up to and including fermium (atomic number 100) are produced in largest quantity through the successive capture of neutrons in nuclear reactors. The yield decreases with increasing atomic number, and the heaviest to be produced in weighable quantity is einsteinium (number 99). Many additional isotopes are produced by bombardment of heavy target isotopes with charged atomic projectiles in accelerators; beyond fermium, all elements are produced by bombardment with heavy ions.

Beyond darmstadtium (atomic number 110), transactinide elements 111–116 have been produced, although their acceptance is pending. *See* Actinide elements; Americium; Berkelium; Bohrium; Californium; Curium; Dubnium; Einsteinium; Element 111; Element 112; Fermium; Hassium; Lawrencium; Meitnerium; Mendelevium; Neptunium; Nobelium; Nuclear chemistry; Nuclear fission; Nuclear reaction; Periodic table; Plutonium; Rare-earth element; Rutherfordium; Seaborgium. [P.J.R.; G.T.S.]

Traps in solids

Traps in solids Localized regions in a material that can capture and localize an electron or hole, thus preventing the electron or hole from moving through the material until supplied with sufficient thermal or optical energy. Traps in solids are associated with imperfections in the material caused by either impurities or crystal defects. *See* Band theory of solids; Crystal defects; Hole states in solids.

Imperfections that behave as traps are commonly distinguished from imperfections that behave as recombination centers. If the probability for a captured electron (or hole) at the imperfection to be thermally reexcited to the conduction (or valence) band before recombination with a free hole (or free electron) is greater than the probability for such recombination, then the imperfection is said to behave like an electron (or hole) trap. If the probability for a captured electron (or hole) at the imperfection to recombine with a free hole (or free electron) is greater than the probability for being thermally reexcited to the band, the imperfection is said to behave like a recombination center. It is possible for a specific chemical or structural imperfection in the material to behave like a trap under one set of conditions of temperature and light intensity, and as a recombination center under another.

Traps play a significant role in many phenomena involving photoconductivity and luminescence. In photoconductors, for example, the presence of traps decreases the sensitivity and increases the response time. Their effect is detectable through changes in the rise and decay transients of photoconductivity and luminescence, thermally stimulated conductivity and luminescence in which the traps are filled at a low temperature and then emptied by increasing the temperature in a controlled way, electron spin responance associated with trapped electrons with unpaired spins, and a variety of techniques involving the capacitance of a semiconductor junction such as photocapacitance and deep-level transient spectroscopy. *See* Electron paramagnetic resonance (EPR) spectroscopy; Luminescence; Photoconductivity; Thermoluminescence. [R.H.Bu.]

Trauma

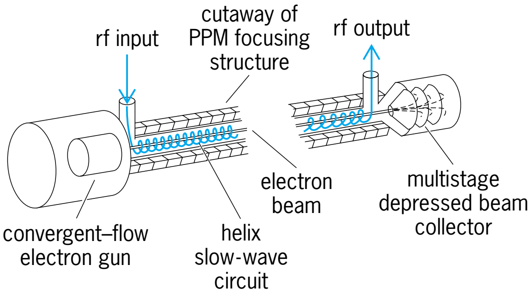
Trauma Injury to tissue by physical or chemical means. Mechanical injury includes abrasions, contusions, lacerations, and incisions, as well as stab, puncture, and bullet wounds. Trauma to bones and joints results in fractures, dislocations, and sprains. Head injuries are often serious because of the complications of hemorrhage, skull fracture, or concussion.

Thermal, electrical, and chemical burns produce severe damage partly because they coagulate tissue and seal off restorative blood flow. Asphyxiation, including that caused by drowning, produces rapid damage to the brain and respiratory centers, as well as to other organs.

Frequent complications of trauma are shock, the state of collapse precipitated by peripheral circulatory failure, and also hemorrhage, infection, and improper healing. *See* Hemorrhage; Infection; Shock syndrome. [E.G.St./N.K.M.]

Traveling-wave tube

Traveling-wave tube A microwave electronic tube in which a beam of electrons interacts continuously with a wave that travels along a circuit, the interaction extending over a distance of many wavelengths. Traveling-wave tubes can provide amplification over exceedingly wide bandwidths. Typical bandwidths are 10–100% of the center frequency, with gains of 20–60 dB. Low-noise traveling-wave tube amplifiers serve as the inputs to sensitive radars or communications receivers. High-efficiency medium-power traveling-wave tubes are the principal final amplifiers used in communication satellites, the space shuttle communications transmitter, and deep-space planetary probes and landers. High-power traveling-wave amplifiers operate as the final stages of radars, wide-band radar countermeasure systems, and scatter communication transmitters. They are capable of delivering continuous-wave power levels in the kilowatt range and pulsed power levels exceeding a megawatt. *See* Communications satellite; Electronic warfare; Radar; Space communications; Space probe.



Periodic-permanent-magnet (PPM) focused traveling-wave tube.

In a forward-wave, traveling-wave tube amplifier (see illustration), a thermionic cathode produces the electron beam. An electron gun initially focuses the beam, and an additional focusing system retains the electron stream as a beam throughout the length of the tube until the beam is captured by the collector electrode. The microwave signal to be amplified enters the tube near the electron gun and propagates along a slow-wave circuit. The tube delivers amplified microwave energy into an external matched load connected to the end of the circuit near the collector. The slow-wave circuit serves to propagate the microwave energy along the tube at approximately the same velocity as that of the electron beam. Interaction between beam and wave is continuous along the tube with contributions adding in phase.

The principle use of this technique is to create a voltage-tunable microwave oscillator. Typically it uses a hollow, linear electron beam and a helix circuit designed to emphasize the backward-wave fields. This represents the earliest type of voltage-tunable microwave oscillator. It is capable of generating power levels of 10–100 milliwatts with a tuning range of 2:1 in frequency. Its use has almost disappeared with the development of magnetically tuned microwave transistor oscillators using yttrium-iron-garnet (YIG) spherical resonators. *See* Ferrimagnetic garnets; Magnetron; Microwave tube; Oscillator. [L.A.Ro.]

Travertine A rather dense, banded limestone, sometimes moderately porous, that is formed either by evaporation about springs, as is tufa, or in caves, as stalactites, stalagmites, or dripstone. Where travertine or tufa (calcareous sinter) is deposited by hot springs, it may be the result of the loss of carbon dioxide from the waters as pressure is released upon emerging at the surface; the release of carbon dioxide lowers the solubility of calcium carbonate and it precipitates. High rates of evaporation in hot-spring pools also lead to supersaturation. Travertine formed in caves is simply the result of complete evaporation of waters containing mainly calcium carbonate. *See* Limestone; Stalactites and stalagmites; Tufa. [R.Si.]

Tree A perennial woody plant at least 20 ft (6 m) in height at maturity, having an erect stem or trunk and a well-defined crown or leaf canopy. However, no sharp lines can be drawn between trees, shrubs, and lianas (woody vines). The essence of the tree form is relatively large size, long life, and a slow approach to reproductive maturity. The difficulty of transporting water, nutrients, and storage products over long distances and high into the air against the force of gravity is a common problem of large treelike plants and one that is not shared by shrubs or herbs.

Classification. Almost all existing trees belong to the seed plants (Spermatophyta). An exception are the giant tree ferns which were more prominent in the forests of the Devonian Period and today exist only in the moist tropical regions. The Spermatophyta are divided into the Pinophyta (gymnosperms) and the flowering plants, Magnoliophyta (angiosperms). The gymnosperms bear their seed naked on modified leaves, called scales, which are usually clustered into structures called cones—for example, pine cones. By contrast the seed of angiosperms is enclosed in a ripened ovary, the fruit. *See* Magnoliophyta; Pinophyta; Polypodiales; Tree ferns.

The orders Cycadales, Ginkgoales, and Pinales of the Pinophyta contain trees. *Ginkgo biloba*, the ancient maidenhair tree, is the single present-day member of the Ginkgoales. The Cycadales, characteristic of dry tropical areas, contain many species which are small trees. The Pinales, found throughout the world, supply much of the wood, paper, and building products of commerce. They populate at least one-third of all existing forest and include the pines (*Pinus*), hemlocks (*Tsuga*), cedars (*Cedrus*), spruces (*Picea*), firs (*Abies*), cypress (*Cupressus*), larches (*Larix*), Douglas-fir (*Pseudotsuga*), sequoia (*Sequoia*), and other important genera. The Pinales are known in the lumber trade as softwoods and are popularly thought of as evergreens, although some (for example, larch and bald cypress) shed their leaves in the winter. *See* Cedar; Cycadales; Cypress; Douglas-fir; Fir; Hemlock; Larch; Paper; Pinales; Pine; Pinophyta; Sequoia; Spruce.

In contrast to the major orders of gymnosperms which contain only trees, many angiosperm families are herbaceous and include trees only as an exception. Only a few are exclusively arborescent. The major classes of the angiosperms are the Liliopsida (monocotyledons) and the Magnoliopsida (dicotyledons). The angiosperm trees, commonly thought of as broad-leaved and known as hardwoods in the lumber market, are dicotyledons. Examples of important genera are the oaks (*Quercus*), elms (*Ulmus*), maples (*Acer*), and poplars (*Populus*). *See* Elm; Liliopsida; Magnoliopsida; Maple; Oak; Poplar.

The Liliopsida contain few tree species, and these are never used for wood products, except in the round as posts. Examples of monocotyledonous families are the palms (Palmae), yucca (Liliaceae), bamboos (Bambusoideae), and bananas (Musaceae). *See* Bamboo; Banana.

Morphology. The morphology of a tree is similar to that of other higher plants. Its major organs are the stem, or trunk and branches; the leaves; the roots; and the reproductive structures. Almost the entire bulk of a tree is nonliving. Of the trunk, branches, and roots, only the tips and a thin layer of cells just under the bark are alive. Growth occurs only in these meristematic tissues. Meristematic cells are undifferentiated and capable of repeated division. *See* Flower; Lateral meristem; Leaf; Plant growth; Root (botany); Stem.

Growth. Height is a result of growth only in apical meristems at the very tips of the twigs. A nail driven into a tree will always remain at the same height, and a branch which originates from a bud at a given height will never rise higher. The crown of a tree ascends as a tree ages only by the production of new branches at the top and by the death and abscission of lower, older branches as they become progressively more shaded. New growing points originate from the division of the apical meristem and appear as buds in the axils of leaves. *See* Apical meristem; Bud; Plant growth.

In the gymnosperms and the dicotyledonous angiosperms, growth in diameter occurs by division in only a single microscopic layer, three or four cells wide, which completely encircles and sheaths the tree. This lateral meristem is the cambium. It divides to produce xylem cells (wood) on the inside toward the core of the tree and phloem cells on the outside toward the bark. In trees of the temperate regions the growth of each year is seen in cross section as a ring. *See* Bark; Phloem; Xylem.

Xylem elements become rigid through the thickening and modification of their cell wall material. The tubelike xylem cells transport water and nutrients from the root through the stem to the leaves. In time the xylem toward the center of the trunk becomes impregnated with various mineral and metabolic products, and it is no longer capable of conduction. This nonfunctional xylem is called heartwood and is recognizable in some stems by its dark color. The light-colored, functional outer layer of the xylem is the sapwood. *See* Wood anatomy.

The phloem tissue transports dissolved carbohydrates and other metabolic products manufactured by the leaves throughout the stem and the roots. Most of the phloem cells are thin-walled and are eventually crushed between the bark and the cambium by the pressures generated in growth. The outer bark is dead and inelastic but the inner bark contains patches of cork cambium which produce new bark. As a tree increases in circumference, the old outer bark splits and fissures develop, resulting in the rough appearance characteristic of the trunks of most large trees.

In the monocotyledons the lateral cambium does not encircle a central core, and the vascular or conducting tissue is organized in bundles scattered throughout the stem. The trunk is not wood as generally conceived although it does in fact have secondary xylem. *See* Dendrology; Forest and forestry; Forest timber resources; Plant physiology; Plant taxonomy. [F.T.L.]

Tree diseases Diseases of both shade and forest trees have the same pathogens, but the trees differ in value, esthetics, and utility. In forests, disease is significant only when large numbers of trees are seriously affected. Diseases with such visible symptoms as leaf spots may be alarming on shade trees but hardly noticed on forest trees. Shade trees with substantial rot may be ornamentals with high value, whereas these trees would be worthless in the forest. Emphasis on disease control for the same tree species thus requires a different approach, depending on location of the tree.

Forest trees. From seed to maturity, forest trees are subject to many diseases. Annual losses of net sawtimber growth from disease (45%) are greater than from insects and fire combined. Young, succulent seedlings, especially conifers, are killed by certain soil-inhabiting fungi (damping-off). Root systems of older seedlings may be destroyed by combinations of nematodes and such fungi as *Cylindrocladium, Sclerotium*, and *Fusarium*. Chemical treatment of seed or soil with formulations containing nematicides and fungicides, and cultural practices unfavorable to root pathogens help to avoid these diseases.

Roots rots are caused by such fungi as *Heterobasidion* (= *Fomes*) *annosus* (mostly in conifers) and *Armillariella* (= *Armillaria*) *mellea* (mostly in hardwoods). These fungi cause heart rot in the roots and stems of large trees and also invade and kill young, vigorous ones.

In natural forests, leaf diseases are negligible, but in nurseries and plantations, fungal infections cause severe defoliation, retardation of height growth, or death. *Scirrhia acicola* causes brown spot needle blight and prevents early height growth of longleaf pine in the South; it defoliates Christmas tree plantations of Scotch pine (*Pinus sylvestris*) in northern states. Fungicides and prescribed burning are used successfully for control.

Oak wilt is a systemic disease, with the entire tree affected through its water-conducting system. The causal fungus, *Ceratocystis fagacearum*, spreads to nearby healthy trees by root grafts and to trees at longer distances by unrelated insects. The sporulating mats of the fungus develop between bark and wood, producing asexual and, sometimes, sexual spores, which are disseminated by insects. Control is possible by eradicating infected trees and by disruption of root grafts by trenching or by chemicals.

Stem rust diseases occur as cankers or galls on coniferous hosts and as minor lesions on other ones. A few, such as white pine blister rust and southern fusiform rust, are epidemic, lethal, and economically important. Others of less immediate importance (such as western gall rust) are capable of serious, widespread infection. Resistant varieties are favored for control. Other control measures include pruning out early infections and spraying nursery trees with chemicals during periods favoring needle infection.

Stem infections by numerous fungi, resulting in localized death of cambium and inner bark, range from lesions killing small stems in a year (annual) to gross stem deformities (perennial), where cankers enlarge with stem growth. Chestnut blight, first known in the United States in 1904, destroyed the American chestnut as a commercial species; and is an example of the annual lesion type. The less dramatic or devastating *Nectria* canker destroys stems of timber value, and is an example of the perennial lesion type.

All tree species, including decay-resistant ones such as redwood, are subject to ultimate disintegration by fungi. Decay fungi (Hymenomycetes) are associated with nondecay fungi (Deuteromycetes) and bacteria. These microflora enter the tree through wounds, branch stubs, and roots, and are confined to limited zones of wood by anatomical and wound-stimulated tissue barriers. The extent of decay is limited by compartmentalization of decay in trees. Trees aged beyond maturity are most often invaded by wood-rotting fungi; losses can be minimized by avoiding wounds and by shortening cutting rotations. Losses from rot are especially serious in overmature coniferous stands in the western United States, Canada, and Alaska. *See* FOREST PEST CONTROL; WOOD DEGRADATION.

Shade trees. Many shade trees are grown under conditions for which they are poorly adapted, and are subject to environmental stresses not common to forest trees. Both native and exotic trees planted out of natural habitats are predisposed to secondary pathogens following environmental stress of noninfectious origins. They are also susceptible to the same infectious diseases as forest trees. Appearance is more important than the wood produced, and individual value is higher per tree than for forest trees. Thus, disease control methods differ from those recommended for forest trees.

The most important and destructive shade tree disease known is Dutch elm disease, introduced from Europe to North America before 1930. The causal fungus, *Ophiostoma ulmi* (*Ceratocytis ulmi*), is introduced to the water-conducting system of healthy elms by the smaller European elm bark beetle (*Scolytus multistriatus*) or the American elm bark beetle (*Hylurgopinus rufipes*). One or more new and more aggressive strains of the fungus have arisen since 1970. More devastating than the original ones, they are destroying the elms in North America and Europe that survived earlier epidemics. Effective means of prevention are sanitation (destroying diseased and dying and dead elm wood); insecticidal sprays; disruption of root systems; and early pruning of new branch infections. Of much promise are resistant varieties of elm, systemic fungicides, and insect pheromones.

The most common bacterial disease of shade trees is wetwood of elm and certain other species. It is reported to be caused by a single bacterial species (*Erwinia nimipressuralis*), although causal associations of other bacteria are now suspected. The bacteria are normally present in the heartwood of mature elms and cause no disease unless they colonize sapwood by exterior wounds. Fermented sap under pressure bleeds from wounds and flows down the side of the tree. Sustained bleeding kills underlying cambial tissue. Internal gas pressure and forced spread of bacterial toxins inside living tissues of the tree can be reduced by strategic bleeding to avoid seepage into bark and cambium.

A second bacterial disease of elm, elm yellows, is caused by a mycoplasmalike organism, considered to be a unique kind of bacterium. Elm yellows is as lethal as Dutch elm disease but is more limited in distribution. The pathogen is carried by the elm leafhopper (*Scaphoideus luteolus*), which sucks phloem juice from leaf veins. Spread of disease also occurs through grafted root systems. Control measures include early destruction of infected trees, disruption of root systems, and insecticidal sprays. Injection with tetracycline and other antibiotics helps to slow the progress of the bacterium.

The most common and complex diseases of shade trees are diebacks and declines (such as maple decline). Many species show similar patterns of symptoms caused by multiple factors, but no single causal factor is known to cause any one of these diseases. Noninfectious agents of shade tree diseases are drought, soil compaction, mineral deficiency, soil pollution from waste or salt, air pollution, and so on. Trees affected experience chlorosis, premature fall coloration and abscission, tufting of new growth, dwarfing and sparseness of foliage, progressive death of terminal twigs and branches, and decline in growth. Such trees are often infested with borers and bark beetles, and infected by branch canker and root rot fungi. Noninfectious stress predisposes trees to infectious disease that is caused by different kinds of weakly parasitic fungi as secondary pathogens. *See* PLANT PATHOLOGY.

[R.J.C.]

Tree ferns Plants belonging to the families Cyatheaceae and Dicksoniaceae, whose members typically develop tall trunks crowned with leaves (fronds) which often reach some 20 ft (6.1 m) in length and 5–6 ft (1.5–1.8 m) in width. Tree ferns reach their greatest development in the rainforests and cloud forests of the mountainous tropics. *See* RAINFOREST.

Tree fern trunks may reach 65 ft (19.8 m) tall; their diameters vary from 0.4 in. (1.0 cm) to 4 ft (1.2 m). The lower trunk is often densely covered with matted adventitious roots which greatly increase its diameter. Certain specimens branch near the base of the trunk or higher up; perhaps this branching occurs in response to injury.

The degree of division of the leaves varies from simple to four or five pinnate. The leaflets (pinnae) are usually smaller toward the base of the leaf; when these basal leaflets are branched into threadlike divisions, they are called aphlebiae. The Dicksoniaceae have marginal sori terminal on the veins and protected by a bivalved indusium. The Cyatheaceae produce sori well away from the margin, usually seated at the forking of a vein or midway along a simple vein.

The typical vascular system of both families is dictyostelic. The Cyatheaceae have accessory vascular strands in the pith and cortex. Fibrous sheaths around the vascular tissue and just inside the epidermis provide mechanical support. The xylem consists of scalariform tracheids and parenchyma, the phloem of sieve tubes and parenchyma. Numerous mucilage canals are embedded in the pith and cortex. *See* Stem; Tree. [G.J.G.]

Tree physiology The study of how trees grow and develop in terms of genetics; biochemistry; cellular, tissue, and organ functions; and interaction with environmental factors. While many physiological processes are similar in trees and other plants, trees possess unique physiologies that help determine their outward appearance. These physiological processes include carbon relations (photosynthesis, carbohydrate allocation), cold and drought resistance, water relations, and mineral nutrition.

Three characteristics of trees that define their physiology are longevity, height, and simultaneous reproductive and vegetative growth. Trees have physiological processes that are more adaptable than those in the more specialized annual and biennial plants. Height allows trees to successfully compete for light, but at the same time this advantage creates transport and support problems. These problems were solved by the evolution of the woody stem which combines structure and function into a very strong transport system. Simultaneous vegetative and reproductive growth in adult trees causes significant competition for carbohydrates and nutrients, resulting in decreased vegetative growth. Trees accommodate both types of growth by having cyclical reproduction: one year many flowers and seeds are produced, followed by a year or more in which few or no flowers are produced.

Carbon relations. While biochemical processes of photosynthesis and carbon assimilation and allocation are the same in trees and other plants, the conditions under which these processes occur in trees are more variable and extreme. In evergreen species, photosynthesis can occur year round as long as the air temperature remains above freezing, while some deciduous species can photosynthesize in the bark of twigs and stem during the winter.

Carbon dioxide fixed into sugars moves through the tree in the phloem and xylem to tissues of high metabolism which vary with season and development. At the onset of growth in the spring, sugars are first mobilized from storage sites, primarily in the secondary xylem (wood) and phloem (inner bark) of the woody twigs, branches, stem, and roots. The sugars, stored as starch, are used to build new leaves and twigs, and if present, flowers. Once the new leaves expand, photosynthesis begins and sugars are produced, leading to additional leaf growth. Activation of the vascular cambium occurs at the same time, producing new secondary xylem and phloem. In late spring, the leaves begin photosynthesizing at their maximum rates, creating excess sugars which are translocated down the stem to support further branch, stem, and root growth. From midsummer through fall until leaf abscission (in deciduous trees) or until temperatures drop to freezing (in evergreen trees), sugars replenish the starch used in spring growth. Root growth may be stimulated at this time by sugar availability and warm soil temperatures. Throughout the winter, starch is used for maintenance respiration, but sparingly since low temperatures keep respiration rates low. *See* Phloem; Photosynthesis; Xylem.

In adult trees, reproductive structures (flowers in angiosperms or strobili in gymnosperms) develop along with new leaves and represent large carbohydrate sinks. Sugars are preferentially utilized at the expense of leaf, stem, and root growth. This reduces the leaf area produced, affecting the amount of sugars produced during that year, thereby reducing vegetative growth even further. The reproductive structures are present throughout the growing season until seed dispersal and continually utilize sugars that would normally go to stem and root growth.

Cold resistance. The perennial nature of trees requires them to withstand low temperatures during the winter. Trees develop resistance to freezing through a process of physiological changes beginning in late summer. A tree goes through three sequential stages to become fully cold resistant. The process involves reduced cell hydration along with increased membrane permeability. The first stage is initiated by shortening days and results in shoot growth cessation, bud formation, and metabolic changes. Trees in this stage can survive temperatures down to 23°F (−5°C). The second stage requires freezing temperatures which alter cellular molecules. Starch breakdown is stimulated, causing sugar accumulation. Trees can survive temperatures as low as −13°F (−25°C) at this stage. The last stage occurs after exposure to very low temperatures (−22 to −58°F or −30 to −50°C), which increases soluble protein concentrations that bind cellular water, preventing ice crystallization. Trees can survive temperatures below −112°F (−80°C) in this stage. A few days of warmer temperatures, however, causes trees to revert to the second stage.

Water relations. Unlike annual plants that survive drought as seeds, trees have evolved traits that allow them to avoid desiccation. These traits include using water stored in the stem, stomatal closure, and shedding of leaves to reduce transpirational area. All the leaves can be shed and the tree survives on stored starch. Another trait of some species is to produce a long tap root that reaches the water table, sometimes tens of meters from the soil surface. On a daily basis, trees must supply water to the leaves for normal physiological function. If the water potential of the leaves drops too low, the stomata close, reducing photosynthesis. To maintain high water potential, trees use water stored in their stems during the morning which is recharged during the night. *See* Plant-water relations.

Transport and support. Trees have evolved a means of combining long-distance transport between the roots and foliage with support through the production of secondary xylem (wood) by the vascular cambium. In older trees the stem represents 60–85% of the aboveground biomass. However, 90% of the wood consists of dead cells. These dead cells function in transport and support of the tree. As these cells develop and mature, they lay down thick secondary walls of cellulose and lignin that provide support, and then they die with the cell lumen becoming an empty tube. The interconnecting cells provide an efficient transport system, capable of moving 106 gal (400 liters) of water per day. The living cells in the wood (ray parenchyma) are the site of starch storage in woody stems and roots. *See* Plant transport of solutes.

Mineral nutrition. Nutrient deficiencies are similar in trees and other plants because of the functions of these nutrients in physiological processes. Tree nutrition is unique because trees require lower concentrations, and they are able to recycle nutrients within various tissues. Trees adapt to areas which are low in nutrients by lowering physiological functions and slowing growth rates. In addition, trees allocate more carbohydrates to root production, allowing them to exploit large volumes of soil in search of limiting nutrients. Proliferation of fine roots at the organic matter-mineral soil interface where many nutrients are released from decomposing organic matter allows trees to recapture nutrients lost by leaf fall. *See* Plant mineral nutrition; Plant physiology; Tree. [J.D.Jo.]

Trematoda A loose grouping of acoelomate, parasitic flatworms of the phylum Platyhelminthes formerly accorded class rank and containing the subclasses (or orders) Digenea, Monogenea, and Aspidobothria. These organisms commonly occur as adults in or on all vertebrate groups. They exhibit cephalization, bilateral symmetry, and well-developed anterior and ventral, or anterior and posterior, holdfast structures. The mouth is anterior, and usually a blind, forked gut occurs, as well as three muscle layers. The excretory system consists of flame cells and collecting tubules. These animals are predominantly hermaphroditic and oviparous with operculated egg capsules. The life histories of the Digenea are complex, while those of the Monogenea and Aspidobothria are simple.

Trematodes parasitize a wide variety of invertebrates and vertebrates and occupy almost every available niche within these hosts. The adaptations demanded of the worms for survival are as varied as the characteristics of the microhabitats. Over the millions of years of coevolution of the hosts and their parasites, delicate balances have, for the most part, been attained, and under normal conditions it is probable that trematodes rarely demand more than the host can supply without undue strain. It seems axiomatic that the host must survive until the parasite can again gain access to another host or until the life cycle is completed. Those parasites which cause the least disruption of the host's activities are probably the oldest as well as the most successful. Immunities are sometimes developed by the hosts. Many trematodes seem to possess such rigid requirements and such responses to particular hosts that host specificity is a phenomenon of considerable significance. Monogeneids appear more host-specific than digeneids, and aspidobothreids seem less specific than both. Trematodes are of considerable veterinary and medical importance because under certain conditions they cause debility, even death. *See* Aspidogastrea; Digenea; Monogenea; Platyhelminthes. [W.J.Ha.]

Tremolite The name given to magnesium-rich monoclinic calcium amphibole $Ca_2Mg_5Si_8O_{22}(OH)_2$ The mineral is white to gray, but colorless in thin section. Unlike other end-member compositions of the calcium amphibole group, very pure tremolite is found in nature. Substitution of Fe for Mg is common, but pure ferrotremolite, $Ca_2Fe_5Si_8O_{22}(OH)_2$ is rare. Intermediate compositions between tremolite and ferrotremolite are referred to as actinolites, and are green in color and encompass a large number of naturally occurring calcium amphiboles. *See* Amphibole. [B.L.D.]

Trepostomata An extinct order of bryozoans in the class Stenolaemata. Trepostomes possess generally robust colonies, composed of tightly packed, moderately complex, long, slender, tubular or prismatic zooecia, with solid calcareous zooecial walls. Colonies show a moderately gradual transition from endozone to exozone regions, and they are exclusively free-walled. Trepostome colonies range from small and delicate to large and massive; they can be thin to thick encursting sheets; tabular, nodular, hemispherical, or globular masses; or bushlike or frondlike erect growths.

Apparently exclusively marine, the trepostomes first appeared about the start of the Middle Ordovician; they apparently share a common ancestor with cystoporates. They remained abundant through Silurian time, declined during the Devonian, and died out in the Late Triassic. *See* Bryozoa; Cystoporata; Stenolaemata. [R.J.Cu.; F.K.McK.]

Trestle A succession of towers of steel, timber, or reinforced concrete supporting the horizontal beams of a roadway, bridge, or other structure. Little distinction can be made between a trestle and a viaduct, and the terms are used interchangeably by many engineers. A viaduct is defined as a long bridge consisting of a series of short concrete or masonry spans supported on piers or towers, and is used to carry a road or railroad over a valley, a gorge, another roadway, or across an arm of the sea. *See* Bridge.

A trestle or a viaduct usually consists of alternate tower spans and spans between towers. For low trestles the spans may be supported on bents, each composed of two columns adequately braced in a transverse direction. A pair of bents braced longitudinally forms a tower. *See* Tower. [C.M.A.]

Triassic The oldest period of the Mesozoic Era. The Triassic encompasses a time frame between about 248 and 213 million years ago (m.y.a.) that was named for the threefold division of rocks at its type locality in central Germany, where continental redbeds and evaporites are separated by a marine limestone. *See* Mesozoic.

The Triassic Period uniquely embraces both the final consolidation of Pangaea and the initial breakup of the landmass, which in the Middle Jurassic led to the origin of the Central Atlantic ocean basin. The Triassic thus marks the beginning of a new cycle of ocean-basin opening, through continental extension, and oceanic closing through subducting oceanic lithospheres along continental margins. *See* Lithosphere; Paleogeography; Plate tectonics.

The most important tectonic event in the Mesozoic Era was the rifting of the Pangaea craton, which began in the Late Triassic, culminating in the Middle Jurassic with the formation of the Central Atlantic ocean basin. Rifting began in the Tethys region in the Early Triassic, and progressed from western Europe and the Mediterranean into the Central Atlantic off Morocco and eastern North America by the Late Triassic. As crustal extension continued throughout the Triassic, the Tethys seaway spread farther westward and inland. By that time, rifting and sea-floor spreading extended into the Gulf of Mexico, separating North and South America.

Continental rift basins, passive continental margins, and ocean basins form in response to divergent stresses that extend the crust. Crustal extension, as it pertains to the Atlantic, embraces a major tectonic cycle marked by Late Triassic–Early Jurassic rifting and Middle Jurassic to Recent (Holocene) drifting. The rift stage, involving heating and stretching of the crust, was accompanied by uplift, faulting, basaltic igneous activity, and rapid filling of deep elongate rift basins. The drift stage, involving the slow cooling of the lithosphere over a broad region, was accompanied by thermal subsidence with concomitant marine transgression of the newly formed plate margin. The transition from rifting to drifting, accompanied by sea-floor spreading, is recorded by the postrift unconformity. *See* Continental drift; Continental margin; Holocene; Unconformity.

Permian-to-Triassic consolidation of Pangaea in western North America led to the Sonoma orogeny (mountain building), which resulted from overthrusting and suturing of successive island-arc and microcontinent terranes to the western edge of the North American Plate. However, toward the end of the Triassic Period, as crustal extension was occurring in the Central Atlantic region, the plate moved westward, overriding the Pacific Plate along a reversed subduction zone. This created for the remainder of the Mesozoic Era an Andean-type plate edge with a subducting sea floor and associated deep-sea trench and magmatic arc. These effects can be studied in the Cordilleran mountain belt. *See* Cordilleran belt; Orogeny.

As these epicontinental seas regressed westward, nonmarine fluvial, lacustrine, and windblown sands were deposited on the craton. Today many of these red, purple, ash-gray, and chocolate-colored beds are some of the most spectacular and colorful scenery in the American West. For example, the Painted Desert of Arizona, which is known for its petrified logs of conifer trees, was developed in the Chinle Formation. *See* Craton; Petrified forests.

Triassic faunas are distinguished from earlier ones by newly evolved groups of plants and animals. In marine communities, molluscan stocks proliferated vigorously. Bivalves diversified greatly and took over most of the niches previously occupied by brachiopods; ammonites proliferated rapidly from a few Permian survivors. The scleractinian (modern) corals appeared, as did the shell-crushing placodont reptiles and the ichthyosaurs. In continental faunas, various groups of reptiles appeared, including crocodiles and crocodilelike forms, the mammallike reptiles, and the first true mammals, as well as dinosaurs. *See* Cephalopoda; Crocodylia; Dinosaur; Mammalia; Mollusca; Placodontia; Scleractinia.

Triassic land plants contain survivors of many Paleozoic stocks, but the gymnosperms became dominant and cycads appeared. *See* Cycadeoidales; Paleozoic; Pinophyta. [W.Man.]

Tribology The science and technology of interactive surfaces in relative motion. It incorporates various scientific and technological disciplines such as surface chemistry, fluid mechanics, materials, lubricants, contact mechanics, bearings, and lubrication systems. It is customarily divided into three branches: friction, lubrication, and wear.

Friction. This phenomenon is encountered whenever there is relative motion between contacting surfaces, and it always opposes the motion. As no mechanically prepared surfaces are perfectly smooth, when the surfaces are first brought into contact under light load, they touch only along the asperities (real area of contact). The early theories attributed friction to the interlocking of asperities; however, it is now understood that the phenomenon is far more complicated. *See* FRICTION.

Lubrication. When clean surfaces are brought into contact, their coefficient of friction decreases drastically if even a single molecular layer of a foreign substance (for example, an oxide) is introduced between the surfaces. For thicker lubricant films, the coefficient of friction can be quite small and no longer dependent on the properties of the surfaces but only on the bulk properties of the lubricant. Most common lubricants are liquids and gases, but solids such as molybdenum disulfide or graphite may be used. *See* LUBRICATION.

Wear. This is the progressive loss of substance of one body because of rubbing by another body. There are many different types of wear, including sliding wear, abrasive wear, corrosion, and surface fatigue. *See* WEAR. [A.Z.S.]

Trichomycetes A polyphyletic class of Eumycota in the subdivision Zygomycotina, containing the orders Amoebidiales, Asellariales, Eccrinales, and Harpellales. These orders are grouped together because they usually exist only as commensals in the mid- and hindgut of arthropods (*Amoebidium parasiticum* can be found on the outside of its hosts).

Asexual reproduction is accomplished by the formation of trichospores (Harpellales), arthrospores (Asellariales), sporgiospores (Eccrinales), or ameboid cells, cystospores, or rigid-walled spores (Amoebidiales). Sexual reproduction (zygospore formation) is known only in Harpellales, although conjugations have been observed in Asellariales. The thallus of Amoebidiales is aseptate, but is regularly septate in the other three orders; septa with plugs in the lenticular cavities are produced by Asellariales and Harpellales. Similar septa and plugs are formed by Dimargaritales and Kickxellales (Zygomycetes). Classification is based on the type of reproduction; thallus branching pattern, complexity, and septation; and nature of the holdfast. Trichomycetes occur worldwide and may be found anywhere a suitable host exists; they inhabit a more or less equatic environment (the gut); and the spores are discharged with feces. *See* EUMYCOTA; FUNGI; ZYGOMYCETES; ZYGOMYCOTINA. [G.L.Be.]

Trichoptera An aquatic order of the class Insecta commonly known as the caddis flies. The adults have two pairs of well-veined hairy wings, long antennae, and mouthparts capable of lapping only liquids. The larvae are wormlike, with distinct heads, three pairs of legs on the thorax, and a pair of hook-bearing legs at the end of the body. The pupae are delicate, with free appendages held close to the body, and have a pair of sharp mandibles, or jaws, which are used to cut an exit from the cocoon.

The Trichoptera include about 10,000 described species, divided into 34 families, and occur in practically all parts of the world. Except for a brackish-water species in New Zealand and a few moss-inhabiting species in Europe and North America, caddis flies occur only in fresh water. They abound in cold or running water relatively free from pollution. Altogether they compose a large and important segment of the biota of such habitats and of the fish feed economy. *See* INSECTA. [H.H.R.]

Trichostomatida An order of the Holotrichia, composed of a small group of ciliates whose species show some advance in structural complexity over the gymnostomes. No true buccal ciliature is present, but a vestibulum, a passageway leading from the outside of the body into the cytostome or true cell-mouth, is characteristically present. These animals exist in a wide range of habitats. A few forms live in cattle, sheep, and horses, but cause no harm to these hosts. *Balantidium* is of some medical significance as it contains the sole ciliated protozoan species parasitic in humans. *Balantidium coli* lives in the large intestine and is the causative agent of the fairly uncommon disease balantidiasis. *See* BALANTIDIASIS; HOLOTRICHIA. [J.O.C.]

Trichroism When certain optically anisotropic transparent crystals are subjected to white light, a cube of the material is found to transmit a different color through each of the three pairs of parallel faces. Such crystals are sometimes termed trichroic, and the phenomenon is called trichroism. This expression is used only rarely today since the colors in a particular crystal can appear quite different if the cube is cut with a different orientation with respect to the crystal axes. Accordingly, the term is frequently replaced by the more general term pleochroism. Even this term is being replaced by the phrase linear dichroism or circular dichroism to correspond with linear birefringence or circular birefringence. *See* BIREFRINGENCE; CRYSTAL OPTICS; DICHROISM; PLEOCHROISM. [B.H.Bi.]

Tricladida An order of the Turbellaria known commonly as planaria. They have a diverticulated intestine with a single anterior branch and two posterior branches separated by the plicate pharynx or pharynges. Rhabdites are numerous and, except in cave planarians, two to many eyes are present. *See* PLANARIA; TURBELLARIA. [E.R.J.]

Triconodonta Extinct mammals that are members of many latest Triassic, Jurassic, and Cretaceous faunas in the Northern Hemisphere. Their records in the Southern Hemisphere include a species of earliest Jurassic age from Africa and questionably referable specimens from the Middle Jurassic of Africa and Late Cretaceous of South America. In all triconodontans the dentary and squamosal bones formed at least part of the articulation of the jaw to the skull (the temporomandibular joint). In some, among the most primitive species referred to the Mammalia, the articular, quadratojugal, and quadrate also participated in this articulation. *See* CRETACEOUS; JURASSIC; TRIASSIC.

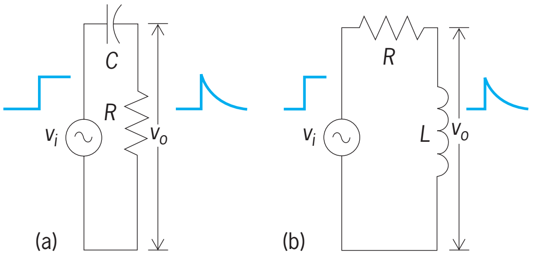
Many modern classifications limit the contents of Triconodonta to the family Triconodontidae and establish new groupings for other, closely related families. This reflects an emerging, poorly understood picture of complex evolutionary interrelationships among the earliest mammals and advanced therapsids, members of the group commonly but inappropriately named the mammallike reptiles. *See* ANIMAL EVOLUTION; THERAPSIDA.

Triconodontids, the central family of the Triconodonta, were relatively large (lower jaw about the size of that of a mink, *Mustella vison*) common members of European and North American, Late Jurassic mammalian faunas. Their temporomandibular joint was formed entirely by the dentary and squamosal.

Occurrence of a specialized mode of occlusion of the molariforms of triconodontids and *Dinnetherium*, from the earliest Jurassic of North America, suggests the latter is a very primitive relative of the triconodontids that had not lost the quadrate and articular from its temporomandibular joint. Another primitive group characterized by a complex temporomandibular joint, the morganucodontids, also might be primitive relatives of the triconodontids. The amphilestids (Middle and Late Jurassic, North American and Europe) and gobiconodontids (Middle Jurassic and Early Cretaceous, North America and Asia) were triconodontanlike mammals. Members of both families had temporomandibular joints formed exclusively by the dentary and squamosal. *Sinoconodon* (Early Jurassic, Asia), another primitive triconodontanlike mammal about the size of contemporaneous morganucodontids, had a complex temporomandibular joint. *See* DOCODONTA; MAMMALIA. [W.A.C.]

Trigger circuit An electronic circuit that generates or modifies an existing waveform to produce a pulse of short time duration with a fast-rising leading edge. This waveform, or trigger, is normally used to initiate a change of state of some relaxation device, such as a multivibrator. The most important characteristic of the waveform generated by a trigger circuit is usually the fast leading edge. The exact shape of the failing portion of the waveform often is of secondary importance, although it is important that the total duration time is not too great. A pulse generator such as a blocking oscillator may also be used and identified as a trigger circuit if it generates sufficiently short pulses. *See* BLOCKING OSCILLATOR; PULSE GENERATOR.

Peaking circuits, which accent the higher-frequency components of a pulse waveform, cause sharp leading and trailing edges and are therefore used as trigger circuits. The simplest form of peaking circuits are the simple *RC* and *RL* networks shown in the illustration. If a steep wavefront of amplitude *V* is applied to either of these circuits, the output will be a sudden rise followed by an exponential decay. These circuits are often called differentiating circuits because the outputs are rough approximations of the derivative of the input waveforms, if the *RC* or *R*/*L* time constant is sufficiently small.

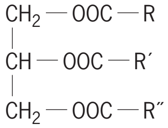


Diagrams of simple peaking circuits. (*a*) Resistance-capacitance network. (*b*) Resistance-inductance network. v_i = input voltage; v_o = output voltage.

A circuit that is highly underdamped, or oscillatory, and is supplied with a step or pulse input is often referred to as a ringing circuit. When used in the output of a field-effect or bipolar transistor, this circuit can be used as a trigger circuit. *See* WAVE-SHAPING CIRCUITS. [G.M.G.]

Triglyceride A simple lipid. Triglycerides are fatty acid triesters of the trihydroxy alcohol glycerol which are present in plant and animal tissues, particularly in the food storage depots, either as simple esters in which all the fatty acids are the same or as mixed esters in which the fatty acids are different. The triglycerides constitute the main component of natural fats and oils.

The generic formula of a triglyceride is shown below, where



$$\begin{array}{l} CH_2-OOC-R \\ | \\ CH-OOC-R' \\ | \\ CH_2-OOC-R'' \end{array}$$

RCO_2H, $R'CO_2H$, and $R''CO_2H$ represent molecules of either the same or different fatty acids, such as butyric or caproic (short chain), palmitic or stearic (long chain), oleic, linoleic, or linolenic (unsaturated). Saponification with alkali releases glycerol and the alkali metal salts of the fatty acids (soaps). The triglycerides in the food storage depots represent a concentrated energy source, since oxidation provides more energy than an equivalent weight of protein or carbohydrate. *See* LIPID METABOLISM; SOAP.

The physical and chemical properties of fats and oils depend on the nature of the fatty acids present. Saturated fatty acids give higher-melting fats and represent the main constituents of solid fats, for example, lard and butter. Unsaturation lowers the melting point of fatty acids and fats. Thus, in the oil of plants, unsaturated fatty acids are present in large amounts, for example, oleic acid in olive oil and linoleic and linolenic acids in linseed soil. *See* FAT AND OIL (FOOD); LIPID. [R.H.G.; H.E.Ca.]

Trigonometry The study of triangles and the trigonometric functions. Trigonometry has evolved from use by surveyors, engineers, and navigators to applications involving ocean tides, the rise and fall of food supplies in certain ecologies, brain-wave patterns, the analysis of alternating-current electricity, and many other phenomena of a vibratory character.

Plane trigonometry. Plane trigonometry mostly deals with the relationships among the three sides and three angles of a triangle that lies in a plane.

A ray is that portion of a line that starts at a point on the line and extends indefinitely in one direction. The starting point of a ray is called its vertex. If two rays are drawn with a common vertex, they form an angle. One of the rays of an angle is called the initial side, and the other ray is the terminal side. The angle that is formed is identified by showing the direction and amount of rotation from the initial side to the terminal side. If the rotation is in the counterclockwise direction, the angle is positive; if the rotation is clockwise, the angle is negative.

The angle formed by rotating the initial side exactly once in the counterclockwise direction until it coincides with itself (1 revolution) is said to measure 360 degrees, written 360°. Thus, one degree, 1°, is 1/360 of a revolution. One-sixtieth of a degree is called a minute, written 1′.

By using a circle of radius *r*, an angle can be constructed whose vertex is at the center of this circle and whose rays subtend an arc on the circle whose length equals *r*. Such an angle measures 1 radian. For a circle of radius *r*, a central angle of θ radians subtends an arc whose length *s* is given by Eq. (1):

$$s = r\theta \tag{1}$$

Because a central angle of 1 revolution (360°) subtends an arc equal to the circumference of the circle ($2\pi r$), it follows that an angle of 1 revolution equals 2π radians; that is, 2π radians = 360°. *See* PLANE GEOMETRY; RADIAN MEASURE.

Trigonometric functions. A unit circle is a circle whose radius is one and whose center is at the origin of a rectangular system of coordinates. For the unit circle, Eq. (1) states that a central angle of θ radians subtends an arc whose length $s = \theta$. If *t* is any real number, let θ be the angle equal to *t* radians and *P* be the point on the unit circle that is also on the terminal side of θ. If $t \geq 0$, then the point *P* is reached by moving counterclockwise along the unit circle, starting at the point with coordinates (1,0), for a length of arc equal to *t* units (Fig. 1*a*). If $t < 0$, this point *P* is reached by moving clockwise along the unit circle beginning at (1,0), for a length of arc equal to $|t|$ units (Fig. 1*b*). Thus, to each real number *t* there corresponds a unique point $P = (a,b)$ on the unit circle. The coordinates of this point *P* are used to define the six trigonometric functions: If $\theta = t$ radians, the sine, cosine, tangent, cosecant, secant, and cotangent of θ, respectively abbreviated as $\sin\theta$, $\cos\theta$, $\tan\theta$, $\csc\theta$, $\sec\theta$, $\cot\theta$, are given by Eqs. (2), (3), and (4).

$$\sin\theta = b \qquad \cos\theta = a \tag{2}$$

$$\text{if } a \neq 0, \quad \tan\theta = b/a, \quad \sec\theta = 1/a \tag{3}$$

$$\text{if } b \neq 0, \quad \tan\theta = a/b, \quad \sec\theta = 1/b \tag{4}$$

See COORDINATE SYSTEMS.

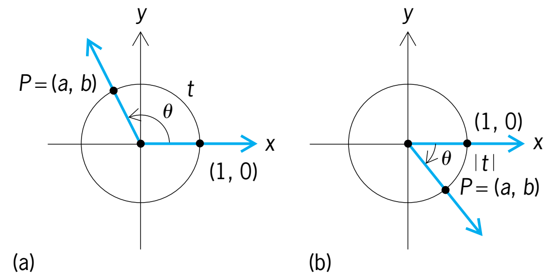


Fig. 1. Point P on the unit circle corresponding to $\theta = t$ radians. (*a*) $t \geq 0$: length of arc from (1,0) to P is t units. (*b*) $t < 0$: length of arc from (1,0) to P is $|t|$ units.

For example, for $\theta = 0$, the point (1,0) is on the terminal side of θ and is on the unit circle so that Eqs. (5) hold, with csc 0 and

$$\sin 0 = 0 \qquad \cos 0 = 1 \qquad \tan 0 = 0 \qquad \sec 0 = 1 \tag{5}$$

cot 0 not defined. The trigonometric functions of angles that are integral multiples of $\pi/2$ (90°) are found similarly (Table 1).

Table 1. Values of trigonometric functions at integral multiples of $\pi/4$ (90°)

θ, radians	θ	$\sin\theta$	$\cos\theta$	$\tan\theta$	$\csc\theta$	$\sec\theta$	$\cot\theta$
0	0°	0	1	0	n.d.	1	n.d.
$\pi/2$	90°	1	0	n.d.	1	n.d.	0
π	180°	0	−1	0	n.d.	−1	n.d.
$3\pi/2$	270°	−1	0	n.d.	−1	n.d.	0

*n.d. = not defined.

The coordinates of points on the unit circle that are on the terminal sides of angles that are integral multiples of $\pi/6$ (30°), $\pi/4$ (45°), and $\pi/3$ (60°) can be found. With Eqs. (2), (3), and (4), the trigonometric functions of these angles are obtained (Table 2).

Properties of trigonometric functions. Based on Eqs. (2) and the above geometric construction (Fig. 1) for sin θ and cos θ, θ can be any angle, so the domain of the sine and cosine functions is all real numbers. In Eqs. (3), if $a = 0$, the tangent and secant functions are not defined, so the domain of these functions is all real numbers, except odd multiples of $\pi/2$ (90°). In Eqs. (4), if $b = 0$, the cotangent and cosecant functions are not defined, so the domain of these functions is all real numbers, except multiples of π (180°). Also, since $|a| \leq 1$ and $|b| \leq 1$, the range of the sine and cosine functions is −1 to 1 inclusive. Since $|b| = |\sin\theta| \leq 1$ and $|a| = |\cos\theta| \leq 1$, it follows that $|\csc\theta| = 1/|b| \geq 1$ and $|\sec\theta| = 1/|a| \geq 1$. Thus the range of the secant and cosecant functions consists of all real numbers less than or equal to −1 or greater than or equal to 1. The range of both the tangent and cotangent functions consists of all real numbers.

Table 2. Values of trigonometric functions at integral multiples of $\pi/6$ (30°), $\pi/4$ (45°), and $\pi/3$ (60°)

θ, radians	θ	$\sin\theta$	$\cos\theta$	$\tan\theta$	$\csc\theta$	$\sec\theta$	$\cot\theta$
$\pi/6$	30°	$1/2$	$\sqrt{3}/2$	$\sqrt{3}/3$	2	$2\sqrt{3}/3$	$\sqrt{3}$
$\pi/4$	45°	$\sqrt{2}/2$	$\sqrt{2}/2$	1	$\sqrt{2}$	$\sqrt{2}$	1
$\pi/3$	60°	$\sqrt{3}/2$	$1/2$	$\sqrt{3}$	$2\sqrt{3}/3$	2	$\sqrt{3}/3$
$2\pi/3$	120°	$\sqrt{3}/2$	$-1/2$	$-\sqrt{3}$	$2\sqrt{3}/3$	-2	$-\sqrt{3}/3$
$3\pi/4$	135°	$\sqrt{2}/2$	$-\sqrt{2}/2$	-1	$\sqrt{2}$	$-\sqrt{2}$	-1
$5\pi/6$	150°	$1/2$	$-\sqrt{3}/2$	$1-\sqrt{3}/3$	2	$-2\sqrt{3}/3$	$-\sqrt{3}$
$7\pi/6$	210°	$-1/2$	$-\sqrt{3}/2$	$\sqrt{3}/3$	-2	$-2\sqrt{3}/3$	$\sqrt{3}$
$5\pi/4$	225°	$-\sqrt{2}/2$	$-\sqrt{2}/2$	1	$-\sqrt{2}$	$-\sqrt{2}$	1
$4\pi/3$	240°	$-\sqrt{3}/2$	$-1/2$	$\sqrt{3}$	$-2\sqrt{3}/3$	-2	$\sqrt{3}/3$
$5\pi/3$	300°	$-\sqrt{3}/2$	$1/2$	$-\sqrt{3}$	$-2\sqrt{3}/3$	2	$-\sqrt{3}/3$
$7\pi/4$	315°	$-\sqrt{2}/2$	$\sqrt{2}/2$	-1	$-\sqrt{2}$	$\sqrt{2}$	-1
$11\pi/6$	330°	$-1/2$	$\sqrt{3}/2$	$-\sqrt{3}/3$	-2	$2\sqrt{3}/3$	$-\sqrt{3}$

Equations (2), (3), and (4) also reveal the reciprocal identities, given in Eqs. (6). Two other useful identities, given in Eqs. (7), also follow.

$$\csc\theta = 1/\sin\theta \qquad \sec\theta = 1/\cos\theta \qquad \cot\theta = 1/\tan\theta \tag{6}$$

$$\tan\theta = \sin\theta/\cos\theta \qquad \cot\theta = \cos\theta/\sin\theta \tag{7}$$

Since (a,b) is on the unit circle, $a^2 + b^2 = 1$, and so $(\sin\theta)^2 + (\cos\theta)^2 = 1$. This is called a pythagorean identity and is written as Eq. (8).

$$\sin^2\theta + \cos^2\theta = 1 \tag{8}$$

Sum and difference formulas. The sum and difference formulas for the cosine function are given in Eqs. (9) and (10), and for the sine function they are given in Eqs. (11) and (12).

$$\cos(\alpha+\beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta \tag{9}$$

$$\cos(\alpha-\beta) = \cos\alpha\cos\beta + \sin\alpha\sin\beta \tag{10}$$

$$\sin(\alpha+\beta) = \sin\alpha\cos\beta + \cos\alpha\sin\beta \tag{11}$$

$$\sin(\alpha-\beta) = \sin\alpha\cos\beta - \cos\alpha\sin\beta \tag{12}$$

Inverse trigonometric functions. In the equation $x = \sin y$, if y is restricted so that $-\pi/2 \leq y \leq \pi/2$, then the solution of the equation for y is unique and is denoted by $y = \sin^{-1}x$ (read "y is the inverse sine of x"). Sometimes $y = \sin^{-1}x$ is written as $y = \text{Arcsin}\, x$. Thus, $y = \sin^{-1}x$ is a function whose domain is $-1 \leq x \leq 1$ and whose range is $-\pi/2 \leq y \leq \pi/2$. For example, $\sin^{-1} 1/2 = \pi/6$ and $\sin^{-1}(-1) = -\pi/2$.

Likewise in the equation $x = \cos y$, if y is restricted so that $0 \leq y \leq \pi$, then the solution of the equation for y is unique and is denoted by $y = \cos^{-1}x$ (read "y is the inverse cosine of x"). Thus, $y = \cos^{-1}x$ is a function whose domain is $-1 \leq x \leq 1$ and whose range is $0 \leq y \leq \pi$. Finally, in the equation $x = \tan y$, if y is restricted so that $-\pi/2 < y < \pi/2$, then the solution of the equation for y is unique and is denoted by $y = \tan^{-1}x$ (read "y is the inverse tangent of x"). Thus, $y = \tan^{-1}x$ is a function whose domain is $-\infty < x < \infty$ and whose range is $-\pi/2 < y < \pi/2$.

Solution of right triangles. The trigonometric functions can be expressed as ratios of the sides of a right triangle. Indeed, by Eqs. (6), (7), and (8), it follows that $\sin\beta = b/c$, $\cos\beta = a/c$, $\tan\beta = b/a$, and so on, where a and b are the sides adjacent to the right angle, c is the hypotenuse, and α and β are the angles opposite a and b respectively (Fig. 2). If an angle and a side or else two sides of a right triangle are known, then the remaining angles and sides can be found.

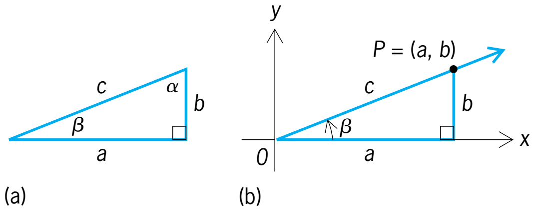

Fig. 2. Right triangle. (*a*) Labeling of sides and angles. (*b*) Relationship of sides to coordinates defining trigonometric functions.

Solution of oblique triangles. If none of the angles of a right triangle is a right angle, the triangle is oblique. To solve such triangles, there are four possibilities to consider: (1) one side and two angles are given; (2) two sides and the angle opposite one of them are given; (3) two sides and the included angle are given; and (4) three sides are given. In the following discussion, the sides are labeled a, b, and c; the angles opposite these sides are α, β, and γ respectively; and the corresponding vertices are A, B, and C (Fig. 3).

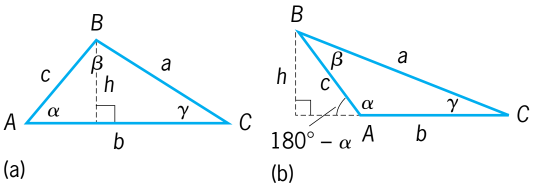

Fig. 3. Labeling of sides, angles, and vertices of oblique triangle, with altitude *h* used in proving the law of sines. (*a*) Angle α is acute. (*b*) Angle α is obtuse.

The law of sines, Eq. (13), is used to solve possibilities (1) and

$$\frac{\sin\alpha}{a} = \frac{\sin\beta}{b} = \frac{\sin\gamma}{c} \tag{13}$$

(2). The law of cosines, used to solve possibilities (3) or (4), may be stated by three equivalent formulas, Eqs. (14), (15), and (16).

$$c^2 = a^2 + b^2 - 2ab\cos\gamma \tag{14}$$

$$b^2 = a^2 + c^2 - 2ac\cos\beta \tag{15}$$

$$a^2 = b^2 + c^2 - 2bc\cos\alpha \tag{16}$$

Infinite series representation. With the definition $n! = 1\cdot 2\cdot 3\cdots n$, the sine and cosine functions may be represented by the two infinite series, given in Eqs. (17) and (18). These series converge for all x. Thus, to find a value of $\sin x$

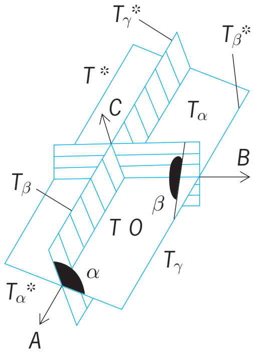
$$\sin x = \sum_{k=0}^{\infty}(-1)^k\frac{x^{2k+1}}{(2k+1)!} = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \cdots \tag{17}$$

$$\cos x = \sum_{k=0}^{\infty}(-1)^k\frac{x^{2k}}{(2k)!} = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \cdots \tag{18}$$

or $\cos x$, only as many terms of the series need to be used, as required to ensure required accuracy. [M.Su.]

Trihedron

A geometric figure bounded by three noncoplanar rays called edges that emanate from a common point called the vertex, and by the plane sectors called faces that are formed by each pair of edges (see illustration). A trihedron has three dihedrons formed by pairs of face planes, and three face angles formed by pairs of edges. [J.S.F.]



Trihedron and trihedral angles. Three planes having a common point *O* cut space into eight trihedrons, *T*, T^*, T_α, T_α^*, T_β, T_β^*, T_γ, and T_γ^*. *A*, *B*, and *C* are directions of common edges of pairs of planes; α, β, and γ are face angles.

Trilobita

A class of extinct Paleozoic arthropods, occurring in marine rocks of Early Cambrian through late Permian age. Their closest living relatives are the chelicerates, including spiders, mites, and horseshoe crabs (Xiphosura). About 3000 described genera make trilobites one of the most diverse and best-known fossil groups. Species diversity peaked during the Late Cambrian then declined more or less steadily until the Late Devonian mass extinction. Only four families survived to the Mississippian, and only one lasted until the group's Permian demise. Their dominance in most Cambrian marine settings is essential to biostratigraphic correlation of that system. *See* ARTHROPODA; CAMBRIAN; CHELICERATA; DEVONIAN; INDEX FOSSIL; PERMIAN.

Trilobites are typically represented in the fossil record by the mineralized portion of their exoskeleton, either as carcass or molt remains. The mineralized exoskeleton was confined mostly to the dorsal surface (see illustration) curved under as a rimlike doublure, a single mineralized ventral plate, the hypostome, was suspended beneath the median region of the head. The mineralized exoskeleton was composed of low magnesian calcite and a minor component of organic material. Most of the ventral exoskeleton, including the appendages, was unmineralized.

***Griffithides*, Mississippian (Indiana). Dorsal view of exoskeleton.**

Most trilobites were benthic deposit feeders or scavengers, living on the sediment-water interface or shallow-burrowing just beneath it. Some were evidently carnivores, equipped with sharp spines and processes projecting ventrally from their appendages. The morphology and broad geographic and environmental ranges of these groups suggest they were active swimmers. Through their history, trilobites became adapted to all marine environments, from shallow high-energy shorefaces to deep-water, disaerobic habitats. [G.D.E.; J.Ad.]

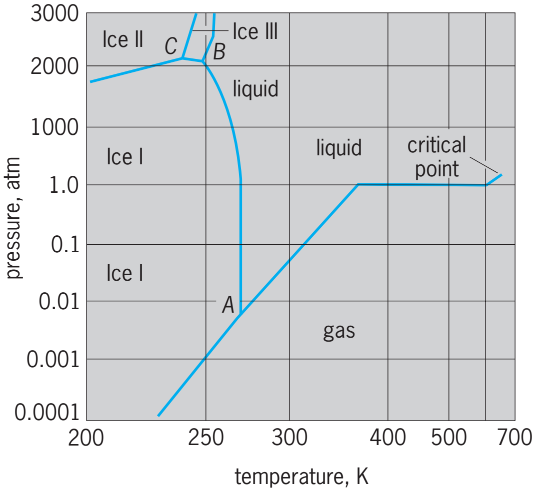
Trimerophytopsida

Mid-Early-Devonian into Middle-Devonian vascular plants at a higher evolutionary level than Rhyniopsida. Branching was profuse and varied, dichotomous, pseudomonopodial, helical to subopposite and almost whorled, and often trifurcate. Vegetative branches were often in a tight helix, terminated by tiny recurved branchlets simulating leaf precursors. The axes were leafless and glabrous or spiny. Xylem is known only in *Psilophyton*. *See* EMBRYOBIONTA; RHYNIOPSIDA. [H.P.B.]

Triple point

A particular temperature and pressure at which three different phases of one substance can coexist in equilibrium. In common usage these three phases are normally solid, liquid, and gas, although triple points can also occur with two solid phases and one liquid phase, with two solid phases and one gas phase, or with three solid phases.

According to the Gibbs phase rule, a three-phase situation in a one-component system has no degrees of freedom (that is, it is invariant). Consequently, a triple point occurs at a unique temperature and pressure, because any change in either variable



Phase diagram for water, showing gas, liquid, and several solid (ice) phases; triple points at *A*, *B*, and *C*. The pressure scale changes at 1 atm from logarithmic scale at low pressure to linear at high pressure. 1 atm = 10^2 kilopascals.

will result in the disappearance of at least one of the three phases. Triple points are shown in the illustration of part of the phase diagram for water. *See* PHASE EQUILIBRIUM.

For most substances the solid-liquid-vapor triple point has a pressure less than 1 atm (10^2 kilopascals); such substances then have a liquid-vapor transition at 1 atm (normal boiling point). However, if this triple point has a pressure above 1 atm, the substance passes directly from solid to vapor at 1 atm. *See* BOILING POINT; ICE POINT; MELTING POINT; SUBLIMATION; TRANSITION POINT; VAPOR PRESSURE; WATER. [R.L.S.]

Triplet state An electronic state of a molecule that occurs when its total spin angular momentum quantum number *S* is equal to one. The triplet state is an important intermediate of organic chemistry. In addition to the wide range of triplet molecules available through photochemical excitation techniques, numerous molecules exist in stable triplet ground states, for example, oxygen molecules. *See* ATOMIC STRUCTURE AND SPECTRA; MOLECULAR STRUCTURE AND SPECTRA; SPIN (QUANTUM MECHANICS).

A triplet may result whenever a molecule possesses two electrons which are both orbitally unpaired and spin unpaired. Orbital unpairing of electrons results when a molecule absorbs a photon of visible or ultraviolet light. Direct formation of a triplet as a result of this photon absorption is a very improbable process since both the orbit and spin of the electron would have to change simultaneously. Thus, a singlet state is generally formed by absorption of light. However, quite often the lifetime of this singlet state is sufficiently long to allow the spin of one of the two electrons to invert, thereby producing a triplet. *See* MOLECULAR ORBITAL THEORY. [N.J.T.]

Tripylida An order of nematodes in which the cephalic cuticle is simple and not duplicated; there is no helmet. The body cuticle is smooth or sometimes superficially annulated. Cephalic sensilla follow the typical pattern in which one whorl is circumoral and the second whorl is often the combination of circlets two and three. The pouchlike amphids have apertures that are inconspicuous or transversally oval. The stoma is variable, being simple, collapsed, funnel shaped or cylindrical, and armed or unarmed. In most taxa the stoma is surrounded by esophageal tissue; that is, it is entirely esophastome. When the stoma is expanded, both the cheilostome and esophastome are evident. Esophagi are cylindrical-conoid. Esophageal glands open anterior to the nerve ring. Males generally have three supplementary organs, more in some taxa. A gubernaculum accompanies the spicules. Caudal glands are generally present.

The two tripylid superfamilies are the Tripyloidea and Ironoidea. The characteristically well-developed cuticular annulation of the Tripyloidea is only rarely seen in other Enoplida. These nematodes are commonly found in fresh water or very moist soils; however, some are found in brackish water and marine habitats. Intestinal contents indicate that their food consists primarily of small microfauna that often include nematodes and rotifers. The Ironoidea contain species (presumably carnivorous) occurring in both fresh-water and soil habitats. *See* NEMATA. [A.R.M.]

Triterpene A hydrocarbon or its oxygenated analog containing 30 carbon atoms and composed of six isoprene units. Triterpenes form the largest group of terpenoids, but are classified into only a few major categories. Resins and saps contain triterpenes in the free state as well as in the form of esters and glycosides.

Biogenetically triterpenes arise by the cyclization of squalene and subsequent skeletal rearrangements. Apart from the linear squalene itself and some bicyclic, highly substituted skeletons, most triterpenes are either tetracyclic or pentacyclic compounds. The various structural classes are designated by the names of representative members. *See* ISOPRENE; TERPENE. [T.Hu.]

Triticale A cereal grass plant (× *Triticosecale*) obtained from hybridization of wheat (*Triticum*) with rye (*Secale cereale*). It is a crop plant with a small-seeded cereal grain that is used for human food and livestock feed. Worldwide, triticale is slowly gaining importance as a cereal grain. The European continent dominates triticale production with 70% of the total area.

Triticale was first developed in 1876, but not until the 1960s were types developed that were suitable for cultivation. Modern varieties are called secondary triticales because they were selected after interbreeding of various triticales, including primary types. In some triticale varieties, one or more rye chromosomes have been replaced by wheat chromosomes, giving secondary-substituted triticales, as contrasted to complete triticale having all seven rye chromosomes.

Triticale is produced by deliberate hybridization of either bread wheat [*Triticum aestivum*; diploid number of chromosomes $(2n) = 42$] or durum wheat (*T. turgidum* var. *durum*; $2n = 28$) with rye ($2n = 14$), followed by the doubling of the chromosome number of the hybrid plant. Hexaploid triticale (durum wheat × rye; $2n = 42$) is a more successful crop plant than octoploid triticale. The octoploid form ($2n = 56$) is produced by hybridization of bread wheat ($2n = 42$) with rye ($2n = 14$).

Triticale is grown from seeds sown in soil by using cultivation practices similar to those of wheat or rye. Both winter-hardy and nonhardy types exist, the latter used where winters are mild or for spring sowing. Triticale tends to have a greater ability than wheat to grow in adverse environments, such as saline or acid soils or under droughty conditions.

Being a cereal grain, triticale can be used in food products made from wheat flour. Varieties tend to have large, somewhat irregularly shaped grains that produce a lower yield of milled flour than wheat. Bread and pastry products can be made very well with triticale flour. As a livestock feed, triticale grain is a good source of carbohydrate and protein.

Intense breeding and selection have made very rapid genetic improvements in triticale seed quality. The agronomic advantages and improved end-use properties of the grain of triticale over wheat make triticale an attractive option for increasing global food production. *See* BREEDING (PLANT); RYE; WHEAT. [C.O.Q.]

Tritium The heaviest isotope of the element hydrogen and the only one which is radioactive. Tritium occurs in very small amounts in nature but is generally prepared artificially by

Property	H_2	T_2
Melting point	−259.20°C (−434.56°F)	−252.54°C (−422.57°F)
Boiling point at 1 atm (10^5 pascals)	−252.77°C (−423.00°F)	−248.12°C (−414.62°F)
Heat of vaporization	216 cal/mol (904 J/mol)	333 cal/mol (1390 J/mol)
Heat of sublimation	247 cal/mol (1030 J/mol)	393 cal/mol (1640 J/mol)

processes known as nuclear transmutations. It is widely used as a tracer in chemical and biological research and is a component of the so-called thermonuclear or hydrogen bomb. It is commonly represented by the symbol ^3_1H indicating that it has an atomic number of 1 and an atomic mass of 3, or by the special symbol T. For information about the other hydrogen isotopes *see* Deuterium; Hydrogen. *See also* Transmutation.

Both molecular tritium, T_2, and its counterpart hydrogen, H_2, are gases under ordinary conditions. Because of the great difference in mass, many of the properties of tritium differ substantially from those of ordinary hydrogen, as indicated in the table. Chemically, tritium behaves quite similarly to hydrogen. However, because of its larger mass, many of its reactions take place more slowly than do those of hydrogen.

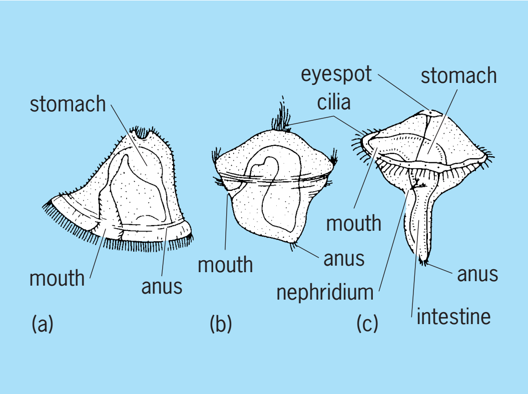
The nucleus of the tritium atom, often called a triton and symbolized *t*, consists of a proton and two neutrons. It undergoes radioactive decay by emission of a β-particle to leave a helium nucleus of mass 3. No γ-rays are emitted in this process. The half-life for the decay is 12.26 years. When tritium is bombarded with deuterons of sufficient energy, a nuclear reaction known as fusion occurs and energy considerably greater than that of the bombarding particle is released. This reaction is one of those which supply the energy of the thermonuclear bomb. It is also of major importance in the development of controlled thermonuclear reactors. *See* Heavy water; Nuclear fusion; Triton. [L.K.]

Triton The nucleus of ^2_1H (tritium); it is the only known radioactive nuclide belonging to hydrogen. The triton is produced in nuclear reactors by neutron absorption in deuterium ($^2_1H + {}^1_0n \rightarrow +\gamma$), and decays by β^- emission to ^3_2H with a half-life of 12.4 years. Much of the interest in producing ^3_1H arises from the fact that the fusion reaction $^3_1H + {}^1_1H \rightarrow {}^4_2H$ releases about 20 MeV of energy. Tritons are also used as projectiles in nuclear bombardment experiments. *See* Nuclear reaction; Tritium. [H.E.D.]

Triuridales A small order of flowering plants, division Magnoliophyta (Angiospermae), subclass Alismatidae of the class Liliopsida (monocotyledons). The order consists of 2 families, the Triuridaceae, with about 70 species, and the Petrosaviaceae, with only 2 species. They are terrestrial, mycotrophic herbs without chlorophyll, and with separate carpels, trinucleate pollen, and well-developed endosperm. They grow in moist, tropical regions, especially of the Old World, and have attracted little botanical attention. *See* Alismatidae; Liliopsida; Magnoliophyta. [A.Cr.; T.M.Ba.]

Trochodendrales An order of flowering plants, division Magnoliophyta (Angiospermae), in the Eudicotyledon. The order consists of two families, the Trochodendraceae and Tetracentraceae, each with only a single species. The group is of considerable botanical and evolutionary interest, as it is situated near the base of the advanced Eudicotyledon and links this larger group with more primitive flowering plants. Trochodendrales comprise trees of eastern and southeastern Asia with primitive (without vessels) wood. The flowers have a much reduced perianth with scarcely sealed carpels that are only slightly fused to each other. *See* Eudicotyledons; Magnoliophyta. [K.J.Sy.]

Trochophore A generalized but distinct type of free-swimming larva found in several invertebrate groups, including nemerteans, marine turbellarians, brachiopods, bryozoans, phoronids, mollusks, sipunculids, and some annelids. The form is somewhat pear-shaped (see illustration), and it is provided externally with a prominent circlet of cilia (a troch) and one or sometimes two accessory circlets. Anterior and posterior apical ciliary tufts and eyespots are often present. The digestive tract is complete and functional; paired nephridia with excretory tubules are present; muscle and nerve fibers, sense organs, and a band of mesoderm complete the internal structure. Presumably, the larva, which develops ontogenetically along many divergent lines, indicates the close evolutionary relationships of the groups it represents. *See* Annelida; Brachiopoda; Bryozoa; Mollusca; Phoronida; Sipunculida; Turbellaria. [S.P.P.]

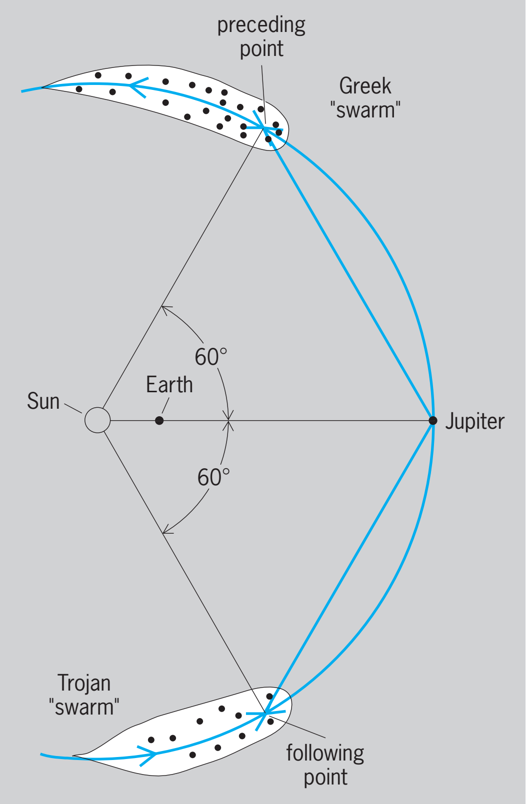


Some trochophore larvae. Pear-shaped form is common in all groups. (*a*) Bryozoan. (*b*) *Patella*, a mollusk. (*c*) *Polygardius*, an annelid. (*After T. I. Storer et al. General Zoology, 4th ed., McGraw-Hill, 1976*)

Trogoniformes A small order of birds that contains only the family Trogonidae, which has 37 species distributed pantropically. The trogons and quetzals are jay-sized birds with large heads, and tails that vary from medium length and squared to elongated and tapered. The dorsal plumage of trogons and quetzals is predominantly metallic green, with blue, violet, red, black, or gray in a few. The ventral feathers are bright red, yellow, or orange. Despite their vivid coloration, the birds are inconspicuous when sitting quietly. The legs of quetzals are short and their feet are weak, with the toes arranged heterodactylously, with the first and second toes reverted. Their flight is rapid, undulating, and brief; trogons rarely walk. Their diet consists of fruit and small invertebrates, and insects caught in flight as the bird darts out from a perch.

Trogons are nonmigratory, arboreal, and sedentary, and they can remain on a perch for hours. The monogamous pairs nest in solitude in a hollow tree or termite nest. After the eggs have been incubated by both parents, the naked hatchlings remain in the nest and are cared for by both. *See* Aves. [W.J.B.]

Trojan asteroids Asteroids located near the equilateral lagrangian stability points of the Sun-Jupiter system (see illustration). As shown by J. L. Lagrange in 1772, these are two of the five stable points in the circular, restricted, three-body system, the other three points being located along a line through the two most massive bodies in the system. In 1906 Max Wolf discovered an asteroid located near the lagrangian point preceding Jupiter in its orbit. Within a year, two more were found, one of which was located near the following lagrangian point. It was quickly decided to name these asteroids after participants in the Trojan War as given in Homer's *Iliad*.



Lagrangian points and Trojan asteroids.

The term "Trojans" is sometimes used in a generic sense to refer to hypothetical objects occupying the equilateral lagrangian points of other pairs of bodies. In 1990 Edward Bowell discovered an asteroid, later named (5261) Eureka, occupying the following lagrangian point of the planet Mars, and in 2001 the first Trojan of Neptune (2001 QR_{322}) was discovered. As of December 2003, as many as five additional potential Martian Trojans had been discovered. As of August 2004 there were 1682 known Jupiter Trojans. *See* ASTEROID. [E.F.T.]

Trombidiformes A suborder of the Acarina (also known as Prostigmata) commonly called the trombidiform mites, more closely related to the Sarcoptiformes than to the other suborders. They are usually distinguished by presence of a respiratory system opening at or near the base of the chelicerae.

The Trombidiformes are probably the most heterogeneous group of mites, both morphologically and ecologically, varying from baglike forms with degenerate legs to the highly evolved, fully developed, parasitic forms. Economically, this group contains two families of plant-feeding mites of great importance to agriculture: the Tetranychidae (spider mites) and the Eriophyidae (bud mites or gall mites). Medically, the Trombiculidae (chiggers or red bugs) are important because the larval forms, which are parasites of vertebrates, can cause intense irritation to their hosts by their feeding. More seriously, some transmit a rickettsial disease, scrub typhus, to humans in the Far East and South Pacific regions. [E.W.B.]

Trophic ecology The study of the structure of feeding relationships among organisms in an ecosystem. Researchers focus on the interplay between feeding relationships and ecosystem attributes such as nutrient cycling, physical disturbance, or the rate of tissue production by plants and the accrual of detritus (dead organic material). Feeding or trophic relationships can be represented as a food web or as a food chain. Food webs depict trophic links between all species sampled in a habitat, whereas food chains simplify this complexity into linear arrays of interactions among trophic levels. Thus, trophic levels (for example, plants, herbivores, detritivores, and carnivores) are amalgamations of species that have similar feeding habits. (However, not all species consume prey on a single trophic level. Omnivores are species that feed on more than one trophic level.) *See* ECOLOGY; ECOSYSTEM; FOOD WEB.

The three fundamental questions in the field of trophic ecology are: (1) What is the relationship between the length of food chains and plant biomass (the relative total amount of plants at the bottom of the food chain)? (2) How do resource supply to producers (plants) and resource demand by predators determine the relative abundance of organisms at each trophic level in a food chain? (3) How long are real food chains, and what factors limit food chain length?

A central theory in ecology is that "the world is green" because carnivores prevent herbivores from grazing green plant biomass to very low levels. Trophic structure (the number of trophic levels) determines trophic dynamics (as measured by the impact of herbivores on the abundance of plants). Indirect control of plant biomass by a top predator is called a trophic cascade. Cascades have been demonstrated to varying degrees in a wide variety of systems, including lakes, streams, subtidal kelp forests, coastal shrub habitats, and old fields. In all of these systems, the removal of a top predator has been shown to precipitate dramatic reductions in the abundance of species at lower trophic levels. Food chain theory predicts a green world when food chains have odd numbers of trophic levels, but a barren world (plants suppressed by herbivores) in systems with even numbers of trophic levels.

Although predators often have strong indirect effects on plant biomass as a result of trophic cascades, both predation (a top-down force) and resource supply to producers (a bottom-up force) play strong roles in the regulation of plant biomass. The supply of inorganic nutrients at the bottom of a food chain is an important determinant of the rate at which the plant trophic level produces tissue (primary production, or productivity). However, the degree to which nutrient supply enhances plant biomass accrual depends on two factors: (1) how many herbivores are present (which in turn depends on how many trophic levels there are in the system) and (2) the degree to which the herbivores can respond to increases in plant productivity and control plant biomass. The relative importance of top-down (demand) versus bottom-up (supply) forces is well illustrated by lake systems, in which the supply of phosphorus (bottom-up force) and the presence of piscivorous (fish-eating) fish (top-down force) have significant effects on the standing stock of phytoplankton, the plant trophic level in lake water columns. *See* BIOLOGICAL PRODUCTIVITY; BIOMASS; FRESH-WATER ECOSYSTEM; LAKE; PHYTOPLANKTON.

Increases in productivity may act to lengthen food chains. However, food chain length may be limited by the efficiency at which members of each trophic level assimilate energy as it moves up the food chain; the resilience of the chain (measured as the inverse of the time required for all trophic levels to return to previous abunance levels after a disturbance); and the size of the ecosystem—small habitats are simply not large enough to support the home range or provide ample habitat for larger carnivorous species. *See* ECOLOGICAL ENERGETICS; SYSTEMS ECOLOGY; THEORETICAL ECOLOGY. [J.L.S.; L.R.G.]

Tropic of Cancer The parallel of latitude about $23^1/_2{}^\circ$ (23.45°) north of the Equator. The importance of this line lies in the fact that its degree of angle from the Equator is the same as the inclination of the Earth's axis from the vertical to the plane of the ecliptic. Because of this inclination of the axis and the revolution of the Earth in its orbit, the vertical overhead rays of the Sun may progress as far north as $23^1/_2{}^\circ$. At no place north of the Tropic of Cancer will the Sun, at noon, be 90° overhead.

On June 21, the summer solstice (Northern Hemisphere), the Sun is vertical above the Tropic of Cancer. On this same day the Sun is 47° above the horizon at noon at the Arctic Circle, and at the Tropic of Capricorn, only 43° above the horizon. The Tropic of Cancer is the northern boundary of the equatorial zone called the tropics, which lies between the Tropic of Cancer and Tropic of Capricorn. *See* Latitude and longitude; Mathematical geography; Solstice. [V.H.E.]

Tropic of Capricorn The parallel of latitude approximately 23$\frac{1}{2}$°(23.45°)south of the Equator. It was named for the constellation Capricornus (the goat), for astronomical reasons which no longer prevail.

Because the Earth, in its revolution around the Sun, has its axis inclined 23$\frac{1}{2}$° from the vertical to the plane of the ecliptic, the Tropic of Capricorn marks the southern limit of the zenithal position of the Sun. Thus, on December 22 (Southern Hemisphere summer, but northern winter solstice) the Sun, at noon, is 90° above the horizon.

The Tropic of Capricorn is the southern boundary of the equatorial zone referred to as the tropics, which lies between the Tropic of Capricorn and the Tropic of Cancer. *See* Mathematical geography; Solstice; Tropic of cancer. [V.H.E.]

Tropical meteorology The study of atmospheric structure and behavior in the areas astride the Equator, roughly between 30° north and south latitude. The weather and climate of the tropics involve phenomena such as trade winds, hurricanes, intertropical convergence zones, jet streams, monsoons, and the El Niño Southern Oscillation. More energy is received from the Sun over the tropical latitudes than is lost to outer space (infrared radiation). The reverse is true at higher latitudes, poleward of 30°. The excess energy from the tropics is transported by winds to the higher latitudes, largely by vertical circulations that span roughly 30° in latitudinal extent. These circulations are known as Hadley cells.

For the most part, the oceanic tropics (the islands) experience very little change of day-to-day weather except when severe events occur. Tropical weather can be more adverse during the summer seasons of the respective hemispheres. The near equatorial belt between 5°S and 5°N is nearly always free from hurricanes and typhoons: the active belt lies outside this region over the tropics. The land areas experience considerable heating of the Earth's surface, and the summer-to-winter contrasts are somewhat larger there. For instance, the land areas of northern India experience air temperatures as high as 108°F (42°C) in the summer (near the Earth's surface), while in the winter season the temperatures remain 72°F (22°C) for many days. The diurnal range of temperature is also quite large over land areas on clear days during the summer (32°F or 18°C) as compared to winter (18°F or 10°C).

The steady northeast surface winds over the oceans of the Northern Hemisphere between 5° and 20°N and southeast winds over the corresponding latitudes of the southern oceans constitute the trade winds. Trade winds have intensities of around 5–10 knots (2.5–5 m/s). They are the equatorial branches of the anticyclonic circulation (known as the subtropical high pressure). The steadiness of wind direction is quite high in the trades. *See* Wind.

Hurricanes are also known as typhoons in the west Pacific and tropical cyclones in Indian Ocean and south Pacific. If the wind speed exceeds 65 knots (33 m/s) in a tropical storm, the storm is labeled a hurricane. A hurricane usually forms over the tropical oceans, north or south of 5° latitude from the Equator. *See* Hurricane.

Intertropical convergence zones are located usually between 5 and 10°N latitude. They are usually oriented west to east and contain cloud clusters with rainfall of the order of 1.2–2 in. (30–50 mm) per day. The trade winds of the two hemispheres supply moisture to this precipitating system. *See* Cloud physics; Precipitation (meteorology).

A number of fast-moving air currents, known as jets, are important elements of the tropical general circulation. With speeds in excess of 30 knots (15 m/s), they are found over several regions of the troposphere. *See* Atmospheric general circulation; Jet stream; Troposphere.

Basically the entire landmass from the west coast of Africa to Asia and extending to the date line experiences a phenomenon known as the monsoon. Monsoon circulations are driven by differential heating between relatively cold oceans and relatively warm landmasses. *See* Monsoon meteorology.

Every 2–6 years the eastern equatorial Pacific Ocean experiences a rise in sea surface temperature of about 5–9°F (3–5°). This phenomenon is known as El Niño, which is part of a larger cycle referred to as the El Niño Southern Oscillation (ENSO). The other extreme in the cycle is referred to as La Niña. El Niño has been known to affect global-scale weather. *See* El Niño; Maritime meteorology. [T.N.Kr.]

Tropopause The boundary between the troposphere and the stratosphere in the atmosphere. The tropopause is broadly defined as the lowest level above which the lapse rate (decrease) of temperature with height becomes less than 5.8°F mi^{-1} (2°C km^{-1}). In low latitudes the tropical tropopause is at a height of 9.3–11 mi at about -135°F (15–17 km at about 180 K), and the polar tropopause between tropics and poles is at about 6.2 mi at about -63°F (10 km at about 220 K). There is a well-marked "tropopause gap" or break where the tropical and polar tropopauses overlap at 30–40° latitude. The break is in the region of the subtropical jet stream and is of major importance for the transfer of air and tracers (humidity, ozone, radioactivity) between stratosphere and troposphere. The height of the tropopause varies seasonally and also daily with the weather systems, being higher and colder over anticyclones than over depressions. *See* Air temperature; Atmosphere; Stratosphere; Troposphere. [R.J.Mu.]

Troposphere The lowest major layer of the atmosphere. The troposphere extends from the Earth's surface to a height of 6–10 mi (10–16 km), the base of the stratosphere. It contains about four-fifths of the mass of the whole atmosphere. *See* Atmosphere.

On the average, the temperature decreases steadily with height throughout this layer, with a lapse rate of about 19°F mi^{-1} (6.5°C km^{-1}), although shallow inversions (temperature increases with height) and greater lapse rates occur, particularly in the boundary layer near the Earth's surface. Appreciable water-vapor contents and clouds are almost entirely confined to the troposphere. Hence it is the seat of all important weather processes and the region where interchange by evaporation and precipitation (rain, snow, and so forth) of water substance between the surface and the atmosphere takes place. *See* Climatology; Cloud physics; Meteorology; Weather. [R.J.Mu.]

Tropospheric scatter A term applied to propagation of radio waves caused by irregularities in the refractive index of air. The phenomenon is predominant in the lower atmosphere; little or no scattering of importance occurs above the troposphere. Tropospheric scatter propagation provides very useful communication services but also causes harmful interference. For example, it limits the geographic separation required for frequency assignments to services such as television and frequency-modulation broadcasting, very-high-frequency omnidirectional ranges (VOR), and microwave relays. It is used extensively throughout most of the world for long-distance point-to-point services, particularly where high information capacity and high reliability are required. Typical tropospheric scatter relay facilities are commonly 200–300 mi (320–480 km) apart. Some single hops in excess of 500 mi (800 km) are in regular use. High-capacity circuits carry 200–300 voice circuits simultaneously. [R.S.Ki.]

Truck A motor vehicle carrying its load on its own wheels and primarily designed for the transportation of goods or cargo. A truck is similar to a passenger car in many basic aspects, but truck construction is usually heavier throughout with strengthened chassis and suspension, and lower transmission and drive-axle ratios to cope with hilly terrain. Other common truck characteristics include cargo-carrying features such as rear doors or tailgate, and a flat floor. However, there are many different kinds of trucks, often specially designed with unique features for performing a particular job. *See* AUTOMOBILE; AUTOMOTIVE ELECTRICAL SYSTEM; BUS.

A truck is rated by its gross vehicle weight (gvw), which is the combined weight of the vehicle and load. Trucks are classified as light-, medium-, or heavy-duty according to gross vehicle weight. Although a variety of models and designs are available in each category, there are two basic types of vehicles, the straight truck and the truck tractor. The straight truck has the engine and body mounted on the same chassis. The truck tractor is essentially a power unit that is the control and pulling vehicle for truck trailers such as full trailers or semitrailers. A full trailer has a front axle and one or more rear axles and is constructed so that all its own weight and that of its load rests on its own wheels. A semitrailer has one or more axles at the rear, and is constructed so that the front end and a substantial part of its own weight and that of its load rests upon another vehicle. A retractable mechanism mounted at the front end of the semitrailer is lowered to support it when the pulling vehicle is disconnected. A full trailer may be drawn by a truck, or behind a semitrailer.

The tractor-semitrailer combination permits the use of longer bodies with greater carrying capacity and better maneuverability than is possible with a straight truck. The forward positioning of the cab, the short wheelbase of the tractor, and the multiplicity of axles provide maximum payloads and operating economy in the face of restriction on overall length imposed by some states, and regulations limiting the weight carried on a single axle. [D.L.An.]

Truss An assemblage of structural members joined at their ends to form a stable structural assembly. If all members lie in one plane, the truss is called a planar truss or a plane truss. If the members are located in three dimensions, the truss is called a space truss.

A plane truss is used like a beam, particularly for bridge and roof construction. A plane truss can support only weight or loads contained in the same plane as that containing the truss. A space truss is used like a plate or slab, particularly for long span roofs where the plan shape is square or rectangular, and is most efficient when the aspect ratio (the ratio of the length and width) does not vary above 1.5. A space truss can support weight and loads in any direction.

Because a truss can be made deeper than a beam with solid web and yet not weigh more, it is more economical for long spans and heavy loads, even though it costs more to fabricate. *See* BRIDGE; ROOF CONSTRUCTION.

The simplest truss is a triangle composed of three bars with ends pinned together. If small changes in the lengths of the bars are neglected, the relative positions of the joints do not change when loads are applied in the plane of the triangle at the apexes.

Multiple-span plane trusses (defined as statically indeterminate or redundant) and space trusses require very complex and tedious hand calculations. Modern high-speed digital computers and readily available computer programs greatly facilitate the structural analysis and design of these structures. *See* COMPUTER; STRUCTURAL ANALYSIS. [C.Th.; I.P.H.]

Trypanorhyncha An order of tapeworms of the subclass Cestoda, also known as the Tetrarhynchoidea. All are parasitic in the intestine of elasmobranch fishes. They are distinguished from all other tapeworm groups by having spiny, eversible proboscides on the head. The head also bears two or four shallow, weakly muscular suckers. A complete life history is not known for any trypanorhynchid, although larval forms have been found in the tissues of various marine invertebrates and teleost fishes. *See* CESTODA. [C.P.R.]

Trypanosomatidae A family of Protozoa, order Kinetoplastida, containing flagellated parasites which change their morphology; that is, they exhibit polymorphism during their life cycles. The life cycles of the organisms may involve only an invertebrate host, or an invertebrate and a vertebrate host, or an invertebrate and a plant host. Several distinct morphological forms are recognized: trypanosomal, crithidial, leptomonad, and leishmanial. Differentiation into genera is dependent upon the host infected as well as the morphologic types involved. None of the stages possesses a mouth opening, and nutritive elements are absorbed through the surface of the body; that is, the organisms are saprozoic.

Trypanosoma is the important genus of the family Trypanosomatidae from a number of standpoints. It contains the largest number of species infecting a wide variety of hosts such as mammals, birds, fishes, amphibians, and reptiles. Although most of the species cause no damage to the hosts, there are several which produce serious diseases in humans, domesticated animals, and wild animals. The pathogenic species are prevalent in Africa.

Leishmania is the second most important genus. Three species parasitize humans but have also been found naturally infecting dogs, cats, and perhaps other lower animals. The sand fly, *Phlebotomus*, transmits the parasite from vertebrate to vertebrate. *See* LEISHMANIASIS. [M.M.B./H.W.S.]

Trypanosomiasis A potentially fatal infection caused by parasites of the genus *Trypanosoma*.

The African trypanosomes, the cause of African trypanosomiasis or African sleeping sickness, are flagellated protozoan parasites. *Trypanosoma brucei rhodesiense* and *T. b. gambiense* cause disease in humans. *Trypanosoma brucei* is restricted to domestic and wild animals. The trypanosomes are transmitted by the tsetse fly (*Glossina*), which is restricted to the African continent. The trypanosomes are taken up in a blood meal and grow and multiply within the tsetse gut. After 2–3 weeks, depending upon environmental conditions, they migrate into the salivary glands, where they become mature infective forms, and are then transmitted by the injection of infected saliva into a new host during a blood meal. The survival of the tsetse fly is dependent upon temperature and humidity, and the fly is confined by the Sahara to the north and by the colder drier areas to the south, an area about the size of the United States. Approximately 50 million people live within this endemic area, and 15,000–20,000 new human cases of African trypanosomiasis are reported annually.

In humans and other mammals the trypanosomes are extracellular. During the early stages of infection, the trypanosomes are found in the blood and lymph but not in cerebrospinal fluid. There are fever, malaise, and enlarged lymph nodes. In the absence of treatment the disease becomes chronic and the trypanosomes penetrate into the cerebrospinal fluid and the brain. The symptoms are headaches, behavioral changes, and finally the characteristic sleeping stage. Without treatment the individual sleeps more and more and finally enters a comatose stage which leads to death. Treatment is more difficult if the infection is not diagnosed until the late neurological stage.

Trypanosoma cruzi, the cause of American trypanosomiasis (Chagas' disease), is predominantly an intracellular parasite in the mammalian host. During the intracellular stage, *T. cruzi* loses its flagellum and grows predominantly in cells of the spleen, liver, lymphatic system, and cardiac, smooth, and skeletal muscle. The cells of the autonomic nervous system are also frequently invaded. *See* MEDICAL PARASITOLOGY; PARASITOLOGY. [J.R.See.]

Tsunami A set of ocean waves caused by any large, abrupt disturbance of the sea surface. If the disturbance is close to the coastline, tsunamis can demolish local coastal communities within minutes. A very large disturbance can both cause local devastation and export tsunami destruction thousands of miles away. Since 1850, tsunamis have been responsible for the loss of over 120,000 lives and billions of dollars of damage to coastal structures and habitats. Methods for predicting when and where the next tsunami will strike have not been developed; but once the tsunami is generated, forecasting its arrival and impact is possible through wave theory and measurement technology. *See* OCEAN WAVES.

Tsunamis are most commonly generated by earthquakes in marine and coastal regions. Major tsunamis are produced by large (greater than 7 on the Richter scale), shallow-focus (<30-km or 19-mi depth in the Earth) earthquakes associated with the movement of oceanic and continental plates. They frequently occur in the Pacific, where dense oceanic plates slide under the lighter continental plates. When these plates fracture, they cause a vertical movement of the sea floor that allows a quick and efficient transfer of energy from the solid earth to the ocean. The resulting tsunami propagates as a set of waves whose energy is concentrated at wavelengths corresponding to the earth movements (~100 km or 60 mi), at wave heights determined by vertical displacement (~1 m or 3 ft), and at wave directions determined by the adjacent coastline geometry. Because each earthquake is unique, every tsunami has unique wavelengths, wave heights, and directionality. From a warning perspective, this makes the problem of forecasting tsunamis in real time daunting. *See* EARTHQUAKE; PLATE TECTONICS.

Other large-scale disturbances of the sea surface that can generate tsunamis are explosive volcanoes and asteroid impacts. The eruption of the volcano Krakatoa in the East Indies on August 27, 1883, produced a 30-m (100-ft) tsunami that killed over 36,000 people. *See* ASTEROID; VOLCANO. [E.N.B.]

Tuberculosis An infectious disease caused by the bacillus *Mycobacterium tuberculosis*. It is primarily an infection of the lungs, but any organ system is susceptible, so its manifestations may be varied. Effective therapy and methods of control and prevention of tuberculosis have been developed, but the disease remains a major cause of mortality and morbidity throughout the world. The treatment of tuberculosis has been complicated by the emergence of drug-resistant organisms, including multiple-drug-resistant tuberculosis, especially in those with HIV infection. *See* ACQUIRED IMMUNE DEFICIENCY SYNDROME (AIDS).

Mycobacterium tuberculosis is transmitted by airborne droplet nuclei produced when an individual with active disease coughs, speaks, or sneezes. When inhaled, the droplet nuclei reach the alveoli of the lung. In susceptible individuals the organisms may then multiply and spread through lymphatics to the lymph nodes, and through the bloodstream to other sites such as the lung apices, bone marrow, kidneys, and meninges.

The development of acquired immunity in 2 to 10 weeks results in a halt to bacterial multiplication. Lesions heal and the individual remains asymptomatic. Such an individual is said to have tuberculous infection without disease, and will show a positive tuberculin test. The risk of developing active disease with clinical symptoms and positive cultures for the tubercle bacillus diminishes with time and may never occur, but is a lifelong risk. Only 5% of individuals with tuberculous infection progress to active disease. Progression occurs mainly in the first 2 years after infection; household contacts and the newly infected are thus at risk.

Many of the symptoms of tuberculosis, whether pulmonary disease or extrapulmonary disease, are nonspecific. Fatigue or tiredness, weight loss, fever, and loss of appetite may be present for months. A fever of unknown origin may be the sole indication of tuberculosis, or an individual may have an acute influenzalike illness. Erythema nodosum, a skin lesion, is occasionally associated with the disease.

The lung is the most common location for a focus of infection to flare into active disease with the acceleration of the growth of organisms. There may be complaints of cough, which can produce sputum containing mucus, pus- and, rarely, blood. Listening to the lungs may disclose rales or crackles and signs of pleural effusion (the escape of fluid into the lungs) or consolidation if present. In many, especially those with small infiltration, the physical examination of the chest reveals no abnormalities.

Miliary tuberculosis is a variant that results from the blood-borne dissemination of a great number of organisms resulting in the simultaneous seeding of many organ systems. The meninges, liver, bone marrow, spleen, and genitourinary system are usually involved. The term miliary refers to the lung lesions being the size of millet seeds (about 0.08 in. or 2 mm). These lung lesions are present bilaterally. Symptoms are variable.

Extrapulmonary tuberculosis is much less common than pulmonary disease. However, in individuals with AIDS, extrapulmonary tuberculosis predominates, particularly with lymph node involvement. Fluid in the lungs and lung lesions are other common manifestations of tuberculosis in AIDS. The lung is the portal of entry, and an extrapulmonary focus, seeded at the time of infection, breaks down with disease occurring.

Development of renal tuberculosis can result in symptoms of burning on urination, and blood and white cells in the urine; or the individual may be asymptomatic. The symptoms of tuberculous meningitis are nonspecific, with acute or chronic fever, headache, irritability, and malaise.

A tuberculous pleural effusion can occur without obvious lung involvement. Fever and chest pain upon breathing are common symptoms.

Bone and joint involvement results in pain and fever at the joint site. The most common complaint is a chronic arthritis usually localized to one joint. Osteomyelitis is also usually present.

Pericardial inflammation with fluid accumulation or constriction of the heart chambers secondary to pericardial scarring are two other forms of extrapulmonary disease.

The principal methods of diagnosis for pulmonary tuberculosis are the tuberculin skin test (an intracutaneous injection of purified protein derivative tuberculin is performed, and the injection site examined for reactivity), sputum smear and culture, and the chest x-ray. Culture and biopsy are important in making the diagnosis in extrapulmonary disease.

A combination of two or more drugs is used in the initial therapy of tuberculous disease. Drug combinations are used to lessen the chance of drug-resistant organisms surviving. The preferred treatment regimen for both pulmonary and extrapulmonary tuberculosis is a 6-month regimen of the antibiotics isoniazid, rifampin, and pyrazinamide given for 2 months, followed by isoniazid and rifampin for 4 months. Because of the problem of drug-resistant cases, ethambutol can be included in the initial regimen until the results of drug susceptibility studies are known. Once treatment is started, improvement occurs in almost all individuals. Any treatment failure or individual relapse is usually due to drug-resistant organisms. *See* DRUG RESISTANCE.

The community control of tuberculosis depends on the reporting of all new suspected cases so case contacts can be evaluated and treated appropriately as indicated. Individual compliance with medication is essential. Furthermore, measures to enhance compliance, such as directly observed therapy, may be necessary. *See* MYCOBACTERIAL DISEASES. [G.Lo.]

Tubeworms The name given to marine polychaete worms (particularly to many species in the family Serpulidae) which construct permanent calcareous tubes on rocks, seaweeds, dock pilings, and ship bottoms. The individual tubes with hard walls of calcite-aragonite are firmly cemented to any hard substrate and to each other. Economically they are among the most important fouling organisms both on ship hulls (where they are second only to barnacles) and inside sea-water cooling pipes of power stations.

About 340 valid species of serpulid tubeworms have been described. The majority are truly marine, but several species thrive in brackish waters of low salinity, and one species occurs in fresh waters in Karst limestone caves. The wide geographical distribution of certain abundant species owes much to human transport on the bottoms of relatively fast ships and occurred within the last 120 years. *See* ANNELIDA; BARNACLE; POLYCHAETA. [W.D.R.-H.]

Tubulidentata An order of mammals which contains a single living genus, the aardvark (*Orycteropus*) of Africa. Little is directly known of the origin and history of this peculiar group of mammals. The oldest undoubted record of the Tubulidentata is an early Miocene discovery in East Africa. Pliocene records in India and the Mediterranean border indicate the aardvarks had dispersed from Africa by that time. Tubular dentine reminiscent of the aardvarks occurs in *Tubulodon* from the early Eocene of North America, but the fragmentary material does not permit further comparison. *See* AARDVARK; MAMMALIA. [R.H.T.]

Tufa A spongy, porous limestone formed by precipitation from evaporating spring and river waters; also known as calcareous sinter. Calcium carbonate commonly precipitates from supersaturated waters on the leaves and stems of plants growing around the springs and pools and preserves some of their plant structures. Tufa tends to be fragile and friable. *See* LIMESTONE; TRAVERTINE. [R.Si.]

Tuff Fragmental volcanic products from explosive eruptions that are consolidated, cemented, or otherwise hardened to form solid rock. In strict scientific usage, the term “tuff” refers to consolidated volcanic ash, which by definition consists of fragments smaller than 2 mm. However, the term is also used for many pyroclastic rocks composed of fragments coarser than ash and even for pyroclastic material that has undergone limited posteruption reworking. If the thickness, temperature, and gas content of a tuff-forming pyroclastic flow are sufficiently high, the constituent fragments can become compacted and fused to form welded tuff. The term “tuff” is also used in the naming of several related types of small volcanic edifices formed by hydrovolcanic eruptions, triggered by the explosive interaction of hot magma or lava with water. *See* IGNIMBRITE; PYROCLASTIC ROCKS; VOLCANO. [R.Ti.]

Tularemia A worldwide disease caused by infection with the bacterium *Francisella tularensis*, which affects multiple animal species. Infection in humans occurs frequently from skinning infected animals bare-handed or from the bites of infected animals, ticks, deer flies. The mortality rate varies by species, but with treatment it is low. Ungulates are frequently infected but generally suffer low mortality.

Tularemia can be difficult to differentiate from other diseases because it can have multiple clinical manifestations. Nonspecific signs frequently include fever, lethargy, anorexia, and increased pulse and respiration rates. The disease can overlap geographically with plague, and both may lead to enlarged lymph nodes (buboes). However, with tularemia, the buboes are more likely to ulcerate. If tularemic infection results from inhalation of dust from contaminated soil, hay, or grain, either pneumonia or a typhoidal syndrome can occur. Rarely, the route of entry for the bacteria is the eyes, leading to the oculoglandular type of tularemia. If organisms are ingested, the oropharyngeal form can develop, characterized by abdominal pain, diarrhea, vomiting, and ulcers. *See* PLAGUE.

Tularemia is not transmitted directly from individual to individual. If the infected person or animal is untreated, blood remains infectious for 2 weeks and ulcerated lesions are infectious for a month. Deer flies (*Chrysops discalis*) are infective for 2 weeks, and ticks are infective throughout their lifetime (usually 2 years).

A number of antibacterial agents are effective against *F. tularensis*, the most effective being streptomycin. Penicillin and the sulfonamides have no therapeutic effect. *See* ANTIBIOTIC. [M.Ei.]

Tulip tree A tree *Liriodendron tulipfera*, also known in forestry as yellow poplar, belonging to the magnolia family, Magnoliaceae. One of the largest and most valuable hardwoods of eastern North America, it is native from southern New England and New York westward to southern Michigan, and south to Louisiana and northern Florida.

Botanically, this tree is distinguished by leaves which are squarish at the tip as if cut off, true terminal buds flattened and covered by two valvate scales, an aromatic odor resembling that of magnolia, and cone-shaped fruit which is persistent in winter. The name tulip refers to the large greenish-yellow and orange-colored flowers.

The wood of the tulip tree is light yellow to brown, hence the common name yellow poplar, which is a misnomer. It is a soft and easily worked wood, used for construction, interior finish, containers (boxes, crates, baskets), woodenware, excelsior, veneer, and sometimes for paper pulp. *See* MAGNOLIALES. [A.H.G./K.P.D.]

Tumbling mill A grinding and pulverizing machine consisting of a shell or drum rotating on a horizontal axis. The material to be reduced in size is fed into one end of the mill. The mill is also charged with grinding material such as iron balls. As the mill rotates, the material and grinding balls tumble against each other, the material being broken chiefly by attrition.

Tumbling mills are variously classified as pebble, ball, or rod depending on the grinding material, and as cylindrical, conical, or tube depending on the shell shape. *See* CRUSHING AND PULVERIZING; GRINDING MILL; PEBBLE MILL. [R.M.H.]

Tumor Literally, a swelling; in the past the term has been used in reference to any swelling of the body, no matter what the cause. However, the word is now being used almost exclusively to refer to a neoplastic mass, and the more general usage is being discarded.

A neoplastic mass or neoplasm is a pathological lesion characterized by the progressive or uncontrolled proliferation of cells. The cells involved in the neoplastic growth have an intrinsic heritable abnormality such that they are not regulated properly by normal methods. The stimulus which elicits this growth is not usually known.

It is common to divide tumors into benign or malignant. The decision as to which category a tumor should be assigned is usually based on information gained from gross or microscopic examination, or both. Benign neoplasms usually grow slowly, remain so localized that they cause little harm, and generally can be successfully and permanently removed. Malignant or cancerous neoplasms tend to grow rapidly, spread throughout the body, and recur if removed. Not all tumors which have been classified as benign are harmless to the host, and some can cause serious problems. Difficulties may occur as a result of mechanical pressure.

The cells of benign tumors are well differentiated. This means that the cells are very like the normal tissue in size, structure, and spatial relationship. The cells forming the tumor usually function normally. Cell proliferation usually is slow enough so that there is not a large number of immature cells. As the cellular mass increases in size, most benign tumors develop a fibrous capsule around them which separates them from the normal tissue. The cells of a benign tumor remain at the site of origin and do not spread throughout the body. Anaplasia (loss of differentiation) is not seen in benign tumors.

The cells of malignant tumors may be well differentiated, but most have some degree of anaplasia. Anaplastic cells tend to be larger than normal and are abnormal, even bizarre, in shape. The nuclei tend to be very large, and irregular, and they often stain darkly. Malignant tumors may be partially but never completely encapsulated. The cells of the cancer infiltrate and destroy surrounding tissue. They have the ability to metastasize; that is, cells from the primary tumor are disseminated to other regions of the body where they are able to produce secondary tumors called metastases.

In most cases the formation of a neoplasm is irreversible. It results from a permanent cellular defect which is passed on to daughter cells. Tumors should undergo medical appraisal to determine what treatment, if any, is needed. [N.K.M.; C.Qu.]

Tumor suppressor genes are a class of genes which, when mutated, predispose an individual to cancer. The mutations result in the loss of function of the particular tumor suppressor protein encoded by the gene. Although this class of genes was named for its link to human cancer, it is now clear that these genes play a critical role in the normal development, growth, and proliferation of cells and organs within the human body. The protein product of many tumor suppressor genes constrains cell growth and proliferation so that these events occur in a controlled manner. Thus, these genes appear to act in a manner antagonistic to that of oncogenes, which promote cell growth and proliferation.

The retinoblastoma (RB), p53, and p16 genes are the best-understood tumor suppressors . Inactivating mutations in the RB gene have been observed in retinoblastomas, osteosarcomas (cancer of the bone), as well as cancers of the lung, breast, and bladder. The p16 mutations have been observed in cancers of the skin, lung, breast, brain, bone, bladder, kidney, esophagus, and pancreas. The tumor suppressor p53 is the most frequently mutated gene associated with the development of many different types of human cancer, including those of the breast, lung, and colon. It is also associated with the rare inherited disease, Li-Fraumeni syndrome. Affected individuals manifest an increased likelihood of breast carcinomas, soft tissue sarcoma, brain tumors, osteosarcoma, leukemia, and adrenocortical carcinoma. Like RB and p16, p53 has a role in cell cycle regulation. In addition, p53 functions in the cell's decision on whether to undergo programmed cell death (apoptosis). Deregulaed cell proliferation and escape from apoptosis appear to be two common pathways leading to tumor formation. *See* CANCER (MEDICINE); GENE; GENE ACTION; MUTATION; ONCOLOGY; TUMOR VIRUSES. [M.Ew.]

Tumor viruses Viruses associated with tumors can be classified in two broad categories depending on the nucleic acid in the viral genome and the type of strategy to induce malignant transformation.

RNA viruses. The ribonucleic acid (RNA) tumor viruses are retroviruses. When they infect cells, the viral RNA is copied into deoxyribonucleic acid (DNA) by reverse transcription and the DNA is inserted into the host genome, where it persists and can be inherited by subsequent generation of cells. Transformation of the infected cells can be traced to oncogenes that are carried by the viruses but are not necessary for viral replication. The viral oncogenes are closely similar to cellular genes, the proto-oncogenes, which code for components of the cellular machinery that regulates cell proliferation, differentiation, and death. Incorporation into a retrovirus may convert proto-oncogenes into oncogenes in two ways: the gene sequence may be altered or truncated so that it codes for proteins with abnormal activity; or the gene may be brought under the control of powerful viral regulators that cause its product to be made in excess or in inappropriate circumstances. Retroviruses may also exert similar oncogenic effects by insertional mutation when DNA copies of the viral RNA are integrated into the host-cell genome at a site close to or even within proto-oncogenes. *See* RETROVIRUS.

RNA tumor viruses cause leukemias, lymphomas, sarcomas, and carcinomas in fowl, rodents, primates, and other species. The human T-cell leukemia virus (HTLV) types I and II are endemic in Southeast Asian populations and cause adult T-cell leukemia and hairy-cell leukemia. *See* AVIAN LEUKOSIS; LEUKEMIA; LYMPHOMA; ROUS SARCOMA.

DNA viruses. DNA viruses replicate lytically and kill the infected cells. Transformation occurs in nonpermissive cells where the infection cannot proceed to viral replication. The transforming ability of DNA tumor viruses has been traced to several viral proteins that cooperate to stimulate cell proliferation, overriding some of the normal growth control mechanisms in the infected cell and its progeny. Unlike retroviral oncogenes, DNA virus oncogenes are essential components of the viral genome and have no counterpart in the normal host cells. Some of these viral proteins bind to the protein products of two key tumor suppressor genes of the host cells, the retinoblastoma gene and the p53 gene, deactivating them and thereby permitting the cell to replicate its DNA and divide. Other DNA virus oncogenes interfere with the expression of cellular genes either directly or via interaction with regulatory factors. There is often a delay of several years between initial viral infection in the natural host species and the development of cancer, indicating that, in addition to virus-induced transformation, other environmental factors and genetic accidents are involved. A specific or general impairment of the host immune responses often plays an important role.

DNA tumor viruses belong to the families of papilloma, polyoma, adeno, hepadna, and herpes viruses and produce tumors of different types in various species. DNA tumor viruses are thought to play a role in the pathogenesis of about 15–20% of human cancers. These include Burkitt's lymphoma, nasopharyngeal carcinoma, immunoblastic lymphomas in immunosuppressed individuals and a proportion of Hodgkin's lymphomas that are all associated with the Epstein-Barr virus of the herpes family; and liver carcinoma associated with chronic hepatitis B virus infection. *See* ANIMAL VIRUS; CANCER (MEDICINE); EPSTEIN-BARR VIRUS; HODGKIN'S DISEASE; INFECTIOUS PAPILLOMATOSIS; MUTATION; ONCOLOGY. [M.G.Ma.]

Tuna Any of the large pelagic marine fishes which form the family Thunnidae, usually included in the order Perciformes. These fishes have a worldwide distribution.

The tunas have no scales on the posterior part of the body, and those on the anterior are fused to form an armored covering. The flesh of many is dark red. The body of these fish is streamlined, with a crescent-shaped tail and a narrow caudal peduncle. *See* PERCIFORMES. [C.B.C.]

Tundra An area supporting some vegetation beyond the northern limit of trees, between the upper limit of trees and the lower limit of perennial snow on mountains, and on the fringes of the Antarctic continent and its neighboring islands. The term is of Lapp or Russian origin, signifying treeless plains of northern regions. Biologists, and particularly plant ecologists, sometimes use the term tundra in the sense of the vegetation of the tundra landscape. Tundra has distinctive characteristics as a kind of landscape and as a biotic community, but these are expressed with great differences according to the geographic region.

Characteristically tundra has gentle topographic relief, and the cover consists of perennial plants a few inches to a few feet or a little more in height. The general appearance during the growing season is that of a grassy sward in the wetter areas, a matted spongy turf on mesic sites, and a thin or sparsely tufted lawn or lichen heath on dry sites. In winter, snow mantles most of the surface. By far, most tundra occurs where the mean annual temperature is below the freezing point of water, and perennial frost (permafrost) accumulates in the ground below the depth of annual thaw and to depths at least as great as 1600 ft (500 m). *See* PERMAFROST. [W.S.B.]

Tung tree The plant *Aleurites fordii*, a species of the spurge family (Euphorbiaceae). The tree, native to central and western

China, is the source of tung oil. It has been grown successfully in the southern United States. The globular fruit has three to seven large, hard, rough-coated seeds containing the oil, which is expressed after the seeds have been roasted. Tung oil is used to produce a hard, quick-drying, superior varnish, which is less apt to crack than other kinds. The foliage, sap, fruit, and commercial tung meal contain a toxic saponin, which causes gastroenteritis in animals that eat it. *See* Drying oil; Euphorbiales; Varnish.
[P.D.St./E.L.C.]

Tungsten A chemical element, W, atomic number 74, and atomic weight 183.85. Naturally occurring tungsten consists of five stable isotopes having the following mass numbers and relative abundances: 180 (0.14%), 182 (26.4%), 183 (14.4%), 184 (30.6%), and 186 (28.4%). Twelve radioactive isotopes ranging from 173 to 189 also have been characterized. *See* Periodic table.

Tungsten crystallizes in a body-centered cubic structure in which the shortest interatomic distance is 274.1 picometers at 25°C (77°F). The pure metal has a lustrous, silver-white appearance. It possesses the highest melting point, lowest vapor pressure, and the highest tensile strength at elevated temperature of all metals. Some important physical properties of tungsten are compiled in the table.

At room temperature tungsten is chemically resistant to water, oxygen, most acids, and aqueous alkaline solutions, but it is attacked by fluorine or a mixture of concentrated nitric and hydrofluoric acids.

Tungsten is used widely as a constituent in the alloys of other metals, since it generally enhances high-temperature strength. Several types of tool steels and some stainless steels contain tungsten. Heat-resistant alloys, also termed superalloys, are nickel-, cobalt-, or iron-based systems containing varying amounts (typically 1.5–25 wt %) of tungsten. Wear-resistant alloys having the trade name Stellites are composed mainly of cobalt, chromium, and tungsten. *See* Alloy; High-temperature materials.

The major use of tungsten in the United States is in the production of cutting and wear-resistant materials. Tungsten carbides (representing 60% of total tungsten consumption) are used for cutting tools, mining and drilling tools, dies, bearings, and armor-piercing projectiles.

Unalloyed tungsten (25% of tungsten consumption) in the form of wire is used as filaments in incandescent and fluorescent lamps, and as heating elements for furnaces and heaters. Because of its high electron emissivity, thorium-doped (thoriated) tungsten wire is employed for direct cathode electronic filaments. Tungsten rods find use as lamp filament supports, electrical contacts, and electrodes for arc lamps.

Tungsten compounds (5% of tungsten consumption) have a number of industrial applications. Calcium and magnesium tungstates are used as phosphors in fluorescent lights and television tubes. Sodium tungstate is employed in the fireproofing of fabrics and in the preparation of tungsten-containing dyes and pigments used in paints and printing inks. Compounds such as WO_3 and WS_2 are catalysts for various chemical processes in the petroleum industry. Both WS_2 and WSe_2 are dry, high-temperature lubricants. Other applications of tungsten compounds have been made in the glass, ceramics, and tanning industries.

Miscellaneous uses of tungsten account for the remainder (2%) of the metal consumed.
[C.Ku.]

Physical properties of tungsten

Property	Value
Melting point	3410 ± 20°C (6170 ± 36°F)
Boiling point	5700 ± 200°C (10,300 ± 360°F)
Density, 27°C (81°F)	19.3 g/cm^3 (11.2 oz/in.^{3})
Specific heat, 25°C (77°F)	0.032 cal/g-°C (0.13 J/g-°C)
Heat of fusion	52.2 ± 8.7 cal/g (218 ± 36 J/g)
Vapor pressure, 2027°C (3681°F)	6.4×10^{-12} atm (6.5×10^{-7} Pa)
3382°C (6120°F)	2.3×10^{-5} atm (2.3 Pa)
5470°C (9878°F)	0.53 atm (5.4×10^4 Pa)
Electrical resistivity, 27°C (81°F)	5.65 microhm-cm
1027°C (1881°F)	34.1
3027°C (5481°F)	103.3
Thermal conductivity, 27°C (81°F)	0.43 cal/cm-s-°C (1.8 J/cm-s-°C)
1027°C (1881°F)	0.27 (1.1)
Absorption cross section, 0.025-eV neutrons	18.5 ± 0.5 barns ($18.5 \pm 0.5 \times 10^{-24}$ cm^2)

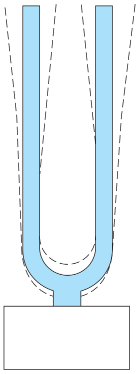
Tunicata A subphylum of marine animals (also known as Urochordata) of the Chordata. They are characterized by a perforated pharynx or branchial sac used for food collection, a dorsal notochord restricted to the tail of the larva (and the adult in one class), absence of mesodermal segmentation or a recognizable coelom, and secretion of an outer covering (the test or tunic) which contains large amounts of polysaccharides related to cellulose. Three classes are usually recognized: the sessile Ascidiacea (sea squirts or ascidians); planktonic Thaliacea (salps, doliolids, and pyrosomids); and Appendicularia, minute planktonic forms with tails living inside a specialized test or house adapted for filtering and food gathering. Approximately 2000 species of Tunicata are recognizable. The group is found in all parts of the ocean. Tunicates have little economic importance except as fouling organisms. A few species have pharmacological properties, and a few larger ascidians are used for food. *See* Appendicularia; Ascidiacea; Chordata; Thaliacea.
[I.Go.]

Tuning The process of adjusting the frequency of a vibrating system to obtain a desired result. In electronic circuits, there are a variety of frequency-determining elements. The most widely used is a combination of an inductance L (which stores energy in a magnetic field) and a capacitance C (which stores it in an electric field). The frequency of oscillation is determined by the rate of exchange of the energy between the two fields, and is inversely proportional to LC. Tuning is accomplished by adjusting the capacitor or the inductor until the desired frequency is reached. The desired frequency may be one that matches (resonates with) another frequency. Another purpose of tuning may be to match a frequency standard, as when setting an electronic watch to keep accurate time. The frequency-determining element in such watches, as well as in radio transmitters, digital computers, and other equipment requiring precise frequency adjustment, is a vibrating quartz crystal. The frequency of vibration of such crystals can be changed over a narrow range by adjusting a capacitor connected to it. *See* Quartz clock; Resonance (alternating-current circuits).

Another function of tuning in electronics is the elimination of undesired signals. Filters for this purpose employ inductors and capacitors, or crystals. The filter is tuned to the frequency of the undesired vibration, causing it to be absorbed elsewhere in the circuit. *See* Electric filter.

Automatic tuning by electrical control is accomplished by a varactor diode. This is a capacitor whose capacitance depends on the direct-current (dc) voltage applied to it. The varactor serves as a portion of the capacitance of the tuned circuit. Its capacitance is controlled by a dc voltage applied to it by an associated circuit, the voltage and its polarity depending on the extent and direction of the mismatch between the desired frequency and the actual frequency. *See* Varactor.
[D.G.F.]

Tuning fork A steel instrument consisting of two prongs and a handle which, when struck, emits a tone of fixed pitch. Because of their simple mechanical structure, purity of tone, and constant frequency, tuning forks are widely used as standards of frequency in musical acoustics. In its electrically driven form, a tuning fork serves to control electric circuits by producing



A tuning fork vibrating at its fundamental frequency.

frequency standards of high accuracy and stability. A tuning fork is essentially a transverse vibrator (see illustration). *See* VIBRATION. [L.E.K.]

Tunnel An underground space of substantial length, usually having a tubular shape. Tunnels can be either constructed or natural and are used as passageways, storage areas, carriageways, and utility ducts. They may also be used for mining, water supply, sewerage, flood prevention, and civil defense.

Tunnels are constructed in numerous ways. Shallow tunnels are usually constructed by burying sections of tunnel structures in trenches dug from the surface. This is a preferred method of tunneling as long as space is available and the operation will not cause disturbance to surface activities. Otherwise, tunnels can be constructed by boring underground. Short tunnels are usually bored manually or by using light machines. If the ground is too hard to bore, a drill-and-blast method is frequently used. For long tunnels, it is more economical and much faster to use tunneling boring machines which work on the full face (complete diameter of the opening) at the same time. In uniform massive rock formations without fissures or joints, tunnels can be bored without any temporary supports to hold up the tunnel crowns. However, temporary supports are usually required because of the presence of destabilizing fissures and joints in the rock mass. *See* DRILLING AND BORING, GEOTECHNICAL.

For tunnels to be constructed across bodies of water, an alternative to boring is to lay tunnel boxes directly on the prepared seabed. These boxes, made of either steel or reinforced concrete, are usually buried in shallow trenches dug for this purpose and covered by ballast so they will not be affected by the movement of the water. The joints between tunnel sections are made watertight by using rubber gaskets, and water is pumped out of the tunnel to make it ready for service. *See* CONCRETE; STEEL. [Z.C.M.; R.N.Hw.]

Tunnel diode A two-terminal semiconductor junction device (also called the Esaki diode) which does not show rectification in the usual sense, but exhibits a negative resistance region at very low voltage in the forward-bias characteristic and a short circuit in the negative-bias direction.

This device is a version of the semiconductor *pn* junction diode which is made of a *p*-type semiconductor, containing mobile positive charges called holes (which correspond to the vacant electron sites), and an *n*-type semiconductor, containing mobile electrons (the electron has a negative charge). The densities of holes and electrons in the respective regions are made extremely high by doping a large amount of the appropriate impurities with an abrupt transition from one region to the other. In semiconductors, the conduction band for mobile electrons is separated from the valence band for mobile holes by an energy gap, which corresponds to a forbidden region. Therefore, a narrow transition layer from *n*-type to *p*-type, 5 to 15 nanometers thick, consisting of the forbidden region of the energy gap, provides a tunneling barrier. Since the tunnel diode exhibits a negative incremental resistance with a rapid response, it is capable of serving as an active element for amplification, oscillation, and switching in electronic circuits at high frequencies. The discovery of the diode, however, is probably more significant from the scientific aspect because it opened up a new field of research—tunneling in solids. *See* BAND THEORY OF SOLIDS; JUNCTION DIODE; NEGATIVE-RESISTANCE CIRCUITS; SEMICONDUCTOR; SEMICONDUCTOR DIODE; TUNNELING IN SOLIDS. [L.E.]

Tunneling in solids A quantum-mechanical process which permits electrons to penetrate from one side to the other through an extremely thin potential barrier to electron flow. The barrier would be a forbidden region if the electron were treated as a classical particle. A two-terminal electronic device in which such a barrier exists and primarily governs the transport characteristic (current-voltage curve) is called a tunnel junction. *See* QUANTUM MECHANICS.

During the infancy of the quantum theory, L. de Broglie introduced the fundamental hypothesis that matter may be endowed with a dualistic nature—particles such as electrons, alpha particles, and so on, may also have the characteristics of waves. This hypothesis found expression in the definite form now known as the Schrödinger wave equation, whereby an electron or an alpha particle is represented by a solution to this equation. The nature of such solutions implies an ability to penetrate classically forbidden regions of negative kinetic energy and a probability of tunneling from one classically allowed region to another. The concept of tunneling, indeed, arises from this quantum-mechanical result. The subsequent experimental manifestations of this concept, such as high-field electron emission from cold metals, alpha decay, and so on, in the 1920s, can be regarded as one of the early triumphs of the quantum theory. *See* FIELD EMISSION; RADIOACTIVITY; SCHRÖDINGER'S WAVE EQUATION.

The tunnel diode (also called the Esaki diode), discovered in 1957 by L. Esaki, demonstrated the first convincing evidence of electron tunneling in solids. *See* TUNNEL DIODE.

Negative resistance phenomena can be observed in novel tunnel structures in semiconductors. Double tunnel barriers and periodic structures with a combination of semiconductors exhibit resonant tunneling and negative resistance effects. *See* SEMICONDUCTOR HETEROSTRUCTURES.

Tunneling had been considered to be a possible electron transport mechanism between metal electrodes separated by either a narrow vacuum or a thin insulating film usually made of metal oxides. In 1960, I. Giaever demonstrated that, if one or both of the metals were in a superconducting state, the current-voltage curve in such metal tunnel junctions revealed many details of that state.

In 1962, B. Josephson made a penetrating theoretical analysis of tunneling between two superconductors by treating the two superconductors and the coupling process as a single system, which would be valid if the insulating oxide were sufficiently thin, say 2 nanometers. His theory predicted the existence of a supercurrent, arising from tunneling of the bound electron pairs. This led to two startling conclusions: the dc and ac Josephson effects. The dc effect implies that a supercurrent may flow even if no voltage is applied to the junction. The ac effect implies that, at finite voltage V, there is an alternating component of the supercurrent which oscillates at a frequency of 483.6 MHz per microvolt of voltage across the junction, and is typically in the microwave range. *See* JOSEPHSON EFFECT. [L.E.]

Tupelo A tree belonging to the genus *Nyssa* of the sour gum family, Nyssaceae. The most common species is *N. sylvatica*, variously called pepperidge, black gum, or sour gum, the authorized name being black tupelo. Tupelo grows in the easternmost third of the United States; southern Ontario, Canada; and Mexico.

The tree can be identified by the comparatively small, obovate, shiny leaves and by branches that develop at a wide angle from the axis. The fruit is a small blue-black drupe, a popular food for birds. The wood is yellow to light-brown and hard to split because of the twisted grain. Tupelo is used for boxes, baskets, and berry crates, and as backing on which veneers of rarer and more expensive woods are glued. It is also used for flooring, rollers in glass factories, hatters' blocks, and gunstocks. *See* MYRTALES. [A.H.G./K.P.D.]

Turbellaria A class of the phylum Platyhelminthes commonly known as the flatworms. These animals are chiefly free-living and have simple life histories. The bodies are elongate and flat to oval or circular in cross section. Their length ranges from less than 0.04 in. (1 mm) to several inches, but may exceed 20 in. (50 cm) in land planaria. Large forms are often brightly colored. This class, which numbers some 3400 described species, is ordinarily subdivided into the orders Acoela, with 200 species; Rhabdocoela, 1110 species; Alloeocoela, 350 species; Tricladida, 1000 species; and Polycladida, 750 species. Although widely distributed in fresh and salt water and moist soil, they are usually overlooked because of their generally small size, secretive habits, and inconspicuous color. *See* ACOELA; ALLOEOCOELA; POLYCLADIDA; RHABDOCOELA; TRICLADIDA. [E.R.J.]

Turbidite A bed of sediment or sedimentary rock that was deposited from a turbidity current. The term turbidite is fundamentally genetic and interpretive in nature, rather than being a descriptive term (like common rock names). Turbidites are clastic sedimentary rocks, but they may be composed of silicic grains (quartz, feldspar, rock fragments) and therefore be a type of sandstone, or they may be composed of carbonate grains and therefore be a type of limestone. A geologist's description of a rock as a turbidite is actually an expression of an opinion that the rock was deposited by a turbidity current, rather than being a description of a particular type of rock. *See* TURBIDITY CURRENT.

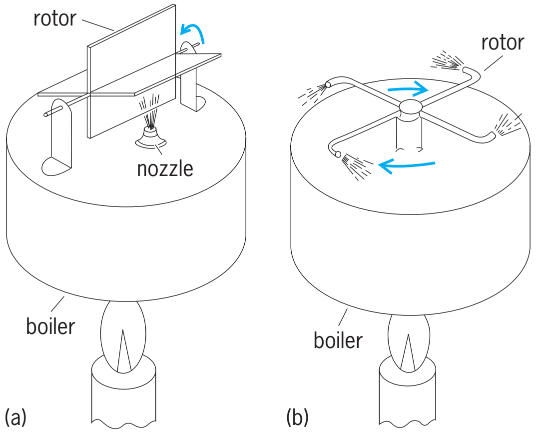
No single feature of a deposit is sufficient to identify it as a turbidite and not all turbidites are marine. There are well-documented examples of modern turbidity currents and turbidites described from lakes. Although probably most turbidites were originally deposited in water of considerable depth (hundreds to thousands of meters), it is generally difficult to be specific about estimating the depth of deposition. The most that can be said is that (in most cases) there is no sign of sedimentary structures formed by the action of waves. *See* DEPOSITIONAL SYSTEMS AND ENVIRONMENTS; SEDIMENTARY ROCKS; SEDIMENTOLOGY. [G.V.M.]

Turbidity current A flow of water laden with sediment that moves downslope in an otherwise still body of water. The driving force of a turbidity current is obtained from the sediment, which renders the turbid water heavier than the clear water above. Turbidity currents occur in oceans, lakes, and reservoirs. They may be triggered by the direct inflow of turbid water, by wave action, by subaqueous slumps, or by anthropogenic activities such as dumping of mining tailings and dredging operations.

Turbidity currents are characterized by a well-defined front, also known as head, followed by a thinner layer known as the body of the current. They are members of a larger class of stratified flows known as gravity or density currents. Sediment can be entrained from or deposited on the bed, thus changing the total amount of sediment in suspension. A turbidity current must generate enough turbulence to hold its sediment in suspension. Under certain conditions, a turbidity current might erode its bed, pick up sediment, become heavier, accelerate, and pick up even more sediment, increasing its driving force in a self-reinforcing cycle akin to the formation of a snow avalanche. *See* DEPOSITIONAL SYSTEMS AND ENVIRONMENTS.

Turbidity currents constitute a major mechanism for the transport of fluvial, littoral, and shelf sediments onto the ocean floor. These flows are considered to be responsible for the scouring of submarine and sublacustrine canyons. These canyons are often of massive proportions and rival the Grand Canyon in scale. Below the mouths of most canyons, turbidity currents form vast depositional fans that have many of the features of alluvial fans built by rivers and constitute major hydrocarbon reservoirs. The sedimentary deposits created by turbidity currents, known as turbidites, are a major constituent of the geological record. *See* MARINE GEOLOGY; MARINE SEDIMENTS; SUBMARINE CANYON; TURBIDITE. [M.H.Ga.]

Turbine A machine for generating rotary mechanical power from the energy in a stream of fluid. The energy, originally in the form of head or pressure energy, is converted to velocity energy by passing through a system of stationary and moving blades in the turbine. Changes in the magnitude and direction of the fluid velocity are made to cause tangential forces on the rotating blades, producing mechanical power via the turning rotor. Turbines effect the conversion of fluid to mechanical energy through the principles of impulse, reaction, or a mixture of the two (see illustration).



Turbine principles. (*a*) Impulse. (*b*) Reaction.

The fluids most commonly used in turbines are steam, hot air or combustion products, and water. Steam raised in fossil fuel-fired boilers or nuclear reactor systems is widely used in turbines for electrical power generation, ship propulsion, and mechanical drives. The combustion gas turbine has these applications in addition to important uses in aircraft propulsion. Water turbines are used for electrical power generation. *See* GAS TURBINE; HYDRAULIC TURBINE; IMPULSE TURBINE; PELTON WHEEL; REACTION TURBINE; STEAM TURBINE; TURBINE PROPULSION; TURBOJET. [F.G.B.]

Turbine propulsion Propulsion of a vehicle by means of a gas turbine. Gas turbines have come to dominate most areas of common carrier aircraft propulsion, have made significant inroads into the propulsion of surface ships, and are being incorporated into military tanks.

The primary power producer common to all gas turbines used for propulsion is the core or gas generator, operating on a continuous flow of air as working fluid. The air is compressed in a rotating compressor, heated at constant pressure in a combustion chamber burning a liquid hydrocarbon fuel, and expanded through a core turbine which drives the compressor. This manifestation of the Brayton thermodynamic cycle generates a continuous flow of high-pressure, high-temperature gas which is the primary source of power for a large variety of propulsion schemes. The turbine is generally run as an open cycle; that is, the airflow is ultimately exhausted to the atmosphere rather than being recycled to the inlet. *See* BRAYTON CYCLE.

The residual energy available in the high-temperature, high-pressure airstream exiting from the core is used for propulsion in a variety of ways. For traction-propelled vehicles (buses, trucks, automobiles, military tanks, and most railroad locomotives), the core feeds a power turbine which extracts the available energy from the core exhaust and provides torque to a high-speed drive shaft as motive power for the vehicle. With a free-turbine arrangement, this power turbine is a separate shaft, driving at a speed not mechanically linked to the core speed. With a fixed turbine, this power turbine is on the same shaft as the core turbine, and must drive at the same speed as the core spool. In traction vehicles the power turbine generally drives through a transmission system which affords a constant- or a variable-speed reduction to provide the necessary torque-speed characteristics to the traction wheels.

Aircraft, ships, and high-speed land vehicles, which cannot be driven by traction, are propelled by reaction devices. Some of the ambient fluid around the vehicle (that is, the water for most ships, and the air for all other vehicles) is accelerated by some turbomachinery (a ship propeller, aircraft propeller, helicopter rotor, or a fan integrated with the core to constitute a turbofan engine). The reaction forces on this propulsion turbomachinery, induced in the process of accelerating the ambient flow, provide the propulsion thrust to the vehicle. In all these cases, motive power to the propeller or fan is provided by a power turbine extracting power from the gas generator exhaust. In the case of a jet engine, exhaust from the gas generator is accelerated through a jet nozzle, so that the reaction thrust is evolved in the gas generator rather than in an auxiliary propeller or fan. Indeed, in turboprop and turbofan engines, both forms of reaction thrust (from the stream accelerated by the propeller or fan and from the stream accelerated by the core and not fully extracted by the power turbine) are used for propulsion. *See* GAS TURBINE; JET PROPULSION; TURBOFAN; TURBOJET; TURBOPROP. [F.F.E.]

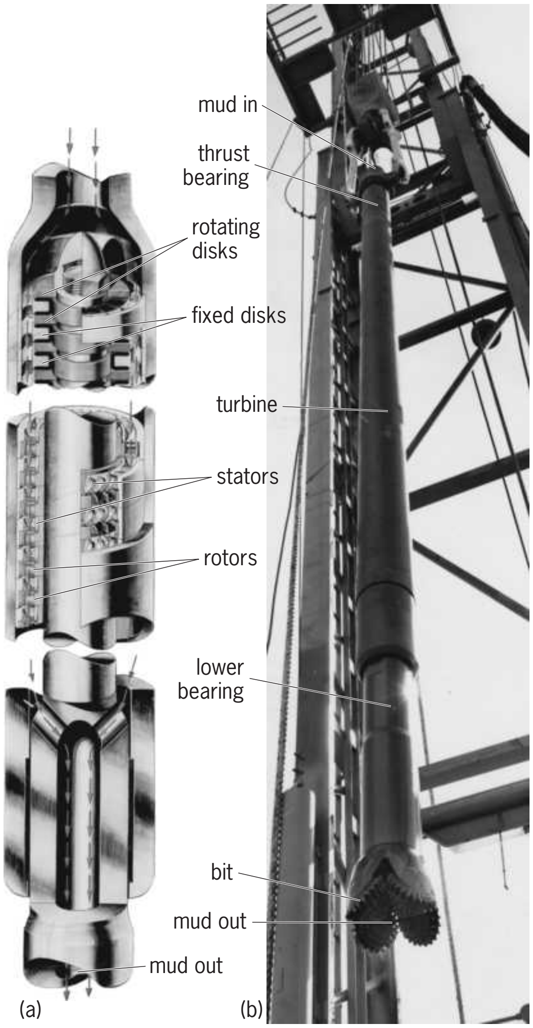
Turbocharger An air compressor or supercharger on an internal combustion piston engine that is driven by the engine exhaust gas to increase or boost the amount of fuel that can be burned in the cylinder, thereby increasing engine power and performance. On an aircraft piston engine, the turbocharger allows the engine to retain its sea-level power rating at higher altitudes despite a decrease in atmospheric pressure. *See* RECIPROCATING AIRCRAFT ENGINE; SUPERCHARGER.

The turbocharger is a turbine-powered centrifugal supercharger. It consists of a radial-flow compressor and turbine mounted on a common shaft. The turbine uses the energy in the exhaust gas to drive the compressor, which draws in outside air, precompresses it, and supplies it to the cylinders at a pressure above atmospheric pressure.

Common turbocharger components include the rotor assembly, bearing housing, and compressor housing. The shaft bearings usually receive oil from the engine lubricating system. Engine coolant may circulate through the housing to aid in cooling. *See* ENGINE COOLING; INTERNAL COMBUSTION ENGINE. [D.L.An.]

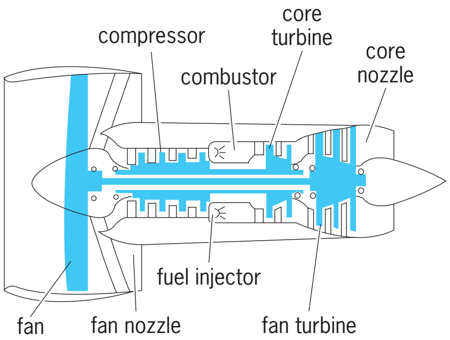
Turbodrill A rotary tool used in drilling oil or gas wells in which the bit is rotated by a turbine motor inside the well. The principal difference between rotary and turbodrilling lies in the manner in which power is applied to the rotating bit or cutting tool. In the rotary method, the bit is attached to a drill pipe rotated through power supplied on the surface. In the turbodrill method, power is generated at the bottom of the hole by a mud-operated turbine. *See* ROTARY TOOL DRILL.

The turbodrill (see illustration) consists of four basic components: the upper, or thrust, bearing; the turbine; the lower bearing; and the bit. In operation, mud is pumped through the drill pipe, passing through the thrust bearing and into the turbine. In the turbine, stators attached to the body of the tool divert the mud flow onto rotors attached to the shaft. This causes the shaft, which is connected to the bit, to rotate. The mud passes through a hollow part of the shaft in the lower bearing and through the bit, as in rotary drilling, to remove cuttings, cool the bit, and perform the other functions of drilling fluid. Capacity of the mud pump, which is the power source, determines rotational speed. *See* OIL AND GAS WELL DRILLING; TURBINE. [A.L.P.]



The components of a turbodrill. (*a*) Cutaway view of turbine, bearings, and bit. (*b*) Drill string suspended above hole. (*Dresser Industries*)

Turbofan An air-breathing aircraft gas turbine engine with operational characteristics between those of the turbojet and the turboprop. Like the turboprop, the turbofan consists of a compressor-combustor-turbine unit, called a core or gas generator, and a power turbine. This power turbine drives a low- or medium-pressure-ratio compressor, called a fan, some or most

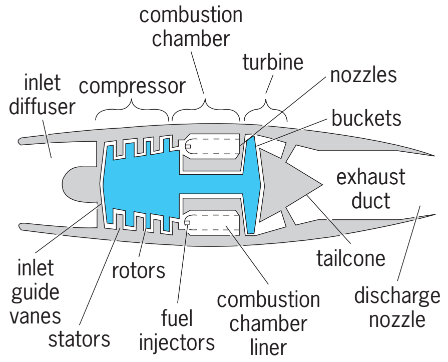


High-bypass, separate-flow turbofan configuration.

of whose discharge bypasses the core (see illustration). *See* Turbojet; Turboprop.

The gas generator produces useful energy in the form of hot gas under pressure. Part of this energy is converted by the power turbine and the fan it drives into increased pressure of the fan airflow. This airflow is accelerated to ambient pressure through a fan jet nozzle and is thereby converted into kinetic energy. The residual core energy is converted into kinetic energy by being accelerated to ambient pressure through a separate core jet nozzle. The reaction in the turbomachinery in producing both streams produces useful thrust. *See* Gas turbine; Turbine propulsion. [F.F.E.]

Turbojet A gas turbine power plant used to propel aircraft, where the thrust is derived within the turbo-machinery in the process of accelerating the air and products of combustion out an exhaust jet nozzle. *See* Gas turbine.



Basic turbojet engine with axial-flow components.

In its most elementary form (see illustration), the turbojet operates on the gas turbine or Brayton thermodynamic cycle. The working fluid, air drawn into the inlet of the engine, is first compressed in a turbo-compressor with a pressure ratio of typically 10:1 to 20:1. The high-pressure air then enters a combustion chamber, where a steady flow of a hydrocarbon fuel is introduced in either spray or vapor form and burned continuously at constant pressure. The exiting stream of hot high-pressure air, at an average temperature whose maximum value may range typically from 1800 to 2800°F (980 to 1540°C), is then expanded through a turbine, where energy is extracted to power the compressor. Because heat had been added to the air at high pressure, there is a surplus of energy left in the stream of combustion products that exits from the turbine and that can be harnessed for propulsion. *See* Brayton cycle; Gas turbine.

Turbojets have retained a small niche in the aircraft propulsion spectrum, where their simplicity and low cost are of paramount importance, such as in short-range expendable military missiles, or where their light weight may be an overriding consideration, such as for lift jets in prospective vertical takeoff and landing aircraft. *See* Aircraft propulsion; Jet propulsion; Turbine propulsion; Vertical takeoff and landing (VTOL). [F.F.E.]

Turboprop A gas turbine power plant producing shaft power to drive a propeller or propellers for aircraft propulsion. Because of its high propulsive efficiency at low flight speeds, it is the power plant of choice for short-haul and low-speed transport aircraft where the flight speeds do not exceed Mach 0.5–0.6. Developments in high-speed, highly loaded propellers have extended the range of propellers to flight speeds up to Mach 0.8–0.9, and there are prospects of these extremely efficient prop-fans assuming a much larger role in powering high-speed transport aircraft. *See* Gas turbine.

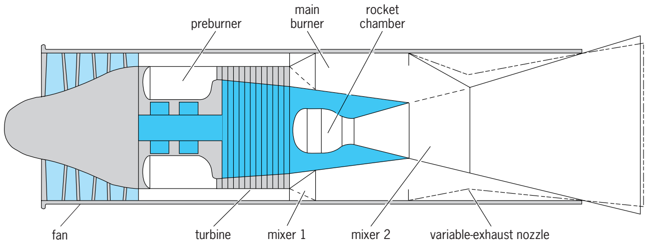
As with all gas turbine engines, the basic power production in the turboprop is accomplished in the gas generator or core of the engine, where a steady stream of air drawn into the engine inlet is compressed by a turbocompressor. The high-pressure air is next heated in a combustion chamber by burning a steady stream of hydrocarbon fuel injected in spray or vapor form. The hot, high-pressure air is then expanded in a turbine that is mounted on the same rotating shaft as the compressor and supplies the energy to drive the compressor. By virtue of the air having been heated at higher pressure, there is a surplus of energy in the turbine that may be extracted in additional turbine stages to drive a useful load, in this case a propeller or propellers.

A large variety of detailed variations are possible within the core. The compressor may be an axial-flow type, a centrifugal (that is, radial-flow) type, or a combination of stages of both types (that is, an axi-centrifugal compressor). In modern machines, the compressor may be split in two sections (a low-pressure unit followed by a high-pressure unit), each driven by its own turbine through concentric shafting, in order to achieve very high compression ratios otherwise impossible in a single spool. *See* Aircraft propulsion; Compressor; Propeller (aircraft); Turbine propulsion. [F.F.E.]

Turboramjet An aircraft engine that is a hybrid of a turbofan and a ramjet. When operated as a ramjet, the engine is capable of relatively efficient propulsion for flight at very high supersonic cruise speeds in the range of Mach numbers 5 to 6. The engine can also be operated as a turbofan engine to give it the capability of relatively efficient propulsion for the low-flight-speed segments of the aircraft's mission such as takeoff, acceleration, approach, and landing. One variation of the engine also includes a rocket engine, which gives the system the additional capability of transatmospheric propulsion. *See* Ramjet; Rocket propulsion; Turbofan.

For operation at subsonic and transonic flight speeds, fuel together with an appropriate amount of an oxidizer such as liquid oxygen is introduced into the preburner in the middle of the engine, where the mixture is burned (see illustration). The resultant hot high-pressure gas stream is expanded through a turbine that drives the fuel and oxidizer pumps and also powers a large fan in the front of the engine. The front-fan discharge air bypasses the preburner and tubine and enters the main burner through a mixer, where it joins the gas stream exiting from the turbine. The stream of mixed gases is then accelerated through a variable-area exhaust nozzle to provide the required propulsive thrust. Thrust augmentation may be obtained by injecting an excess of fuel in the preburner so that, when the fan air is mixed with the fuel-rich turbine exhaust, additional combustion, or afterburning, takes place in the main burner. *See* Afterburner.

At very high flight speed, with air at very high ram pressure entering the engine, the pumping action of the fan is no longer necessary and the fan may be feathered, or otherwise made inoperative, while permitting the ram air to pass through. Propulsion is now provided exclusively by the combustion of the ram air in the main burner with the fuel-rich gas stream from the preburner.



Section drawing of an air turboramjet with rocket combustion chamber for exoatmospheric flight. Such a power plant would combine turbojet, ramjet, and rocket propulsion modes. (*Aerojet*)

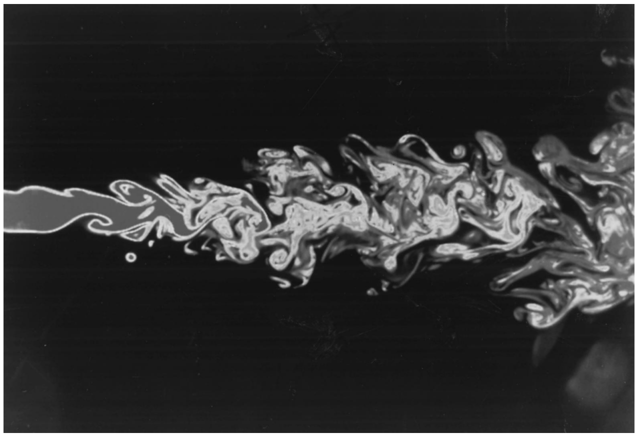
For aircraft that are designed to proceed from high-speed atmospheric flight to transatmospheric flight, a rocket chamber may be provided in the engine where fuel and oxidant are burned in greater quantity than is possible in the preburner, and the exhaust stream may be discharged through the thrust nozzle without having to pass through the turbine. *See* TURBINE PROPULSION. [F.F.E.]

Turbulent flow A fluid motion in which velocity, pressure, and other flow quantities fluctuate irregularly in time and space. The illustration shows a slice of a water jet emerging from a circular orifice into a tank of still water. A small amount of fluorescent dye mixed in the jet makes it visible when suitably illuminated by laser light, and tags the water entering the tank. There is a small region close to the orifice where the dye concentration does not vary with position, or with time at a given position. This represents a steady laminar state. Generally in laminar motion, all variations of flow quantities, such as dye concentration, fluid velocity, and pressure, are smooth and gradual in time and space. Farther downstream, the jet undergoes a transition to a new state in which the eddy patterns are complex, and flow quantities (including vorticity) fluctuate randomly in time and three-dimensional space. This is the turbulent state. *See* JET FLOW; LAMINAR FLOW.

Turbulence occurs nearly everywhere in nature. It is characterized by the efficient dispersion and mixing of vorticity, heat, and contaminants. In flows over solid bodies such as airplane wings or turbine blades, or in confined flows through ducts and pipelines, turbulence is responsible for increased drag and heat transfer. Turbulence is therefore a subject of great engineering interest. On the other hand, as an example of collective interaction of many coupled degrees of freedom, it is also a subject at the forefront of classical physics. *See* DEGREE OF FREEDOM (MECHANICS); DIFFUSION; HEAT TRANSFER; PIPE FLOW; PIPELINE.

The illustration demonstrates the principal issues associated with turbulent flows. The first is the mechanism (or mechanisms) responsible for transition from the steady laminar state to the turbulent state. A second issue concerns the description of fully developed turbulence typified by the complex state far downstream of the orifice. Finally, it is of technological importance to be able to alter the flow behavior to suit particular needs. Less is known about eddy motions on the scale of centimeters and millimeters than about atomic structure on the subnanometer scale, reflecting the complexity of the turbulence problem. *See* NAVIER-STOKES EQUATION.

Origin of turbulence. A central role in determining the state of fluid motion is played by the Reynolds number. In general, a given flow undergoes a succession of instabilities with increasing Reynolds number and, at some point, turbulence appears more or less abruptly. It has long been thought that the origin of turbulence can be understood by sequentially examining the instabilities. This sequence depends on the particular flow and, in many circumstances, is sensitive to a number of details. A careful analysis of the perturbed equations of motion has resulted in a good understanding of the first two instabilities in a variety of circumstances. *See* REYNOLDS NUMBER.



Two-dimensional image of an axisymmetric water jet, obtained by the laser-induced fluorescence technique. (*From R. R. Prasad and K. R. Sreenivasan, Measurement and interpretation of fractal dimension of the scalar interface in turbulent flows, Phys. Fluids A, 2:792–807, 1990*)

Fully developed turbulence. Quite often in engineering, the detailed motion is not of interest, but only the long-time averages or means, such as the mean velocity in a boundary layer, the mean drag of an airplane or pressure loss in a pipeline, or the mean spread rate of a jet. It is therefore desirable to rewrite the Navier-Stokes equations for the mean motion. The basis for doing this is the Reynolds decomposition, which splits the overall motion into the time mean and fluctuations about the mean. These macroscopic fluctuations transport mass, momentum, and matter (in fact, by orders of magnitude more efficiently than molecular motion), and their overall effect is thus perceived to be in the form of additional transport or stress. This physical effect manifests itself as an additional stress (called the Reynolds stress) when the Navier-Stokes equations are rewritten for the mean motion (the Reynolds equations). The problem then is one of prescribing the Reynolds stress, which contains the unknown fluctuations in quadratic form. A property of turbulence is that the Reynolds stress terms are comparable to the other terms in the Reynolds equation, even when fluctuations are a small part of the overall motion. An equation for the Reynolds stress itself can be obtained by suitably manipulating the Navier-Stokes equations, but this contains third-order terms involving fluctuations, and an equation for third-order terms involves fourth-order quantities, and so forth. This is the closure problem in turbulence. The Navier-Stokes equations are themselves closed, but the presence of nonlinearity and the process of averaging result in nonclosure.

Given this situation, much of the progress in the field has been due to (1) exploratory experiments and numerical simulations of the Navier-Stokes equations at low Reynolds numbers; and (2) plausible hypotheses in conjunction with dimensional reasoning, scaling arguments, and their experimental verification.

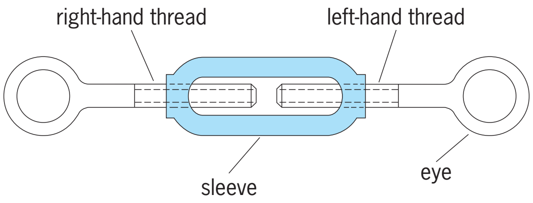
Control of turbulent flows. Some typical objectives of flow control are the reduction of drag of an object such as an airplane wing, the suppression of combustion instabilities, and the suppression of vortex shedding behind bluff bodies. Interest in flow control has been stimulated by the discovery that some turbulent flows possess a certain degree of spatial coherence at large scales. Successful control has also been achieved through the reduction of the skin friction on a flat plate by making small longitudinal grooves, the so-called riblets, on the plate surface, imitating shark skin. *See* FLUID FLOW; FLUID-FLOW PRINCIPLES. [K.R.S.]

Turmeric A dye or a spice obtained from the plant *Curcuma longa*, which belongs to the ginger family (Zingiberaceae). It is a stout perennial with short stem, tufted leaves, and short, thick rhizomes which contain the colorful condiment. As a natural dye, turmeric is orange-red or reddish brown, but it changes color in the presence of acids or bases. As a spice, turmeric has a decidedly musky odor and a pungent, bitter taste. It is an important item in curry and is used to flavor and color butter, cheese, pickles, and other food. *See* SPICE AND FLAVORING; ZINGIBERALES. [P.D.St./E.L.C.]

Turn and bank indicator A combination instrument which provides an aircraft pilot with two distinct pieces of information: the aircraft's rate of turn about the vertical axis, and the relationship between this rate and the aircraft's angle of bank. It is also known as the needle and ball indicator or the turn and slip indicator. The turn needle is operated by a gyroscope and indicates the rate at which the aircraft is turning about the vertical axis in degrees per second. In a turn, gyroscopic precession causes the rotor to tilt in the direction opposite the turn with a magnitude proportional to the turn rate. A mechanical linkage converts this precession to reversed movement of a turn needle, thus indicating proper turn direction. *See* GYROSCOPE.

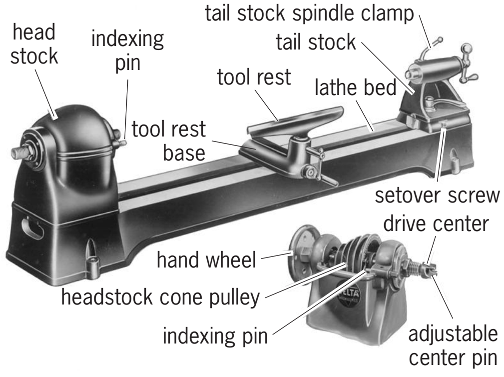
The bank or slip indicator is a simple inclinometer consisting of a curved glass tube containing fluid and a black ball bearing which is free to move in the fluid. The indicator is actually a balance indication, showing the relationship between the rate of turn and the angle of bank of the aircraft. *See* AIRCRAFT INSTRUMENTATION; ROTATIONAL MOTION. [G.W.W.]

Turnbuckle A device for tightening a rod or wire rope. Its parts are a sleeve with a screwed connection at one end and a swivel at the other or, more commonly, a sleeve with screwed connections of opposite hands (left and right) at each end so that by turning the sleeve, the connected parts will be drawn together, taking up slack and producing tension (see illustration). Types of ends are hook, eye, and clevis. The turn-buckle can be connected at any convenient place in the rod or rope, and several may be used in series if required. [P.H.B.]



Turnbuckle with eyes.

Turning (woodworking) The shaping of wood by rotating it in a lathe and cutting it with a chisel. The lathe consists essentially of a bed on which are mounted a headstock, a tailstock, and a tool rest (see illustration). The headstock is rotated by a motor and holds one end of the wood to be turned. The tailstock holds the other end of the wood, allowing it to rotate freely. The tool rest provides a fixed guide along which the operator can handle the chisels if the turning is by hand, or along which the tool is driven if the turning is mechanized. *See* WOODWORKING. [A.H.T.]



Wood-turning lathe and detail of headstock. (*Delta*)

Turnip The plant *Brassica rapa*, or *B. campestris* var. *rapa*, a cool-season, hardy crucifer of Asiatic origin belonging to the order Capparales which is grown for its enlarged root and its foliage, which are eaten cooked as a vegetable. Popular white-fleshed varieties (cultivars) grown for their roots are Purple Top Globe and White Milan; Yellow Globe and Golden Ball are common yellow-fleshed varieties. Shogoin is a popular variety grown principally in the southern United States for turnip greens. Principal areas of production in the United States are in the South. *See* CAPPARALES. [H.J.C.]

Turquoise A mineral of composition $CuAl_6(PO_4)_4(OH)_8 \cdot 5H_2O$ in which considerable ferrous ion (Fe^{2+}) may substitute for copper. Ferric ion (Fe^{3+}) may also substitute for part or all of the aluminum (Al), forming a complete chemical series from turquoise to chalcosiderite [$CuFe_6(PO_4)_4(OH)_8 \cdot 5H_2O$]. Turquoise with a strong sky-blue or bluish-green to apple green color is easily recognized, and such material is commonly used as a gem. Some variscite, of composition $AlPO_4 \cdot 2H_2O$ with minor chemical substitutions of Fe^{3+} and or chromium ion (Cr^{3+}) for aluminum and with a soft, clear green color, may be marketed as green turquoise. *See* GEM.

Most turquoise is massive, dense, and cryptocrystalline to fine-granular. It commonly occurs as veinlets or crusts and in stalactitic or concretionary shapes. It has a hardness on the Mohs scale of about 5 to 6 and a vitreous to waxy luster. The distinctive light blue coloration of much turquoise is the result of the presence of cuprous ion (Cu^{2+}); limited substitution of the copper by Fe^{2+} produces greenish colors. *See* HARDNESS SCALES.

Turquoise is a secondary mineral, generally formed in arid regions by the interaction of surface waters with high-alumina igneous or sedimentary rocks. It occurs most commonly as small veins and stringers traversing more or less decomposed volcanic rocks. Since the times of antiquity, turquoise of very fine quality has been produced from a deposit in Persia (now Iran) near Nishapur. It occurs also in Siberia, Turkistan, China, the Sinai Peninsula, Germany, and France.

The southwestern United States has been a major source of turquoise, especially the states of Nevada, Arizona, New Mexico, and Colorado. Extensive deposits in the Los Cerillos Mountains, near Santa Fe, New Mexico, were mined very early by Native Americans and were a major early source of gem turquoise. However, much of the gem-quality turquoise has been depleted in the Southwest. [C.K.]

Twilight The period between sunset and darkness in the evening, and between darkness and sunrise in the morning. The characteristic light is caused by atmospheric scattering, which transmits sunlight to the observer for some time after sunset and before sunrise. It depends geometrically on latitude, longitude, and elevation of the observer, and on the time of year. Physically it depends also on local conditions, particularly the weather. [G.M.C.]

Twinkling stars A phenomenon by which light from the stars, as it passes through fluctuations in the Earth's atmosphere, is rapidly modulated and redirected to make the starlight appear to flicker. The twinkling phenomenon affects all wavelengths that manage to penetrate the Earth's atmosphere, from the visible to the radio wavelengths. At visible wavelengths, atmospheric fluctuations are caused predominantly by temperature irregularities along the line of sight. Such irregularities introduce slight changes in the index of refraction of air, and these changes affect light waves in two ways: they modulate the intensity of the light, and they deflect the light waves in one direction and then another. At radio wavelengths, electron density irregularities in the ionosphere modulate and redirect radio waves. *See* REFRACTION OF WAVES.

The twinkling phenomenon is of utmost interest to astronomers who view the skies from ground-based telescopes. While modulation variations are present, it is the deflection of light that causes the most serious problems. The composite star image produced by a large telescope is a blurry circle that results when the randomly deflected light waves are added together in an extended time exposure. To diminish atmospheric effects, telescopes are built on high mountains, and are placed at least 30–45 m (100– 150 ft) above the ground. *See* ASTRONOMICAL OBSERVATORY.

To completely remove the twinkling effects of the atmosphere, there are two alternatives. The first is to place a telescope in orbit above the atmosphere, as with the Hubble Space Telescope. The second alternative is to monitor the random deflections of the atmosphere and, within the telescope, to bend the deflected light back onto its original path. This optical technique is given the name adaptive optics. *See* ADAPTIVE OPTICS; SATELLITE ASTRONOMY. [L.A.T.]

Twinning (crystallography)

A process in which two or more crystals, or parts of crystals, assume orientations such that one may be brought to coincidence with the other by reflection across a plane or by rotation about an axis. Crystal twins represent a particularly symmetric kind of grain boundary; however, the energy of the twin boundary is much lower than that of the general grain boundary because some of the atoms in the twin interface are in the correct positions relative to each other. *See* GRAIN BOUNDARIES. [R.M.T.]

Twins (human)

Two babies born to a mother at one birth. There are two types of twins, monozygotic and dizygotic. Members of a twin pair are called co-twins.

Controversy surrounding the definition of a twin arose with the advent of reproductive technologies enabling the simultaneous fertilization of eggs, with separate implantation. The unique "twinlike" relationships that would result between parents and cloned children (who would be genetically identical to their parents) also challenge current conceptions of twinship. Monozygotic twins are clones (genetically identical individuals derived from a single fertilized egg), but parents and cloned children would not be twins for several reasons, such as their differing prenatal and postnatal environments. *See* REPRODUCTIVE TECHNOLOGY.

Monozygotic twins. The division of a single fertilized egg (or zygote) between 1 and 14 days postconception results in monozygotic twins. They share virtually all their genes and, with very rare exception due to unusual embryological events, are of the same sex. A common assumption is that because monozygotic co-twins have a shared heredity, their behavioral or physical differences are fully explained by environmental factors. However, monozygotic twins are never exactly alike in any measured trait, and may even differ for genetic reasons.

Sometimes chromosomes fail to separate after fertilization, causing some cells to contain the normal chromosome number (46) and others to contain an abnormal number. This process, mosaicism, results in monozygotic co-twins who differ in chromosomal constitution. There are several other intriguing variations of monozygotic twinning. Splitting of the zygote after day 7 or 8 may lead to mirror-image reversal in certain traits, such as handedness or direction of hair whorl. The timing of zygotic division has also been associated with placentation. Monozygotic twins resulting from earlier zygotic division have separate placentae and fetal membranes (chorion and amnion), while monozygotic twins resulting from later zygotic division share some or all of these structures. Should the zygote divide after 14 days, the twins may fail to separate completely. This process, known as conjoined twinning, occurs in approximately 1 monozygotic twin birth out of 200. The many varieties of conjoined twins differ as to the nature and extent of their shared anatomy. Approximately 70% of such twins are female. There do not appear to be any predisposing factors to conjoined twinning. *See* MOSAICISM.

Dizygotic twins. Dizygotic twins result when two different eggs undergo fertilization by two different spermatozoa, not necessarily at the same time. Dizygotic twins share, on average, 50% of their genes, by descent, so that the genetic relationship between dizygotic co-twins is exactly the same as that of ordinary brothers or sisters. Dizygotic twins may be of the same or opposite sex, outcomes that occur with approximately equal frequency.

There are some unusual variations of dizygotic twinning. There is the possibility of polar body twinning, whereby divisions of the ovum prior to fertilization by separate spermatozoa could result in twins whose genetic relatedness falls between that of monozygotic and dizygotic twins. Blood chimerism, another variation, refers to the presence of more than one distinct red blood cell population, derived from two zygotes, and has been explained by connections between two placentae. In humans, chimerism can occur in dizygotic twins. Superfecundation is the conception of dizygotic twins following separate fertilizations, usually within several days, in which case each co-twin could have a different father. Superfetation, which refers to multiple conceptions occurring several weeks or even one month apart, may be evidenced by delivery of full-term infants separated by weeks or months and by the birth or abortion of twin infants displaying differential developmental status. *See* FERTILIZATION; OOGENESIS.

Epidemiology. According to conventional twinning rates, monozygotic twins represent approximately one-third of twins born in Caucasian populations and occur at a rate of 3–4 per 1000 births. The biological events responsible for monozygotic twinning are not well understood. It is generally agreed that monozygotic twinning occurs randomly and not as a genetically transmitted tendency. Some recent evidence from Sweden suggests an increased tendency for mothers who are monozygotic twins to bear same-sex twins themselves; further work will be needed to resolve this question.

Dizygotic twinning represents approximately two-thirds of twins born in Caucasian populations. The dizygotic twinning rate is lowest among Asian populations (2 per 1000 births), intermediate among Caucasian populations (8 per 1000 births), and highest among African populations (50 per 1000 births in parts of Nigeria). The natural twinning rate increases with maternal age, up to between 35 and 39 years, and then declines. Dizygotic twinning has also been linked to increased parity, or the number of children to which a woman has previously given birth. Mothers of dizygotic twins are also significantly taller and heavier, on average, than mothers of monozygotic twins and singletons. Dizygotic twinning appears to be genetically influenced, although the pattern of transmission within families is unknown.

Twinning rates have risen dramatically since about 1980 mainly due to advances in fertility treatments (for example, in vitro fertilization and ovulation induction), but also due to delays in the child-bearing years. The increase has mainly involved dizygotic twinning in which multiple ovulation and maternal age matter. [N.L.S.]

Two-phase flow

The simultaneous flow of two phases or two immiscible liquids within common boundaries. Two-phase flow has a wide range of engineering applications such as in the power generation, chemical, and oil industries. Flows of this type are important for the design of steam generators (steam-water flow), internal combustion engines, jet engines, condensers, cooling towers, extraction and distillation processes, refrigeration systems, and pipelines for transport of gas and oil mixtures.

The most important characteristic of two-phase flow is the existence of interfaces, which separate the phases, and the associated discontinuities in the properties across the phase interfaces. Because of the deformable nature of gas-liquid and liquid-liquid interfaces, a considerable number of interface configurations are possible. Consequently, the various heat and mass transfers that occur between a two-phase mixture and a surrounding surface, as well as between the two phases, depend strongly on the two-phase flow regimes. Multiphase flow, when the flow under consideration contains more than two separate phases, is a natural extension of these principles. *See* FLUID MECHANICS; INTERFACE OF PHASES.

From a fundamental point of view, two-phase flow may be classified according to the phases involved as (1) gas-solid mixture, (2) gas-liquid mixture, (3) liquid-solid mixture, and (4) two-immiscible-liquids mixture. *See* Gas; Liquid; Phase equilibrium.

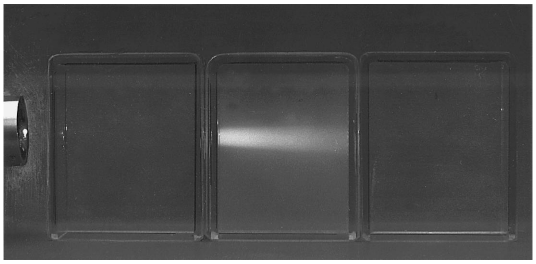
Industrial applications of two-phase flow include systems that convert between phases, and systems that separate or mix phases without converting them (adiabatic systems). Many of the practical cycles used to convert heat to work use a working fluid. In two or more of the components of these cycles, heat is either added to or removed from the working fluid, which may be accompanied by a phase-change process. Examples of these applications include steam generators, evaporators, and condensers, air conditioning, and refrigeration systems, and steam power plants.

In adiabatic systems, the process of phase mixing or separation occurs without heat transfer or phase change. Examples of these systems are airlift pumps, pipeline transport of gas-oil mixtures, and gas-pulverization of solid particles. *See* Adiabatic process. [H.H.Br.; F.H.; B.K.P.]

Tylenchida An order of nematodes in which the labial region is variable and may be distinctly set off or smoothly rounded and well developed; the hexaradiate symmetry is most often retained or discernible. The hollow stylet is the product of the cheilostome (conus, guiding apparatus, and framework) and the esophastome (shaft and knobs). Throughout the order the stylet may be present or absent and may be adorned with knobs. The variable esophagus is most often divisible into the corpus, isthmus, and glandular posterior bulb. The corpus is divisible into the procorpus and metacorpus. The metacorpus is generally valved but may not occur in some females and males, and the absence is characteristic of some taxa. The orifice of the dorsal esophageal gland opens either into the anterior procorpus or just anterior to the metacorporal valve. The excretory system is asymmetrical, and there is but one longitudinal collecting tubule. Females have one or two genital branches; when only one branch is present, it is anteriorly directed. Except for sex-reversed males, there is only one genital branch. Males may have one (=phasmid) or more caudal papillae. The spicules are always paired and variable in shape; they may be accompanied by a gubernaculum. The order comprises five superfamilies: Tylenchoidea, Criconematoidea, Saphaerularoidea, Aphelenchoidea, and Aphelenchoidoidea. *See* Nemata; Plant pathology. [A.R.M.]

Tyndall effect Visible scattering of light along the path of a beam of light as it passes through a system containing discontinuities. The luminous path of the beam of light is called a Tyndall cone. An example is shown in the illustration. In colloidal systems the brilliance of the Tyndall cone is directly dependent on the magnitude of the difference in refractive index between the particle and the medium.

For systems of particles with diameters less than one-twentieth the wavelength of light, the light scattered from a polychromatic beam is predominantly blue in color and is polarized to a degree which depends on the angle between the observer and the incident beam. The blue color of tobacco smoke is an example of Tyndall blue. As particles are increased in size, the blue color of scattered light disappears and the scattered radiation appears white. If this scattered light is received through a nicol prism which is oriented to extinguish the vertically polarized scattered light, the blue color appears again in increased brilliance. This is called residual blue, and its intensity varies as the inverse eighth power of the wavelength. *See* Colloid; Scattering of electromagnetic radiation. [Q.V.W.]



The luminous light path known as the Tyndall cone or Tyndall effect. (*Courtesy of H. Steeves and R. G. Babcock*)

Type (printing) The intelligible images organized into readable text of various styles and sizes. Type used in printing on paper or video display is divided into four categories: foundry, machine-cast, photocomposed, and digitized type. In the first two the face of the letter is raised on one end of a piece of metal. It is from that surface, when inked, that the impression of type was made from its invention until the 1970s. In photocomposition, the type is reproduced photographically. Digitized methods assemble dots into typographic letters, lines, or pages.

Classification. Foundry type, also known as hand type, is cast as single characters. Machine-cast metal type is produced by Linotype, Intertype, Ludlow, and Monotype machines. Very few of these machines are still in operation. All but the last cast type in lines, or slugs. The Monotype—in reality two devices, a keyboard and a caster—produces individual types that are then manually set in lines of desired lengths.

The output of the photographic type machine is the image of type on film or on photosensitized paper in negative or positive form.

The term cold type is applied to text matter produced on a typewriter or laser printer and to words or lines made up of individual printed characters assembled or pasted together for photographic reproduction. Digital type uses a number of printout technologies, imaging small dots into lines (called rasters) and positioning them on pages from patterns of zeros and ones called bitmaps. Because this method is electronic, more sizes and variations (for example, condensing or expanding or other distortion) are possible.

About 6000 styles of type are in everyday use throughout the world. The most widely used method for classifying them is the serif-evolution system, based on the different shapes of the terminals or endings of letters. This provides eight classifications: Venetian, Old Style (Dutch-English and French), Transitional, Modern, Contemporary (sans serif and square serif), Scripts, Black Letter, and Decorative Letters.

Type measurements. The American point system made the unit of type measurement a point, 0.01383 in. (0.35128 mm) or nearly $^{1}/_{72}$ in. This system replaced the sixteenth-century practice of giving all type sizes names such as pearl, agate, nonpareil, brevier, long primer, and pica. Some names remained and have been assigned other functions. Agate, $5^{1}/_{2}$-point type or 14 lines of type to an inch, has come to be used for measuring newspaper advertising space. Publications quote small space rates by the agate line. Nonpareil is used to designate 6 points of space in and around type. The word pica is commonly used to denote a unit of space measuring 12 points. It is applied as a dimensional unit to the length of type lines and to the width and depth of page. With the advent of desktop publishing, many software programs have standardized on 72 points equaling exactly 1 inch. With these programs, the point now equals 0.01389 in., compared with the traditional point, 0.01383 in. Some of these programs allow the user to select which point system to use.

The standard height of metal type in the United States is 0.918 in. (2.3 cm), a dimension called type-high and one observed by photoengravers and electrotypers who make plates to be combined with cast type. Letterpress printing presses are adjusted to fit this standard height.

Fonts. A complete complement of letters of one size and style from A to Z, together with the arabic numerals, punctuation, reference marks and symbols, is called a font. Most fonts also

A family of type.

include the ampersand and currency symbols and the ligatures, ff, fe, ffi, fl, ffl, æ, and œ. A letter from a different font that is included by accident in type composition is known as a wrong font. All typographic images, from letters to symbols to oriental ideographs, are called glyphs.

Type families. A family of type may be likened to the shades of a color in that it includes variations of a given type face or design. Weights are varied, from light to medium, bold, and extra bold; letters are condensed and expanded, as well as outlined, inlined, and shadowed (see illustration).

Type for desktop publishing. Most typesetting today is performed using desktop publishing (DTP), which refers to the creation of documents through the use of an inexpensive personal computer off-the-shelf software that uses page description language, and laser-based output devices that convert the digital information into images on paper and other surfaces, such as printing plates for offset lithography. [E.M.E.; F.J.Ro.; T.De.]

Typewriter A machine that produces printed copy, character by character, as it is operated. Its essential parts are a keyboard, a set of raised characters or a thermal print head, an inked ribbon, a platen for holding paper, and a mechanism for advancing the position at which successive characters are printed. The QWERTY keyboard (named for the sequence of letters of the top row of the alphabet worked by the left hand) was designed in the 1870s. It contains a complete alphabet, along with numbers and the symbols commonly used in various languages and technical disciplines. The manual typewriter was introduced in 1874, followed by the electrically powered typewriter in 1934. By the late 1970s, electronic typewriters offered memory capability, additional automatic functions, and greater convenience. Further advances in electronic technology led to additional capabilities, including plug-in memory and function diskettes and cartridges, visual displays, nonimpact printing, and communications adapters. Although many typewriters are still in use, computers and word processing software largely have supplanted them. *See* WORD PROCESSING. [E.W.G.; R.A.Rah.]

U

Ulcer A lesion on the surface of the skin or a mucous membrane characterized by a superficial loss of tissue. Ulcers are most common on the skin of the lower extremities and in the gastrointestinal tract, although they may be encountered at almost any site. The diverse causes of ulcers range from circulatory disturbances or bacterial infections to complex, multifactorial disorders. The superficial tissue sloughs, leaving a crater that extends into the underlying soft tissue, which then becomes inflamed and is subject to further injury by the original offender or secondary infection.

Peptic ulcer is the most common ulcer of the gastrointestinal tract and refers to breaks in the mucosa of the stomach or the proximal duodenum that are produced by the action of gastric secretions. It is still unknown why peptic ulcers develop. However, with rare exceptions, a person who does not secrete hydrochloric acid will not develop a peptic ulcer. Ulcers of the stomach tend to develop as a result of superficial inflammation of the stomach. These individuals tend to have normal or decreased amounts of hydrochloric acid. By contrast, most individuals with peptic ulcers of the proximal duodenum secrete excessive amounts of acid. Importantly, a bacterium, *Helicobacter pylori*, has been isolated from the stomach of most people with peptic ulcers and is thought to play a causative role. Although stress has been anecdotally related to peptic ulcers for at least a century, serious doubt has been cast upon this concept. *See* Inflammation.

Ulcerative colitis is a disease of the large intestine characterized by chronic diarrhea and rectal bleeding. The disorder is common in the Western world, occurring principally in young adults. Its cause is not known, but there is some evidence for a familial predisposition to the disease.

Other ulcers of the gastrointestinal tract are caused by infectious agents. Bacterial and viral infections produce ulcers of the oral cavity. Diseases such as typhoid, tuberculosis, and bacillary dysentery and parasitic infestation with ameba lead to ulcers of the small and large intestines. Narrowing of the arteries to the legs caused by atherosclerosis, particularly in persons with diabetes mellitus, often causes ulcers of the lower extremities. *See* Arteriosclerosis; Bacillary dysentery; Diabetes; Tuberculosis.

[E.Ru.]

Ultracentrifuge A centrifuge of high or low speed which provides convection-free conditions and which is used for quantitative measurement of sedimentation velocity or sedimentation equilibrium or for the separation of solutes in liquid solution. *See* Centrifugation.

The ultracentrifuge is used (1) to measure molecular weights of solutes and to provide data on molecular weight distributions in polydisperse systems; (2) to determine the frictional coefficients, and thereby the sizes and shapes, of solutes; and (3) to characterize and separate macromolecules on the basis of their buoyant densities in density gradients. *See* Molecular weight.

The ultracentrifuge is most widely used to study high polymers, particularly proteins, nucleic acids, viruses, and other macromolecules of biological origin. However, it is also used to study solution properties of small solutes. In applications to macromolecules, the analytical ultracentrifuge, which is used for accurate determination of sedimentation velocity or equilibrium, is distinguished from the preparative ultracentrifuge, which is used to separate solutes on the basis of their sedimentation velocities or buoyant densities.

The application of a centrifugal field to a solution causes a net motion of the solute. If the solution is denser than the solvent, the motion will be away from the axis of rotation. The nonuniform concentration distribution produced in this way leads to an opposing diffusion flux tending to reestablish uniformity. In sedimentation-velocity experiments, sedimentation prevails over diffusion, and the solute sediments with finite velocity toward the bottom of the cell, although the concentration profile may be markedly influenced by diffusion. In sedimentation-equilibrium experiments, centrifugal and diffusive forces balance out, and an equilibrium concentration distribution results which may be analyzed by thermodynamic methods. *See* Centrifugal force.

[V.A.B.]

Ultrafast molecular processes Various types of physical and molecular changes occurring on time scales of 10^{-14} to 10^{-9} s that are studied in the field of photophysics, photochemistry, and photobiography. The time scale ranges from near the femtosecond regime (10^{-15} s) on the fast side, embodies the entire picosecond regime (10^{-12} s), and borders the nanosecond regime (10^{-9} s) on the slow side.

A typical experiment is initiated with an ultrashort pulse of energy—radiation (light) or particles (electrons). Rapid changes in the system under study are brought about by the absorption of these ultrashort energy pulses. These changes can be measured by ultrafast detection methods. Such methods are usually based on some type of linear or nonlinear spectroscopic monitoring of the system, or on optical delay lines that employ the speed of light itself to create a yardstick of time (a distance of 3 mm equals a time of 10 picoseconds). These studies are important because elementary motion, such as rotation, vibrational exchange, chemical bond breaking, and charge transfer, takes place on these ultrafast time scales. The relationship between such motions and overall physical, chemical, or biological changes can thus be observed directly. *See* Chemical dynamics; Optical pulses; Spectroscopy.

Just as a very fast shutter speed is necessary to obtain a sharp photograph of a fast-moving object, energy pulses for the study of ultrafast molecular motions must be extremely narrow in time. The basic technique for producing ultrashort light pulses is mode-locking a laser. One way to do this is to put a nonlinear absorption medium in the laser cavity, which functions somewhat like a shutter. In the time domain, the developing light pulse, bouncing back and forth between the laser cavity reflectors, experiences an intensity-dependent loss each time it passes through the nonlinear absorption medium. Highintensity light penetrates the medium, and its intensity is allowed to build up in the laser cavity; weak-intensity light is blocked. This process shaves off the low-amplitude edges of a pulse, thus shortening it. One of the laser cavity reflectors has less than 100% reflectance at the laser wavelength, so part of the pulse energy is coupled out of the cavity each time the pulse reaches that reflector. In this way, a train of pulses is emitted from the mode-locked laser, each pulse separated from the next by the round-trip time for a pulse traveling at the speed of light in the laser cavity, about

13 nanoseconds for a 2-m (6.6-ft) laser cavity length. *See* LASER; NONLINEAR OPTICS.

In addition to the extremely narrow energy pulses in the time domain, special ultrafast detection techniques are required in order to preserve the time resolution of an experiment.

A photobiological process, which has received considerable attention by spectroscopists studying the femtosecond regime, is light-driven transmembrane proton pumping in purple bacteria (*Halobacterium halobium*). Each link in the complex chain of molecular processes, such as an ultrafast photoionization event, is "fingerprinted" by a somewhat different absorption spectrum, making it possible to sort out these events by methods of ultrafast laser spectroscopy. The necessity for use of fast primary events in nature concerns overriding unwanted competing chemical and energy loss processes. The faster the wanted process, the less is the likelihood that unwanted, energy-wasting processes will take place. *See* LASER PHOTOBIOLOGY; LASER SPECTROSCOPY. [G.W.R.; N.L.]

Ultrafiltration A filtration process in which particles of colloidal size are retained by a filter medium while solvent and accompanying low-molecular-weight solutes are allowed to pass through. Ultrafilters are used (1) to separate colloid from suspending medium, (2) to separate particles of one size from particles of another size, and (3) to determine the distribution of particle sizes in colloidal systems by the use of filters of graded pore size.

Ultrafilter membranes have been prepared from various types of gel-forming substances: Unglazed porcelain has been impregnated with gels such as gelatin or silicic acid. Filter paper has been impregnated with glacial acetic acid collodions. Another type of ultrafilter membrane is made up of a thin plastic sheet containing millions of tiny pores evenly distributed over its surface. *See* COLLOID; FILTRATION. [Q.V.W.]

Ultralight aircraft A lightweight, single-seat aircraft with low flight speed and power, used for sport or recreation. Ultralights evolved from hang gliders. *See* GLIDER.

There have been tremendous variety of ultralight airframe configurations and control systems. Airframe types include powered weight-shift hang gliders, flying wings, canard designs, antique biplane replicas, and traditional, monoplane structures with conventional tail designs. Control systems can be either weight-shift systems, two-axis controls, or conventional three-axis controls. In weight-shift designs pilots must shift their weight, using a movable seat, to change the attitude. Two-axis designs use controls to the elevator and rudder only; there are no ailerons. Modern designs use three-axis control systems; weight-shift and two-axis control systems are no longer in production. Three-axis controls resemble those of a standard airplane and include either ailerons or spoilerons (spoiler-type systems used to make turns). Some more sophisticated ultralights are equipped with wing flaps, used to steepen approach profiles and to land at very slow airspeeds. *See* AIRFRAME; FLIGHT CONTROLS.

Typically, ultralight airframes are made of aircraft-grade aluminum tubes covered with Dacron sailcloth. Areas of stress concentration are reinforced with double-sleeving or solid aluminum components. Most ultralights are cable-braced and use aircraft-grade stainless steel cables with reinforced terminals. Wingspans average 30 ft (9 m), and glide ratios range from 7:1 to 10:1, depending primarily on gross weight and wing aspect ratio. *See* AIRFOIL; ASPECT RATIO; WING.

Ultralight engines are lightweight, two-stroke power plants with full-power values in the 28–35-hp (21–26-kW) range. They operate on a mixture of gasoline and oil, and most transmit power to the propeller via a reduction or belt drive, a simple transmission that enables the propeller to rotate at a lower, more efficient rate than the engine shaft. *See* AIRPLANE; PROPELLER (AIRCRAFT); RECIPROCATING AIRCRAFT ENGINE. [T.A.Ho.]

Ultrasonics The science of sound waves having frequencies above the audible range, that is, above about 20,000 Hz. Original workers in this field adopted the term supersonics. However, this name was also used in the study of airflow for velocities faster than the speed of sound. The present convention is to use the term ultrasonics as defined above. Since there is no marked distinction between the propagation and the uses of sound waves above and below 20,000 Hz, the division is artificial. *See* SOUND.

Ultrasonic generators and detectors. Ultrasonic transducers have two functions: transmission and reception. There may be separate transducers for each function or a single transducer for both functions. The usual types of generators and detectors for air, liquids, and solids are piezoelectric and magnetostrictive transducers. Quartz and lithium niobate ($LiNbO_3$) crystals are used to produce longitudinal and transverse waves; thin-film zinc oxide (ZnO) transducers can generate longitudinal waves at frequencies up to 96 GHz. Another class of materials used to generate ultrasonic signals is the piezoelectric ceramics. In contrast to the naturally occurring piezoelectric crystals, these ceramics have a polycrystalline structure. The most commonly produced piezoelectric ceramics are lead zirconate titanate (PZT), barium titanate ($BaTiO_3$), lead titanate ($PbTiO_3$), and lead metaniobate ($PbNb_2O_6$). Composite transducers are transducers in which the radiating or receiving element is a diced piezoelectric plate with filler between the elements. They are called "composite" to account for the two disparate elements, the piezoelectric diced into rods and the compliant adhesive filler. *See* MAGNETOSTRICTION; PIEZOELECTRICITY.

High-power ultrasound (typically 600 W) can be obtained with sonicators, consisting of a converter, horn, and tip. The converter transforms electrical energy to mechanical energy at a frequency of 20 kHz. Oscillation of piezoelectric transducers is transmitted and focused by a titanium horn that radiates energy into the liquid being treated. Horn and tip sizes are determined by the volume to be processed and the intensity desired. As the tip diameter increases, intensity or amplitude decreases.

Engineering applications. The engineering applications of ultrasonics can be divided into those dealing with low-amplitude sound waves and those dealing with high-amplitude (usually called macrosonics) waves.

Low-amplitude applications. Low-amplitude applications are in sonar (an underwater-detection apparatus), in the measurement of the elastic constants of gases, liquids, and solids by a determination of the velocity of propagation of sound waves, in the measurement of acoustic emission, and in a number of ultrasonic devices such as delay lines, mechanical filters, inspectoscopes, thickness gages, and surface-acoustic-wave devices. All these applications depend on the modifications that boundaries and imperfections in the materials cause in wave propagation properties. The attenuation and scattering of the sound in the media are important factors in determining the frequencies used and the sizes of the pieces that can be utilized or investigated. *See* SONAR.

High-amplitude applications. High-amplitude acoustic waves (macrosonic) have been used in a variety of applications involving gases, liquids, and solids. Some common applications are mentioned below.

A liquid subjected to high-amplitude acoustic waves can rupture, resulting in the formation of gas- and vapor-filled bubbles. When such a cavity collapses, extremely high pressures and temperatures are produced. The process, called cavitation, is the origin of a number of mechanical, chemical, and biological effects.

Cavitation plays an integral role in a wide range of processes such as ultrasonic cleaning and machining, catalysis of chemical reactions, disruption of cells, erosion of solids, degassing of liquids, emulsification of immiscible liquids, and dispersion of solids in liquids. Cavitation can also result in weak emission of light, called sonoluminescence. *See* CAVITATION; SONOCHEMISTRY.

One of the principal applications of ultrasonics to gases is particle agglomeration. This technique has been used in industry to collect fumes, dust, sulfuric acid mist, carbon black, and other substances.

Another industrial use of ultrasonics has been to produce alloys, such as lead-aluminum and lead-tin-zinc, that could not be produced by conventional metallurgical techniques. Shaking by ultrasonic means causes lead, tin, and zinc to mix.

Analytical uses. In addition to their engineering applications, high-frequency sound waves have been used to determine the specific types of motions that can occur in gaseous, liquid, and solid mediums. Both the velocity and attenuation of a sound wave are functions of the sound frequency. By studying the changes in these properties with changes of frequency, temperature, and pressure, indications of the motions taking place can be obtained. *See* SOUND ABSORPTION.

Medical applications. Application of ultrasonics in medicine can be generally classified as diagnostic and therapeutic. The more common of these at present is the diagnostic use of ultrasound, specifically ultrasonic imaging. *See* BIOMEDICAL ULTRASONICS; MEDICAL IMAGING; NONLINEAR ACOUSTICS.

Ultrasonic fields of sufficient amplitude can generate bioeffects in tissues. Although diagnostic ultrasound systems try to limit the potential for these effects, therapeutic levels of ultrasound have been used in medicine for a number of applications. Conventional therapeutic ultrasound is a commonly available technique used in physical therapy. High-frequency acoustic fields (typically 1 MHz) are applied through the skin to the affected area in either a continuous wave or long pulses.

Extracorporeal shock-wave lithotripsy (ESWL) disintegrates kidney stones with a high-amplitude acoustic pulse passing through the skin of the patient. The procedure eliminates the need for extensive surgery. Bioeffects are limited to the location of the stone by using highly focused fields which are targeted on the stone by imaging techniques such as ultrasound or fluoroscopy. [H.E.Ba.; J.B.Fo.; V.M.K.]

Ultraviolet astronomy Astronomical observations carried out in the region of the electromagnetic spectrum with wavelengths from approximately 10 to 350 nanometers. Ultraviolet radiation from astronomical sources contains important diagnostic information about the composition and physical conditions of these objects. This information includes atomic absorption and emission lines of all the most abundant elements in many states of ionization. The hydrogen molecule (H_2), the most abundant molecule in the universe, has its absorption and emission lines in the far-ultraviolet. *See* ASTRONOMICAL SPECTROSCOPY; ULTRAVIOLET RADIATION.

Ultraviolet radiation with wavelengths less than 310 nm is strongly absorbed by molecules in the atmosphere of the Earth. Therefore, ultraviolet observations must be carried out by using instrumentation situated above the atmosphere. Ultraviolet astronomy began with instrumentation aboard sounding rockets. The first major ultraviolet satellite observatories to be placed in space were the United States *Orbiting Astronomical Observatories* (*OAO*s). The *International Ultraviolet Explorer* (*IUE*), launched into a geosynchronous orbit in 1978, realized the full potential of ultraviolet astronomy. *See* ROCKET ASTRONOMY; SATELLITE ASTRONOMY.

NASA's *Extreme Ultraviolet Explorer* (*EUVE*) satellite (1992–2001) contained telescopes designed to produce images of the extreme-ultraviolet sky and spectra of bright extreme-ultraviolet sources in the wavelength range from approximately 10 to 90 nm. Most of the sources of radiation detected with the *EUVE* were stars with hot active outer atmospheres (or coronae) and hot white dwarf stars. *See* WHITE DWARF STAR.

Although it had an inauspicious beginning, the Hubble Space Telescope, launched in 1990, has become the centerpiece of both ultraviolet and visible astronomy. The complement of instruments aboard the Hubble Space Telescope has included imaging cameras operating at ultraviolet, visual, and infrared wavelengths, and spectrographs operating at ultraviolet and visual wavelengths. *See* SPACE TELESCOPE, HUBBLE; SPECTROGRAPH; TELESCOPE.

The *Far-ultraviolet Spectrograph Explorer* (*FUSE*) satellite, launched in 1999, is designed to explore the universe in the 90–120-nm region of the spectrum at high spectral resolution. *Galaxy Evolution Explorer* (*GALEX*), launched in 2003, is a modest-sized ultraviolet imaging and spectroscopic survey mission that probes star formation over 80% of the age of the universe.

The important discoveries of ultraviolet astronomy span all areas of modern astronomy and astrophysics. Some of the notable discoveries in the area of solar system astronomy include new information on the upper atmospheres of the planets, including planetary aurorae and the discovery of the enormous hydrogen halos surrounding comets. In studies of the interstellar medium, ultraviolet astronomy has provided fundamental information about the molecular hydrogen content of cold interstellar clouds along with the discovery of the hot phase of the interstellar medium, which is created by the supernova explosions of stars. In stellar astronomy, ultraviolet measurements led to important insights about the processes of mass loss through stellar winds and have permitted comprehensive studies of the conditions in the outer chromospheric and coronal layers of cool stars. The *IUE*, Hubble Space Telescope, and *FUSE* observatories have contributed to the understanding of the nature of the hot gaseous corona surrounding the Milky Way Galaxy. Ultraviolet observations of exotic astronomical objects, including exploding stars, active galactic nuclei, and quasars, have provided new insights about the physical processes affecting the behavior of matter in extreme environments. The spectrographs aboard the Hubble Space Telescope have revealed the existence of large numbers of hydrogen clouds in the intergalactic medium. These intergalactic clouds may contain as much normal (baryonic) matter as there exists in the known luminous galaxies and stars. *See* COMET; COSMOLOGY; GALAXY, EXTERNAL; INTERSTELLAR MATTER; MILKY WAY GALAXY; PLANETARY PHYSICS; QUASAR; SATELLITE (ASTRONOMY); STAR; SUPERNOVA. [B.D.S.]

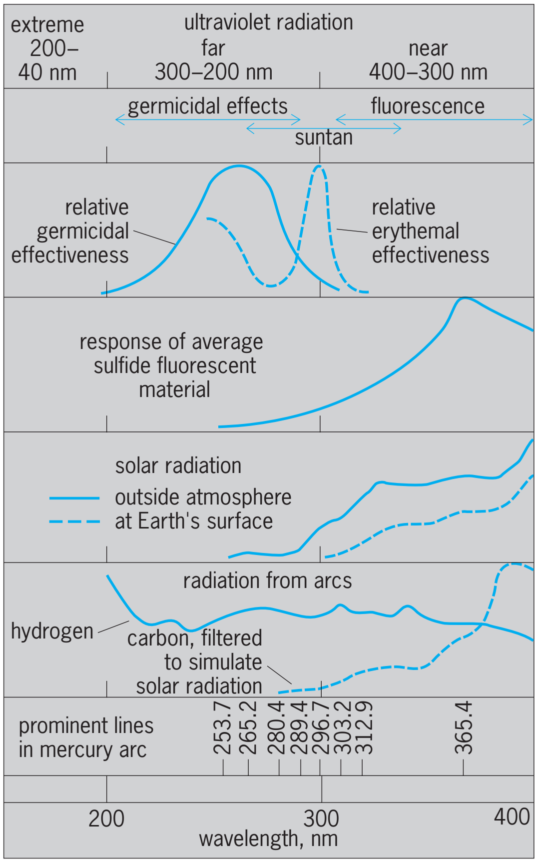
Ultraviolet lamp A mercury-vapor lamp designed to produce ultraviolet radiation. Also, some fluorescent lamps and mercury-vapor lamps that produce light are used for ultraviolet effects. *See* FLUORESCENT LAMP; MERCURY-VAPOR LAMP.

Fluorescent and mercury lamps can be filtered so that visible energy is absorbed and emission is primarily in the near-ultraviolet or black-light spectrum (320–400 nanometers). The ultraviolet energy emitted is used to excite fluorescent pigments in paints, dyes, or natural materials.

Mercury-vapor lamps are sometimes designed with pressures that produce maximum radiation in the middle ultraviolet region (280–320 nm), using special glass bulbs that freely transmit this energy. One such lamp type is the sunlamp. Other lamps designed for middle-ultraviolet radiation are known as photochemical lamps. *See* SUNLAMP.

Some radiation in the 220–280-nm wavelength band has the capacity to destroy certain kinds of bacteria. Mercury lamps designed to produce energy in this region (the 253.7-nm mercury line) are electrically identical with fluorescent lamps; they differ from fluorescent lamps in the absence of a phosphor coating and in the use of glass tubes that transmit far ultraviolet. *See* ULTRAVIOLET RADIATION (BIOLOGY). [A.M.]

Ultraviolet radiation Electromagnetic radiation in the wavelength range 4–400 nanometers. The ultraviolet region begins at the short wavelength (violet) limit of visibility and extends to the wavelength of long x-rays. It is loosely divided into the near (400–300 nm), far (300–200 nm), and extreme (below 200 nm) ultraviolet regions (see illustration). In the extreme ultraviolet, strong absorption of the radiation by air requires the use



Phenomena associated with ultraviolet radiation. (*After L. R. Koller and General Electric*)

of evacuated apparatus; hence this region is called the vacuum ultraviolet. Important phenomena associated with ultraviolet radiation include biological effects and applications, the generation of fluorescence, and chemical analysis through characteristic absorption or fluorescence. *See* ULTRAVIOLET RADIATION (BIOLOGY).

Sources of ultraviolet radiation include the Sun (although much solar ultraviolet radiation is absorbed in the atmosphere); arcs of elements such as carbon, hydrogen, and mercury; and incandescent bodies. *See* ULTRAVIOLET LAMP. [F.W.B.]

Ultraviolet radiation (biology)

Radiations between 200 and 300 nanometers are selectively absorbed by organic matter, and produce the best-known effects of ultraviolet radiations on organisms. Ultraviolet radiations, in contrast to x-rays, do not penetrate far into larger organisms; therefore, the effects they produce are surface effects, such as sunburn and development of D vitamins from precursors present in skin or fur. The effects of ultraviolet radiations on life have, therefore, been assayed chiefly with unicellular organisms such as bacteria, yeast, and protozoans, although suspensions of cells of higher organisms, for example, eggs and blood corpuscles, have been useful as well.

Photobiological effects. Only the ultraviolet radiations which are absorbed can produce photobiological action. All life activities are shown to be affected by ultraviolet radiations, the effect depending upon the dosage. Small dosages activate unfertilized eggs of marine animals, reduce the rate of cell division, decrease the synthesis of nucleic acid, especially in the nucleus, reduce the motility of cilia and of contractile vacuoles, and sensitize cells to heat. Large doses increase the permeability of cells to various substances, inhibit most synthetic processes, produce mutations, stop division of cells, decrease the rate of respiration, and may even disrupt cells. The effect of ultraviolet radiations upon cells is invariably deleterious.

Effects on the skin. Erythema is the reddening of the skin following exposure to ultraviolet radiation of wavelength shorter than 320 nm. wavelength 296.7 nm being most effective. These radiations injure cells in the outer layer of the skin, or epidermis, liberating substances which diffuse to the inner layer of the skin, or dermis, causing enlargement of the small blood vessels. A minimal erythemal dose just induces reddening of the skin observed 10 h after exposure. A dose several times the minimal gives a sunburn, killing some cells in the epidermis after which serum and white blood cells accumulate, causing a blister. After the dried blister peels, the epidermis is temporarily thickened and pigment develops in the lower layers of the epidermis, both of these factors serving to protect against subsequent exposure to ultraviolet.

Both thickening of the epidermis and tanning may occur without blistering. Since the pigment in light-skinned races develops chiefly below the sensitive cells in the epidermis, it is not as effective as in dark-skinned races where the pigment is scattered throughout the epidermis. Consequently, the minimal erythemal dose is much higher for the dark- than for the lightskinned races.

Excessive exposure to ultraviolet radiation has been found to lead to cancer in mice, and it is claimed by some to cause cutaneous cancer in humans.

Clinical use. Ultraviolet radiations were once used extensively in the treatment of rickets, many skin diseases, tuberculosis other than pulmonary, especially skin tuberculosis (lupus vulgaris), and of many other diseases. The enthusiasm for sun bathing is, in part, a relic of the former importance of ultraviolet radiation as a clinical tool. Vitamin preparations, synthetic drugs, and antibiotics have either displaced ultraviolet radiations in such therapy or are used in conjunction with the radiations.

Ultraviolet radiations alone are still employed to treat rickets in individuals sensitive to vitamin D preparations. In conjunction with chemicals, they are used in treating skin diseases, for example, psoriasis, pityriasis rosea, and sometimes acne, as well as for the rare cases of sensitivity to visible light. Ultraviolet radiations, however, are more important in research than in clinical practice. [A.C.Gi.]

Umklapp process

A concept in the theory of transport properties of solids which has to do with the interaction of three or more waves in the solid, such as lattice waves or electron waves. In a continuum, such interactions occur only among waves described by wave vectors $\mathbf{k}_1$, $\mathbf{k}_2$, and so on, such that the interference condition, given by Eq. (1), is satisfied. The sign of

$$\mathbf{k}_1 + \mathbf{k}_2 + \mathbf{k}_3 = 0 \tag{1}$$

$\mathbf{k}$ depends on whether the wave absorbs or emits energy. Since $\hbar\mathbf{k}$ is the momentum of a quantum (or particle) described by the wave, Eq. (1) corresponds to conservation of momentum. In a crystal lattice further interactions occur, satisfying Eq. (2),

$$\mathbf{k}_1 + \mathbf{k}_2 + \mathbf{k}_3 = \mathbf{b} \tag{2}$$

where $\mathbf{b}$ is any integral combination of the three inverse lattice vectors $\mathbf{b}_i$, defined by $\mathbf{a} \cdot \mathbf{b}_j = 2\pi\delta_{ij}$, the $\mathbf{a}$'s being the periodicity vectors. The group of processes described in Eq. (2) are the Umklapp processes or flip-over processes, so called because the total momentum of the initial particles or quanta is reversed. *See* CRYSTAL. [P.G.Kl.]

Uncertainty principle

A fundamental principle of quantum mechanics, which asserts that it is not possible to know both the position and momentum of an object with arbitrary accuracy. This contrasts with classical physics, where the position and momentum of an object can both be known exactly. In quantum mechanics, this is no longer possible, even in principle. More precisely, the indeterminacy or uncertainty principle, derived by W. Heisenberg, asserts that the product of

Δx and Δp—measures of indeterminacy of a coordinate and of momentum along that coordinate—must satisfy inequality (1).

$$\Delta x \times \Delta p \gtrsim \hbar = \frac{h}{2\pi} \qquad (1)$$

The Planck constant, $h \simeq 6.63\ 10^{-34}$ joule-second, is very small, which makes inequality (1) unimportant for the measurements that are carried out in everyday life. Nevertheless, the consequences of the inequality are critically important for the interactions between the elementary constituents of matter, and are reflected in many of the properties of matter that are ordinarily taken for granted. For example, the density of solids and liquids is set to a large degree by the uncertainty principle, because the sizes of atoms are determined with decisive help of inequality (1).

In classical physics, simultaneous knowledge of position and momentum can be used to predict the future trajectory of a particle. Quantum indeterminacy and the limitations it imposes force such classical notions of causality to be abandoned.

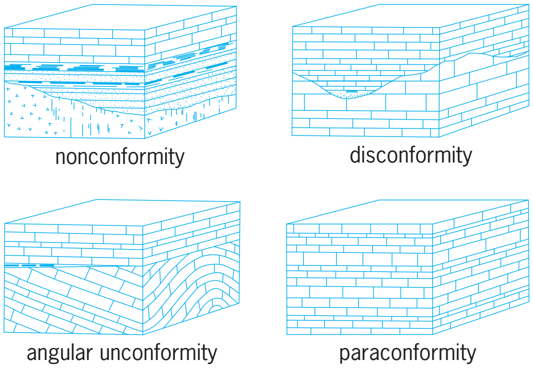
Another well-known example of indeterminacy involves energy and time, as given by inequality (2). Physically, its origins

$$\Delta E \times \Delta t \gtrsim \hbar \qquad (2)$$

are somewhat different from those of inequality (1). Inequality (2) relates, for example, lifetimes of unstable states with the widths of their lines. *See* LINEWIDTH.

In quantum physics, relations similar to inequalities (1) and (2) hold for pairs of many other quantities. They demonstrate that the acquisition of the information about a quantum object cannot be usually achieved without altering its state. Much of the strangeness of quantum physics can be traced to this impossibility of separating the information about the state from the state itself. *See* NONRELATIVISTIC QUANTUM THEORY; QUANTUM MECHANICS. [W.H.Z.]

Unconformity In the stratigraphic sequence of the Earth's crust, a surface of erosion that cuts the underlying rocks and is overlain by sedimentary strata. The unconformity represents an interval of geologic time, called the hiatus, during which no deposition occurred and erosion removed preexisting rock. The result is a gap, in some cases encompassing millions of years, in the stratigraphic record. *See* STRATIGRAPHY.



nonconformity

disconformity

angular unconformity

paraconformity

Four types of unconformity. (*After C.O. Dunbar and J. Rodgers, Principles of Stratigraphy, Wiley, 1957*)

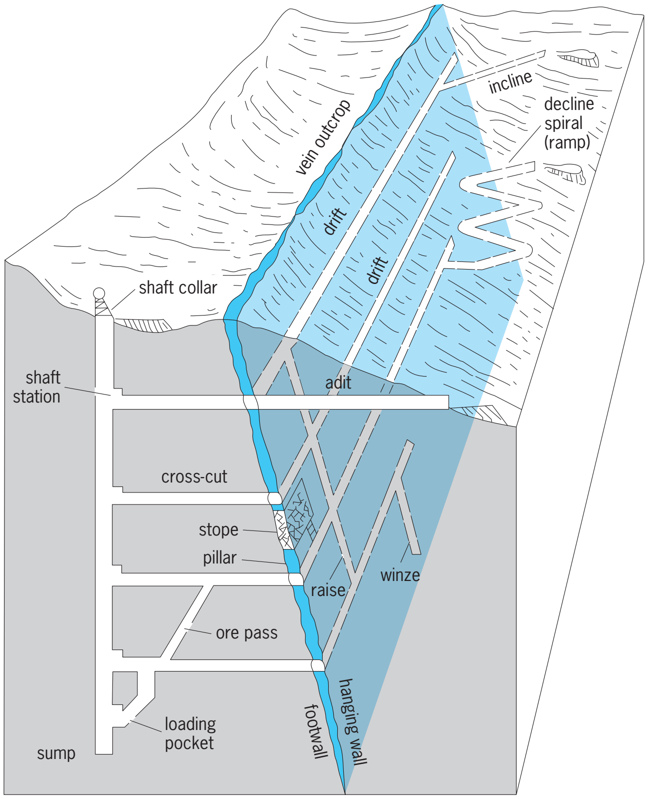
There are four kinds of unconformable relations (see illustration): *Nonconformity*—underlying rocks are not stratified, such as massive crystalline rocks formed deep in the Earth. *Angular unconformity*—underlying rocks are stratified but were deformed before being eroded, resulting in angular discordance; this was the first type to be recognized; the term unconformity was originally used to describe the geometric relationship between the underlying and overlying bedding planes. *Disconformity*—underlying strata are undeformed and parallel to overlying strata, but separated by an evident erosion surface. *Paraconformity*—strata are parallel and the erosion surface is subtle, or even indistinguishable from a simple bedding plane. [C.W.By.]

Underground mining The extraction of ore from beneath the surface of the ground. Underground mining is also applied to deposits of industrial (nonmetallic) minerals and rocks, and underground or deep methods are used in coal mining. Some ores and industrial minerals can be recovered from beneath the ground surface by solution mining or in-place leaching using boreholes. *See* COAL MINING; SOLUTION MINING.

Underground mining is done where mineral deposits are situated beyond the economic depth of open pit mining; it is generally applied to steeply dipping or thin deposits and to disseminated or massive deposits for which the cost of removing the overburden and the maintaining of a slope angle in adjacent waste rock would be prohibitive. *See* OPEN PIT MINING.

Underground mine entries are by shaft, adit, incline, or spiral ramp (see illustration). Development workings, passageways for gaining access to the orebody from stations on individual mine levels, are called drifts if they follow the trend of the mineralization, and cross-cuts if they are driven across the mineralization. Workings on successive mine levels are connected by raises, passageways that are driven upward. Winzes are passageways that are sunk downward, generally from a lowermost mine level.

In a fully developed mine with a network of levels, sublevels, and raises for access, haulage, pumping, and ventilation, the ore is mined from excavations referred to as stopes. Pillars of unmined material are left between stopes and other workings for temporary or permanent natural support. In large-scale mining methods and in methods where an orebody and its overlying waste rock are allowed to break and cave under their own weight, the ore is extracted in large collective units called blocks, panels, or slices. *See* MINING.



Underground mining entries and workings.

Information on the size, shape, and attitude of a deposit and information for estimating the tonnage and grade of the ore is taken from drill holes and underground exploration workings. Underground exploration workings are used for bulk and detailed sampling, rock mechanics testing, and the siting of machinery for underground drilling.

Where high topographic relief allows for an acceptable tonnage of ore above a horizontal entry site, an adit or blind tunnel is driven as a cross-cut to the deposit or as a drift following the deposit from a portal at a favorable location for the surface plant, drainage facilities, and waste disposal. In situations where the deposit lies below or at a great distance from any portal site for an adit, entry must be made from a shaft collar or from an incline or decline portal. A large mine will commonly have a main multipurpose entry and several more shafts or adits to accommodate personnel, supplies, ventilation, communication, and additional production.

A fundamental condition in the choice of mining method is the strength of the ore and wall rock. Strong ore and rock permit relatively low-cost methods with naturally supported openings or with a minimum of artificial support. Weaker ore and wall rock necessitate more costly methods requiring widespread temporary or permanent artificial support such as rock bolting. Large deposits with weak ore and weak walls that collapse readily and provide suitably broken material for extraction may be mined by low-cost caving methods. Few mineral deposits are so uniform that a single method can be used without modification in all parts of the mine. [W.C.Pe.]

Underwater demolition The controlled use of explosives to achieve specific underwater work requiring cutting, fragmenting, perforating, or pounding.

In addition to wreck removal and channel widening and deepening uses, a wide range of commercial applications has been developed for underwater demolition. In the offshore oil and gas industries, charges may be placed and fired well below the ocean floor to open fissures in the rock, cut off steel pipe, open trenches, and remove old structures. The military uses underwater demolition to remove obstacles to amphibious assault.

Special charge shapes and sizes allow very precise work to be done with explosives. While charges for military purposes are usually placed by divers, explosives used commercially can also be placed by crewed submersibles or remote-operated vehicles. *See* DIVING; EXPLOSIVE; SHIP SALVAGE. [W.I.M.]

Underwater navigation The process of directing the movements of submersible vehicles, and divers, from one point to another. The development of improved submersible vehicles, coupled with advances in saturated diving, has resulted in new requirements for underwater navigation. Various methods which have proved successful include acoustic transponder systems, dead reckoning, surface-referenced navigation from a support ship, homing, and various combinations of these. The choice of the navigation system depends on such factors as precision required, area to be covered, availability of surface vessels, sea state under which they are expected to operate, and for crewed vehicles the redundancy necessary for safety. *See* DIVING; SUBMARINE; UNDERWATER VEHICLE.

Acoustic transponders. The most accurate undersea navigation systems use acoustic transponders to precisely determine position with respect to points on the sea floor. A minimum of two transponders are normally dropped from a surface or submerged vehicle to establish a bottom-tethered array. The transponders can be interrogated by surface vessels, submersible vehicles, or divers. When the navigation solution is computed on the surface vessel, the submerged vehicle also carries a transponder, and the position of the submerged vehicle is computed relative to the bottom-tethered array.

Dead reckoning. An undersea vehicle needs sensors to show distance traveled and direction of travel for dead-reckoning estimation of position. The most promising sensor for operation near the sea floor is a Doppler sonar. Ground speed, fore-aft and athwartship, can be determined from the Doppler shift in frequency of signals returned from the sea floor. Pulse-type and continuous-wave Doppler sonars are available. The pulse type, which makes use of a frequency tracker circuit to lock on the received pulse, appears to offer the best accuracy, and it has the ability to operate to 600 ft (180 m) above the sea floor. *See* SONAR.

In addition to Doppler sonar, some specialized submersibles carry inertial dead reckoning in the form of a small, stabilized platform. *See* DEAD RECKONING; INERTIAL GUIDANCE SYSTEM.

Other methods. Most submersible vehicles carry additional navigation sensors. The horizontal obstacle sonar (HOS) which is a constant-transmission frequency-modulated sonar (CTFM), is normally used to detect objects ahead of the submersible. This sonar also has a transponder channel for determining bearing and range to specially designed transponders. An altitude-depth sonar provides vertical navigation by furnishing depth and altitude off the bottom. Finally, a vertical obstacle sonar (VOS) determines heights of objects in the path of the vehicle. Both horizontal and vertical obstacle-avoidance sonars are useful in under-ice navigation. *See* HOMING; PILOTING.

An acoustic tracking system allows the monitoring and vectoring of the position of a vehicle from a surface vessel, where space and weight are not at a premium, and Loran C, the Global Positioning System, Omega, or other radio techniques can be used to determine the ship's own position in geographic coordinates. Surface tracking systems are of two types: ultrashort baseline, employing orthogonal line hydrophone arrays; and short baseline, employing four separate hydrophones. *See* MARINE NAVIGATION.

Submarines must operate over wide areas of the ocean and often under highly secure and covert conditions; therefore, navigation techniques which depend upon sonic or electromagnetic emissions, or which restrict movements of the vehicle to either near-bottom or near-surface regions, are judged to be too restrictive. The ability of inertial navigation systems to operate without frequent recourse to external position updates makes them prime candidates for submarine navigation. The need for covert and secure long-duration navigation has resulted in the evolution of a navigation configuration that uses a pair of electrostatic gyroscope navigators (ESGNs) as the primary elements of an integrated navigation subsystem. The very stable, low-drift characteristics of the electrostatic gyroscope result in an inertial navigation system with a low and highly predictable error growth. Weapons system accuracy is further enhanced by velocity derived from both gyroscopes and secure correlation velocity sonar techniques to give a direct measure of the submarine ground speed. Vertical deflection maps, which are used for vertical-axis tilt compensation of the gyroscopes, are generated from combined satellite and oceanographic surveys of the Earth's gravity field. The relatively rare position resets are selected from either Global Positioning System satellite or bathymetric sonar data. The passive electromagnetic-log, which measures vehicle velocity relative to the water and is therefore subject to ocean current errors, is used primarily to damp the gyroscope computational (Schuler) oscillations. The various data are processed in a central navigation computer which uses statistical estimation algorithms. *See* ESTIMATION THEORY.

Navigation has always been a difficult problem for divers. Some of the same sonars developed for submersible pilotage offer an answer for a diver. A horizontally swept constant-transmission frequency-modulated sonar is well matched to the excursions of saturated divers, who are limited in allowable vertical movement. By communication with the habitat, divers who stray too far or lose their orientation can be guided back to safety. [C.J.Hr.; J.A.C.; E.St.G.]

Underwater photography The techniques involved in using photographic equipment underwater. By far the greatest percentage of underwater photography is done within sport-diving limits in the tropical oceans.

Underwater photographers are faced with specific technical challenges. Water is 600 times denser than air and is predominantly blue in color. Depth affects light and creates physiological considerations for the photographer. As a result, underwater photography requires an understanding of certain principles of light beneath the sea.

As in all photography, consideration of the variables of light transmission is crucial to underwater photography. When sunlight strikes the surface of the sea, its quality and quantity change in several ways. As light travels from air to a denser medium, such as water, the light rays are bent (refracted); one result is magnification of underwater objects by one-third as compared to viewing them in air. The magnification effect must be considered when estimating distances underwater, which is critical for both focus and exposure. Light is absorbed when it propagates through water. Variables affecting the level of light penetration include the time of day (affects the angle at which the sunlight strikes the surface of the water); cloud cover; clarity of the water; depth (light is increasingly absorbed with increasing depth); and surface conditions (if the sea is choppy, more light will be reflected off the surface and less light transmitted to the underwater scene). *See* LIGHT; PHOTOGRAPHY; REFRACTION OF WAVES.

Depth affects not only the quantity of light but also the quality of light. Once light passes from air to water, different wavelengths of its spectrum are absorbed as a function of the color of the water and depth. Even in the clearest tropical sea, water serves as a powerful cyan (blue-green) filter. Natural full-spectrum photographs can be taken only with available light in very shallow depths. In ideal daylight conditions and clear ocean water, photographic film fails to record red at about 15 ft (4.5 m) in depth. Orange disappears at 30 ft (9 m), yellow at 60 ft (18 m), green at 80 ft (24 m), and at greater depth only blue and black are recorded on film. To restore color, underwater photographers must use artificial light. *See* SEAWATER.

The water column between photographer and subject degrades both the resolution of the image and the transmission of artificial light (necessary to restore color). Therefore, the most effective underwater photos are taken as close as possible to the subject, thereby creating the need for a variety of optical tools to capture subjects of various sizes within this narrow distance limitation.

There are two types of underwater cameras—amphibious and housed. Amphibious cameras may be used either underwater or topside, although some lenses are for underwater use only (known as water contact lenses). A housed camera is a conventional above-water camera that has been protected from the damaging effects of seawater by a waterproof enclosure. The amphibious camera is protected by a series of O-rings, primarily located at the lens mount, film loading door, shutter release, and other places where controls are necessary. The O-rings make the system not only resistant to leaks but also impervious to dust or inclement weather when used above water. [S.Fri.]

Deep-sea underwater photography—approximately 150 ft (35 m)—requires the design and use of special camera and lighting equipment. Watertight cases are required for both camera and light source, and they must be able to withstand the pressure generated by the sea. For each 33 ft (10 m) of depth, approximately one additional atmosphere ($\sim 10^2$ kilopascals) of pressure is exerted. At the greatest ocean depths, about 40,000 ft (12,000 m), a case must be able to withstand 17,600 lb/in.^{2} (1200 kg/cm^2). The windows for the lens and electrical seals must also be designed for such pressure to prevent water intrusion.

Auxiliary lighting is required, since daylight is absorbed in both intensity and hue. The camera must be positioned and triggered to render the desired photograph, and the great depths preclude a free-swimming human operator. Operation is often from a cable via sonar sensing equipment or from deep-diving underwater vehicles. Bottom-sensing switches can operate deep-sea cameras for photographing the sea floor, and remotely operated vehicles (ROVs) can incorporate both video and still cameras. *See* SONAR; UNDERWATER VEHICLE.

When an observer descends to great depths in a diving vehicle, the camera can assist in documentation by recording what is seen. Furthermore, the visual data will assist in accurate description of the observed phenomena. Elapsed-time photography with a motion picture camera in the sea is important in studying sedimentation deposits caused by tides, currents, and storms. Similarly, the observation of biological activity taken with the elapsed-time camera and then speeded up for viewing may reveal processes that cannot ordinarily be observed. *See* DIVING; PHOTOGRAPHY; UNDERWATER TELEVISION. [H.E.E.; S.Fri.]

Underwater sound The production, propagation, reflection, scattering, and reception of sound in seawater. The sea covers approximately 75% of the Earth's surface. In terms of exploration, visible observation of the sea is limited due to the high attenuation of light, and radar has very poor penetrability into salt water. Because of the extraordinary properties that sound has in the sea, and because of some of the inherent characteristics of the sea, acoustics is the principal means by which the sea has been explored. *See* OCEAN.

Absorption. Sound has a remarkably low loss of energy in seawater, and it is that property above all others that allows it to be used in research and other application. Absorption is the loss of energy due to internal causes, such as viscosity. Over the frequency range from about 100 Hz (cycles per second) to 100 kHz, absorption is dominated by the reactions of two molecules, magnesium sulfate ($MgSO_4$) and boric acid [$B(OH)_3$]. These molecules are normally in equilibrium with their ionic constituents. The pressure variation caused by an acoustic wave changes the ionic balance and, during the passage of the pressure-varying acoustic field, it cannot return to the same equilibrium, and energy is given up. This is called chemical relaxation. At about 65 kHz magnesium sulfate dominates absorption, and boric acid is important near 1 kHz. *See* SEAWATER; SOUND; SOUND ABSORPTION.

Sound speed. The speed of sound in seawater and its dependence on the parameters of the sea, such as temperature, salinity, and density, have an enormous effect on acoustics in the sea. Generally the environmental parameter that dominates acoustic processes in oceans is the temperature, because it varies both spatially and temporally. Solar heating of the upper ocean has one of the most important effects on sound propagation. As the temperature of the upper ocean increases, so does the sound speed. Winds mix the upper layer, giving rise to a layer of water of approximately constant temperature, below which is a region called the thermocline. Below that, most seawater reaches a constant temperature. All these layers depend on the season and the geographical location, and there is considerable local variation, depending on winds, cloud cover, atmospheric stability, and so on. Shallow water is even more variable due to tides, fresh-water mixing, and interactions with the sea floor. Major ocean currents, such as the Gulf Stream and Kuroshio, have major effects on acoustics. The cold and warm eddies that are spun off from these currents are present in abundance and significantly affect acoustic propagation. *See* GULF STREAM; KUROSHIO; OCEANOGRAPHY.

Pressure waves. The science of underwater sound is the study of pressure waves in the sea over the frequency range from a few hertz to a few megahertz. The International System (SI) units are the pascal (Pa) for pressure (equal to one newton per square meter) and the watt per square meter (W/m^2) for sound intensity (the flow of energy through a unit area normal to the direction of wave propagation). In acoustics, it is more convenient to refer to pressures, which are usually much smaller than a pascal, and the consequent intensities with a different reference, the decibel. Intensity in decibels (dB) is ten times the logarithm to the base ten of the measured intensity divided by a reference intensity. *See* DECIBEL; SOUND INTENSITY; SOUND PRESSURE.

Wave propagation. The mathematical equation that sound obeys is known as the wave equation. Its derivation is based on the mathematical statements of Newton's second law for fluids (the Navier-Stokes equation), the equation of continuity (which essentially states that when a fluid is compressed, its mass is conserved), and a law of compression, relating a change of volume to a change in pressure. By the mathematical manipulation of these three equations, and the assumption that only very small physical changes in the fluid are taking place, it is possible to obtain a single differential equation that connects the acoustic pressure changes in time to those in space by a single quantity, the square of the sound speed (c), which is usually a slowly varying function of both space and time. *See* NAVIER-STOKES EQUATION; WAVE EQUATION.

Knowing the sound speed as a function of space and time allows for the investigation of the spatial and temporal properties of sound, at least in principle. The mathematics used to find solutions to the wave equation are the same as those that are used in other fields of physics, such as optics, radar, and seismics. *See* WAVE MOTION.

In addition to knowing the speed of sound, it is necessary to know the location and nature of the sources of sound, the location and features of the sea surface, the depth to the sea floor, and, in many applications, the physical structure of the sea floor. It is not possible to know the sound speed throughout the water column or know the boundaries exactly. Thus the solutions to the wave equation are never exact representations of nature, but estimates, with an accuracy that depends on both the quality of the knowledge of the environment and the degree to which the mathematical or numerical solutions to the wave equation represent the actual physical situation.

Ambient noise. A consequence of the remarkable transmission of sound is that unwanted sounds are transmitted just as efficiently. One of the ultimate limitations to the use of underwater sound is the ability to detect a signal above the noise. In the ocean, there are four distinct categories of ambient sound: biological, oceanographic physical processes, seismic, and anthropogenic. *See* ACOUSTIC NOISE; INFRASOUND.

Scattering and reverberation. The other source of unwanted sound is reverberation. Sound that is transmitted inevitably finds something to scatter from in the water column, at the sea surface, or at the sea floor. The scatter is usually in all directions, and some of it will return to the system that processes the return signals. Sources of scattering in the water column are fish, particulates, and physical inhomogeneities. The sea surface is, under normal sea conditions, agitated by winds and has the characteristic roughness associated with the prevailing atmospheric conditions. Rough surfaces scatter sound with scattering strengths that depend on the roughness, the acoustic frequency (or wavelength), and the direction of the signal. The scattering is highly time-dependent, and needs to be studied with an appropriate statistical approach. The sea floor has inherent roughness and is usually inhomogeneous, both properties causing scatter. Although scatter degrades the performance of sonars, the characteristics of the return can be determined to enable its cancellation through signal processing or array design. Scattering can also be used to study the sea surface, the sea floor, fish types and distribution, and inhomogeneities in the water column. *See* SCATTERING LAYER; SONAR. [R.R.G.]

Underwater television

Any type of electronic camera that is located underwater in order to collect and display images. It must be packaged in a waterproof housing. The underwater camera may be packaged with its own recording device, or it can be attached to a television that is located on a ship, in a laboratory, or at a remote site. In the latter case, the images by the camera are real-time images. An underwater television may be used for sport, ocean exploration, industrial applications, or military purposes. Common imaged subjects are animals, coral reefs, underwater shipwrecks, and underwater structures such as piers, bridges, and offshore oil platforms.

During the daytime and at minimal depths, underwater television can be used to view objects illuminated with natural sunlight. For nighttime viewing or at very deep depths, artificial lights must be used. Light in the ocean is reduced in intensity quite severely: even in the clearest natural waters, a beam of blue or green light will be reduced in intensity by approximately 67% every 230 ft (70 m). Light that is propagating through an aqueous medium such as seawater or lake water will also be selectively reduced in intensity, based on wavelength. In most situations, the extreme reds and blues will be most severely attenuated, with the region of highest clarity being the yellow to blue-green wavelengths. *See* ELECTROMAGNETIC RADIATION.

Modern advances in television cameras have opened up a host of applications for underwater viewing, such as of standard-video, charge-injection-device, silicon-intensified-target, or charge-coupled-device cameras. These cameras can be adapted for high frame rate, low light level, or underwater color imaging. Computer modeling of underwater images can be used to predict the performance of an underwater imaging system in terms of range of viewing and quality of images as a function of the clarity of the water. *See* CHARGE-COUPLED DEVICES; TELEVISION; TELEVISION CAMERA; UNDERWATER PHOTOGRAPHY. [J.S.J.]

Underwater vehicle

A submersible work platform designed to be operated either remotely or directly. Underwater vehicles are grouped into three categories: deep submersible vehicles (DSVs), remotely operated vehicles (ROVs), and autonomous underwater vehicles (AUVs). There are also hybrid vehicles which combine two or three categories on board a single platform. Within each category of submersible there are specially adaped vehicles for specific work tasks. These can be purpose-built or modifications of standard submersibles.

There are five types of DSVs: one-atmosphere untethered vehicles; one-atmosphere tethered vehicles, including observation/work bells; atmospheric diving suits; diver lockout vehicles; and wet submersibles. While they differ mainly in configuration, source of power, and number of crew members, all carry a crew at 1-atm (10^2-kilopascal) pressure within a dry chamber. An exception is the wet submersible, where the crew is exposed to full depth pressure. The purpose of the DSV is to put the trained mind and eye to work inside the ocean. The earliest submersibles had very small viewing ports fitted into thick-walled steel hulls. In the mid-1960s, experimental work began on use of massive plastics (acrylics) as pressure hull materials. Today, submersibles with depth capabilities to 3300 ft (1000 m) are being manufactured with pressure hulls made entirely of acrylic. Essentially the hull is now one huge window.

The first ROVs were developed in the late 1950s for naval use. By the mid-1970s, they were used in the civil sector. The rapid acceptance of these submersibles is due to their relatively low cost and the fact that they do not put human life at risk when undertaking hazardous missions. However, their most important attribute is that they are less complex. By virtue of their surface-connecting umbilical cable, they can operate almost indefinitely since there is no human inside requiring life support and no batteries to be recharged. There are four types of ROV: tethered free-swimming vehicles, towed vehicles, bottom reliant vehicles, and structurally reliant vehicles.

AUVs are crewless and untethered submersibles which operate independent of direct human control. Their operations are controlled by a preprogrammed, on-board computer. They were first developed in the military where applications include such tasks as minefield location and mapping, minefield installation, submarine decoys, and covert intelligence collection. Civilian tasks include site monitoring, basic oceanographic data gathering, under-ice mapping, offshore structure and pipeline inspection, and bottom mapping. These submersibles are particularly useful where long-duration measurements and observations are to be made and where human presence is not required.

AUVs span a wide range of sizes and capabilities, related to their intended missions. Each is a mobile instrumentation platform with propulsion, sensors, and on-board intelligence designed to complete sampling tasks autonomously. At the large end of the scale, transport-class platforms in the order of 10 m (33 ft) length and 10 metric ton (11 tons) weight in air have been designed for missions requiring long endurance, high speed, large payloads, or high-power sensors. At the small end of the scale, network-class platforms in the order of 1 m (3.3 ft) length and 100 kg (220 lb) weight in air address missions requiring portability, multiple platforms, adaptive spatial sampling, and sustained presence in a specific region. Vehicles can also be categorized in terms of propulsion method (propeller-driven or buoyancy-driven) or in terms of their maximum operating depth.

Hybrid vehicles are those that combine crewed vehicles, remotely operated vehicles, and divers. For example, the hybrid *DUPLUS II* can operate either as a tethered free-swimming ROV or as a 1-atm tethered crewed vehicle. This evolved to provide capability for remotely conducting those tasks for which human skills are not needed, and then to put the human at the place where those skills are required. Other hybrid examples include ROVs that can be controlled remotely from the surface or at the work site by a diver performing maintenance and repair tasks. [D.Wal.; T.B.C.]

Uninterruptible power system A system that provides protection against commercial power failure and variations in voltage and frequency. Uninterruptible power systems (UPS) have a wide variety of applications where unpredictable changes in commercial power will adversely affect equipment. This equipment may include computer installations, telephone exchanges, communications networks, motor and sequencing controls, electronic cash registers, hospital intensive care units, and a host of others. The uninterruptible power system may be used on-line between the commercial power and the sensitive load to provide transient free well-regulated power, or off-line and switched in only when commercial power fails.

There are three basic types of uninterruptible power system. These are, in order of complexity, the rotary power source, the standby power source, and the solid-state uninterruptible power system.

The rotary power source consists of a battery-driven dc motor that is mechanically connected to an ac generator. The battery is kept in a charged state by a battery charger that is connected to the commercial power line. In the event of a commercial power failure, the battery powers the dc motor which mechanically drives the ac generator. The sensitive load draws its power from the ac generator and operates through the outage.

The standby power source consists of a battery connected to a dc-to-ac static inverter. The inverter provides ac power for the sensitive load through a switch. A battery charger, once again, keeps the battery on full charge. Normally, the load operates directly from the commercial power line. In the event of commercial power failure, the switch transfers the sensitive load to the output of the inverter.

The solid-state uninterruptible power system has a general configuration much like that of the standby power system with one important exception. The sensitive load operates continually from the output of the static inverter. This means that all variations on the commercial power lines are cleaned and regulated through the output of the uninterruptible power system. A commercial power line, known as a bypass, is provided around the uninterruptible power system through a switch. Should the uninterruptible power system fail at some point, the commercial power is automatically transferred to the sensitive load through the switch. This scheme is known as an on-line automatic reverse-transfer uninterruptible power system.

An uninterruptible power system consists of four major subsystems: a method to put energy into a storage system, a battery charger; an energy storage system, the battery; a system to convert the stored energy into a usable form, the static inverter; and a circuit that electrically connects the sensitive load to either the output of the uninterruptible power system or to the commercial power line, the transfer switch. The position of the transfer switch is controlled by a monitor circuit. Generally the switch in an uninterruptible power system is a high-speed solid-state device that can transfer the load from one ac source to another with little or no break in power. *See* ELECTRIC POWER SYSTEMS; ELECTRIC SWITCH. [J.Su.]

Unit operations A structure of logic used for synthesizing and analyzing processing schemes in the chemical and allied industries, in which the basic underlying concept is that all processing schemes can be composed from and decomposed into a series of individual, or unit, steps. If a step involves a chemical change, it is called a unit process; if physical change, a unit operation. These unit operations cut across widely different processing applications, including the manufacture of chemicals, fuels, pharmaceuticals, pulp and paper, processed foods, and primary metals. The unit operations approach serves as a very powerful form of morphological analysis, which systematizes process design, and greatly reduces both the number of concepts that must be taught and the number of possibilities that should be considered in synthesizing a particular process.

Most unit operations are based mechanistically upon the fundamental transport processes of mass transfer, heat transfer, and fluid flow (momentum transfer). Unit operations based on fluid mechanics include fluid transport (such as pumping), mixing/agitation, filtration, clarification, thickening or sedimentation, classification, and centrifugation. Operations based on heat transfer include heat exchange, condensation, evaporation, furnaces or kilns, drying, cooling towers, and freezing or thawing. Operations that are based on mass transfer include distillation, solvent extraction, leaching, absorption or desorption, adsorption, ion exchange, humidification or dehumidification, gaseous diffusion, crystallization, and thermal diffusion. Operations that are based on mechanical principles include screening, solids handling, size reduction, flotation, magnetic separation, and electrostatic precipitation. The study of transport phenomena provides a unifying and powerful basis for an understanding of the different unit operations. *See* ABSORPTION; ADSORPTION; CENTRIFUGATION; CHEMICAL ENGINEERING; CLARIFICATION; COOLING TOWER; CRYSTALLIZATION; DEHUMIDIFIER; DIFFUSION; DISTILLATION; DRYING; ELECTROSTATIC PRECIPITATOR; EVAPORATION; FILTRATION; FLOTATION; HEAT EXCHANGER; HUMIDIFICATION; ION EXCHANGE; KILN; LEACHING; MAGNETIC SEPARATION METHODS; MECHANICAL SEPARATION TECHNIQUES; MIXING; PUMP; PUMPING MACHINERY; SEDIMENTATION (INDUSTRY); SOLIDS PUMP; SOLVENT EXTRACTION; THICKENING; TRANSPORT PROCESSES; UNIT PROCESSES. [C.J.Ki.]

Unit processes Processes that involve making chemical changes to materials, as a result of chemical reaction taking place. For instance, in the combustion of coal, the entering and leaving materials differ from each other chemically: coal and air enter, and flue gases and residues leave the combustion chamber. Combustion is therefore a unit process. Unit processes are also referred to as chemical conversions.

Together with unit operations (physical conversions), unit processes (chemical conversions) form the basic building blocks of a chemical manufacturing process. Most chemical processes consist of a combination of various unit operations and unit processes.

The basic tools of the chemical engineer for the design, study, or improvement of a unit process are the mass balance, the energy balance, kinetic rate of reaction, and position of equilibrium (the last is included only if the reaction does not go to completion). *See* CHEMICAL ENGINEERING; UNIT OPERATIONS. [W.F.F.]

Unitary symmetry A type of symmetry law, an important example of which is flavor symmetry, one of the approximate internal symmetry laws obeyed by the strong interactions of elementary particles. According to the successful theory of strong interactions, quantum chromodynamics, flavor symmetry is the consequence of the fact that the so-called glue force (mediated by the SU_3^{color} gauge field) is the same between all the kinds (flavors) of quarks. If the quarks all had the same mass, they then would be dynamically equivalent constituents of hadrons, and hadrons would occur as degenerate multiplets of the group SU_N, where N is the number of quark flavors. The lightest quarks (u and d) have similar masses, so the lightest hadrons, made of u and d quarks, do exhibit an SU_2^{flavor} symmetry known as *i*-spin invariance. The mass of the next heavier quark (s) is much larger than the masses of the u and d quarks, but much smaller than the masses of the yet heavier quarks (c, b, . . .); consequently the hadrons that contain no quarks heavier than the s quark clearly may be grouped into SU_3^{flavor} multiplets. *See* COLOR (QUANTUM MECHANICS); FLAVOR; HADRON; QUANTUM CHROMODYNAMICS; QUARKS.

An example of unitary symmetry is the approximate spin independence of the forces on electrons (as in an atom): There is a fundamental doublet, comprising the spin-up electron and the spin-down electron. Denoting these two states by $|u\rangle$ and $|d\rangle$, all physical properties (energy eigenvalues, charge density, and so on) are unchanged by the replacements shown in the equations below, where α and β are complex numbers. The group

$$|u\rangle \rightarrow \alpha|u\rangle + \beta|d\rangle$$

$$|d\rangle \rightarrow -\beta^*|u\rangle + \alpha^*|d\rangle$$

$$|\alpha|^2 + |\beta|^2 = 1$$

of all the transformations of two states that preserves their hermitean scalar products [$\langle u|d\rangle = 0$, $\langle u|u\rangle = \langle d|d\rangle = 1$] is known as the two-dimensional unitary group, U_2; the transformations of the equations above form a subgroup SU_2 which merely lacks the uninteresting transformations of the form $|u\rangle \rightarrow e^{i\varphi}|u\rangle$ and $|d\rangle \rightarrow e^{i\varphi}|d\rangle$, that is, an equal change of phase of the two states.

The strong interactions are approximately invariant to an SU_2 group; the fundamental doublet can be taken to be the nucleon, with the up and down states proton and neutron. This SU_2 symmetry is known as charge independence, or, loosely, as *i*-spin conservation, the analog to the electron spin being known as *i*-spin $\mathbf{I}$. *See* I-SPIN.

When a sufficient number of strange particles had been observed, it was seen that they, together with the old nonstrange particles, were grouped into multiplets of particles with the same space-time quantum numbers (except for mass; the masses of the members are only similar, not equal). This suggested the existence of a yet larger symmetry; it has turned out that this symmetry is the group of all unitary transformations of a triplet of fundamental particles, U_3, or SU_3 if the uninteresting equal phase change of all particles is omitted. This symmetry is often loosely called unitary symmetry. *See* STRANGE PARTICLES.

A striking difference in the manifestations of SU_2 and SU_3 is that whereas all possible multiplets of the former appear in nature, only those multiplets of the latter appear that can be regarded as compounds of the fundamental triplet in which the net number of component fundamental particles (number of particles minus number of antiparticles) is an integral multiple of 3. In particular, no particle that could be regarded as the fundamental triplet is found. Despite this nonappearance, it turns out that a great deal about the strongly interacting particles (hadrons) is at least qualitatively explained if they are regarded as physical compounds of a fundamental triplet of particles, to which the name quark has been given. The color theory (quantum chromodynamics) of strong interactions explains why single quarks are never observed.

According to the argument given above, hadrons have the approximate symmetry SU_N, where N is the number of kinds of quarks, or flavors. Six flavors of quark are known; in addition to the quarks with the flavors up, down, and strange described above, three more quarks, charm, bottom, and top, have been found. *See* CHARM; ELEMENTARY PARTICLE; J/PSI PARTICLE; UPSILON PARTICLES. [C.J.G.]

Units of measurement Values, quantities, or magnitudes in terms of which other such are expressed. Units are grouped into systems, suitable for use in the measurement of physical quantities and in the convenient statement of laws relating physical quantities. A quantity is a measurable attribute of phenomena or matter.

A given physical quantity A, such as length, time, or energy, is the product of a numerical value or measure $\{A\}$ and a unit $[A]$. Thus Eq. (1) holds.

$$A = \{A\}[A] \tag{1}$$

The unit $[A]$ can be chosen arbitrarily, but it is desirable to define units in such a way that they are derived from a few base units by equations without numerical factors other than unity, and that the equations between numerical values of quantities have exactly the same form as the equations between the quantities. For example, the kinetic energy E of a body is given in terms of its mass M and speed V by Eq. (2), where $E = \{E\}[E]$,

$$E = {}^1\!/\!_2 MV^2 \tag{2}$$

$M = \{M\}[M]$, $V = \{V\}[V]$, and $^1\!/\!_2$ is called a definitional factor and is dimensionless. If the units of E, M, and V are defined in such a way that Eq. (3) holds, then the equation between the numerical values is Eq. (4). A system of units defined in this way

$$[E] = [M][V]^2 \tag{3}$$

$$\{E\} = {}^1\!/\!_2 \{M\}\{V\}^2 \tag{4}$$

is called a coherent system. It is constructed by defining the units of a few base quantities independently; these are called base units. The units of all other quantities are defined by equations similar to Eq. (3) with no numerical factors other than unity, and are called derived units.

In 1960 the General Conference on Weights and Measures (CGPM) gave official status to a single practical system, the International System of Units, abbreviated SI in all languages. The system is a modernized version of the metric system. The SI, as subsequently extended, includes seven base units and twenty-two derived units with special names. These derived units, and others without special names, are derived from the base units in a coherent manner. A set of prefixes is used to form decimal multiples and submultiples of the SI units. Certain units which are not part of the SI but which are widely used or are useful in specialized fields have been accepted for use with the SI or for temporary use in those fields. *See* METRIC SYSTEM.

Geometrical units. Units of plane angle and solid angle are purely geometrical. The SI units of plane and solid angle are regarded as dimensionless derived units.

Plane angle units. The radian (rad), the SI unit of plane angle, is the plane angle between two radii of a circle which cut off on the circumference an arc equal in length to the radius. Since the circumference of a circle is 2π times the radius, the complete angle about a point is 2π rad. *See* RADIAN MEASURE.

The degree and its decimal submultiples can be used with the SI when the radian is not a convenient unit. By definition, 2π rad $= 360^\circ$. The minute $[1' = (1/60)^\circ]$ and the second $[1'' = (1/60)']$ can also be used.

Steradian. The steradian (sr), the SI unit of solid angle, is the solid angle which, having its vertex at the center of a sphere, cuts off an area on the surface of the sphere equal to that of a square with sides of length equal to the radius of the sphere.

Mechanical units. In mechanics, it is convenient to have three base quantities, and two of these are generally chosen to be length and time. Systems of mechanical units may be classified as absolute systems, in which the third base quantity is mass, and gravitational systems, in which the third base quantity is force.

Two absolute systems of metric units are commonly employed, each named for its base units of length, mass, and time: the mks (meter-kilogram-second) absolute system, and the cgs (centimeter-gram-second) absolute system. The mks absolute system is the mechanical portion of the SI. A coherent absolute system of British units is based on the foot, the pound (1 lb $\cong$ 0.4536 kg), and the second.

Gravitational systems, in which the base quantities are length, force, and time, have been frequently employed by engineers, and are therefore sometimes called technical systems.

Length units. The meter (m) is the SI base unit of length. The use of special names for decimal submultiples of the meter should be avoided, and units formed by attaching appropriate SI prefixes to the meter should be used instead.

The angstrom (Å) is equal to 10^{-10} m. Although it has been accepted for temporary use with the SI, it is preferable to replace this unit with the nanometer, using the relation $1\ \text{Å} = 0.1$ nm.

The nautical mile (nmi), equal to 1852 m, has been accepted for temporary use with the SI in navigation. *See* Navigation.

The foot (ft) is, as discussed above, the unit of length in the British systems of units, and it is also in customary use in the United States. Since 1959 the foot has been defined as exactly 0.3048 m. The yard (yd) is defined as exactly 3 ft or 0.9144 m. *See* Length; Measure.

Relative measurements of x-ray wavelengths can be made to a higher accuracy than absolute measurements. Before 1965, most x-ray wavelengths were expressed in terms of the X-unit, which is approximately 10^{-13} m. The X-unit has been superseded by the A* unit, which is based on the tungsten $K\alpha_1$ line as a standard. The peak of this line is defined as exactly 0.2090100 A*. X-ray wavelength tables have been published in terms of this unit. At the time the A* unit was defined, it was thought to equal 10^{-10} m (the angstrom unit, Å) to within 5 parts per million, but the A* unit is now believed to be 20 ± 5 parts per million larger than 10^{-10} m.

Special units whose values are obtained experimentally are used in astronomy. For their definitions *See* Astronomical unit; Light-year; Parsec.

Area units. The square meter (m^2), the SI unit of area, is the area of a square with sides of length 1 m. Other area units are defined by forming squares of various length units in the same manner. *See* Area.

Cross sections, which measure the probability of interaction between an atomic nucleus, atom, or molecule and an incident particle, have the dimensions of area, and the appropriate SI unit for expressing them is therefore the square meter. The barn (b), a unit of cross section equal to $10^{-28}\ m^2$, has been accepted for temporary use with the SI.

Units of volume. The cubic meter (m^3), the SI unit of volume, is the volume of a cube with sides of length 1 m. Other units of volume are defined by forming cubes of various length units in the same manner. The liter (symbol L in the United States) is equal to 1 cubic decimeter (1 dm^3), or equivalently to $10^{-3}\ m^3$. It has been accepted for use with the SI for measuring volumes of liquids and gases.

Time units. The second (s) is the SI base unit of time. However, other units of time in customary use, such as the minute (1 min = 60 s), hour (1 h = 60 min), and day (1 d = 24 h), are acceptable for use with the SI. *See* Time.

Frequency units. The hertz (Hz), the SI unit of frequency, is equal to 1 cycle per second. A periodic oscillation has a frequency of n hertz if it goes through n cycles in 1 s. *See* Frequency (wave motion).

Speed and velocity units. The meter per second (m/s), the SI unit of speed or velocity, is the magnitude of the constant velocity at which a body traverses 1 m in 1 s. Other speed and velocity units are defined by dividing a unit of length by a unit of time in the same manner. *See* Speed; Velocity.

The knot (kn) is equal to 1 nautical mile per hour (1 nmi/h); it has been accepted for temporary use with the SI.

Acceleration units. The meter per second squared (m/s^2), the SI unit of acceleration, is the acceleration of a body whose velocity changes by 1 m/s in 1 s. Other units of acceleration are defined by dividing a unit of velocity by a unit of time in the same manner. *See* Acceleration.

The gal or galileo (symbol Gal) is equal to 1 cm/s^2, or equivalently to $10^{-2}\ m/s^2$.

Mass units. The kilogram (kg), the SI base unit of mass, is the only SI unit whose name, for historical reasons, contains a prefix. Names of decimal multiples and submultiples of the kilogram are formed by attaching prefixes to the word gram (g). The metric ton (t), which is equal to 10^3 kg or 1 megagram (Mg), is permitted in commercial usage of the SI.

The pound (lb), the unit of mass in British absolute system, is also in customary use in the United States. In 1959 the pound was defined to be exactly 0.45359237 kg.

The slug is the unit of mass in the British gravitational system. By definition 1 pound force (lbf) acting on a body of mass 1 slug produces an acceleration of 1 foot per second squared (1 ft/s^2). The slug is equal to approximately 32.174 lb or 14.594 kg. *See* Mass.

Force units. The newton (N), the SI unit of force, is the force which imparts an acceleration of 1 meter per second squared (1 m/s^2) to a body having a mass of 1 kg.

The dyne, the cgs absolute unit of force, is the force which imparts an acceleration of 1 centimeter per second squared (1 cm/s^2) to a body having a mass of 1 g.

The unit of force in the British absolute system is the poundal (pdl), the force which imparts an acceleration of 1 foot per second squared (1 ft/s^2) when applied to a body of mass 1 lb. One poundal is approximately 0.13825 N.

The units of force in the mks gravitational, cgs gravitational, and British gravitational systems are the forces which impart an acceleration equal to the standard acceleration of gravity, $g_n = 9.80665\ m/s^2 \cong 32.174\ ft/s^2$, when applied to bodies having masses of 1 kg, 1 g, and 1 lb, respectively. These units are named the kilogram force (kgf), gram force (gf), and pound force (lbf), respectively. Unfortunately, these units have also been called simply the kilogram, gram, and pound, giving rise to confusion with the mass units of the same name. *See* Force.

Pressure and stress units. The pascal (Pa), the SI unit of pressure and stress, is the pressure or stress of 1 newton per square meter (N/m^2). Other units of pressure can also be formed by dividing various units of force by various units of area, such as the pound force per square inch ($lbf/in.^2$, frequently abbreviated psi).

Pressure has been frequently expressed in terms of the bar and its decimal submultiples, where 1 bar = $10^6\ dynes/cm^2 = 10^5$ Pa. Pressures are also frequently expressed in terms of the height of a column of either mercury or water which the pressure will support.

Two other units which have been frequently used for measuring pressure are the standard atmosphere and the torr. The standard atmosphere (atm) is exactly 101,325 Pa, which is approximately the average value of atmospheric pressure at sea level. The torr is exactly 1/760 atmosphere, or approximately 133.322 Pa. To within 1 part per million, the torr equal to the pressure of a column of mercury of height 1 millimeter (1 mmHg) at a temperature of 0°C when the acceleration due to gravity has the standard value $g_n = 9.80665\ m/s^2$. *See* Atmosphere; Pressure; Pressure measurement.

Energy and work units. The joule (J), the SI unit of energy or work, is the work done by a force of magnitude 1 newton when the point at which the force is applied is displaced 1 m in the direction of the force. Thus, joule is a short name for newton-meter (N-m) of energy or work. *See* Energy; Work.

Units of energy or work in other systems are defined by forming the product of a unit of force and a unit of length in precisely the same manner as in the definition of the joule. Thus, the erg, the cgs absolute unit of energy or work, is the product of 1 dyne and 1 cm.

The foot-poundal (ft-pdl), the British absolute unit of energy or work, is the product of 1 poundal and 1 foot. The foot-pound, or, more properly, the foot-pound force (ft-lbf), the British gravitational unit of energy or work, is the product of 1 lbf and 1 ft.

Sometimes energy is measured in units which are products of a unit of power and a unit of time. Since 1 watt (W) of power equals 1 joule per second (1 J/s), as discussed below, the joule is equivalent to 1 watt-second (1 W · s). In electrical power applications, energy is frequently measured in kilowatthours (kWh), where 1 kWh = $(10^3$ W) (3600 s) $= 3.6 \times 10^6$ J.

The calorie was originally defined as the quantity of heat required to raise the temperature of 1 g of air-free water 1°C under a constant pressure of 1 atm. However, the magnitude of the calorie, so defined, depends on the place on the Celsius temperature scale at which the measurement is made. The International (Steam) Table calorie is defined as exactly 4.1868 J; this is the type of calorie most frequently used in mechanical engineering. The thermochemical calorie, which has been used in thermochemistry in preference to the other types of calorie, is exactly 4.184 J.

The British thermal unit (Btu) was originally defined as the quantity of heat required to raise the temperature of 1 lb of air-free water 1°F under a constant pressure of 1 atm. The International Table Btu is approximately 1055.056 J, and the thermochemical Btu is approximately 1054.350 J.

Power units. The watt (W), the SI unit of power, is the power which gives rise to the production of energy at the rate of 1 joule per second (1 J/s). Other units of power can be defined by forming the ratio of a unit of energy to a unit of time in the same manner. *See* POWER.

The horsepower (hp) is equal to exactly 550 ft · lbf/s, or approximately 745.700 W.

Torque units. The newton-meter (N · m), the SI unit of torque, is the magnitude of the torque produced by a force of 1 newton acting at a perpendicular distance of 1 m from a specified axis of rotation. The joule should never be used as a synonym for this unit.

Units of torque in other systems are defined by forming the product of a unit of force and a unit of length in precisely the same manner as in the definition of the newton-meter.

The foot-poundal (ft · pdl), the British absolute unit of torque, is the product of 1 poundal and 1 foot. The foot-pound (ft · lbf), the British gravitational unit of torque, is the product of 1 lbf and 1 ft. These units are sometimes called the poundal-foot (pdl · ft) and pound-foot (lbf · ft) to distinguish them from the units of energy or work. *See* TORQUE.

Electrical units. For a general discussion of electrical units, including the SI or mks system, three cgs systems [electrostatic system of units (esu), electromagnetic system of units (emu), and gaussian system], and definitions of the SI units ampere (A), volt (V), ohm (Ω), coulomb (C), farad (F), henry (H), weber (Wb), and tesla (T) *see* ELECTRICAL UNITS AND STANDARDS.

This section discusses some additional SI units and some units in the cgs electromagnetic system which are frequently encountered in scientific literature in spite of the fact that their use has been discouraged.

Siemens. The siemens (S), the SI unit of electrical conductance, is the electrical conductance of a conductor in which a current of 1 ampere is produced by an electric potential difference of 1 volt. *See* CONDUCTANCE; ELECTRICAL RESISTANCE.

The siemens was formerly called the mho (℧) to illustrate the fact the unit is the reciprocal of the ohm.

Abampere. The abampere (abA), the cgs electromagnetic unit of current, is that current which, if maintained in two straight, parallel conductors of infinite length, of negligible circular cross section, and placed 1 cm apart in vacuum, would produce between these conductors a force equal to 2 dynes per centimeter of length. The abampere is equal to exactly 10 A.

Abvolt. The abvolt (abV), the cgs electromagnetic unit of electrical potential difference and electromotive force, is the difference of electrical potential between two points of a conductor carrying a constant current of 1 abA, when the power dissipated between these points is equal to 1 erg per second. Then 1 abV $= 10^{-8}$ V.

Maxwell. The maxwell (Mx), the cgs electromagnetic unit of magnetic flux, is the magnetic flux which, linking a circuit of one turn, produces in it an electromotive force of 1 abV as it is reduced to zero in 1 s. Then 1 maxwell $= 10^{-8}$ weber.

Units of magnetic flux density. The gauss (Gs), the cgs electromagnetic unit of magnetic flux density (also called magnetic induction), is a magnetic flux density of 1 maxwell per square centimeter (1 Mx/cm^2). Then 1 gauss $= 10^{-4}$ tesla.

Units of magnetic field strength. The SI unit of magnetic field strength is 1 ampere per meter (1 A/m), which is the magnetic field strength at a distance of 1 m from a straight conductor of infinite length and negligible circular cross section which carries a current of 2π A. This definition is based on the definition, in the SI, of the magnetic field strength H_{SI}. At a distance r from a long straight conductor carrying I, H_{SI} is given by Eq. (5). The left-hand side of this equation is the line integral of H_{SI} around a circular path, all of whose points are at distance r from the conductor. Substituting $r = 1$ m, and $I = 2\pi$ A in this equation gives $H_{\mathrm{SI}} = 1$ A/m.

$$2\pi r H_{\mathrm{SI}} = I \tag{5}$$

The oersted (Oe), the cgs electromagnetic unit of magnetic field strength, is the magnetic field strength at a distance of 1 cm from a straight conductor of infinite length and negligible circular cross section which carries a current of 0.5 abA.

Units of magnetic potential and mmf. The ampere serves as the SI unit of magnetic potential difference and magnetomotive force (mmf), as well as the unit of current. In the SI, the magnetomotive force around a closed path equals the current passing through a surface enclosed by the path. Thus, 1 A is the magnetomotive force around a closed path when a current of 1 A passes through an enclosed surface.

The gilbert (Gb), the cgs electromagnetic unit of magnetic potential difference and magnetomotive force, is the magnetomotive force around a closed path enclosing a surface through which flows a current of $(1/4\pi)$ abA.

Photometric units. Photometric units involve a new base quantity, luminous intensity. For the definition of the candela (cd), the SI unit of luminous intensity, *see* PHOTOMETRY; PHYSICAL MEASUREMENT.

For a general discussion of photometric units, including units of illuminance (illumination) and luminance, and in particular the SI units lux (lx) and candela per square meter (cd/m^2), *see* ILLUMINATION. *See also* LUMINANCE.

Lumen. The lumen (lm), the SI unit of luminous flux, is the luminous flux emitted within a unit solid angle (1 steradian) by a point source having a uniform intensity of 1 candela. *See* LUMINOUS FLUX.

Luminous energy units. The lumen-second (lm·s), the SI unit of luminous energy (also called quantity of light), is the luminous energy radiated or received over a period of 1 s by a luminous flux of 1 lumen. This unit is also called the talbot. *See* LUMINOUS ENERGY.

Radiation units. Certain quantities and units are used particularly in the area of ionizing radiation. The special units curie, roentgen, rad, and rem, which were previously adopted for use in this area, are not coherent with the SI, but their temporary use with the SI has been approved while the transition to SI units takes place.

Activity units. The becquerel (Bq), the SI unit of activity (radioactive disintegration rate), is the activity of a radionuclide decaying at the rate of one spontaneous nuclear transition per second. Thus 1 Bq = 1 s^{-1}.

The curie (Ci), the special unit of activity, is equal to 3.7 × 10^{10} Bq. *See* RADIOACTIVITY.

Exposure units. The SI unit of exposure to ionizing radiation, 1 coulomb per kilogram (1 C/kg), is the amount of electromagnetic radiation (x-radiation or gamma radiation) which in 1 kg of pure dry air produces ion pairs carrying 1 coulomb of charge of either sign. (The ionization arising from the absorption of bremsstrahlung emitted by electrons is not to be included in measuring the charge.) *See* BREMSSTRAHLUNG.

The roentgen (R), the special unit of exposure, is equal to 2.58 × 10^{-4} C/kg.

Absorbed dose units. The gray (Gy), the SI unit of absorbed dose, is the absorbed dose when the energy per unit mass imparted to matter by ionizing radiation is 1 joule per kilogram (1 J/kg).

The rad (rd), the special unit of absorbed dose, is equal to 10^{-2} Gy.

Dose equivalent units. Different types of radiation cause slightly different effects in biological tissue. For this reason, a weighted absorbed dose called the dose equivalent is used in comparing the effects of radiation on living systems. The dose equivalent is the product of the absorbed dose and various dimensionless modifying factors.

The sievert (Sv), the SI unit of dose equivalent, is the dose equivalent when the absorbed dose of ionizing radiation multiplied by the stipulated dimensionless factors is 1 joule per kilogram (1 J/kg).

The rem, the special unit of dose equivalent, is equal to 10^{-2} Sv.

Other units. Logarithmic measures may be used with the SI. *See* DECIBEL; NEPER; PH; VOLUME UNIT (VU).

For units of loudness (sone, phon) *see* LOUDNESS. For units of sound absorption by surfaces *see* ARCHITECTURAL ACOUSTICS. For units of pitch *see* PITCH. For quantities and units pertaining to sound transmission *see* SOUND.

For temperature scales *see* TEMPERATURE.

For units measuring quantities in chemistry *see* ATOMIC MASS UNIT; CONCENTRATION SCALES; ELECTROCHEMICAL EQUIVALENT; GRAM-MOLECULAR WEIGHT; MOLE (CHEMISTRY); MOLECULAR WEIGHT; RELATIVE ATOMIC MASS; RELATIVE MOLECULAR MASS.

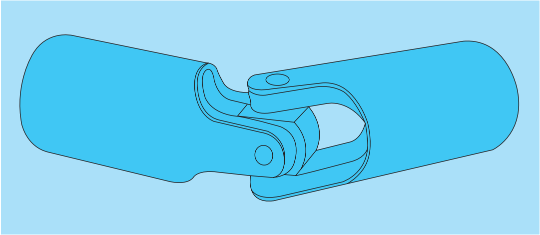
For quantities and units pertaining to nuclear reactors *see* REACTOR PHYSICS.

For units of information content *see* BIT; INFORMATION THEORY.
[J.F.We.]

Universal joint

A linkage that transmits rotation between two shafts whose axes are coplanar but not coinciding. The universal joint is used in almost every class of machinery: machine tools, instruments, control devices, and, most familiarly, automobiles.

A simple universal joint, known in English-speaking countries as Hooke's joint and in continental Europe as a Cardan joint, is shown in the illustration. It consists of two yokes attached to their respective shafts and connected by means of a spider. The angle between the shafts may have any value up to approximately 35°, if angular velocity is moderate when the angle is large. Although one shaft must make a single revolution for each revolution of the second shaft, the instantaneous angular displacement of the first shaft is the same as that of the second shaft only at the end of each 90° of shaft rotation. Thus, only at four positions during each revolution is angular velocity of both shafts the same.



Simple universal joint. (***After C. W. Ham, E. J. Crane, and W. L. Rogers, Mechanics of Machinery, McGraw-Hill, 1958***)

The variation in angular displacement and angular velocity between driving and driven shafts, which is objectionable in many mechanisms, can be eliminated by using two Hooke's joints, with an intermediate shaft. This arrangement is conventional for an automobile drive shaft. The axes of the driving and driven shafts need not intersect; however, it is necessary that the axes of the two yokes attached to the intermediate shaft lie respectively in planes containing the axes of adjoining shafts. *See* FOUR-BAR LINKAGE.
[D.P.Ad.]

Universal motor

A series motor built to operate on either alternating current (ac) or direct current (dc). It is normally designed for capacities less than 1 hp (0.75 kW). It is usually operated at high speed, 3500 revolutions per minutes (rpm) loaded and 8000 to 10,000 revolutions per minute unloaded. For lower speeds, reduction gears are often employed, as in the case of electric hand drills or food mixers. As in all series motors, the rotor speed increases as the load decreases and the no-load speed is limited only by friction and windage. *See* ALTERNATING-CURRENT MOTOR; DIRECT-CURRENT MOTOR.
[I.L.K.]

Universe

The universe comprises everything in existence, including all matter and energy, and the enormous volume which contains them. The observable universe currently spans about 6 × 10^{22} km (4 × 10^{22} mi), and contains 2 × 10^{50} to 1 × 10^{51} kg (4 × 10^{50} to 2 × 10^{51} lb) of matter, yielding an average density of a few atoms per cubic meter. Most of the universe, then, is empty space; the matter is distributed thinly throughout, forming objects and structures at a variety of different sizes.

Constituents. This article will start the cosmic survey with the more familiar objects, following a sequence of increasing size. A number of lesser-known and less tangible entities will complete the survey.

Baryonic matter. Most of the matter encountered in everyday life is in the form of atoms. An atom consists of a positively charged nucleus of protons and neutrons, surrounded by clouds or shells of negatively charged electrons. The protons and neutrons are responsible for most of the mass of the atom. Since both protons and neutrons belong to a class of subatomic particles known as baryons, this ordinary form of atomic matter is called baryonic matter in astronomical contexts. *See* BARYON.

A large fraction of the visible matter elsewhere in the universe—planets, stars, nebulae, galaxies—is also baryonic in nature, but the relative proportions of the chemical elements are very different from here on Earth. Hydrogen is by far the most abundant element in the universe, representing 75% of the total baryonic mass. Helium is also plentiful at about 23% of the total mass. All the heavier elements make up the remaining 2%.

Stars and stellar evolution. The most plentiful denizens of the nearby universe, as seen in the night sky, are the stars. These points of light are objects much like the Sun, which appear faint due to their great distance from Earth. Most visible stars are enormous balls of hot gas (primarily hydrogen and helium) held together by their own gravitation. They are powered by nuclear reactions deep in their interiors, where temperatures and pressures are high enough to fuse hydrogen atoms into helium, releasing energy in the process. *See* CARBON-NITROGEN-OXYGEN CYCLES; NUCLEAR FUSION; PROTON-PROTON CHAIN.

Once a star has used up all of its core hydrogen, it must change its internal structure to burn new fuel sources. A low-mass star (less than a few solar masses) will burn helium for a time, but as the helium fuel is exhausted and its internal furnace wanes, the outer layers of the star are ejected into space, and the core will gradually shrink into a tiny, dense ember, a white dwarf, glowing only from its residual heat.

Higher-mass stars will burn helium, then carbon, and then a succession of even heavier elements, each for a progressively shorter time, until fusable material of any sort abruptly runs out and the star collapses catastrophically. Much of the interior mass of the star is compacted into an ultradense core; the outer layers rebound off this core and explode into space, forming an exceptionally bright type II supernova, shining for several weeks at a billion times the luminosity of the Sun. The stellar core is usually left behind as a neutron star, a small, rapidly rotating body consisting almost entirely of neutrons. Powerful magnetic fields on the surface of a neutron star produce radio waves which appear to blink on and off as the star spins, and the neutron star is observed as a pulsar. In the most extreme cases, the stellar core is compressed so far that it collapses to an infinitesimal point, forming a black hole. *See* BLACK HOLE; NEUTRON STAR; NUCLEOSYNTHESIS; PULSAR; STAR; STELLAR EVOLUTION.

Solar system. The Sun is accompanied by a number of smaller objects of various sizes and compositions. The Sun's gravitational domain extends out to almost half a parsec (1 parsec equals 3.1×10^{13} km or 1.9×10^{13} mi) but the planets, the best-known elements of the solar system, lie much closer, within about 5×10^9 km (3×10^9 mi) of the center. *See* PLANET; SOLAR SYSTEM.

Extrasolar planets. In recent years, strong evidence has been mounting that the Sun is not the only star with a planetary system. At least 60 nearby stars, similar in type to the Sun, exhibit subtle periodic shifts in their motion which are most likely due to the gravitational influence of small orbiting companions.

Interstellar material. The "empty" space between the stars actually contains significant amounts of matter—some of it distributed continuously, some of it concentrated in enormous dark clouds—collectively known as the interstellar medium. Also scattered throughout space are denser clouds of molecular hydrogen (H_2), which contain traces of carbon monoxide (CO) and more complex molecules, and are sprinkled with the heavier elements. These clouds often are the site of star formation, when external gravitational disturbances or shock waves trigger the collapse of portions of these clouds. *See* INTERSTELLAR MATTER; MOLECULAR CLOUD.

Galaxies. Stars and interstellar matter are not distributed uniformly throughout the universe but cluster together in vast units known as galaxies, each containing from 10 million to 1 trillion stars. Galaxies are categorized into three types—spiral, elliptical, and irregular—with numerous subclasses based on size and structure. The Milky Way Galaxy is a typical spiral galaxy—a flattened disk of some 10^{11} stars. *See* GALAXY, EXTERNAL.

Quasars. Supermassive black holes, similar to the stellar-sized black holes which form during the supernova explosion of a massive star but containing 10^6 to 10^7 solar masses instead of only a few, are thought to exist at the centers of many galaxies—including, perhaps, the Milky Way. As stellar or interstellar matter is drawn into the black hole, it forms an accretion disk around the central point, where it is heated by friction to temperatures of millions of kelvins and glows brightly with a luminosity equivalent to 10^{12} Suns. At the far reaches of the universe, these galaxy cores appear to observers as starlike point sources, and were thus labeled quasistellar objects or quasars when first discovered. *See* QUASAR.

Groups, clusters, and large-scale structure. Galaxies themselves are usually bound together in groups (up to about 50 galaxies) and clusters (50 to thousands of galaxies) spanning regions 2–10 Mpc in diameter. Clusters accumulate into yet larger agglomerations called superclusters. Groups and clusters seem to be concentrated in thin sheets, surrounding enormous voids with very few galaxies. Superclusters sit at the edges and vertices where several surfaces intersect.

Antimatter. All subatomic particles have oppositely charged antiparticle counterparts. When a particle and its corresponding antiparticle collide, they annihilate one another, converting all their mass to energy. Both matter and antimatter are expected to have been formed in the early universe, but clearly not in precisely equal amounts, since the universe (at least the part that observers can see) is predominantly composed of matter. *See* ANTIMATTER.

Nonbaryonic particles. Although most of the matter observed is baryonic in nature, several kinds of nonbaryonic matter also exist in the universe or have been predicted by particle physicists, and may also account for a substantial fraction of the mass of the universe.

Neutrinos are electrically neutral, very low mass particles that are generated in nuclear reactions. They were once suspected to be completely massless entities, but theoretical and experimental evidence is now mounting that they have a tiny but nonzero mass, so that they could exert a small gravitational influence on the universe at large. *See* NEUTRINO.

Other particle species, also appear in cosmic contexts. WIMPs, a sort of slow-moving superneutrino, have been proposed as being responsible for the missing dark mass component of the universe. *See* WEAKLY INTERACTING MASSIVE PARTICLE (WIMP).

Dark matter. A large fraction of the mass of the universe is in some form which cannot be seen but which is evident from its gravitational effect on the motions of bright objects, such as stars and galaxies. This dark matter, or "missing mass," is present on many different scales, from galaxies to clusters to the universe as a whole.

Energy. Energy is a physical entity as real as matter, but somewhat less tangible, which makes it more difficult to categorize easily. Like matter, energy comes in many different forms, which can be readily transformed from one to another. Energy can also be converted to and from matter.

The four basic forces of nature—gravity, electromagnetism, and the strong and weak nuclear forces—may in fact be different facets of a single fundamental force. Particle physics experiments show that under conditions of extremely high energy, the weak nuclear force and electromagnetism merge into a single "electroweak" force. Theoretical efforts are being made to devise a grand unified theory under which the strong force and gravity are also incorporated. Such a unified force may have existed during the moments following the big bang and then fragmented into separate forces as the universe expanded and cooled. *See* ELECTROWEAK INTERACTION; FUNDAMENTAL INTERACTIONS; GRAND UNIFICATION THEORIES; STANDARD MODEL.

Origin and fate. The universe is a dynamically evolving system. By closely studying the current distribution and motion of matter and energy, and collecting the "fossil light" from distant objects, scientists have constructed a fairly consistent picture of the creation of the universe, the big bang theory, which explains the observations fairly well.

Big bang. The observable universe originated some 9–18 billion years ago in a fiery cataclysm termed the big bang. This was not an explosion of compressed matter and energy into a previously empty space. Instead, space itself, as well as everything contained therein, sprang from a single point of infinite density and temperature, and grew to the volume observed today. As it expanded, it cooled, allowing familiar forms of matter to condense from the high-energy "soup" of subatomic particles that constituted the very early universe.

Cosmological redshifts. Distinct spectral features, characteristic of the different chemical elements that are present, appear at well-established locations in the spectrum of an astronomical object, but the entire spectrum is shifted toward shorter wavelengths (bluewards) for an object approaching the observer, or toward longer wavelengths (redwards) for a receding object. The amount of this Doppler shift is closely related to the actual relative speed of the object. *See* DOPPLER EFFECT.

With the exception of a few nearby galaxies, all of the galaxies exhibit redshifts of varying amounts, implying that they are all moving away from the Earth. Edwin Hubble extended this work by determining the distances to these galaxies, and found that the redshift was directly proportional to the distance; that is, translating redshift into recession velocity, the more distant the galaxy, the faster it is moving away from the Earth. The constant of proportionality relating speed and distance now bears Hubble's name, and an accurate determination of this Hubble constant (H_0) is a central pursuit of modern astronomy. Recent studies seem to be converging towards a value of $H_0 = 72$ km/(s)(Mpc).

If space itself is expanding uniformly in all directions, and the galaxies are being carried along in this general expansion, then any point in the universe would see all other points moving away. The greater the distance between two points, the more space exists between them, and the faster this distance increases. Hubble's law is therefore a consequence of the uniform expansion of space, which causes more distant galaxies to exhibit larger redshifts because they are receding from the Earth faster.

If space is expanding uniformly in all directions, then it follows that in the past the universe was smaller. At some point in the past, all matter and energy may have existed in a single point of infinite temperature and density. *See* Hubble constant; Redshift.

Cosmic background radiation. If this picture is correct, and the current universe was spawned from a primordial fireball, then observers should see a residual afterglow from the era when the matter in the universe was hot and emitting strongly, in much the same way that the surfaces of stars shine today. This microwave background was first observed in 1961. The *Cosmic Background Explorer* (*COBE*) satellite mission in 1990 that the spectrum was measured its spectrum over a wide range of wavelengths, establishing the cosmic background radiation temperature at 2.726 K.

Since the cosmic background radiation is an intrinsic characteristic of the universe, observers expect to see it reaching the Earth uniformly from all directions in space. However, reanalysis of the *COBE* data, as well as more recent observations of the cosmic background radiation, shows minute ripples or anisotropies in the temperature of the background radiation. The amplitude and spatial scale of these ripples are of keen interest, since they probably result from the very first clumps of matter that accreted in the early universe. *See* Cosmic background radiation.

Evolution of the universe. The best models for the beginning of the universe start at 10^{-43} second after the big bang itself. At 10^{-43} s, the universe was 10^{30} times smaller than it is today (barely larger than an atom), and had a mean temperature of 10^{30} K. At such temperatures, matter as presently known cannot exist, because the energies are so enormous that even the protons and neutrons themselves are torn apart into separate subsubatomic particles called quarks. The universe was a featureless mixture of quarks, leptons (another class of particles including electrons and neutrinos), and high-energy photons. *See* Lepton; Quantum gravitation; Quarks; Supergravity; Supersymmetry.

At 10^{-34} s, when the temperature had dropped to 3×10^{26} K, heavier exotic particles such as magnetic monopoles could have emerged. Around this time, the rapidly enlarging structure of space may have undergone even faster expansion, driven by the energy of space itself. This era of hyperfast inflation helps explain features of the present-day observable universe, such as the uniformity of the cosmic background radiation over the entire sky, and the way in which the average mass density of the universe is high enough for structures like stars and galaxies to form, but not so large that it would recollapse quickly. *See* Inflationary universe cosmology; Magnetic monopoles.

When the temperature had dropped further, to about 3×10^{12} K, protons and neutrons condensed out of the quark mixture. It was still much too hot for electrons to join them and form atoms, but more complex atomic nuclei were created in a fashion similar to stellar core fusion. This era of big bang nucleosynthesis established the initial composition of the universe, about three-quarters hydrogen, one-quarter helium, and small amounts of lithium, from which all subsequent stellar and supernova nucleosynthesis has proceeded.

Until a time about 100,000 years after the big bang, temperatures were still too high for electrons to join these nuclei to make complete atoms. Up to this point, the universe was relatively opaque, since free charged particles like electrons are very good at absorbing light and other electromagnetic radiation. Once the temperature fell below 3000 K, however, atoms formed, and the universe suddenly became transparent to most wavelengths. The cosmic background radiation formed at this point and has had little interaction with matter since. The formation of structure—the development of clumpiness in the universe, which is seen today as stars, galaxies, and clusters—started slightly before matter-radiation decoupling.

Ultimate fate of the universe. The motions of galaxies indicate that the universe has continued to expand after the initial impulse of the big bang, but it is not known whether this expansion will continue. The situation is complicated by the possible presence of an additional cosmological force, predicted by general relativity, which has the opposite effect from gravitational mass. This cosmological constant, represented by Λ, pushes outward instead of pulling inward like gravity, adding an acceleration term to the expansion of the universe. Interest in Λ has revived in recent years in an attempt to explain deviations in redshift velocities of some very distant galaxies. If $\Lambda > 0$, as some researchers now think, then this would make an infinite expansion more likely, even with significant amounts of dark matter. Currently favored models yield a topologically flat universe. *See* Big bang theory; Cosmology. [B.B.Be.]

Upper-atmosphere dynamics The motion of the atmosphere above 50 km (30 mi). The predominant dynamical phenomena of the upper atmosphere are quite different from those encountered in the lower atmosphere. Among those encountered in the lower atmosphere are cyclones, anticyclones, tropical hurricanes, thunderstorms and shower clouds, tornadoes, and dust devils. Even the largest of these phenomena do not penetrate far into the upper atmosphere. Above an altitude of about 50 km (30 mi), the predominant dynamical phenomena are internal gravity waves, tides, sound waves (including infrasonic), turbulence, and large-scale circulation.

Except under meteorological conditions characterized by convection, the atmosphere is stable against small vertical displacements of small air parcels; this results from buoyancy forces that tend to restore displaced air parcels to their original levels. An air parcel therefore tends to oscillate around its undisturbed position at a frequency known as the Brunt-Vaisala frequency ω_B. If pressure waves are generated in the atmosphere with frequencies much greater than ω_B, they propagate as sound waves. For frequencies much less than ω_B, the waves propagate as internal gravity waves; in this case, the restoring forces for the wave motion are provided primarily by buoyancy (that is, gravity) rather than by compression.

Tides are internal gravity waves of particular frequencies. The term tidal usually implies that the exciting force is gravitational attraction by the Moon or Sun. However, it is conventional in the case of atmospheric tides to include also those waves that are excited by solar heating. One is therefore concerned with three separate excitation functions—lunar gravitation, solar gravitation, and solar heating.

Tidal wind patterns in the upper atmosphere generate electrical currents in the ionosphere through a dynamo action. These in turn give rise to diurnal variations in the geomagnetic field that can be observed at the Earth's surface. *See* Atmospheric tides; Geomagnetic variations; Ionosphere.

Sound waves generated in the lower atmosphere may propagate upward; to maintain continuity of energy flow, the waves might be expected to grow in relative amplitude as they move into the more rarefied upper atmosphere. However, higher temperatures in the upper atmosphere refract most of the energy back toward the Earth's surface, giving rise to the phenomenon known as anomalous propagation. This involves the redirection of upward-moving sound waves back to the surface beyond the point where the source can be heard by waves propagating along the surface. Infrasonic waves with periods from 20 to 80 s have been observed occasionally with detectors at the Earth's surface in connection with auroral activity. *See* SOUND.

There is clear visual evidence of turbulence in the upper atmosphere; this evidence is obtained by examination of vapor trails released from rockets or of long-persisting meteor trails. The source of the turbulence is not clear. The atmosphere is thermodynamically stable against vertical displacements throughout the region above the troposphere, and work has to be done against buoyancy forces in order to produce and maintain turbulence. The only apparent source of energy is internal gravity waves, either tidal or of random period.

There are prevailing patterns of atmospheric circulation in the upper atmosphere, but they are very different from those that occur in the lower atmosphere, which are associated with weather systems and have complicated structures resulting from growth of instabilities. The upper atmospheric large-scale wind systems are mainly diurnal in nature and global in scale.

The main heat source that is responsible for the upper atmospheric circulation is ultraviolet radiation from the Sun, radiation that is mainly absorbed at altitudes between 100 and 200 km (60 and 120 mi). The atmosphere is not a good infrared radiator in this altitude region, so the temperature rises rapidly with altitude, providing a temperature gradient of such a magnitude that molecular conduction transfers the absorbed heat downward to altitudes below 100 km (60 mi) where the atmosphere does have the capability of radiating the energy back to space. Above about 300 km (180 mi), the temperature becomes roughly constant with altitude because very little energy is absorbed there (the gas is exceedingly rarefied) and the thermal conductivity is good enough under these circumstances to virtually eliminate vertical temperature gradients. *See* SOLAR RADIATION.

The region of rising temperature above 80 km (48 mi) is known as the thermosphere. The exosphere is that region of the atmosphere that is so rarefied that for many purposes collisions between molecules can be neglected; it is roughly the region above 500 km (300 mi).

At high latitudes, the ionosphere moves in response to electric fields imposed as a consequence of interactions between the Earth's magnetic field and the solar wind. The imposed electric field causes the ionosphere to drift in a generally antisunward direction over the polar caps (regions at higher latitudes than the auroral zone, or magnetic latitudes greater than about 68°), with a return circulation (that is, generally sunward in direction) just outside the polar caps. *See* ATMOSPHERIC GENERAL CIRCULATION; SOLAR WIND; WIND.

Ultraviolet radiation of suitable wavelengths can photodissociate atmospheric molecules—something of great importance in the upper atmosphere. It is even important in the stratosphere, where ozone is formed as a result of absorption by molecular oxygen of ultraviolet radiation, the important wavelengths being below 242 nanometers. *See* OZONE; STRATOSPHERE. [F.S.J.]

Upsilon particles A family of elementary particles whose first three members were discovered in 1977. The upsilon mesons, Υ, are the heaviest known vector mesons, with masses greater than 10 times that of the proton. They are bound states of a heavy quark and its antiquark. The quarks which bind to form the upsilons carry a new quantum number called beauty or bottomness, and they are called *b*-quarks or *b*. The mass of the *b*-quark is around 5 GeV. The anti-*b*-quark or *b* carries antibeauty, and therefore the upsilons carry no beauty and are often called hidden beauty states. Direct proof of the existence of the *b*-quark was obtained by observing the existence of *B* mesons which consist of a *b*-quark bound to a lighter quark. Thirteen *bb*-mesons have also been observed thus far. *See* ELEMENTARY PARTICLE; MESON; QUARKS. [P.F.]

Upwelling The phenomenon or process involving the ascending motion of water in the ocean. Vertical motions are an integral part of ocean circulation, but they are a thousand to a million times smaller than the horizontal currents. Vertical motions are inhibited by the density stratification of the ocean because with increasing depth, as the temperature decreases, the density increases, and energy must be expended to displace water vertically. The ocean is also stratified in other properties; for example, nutrient concentration generally increases with depth. Thus even weak vertical flow may cause a significant effect by advecting nutrients to a new level. *See* GEOPHYSICAL FLUID DYNAMICS.

There are two important upwelling processes. One is the slow upwelling of cold abyssal water, occurring over large areas of the world ocean, to compensate for the formation and sinking of this deep water in limited polar regions. The other is the upwelling of subsurface water into the euphotic (sunlit) zone to compensate for a horizontal divergence of the flow in the surface layer, usually caused by winds. *See* OCEAN CIRCULATION. [R.L.Sm.]

Uraninite The chief ore mineral of uranium. Uraninite has the idealized chemical composition UO_2, uranium dioxide. Thorium and rare earths, chiefly cerium, are usually present in variable and sometimes large amounts. Lead always is present by radioactive decay of the thorium and uranium present. Complete solid-solution series extend between UO_2, ThO_2 (thorianite), and CeO_2 (cerianite). *See* RADIOACTIVE MINERALS; RARE-EARTH ELEMENTS; THORIANITE; URANIUM.

The color of uraninite is black, grading to brownish black and dark brown in the more highly oxidized material. The luster of fresh material is steel-gray. The hardness is $5^1/_2$–6 on Mohs scale. The specific gravity of pure UO_2 is 10.9, but that of most natural material is 9.7–7.5. [C.Fr.]

Uranium A chemical element, symbol U, atomic number 92, atomic weight 238.03. The melting point is 1132°C (2070°F) and the boiling point is 3818°C (6904°F). Uranium is one of the actinide series. *See* ACTINIDE ELEMENTS; PERIODIC TABLE.

Uranium in nature is a mixture of three isotopes: ^{234}U, ^{235}U, and ^{238}U. Uranium is believed to be concentrated largely in the Earth's crust, where the average concentration is 4 parts per million (ppm). The total uranium content of the Earth's crust to a depth of 15 mi (25 km) is calculated to be 2.2×10^{17} lb (10^{17} kg); the oceans may contain 2.2×10^{13} lb (10^{13} kg) of uranium. Several hundred uranium-containing minerals have been identified, but only a few are of commercial interest. *See* RADIOACTIVE MINERALS; URANINITE.

Because of the great importance of the fissile isotope ^{235}U, rather sophisticated industrial methods for its separation from the natural isotope mixture have been devised. The gaseous diffusion process, which in the United States is operated in three large plants (at Oak Ridge, Tennessee; Paducah, Kentucky; and Portsmouth, Ohio) has been the established industrial process. Other processes applied to the separation of uranium include the centrifuge process, in which gaseous uranium hexafluoride is separated in centrifuge cascades, the liquid thermal diffusion process, the separation nozzle, and laser excitation. *See* ISOTOPE (STABLE) SEPARATION.

Uranium is a very dense, strongly electropositive, reactive metal; it is ductile and malleable, but a poor conductor of electricity. Many uranium alloys are of great interest in nuclear technology because the pure metal is chemically active and anisotropic and has poor mechanical properties. However, cylindrical rods of pure uranium coated with silicon and canned in aluminum tubes (slugs) are used in production reactors. Uranium alloys can also be useful in diluting enriched uranium for reactors and in providing liquid fuels. Uranium depleted of the fissile isotope ^{235}U has been used in shielded containers for storage and transport of radioactive materials. *See* NUCLEAR FUELS; NUCLEAR REACTOR.

Uranium reacts with nearly all nonmetallic elements and their binary compounds. Uranium dissolves in hydrochloric acid and nitric acid, but nonoxidizing acids, such as sulfuric, phosphoric, or hydrofluoric acid, react very slowly. Uranium metal is inert to alkalies, but addition of peroxide causes formation of water-soluble peruranates. *See* URANIUM METALLURGY.

Uranium reacts reversibly with hydrogen to form UH_3 at 250°C (482°F). Correspondingly, the hydrogen isotopes form uranium deuteride, UD_3, and uranium tritide, UT_3. The uranium-oxygen system is extremely complicated. Uranium monoxide, UO, is a gaseous species which is not stable below 1800°C (3270°F). In the range UO_2 to UO_3, a large number of phases exist. The uranium halides constitute an important group of compounds. Uranium tetrafluoride is an intermediate in the preparation of the metal and the hexafluoride. Uranium hexafluoride, which is the most volatile uranium compound, is used in the isotope separation of ^{235}U and ^{238}U. The halides react with oxygen at elevated temperatures to form uranyl compounds and ultimately U_3O_8. [F.We.]

Uranium metallurgy The processing treatments for the production of uranium concentrates and the recovery of pure uranium compounds, as well as the conversion chemistry for producing uranium metal and the processes employed for preparing uranium alloys.

The procedures to recover uranium from its ores are numerous, because of the great variety in the nature of uranium minerals and associated materials and the wide range of concentration in the naturally occurring ores. Recovery of uranium requires chemical processing; however, preliminary treatment of the ore may involve a roasting operation, a physical or chemical concentration step, or a combination of these. In general, one of two leaching treatments—acid leaching and carbonate leaching—is used as the initial step in chemical concentration. The choice depends on the nature of the ore, which largely determines the efficiency and the cost of the process employed. *See* LEACHING.

The concentrate, whether obtained by chemical or physical means, is treated chemically to give a uranyl nitrate solution that can be further purified by solvent extraction. The impurities remain in the aqueous phase, while the uranium is extracted into the organic phase. *See* SOLVENT EXTRACTION.

Uranium metal can be obtained from its halides by fused-salt electrolysis or by reduction with more reactive metals. The reaction of UO_2 with calcium yields metal of fair quality. The largest tonnages of good-quality uranium have been produced by metallothermic reduction of finely divided UF4 with calcium or magnesium in steel bombs lined with fused dolomitic oxide (Ames process). The charge, consisting of an intimate mixture of UF_4 with the reductant metal in granular form together with a suitable booster (usually calcium plus iodine), is placed into the reduction bomb, the lid is bolted down, and the bomb is heated to ignition temperature. The shape of the metal ingot (also referred to as a biscuit) depends on the shape of the reduction bomb.

Uranium alloys are prepared by fusing the components together. All procedures following conventional metallurgical techniques, however, may have to be carried out inside inert-gas glove boxes because many alloys are attacked by oxygen or moisture. *See* NUCLEAR FUELS; NUCLEAR FUELS REPROCESSING; URANIUM. [F.We.]

Uranus The first planet to be discovered with the telescope and the seventh in the order of distance from the Sun. It was found accidentally by W. Herschel in England on March 13, 1781. *See* PLANET.

The obliquity (inclination of rotational axis to orbit plane) of Uranus is 98°, exceeded only by the obliquities of Pluto and Venus. This means that the axis is almost in the plane of the orbit, and thus the seasons on Uranus are very unusual. During summer in one hemisphere, the pole points almost directly toward the Sun while the other hemisphere is in total darkness. Forty-two years later, the situation is reversed. *See* PLUTO; VENUS.

The linear equatorial diameter is 31,770 mi (51,120 km). The mass is 14.5 times the mass of the Earth. The corresponding mean density is greater than that of Saturn even though Uranus is smaller than Saturn. This means that Uranus is richer than Saturn (or Jupiter) in elements heavier than hydrogen and helium but not nearly so rich in these elements as Earth. The same is true for Neptune. *See* JUPITER; NEPTUNE; SATURN.

The temperature that Uranus would assume in simple equilibrium with incident solar radiation at this distance is about 55 K (−360°F). This is essentially identical with the value found by direct measurement. There is thus no evidence for the existence of an internal energy source as observed for Jupiter, Saturn, and Neptune.

Through the telescope, Uranus appears as a small, slightly elliptical blue-green disk. This appearance is confirmed in the nearly featureless pictures of the planet obtained by *Voyager 2*. Uranus owes its characteristic aquamarine color to the relatively high proportion of methane in its atmosphere. The methane abundance is 20 to 30 times the amount corresponding to a solar distribution of the elements, in agreement with the enrichment of heavy elements in the planet deduced from its average density. In striking contrast, the proportion of helium to hydrogen, the two most abundant gases in the planet's atmosphere, is essentially equal to that observed in the Sun. Like Jupiter and Saturn, Uranus exhibits zonal winds that are parallel to the equator, despite the unusual orientation of the planet's rotational axis.

Before the *Voyager 2* encounter, only five satellites of Uranus had been discovered. They form a remarkably regular system with low orbital eccentricities and inclinations close to the plane of the planet's equator. The *Voyager* cameras found 10 additional small satellites, including two that may serve as gravitational "shepherds" for the outermost ring. Like Jupiter, Saturn, and Neptune, Uranus also has more distant, irregular satellites (moons that move in orbits with high inclinations or eccentricities). As of August 2004, six of these unusual moons were definitely established, all discovered since 1997.

A system of 10 narrow rings can be observed around Uranus. The mean width of the widest is only 36 mi (58 km) which is still six to seven times larger than that of the next widest rings. [T.C.O.]

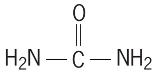
Urban climatology The branch of climatology concerned with urban areas. These locales produce significant changes in the surface of the Earth and the quality of the air. In turn, surface climate in the vicinity of urban sites is altered. The era of urbanization on a worldwide scale has been accompanied by unintentional, measurable changes in city climate. *See* CLIMATOLOGY.

The process of urbanization changes the physical surroundings and induces alterations in the energy, moisture, and motion regime near the surface. Most of these alterations may be traced to causal factors such as air pollution; anthropogenic heat; surface waterproofing; thermal properties of the surface materials; and morphology of the surface and its specific three-dimensional geometry—building spacing, height, orientation, vegetative layering, and the overall dimensions and geography of these elements. Other factors that must be considered are relief, nearness to water bodies, size of the city, population density, and land-use distributions.

In general, cities are warmer than their surroundings, as documented over a century ago. They are islands or spots on the broader, more rural surrounding land. Thus, cities produce a heat island effect on the spatial distribution of temperatures. The timing of a maximum heat island is followed by a lag shortly after sundown, as urban surfaces, which absorbed and stored daytime heat, retain heat and affect the overlying air. Meantime, rural areas cool at a rapid rate.

A number of energy processes are altered to create warming, and various features lead to those alterations. City size, the morphology of the city, land-use configuration, and the geographic setting (such as relief, elevation, and regional climate) dictate the intensity of the heat island, its geographic extent, its orientation, and its persistence through time. Individual causes for heat island formation are related to city geometry, air pollution, surface materials, and anthropogenic heat emission. There are two atmosphere layers in an urban environment, besides the planetary boundary layer outside and extending well above the city: (1) The urban boundary layer is due to the spatially integrated heat and moisture exchanges between the city and its overlying air. (2) The surface of the city corresponds to the level of the urban canopy layer. Fluxes across this plane comprise those from individual units, such as roofs, canyon tops, trees, lawns, and roads, integrated over larger land-use divisions (for example, suburbs). [A.J.B.]

Urea A colorless crystalline compound, formula CH_4N_2O, melting point 132.7°C (270.9°F). Urea is also known as carbamide and carbonyl diamide, and has numerous trade names as well. It is highly soluble in water and is odorless in its purest state, although most samples of even high purity have an ammonia odor. The diamide of carbonic acid, urea has the structure below.



$$H_2N-\overset{\overset{\displaystyle O}{\|}}{C}-NH_2$$

Urea occurs in nature as the major nitrogen-containing end product of protein metabolism by mammals, which excrete urea in the urine. The adult human body discharges almost 50 g (1.8 oz) of urea daily. Urea was first isolated in 1773 by G. F. Rouelle. By preparing urea from potassium cyanate (KCNO) and ammonium sulfate (NH_4SO_4) in 1828, F. Wöhler achieved a milestone, the first synthesis of an organic molecule from inorganic starting materials, and thus heralded the modern science of organic chemistry. *See* Nitrogen; Protein metabolism.

Because of its high nitrogen content (46.65% by weight), urea is a popular fertilizer. About three-fourths of the urea produced commercially is used for this purpose. After application to soil, usually as a solution in water, urea gradually undergoes hydrolysis to ammonia (or ammonium ion) and carbonate (or carbon dioxide). Another major use of urea is as an ingredient for the production of urea-formaldehyde resins, extremely effective adhesives used for laminating plywood and in manufacturing particle board, and the basis for such plastics as malamine. *See* Fertilizer; Urea-formaldehyde resins.

Other uses of urea include its utilization in medicine as a diuretic. In the past, it was used to reduce intracranial and intraocular pressure, and as a topical antiseptic. It is still used for these purposes, to some extent, in veterinary medicine and animal husbandry, where it also finds application as a protein feed supplement for cattle and sheep. Urea has been used to brown baked goods such as pretzels. It is a stabilizer for nitrocellulose explosives because of its ability to neutralize the nitric acid that is formed from, and accelerates, the decomposition of the nitrocellulose. Urea was once used for flameproofing fabrics. Mixed with barium hydroxide, urea is applied to limestone monuments to slow erosion by acid rain and acidic pollutants. [R.D.Wa.]

Urea-formaldehyde-type resins The condensation products obtained by the reaction of urea or melamine with formaldehyde. Resinous condensation products of formaldehyde with other nitrogen-containing compounds, for example, aniline and amides, also belong to this group of resins but have gained only limited utility.

The urea- and melamine-formaldehyde resins (amino resins) possess an excellent combination of physical properties and can be easily fabricated in a variety of colors. They are widely used as adhesives, laminating resins, molding compounds, paper and textile finishes, and surface coatings.

The aniline- and sulfonamide-formaldehyde resins are produced from other compounds containing $—NH_2$ groups that condense with formaldehyde to form methylol derivatives which are capable of further reaction. These resins have received limited attention except for aniline and *p*-toluenesulfonamide. Because of their resistance to the absorption of water, the aniline-formaldehyde resins have been used in electrical applications, such as insulation or panels, where their natural brown color is not objectionable. The sulfonamide-formaldehyde polymers are less colored than the aniline-type resins and have been employed in surface coatings. *See* Condensation reaction; Formaldehyde; Polymerization; Urea. [J.A.M.]

Uredinales An order of fungi known as plant rusts that belong to the division (phylum) Basidiomycota. In nature, all 7000 species are obligate parasites of many vascular plant species. They cause diseases known as rust on numerous cultivated crops, and many trees are also attacked. Each rust species infects one or just a few closely related plant host species. Rust fungi occur on all continents except Antarctica.

The body of a rust fungus consists of numerous microscopic, threadlike, branching hyphae that grow inside the tissues and between the cells of the host plant. Specialized feeding structures, haustoria, grow from these hyphae into the host cells of the plant and provide nourishment for the hyphae. Hyphal cells are binucleate. Depending upon the rust species and environmental conditions, up to six different kinds of spore-producing structures, the sori, may be produced by one rust species. These sori may be powdery, waxy, or crustlike, and whitish, yellow, orange, brown, or blackish.

Rust teliospores that are produced in sori called telia are essential elements for classification. Teliospores consist of one or more specialized probasidial cells. During the development of each of these cells, nuclei fuse and meiosis occurs, resulting in a septate metabasidium from which four haploid meiospores (basidiospores) are formed. Basidiospores are forcibly ejected from the tips of their tiny stalks and are wind-disseminated. After landing on a susceptible host, under proper conditions basidiospores produce new infections. In cold regions, a rust may survive the winter as dormant, thick-walled, dark-colored teliospores. In many rust species, teliospores mature and produce basidiospores with no or little dormancy, especially in the tropics.

Although most rust species require only one host species to complete their life cycles (autoecious rusts), some of the best-known rusts require two taxonomically unrelated hosts (heteroecious rusts).

Rust diseases are controlled most effectively by breeding resistant host varieties. Fungicides are used for some rusts. In the case of some heteroecious rusts, eradication of one of the hosts (the noneconomic one) has been successful. Some rust species are used to aid in biological control of weeds. *See* Basidiomycota; Eumycota; Fungi; Plant pathology. [J.F.Hen.]

Uric acid The main excretory end product of protein metabolism in certain species of birds and reptiles. In mammals, uric acid is derived from purines; in higher primates, including humans, it is excreted as such and is not oxidized to allantoin, the main excretory purine metabolism product of most species. In humans, uric acid levels are increased following excessive intake of dietary purines, primary synthesis in certain diseases (gout, Lesch-Nyhan syndrome), endogenous nucleic acid metabolism (leukemia, an abnormal number of erythrocytes in blood, chemotherapy-induced tumor lysis), and restricted renal excretion (renal diseases, ketoacidosis, lacticidosis, diuretics). Uric acid levels are lowered by the use of drugs causing increased uric acid excretion, and by renal tubular defects. *See* Gout; Kidney disorders; Leukemia; Liver; Nucleic acid; Protein metabolism; Purine; Tumor. [M.K.S.]

Uridine diphosphoglucose (UDPG) A compound in which α-glucopyranose is esterified, at carbon atom 1, with the terminal phosphate group of uridine-$5'$-pyrophosphate (that is, uridine diphosphate, UDP). On very mild acid hydrolysis, glucose and UDP are liberated. Uridine diphosphoglucose occurs in animal, plant, and microbial cells and is synthesized enzymatically from uridine triphosphate (UTP) and α-glucose-1-phosphate. This compound functions as a key in the transformation of glucose to other sugars.

In general, UDP-glucose is a prominent member of a family of compounds composed of sugars activated as derivatives of nucleoside diphosphates. In these active forms they can be used directly as glycosyl donors, or they may be transformed to other more complex sugars before their utilization for the biosynthesis of both simple saccharides and complex polysaccharides. *See* Carbohydrate metabolism; Nucleic acid. [J.L.Str.]

Urinalysis Laboratory examination of urine. Urine is a filtrate of the blood and is produced in the kidneys. It is a reflection of the metabolic activity of the body; conditions that affect the normal homeostatic mechanisms are often revealed by a careful analysis of the composition of the urine. Modern routine urinalysis can be divided into two basic procedures: macroscopic and chemical examination, and microscopic analysis.

Macroscopic and chemical examination. Macroscopic examination includes noting the color and clarity of the urine. Normal urine is pale yellow or straw colored and is usually transparent or clear; abnormal urine may vary greatly in color and may show varying degrees of cloudiness. The specific gravity of urine, that is, the ratio of the weight of a volume of urine to that of the same volume of water, is measured routinely. Specific gravity is an indicator of the kidney's ability to concentrate or dilute the urine and thus of renal tubular function. The normal range is 1.003–1.032.

Most routine chemical urinalysis is now carried out by dipstick testing, which involves the use of plastic strips, or dipsticks, bearing pads embedded with chemical reactants and color indicators. The reaction of each pad represents a separate chemical test for a specific product in the urine. Dipstick testing includes the following categories: protein, glucose, ketone bodies, blood, and bile. *See* Protein.

Microscopic examination. The urine normally contains a wide variety of formed elements that can be identified by using a light microscope. Together these elements form the urinary sediment.

Cells in the urine originate in the bloodstream or in the epithelium lining the urinary tract. The main types of epithelial cells are renal tubular cells, transitional (urothelial) cells, and squamous cells. All three types occur in relatively small numbers in the normal sediment. Blood cells occur normally in the urine in small numbers, and consist mainly of polymorphonuclear neutrophils (a type of granular leukocyte) and red blood cells.

Casts, proteinaceous products of the kidney, are of major importance when present in increased numbers or seen in abnormal forms, because they usually indicate intrinsic renal disease. Casts are cylindrical and are named on the basis of their microscopic appearance and the cells they contain.

Normally, urine is sterile, and the urinary sediment should not contain microorganisms. However, in patients with serious urinary tract infections, microorganisms are usually present in the urine in considerably greater numbers. *See* Clinical pathology.

Mucus is frequently found in urine sediment and has no known pathologic significance. A wide variety of crystals appear in the urine; their presence may be normal or may indicate an abnormal state. *See* Kidney; Kidney disorders. [M.H.Ha.]

Urinary bladder A distensible, muscular sac in most vertebrates which serves as a reservoir for urine. Snakes, crocodilians, birds (with the exception of the ostrich), most lizards, and a few fish lack a urinary bladder. In these organisms, urine empties directly into the cloaca. The development of the urinary system is intimately associated with the development of the reproductive system. Three general types of urinary bladder are recognized among the vertebrates: tubal, cloacal, and allantoic. *See* Urine.

Most fish possess tubal bladders, that is, enlargements of the mesonephric ducts. The cloacal bladder is found in monotremes, amphibians, and some dipnoans. There is no direct connection between the excretory ducts and this type of bladder. The bladder is an outpouching or diverticulum of the cloacal wall. The cloacal opening is closed by a sphincter muscle and the urine which seeps into the cloaca from the excretory ducts is forced into the bilobed bladder.

The allantoic bladder is derived from the ventral wall of the cloaca and possibly the allantoic diverticulum. The role of the allantois in the formation of this type of bladder, which is found in most mammals, the turtles, and those lizards which have a bladder, is questioned by some embryologists. *See* Allantois.

The mammalian bladder is lined with a special epithelium composed of transitional cells. The muscular layer is composed of vertical, horizontal, and oblique fibers. The bladder drains through the urethra, the opening being controlled by a sphincter. Innervation is by the hypogastric sympathetic plexus and partly by parasympathetic fibers from the second and third sacral nerves. Stimulation of the parasympathetic causes the bladder muscle to contract and relaxes the internal sphincter. Micturition is a reflex act which is initiated voluntarily except in children. *See* Parasympathetic nervous system; Sympathetic nervous system; Urinary system. [C.B.C.]

Urinary system The urinary system consists of the kidneys, urinary ducts, and bladder. Similarities are not particularly evident among the many and varied types of excretory organs found among vertebrates. The variations that are encountered are undoubtedly related to problems with which vertebrates have had to cope in adapting to different environmental conditions.

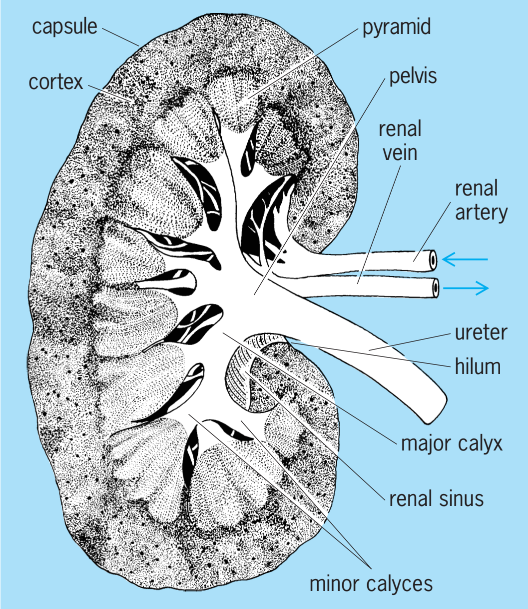


Fig. 1. Sagittal section of a human metanephric kidney (semidiagrammatic). (*After C. K. Weichert and W. Presch, Elements of Chordate Anatomy, 4th ed., McGraw-Hill, 1975*)

Kidneys. In reptiles, birds, and mammals three types of kidneys are usually recognized: the pronephros, mesonephros, and metanephros. These appear in succession during embryonic development, but only the metanephros persists in the adult.

The metanephric kidneys of reptiles lie in the posterior part of the abdominal cavity, usually in the pelvic region. They are small, compact, and often markedly lobulated. The posterior portion on each side is somewhat narrower. In some lizards the hind parts may even fuse. The degree of symmetry varies.

The kidneys of birds are situated in the pelvic region of the body cavity; their posterior ends are usually joined. They are lobulated structures with short ureters which open independently into the cloaca.

A rather typical mammalian metanephric kidney (Fig. 1) is a compact, bean-shaped organ attached to the dorsal body wall outside the peritoneum. The ureter leaves the medial side at a depression, the hilum. At this point a renal vein also leaves the kidney and a renal artery and nerves enter it. The kidneys of mammals are markedly lobulated in the embryo, and in many forms this condition is retained throughout life. *See* Kidney. [C.K.W.]

Urinary bladder. At or near the posterior ends of the nephric ducts there frequently is a reservoir for urine. This is the urinary bladder. Actually there are two basic varieties of bladders in vertebrates. One is found in fishes in which the reservoir is no more than an enlargement of the posterior end of each urinary duct. Frequently the urinary ducts are conjoined and a small bladder is formed by expansion of the common duct. The far more common type of bladder is that exhibited by tetrapods. This is a sac which originates embryonically as an outgrowth from the ventral side of the cloaca. Present in all embryonic life, it is exhibited differentially in adults. All amphibians retain the bladder, but it is lacking in snakes, crocodilians, and most lizards; birds, also, with the exception of the ostrich, lack a bladder. It is present in all mammals. *See* Urinary bladder. [T.W.T.]

Physiology. Urine is produced by individual renal nephron units which are fundamentally similar from fish to mammals (Fig. 2); however, the basic structural and functional pattern of these nephrons varies among representatives of the vertebrate classes in accordance with changing environmental demands. Kidneys serve the general function of maintaining the chemical and physical constancy of blood and other body fluids. The most striking modifications are associated particularly with the relative amounts of water made available to the animal. Alterations in degrees of glomerular development, in the structural complexity of renal tubules, and in the architectural disposition of the various nephrons in relation to one another within the kidneys may all represent adaptations made either to conserve or eliminate water.

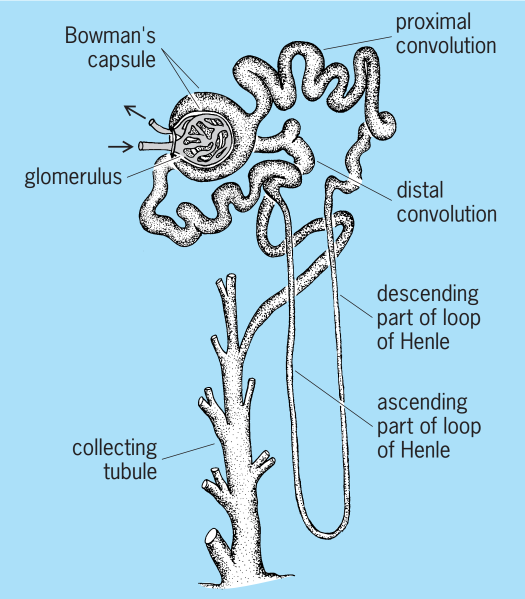

Fig. 2. A mammalian metanephric tubule, showing the renal corpuscle and secretory and collecting portions. (*After C. K. Weichert and W. Presch, Elements of Chordate Anatomy, 4th ed., McGraw-Hill, 1975*)

Regulation of volume. Except for the primitive marine cyclostome *Myxine*, all modern vertebrates, whether marine, fresh-water, or terrestrial, have concentrations of salt in their blood only one-third or one-half that of seawater. The early development of the glomerulus can be viewed as a device responding to the need for regulating the volume of body fluids. Hence, in a hypotonic fresh-water environment the osmotic influx of water through gills and other permeable body surfaces would be kept in balance by a simple autoregulatory system whereby a rising volume of blood results in increased hydrostatic pressure which in turn elevates the rate of glomerular filtration. Similar devices are found in fresh-water invertebrates where water may be pumped out either as the result of work done by the heart, contractile vacuoles, or cilia found in such specialized "kidneys" as flame bulbs, solenocytes, or nephridia that extract excess water from the body cavity rather than from the circulatory system. Hence, these structures which maintain a constant water content for the invertebrate animal by balancing osmotic influx with hydrostatic output have the same basic parameters as those in vertebrates that regulate the formation of lymph across the endothelial walls of capillaries. *See* Osmoregulatory Mechanisms.

Electrolyte balance. A system that regulates volume by producing an ultrafiltrate of blood plasma must conserve inorganic ions and other essential plasma constituents. The salt-conserving operation appears to be a primary function of the renal tubules which encapsulate the glomerulus. As the filtrate passes along their length toward the exterior, inorganic electrolytes are extracted from them through highly specific active cellular resorptive processes which restore plasma constituents to the circulatory system.

Movement of water. Concentration gradients of water are attained across cells of renal tubules by water following the active movement of salt or other solute. Where water is free to follow the active resorption of sodium and covering anions, as in the proximal tubule, an isosmotic condition prevails. Where water is not free to follow salt, as in the distal segment in the absence of antidiuretic hormone, a hypotonic tubular fluid results.

Nitrogenous end products. Of the major categories of organic foodstuffs, end products of carbohydrate and lipid metabolism are easily eliminated mainly in the form of carbon dioxide and water. Proteins, however, are more difficult to eliminate because the primary derivative of their metabolism, ammonia, is a relatively toxic compound. For animals living in an aquatic environment ammonia can be eliminated rapidly by simple diffusion through the gills. However, when ammonia is not free to diffuse into an effectively limitless aquatic environment, its toxicity presents a problem, particularly to embryos of terrestrial forms that develop wholly within tightly encapsulated eggshells or cases. For these forms the detoxication of ammonia is an indispensable requirement for survival. During evolution of the vertebrates two energy-dependent biosynthetic pathways arose which incorporated potentially toxic ammonia into urea and uric acid molecules, respectively. Both of these compounds are relatively harmless, even in high concentrations, but the former needs a relatively large amount of water to ensure its elimination, and uric acid requires a specific energy-demanding tubular secretory process to ensure its efficient excretion. *See* Urea; Uric acid.

Urine concentration. The unique functional feature of the mammalian kidney is its ability to concentrate urine. Human urine can have four times the osmotic concentration of plasma, and some desert rats that survive on a diet of seeds without drinking any water have urine/plasma concentration ratios as high as 17. More aquatic forms such as the beaver have correspondingly poor concentrating ability.

The concentration operation depends on the existence of a decreasing gradient of solute concentration that extends from the tips of the papillae in the inner medulla of the kidney outward toward the cortex. The high concentration of medullary solute is achieved by a double hairpin countercurrent multiplier system which is powered by the active removal of salt from urine while it traverses the ascending limb of Henle's loop (Fig. 2). The salt is redelivered to the tip of the medulla after it has diffused back into the descending limb of Henle's loop. In this way a hypertonic condition is established in fluid surrounding the terminations of the collecting ducts. Urine is concentrated by an entirely passive process as water leaves the lumen of collecting ducts to come into equilibrium with the hypertonic fluid surrounding its terminations. *See* URINE; UROGENITAL SYSTEM. [R.P.F.]

Urinary tract disorders

Disorders of the outflow tract of the urinary system from the renal pelves to the external portion of the urethra. Disorders of the kidney itself are considered in a separate article. *See* KIDNEY DISORDERS.

Renal pelves. The renal pelves, the sacs that carry urine from the kidney to the ureter, are subject to a number of disorders.

Anomalies of the renal pelves are common. The pelvis may be subdivided into two or more sacs which may end in a single or separate ureters. By itself such an anomaly is harmless, but if there is associated obstruction there may be symptoms of pain and also destruction of the renal tissue.

Calculi may arise in the renal pelvis, usually below the epithelial layer. The cause of calculi is usually some metabolic defect with excessive excretion of a waste material such as oxalates, urates, cystine, or calcium salts.

Fibrous bands and aberrant vessels to the kidneys are usually blamed for obstruction when no other intrinsic cause can be found for uretero-pelvic obstruction.

Acute infection of the pelvis is usually associated with infection of the kidney (pyelonephritis). Most commonly occurring in young girls, it produces fever, back pain, and dysuria.

Tumors of the pelvis are rare; when they do occur they are usually transitional-cell carcinomas of varying degrees of malignancy. They cause obstruction and blood in the urine (hematuria).

Ureters. These long thin tubes carry the urine from the renal pelvis to the bladder; they are subject to the same diseases as are the renal pelves.

Reduplication of the ureters at any point, from a double beginning and later fusion, to complete separation and separate implantation into the bladder, may be found. This anomaly is generally harmless unless obstruction is produced.

One of the commonest causes of excruciating abdominal and flank pain, often radiating to the groin or testicle, is the passage of small calculi or even showers of crystals through the ureter.

Occasionally the ureter is obstructed by external pressure from retroperitoneal fibrosis, tumor, or aortic aneurysm.

If the normal valvelike mechanism that prevents bladder urine from going back into the ureter is defective, vesico-ureteral reflux results. When the individual, usually a young girl, voids, some of the urine goes back into the ureter so the bladder is not completely emptied. This residual urine is subject to bacterial infection.

Tumors are usually transitional-cell carcinomas and do not differ appreciably from those seen in the pelvis and bladder.

Bladder. The urinary bladder is subject to anomalies, obstructions, inflammations, calculi, fistulae, and tumors.

A fairly common, distressing anomaly is exstrophy of the bladder, which is a failure of both the lower abdominal wall and anterior bladder wall to close. The urine appears directly through the abdominal wall defect.

Interference with normalcomplete emptying of the bladder may be the result of various factors. In one form, an elevation of the internal urethral opening above its normal dependent position creates an unemptied pool of residual urine in the bottom of the bladder. This elevation is usually caused in the male by prostatic enlargement and in the female by cystocele, a bulging of the lower bladder wall into the vagina. Another form of obstruction is blockage of the bladder neck or urethra by such diverse lesions as anomalous congenital valves, prostatic enlargement, calculi, tumors, or postgonorrheal urethral strictures. A third major cause of inadequate emptying is neurogenic, usually following spinal cord injury or disease.

Cystitis or inflammation of the urinary bladder is an extremely common affliction, annoying because of the accompanying painful, frequent micturition. Bladder calculi usually develop as a result of infection and obstruction. They often reach a considerable size, up to several inches in diameter. They are usually composed of multiple urinary constituents, particularly phosphates and urates.

Abnormal openings between the bladder or female urethra and the vagina are not unusual. Such fistulae most often follow injury during childbirth. The chief effects are infection and the constant leakage of urine through the vagina.

The bladder is frequently the site of tumors which are almost always of transitional-cell epithelial origin. Malignant change into transitional-cell carcinoma is common.

Female urethra. This structure is not often diseased. In older women a painful raspberrylike swelling composed of inflammatory tissue may appear at the external urethral opening and is known as a caruncle. [R.N.B.]

Male urethra. The prostate gland may develop cancer. However, options are available to treat this disease if detected at an early stage.

The urethra is prone to obstruction. The most common cause is a noncancerous growth of the prostate called benign prostatic hyperplasia. This growth is a natural process associated with aging and can occlude the prostatic urethra, causing progressive difficulty in starting the urinary stream and completely emptying the bladder. *See* REPRODUCTIVE SYSTEM DISORDERS. [B.K.R.; M.L.St.]

Urine

An aqueous solution of organic and inorganic substances, mostly waste products of metabolism. The kidneys maintain the internal milieu of the body by excreting these waste products and adjusting the loss of water and electrolytes to keep the body fluids relatively constant in amount and composition. The urine normally is clear and has a specific gravity of 1.017–1.020, depending upon the amount of fluid ingested, perspiration, and diet. The increase in specific gravity above that of water is due to the presence of dissolved solids, about 60% of which are organic substances such as urea, uric acid, creatinine, and ammonia; and 40% of which are inorganic substances such as sodium, chloride, calcium, potassium, phosphates, and sulfates. Its reaction is usually acid (pH 6) but this too varies with the diet. It usually has a faint yellow color due to a urochrome pigment, but the color varies depending upon the degree of concentration, and the ingestion of certain foods (for example, rhubarb) or cathartics. It usually has a characteristic aromatic odor, the cause of which is not known. *See* KIDNEY; UREA; URIC ACID; URINALYSIS; URINARY SYSTEM. [R.Str.]

Urodela

One of the orders of the class Amphibia, also known as the Caudata. The members of this order are the tailed amphibians, or salamanders, and are distinguished superficially from the frogs and toads (order Anura) by the possession of a tail, and from the caecilians (order Apoda) by the possession of limbs. Salamanders resemble lizards in that members of both groups normally have a relatively elongate body, four limbs, and a tail. The similarity is however, only superficial. The most obvious external difference, the moist glandular skin of the amphibian and dry scaly skin of the reptile, is underlain by the numerous characters that distinguish reptiles from amphibians. *See* ANURA.

The vast majority of salamanders are well under a foot (0.3 m) in length. The largest is the giant salamander of Japan and China, which may attain a length of 5 ft (1.5 m). A close relative, the hellbender, which lives in streams in the eastern United States, grows to over 2 ft (0.6 m) in length.

Four well-developed limbs are typically present in salamanders, but the legs of the mud eel (*Amphiuma*) of the southeastern United States are very tiny appendages and of no use in locomotion. The sirens (*Siren* and *Pseudobranchus*), also aquatic salamanders of the same region, have undergone even further degeneration of the limbs and retain only tiny forelimbs. Salamanders with normal limbs usually have four toes on the front feet and five on the rear, though a few have only four on all feet. A feature of the Urodela not shared with the Anura is the ability to regenerate limbs.

The moist and highly vascularized skin of a salamander serves as an organ of respiration, and in some forms shares with the buccal region virtually the whole burden. In one entire family of salamanders, the Plethodontidae, lungs are not present. Even in those forms with lungs and gills, dermal respiration plays a very important part. The tympanum is absent in salamanders and the middle ear is degenerate. Hence these animals are deaf to airborne sounds. Undoubtedly correlated with this is the reduction of voice; salamanders are mute or produce only slight squeaking or, rarely, barking sounds when annoyed. However, salamanders can detect sounds carried through ground or water.

Salamanders live in a variety of aquatic or moist habitats. Many forms are wholly aquatic, living in streams, rivers, lakes, and ponds. Others live on land most of the year but must return to water to breed. The most advanced species live out their lives in moist places on land or, in the case of some tropical species, in trees, and never go in the water.

Producing the young alive rather than by laying eggs is very rare among salamanders. The eggs of salamanders may be deposited in water or in moist places on land. Presumably, aquatic breeding is the more primitive. Fertilization is external in most of the Cryptobranchoidea, internal by means of spermatophores in the remaining suborders. *See* NEOTENY.

The greatest concentration of families and genera of salamanders is found in the eastern United States, and these animals are one of the few major groups of vertebrate animals that is distinctly nontropical. No salamander occurs south of the Equator in the Old World, and only 18 species of the evolutionarily advanced family Plethodontidae are found as far south as South America in the New World.

The Urodela are readily arranged in seven families, but authorities differ as to the relationships among these families and their classification into suborders. Three to five suborders may be recognized, and one of these is thought by some to merit ordinal rank, equivalent to the Urodela. About 300 species of salamanders are known to be living today, and these are distributed among about 54 genera. *See* AMPHIBIA. [R.G.Z.]

Urogenital system

The combined structures composing the urinary and genital, or reproductive, organs of vertebrates. The terms urinogenital or genitourinary system are equally applicable and just as frequently used. During embryonic development, the urinary and reproductive systems are closely interrelated, as their ducts arise in associated mesodermal regions. Common passages are associated with both these systems in various vertebrates, such as the single orifice for emission of urine and sperm. *See* KIDNEY; REPRODUCTIVE SYSTEM; URINARY SYSTEM. [C.B.C.]

Urokinase

An enzyme that is a plasminogen activator. Urokinase cleaves the plasma protein plasminogen, forming the active enzyme plasmin, which subsequently degrades fibrin. Thus urokinase is an essential component in the fibrinolytic clot-dissolving system in the human body. *See* FIBRINOGEN.

Urokinase is found in human urine and in much lower concentrations in human plasma. In the body, urokinase is produced by kidney cells, and its presence in the urine promotes the dissolution of any blood clots in the urine-collecting system of the kidneys or the bladder. Urokinase is also produced by a variety of tumor cells, and it is thought to be involved in the formation of tumor metastases. Urokinase can be inhibited by plasma inhibitor proteins. The presence of cell receptors and inhibitors suggests that the regulation of urokinase function is complex.

Urokinase is employed in clinical medicine in the treatment of venous blood clots (thrombophlebitis and pulmonary emboli), acute myocardial infarction, and arterial blood clots in the legs and arms. It is also used to prevent the accumulation of blood clots in intravenous catheters used to administer long-term chemotherapy. *See* BLOOD; ENZYME; PLASMIN. [P.C.C.]

Uropygi

An order of arachnids, the tailed whip scorpions, comprising about 70 species from tropical and warm temperate Asia and the Americas. Most are dark reddish-brown, of medium to giant size, 0.7–2.6 in. (18–65 mm), the largest one being *Mastigoproctus giganteus* of the southern United States and Mexico. The elongate, flattened body bears in front a pair of greatly thickened, raptorial pedipalps set with many sharp spines and used to hold and crush insect prey. The first pair of legs is elongated and modified into feelers. The abdomen terminates in a slender, many jointed, whiplike flagellum. The uropygids are harmless, nocturnal creatures without poison glands that live in dark places and burrow into the soil. When disturbed, they expel a volatile liquid, with the strong odor of acetic acid, from a gland at the base of the tail. This accounts for the name "vinegaroon" given by many Americans to these much-feared animals. *See* ARACHNIDA. [W.J.Ger.]

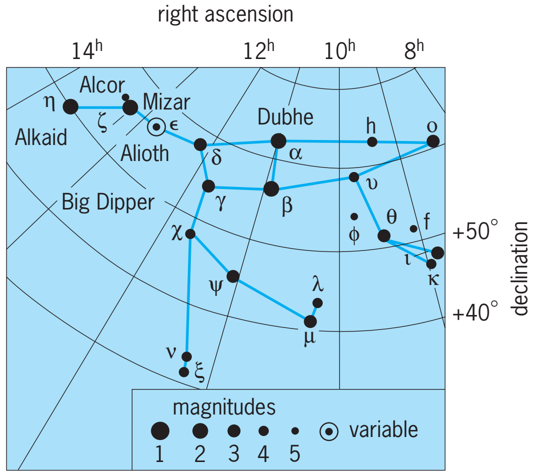
Uropygial gland

A relatively large, compact, bilobed, secretary organ located at the base of the tail (uropygium) of most birds having a keeled sternum. It is known also as the preen, oil, or scent gland. This is the only true skin gland possessed by this class of vertebrates.

The glandular secretion, predominantly oily and sometimes of offensive odor (musk-duck, hoopoe, petrel) is discharged through an orifice at the tip of a nipplelike protuberance often encircled by short, bristly feathers. The act of preening induces a flow of secretion from the nipple which is transferred by the beak to the body plumage. In water fowl there is some evidence that this oily secretion assists in maintaining the water-repellent quality of the feathers, either directly or by preserving their physical structure. *See* FEATHER; SCENT GLAND. [M.E.R.]

Ursa Major

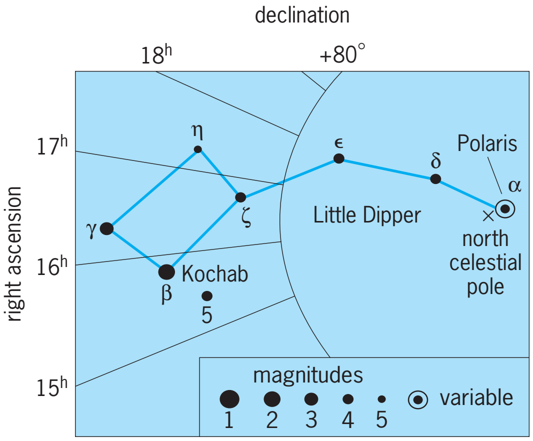
The most widely known and oldest of the astronomical constellations. Ursa Major, or the Great Bear, is a



Line pattern of the constellation Ursa Major. The grid lines represent the coordinates of the sky. The apparent brightness, or magnitude, of the stars is shown by the sizes of the dots, which are graded by appropriate numbers as indicated.

circumpolar group as viewed from the middle latitudes of the Northern Hemisphere. One part of the configuration, a group of seven bright stars, which is pictured as the tail of the Great Bear, is commonly known in the United States as the Big Dipper which it resembles (see illustration). The two stars α and β at the front of the bowl of the dipper are called pointers, because a line joining them points to Polaris, the North Star. *See* Constellation. [C.S.Y.]

Ursa Minor The astronomical constellation Little Bear, Ursa Minor is a circumpolar constellation whose brightest star, Polaris, is almost at the north celestial pole. Seven of the eight stars appear to form a dipper, hence the constellation is alternately known as the Little Dipper (see illustration). The two bright stars β and γ at the front of the bowl are often called the Guardian of the Pole, because they circle about Polaris closer than other conspicuous stars. *See* Constellation; Ursa Major. [C.S.Y.]



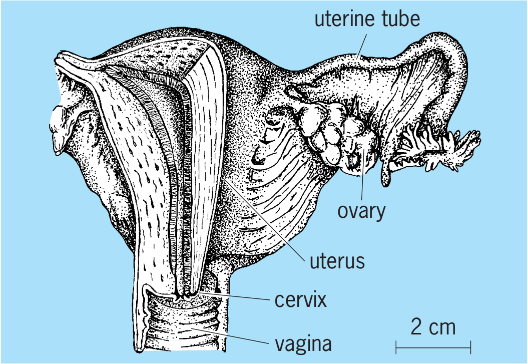
Line pattern of the constellation Ursa Minor. The grid lines represent the coordinates of the sky. The apparent brightness, or magnitude, of the stars is shown by the sizes of the dots, which are graded by appropriate numbers as indicated.

Ustilaginomycetes A class of the subdivision Basidiomycotina. These microscopic plant-parasitic fungi are commonly known as smut fungi. Many species may have a shorter or longer saprophytic life cycle, capable of yeastlike reproduction. Several nonparasitic yeasts have been identified as closely related to the smuts. About 1500 true Ustilaginales species are known. Until recently, the Ustilaginales have been divided into two families: Ustilaginaceae and Tilletiaceae. In the new classification the true smut fungi are divided into 2 classes, 8 orders, 17 families, and 62 genera.

The body (mycelium) of the smut fungi consists of hyphae that are thin, transparent, branched, septate, and binucleate. Usually parasitic, the fungus grows in the host tissues and gives little, if any, evidence of its presence before spore formation sets in. The smut spores (teliospores or ustilospores) are the organs of dispersion and resistance, and are thick walled, pigmented, and variously ornamented. They are formed in great number in the sori, which consist of host tissues, spore masses, and sometimes modified fungal cells or tissues. The smut fungi develop variable sori in different organs (such as the roots, stems, leaves, inflorescences, flowers, anthers, and seeds) filled by powdery or agglutinated, usually colored (black, brown, violet, or yellow) spore masses. The spores may develop singly, in pairs, or in aggregates of spore balls. Spore germination results in a basidium (promycelium or ustidium) which gives rise to hyaline basidiospores. *See* Basidiomycota; Eumycota; Fungi; Smut (microbiology).

Many smut fungi produce severe losses of cereals and other cultivated plants. [K.V.]

Uterus The hollow, muscular womb, being an enlarged portion of the oviduct in the adult female. An adult human uterus, before pregnancy, measures 3 × 2 × 1 in. (7.5 × 5 × 2.5 cm) in size and has the shape of an inverted, flattened pear. The paired Fallopian tubes enter the uterus at its upper corners; the lower, narrowed portion, the cervix, projects into the vagina (see illustration). Normally the uterus is tilted slightly forward and lies behind the urinary bladder.



Human uterus and associated structures. (*After L. B. Arey, Developmental Anatomy, 7th ed., Saunders, 1965*)

The lining, or mucosa, responds to hormonal stimulation, growing in thickness with a tremendous increase in blood vessels during the first part of the menstrual cycle. If fertilization does not occur, the thickened vascular lining is sloughed off, producing the menstrual flow at the end of the cycle, and a new menstrual cycle begins with growth of the mucosa. When pregnancy occurs, the mucosa continues to thicken and forms an intimate connection with the implanted and enlarging placenta. *See* Menstruation; Pregnancy; Reproductive system. [W.J.B.]

V

Vaccination Active immunization against a variety of microorganisms or their components, with the ultimate goal of protecting the host against subsequent challenge by the naturally occurring infectious agent. The terms vaccine and vaccination were originally used only in connection with Edward Jenner's method for preventing smallpox, introduced in 1796. In 1881 Louis Pasteur proposed that these terms should be used to describe any prophylactic immunization. Vaccination now refers to active immunization against a variety of bacteria, viruses, and parasites (for example, malaria and trypanosomes). *See* Smallpox.

Implicit within Jenner's method of vaccinating against smallpox was the recognition of immunologic cross-reactivity together with the notion that protection can be obtained through active immunization with a different, but related, live virus. It was not until the 1880s that the next immunizing agents, vaccines against rabies and anthrax, were introduced by Pasteur. Two facts of his experiments on rabies vaccines are particularly noteworthy.

First, Pasteur found that serial passage of the rabies agent in rabbits resulted in a weakening of its virulence in dogs. During multiple passages in an animal or in tissue culture cells, mutations accumulate as the virus adapts to its new environment. These mutations adversely affect virus reproduction in the natural host, resulting in lessened virulence. Only as the molecular basis for virulence has begun to be elucidated by modern biologists has it become possible to deliberately remove the genes promoting virulence so as to produce attenuated viruses.

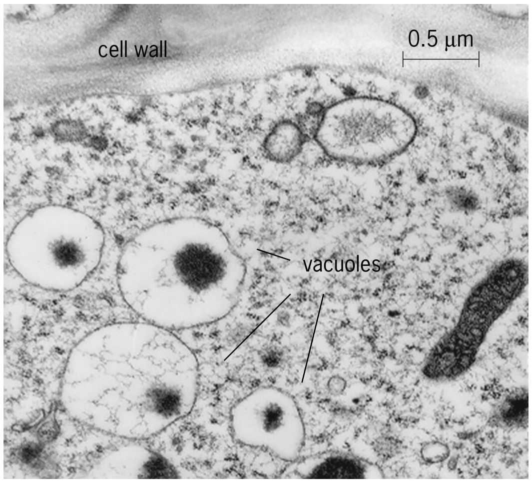
Second, Pasteur demonstrated that rabies virus retained immunogenicity even after its infectivity was inactivated by formalin and other chemicals, thereby providing the paradigm for one class of noninfectious virus vaccine, the "killed"-virus vaccine.

Attenuated-live and inactivated vaccines are the two broad classifications for vaccines. Anti-idiotype antibody vaccines and deoxyribonucleic acid (DNA) vaccines represent innovations in inactivated vaccines. Recombinant-hybrid viruses are novel members of the live-virus vaccine class recently produced by genetic engineering.

Because attenuated-live-virus vaccines reproduce in the recipient, they provoke both a broader and more intense range of antibodies and T-lymphocyte-associated immune responses than noninfectious vaccines. Live-virus vaccines have been administered subdermally (vaccinia), subcutaneously (measles), intramuscularly (pseudorabies virus), intranasally (infectious bovine rhinotracheitis), orally (trivalent Sabin poliovirus), or by oropharyngeal aerosols (influenza). Combinations of vaccines have also been used. Live-virus vaccines administered through a natural route of infection often induce local immunity, which is a decided advantage. However, in the past, attenuated-live virus vaccines have been associated with several problems, such as reversion to virulence, natural spread to contacts, contaminating viruses, lability, and viral interference. *See* Animal virus; Virulence; Virus classification; Virus interference.

Noninfectious vaccines include inactivated killed vaccines, subunit vaccines, synthetic peptide and biosynthetic polypeptide vaccines, oral transgenic plant vaccines, anti-idiotype antibody vaccines, DNA vaccines, and polysaccharide-protein conjugate vaccines. With most noninfectious vaccines a suitable formulation is essential to provide the optimal antigen delivery for maximal stimulation of protective immune responses. Development of new adjuvant (a substance that enhances the potency of the antigen) and vector systems is pivotal to produce practical molecular vaccines. *See* Antibody; Antigen; Immunity. [S.Kit.]

Vacuole An intracellular compartment, bounded by a single membrane bilayer, which functions as a primary site of protein and metabolite degradation and recycling in animals, but serves additional complex functions in fungi and plants (see illustration). Scientists who study vacuoles also define them as the terminal product of the secretory pathway. The secretory pathway functions to transport protein and metabolite-containing membrane vesicles from sites of synthesis or uptake to the vacuole. *See* Cell membranes; Cell metabolism; Golgi apparatus; Secretion.



Electron micrograph of a barley root tip cell, showing multiple vacuoles within the cytoplasm.

In animals, a lytic vacuole known as the lysosome typically functions to process macromolecules. Such macromolecules can be targeted to the lysosome from sites of synthesis. For example, proteins that assemble incorrectly in the endoplasmic reticulum (ER) can be degraded in the lysosome and their constituent amino acids recycled. Proteins that can serve as nutrients are also targeted to the lysosome from the cell surface. An important process for the recycling of cytoplasm in eukaryotic cells is autophagy, in which molecules or organelles are encapsulated in membrane vesicles that fuse with the lysosome. *See* Endocytosis; Endoplasmic reticulum; Lysosome.

In the mammalian immune system, macrophages and neutrophils take up particles and pathogens in the process of phagocytosis, during which the pathogen is eventually digested in the lysosome. A number of diseases in humans can be caused when intracellular pathogens evade destruction in the lysosome. *See* Phagocytosis.

In fungi, vacuoles can serve functions not found in animals. Besides a lytic function, they serve in the storage of ions as well as amino acids for protein synthesis. In yeast, vacuoles can also function in the destruction and recycling of cellular organelles, such as peroxisomes, which help protect the cell from toxic oxygen-containing molecules. The process of peroxisome digestion by vacuoles is known as pexophagy.

The most complex vacuoles are found in plants. Some contain hydrolytic enzymes and store ions similar to those found in lysosomes, whereas others serve a role in storing pigments which impart color to flowers to attract pollinators. Specialized ER-derived vacuoles in plant seeds, known as protein bodies, function in the storage of proteins called prolamines that are common in the endosperm of cereals. Upon germination, the proteins are degraded and used as a source of amino acids and nitrogen for the growing plant. Toxins, such as alkaloids, are stored in vacuoles in parts of the plant, such as the leaves, which are subject to frequent herbivory. Scientists have learned that plants produce and store in their vacuoles a vast array of unique chemicals which may, in addition to their natural functions, have medicinal value. *See* PLANT CELL.

Another unique function that vacuoles serve in plants is in cell growth. As a consequence of the accumulation of ions, metabolites, and water, plant vacuoles are under considerable internal osmotic pressure. The vacuolar membrane in plants, known as the tonoplast, as well as the cell itself would burst under this pressure if not for the rigid wall that surrounds the cells. The resulting turgor pressure provides mechanical stability to plant stems. Loss of osmotic pressure in the vacuole due to a lack of water results in plant wilting. The osmotic pressure of the vacuoles also provides the driving force that allows plants to grow by enlarging their cell volume. Enzymes reduce the rigidity of the cell wall, which permits cell expansion under the force of turgor. This is a fundamental process in plants and explains why vacuoles can occupy as much as 95% of the volume of some cells. *See* CELL WALLS (PLANT). [G.R.Hi.; N.Ra.]

Vacuum fusion A technique of analytical chemistry for determining the oxygen, hydrogen, and sometimes nitrogen content of metals.

The metal sample is either fused or dissolved in a bath, or flux, of a second metal in a heated graphite crucible supported inside an evacuated glass or quartz vessel. Oxygen is released from the metal as carbon monoxide by reaction of oxides or dissolved oxygen with carbon from the graphite crucible at high temperature. Metal nitrides dissociate to form elemental nitrogen. Hydrogen is evolved as elemental hydrogen. The mixture of carbon monoxide, nitrogen, and hydrogen is analyzed to determine individual component concentrations by various techniques.

Inert gas fusion has been developed for determination of gases in metals. The techniques used are similar to vacuum fusion but substitute inert gases for the vacuum environment. *See* VACUUM METALLURGY. [F.C.B.]

Vacuum measurement The determination of a gas pressure that is less in magnitude than the pressure of the atmosphere. This low pressure can be expressed in terms of the height in millimeters of a column of mercury which the given pressure (vacuum) will support, referenced to zero pressure. The height of the column of mercury which the pressure will support may also be expressed in micrometers. The unit most commonly used is the torr, equal to 1 mm (0.03937 in.) of mercury (mmHg). Less common units of measurement are fractions of an atmosphere and direct measure of force per unit area. The unit of pressure in the International System (SI) is the pascal (Pa), equal to 1 newton per square meter (1 torr = 133.322 Pa). Atmospheric pressure is sometimes used as a reference. The pressure of the standard atmosphere is 29.92 in. or 760 mm of mercury (101,325 Pa or 14.696 lbf/in.^{2}).

Pressures above 1 torr can be easily measured by familiar pressure gages, such as liquid-column gages, diaphragm-pressure gages, bellows gages, and bourdon-spring gages. At pressures below 1 torr, mechanical effects such as hysteresis, ambient errors, and vibration make these gages impractical. *See* MANOMETER; PRESSURE MEASUREMENT.

Pressures below 1 torr are best measured by gages which infer the pressure from the measurement of some other property of the gas, such as thermal conductivity or ionization. The thermocouple gage, in combination with a hot- or cold-cathode gage (ionization type), is the most widely used method of vacuum measurement today. *See* IONIZATION GAGE.

Other gages used to measure vacuum in the range of 1 torr or below are the McLeod gage, the Pirani gage, and the Knudsen gage. The McLeod gage is used as an absolute standard of vacuum measurement in the 10–10^{-4} torr (10^3–10^{-2} Pa) range. *See* MCLEOD GAGE; PIRANI GAGE.

The Knudsen gage is used to measure very low pressures. It measures pressure in terms of the net rate of transfer of momentum (force) by molecules between two surfaces maintained at different temperatures (cold and hot plates) and separated by a distance smaller than the mean free path of the gas molecules. [R.C.]

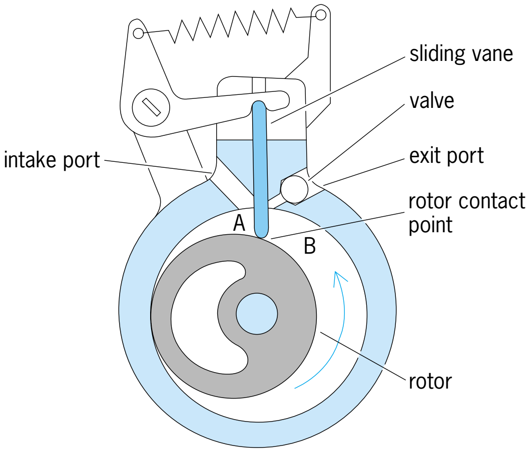
Vacuum metallurgy The making, shaping, and treating of metals, alloys, and intermetallic and refractory metal compounds in a gaseous environment where the composition and partial pressures of the various components of the gas phase are carefully controlled. In many instances, this environment is a vacuum ranging from subatmospheric to ultrahigh vacuum (less than 760 torr or 101 kilopascals to 10^{-12} torr or 10^{-10} pascal). In other cases, reactive gases are deliberately added to the environment to produce the desired reactions, such as in reactive evaporation and sputtering processes and chemical vapor depositon. The processes in vacuum metallurgy involve liquid/solid, vapor/solid, and vapor/liquid/solid transitions. In addition, they include testing of metals in controlled environments.

There are three basic reasons for vacuum processing of metals: elimination of contamination from the processing environment, reduction of the level of impurities in the product, and deposition with a minimum of impurities. Contamination from the processing environment includes the container for the metal and the gas phase surrounding the metal. In the vacuum process, impurities, particularly oxygen, nitrogen, hydrogen, and carbon, are released from the molten metal and pumped away; and metals, alloys, and compounds are deposited with a minimum of entrained impurities. There are numerous and varied application areas for vacuum metallurgy including special areas of extractive metallurgy, melting processes, casting of shaped products, degassing of molten steel, heat treatment, surface treatment, vapor deposition, space processing, and joining processes. *See* ARC WELDING; STEEL MANUFACTURE; WELDING AND CUTTING OF METALS. [R.F.Bu.]

Vacuum pump A device that reduces the pressure of a gas (usually air) in a container. When gas in a closed container is lowered from atmospheric pressure, the operation constitutes an increase in vacuum in this container. *See* PRESSURE.

Vacuum pumps are evaluated for the degree of vacuum they can attain and for how much gas they can pump in a unit of time. In practice, where high vacuum is required, two or more different types of pumps are used in series.

In the rotary oil-seal pump (see illustration), gas is sucked into chamber A through the opening intake port by the rotor. A sliding vane partitions chamber A from chamber B. The compressed gas that has been moved from position A to position B is pushed out of the exit port through the valve, which prevents the gas from flowing back. The valve and the rotor contact point are oil-sealed. Since each revolution sweeps out a fixed volume, it is called a constant-displacement pump. Other mechanical pumps are the rotary blower pump, which operates by the propelling action of one or more rapidly rotating lobelike vanes, and the molecular drag pump, which operates at very high speeds, as much as 16,000 rpm. Pumping is accomplished by imparting a



Chief components of a typical mechanical pump, the rotary oil-seal pump.

high momentum to the gas molecules by the impingement of the rapidly rotating body.

The water aspirator is an ejector pump. When water is forced under pressure through the jet nozzle, it will force the gas in the inlet chamber to go through the diffuser, thus lowering the pressure in the inlet chamber. When high-pressure steam is used instead of water, it is called a steam ejector.

In addition, a number of pumps have been developed which meet special pumping requirements. The ion pump operates electronically. Electrons that are generated by a high voltage applied to an anode and a cathode are spiraled into a long orbit by a high-intensity magnetic field. These electrons colliding with gas molecules ionize the molecules, imparting a positive charge to them. These are attracted to, and are collected on, the cathode. Thus a pumping action takes place. Sorption pumping is the removal of gases by adsorbing and absorbing them on a granular sorbent material such as a molecular sieve held in a metal container. Cryogenic pumping is accomplished by condensing gases on surfaces that are at extremely low temperatures. [E.S.Ba.]

Vacuum tube An electron device in which use is made of the electrostatically or magnetically controlled flow of electrons in an evacuated space, or of the phenomena accompanying the electron emission, acceleration, and collection associated with the flow. In common usage, completely evacuated tubes are called hard tubes; tubes containing a small amount of deliberately added gas or vapor are called soft tubes, but they are usually included in the family of vacuum tubes.

Vacuum tubes are used as active and passive electrical circuit elements. In suitable circuitry they rectify, detect, gate, amplify, and oscillate. They can also scan and display images; generate heat, light, and radiation; ionize and accelerate atoms and molecules; and measure high vacuum.

Most vacuum tubes employ the Edison effect, in which a unidirectional flow of current takes place through a vacuum by thermionic emission of electrons from a hot surface (the cathode). The electrons are collected by a nearby positively charged electrode (the anode or plate). Two-electrode Edison-effect tubes were first employed as radio-frequency detectors, but the enormous potential of the device was not realized until it was shown that the current could be controlled with large amplification ratios and great sensitivity by small electrical charges on a third, meshlike electrode (the grid) interposed between cathode and anode. From the resulting three-element tube (the triode) came all the characteristic inventions of the modern electronic age. *See* ELECTRON EMISSION; ELECTRON MOTION IN VACUUM; THERMIONIC EMISSION.

Later refinements included additional grids by which certain problems inherent in triodes were overcome, and combination tubes were developed in which several functions were combined within one vacuum envelope. Elaborations of the basic idea include camera and picture tubes and magnetrons, klystrons, and traveling-wave tubes for microwave radar. *See* KLYSTRON; MAGNETRON; MICROWAVE TUBE; PICTURE TUBE; RADAR; TELEVISION CAMERA TUBE; TRAVELING-WAVE TUBE.

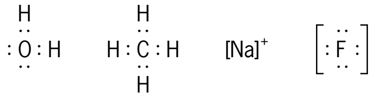
Originally, vacuum tubes were enclosed in cylindrical glass structures. Through the walls or base of the tube were sealed the metal electrodes which emitted, controlled, or collected the electrons traversing the empty space within. Up through the 1960s, vast numbers of small tubes were used in radio and television broadcast receivers. They also found their way into industrial instruments and controls, and into the early electronic computers, but their size, fragility, inordinate power consumption, and short lifetimes made them unpopular for these more demanding purposes. Since that time, such vacuum tubes have been almost entirely replaced by the much smaller, cheaper, and longer-lived solid-state devices. Only a few standard receiving-tube types still remain in production, and are used where their electrical characteristics are particularly apt, or where environmental or circuit conditions would destroy solid-state devices. A significant exception is the cathode-ray tube (CRT), which is still made in great numbers for consumer applications. Though bulky, complex, and fragile, it is highly versatile, and so remains in favor as a display device for television, computers, and instruments of all kinds. *See* CATHODE-RAY TUBE; ELECTRONIC DISPLAY.

Other vacuum tubes in widespread use are high-power transmitting and microwave tubes; x-ray and accelerator tubes; mass spectrometer, electron microscope, night-vision, and surface-analytical tubes; and electron beam guns (partial tubes) for evaporators and welders. Since there is no prospect that any of these types will be replaced by solid-state devices, research and development on them continues, and new types occasionally appear. *See* ELECTRON MICROSCOPE; IMAGE TUBE (ASTRONOMY); ION SOURCES; LIGHT AMPLIFIER; MASS SPECTROSCOPE; PARTICLE ACCELERATOR; PHOTOMULTIPLIER; PHOTOTUBE; SURFACE PHYSICS; WELDING AND CUTTING OF MATERIALS; X-RAY TUBE. [N.Re.]

Valence A term commonly used by chemists to characterize the combining power of an element for other elements, as measured by the number of bonds to other atoms which one atom of the given element forms upon chemical combination. The term also has come to signify the theory of all the physical and chemical properties of molecules that specially depend on molecular electronic structure.

Thus, in water, H_2O, the valence of each hydrogen atom is 1; the valence of oxygen, 2. In methane, CH_4, the valence of hydrogen again is 1; of carbon, 4. In NaCl and CCl_4 the valence of chlorine is 1, and in CH_2 the valence of carbon is 2. *See* CHEMICAL BONDING.

Most of the simple facts of valence (though certainly not all) follow from the postulate that atoms combine in such a way as to seek closed-shell or inert-gas structures (rule of eight) by the transfer of electrons between them or the sharing of a pair of electrons between them. Many molecular structures may be obtained by inspection using these rules; letting a dot represent an electron:



$$:\overset{H}{\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}}:H \qquad H:\overset{H}{\overset{\cdot\cdot}{\underset{\underset{H}{\cdot\cdot}}{C}}}:H \qquad [Na]^+ \qquad \left[:\overset{\cdot\cdot}{\underset{\cdot\cdot}{F}}:\right]$$

In these electron-dot symbols, the electrons in the *K* shell are not included for atoms after He, nor are the electrons in the *K* and *L* shells for atoms following Ne.

As generally used and here defined, the word valence is ambiguous. Before a value can be assigned to the valence of an atom in a molecule, the electronic structure of the molecule must be exactly known, and this structure must be describable simply in terms of simple bonds. In practice neither of these conditions is ever precisely fulfilled. A term not so ambiguous is oxidation number or valence number. Oxidation numbers are useful for the balancing of oxidation-reduction equations, but they are not related simply to ordinary valences. Thus the valence of carbon in CH_4, $CHCl_3$, and CCl_4 is 4; oxidation numbers of carbon in these three substances are −4, +2, and +4. *See* CHEMICAL STRUCTURES; ELECTRONEGATIVITY; MOLECULAR ORBITAL THEORY; OXIDATION-REDUCTION. [R.G.P.]

Valence band The highest electronic energy band in a semiconductor or insulator which can be filled with electrons. The electrons in the valence band correspond to the valence electrons of the constituent atoms. In a semiconductor or insulator, at sufficiently low temperatures, the valence band is completely filled and the conduction band is empty of electrons. Some of the high energy levels in the valence band may become vacant as a result of thermal excitation of electrons to higher energy bands or as a result of the presence of impurities. The net effect of the valence band is then equivalent to that of a few particles which are equal in number and similar in motion to the missing electrons but each of which carries a positive electronic charge. These "particles" are referred to as holes. *See* BAND THEORY OF SOLIDS; CONDUCTION BAND; ELECTRIC INSULATOR; HOLE STATES IN SOLIDS; SEMICONDUCTOR; VALENCE. [H.Y.F.]

Value engineering A thinking system (also called value management or value analysis) used to develop decision criteria when it is important to secure as much as possible of what is wanted from each unit of the resource used. The resource may be money, time, material, labor, space, energy, and so on. The system is unique in that it effectively uses both knowledge and creativity, and provides step-by-step techniques for maximizing the benefits from both. It promotes development of alternatives suitable for the future as well as the present. This is accomplished by identifying and studying each function that is wanted by the customer or user, then applying knowledge and creativity to achieve the desired function. Resources are converted into costs to achieve direct, meaningful comparisons. By using the methods of value engineering, 15 to 40% reduction in the required resources often results.

Value engineering has applications in five broad areas: in design, purchase, and manufacture of products; in administrative groups, private or public, where the task is to achieve accomplishment through people; in all areas of social service work, such as hospitals, insurance services, or colleges; in architectural design and construction; and in development as well as research.

The system is used to improve value in either or both of two situations: (1) The product or service as used or as planned may provide 100% of the functions the user wants, but lower costs may be needed. The system then holds those functions but achieves them at lower cost. (2) The product or service may have deficiencies, that is, it does not perform the desired functions or lacks quality, and so also lacks good value. The system aims at correcting those deficiencies, providing the functions wanted, while at the same time holding the use of resources (costs) at a minimum. *See* INDUSTRIAL COST CONTROL; INDUSTRIAL ENGINEERING; METHODS ENGINEERING; OPERATIONS RESEARCH; OPTIMIZATION; PROCESS ENGINEERING; PRODUCTION ENGINEERING; PRODUCTION PLANNING. [L.D.M.]

Valvatida An order of Asteroidea in which pedicellariae, when present, are valvate and sunk into the skeletal ossicles. The mouth plates are inconspicuous, and the inferomarginal and superomarginal plates correspond and lack intermarginal grooves. There are two rows of tube feet. The order is thought to include seven families. *See* ASTEROIDEA; ECHINODERMATA. [A.C.C.]

Valve A flow-control device. Valves are used to regulate the flow of fluids in piping systems and machinery. In machinery the flow phenomenon is frequently of a pulsating or intermittent character and the valve, with its associated gear, contributes a timing feature.

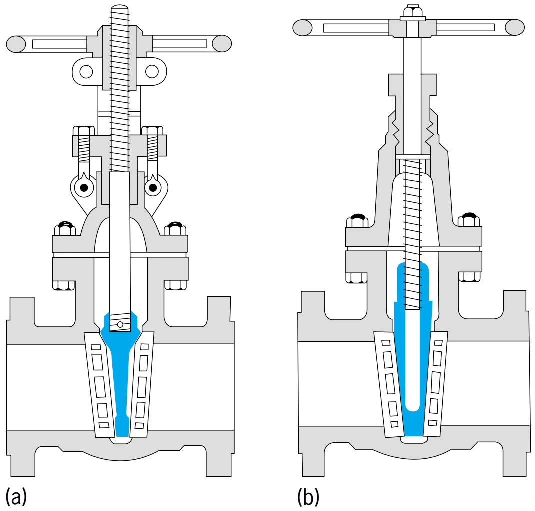


Fig. 1. Gate valves with disk gates shown in color. (*a*) Rising threaded stem shows when valve is open. (*b*) Nonrising stem valve requires less overhead.

The valves commonly used in piping systems are gate valves (Fig. 1), usually operated closed or wide open and seldom used for throttling; globe valves, frequently fitted with a renewable disk and adaptable to throttling operations; check valves, for automatically limiting flow in a piping system to a single direction; and plug cocks, for operation in the open or closed position by turning the plug through 90° and with a shearing action to clear foreign matter from the seat. Safety and relief valves are automatic protective devices for the relief of excess pressure. *See* SAFETY VALVE.

For hydraulic turbines and hydroelectric systems, valves and gates control water flow for (1) regulation of power output at sustained efficiency and with minimum wastage of water, and (2) safety under the inertial flow conditions of large masses of water.

To control the kinematics of the cycle, steam-engine valves range from simple D-slide and piston valves to multiported types. Many types of reversing gear have been perfected which use the same slide valve or piston valve for both forward and backward

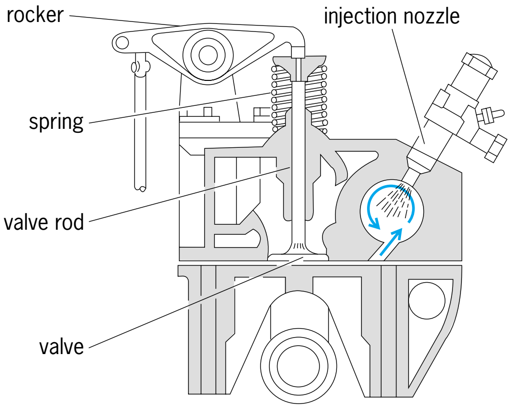

Fig. 2. Poppet valve for internal combustion engine. (*After T. Baumeister, ed., Marks' Standard Handbook for Mechanical Engineers, 8th ed., McGraw-Hill, 1978*)

rotation of an engine, as in railroad and marine service. *See* STEAM ENGINE.

Poppet valves are used almost exclusively in internal combustion reciprocating engines because of the demands for tightness with high operating pressures and temperatures (Fig. 2). Two-cycle engines utilize ports, alternately covered and uncovered by the main piston, for inlet or exhaust. *See* CAM MECHANISM; INTERNAL COMBUSTION ENGINE; VALVE TRAIN.

In compressors, valves are usually automatic, operating by pressure difference on the two sides of a movable, springloaded member and without any mechanical linkage to the moving parts of the compressor mechanism. Like those for compressors, pump valves are usually of the automatic type operating by pressure difference. [T.Ba.]

Valve train The valves and valve-operating mechanism by which an internal combustion engine takes air or fuel-air mixture into the cylinders and discharges combustion products to the exhaust. *See* VALVE.

Mechanically, an internal combustion engine is a reciprocating pump, able to draw in a certain amount of air per minute. Since the fuel takes up little space but needs air with which to combine, the power output of an engine is limited by its air-pumping capacity. The flow through the engine should be restricted as little as possible. This is the first requirement for valves. The second is that the valves close off the cylinder firmly during the compression and power strokes. *See* INTERNAL COMBUSTION ENGINE.

In most four-stroke engines the valves are the inward-opening poppet type, with the valve head ground to fit a conical seat in the cylinder block or cylinder head. The valve is streamlined and as large as possible to give maximum flow, yet of low inertia so that it follows the prescribed motion at high engine speed.

Engine valves are usually opened by cams that rotate as part of a camshaft, which may be located in the cylinder block or cylinder head. Riding on each cam is a cam follower or valve lifter, which may have a flat or slightly convex surface or a roller, in contact with the cam. The valve is opened by force applied to the end of the valve stem. A valve rotator may be used to rotate the valve slightly as it opens. In engines with the camshaft and valves in the cylinder head, the cam may operate the valve directly through a cup-type cam follower. To ensure tight closing of the valve even after the valve stem lengthens from thermal expansion, the valve train is adjusted to provide some clearance when the follower is on the low part of the cam. *See* CAM MECHANISM. [D.L.An.]

Valvifera A suborder of isopod crustaceans resembling woodlice and pill bugs. They are distinguished from these and other isopods by having a pair of flat, valvelike uropods which hinge laterally and fold inward beneath the rear part of the body. The uropods open like doors to reveal five pairs of leaflike appendages, or pleopods, which are used for respiration and swimming. Members of the group are almost exclusively marine. Some species are omnivorous and have been found in dense populations on accumulations of broken algae and fish waste. *See* ISOPODA. [E.N.]

Vampyromorpha An order of coleoid cephalopods that contains only one species, *Vampyroteuthis infernalis*. It is characterized by a flat, broad, leaflike, chitinous internal shell (gladius); eight arms around the mouth connected by a deep web; no tentacles, but two small sensory filaments that retract into pockets between the bases of the first and second arms; fingerlike cirri and a single row of suckers with chitinous rings along the arms; one pair of paddle-shaped fins on the body in adults (two pairs at the juvenile stage); very dark maroon, mostly black pigmentation; and photophores on the body, head, and arms. Vampyromorphs superficially resemble cirrate octopods, but they bear features that show distinct teuthoid (squid) relationships, and in many characteristics are intermediate between teuthoids and octopods.

Vampyroteuthis infernalis is a gelatinous bathypelagic (very deep, midwater living) species that inhabits worldwide tropical, subtropical, and temperate waters. It occurs mostly at depths of 1600–3800 ft (500–1200 m), occasionally to 4800 ft (150 m). *See* CEPHALOPODA; COLEOIDEA; OCTOPODA; TEUTHOIDEA. [C.F.E.R.]

Van Allen radiation The high-energy, charged particles that are trapped into orbits by the geomagnetic field, forming radiation belts that surround the Earth. The belts consist primarily of electrons and protons and extend from a few hundred kilometers above the Earth to a distance of about $8\ R_e$ (R_e = radius of Earth = 6371 km = 3959 mi). James Van Allen and coworkers discovered them in 1958 using radiation detectors carried on satellites *Explorer 1* and *3*, and they are often referred to as the Van Allen belts.

A charged particle under the influence of the geomagnetic field follows a trajectory that can be conveniently described as a superposition of three separate motions. The first motion, produced by the magnetic force acting at right angles to both the particle velocity and the magnetic field, is a rapid spiral about magnetic field lines. As the spiraling particle moves along the field line toward either the North Pole or South Pole, the increase in magnetic field strength causes the particle to be reflected so that it bounces between the Earth's two hemispheres. Superimposed on the spiral and bounce motions is a slow east-west drift; electrons drift eastward and protons or heavier ions drift westward. (The resulting current, called the ring current, acts to decrease the strength of the Earth's (surface) northward magnetic field at low latitudes.) Thus, individual trapped particles move completely around the Earth in a complicated pattern, their motion being constrained to lie on magnetic shells.

The spatial structure of trapped radiation shows two maxima: an inner radiation belt centered at about $1.5R_e$ and an outer belt centered at $4\text{–}5R_e$. In the inner radiation belt, the most penetrating particles are protons with energies extending to several hundred megaelectronvolts (MeV). However, the flux of high-energy protons decreases rapidly with increasing distance from the Earth and becomes insignificant beyond $4R_e$. Electrons and low-energy protons with energies up to a few MeV occur throughout the stable trapping region. The electron energies extend to several MeV, and in the outer radiation belt electrons are the most penetrating component.

The intensity, energy spectrum, and spatial distribution of particles within the radiation belts vary with time. The most dramatic variations are associated with magnetic storms. The changes are most pronounced for particles in the outer belt where the magnetic variations are the largest. During a magnetic storm, the electron flux in the outer belt may increase by an order of magnitude or more.

It is believed that most of the very high energy protons (>50 MeV) in the inner belt result from the spontaneous decay of high-energy neutrons, produced by collisions of cosmic rays with atmospheric atoms. However, the vast majority of the radiation belt populations are ions and electrons that originate from either the atmosphere or the solar wind and are accelerated by processes only partly understood.

The radiation belts are just one feature of the space plasma environment. For example, plasma from the Sun is continually impinging on the Earth's magnetic field, resulting in a "cavity" known as the magnetosphere.

Because the conditions that lead to the formation of Earth's radiation belts are so general, it is believed that any planet or moon that has a large enough magnetic field will also have radiation belts. Jupiter, Saturn, Uranus, and Neptune have strong magnetic fields and very large, intense radiation belts analogous to those of the Earth.

The term “space weather” describes the conditions in space that affect Earth and its technological systems. It is a consequence of the behavior of the Sun, and the interaction of the solar wind with the Earth’s magnetic field. The fluxes of electrons and protons trapped in the radiation belts can injure both personnel and equipment on board spacecraft if the vehicle is exposed to these energetic particles for a sufficiently long time. Because of the spatial structure of the belts, the degree of damage will be strongly dependent on the position in space and hence on the orbit of the vehicle. In the inner belt region, high-energy protons can pass through several centimeters of aluminum structure and injure components in the interior of the spacecraft. In most other regions of the radiation belts, the trapped particles are less penetrating, and damage is confined to exposed equipment such as solar cells. [P.Ril.; M.W.]

Van der Waals equation An equation of state of gases and liquids proposed by J. D. van der Waals in 1873 that takes into account the nonzero size of molecules and the attractive forces between them. He expressed the pressure p as a function of the absolute temperature T and the molar volume $V_m = V/n$, where n is the number of moles of gas molecules in a volume V (see equation below). Here $R = 8.3145\ \mathrm{J\ K^{-1}\ mol^{-1}}$ is the universal gas constant, and a and b are parameters that depend on the nature of the gas.

$$p = \frac{RT}{V_m - b} - \frac{a}{V_m^2}$$

Parameter a is a measure of the strength of the attractive forces between the molecules, and b is approximately equal to four times the volume of the molecules in one mole, if those molecules can be represented as elastic spheres. The equation has no rigorous theoretical basis for real molecular systems, but is important because it was the first to take reasonable account of molecular attractions and repulsions, and to emphasize the fact that the intermolecular forces acted in the same way in both gases and liquids. It is accurate enough to account for the fact that all gases have a critical temperature T_c above which they cannot be condensed to a liquid. The expression that follows from this equation is $T_c = 8a/27\,Rb$. *See* CRITICAL PHENOMENA; GAS; INTERMOLECULAR FORCES; LIQUID.

In a gas mixture, the parameters a and b are taken to be quadratic functions of the mole fractions of the components since they are supposed to arise from the interaction of the molecules in pairs. The resulting equation for a binary mixture accounts in a qualitative but surprisingly complete way for the many kinds of gas-gas, gas-liquid, and liquid-liquid phase equilibria that have been observed in mixtures. *See* PHASE EQUILIBRIUM.

The equation is too simple to represent quantitatively the behavior of real gases, and so the parameters a and b cannot be determined uniquely; their values depend on the ranges of density and temperature used in their determination. For this reason, the equation now has little practical value, but it remains important for its historical interest and for the concepts that led to its derivation. *See* THERMODYNAMIC PRINCIPLES. [J.S.Ro.]

Vanadium A chemical element, V, with atomic number 23. Natural deposits contain two isotopes, ^{50}V (0.24%), which is weakly radioactive, and ^{51}V (99.76%). Commercially important as an oxidation catalyst, vanadium also is used in the production of alloy steel and ceramics and as a colorizing agent. Studies have demonstrated the biological occurrence of vanadium, especially in marine species; in mammals, vanadium has a pronounced effect on heart muscle contraction and renal function. *See* PERIODIC TABLE; TRANSITION ELEMENTS.

Very pure vanadium is difficult to prepare because the metal is highly reactive at temperatures above the melting point of its oxide (663°C or 1225°F) from which it is produced. Vanadium is a bright white metal that is soft and ductile. It has a melting point of 1890°C (3434°F), a boiling point of 3380°C (6116°F), and a density of 6.11 g/cm^3 (3.53 oz/in.^{3}) at 18.7°C (65.7°F). The thermal and electrical conductivity of vanadium is superior to that of titanium.

At room temperature, the metal is resistant to corrosion by oxygen, salt water, alkalies, and nonoxidizing acids, the exception being hydrogen fluoride (HF). Vanadium cannot withstand the oxidizing conditions presented by nitric acid or aqua regia. At elevated temperatures it will combine with most nonmetals to form oxides, nitrides, carbides, arsenides, and other such compounds.

The physical properties of vanadium are very sensitive to interstitial impurities. The strength varies from 30,000 lb/in.^{2} (200 megapascals) in the purest form to 80,000 lb/in.^{2} (550 MPa) in the commercial grade. The melting point is markedly altered by small impurities; vanadium containing 10% carbon has a melting point of 2700°C (4892°F).

Vanadium has a low fission neutron cross section. This property combined with the metal’s excellent retention of strength at elevated temperatures has made its use in atomic energy applications attractive.

Carbon and alloy steels consume more than half the vanadium produced in the United States. Many plate, structural, bar, and pipe steels contain vanadium to enhance strength and toughness. The basis for the unique properties of these carbon alloy steels is the formation of vanadium carbide. These carbides are extremely hard and wear-resistant; they do not coalesce readily, but maintain a state of fine dispersion. Many large steel forgings contain vanadium in the range 0.05–0.15%; here vanadium acts as a grain refiner, and also improves the mechanical properties of the forgings. Tool steels are another large class of vanadium-containing steels; vanadium ensures the retention of hardness and cutting ability at the elevated temperatures generated by the rapid cutting of metals.

The production of ferrovanadium, an iron alloy, is very important since the primary commercial use of vanadium is in steel. Ferrovanadium is produced by aluminum or silicon reduction of V_2O_5 in the presence of iron in an electric arc furnace. The commonly practiced aluminum reduction is exothermic, so that little additional heat from the arc is required. Silicon processing requires a two-stage reduction to achieve efficient operation. *See* FERROALLOY; STEEL MANUFACTURE.

Vanadium compounds, especially V_2O_5 and NH_4VO_3, are excellent oxidation catalysts in the chemical industry. Processes that employ such catalysts include the manufacture of polyamides, such as nylon; sulfuric acid production by the contact process; phthalic and maleic anhydride syntheses; and various oxidations of organic compounds such as the conversion of anthracene to anthraquinone, ethanol to acetaldehyde, and sugar to oxalic acid. Vanadium pentoxide is used as a mordant in dyeing and printing fabrics and in producing aniline black for the dye industry. Vanadium compounds are used in the ceramics industry for glazes and enamels. A wide range of colors can be obtained with combinations of vanadium oxide, zirconia, silica, lead, tin, zinc, cadmium, and selenium. *See* CERAMICS; DYEING; MORDANT.

Vanadium has long been recognized as an essential element in biological systems; however, the role of the metal often is obscure. Tunicates accumulate vanadium to levels 1 million times greater than the surrounding seawater. This vanadium was once thought to act as an oxygen carrier but now is believed to be an oxidation catalyst that repairs damage to the polymeric, protective tunic of these animals. The first vanadium-dependent enzyme, vanadium bromoperoxidase, was isolated from brown, red, and green marine algae (for example, *Ascophyllum nodosum*); this enzyme catalyzes the bromination of a variety of organic molecules by using hydrogen peroxide and bromide. This activity may be the source of many important brominated compounds that potentially may be used as antifungal and antineoplastic agents. *See* ENZYME.

A variety of physiological effects in mammalian systems have been reported, the most significant being in cardiovascular and renal function. Vanadate causes constriction of veins in the kidney and can alter the retention and excretion of sodium and chloride ions. Cardiac effects of vanadium are species-specific, with observed increases (rabbit and rat) and decreases (guinea pig and cat) in heart muscle contractility. Because vanadate is a potent inhibitor of Na,K-ATPase in the laboratory, it has been suggested that this is the site of the metal's action. However, the physiology of vanadate is probably more complicated, since vanadium behaves as a hormone mimic by elevating intracellular calcium ion (Ca^{2+}) levels in a process that is poorly understood. *See* BIOINORGANIC CHEMISTRY. [V.L.P.]

Vanilla A choice flavoring obtained from a climbing orchid, *Vanilla fragrans*, a native of tropical American forests. Its fruits are pods called vanilla beans. These are picked at the proper time before they have fully matured.

Vanillin (4-hydroxy-3-methoxybenzaldehyde) is the principal component of vanilla, although other components contribute to the distinctive flavor of the extract compared to synthetic vanilla. When they are harvested, the beans contain no free vanillin; it develops during the curing period from glucosides that break down during the fermentation and sweating of the beans. The sweating process consists of alternately drying the beans in sunlight and bunching them so that they heat and ferment. [P.D.St./E.L.C.]

Vapor condenser A heat-transfer device that reduces a thermodynamic fluid from its vapor phase to its liquid phase. The vapor condenser extracts the latent heat of vaporization from the vapor, as a higher-temperature heat source, by absorption in a heat-receiving fluid of lower temperature. The vapor to be condensed may be wet, saturated, or superheated. The heat receiver is usually water but may be a fluid such as air, a process liquid, or a gas. When the condensing of vapor is primarily used to add heat to the heat-receiving fluid, the condensing device is called a heater and is not within the normal classification of a condenser.

Condensers may be divided into two major classes according to use: those used as part of a processing system (process condensers) and those used for serving engines or turbines in a steam power plant cycle (power cycle condensers). Condensers may be further classified according to mode of operation as surface condensers or as contact condensers. *See* CONTACT CONDENSER; SURFACE CONDENSER.

Condensers are required, almost without exception, to condense impure vapors, that is, vapors containing air or other noncondensable gases. Because most condensers operate at subatmospheric pressures, air leaking into the apparatus or system becomes a common cause for vapor contamination, and a variety of designs have been developed to reduce such problems. Accumulation of noncondensable gases seriously affects heat transfer, and means must be provided to direct them to a suitable outlet. Most surface and contact condensers are arranged with a separate zone of heat-transfer surface within the condenser and located at the outlet end of the vapor flow path for efficient removal of the noncondensable gases through dehumidification. [J.F.Se.]

Vapor cycle A thermodynamic cycle, operating as a heat engine or a heat pump, during which the working substance is in, or passes through, the vapor state. A vapor is a substance at or near its condensation point. It may be wet, dry, or slightly superheated. One hundred percent dryness is an exactly definable condition which is only transiently encountered in practice. *See* HEAT PUMP; THERMODYNAMIC CYCLE.

A steam power plant operates on a vapor cycle where steam is generated by boiling water at high pressure, expanding it in a prime mover, exhausting it to a condenser, where it is reduced to the liquid state at low pressure, and then returning the water by a pump to the boiler (Fig. 1).

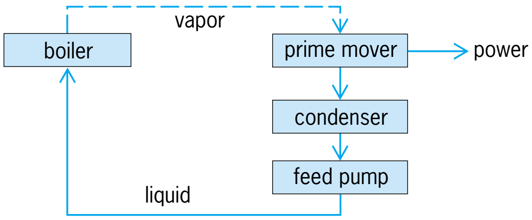

Fig. 1. Rudimentary steam power plant flow diagram.

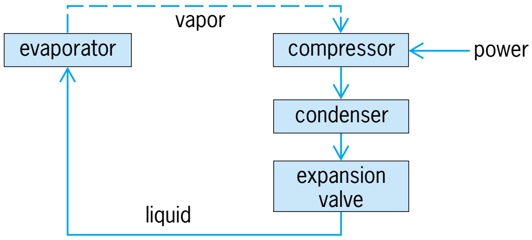

Fig. 2. Rudimentary vapor-compression refrigeration plant flow diagram.

In the customary vapor-compression refrigeration plant, the process is essentially reversed with the refrigerant evaporating at low temperature and pressure, being compressed to high pressure, condensed at elevated temperature, and returned as liquid refrigerant through an expansion valve to the evaporating coil (Fig. 2). *See* REFRIGERATION.

The Carnot cycle, between any two temperatures, gives the limit for the efficiency of the conversion of heat into work. This efficiency is independent of the properties of the working fluid. The Rankine cycle is more realistic in describing the ideal performance of steam power plants and vapor-compression refrigeration systems. *See* CARNOT CYCLE; RANKINE CYCLE. [T.Ba.]

Vapor deposition Production of a film of material often on a heated surface and in a vacuum. Vapor deposition technology is used in a large variety of applications. Coatings are produced from a wide range of materials, including metals, alloys, compound, cermets, and composites. The vapor deposition processes can be classified into the two basic groups, physical (evaporation and sputtering) and chemical. In addition, there are hybrid processes such as ion plating, which is a subset of evaporation or sputter deposition. This process involves an electrically biased substrate and uses a working gas such as argon, which results in ion bombardment of the substrate/depositing film that produces changes in microstructure, residual stress, and impurity content. *See* ALLOY; CERMET; COMPOSITE MATERIAL; METAL.

All deposition processes consist of three major steps: generation of the depositing species, transport of the species from source to substrate, and film growth on the substrate. In chemical vapor deposition, these steps occur simultaneously at or near the substrate. Physical vapor deposition processes are more versatile, because the steps occur sequentially and can be controlled independently.

In physical vapor deposition the first step involves generation of the depositing species by evaporation using resistance, induction, electron-beam, or laser-beam heating, or by sputtering using direct-current or radio-frequency plasma generation. The second step involves transport from source to substrate.

The third step is film growth on the substrate. The two basic processes for physical vapor deposition are evaporation deposition and sputter deposition. In evaporation, thermal energy converts a solid or liquid target material to the vapor phase. In sputtering, the target is biased to a negative potential and bombarded by positive ions of the working gas from the plasma, which knock out the target atoms and convert them to vapor by momentum transfer. *See* SPUTTERING.

In the basic thermal chemical vapor deposition process, the reactants flow over a heated substrate and react at or near the substrate surface to deposit a film. The kinetics of the process are dependent on diffusion through the boundary layer between the substrate and the bulk gas-flow region. *See* DIFFUSION IN SOLIDS.

Chemical vapor deposition is one of several process steps for fabrication of integrated circuits. Thus, much effort is being directed at lowering the deposition processing temperatures in order to achieve more economical processing as well as increasing the compatibility with preceding and subsequent steps in device processing. *See* INTEGRATED CIRCUITS.

Coatings provided by vapor deposition have many applications. For optical functions they are used as reflective or transmitting coatings for lenses, mirrors, and headlamps; for energy transmission and control they are used in glass, optical, or selective solar absorbers and in heat blankets; for electrical and magnetic functions they are used for resistors, conductors, capacitors, active solid-state devices, photovoltaic solar cells, and magnetic recording devices; for mechanical functions they are used for solid-state lubricants, tribological coatings for wear and erosion resistance in cutting and forming tools and other engineering surfaces; and for chemical functions they are used to provide resistance to chemical and galvanic corrosion in high-temperature oxidation, corrosion, and catalytic applications as well as to afford protection in the marine environment. Decorative applications include toys, costume jewelry, eyeglass frames, watchcases and bezels, and medallions. Vapor-deposited coatings also act as moisture barriers for paper and polymers. They can be used for bulk or free-standing shapes such as sheet or foil tubing, and they can be formulated into submicrometer powders. *See* VACUUM METALLURGY. [R.F.Bu.]

Vapor lamp A source of radiant energy excited by a supply of electricity which creates a current of ionized gas between electrodes in an enclosure that contains the arc while permitting transmission of the radiant energy. Gaseous-discharge lamps or vapor lamps are given various names relating to the element responsible for the majority of the radiation (mercury, sodium metal-halide, xenon), to the physical attribute of the lamp (short-arc, high-pressure), or, in the case of fluorescent lamps, to the way a phosphor on the bulb wall fluoresces as a result of the lamp's low-pressure mercury-vapor excitation. *See* ARC DISCHARGE; ELECTRICAL CONDUCTION IN GASES.

Gaseous-discharge lamps are broadly used throughout the world because the conversion of electric energy to radiant energy in a gaseous discharge provides radiation in narrow bands within the range of visible light in which the rods and cones of the eye are most sensitive. These light sources have high efficiency in conversion of electricity to light.

For discussions of common types of vapor lamps *see* FLUORESCENT LAMP; MERCURY-VAPOR LAMP; NEON GLOW LAMP; SODIUM-VAPOR LAMP. [T.F.N.]

Vapor lock Interruption of fuel flow to an engine due to blockage of passages in the fuel system by fuel vapor.

To promote easy starting, all gasolines contain volatile constituents that under some conditions, such as high ambient temperature, tend to produce more vapor than the fuel-system vents can handle. The action of an engine-mounted fuel pump, in decreasing the pressure at its inlet, tends to vaporize the fuel. If the vapor forms faster than the pump can draw it from the fuel line, the flow of fuel to a carburetor is effectively stopped and the engine stalls. Vapor lock is much less likely on a fuel-injected engine with an electric pump in the fuel tank. However, an engine with port fuel injection may experience vapor lock if the injector or fuel overheats, or if the Reid vapor pressure of the fuel is too high. *See* CARBURETOR; FUEL SYSTEM; GASOLINE; INTERNAL COMBUSTION ENGINE; VAPOR PRESSURE. [D.L.An.]

Vapor pressure The saturation pressures exerted by vapors which are in equilibrium with their liquid or solid forms. One of the most important physical properties of a liquid, the vapor pressure, enters into many thermodynamic calculations and underlies several methods for the determination of the molecular weights of substances dissolved in liquids. For a discussion of the vapor pressure relationships of solids *see* SUBLIMATION. *See* MOLECULAR WEIGHT; SOLUTION.

If a liquid is introduced into an evacuated vessel at a given temperature, some of the liquid will vaporize, and the pressure of the vapor will attain a maximum value which is termed the vapor pressure of the liquid at that temperature. Although the quantity of liquid remaining does not diminish thereafter, the process of evaporation does not cease. A dynamic equilibrium is established, in which molecules escape from the liquid phase and return from the vapor phase at equal rates. *See* EVAPORATION.

It is important to make a distinction between the vapor pressure of a liquid, as described above, and the pressure of a vapor. The vapor pressure of a pure liquid is a unique and characteristic property of the liquid and depends only upon the temperature. A gas or vapor may, on the other hand, exert any pressure within reason, depending upon the volume to which it is confined, provided it is not in contact with its liquid phase. *See* PHASE EQUILIBRIUM. [N.H.N.]

Varactor A solid-state device which has a capacitance that varies with the voltage applied across it. The name varactor is a contraction of the words variable and reactor. Typically the device consists of a reverse-biased *pn* junction that has been doped to maximize the change in capacitive reactance for a given change in the applied bias voltage. The device has two primary applications: frequency-tuning of radio-frequency circuits including frequency-modulation (FM) transmitters and solid-state receivers, and nonlinear frequency conversion in parametric oscillators and amplifiers. *See* CAPACITANCE; FREQUENCY MODULATOR; PARAMETRIC AMPLIFIER; REACTANCE.

A *pn* junction in reverse bias has two adjacent microscopic space-charge or depletion regions which function like the plates of a capacitor. These depletion regions get larger as the applied reverse-bias voltage is increased; however, the increase in the width of the depletion region is not linear with bias voltage, but instead is sublinear, the exact nature of the relationship depending upon the doping profile in the *pn* junction. For example, in a *pn* junction with constant doping density, the depletion region width varies as the square root of the applied reverse-bias voltage. Because the capacitance of the device is proportional to the width of the depletion region, the nonlinear relationship between bias voltage and depletion width results in a nonlinear voltage-capacitance relationship as well. The *pn* junction doping profile is adjusted by the device designer to obtain the desired capacitive nonlinearity.

The frequency response of the varactor is governed by the relationship between the series linear resistance of the diode and its nonlinear capacitance. The highest frequency for which the device will function properly is that at which the capacitive reactance (the reciprocal of the product of nonlinear capacitance and frequency) is equal to the series resistance of the device. Thus, designing a varactor for maximum frequency response involves choosing a doping density high enough for a small series resistance but low enough so that the capacitance of the device is small.

Varactors, as well as other solid-state devices, possess the advantage that they are compact and robust, permitting their use in hostile environments, as well as improving the reliability of the circuits in which they are employed. *See* JUNCTION DIODE; MICROWAVE SOLID-STATE DEVICES; SEMICONDUCTOR; SEMICONDUCTOR DIODE. [D.R.A.]

Variable (mathematics) A symbol x is usually defined to be a variable if it may denote any member of a set of objects. A variable is discrete or continuous according to whether its range (the set) is discrete (for example, a subset of the natural numbers) or continuous (for example, all real numbers between two real numbers), respectively. *See* Analytic geometry; Number theory; Parametric equation. [L.M.Bi.]

Variable star A star that has a detectable change in brightness which is often accompanied by other physical changes. During the life of a star, changes in brightness occur in the early stages, while it is forming, or in the late stages, close to its death. Therefore, variability provides important clues about the evolution and nature of stars. Depending upon the type of star, variability in brightness can provide information about its size, radius, mass, temperature, luminosity, internal and external structure, composition, and distance from the Earth. Over 31,900 stars are known to vary in brightness.

Variable stars can be divided into two major types: extrinsic and intrinsic variables. The extrinsic variables are those stars in which the variability in brightness occurs because of the occultation of one star by another (eclipsing binary) or rotation of a star that has dark or bright spots on its surface, similar to sunspots. *See* Binary star; Eclipsing variable stars.

Intrinsic variables are those stars in which the variability of brightness occurs because of physical change in or on the star itself. These stars are divided into two classes: pulsating and eruptive (see table).

Pulsating variables. Periodic pulsation (contraction and expansion) of the star and its outer layer results in the variation in brightness, as well as variations in the star's temperature, spectrum, and radius.

Cepheids are rare, highly luminous (supergiant), yellow variable stars. They vary with periods from 1 to 100 days, and have a range of variation from 0.1 to 2 magnitudes. Cepheids show an important correlation between their period of variation and their relative brightness, in that those stars with longer periods are also brighter. Due to this period-luminosity relationship, cepheids have been used to measure distances to nearby galaxies and in the determination of the distance scale of the universe.

A similar group of variable stars, W Virginis stars, found in globular star clusters and the corona of the Milky Way Galaxy, are bluer (and thus hotter) and older (population II) than the cepheids. They have periods from 10 to 30 days, and obey a similar period-luminosity relationship. They are sometimes called type II cepheids to distinguish them from the classical type I cepheids. *See* Cepheids.

RR Lyrae variables are the second most common type of variable in the Galaxy. They have periods of less than 1 day, and have a small range of variation, from 0.5 to 1.5 magnitudes. They are particularly numerous in globular clusters, and thus are sometimes referred to as cluster variables. All RR Lyrae variables have the same intrinsic luminosity, of magnitude 0.5. Thus, if an RR Lyrae star can be identified in a star cluster and its apparent magnitude determined, the above equation and the star's known absolute magnitude can be used to obtain the distance to the cluster.

Long-period variable stars are the most abundant of all variables in the Milky Way Galaxy. They are red, cool, giant or supergiant stars with spectral class M or R, S, or C carbon types. Long-period variables are old stars which have evolved from the main sequence and are in the late stages of their evolution. *See* Stellar evolution.

The prototype of long-period variables is *o* Ceti (Mira), which has given its name to those long-period variables that have a range of variation of 2.5 magnitudes and more. Mira variables have periods ranging from 100 to 1000 days. Although the change in brightness is periodic, some cycles may be much brighter or fainter than others. *See* Mira.

Red giant and supergiant stars with less regularity of variation, shorter periods, and smaller ranges of variation, less than 2.5 magnitudes, are called semiregular variables. Other red variable stars that do not exhibit any regularity in their brightness change are called irregular stars.

Rare, very luminous, yellow supergiant stars that generally show alternating shallow and deep fadings are called RV Tauri stars. These pulsating variables vary by 2 to 3 magnitudes within 30 to 150 days.

Eruptive variables. Eruptive variables are those stars that have one or more eruptions—the ejection of matter into space—in their lifetime. The most spectacular type of stellar explosion is that of a supernova, wherein a star's luminosity suddenly increases to tens of thousands of times the original brightness and the star outshines the total brightness of its galaxy. The gigantic explosion may be due to the gravitational collapse of a very hot and massive star that has exhausted the energy available from nuclear reactions; the collapse then creates enormous energy to blast outward the layers surrounding the stellar core. Alternatively, the explosion may occur in a close binary system in which one of the components is a massive white dwarf, an Earth-sized, very compact, old star, that explodes when it receives too much material from the other component. *See* Supernova.

Representative types of intrinsic variables

Type	Range of period, days	Amplitude, magnitude	Spectra and luminosity	Example	Number known
Pulsating					
RR Lyrae	<1	<2	A to F (blue), giants	RR Lyrae	6107
Cepheids (types I and II)	1–70	0.1–2	F to G (yellow), supergiants	δ Cephei	812
Long-period					
Mira	80–1000	2.5–6+	M (red), giants	o Ceti (Mira)	5827
Semiregular	30–1000	1–2	M (red), giants and supergiants	Z Ursae Majoris	3383
RV Tauri	30–150	Up to 3	G to K (yellow and red), supergiants	RV Tauri	122
Irregular	Irregular	Up to several magnitudes	All types		2391
Others					359
Eruptive					
Supernovae	?	15 or more		CM Tauri (Crab Nebula)	7
Novae	Centuries?	7–16	O to A, subdwarfs	GK Persei	281
Recurrent novae	20 years?	7–9		RS Ophiuchi	8
Dwarf novae (U Geminorum and Z Camelopardalis)	10–600	2–6	A to F, subdwarfs	SS Cygni, Z Camelopardalis	332
Flare	?	Up to 6	M, dwarfs	UV Ceti	1144
Nebular	Rapid and erratic	Up to a few magnitudes	B to M, main sequence and subgiants	T Tauri	1444
R Coronae Borealis		1–9	F to K, supergiants	R Coronae Borealis	37
Others					277

Cataclysmic variables are very close binary systems made up of an evolved, hot, dense white dwarf and a less evolved cool star which transfers mass onto the white dwarf accretion disk. The best known of the cataclysmic variables are stars that brighten by 7 to 16 magnitudes within about a day. They stay at maximum brightness for a few days or weeks and then slowly fade. The word nova, meaning new, was used for these stars. Actually a nova is not a new star, but an already existing star which due to the eruption has become very luminous and thus visible. Recurrent novae are stars that about evey 20 years or more have eruptions during which the system brightens by 7 to 9 magnitudes. Dwarf novae have smaller-scale eruptions, in which the star brightens by 2 to 6 magnitudes within a day, stays bright 1 to 2 weeks, and then fades to the original brightness.

R Coronae Borealis stars, instead of brightening through eruptions, irregularly decrease in brightness every 2 to 3 years by 1 to 9 magnitudes. The decrease in brightness is caused by the veiling of the star by thick carbon clouds expelled to the star's atmosphere. *See* CATACLYSMIC VARIABLE; STAR.

Nebular variables are young stars in the early stages of stellar formation. [J.A.Ma.]

Variational methods (physics) Methods based on the principle that, among all possible configurations or histories of a physical system, the system realizes the one that minimizes some specified quantity. Variational methods are used in physics both for theory construction and for calculational purposes.

The earliest use of a variational principle for physics is Fermat's principle in optics, which states that when a light ray traverses a medium with nonuniform index of refraction its path is such as to minimize its travel time. An integral expresses the time that the light takes to travel from one point to another along a particular path, and an application of the calculus of variations to this integral makes it possible to determine the particular path for which the travel time is a minimum. This problem is mathematically identical to the variational principle that determines a geodesic, the path of shortest distance, in a given geometry. In that form, the same principle determines the world lines of all objects in the general theory of relativity. *See* RELATIVITY; RIEMANNIAN GEOMETRY.

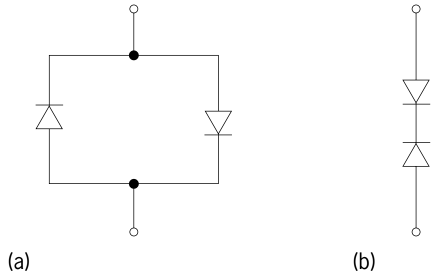
Similarly, in mechanics, Hamilton's principle for the action is defined for any system of point particles by an integral (called the action) that extends over an arbitrarily prescribed path Γ in configuration space. Hamilton's principle asserts that the trajectories of all the particles are determined by the requirement that Γ be such that, for given initial and final times, the action is a minimum; for this reason it is also called the principle of least action. If the calculus of variations is applied to implement this principle, the corresponding Euler-Lagrange equations are obtained. These are the lagrangian equations of motion, that is, Newton's equations of motion in lagrangian form. *See* ACTION; HAMILTON'S PRINCIPLE ; LAGRANGIAN FUNCTION; LEAST-ACTION PRINCIPLE.

The principle of least action has been generalized to systems with infinitely many degrees of freedom, that is, fields. A Lagrange density function is then defined, which is a function of the fields and their time derivatives at any given point in space and time. For any field theory, only the Lagrange density needs to be given; the field equations are then derivable as the corresponding Euler-Lagrange equations. A similar technique makes it possible to derive the Schrödinger equation and the Dirac equation in quantum mechanics from specific Lagrange density functions. *See* QUANTUM MECHANICS; QUANTUM THEORY OF MATTER; RELATIVISTIC QUANTUM THEORY.

This method has great procedural advantages. For example, it facilitates a check of whether the theory satisfies certain invariance principles (such as relativistic invariance or rotational invariance) by simply ascertaining whether the Lagrange density satisfies them. The corresponding conservation laws can also be derived directly from the lagrangian. *See* CONSERVATION LAWS (PHYSICS); QUANTUM FIELD THEORY; SYMMETRY LAWS (PHYSICS).

The variational method also plays an important role in quantum-mechanical calculations. For the computation of needed quantities in terms of functions that result from the solution of differential equations, it is always of great advantage to use formulas that have the special form required to make them stationary with respect to small variations of the input functions in the vicinity of the unknown, exact solutions. *See* MINIMAL PRINCIPLES. [R.G.Ne.]

Varistor Any two-terminal solid-state device in which the electric current I increases considerably faster than the voltage V. This nonlinear effect may occur over all, or only part, of the current-voltage characteristic. It is generally specified as $I \propto V^n$, where n is a number ranging from 3 to 35 depending on the type of varistor. The main use of varistors is to protect electrical and electronic equipment against high-voltage surges by shunting them to ground. *See* ELECTRIC PROTECTIVE DEVICES.



Symmetrical rectifier varistors. (*a*) Low voltage. (*b*) High voltage.

One type of varistor comprises a sintered compact of silicon carbide particles with electrical terminals at each end. It has symmetrical characteristics (the same for either polarity of voltage) with n ranging from 3 to 7. These devices are capable of application to very high power levels, for example, lightning arresters. *See* LIGHTNING AND SURGE PROTECTION.

Another symmetrical device, the metal-oxide varistor, is made of a ceramiclike material comprising zinc oxide grains and a complex amorphous intergranular material. It has a high resistance (about 10^9 ohms) at low voltage due to the high resistance of the intergranular phase, which becomes nonlinearly conducting in its control range (100–1000 V) with $n > 25$.

Semiconductor rectifiers, of either the *pn*-junction or Schottky barrier (hot carrier) types, are commonly utilized for varistors. A single rectifier has a nonsymmetrical characteristic which makes it useful as a low-voltage varistor when biased in the low-resistance (forward) polarity, and as a high-voltage varistor when biased in the high-resistance (reverse) polarity. Symmetrical rectifier varistors are made by utilizing two rectifiers connected with opposing polarity, in parallel (illus. *a*) for low-voltage operation and in series (illus. *b*) for high-voltage use. For the high-voltage semiconductor varistor, n is approximately 35 in its control range, which can be designed to be anywhere from a few volts to several hundred. *See* SEMICONDUCTOR RECTIFIER. [I.A.Le.]

Varnish A transparent surface coating which is applied as a liquid and then changes to a hard solid. Varnishes are solutions of resinous materials in a solvent, and dry by the evaporation of the solvent or by a chemical reaction, either with oxygen from the air or by some other means, including absorption of atmospheric moisture.

Spirit varnishes are those in which the evaporation of solvent is the only drying process; the solvent is usually alcohol, although the term is used for similar coatings made with other solvents. Shellac varnish, made by dissolving shellac in alcohol, is the most common of this type. Oleoresinous varnishes are made by treating a drying oil with a resin, usually with heat, and dissolving the reaction product in a solvent, usually a petroleum fraction; drying results from the evaporation of the solvent, followed by polymerization of the drying oil portion, a reaction which is accelerated by metallic driers added to the varnish. For a discussion of the mechanism of this drying action. *See* DRIER (PAINT); SHELLAC; SOLVENT.

Varnish coatings on wood are used to protect against abrasion, staining, and weather and to reduce the penetration of water and other materials without obscuring the grain or changing the color materially. Varnishes are used on masonry to reduce the penetration of moisture and the damage from freezing. Paper is coated with varnish to resist moisture and keep printing from being damaged. *See* PRINTING; SURFACE COATING. [C.R.Ma.; C.N.S.]

Varnish tree The plant *Toxicodendron vernicifluum* (previously known as *Rhus vernicifera*), also called lacquer tree, a member of the sumac family (Anacardiaceae). It is a native of China, but has long been cultivated in Japan. When the bark is cut, it exudes a milky juice which darkens and thickens on exposure. This is the lacquer long used in China and Japan. When properly applied, the thin transparent film becomes a varnish of extreme hardness. *See* LACQUER; SAPINDALES. [P.D.St.; E.L.C.]

Varve Any of a variety of distinct sediment laminations or beds deposited within the span of a single year. They are formed commonly in saline or fresh-water lakes, but examples from marine environments are known as well. Usually, varves occur in repetitive series and thus comprise vertical sequences of annual cyclic deposits. Varves range in thickness from less than a millimeter (0.04 in.) to over a meter (3 ft), but typically are a few millimeters or centimeters thick.

The classic varves are found in glacial lake sediments formed during the Pleistocene ice ages. These glacial varves occur typically as couplets of light-colored silt or sand and dark clay. The relatively coarse silt-sand layers are formed during the warm summer months when meltwater inflows and sediment yields to the lake are large. During winter when meltwater inflow is greatly reduced or stopped, the fine-grained clay settles slowly to the lake bottom to deposit the fine, dark winter layer of the varve. Similar varved sediments are found commonly in modern glacier-fed lakes that undergo large seasonal variations in inflow. *See* GLACIATED TERRAIN; PLEISTOCENE.

Varves can be used as tools for correlation as well as for chronological reconstructions. In addition to their use in dating sedimentary deposits, varves have been used to investigate sedimentation rates, cyclic deposition, climate variations, glacial histories, and as standards of comparison for other dating techniques. Varves have been identified occasionally in ancient sedimentary rocks. *See* DATING METHODS; GLACIAL EPOCH; MARINE SEDIMENTS; SEDIMENTARY ROCKS; SEDIMENTOLOGY. [N.D.S.]

Vascular disorders Those disorders that involve the arteries, veins, and lymphatics.

Arteries. Diseases of the large and medium-sized arteries are the major cause of morbidity and mortality in the Western world.

Arteriosclerotic vascular disease, also known as arteriosclerosis, affects large and medium arteries and is particularly common in the arteries supplying the heart, those supplying the brain, and those supplying the lower extremities. Progressive narrowing and finally total occlusion of these arteries lead to the development of angina pectoris, myocardial infarction, stroke, and vascular insufficiency in the limbs. Although the cause of the disease is not known, certain factors appear to predispose to its development. These include cigarette smoking, hypertension, elevated serum cholesterol, and diabetes mellitus. There can also be a genetic predisposition to the disorder. *See* ARTERIOSCLEROSIS; DIABETES; HYPERTENSION; INFARCTION.

Much less common are diseases that lead to arteritis, an inflammation of the large or medium arteries, with subsequent occlusion or rupture of the artery. The causes include bacterial infection, syphilis, allergic disorders, and hypersensitivity states. *See* HYPERSENSITIVITY; SYPHILIS.

Several generalized disorders can involve the small arteries. These include scleroderma, periarteritis nodosa, lupus erythematosus, rheumatoid arthritis, and dermatomyositis. The involvement can produce areas of cell death (necrosis) and ulceration of the skin, particularly of the limbs. This appears to occur because of the occlusion of the involved small arteries, with consequent loss of blood supply. Such involvement often is preceded by a type of hypersensitivity to cold, a condition known as Raynaud's syndrome. *See* CONNECTIVE TISSUE DISEASE.

Veins. The most common disorder of the venous circulation is varicose veins. It develops because of the loss of function of the valves in the superficial veins of the limbs. The two most commonly involved veins are the greater and lesser saphenous. In this condition, the veins are enlarged and often tortuous. If the deep veins are not involved, the varicose veins are termed primary. Varicose veins tend to cluster in families and are more common in women than men. Primary varicose veins may be cosmetically unpleasing, but they rarely cause serious symptoms in the involved limbs. A more serious problem develops when the varicose veins are associated with destruction of valves in the deep veins, secondary to deep-vein thrombosis. When varicose veins develop because of problems within the deep venous system, they are called secondary varicose veins.

When patients undergo major surgery or are confined to bed because of a serious medical illness, thrombosis of the veins of the leg can occur. The thrombosis occurs most commonly in the deep veins of the calf but can progress and extend proximally to involve the popliteal, femoral, and iliac veins. *See* THROMBOSIS.

Lymphatics. When the drainage function is disturbed by obstruction of the lymphatics by tumors, parasites, or surgical excision, serious swelling (edema) can occur. This condition is called lymphedema. The pattern of swelling involves not only the lower leg but the foot and toes as well. Obstruction of the lymphatics can also be congenital or can appear unexpectedly at the time of the onset of the menses. Regardless of its cause, lymphedema is a permanent condition. *See* EDEMA; LYMPHATIC SYSTEM.

Arteriovenous communications. If there are anomalous communications between the arteries and veins proximal to the capillaries, blood is shunted away from the capillary bed. Such shunting can be congenital or acquired.

The congenital form can occur at almost any site in the vascular system. When these communications are present, they may appear as prominent veins that are much larger and more numerous than normal. These are commonly referred to as hemangiomas. The extent to which they cause problems depends upon their location, their size, and numbers of feeding communications that are present. If a foreign body such as a bullet or knife passes between a major artery and vein, an artificial communication can develop that results in the shunting of a large volume of blood. When the communication is between very large vessels such as the abdominal aorta and inferior vena cava, the amount of blood shunted may be so large that heart failure occurs. *See* CARDIOVASCULAR SYSTEM. [D.E.Str.]

Vector (mathematics) A directed line segment. As such, vectors have magnitude and direction. Many physical quantities, for example, velocity, acceleration, and force, are vectors. Vectors are widely used in mathematical physics. *See* CALCULUS OF VECTORS. [M.Ye.]

Vector methods (physics) Methods that make use of the behavior of physical quantities under coordinate transformations.

From the point of view of physics, the most appropriate definition of a vector in three-dimensional space is a quantity that has three components which transform under rotations of the coordinate system like the coordinates of a point in space.

What characterizes rotations is that the distance from the origin—

$$\sqrt{x_1^2 + x_2^2 + x_3^2}$$

of all points $\mathbf{x}$ with cartesian coordinates x_i, $i = 1, 2, 3$—remains unchanged. Specifically, if the rotation takes the x_i to new coordinates x_i', given by Eqs. (1) [in which $\det\{a_{ij}\}$ is the determinant

$$\begin{aligned} x_i' &= \sum_{j=1}^{3} a_{ij} x_j \qquad i = 1, 2, 3 \\ \sum_{k=1}^{3} a_{ik} a_{jk} &= \begin{cases} 1 & \text{if } i = j, \\ 0 & \text{if } i \neq j, \end{cases} \qquad \det\{a_{ij}\} = 1 \end{aligned} \tag{1}$$

of the matrix $\{a_{ij}\}$], then the three quantities V_i, $i = 1, 2, 3$, form the components of a vector $\mathbf{V}$, if in the new coordinate system the transformed coordinates are given by Eq. (2).

$$V_i' = \sum_{j=1}^{3} a_{ij} V_j \qquad i = 1, 2, 3 \tag{2}$$

If the coordinate transformation of Eqs. (1) is such that $|a_{ij}| = 1$ for $i = j$ and $a_{ij} = 0$ for $i \neq j$, but such that $\det\{a_{ij}\} = -1$ rather than $+1$ as in Eqs. (1), then it describes a reflection, in which a right-handed coordinate system is replaced by a left-handed one. If, for such a transformation, Eq. (2) also holds, then $\mathbf{V}$ is called a polar vector, whereas if the components of $\mathbf{V}$ do not change sign, it is called an axial vector or pseudovector. The vector $\mathbf{V}$ can also be looked upon as a quantity with a direction, with the magnitude

$$\sqrt{V_1^2 + V_2^2 + V_3^2}$$

pointing from the origin of the coordinate system to the point in space with the cartesian coordinates (V_1, V_2, V_3).

A quantity that remains invariant under a rotation of the coordinate system is called a scalar. The importance of vectors and scalars in physics derives from the assumed isotropy of the universe, which implies that all general physical laws should have the same form in any two coordinate systems that differ only by a rotation. It is therefore useful to classify physical quantities according to their transformation properties under coordinate rotations. Examples of scalars include the mass of an object, its electric charge, its volume, its surface area, the energy of a system, and its temperature. Other quantities have a direction and thus are vectors, such as the force exerted on a body, its velocity, its acceleration, its angular momentum, and the electric and magnetic fields. Since the sum of two scalars is a scalar, and the sum of two vectors is a vector, it is important in the formulation of physical laws not to mix quantities that have different transformation properties under coordinate rotations. The sum of a vector and a scalar has no simple transformation properties; a law that equated a vector to a scalar would have different forms in different coordinate systems and would thus not be acceptable. [R.G.Ne.]

Vega The fifth brightest of all stars, and the third brightest in the northern sky. It will be the north polar star in about 12,000 years. In moving through the Milky Way Galaxy, the Sun is generally heading toward the position now occupied by Vega. At a distance of 7.8 parsecs (25.3 light-years, or 2.4×10^{14} km, or 1.49×10^{14} mi), Vega, or α Lyrae, is the prototypical star of spectral class A0V, indicating that it has an effective surface temperature of 9600 K (16,800°F) and derives its energy from the thermonuclear burning of hydrogen in a stable core region. Stars of this class have main-sequence lifetimes of about 5×10^8 years, 20 times shorter than the Sun. In comparison with the Sun, Vega is approximately 2.9 times larger in diameter, 2.5 times more massive, and 60 times more luminous. *See* Precession of equinoxes; Spectral type.

Vega emits far more radiation at infrared wavelengths than would be expected. This radiation originates from a shell or disk of particles with a temperature of 100 K (−280°F) surrounding Vega out to a distance of 1.3×10^{10} km (8×10^9 mi), twice the radius of the solar system. *See* Infrared astronomy; Star. [H.A.McA.]

Vegetable ivory The seed of the tagua palm (*Phytelephas macrocarpa*) of tropical America. Each drupelike fruit contains six to nine bony seeds. The extremely hard endosperm of the seed is used as a substitute for ivory. Vegetable ivory can be carved and tooled to make buttons, chessmen, knobs, inlays, and various ornamental articles. *See* Arecales. [P.D.St./E.L.C.]

Vegetation and ecosystem mapping The graphic portrayal of spatial distributions of vegetation, ecosystems, or their characteristics. Vegetation is one of the most conspicuous and characteristic features of the landscape and has long been a convenient way to distinguish different regions; maps of ecosystems and biomes have been mainly vegetation maps. As pressure on the Earth's natural resources grows and as natural ecosystems are increasingly disturbed, degraded, and in some cases replaced completely, the mapping of vegetation and ecosystems, at all scales and by various methods, has become more important. *See* Biome; Ecosystem.

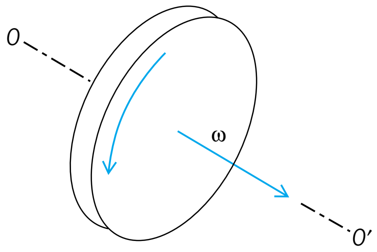
Three approaches have arisen for mapping general vegetation patterns, (1) based on vegetation structure or gross physiognomy, (2) based on correlated environmental patterns, and (3) based on important floristic taxa. The environmental approach provides the least information about the actual vegetation but succeeds in covering regions where the vegetation is poorly understood. Most modern classification systems use a combination of physiognomic and floristic characters. *See* Plant geography.

Mapping has expanded to involve other aspects of vegetation and ecosystems as well as new methodologies for map production. Functional processes such as primary production, decomposition rates, and climatic correlates (such as evapotranspiration) have been estimated for enough sites so that world maps can be generated. Structural aspects of ecosystems, such as total standing biomass or potential litter accumulations, are also being estimated and mapped. Quantitative maps of these processes or accumulations can be analyzed geographically to provide first estimates of important aspects of world biogeochemical budgets and resource potentials.

Computer-produced maps, using Geographic Information Systems (GIS), often coupled directly with predictive models, remote-sensing capabilities, and other techniques, have also revolutionized vegetation and ecosystem mapping. This gives scientists a powerful tool for modeling and predicting the outcome from global climate change, in that feedback from the world's vegetation can be accounted for. Before computer technology exploded in the early 1980s, the spatial scale and related resolution or grain of vegetation and ecosystem mapping was limited by the static nature of hard-copy maps. The advent of GIS technology enabled the analysis of digital maps at any spatial scale, and the only limitation was the resolution at which the data were originally mapped. In addition, GIS software is used for sophisticated spatial analyses on maps, and this was virtually impossible before. *See* Cartography; Climate modeling; Geographic information systems; Remote sensing. [B.E.F.; E.O.B.]

Velocity The time rate of change of position of a body in a particular direction. Linear velocity is velocity along a straight line, and its magnitude is commonly measured in such units as meters per second (m/s), feet per second (ft/s), and miles per hour (mi/h). Since both a magnitude and a direction are implied in a measurement of velocity, velocity is a directed or vector quantity, and to specify a velocity completely, the direction must always be given. The magnitude only is called the speed. *See* Speed.

A body need not move in a straight line path to possess linear velocity. When a body is constrained to move along a curved



Angular velocity shown as an axial vector. Axis of rotation is *OO′*.

path, it possesses at any point an instantaneous linear velocity in the direction of the tangent to the curve at that point. The average value of the linear velocity is defined as the ratio of the displacement to the elapsed time interval during which the displacement took place.

The representation of angular velocity ω as a vector is shown in the illustration. The vector is taken along the axis of spin. Its length is proportional to the angular speed and its direction is that in which a right-hand screw would move. If a body rotates simultaneously about two or more rectangular axes, the resultant angular velocity is the vector sum of the individual angular velocities. [R.D.Ru.]

Velocity analysis

A technique for the determination of the velocities of the parts of a machine or mechanism. Graphical and analytical analyses of plane mechanisms are the two main methods that are used. Visualization is an inherent part of the graphical analysis and generally gives a better physical feel for the problem than most purely analytical methods. Analytical methods, however, are necessary for computer analyses. *See* VELOCITY.

In a high-speed machine it is important that the inertia forces be determined. This requires an acceleration analysis of the machine, and the first step in an acceleration analysis usually is a velocity analysis. In the analysis of some machines, the velocity of a particular point in the machine may itself be the important thing to be determined in the analysis—for example, the cutting speed and return speed of the cutting tool in a shaper, or the shuttle velocity in a textile machine.

In the graphical method of velocity analysis, the geometry of the mechanism is known in each phase of its motion cycle from the drawing of the mechanism in each position. In an analytical velocity analysis, the geometry is usually determined analytically; that is, a position analysis of the mechanism is performed by using trigonometry, vector mathematics, or some other analytical method as the first step in the velocity analysis.

One analytical method for the position analysis of mechanisms, developed by M. A. Chace, makes use of vector mathematics. It consists essentially of solving vector triangles containing two unknowns. Computer subprograms for Chace solutions to the plane vector equation and for all the various vector operations have been written, thus making the position and velocity analyses (as well as the acceleration analysis) of mechanisms by computer using Chace's method quite convenient. Computer analyses are particularly useful when complex mechanisms must be analyzed in many positions of their cycle of motion. *See* STRAIGHT-LINE MECHANISM; VECTOR (MATHEMATICS). [J.C.Wo.]

Veneer

A thin sheet of wood of uniform thickness produced by peeling, slicing, or sawing. Depending on the manner of production and the portion of wood from which a veneer is made, the grain may be flat, vertical, or biased. Most veneer is rotary-cut from a bolt of wood, called a flitch, centered in chucks of a lathe. A nose bar bears against the flitch parallel to the center line of the lathe and a knife, also extending nearly the length of the lathe, peels off the veneer. Knives near the ends of the flitch cut the edges of the veneer.

Veneers cut from selected hardwoods, burls, crotches, and stumps are used for facings on furniture and the interior decoration of buildings. Other uses of veneer include plate separators in storage batteries, boxes for fruit and vegetables, drums for cheeses, and crates, hampers, and baskets for transportation and storage. Most veneer is used in plywood panels. *See* PLYWOOD; WOOD PRODUCTS. [F.H.R.]

Ventilation

The supplying of air motion in a space by circulation or by moving air through the space. Ventilation may be produced by any combination of natural or mechanical supply and exhaust. Such systems may include partial treatment such as heating, humidity control, filtering or purification, and, in some cases, evaporative cooling. More complete treatment of the air is generally called air conditioning. *See* AIR CONDITIONING.

Natural ventilation may be provided by wind force, convection, or a combination of the two. Although largely supplanted by mechanical ventilation and air conditioning, natural ventilation still is widely used in homes, schools, and commercial and industrial buildings.

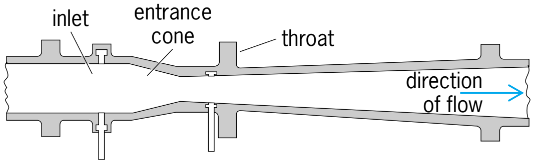
Mechanical supply ventilation may be of the central type consisting of a central fan system with distributing ducts serving a large space or a number of spaces, or of the unitary type with little or no ductwork, serving a single space or a portion of large space. Outside air connections are generally provided for all ducted systems. Outside air is needed in controlled quantities to remove odors and to replace air exhausted from the various building spaces and equipment.

Exhaust ventilation is required to remove odors, fumes, dust, and heat from an enclosed occupied space. Such exhaust may be of the natural variety or may be mechanical by means of roof or wall exhaust fans or mechanical exhaust systems. The mechanical systems may have minimal ductwork or none at all, or may be provided with extensive ductwork which is used to collect localized hot air, gases, fumes, or dust from process operations. Where it is possible to do so, the process operations are enclosed or hooded to provide maximum collection efficiency with the minimum requirement of exhaust air. [J.H.Cl.]

Venturi tube

A device that consists of a gradually decreasing nozzle through which the fluid in a pipe is accelerated, followed by a gradually increasing diffuser section that allows the fluid to nearly regain its original pressure head (see illustration). It can be used to measure the flow rate in the pipe, or it can be used to pump a secondary fluid by aspirating it at the nozzle exit. The ability of the venturi tube to regain much of the original pressure head makes it especially useful in measuring the flow rate in systems which have a low pressure differential or pressure head that drives the fluid through the pipe or where the cost of pumping the fluid is an important factor. Conserving the pressure head decreases the amount of energy required to pump the fluid through the pipe.

A gradual expansion of flow downstream of a nozzle eliminates flow separation, allowing recovery of most of the original pressure head. In the case where the main flow separates from the wall, a large percentage of the fluid energy is lost in the eddies caused by the separation.



Proportions of a Herschel-type venturi tube for standard fluid-flow measurement.

The flow through the device obeys Bernoulli's equation, and the formula for calculating the flow is similar to the equation for orifices. The venturi meter belongs to the class of differential pressure-sensing devices that are used to indicate flow. *See* Bernoulli's theorem; Flow measurement; Metering orifice. [M.P.W.]

Venus The second planet in distance from the Sun. This neighbor of the Earth is very similar to it in such gross characteristics as mass, radius, and density. In other ways Venus is apparently different. Its atmospheric mass is almost a hundred times that of the Earth; its atmosphere is mostly carbon dioxide instead of nitrogen and oxygen; an extensive cloud layer of concentrated sulfuric acid is present; its surface temperature is an unbearable 850°F (730 K); and it rotates with a period of 243 days, and from east to west, in the opposite sense of most other planets. Some of these differences are due more to alternate evolutionary paths of the two planets than to totally different initial conditions.

To the naked eye, Venus is the brightest starlike object in the sky. It is usually visible during the night either soon after sunset or close to sunrise. It can sometimes be seen during the daytime.

The light seen coming from Venus is entirely due to sunlight that is reflected from a dense cloud layer whose top is located about 45 mi (70 km) above the surface and whose bottom lies within 30 mi (50 km) of the surface. In contrast to the Earth's approximately 50% cloud cover, the clouds of Venus are present over the entire planet. The clouds of Venus consist of a large number of tiny particles, about 1 micrometer in size, that are made of a water solution of concentrated sulfuric acid.

By far, the chief gas species of Venus's atmosphere is carbon dioxide, which makes up 96% of the atmospheric molecules, while nitrogen accounts for almost all the remainder. In contrast to the dominance of carbon dioxide in Venus's atmosphere, the Earth's atmosphere consists mostly of nitrogen and oxygen, with carbon dioxide being present at a level of only 340 ppm. In part, this difference may stem more from temperature differences than from intrinsic differences. Over the lifetime of the Earth, an amount of carbon dioxide comparable to that in Venus's atmosphere was vented out of the Earth's hot interior, but almost all of it participated with rain in dissolving land rocks, and rivers carried the dissolved rock and carbon dioxide into the oceans, where they subsequently precipitated to form carbonate rocks, such as limestone. Venus's surface is much too hot for oceans of water to be present, and hence its atmosphere has been able to retain essentially all of the carbon dioxide vented from its interior. *See* Atmospheric chemistry.

The atmospheric temperature has a relatively cool value of −10°F (250 K) near the top of the cloud layer, which is at a pressure of about 1/20 that at the Earth's surface. The temperature gradually increases with decreasing altitude until it reaches 850°F (730 K) at the surface, where the pressure is 90 times that at the Earth's surface. The high value of Venus's surface temperature is not due to its being closer to the Sun than the Earth. Because its cloud layer reflects to space about 75% of the incident sunlight, Venus actually absorbs less solar energy than does the Earth. Rather, the high temperature is the result of a very efficient greenhouse effect that allows a small but significant fraction of the incident sunlight to penetrate to the surface (about 2.5%), but prevents all except a negligible fraction of the heat generated by the surface from escaping directly to space. *See* Greenhouse effect.

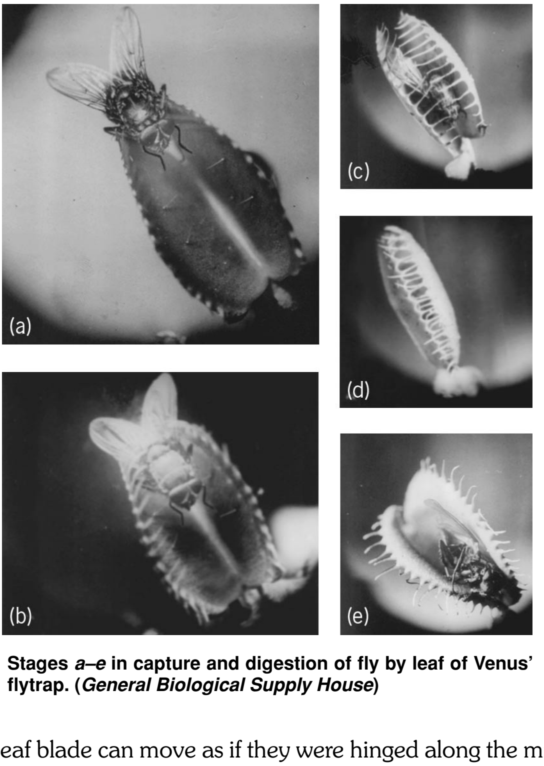
The very similar mean densities of Venus and the Earth imply that Venus is made of rocks similar to those that make up the Earth. Venus's interior may be qualitatively similar to that of the Earth in having a central iron core, a middle mantle made of rocks rich in silicon, oxygen, iron, and magnesium, and a thin outer crust containing rocks enriched in silicon in comparison with the rocks of the mantle. However, in contrast to the situation for the Earth, Venus's core may now be either entirely solid or entirely liquid, which could account for the absence of a detectable magnetic field. *See* Earth interior. [J.B.Po.]

Venus has been more intensely explored by spacecraft than any other planet. United States and Soviet spacecraft provided data on the composition of the surface and atmosphere, and the dynamics of the upper atmosphere. The Soviet *Venera* landers transmitted back the first images from the surface of another planet. The United States *Magellan* mapped nearly 98% of the surface. *See* Space probe.

Magellan's mapping mission revealed a unique global volcanic and tectonic style on Venus. Broad volcanic plains make up about 85% of the surface of Venus. The rest is tectonically deformed, higher-standing terrains with complex systems of folds and faults. Regional tectonism is evident in the widespread compressional and extensional deformation of much of the surface material. Venus apparently has had a dynamic mantle that has driven crustal warping, which may be ongoing. However, while various regions of the planet show evidence of motion, no evidence of Earth-like plate tectonics has been found. *See* Plate tectonics.

Long, narrow troughs are seen in many areas where the crust has ruptured; these linear rift zones are associated with extensive broad, domical rises and shield-volcano complexes. The planet also has some unexplained surface features, including long channels meandering across the plains. Also seen are oval to circular volcanic-tectonic structures called coronae that range in diameter from 60 to 1300 mi (100 to 2100 km). Impact craters are much less abundant on Venus than on the Moon or Mars, and currently active volcanism has not been detected on Venus. *See* Planet; Planetary physics. [R.S.Sa.]

Venus' flytrap *Dionaea muscipula*, an insectivorous plant of North and South Carolina (see illustration). The two halves of a leaf blade can move as if they were hinged along the midrib and, swinging upward and inward, the two surfaces come together. Any insect alighting on a leaf triggers this sensitive motor mechanism, and is caught between the closing halves of the leaf blade. In this trap, the insect is slowly digested by enzymes secreted by cells in the leaf. *See* Insectivorous plants; Nepenthales; Secretory structures (plant). [P.D.St./E.L.C.]



Stages *a–e* in capture and digestion of fly by leaf of Venus' flytrap. (*General Biological Supply House*)

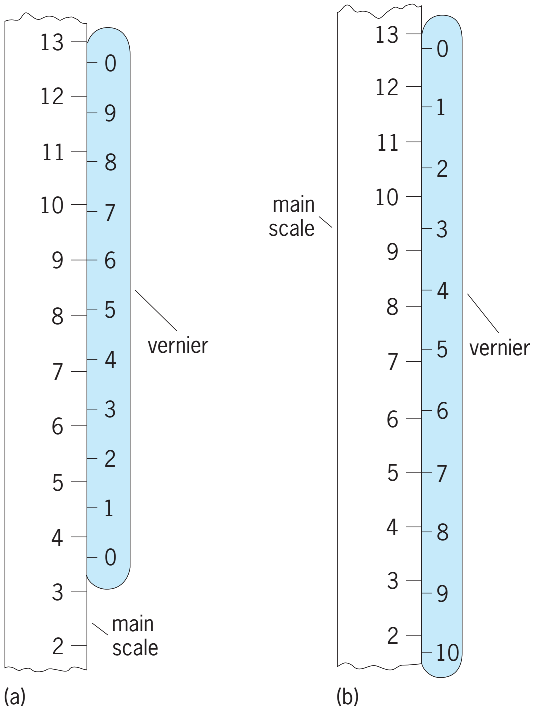
Vermiculite A group of minerals common in some soils and clays and belonging to the family of minerals called layer silicates. Species within the vermiculite group are denoted as either dioctahedral vermiculite or trioctahedral vermiculite, with two or three octahedral cation sites occupied per formula unit, respectively. Trioctahedral vermiculite is a 2:1 layer silicate with a fundamental unit similar to that of mica. An octahedral sheet forms the basis of the layer and is sandwiched between two opposing tetrahedral sheets. *See* Mica.

Perfect basal cleavage develops by the layerlike structure. Density varies but is near 2.4 g/cm^3; hardness on Mohs scale is near 1.5; and luster is pearly. Thin sheets deform easily and may be yellow to brown. *See* Hardness scales.

Heat-treated and expanded vermiculite is used as an insulator in construction. Mixed with plaster and cement, vermiculite is used to make lightweight versions of these materials. Vermiculite is also useful as an absorbent for some environmentally hazardous liquids. *See* Clay minerals; Silicate minerals. [S.Gu.]

Vernalization The induction in plants of the competence or ripeness to flower by the influence of cold, that is, temperatures below the optimal temperature for growth. Vernalization thus concerns the first of the three phases of flower formation in plants. In the second stage, for which a certain photoperiod frequently is required, flowers are initiated. In the third stage flowers are unfolded. *See* Flower; Photoperiodism; Plant growth. [K.N.Z.]

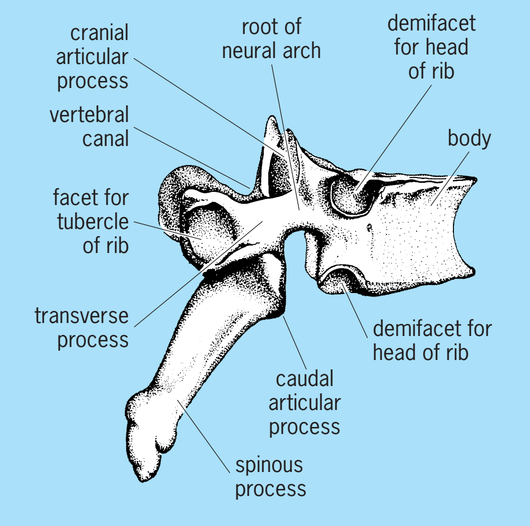
Vernier A short, auxiliary scale placed along the main instrument scale to permit accurate fractional reading of the least main division of the main scale. The auxiliary, or vernier, scale is graduated in one or both directions from the fiducial (index) mark in numbered divisions which are fractionally shorter (in a direct vernier) or longer (in a retrograde vernier) than those on the main scale (see illustration). The position of the fiducial mark (the zero mark of the vernier scale) between divisions on the main scale is indicated by the number of the graduation on the vernier scale which lines up exactly with a graduation on the main scale. [W.A.Wi.]



Two types of vernier scales. (*a*) Direct (reading 3.6). (*b*) Retrograde (reading 12.7)

Verrucomorpha A suborder of the Thoracica comprising one Recent genus, *Verruca*, and one fossil, *Proverruca*, from the Lower Devonian. These barnacles are sessile and asymmetrical. In *Verruca* only four plates form the wall, rostrum, carina, and scutum and tergum of one side. In *Proverruca* two additional lateral plates are inserted between the rostrum and the carina. These barnacles are hermaphroditic. Most species live in deep water, though *V. stroemia* is from the lower intertidal and sublittoral. *See* Thoracica. [H.G.St.]

Vertebra The basic unit of the vertebral column. Collectively, the vertebrae surround and protect the spinal cord and provide some type of axial support for the body. The stresses that the vertebral column must meet change somewhat from one end of the animal to the other, and also differ greatly between aquatic and terrestrial vertebrates because the problems of support and locomotion in these media are quite different. Accordingly, vertebral structure varies widely; yet all vertebrae have many features in common. *See* Spine.



Lateral view of a human thoracic vertebra. Anterior is toward the right.

A vertebra from the thoracic region of a mammal illustrates the basic morphology well (see illustration). The ventral portion consists of a disc-shaped mass of bone known as the body or centrum. An arch of bone, the neural arch, extends dorsally from the centrum and encompasses a space, the vertebral canal, in which the spinal cord lies. The bases, or roots, of the arch are narrower than other parts so that clefts, the intervertebral foramina, lie between the arch bases of successive vertebrae. Spinal nerves pass through these foramina.

Certain muscles and ligaments attach onto the spinous process, which extends dorsally from the top of the arch, and onto a pair of transverse processes, which extend laterally from the arch. One pair of articular processes, or zygapophyses, extends forward from the neural arch, and another pair extends posteriorly. Articular processes of successive vertebrae overlap and help to hold the vertebrae together. The centra of adjacent vertebrae are also joined together by invertebral discs of fibrocartilage. Numerous ligaments interlace the vertebrae.

Ribs articulate onto the thoracic vertebrae. Typically, each mammalian rib has two articular surfaces—a terminal head and a tubercle situated a short distance distal to the head. The tubercle articulates with a facet located on the end of the transverse process; the head usually articulates intervertebrally onto the intervertebral disc and adjacent parts of the bordering centra.

In mammals different parts of the column are clearly specialized to subserve certain functions in addition to their general supportive role.

The head moves independently of the trunk, and a distinct neck region, consisting of cervical vertebrae, is present. With few exceptions all mammals from a shrew to a giraffe have seven cervical vertebrae.

Well-developed ribs, which play an important role in respiratory movements, articulate with the anterior trunk or thoracic vertebrae of mammals. The number of thoracic vertebrae varies between species but is on the order of 11 (bat) to 18 or 20 (horse). Humans have 12.

Lumbar vertebrae occupy the posterior part of the mammal trunk region. They are characterized by relatively large transverse processes to which certain of the powerful back muscles attach. Again the number of lumbar vertebrae vary between species but is on the order of 5 (bat) to 8 (whale). Humans have 5.

Correlated with the greater efficiency of terrestrial locomotion and the need for strong support for the powerful hindlegs, the number of sacral vertebrae increases during evolution from the single one of amphibians. Reptiles usually have two, and most mammals have three which are fused together, along with their embryonic rib rudiments, into a solid complex of bone called the sacrum. Humans, which are bipeds, have 5, and certain of the powerful hoofed mammals, for example, the horse, also have 5. Birds, whose hindlegs act as shock absorbers upon landing, have between 10 and 23 vertebrae fused together in their synsacrum.

The tail and caudal musculature no longer play an important role in the locomotion of most mammals (the Cetacea being a conspicuous exception), and the tail is greatly reduced in size. The spinal cord of mammals ends within the lumbar region, and only a few spinal nerves continue through the vertebrae canal into the tail. Caudal vertebrae are small and become progressively incomplete as one moves distally along the tail until only centra are left. Tail length, and hence the number of caudal vertebrae, vary widely. Some opossums have as many as 35, and humans, in which the tail is absent as an external structure, have only 3 to 5 caudal vertebrae. These form an internal coccyx to which certain anal muscles attach.

Vertebrata The major subphylum of the phylum Chordata, comprising the backboned animals, including humans. The subphylum is sometimes called the Craniata, because of the common possession of a cranium or braincase, but that term has dropped out of use in scientific nomenclature.

The characteristic features of the Vertebrata are a vertebral column, or backbone, and a cranium, which protects the central nervous system (brain and spinal cord) and major sense organs; the presence of bone, which is a tissue unique to vertebrates; and a neural crest of nerve cells that remain after the formation of the central nervous system. Other distinctive vertebrate features are a kidney, with the nephron as its functional unit; a heart; red and white blood cells; a liver and a pancreas; specialized sense organs, such as a complex eye, a lateral-line system, ears, and a sense of smell; several unique endocrine organs, such as the pituitary and thyroid; and a complex skin comprising an epidermis and dermis. *See* Chordata; Vertebra.

Vertebrates evolved from a lower chordate similar to the present-day Cephalochordata (amphioxus). They originated in fresh water and developed a kidney as their organ of water balance. They became free-swimming, with several evolutionary lines invading the oceans. The main line of evolution in the vertebrates, that which led to the tetrapods, remained in fresh waters.

The Vertebrata are divided into the following eight classes, which are arranged into several partly overlapping informal groups, and often two superclasses, Pisces and Tetrapoda, are used to differentiate the aquatic and the terrestrial vertebrates. *See* Pisces (zoology); Tetrapoda.

Superclass Pisces	Superclass Tetrapoda
Class: Agnatha	Class: Amphibia
Placodermi	Reptilia
Chondrichthyes	Aves
Osteichthyes	Mammalia

The term Gnathostomata designates the seven classes of jawed vertebrates, in contrast to the jawless Agnatha. The Anamniota include the Pisces (fishes) and the Amphibia (amphibians). The Amniota consists of the Reptilia, Aves, and Mammalia. *See* Amniota; Animal kingdom. [W.J.B.]

Vertebrate brain (evolution) A highly complex organ consisting of sensory and motor systems that constitutes part of the nervous system. Virtually all of the brain systems that are found in mammals occur in birds, reptiles, and amphibians, as well as in fishes and sharks. These systems have become more complex and sophisticated as the adaptive requirements of the animals changed. Occasionally, new sensory systems arose, most likely as specializations of existing systems; however, some of these disappeared as animals left the aquatic world. Some sensory systems arose and declined several times in different lineages. In spite of the many changes in brain structure, some of them quite dramatic, the evolution of the nervous system, from the earliest vertebrates through to those of today, has been relatively conservative. *See* Nervous system (invertebrate); Nervous system (vertebrate).

Central nervous system. The nervous system consists of two main divisions: the central nervous system, which is made up of the brain and the spinal cord, and the peripheral nervous system. The peripheral nervous system consists of the nerves that bring information from the outside world via the sensory systems, and the nerves that carry information from the body's interior to the spinal cord and brain. These nerves also convey commands from the brain and spinal cord to the external muscles that move the skeleton, as well as to various internal organs and glands. *See* Central nervous system.

The brain consists of a variety of systems, some of which are sensory and deal with the acquisition of information from the internal and external environments. Other systems are motor and are involved with the movement of the skeletal muscles; the muscles of the internal organs, such as the heart and the digestive and respiratory systems; and the secretions of certain glands, such as the salivary and tear glands. The bulk of the brain, however, is composed of systems that are integrative and organize, coordinate, and direct the activities of the sensory and motor systems. These integrative systems regulate such processes as sleep and wakefulness, attention, the coordination of various muscle groups, emotion, social behavior, learning, memory, thinking, planning, and other aspects of mental life. Social behavior itself is highly complex and includes such interactions between individuals as courtship, mating, parental care, and the organization and structure of groups of individuals. *See* Brain; Motor systems.

Development. The nervous system develops in the embryo as a hollow tube. The remnants of this hollow tube in the adult are known as the brain ventricles and are filled with the cerebrospinal fluid. Two types of overall brain organization are found among vertebrates based on the relationship of the neurons to these ventricles. In brains with laminar organization, the neurons have not migrated very far from the layer immediately surrounding the hollow ventricular core of the brain. This type of organization is typical of amphibia and is also found in the brains of some sharks, fishes (especially those in which their skeletons are partly or mostly made of cartilage rather than bone), and lampreys. In contrast, in the brains of those vertebrates with the elaborated type of organization, the neurons have migrated from the zone around the ventricles to occupy nearly all of the interior of the brain. This type of organization is typical of reptiles, mammals, birds, fishes (with fully bony skeletons), as well as skates, rays, some sharks, and hagfishes. *See* NEURON.

In general, brain size or weight varies in proportion to the size of the body. In some species, however, brain size or weight is greater than would be expected for that body weight, for example, in humans, chimpanzees, and porpoises. Birds have brains that are comparable to those of mammals of equivalent body weight. In fact, crows have brain weights that would be expected of a small primate of equivalent body weight. In contrast to birds and mammals, amphibians, reptiles, and bony fishes have relatively small brains for their body weights, as do jawless fishes.

Subdivisions of brain. The brain is divided into a hindbrain, a midbrain, and a forebrain.

Hindbrain. The hindbrain is a region that contains nerve endings that receive information from the outside world and from the body interior; these are known as sensory cranial nerves. The neuron groups upon which they terminate are known as sensory cranial nuclei. Also found in the hindbrain are motor nerves that control internal and skeletal muscles and glands, which are called motor cranial nerves; the neuron groups from which they originate are known as motor cranial nerve nuclei.

Many animals possess senses that humans do not possess. One such is the lateral line sense, which derives from receptors located in the lateral line organ which can easily be seen on most bony fishes as a thin, horizontal line running the length of the body from behind the gill opening to the tail. Other lateral line organs can be found on the head and jaws. These organs contain mechanoreceptors that respond to low-frequency pressure waves that might be produced by other fishes nearby or the bow wave of a fast-swimming predator about to strike. Lateral line systems and a special region of the hindbrain dedicated to lateral line sense are found in fishes and sharks, jawless fishes, and bony fishes of various sorts.

Electroreception is another way of dealing with a murky environment. Scientists have described two types of electroreception: active and passive. The receptors are also located in the lateral line canals and sometimes on the skin. Animals with passive electroreception, such as sharks and rays, platypuses, and echidna, can detect the presence of the very weak electric fields that are generated around a living body, which they then follow to capture their prey. Animals with active electroreception generate stronger electric fields around themselves using specialized electric organs. By detecting changes in these electric fields, they can derive a picture of their environment. Electrosensory cranial nerves terminate in a region of the hindbrain known as the electrosensory area. A second group of active electrosensory fishes are capable of generating electric fields so powerful they can stun a prey or an enemy. Among these are the electric eel, the electric catfish, and an electric shark (the torpedo). These animals also use their low-level electric fields to detect objects and creatures in the environment. *See* ELECTRIC ORGAN (BIOLOGY).

Not only did the hindbrain change in response to sensory evolution, but it also underwent major motor transformations; for example, motor-neuron groups involved in swallowing, chewing, and salivating evolved as a consequence of the transition to land and the loss of the water column to carry food from the opening of the mouth into the throat.

The hindbrain also contains two important coordinating or integrating systems: the cerebellum and the reticular formation. The functions of the cerebellum are varied; they include the integration of a sense of balance with aspects of movement and motor learning and motor memory, as well as playing an important role in electrosensory reception.

The reticular formation coordinates the functions of various muscle groups. For example, the actions of the jaws and tongue must be coordinated so that an animal does not eat its own tongue while eating its meal. It also coordinates the motor-neuron groups that control the air column that enters and leaves the mouth and throat, which produces the various vocalizations of land animals, including speech. The reticular formation also is involved in sleep, wakefulness, and attention.

Midbrain. The midbrain contains the motor cranial nerves that move the eyes. It also contains neuron groups that are organized to form maps of visual space, auditory space, and the body. These maps are coordinated with each other such that a sudden, unexpected sound will cause the head and eyes to move to the precise region of space from which the sound originated. In those animals that make extensive use of sound localization, such as owls and bats, the map areas of the midbrain are very highly developed. In addition, certain snakes, such as rattlesnakes and boa constrictors, have infrared detectors on the snout or under the eyes that can sense the minute heat from a small animal's body at a distance of 1 m (3 ft) or more. The midbrains of these animals also have infrared maps that are in register with the auditory, visual, and body maps to permit the animal to correlate all the necessary information to make a successful strike on prey in virtually total darkness.

Forebrain. The forebrain is a very complex region that consists of the thalamus, the hypothalamus, the epithalamus, and the cerebrum or telencephalon. In addition, the forebrain contains the limbic system, which has components in all regions of the forebrain as well as continuing into the midbrain. The thalamus processes and regulates a large quantity of the information that enters and emanates from the forebrain. As the cerebrum increases in size and complexity in land animals, the thalamus increases accordingly. The hypothalamus regulates autonomic functions as well as behaviors such as feeding, drinking, courtship and reproduction, parental, territoriality, and emotional, which it controls in conjunction with the limbic system. The hypothalamus also regulates the endocrine system. The size and complexity of the hypothalamus, relative to the rest of the brain, is greatest in fishes and sharks; it declines considerably in proportion to the rest of the brain in land animals. The epithalamus contains the pineal gland, which is involved in various biological rhythms that depend on daylight, including seasonal changes. In some animals, such as certain reptiles, the pineal takes on the form of an eye, located on the top of the head and known as the parietal eye. This eye has a lens and a primitive retina that capture light and transmit information, such as the amount of daylight, to the hypothalamus. The epithalamus, like the hypothalamus, is relatively smaller in the brains of land animals.

The greatest evolutionary expansion of the forebrain is seen in the cerebrum. The cerebrum consists of an outer layer, the pallium, and a series of deep structures, known as the subpallium. The subpallium is composed of the corpus striatum, the amygdala, and the hippocampus. The outer layer of the cerebrum in mammals is known as the cerebral cortex. Considerable debate surrounds the evolutionary relationship between the cerebral cortex of mammals and the pallium and subpallium of nonmammals. Most specialists, however, seem to agree that the mammalian cortex arose from the pallium and certain regions of the subpallium. The cerebrum is relatively small in animals with laminar brains and larger in those with complex brains. Scientists have only begun to catalog the many complicated behavioral functions of the cerebrum. Among them appear to be memory, thinking and reasoning, and planning. With the advent of life on the land, the cerebrum underwent an extreme degree of elaboration in reptiles and birds and especially in mammals. *See* ENDOCRINE SYSTEM (VERTEBRATE). [W.Ho.]

Vertical takeoff and landing (VTOL)

A flight technique in which an aircraft rises directly into the air and settles vertically onto the ground. Such aircraft do not need runways but can operate from a small pad or, in some cases, from an unprepared site. The helicopter was the first aircraft that could hover and take off and land vertically, and is now the most widely used VTOL concept. *See* HELICOPTER.

The helicopter is ideally suited for hovering flight, but in cruise its rotor must move essentially edgewise through the air, causing vibration, high drag, and large power losses. The aerodynamic efficiency of the helicopter in cruising flight is only about one-quarter of that of a good conventional airplane. The success of the helicopter in spite of these deficiencies started a wide-ranging study of aircraft concepts that could take off like a helicopter and cruise like an airplane. The term VTOL is usually used to designate the aircraft other than the helicopter that can take off and land vertically. The term V/STOL indicates an aircraft that can take off vertically when necessary, but can also use a short running takeoff, when space is available, to lift a greater load. *See* SHORT TAKEOFF AND LANDING (STOL).

The tiltrotor is closest to the conventional helicopter and relies heavily on helicopter technology. The rotor disks are horizontal in VTOL operation and are tilted 90° to act as propellers in cruising flight. Such aircraft can have cruise efficiencies at least twice those of the helicopter, making them especially useful for helicopter missions where greater range, speed, and time on station are desired.

Numerous advanced rotorcraft concepts are being investigated in research programs. These include designs that take off and land as a rotor system and fix the blades to act as wings for cruise flight. Other concepts feature tiltrotor technology for vertical flight, but fold the blades and employ other propulsion modes for cruise.

The vectored-thrust concept features an engine with four rotating nozzles that deflect the thrust from horizontal for conventional flight to vertical for VTOL operation. This activity led to the very successful British Harrier aircraft, which is considered to be a V/STOL aircraft because its normal mode of operation is to use a short takeoff run, when space is available, to greatly increase its payload and range capability.

With the success of the Harrier, design studies and technology development programs have been directed at expanding the flight envelope of this class of aircraft to include supersonic capability. The term STOVL (short takeoff vertical landing) is used to define this supersonic fighter-attack aircraft since the large benefits in payload and range of a short takeoff will be factored into the basic design. *See* CONVERTIPLANE. [W.P.N.]

Vessel traffic service An interactive system for improving the safety and efficiency of marine vessel traffic and protecting the environment within designated service areas. A vessel traffic service (VTS) system improves order and predictability throughout its service area by providing an organizational structure, a communications network, and standard procedures for enhanced information sharing and decision making in response to developing traffic situations. Opportunities for human error are reduced through the acquisition, interpretation, and broadcasting of traffic position, and navigation safety information and alerts for use by captains, mates, and marine pilots (local-area experts) in directing and controlling the maneuvering of participating vessels.

Traditional vessel traffic service systems consist of a crewed vessel traffic center (VTC) or centers, operational policies, a voice radio network with dedicated frequencies, radar surveillance, and when needed, regulated navigation areas or routing measures. Visual overlooks and closed-circuit television are sometimes available, and multimedia displays are increasingly common. Remote vessel traffic centers and communications and surveillance equipment are linked by microwave or dedicated land-line networks, such as telephone lines. Although participation is voluntary in some vessel traffic service systems, requirements for mandatory participation are increasing worldwide to help prevent shipping accidents.

Advanced shipboard and aviation radar technology has been developed specifically for vessel traffic service applications. Shipboard collision avoidance radar with automatic target acquisition and tracking features, known as ARPA (automatic radar plotting aid), has been installed in some traffic centers. Advanced multimedia displays have been developed for vessel traffic service use or adapted from technology transferred from defense or air-traffic control applications. The most advanced systems use high-fidelity, multicolor electronic display systems that correlate and fuse radar data from multiple sensors, closed-circuit television video, vessel-specific data, automated data management, electronic charts, and expert system decision aids. Technology capable of integrating position transponders, digital selective calling, meteorological and hydrological sensors, and other features has appeared. Portable interactive communications and positioning systems with integrated electronic charts and data links provide comprehensive information for on-board interpretation and use by operators of participating vessels and marine pilots. *See* COMPUTER GRAPHICS; ELECTRONIC NAVIGATION SYSTEMS; EXPERT SYSTEMS; MARINE NAVIGATION; NAVIGATION. [W.Y.]

Vestibular system The system that subserves the bodily functions of balance and equilibrium. It accomplishes this by assessing head and body movement and position in space, generating a neural code representing this information, and distributing this code to appropriate sites located throughout the central nervous system. Vestibular function is largely reflex and unconscious in nature.

The centrifugal flow of information begins at sensory hair cells located within the peripheral vestibular labyrinth. These hair cells synapse chemically with primary vestibular afferent nerve fibers, causing them to fire with a frequency code of action potentials that include the parameters of head motion and position. These vestibular afferents, in turn, enter the brain and terminate within the vestibular nuclei and cerebellum. Information carried by the firing patterns of these afferents is combined within these central structures with incoming sensory information from the

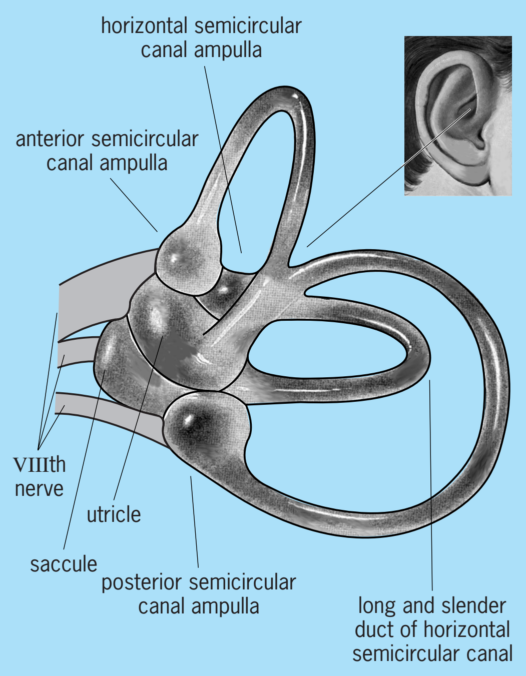


Fig. 1. The vestibular labyrinth is located within the inner ear. It communicates with the brain via the VIIIth nerve. Each of the three semicircular canals has an ampulla and a long and slender duct. The utricle primarily senses motion in an earth-parallel plane, while the saccule primarily senses motion and gravity in an earth-perpendicular plane.

visual, somatosensory, cognitive, and visceral systems to compute a central representation of head and body position in space. This representation is called the gravito-inortial vector and is an important quantity that the central nervous system employs to achieve balance and equilibrium. *See* Brain; Nervous system (vertebrate); Postural equilibrium; Reflex.

The vestibular labyrinth is housed within the petrous portion of the temporal bone of the skull along with the cochlea, the organ of hearing (Fig. 1). The receptor element or primary motion sensor within the labyrinth is the hair cell (Fig. 2). Hair cells respond to bending of their apical sensory hairs by changing the electrical potential across their cell membranes. These changes are called receptor potentials, and the apical surface of the hair cell thus functions as a mechanical-to-electrical transducer. The frequency of the resulting action potentials in the VIIIth cranial (vestibulocochlear) nerve encodes the parameters of angular and linear motion. *See* Biopotentials and ionic currents; Ear (vertebrate); Synaptic transmission.

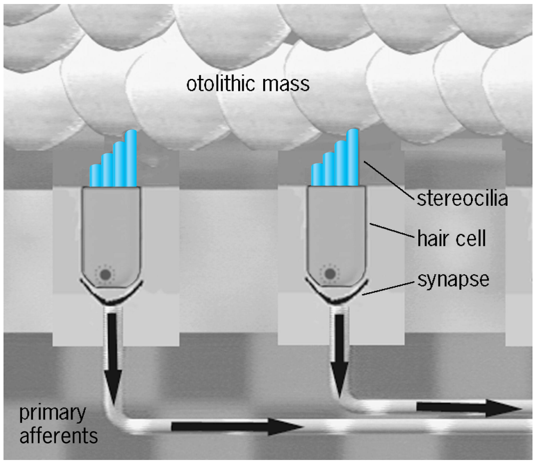

Fig. 2. Otolithic macula at rest. The arrows within the primary afferents or VIIIth nerve fibers indicate spontaneous activity in these fibers in the absence of motion of the otolithic mass relative to the hair cell stereocilia. (The otolithic membrane is not illustrated for clarity.)

Hair cells are the common sensory element in both the angular and linear labyrinthine sensors as well as within the cochlea. The particular frequency of energy that hair cells sense within these diverse end organs arises because of the accessory structures surrounding the hair cells. Thus, angular motion is sensed by the semicircular canals, linear motion by the otolith organs, and sound energy by the cochlea.

The primary afferents innervated by hair cells are the peripheral processes of bipolar neurons having cell bodies located in Scarpa's ganglion within the internal auditory meatus. The central processes of these cells contact neurons in the brainstem of the central nervous system. The vestibular nuclei complex is defined as the brainstem region where primary afferents from the labyrinth terminate. It is composed of four main nuclei: the superior, medial, lateral, and descending nuclei. The axonal projections of vestibular nuclear neurons travel to all parts of the neuraxis, including the brainstem, cerebellum, spinal cord, and cerebrum. *See* Motor systems.

In all vertebrates, there is an efferent system that originates from cell bodies within the central nervous system and terminates upon labyrinthine hair cells and primary afferents. The efferent vestibular system is presently a subject of intense study but undoubtedly is in place to enhance vestibular function. It is interesting that evolution felt it necessary to modify incoming vestibular information before it could enter the central nervous system. [S.M.H.]

Vestimentifera A phylum of benthonic marine worms that is restricted to habitats rich in sulfide (for example, hydrothermal vents and sulfide seeps) and that as adults lack a mouth, gut, and anus, so they are nourished by internal symbionts. All vestimentiferans live in tubes of varying hardness and rigidity. Tube material is secreted by internal glands and is a mixture of chitin and protein. *See* Hydrothermal vent.

The phylum has two classes based on the arrangement and orientation of lamellae formed by fusion of branchial filaments: Axonobranchia with one order, Riftiida, and one monogeneric family with one species; and Basibranchia with two orders, Lamellibrachiida and Tevniida.

Vestimentiferans have four regions along their length. The most anterior, obturacular region is provided with a mass of well-vascularized filaments supported by a paired structure, the obturaculum. Normally these branchial filaments protrude from the opening of the tube and act as a gill, allowing for the exchange of dissolved substances between the worm's body and the seawater. The second region, the vestimentum, is quite muscular and serves to maintain the plume of branchial filaments in the open seawater by pressure on the inner tube surface at its opening. The vestimentum is the site of many glands that contribute material for lengthening the tube and thickening it near the opening. The third region, the trunk, is a single segment and constitutes about 75% of the total length of the worm. It is provided with a pair of large longitudinal blood vessels. The remains of the larval gut containing sulfide-oxidizing bacteria and the gonads are also present. The fourth and most posterior region, the opisthosome, is made up of many segments, each segment in the anterior portion bearing a row of small hooks that can be set into the inner surface of the tube. This provides an anchor against which the body of the worm retracts when the longitudinal muscles of the trunk contract during withdrawal into the tube. [M.L.J.]

Vesuvianite A sorosilicate mineral of complex composition crystallizing in the tetragonal system; also known by the name idocrase. Crystals, frequently well formed, are usually prismatic with pyramidal terminations. It commonly occurs in columnar aggregates but may be granular or massive. The luster is vitreous to resinous; the color is usually green or brown but may be yellow, blue, or red. Hardness is $6^1/_2$ on Mohs scale; specific gravity is 3.35–3.45. *See* Hardness scales.

The composition of vesuvianite is expressed by the formula $Ca_{10}Al_4(Mg,Fe)_2Si_9O_{34}(OH)_4$. Magnesium and ferrous iron are present in varying amounts, and boron or fluorine is found in some varieties. Beryllium has been reported in small amounts.

Vesuvianite is found characteristically in crystalline limestones resulting from contact metamorphism. It is there associated with other contact minerals such as garnet, diopside, wollastonite, and tourmaline. Noted localities are Zermatt, Switzerland; Christiansand, Norway; River Vilui, Siberia; and Chiapas, Mexico. In the United States it is found in Sanford, Maine; Franklin, New Jersey; Amity, New York; and at many contact metamorphic deposits in western states. A compact green variety resembling jade is found in California and is called californite. *See* Silicate minerals. [C.S.Hu.]

Vetch Any of a group of plants which are mostly annual and perennial legumes with weak viny stems often terminating in tendrils. There are about 150 species in the temperate zones of four continents. The leaves are compound with many leaflets. Vetches are used mainly for green manure, cover crops, hay, and pasture and silage. The seeds are used as concentrate in animal feeds, and some vetches are used as a vegetable for human consumption. Cool temperatures promote best development. In general, are vetches more tolerant of acidic soil conditions than are most legume crops, but they have a relatively high requirement for phosphorus. Identification of vetches is difficult until pods and seeds develop. *See* Leaf; Legume.

Purple vetch in flower. (*USDA*)

By the 1960s, some 35 vetch species and subspecies had been found in the United States. Of these 35 species, 16 are native to the United States.

The vetch complex *Vicia villosa* is the most widely grown. The subspecies of this complex (*V. villosa* ssp. *villosa*), commonly known as hairy vetch, is the most winter-hardy and is mostly adapted to the eastern and southern United States, where it is grown as a winter annual or biannual. A second subspecies of this group is woollypod or smooth vetch (*V. villosa* ssp. *varia*). It is less winter-hardy than the hairy vetch type and is adapted to the Pacific Coast states.

The vetch complex *V. sativa* is the second most important species in use in the United States. Common vetch (*V. sativa* ssp. *sativa*) is used throughout the United States. Narrow-leaf or blackpod vetch (*V. sativa* ssp. *nigra*) occurs mostly as a weed in waste places in the United States. Underground vetch (*V. sativa* ssp. *amphicarpa*) produces pods above and below the ground and is being studied for revegetation on marginal lands of the Far East.

Commonly known as the faba bean, horsebean, or broadbean, *V. faba* produces coarse, upright plants with large leaves and pods. It is one of only several vetches that are important sources of food for human beings.

Purple vetch (*V. bengalensis*) possesses poor winter hardiness; however, it is useful in the California rice-growing area, where it is used as a soil-improving crop in rotation with the rice (see illustration). Hungarian vetch (*V. pannonica*), a more winter-hardy type from Central Europe, is grown in the Pacific Northwest for forage, green manure, and seed.

One-flowered vetch (*V. articulata*) has fine leaves and stems but, lacking winter hardiness, is confined to warm regions. Its flat seeds distinguish it from its nearest look-alike, bard or barn vetch (*V. monantha*), which is very restricted in adaptation. Bitter vetch (*V. ervilia*) is an erect vetch without tendrils. Bigflower or large yellow vetch (*V. grandiflora*), an introduced annual that has naturalized in the southern states, the western seaboard states, and the Great Lakes states, has promise as winter cover and reseeds freely. Tiny vetch (*V. hirsuta*) is an introduced annual that has naturalized along the southern states bordering the Mississippi River, Texas, the eastern seaboard states, the Great Lakes states, and the Pacific Coast states. Narbonne or French vetch (*V. narbonensis*), a possible wild relative of *V. fava*, has been cultivated as a forage crop in the eastern United States and has locally established as a weed in Maryland and the District of Columbia. Bird or purple-white tufted vetch (*V. cracca*) is a winter-hardy perennial, and its subspecies, cow or bramble vetch (*V. cracca* ssp. *tenuifolia*), is considered to be an invasive weed in the eastern United States and parts of Canada. Four-seeded, sparrow, or lentil vetch (*V. tetrasperma*), also considered an invasive weed, is an introduced annual that has naturalized along and east of the Mississippi River and in the Pacific states.

Crown vetch, *Coronilla varia*, is a long-lived, winter-hardy perennial legume, but it is not a true vetch. Spreads by seeds and rhizomes to form a dense, weed-free, erosion-resisting ground cover. Its greatest use is for erosion and weed control on unmowed slopes of highways, industrial developments, and military installations. Its forage value is being studied. *See* Cover crops; Soil conservation. [F.V.G.; W.Gra.]

Vibration The term used to describe a continuing periodic change in the magnitude of a displacement with respect to a specified central reference. The periodic motion may range from the simple to-and-fro oscillations of a pendulum, through the more complicated vibrations of a steel plate when struck with a hammer, to the extremely complicated vibrations of large structures such as an automobile on a rough road. Vibrations are also experienced by atoms, molecules, and nuclei. *See* Pendulum.

A mechanical system must possess the properties of mass and stiffness or their equivalents in order to be capable of self-supported free vibration. Stiffness implies that an alteration in the normal configuration of the system will result in a restoring force tending to return it to this configuration. Mass or inertia implies that the velocity imparted to the system in being restored to its normal configuration will cause it to overshoot this configuration. It is in consequence of the interplay of mass and stiffness that periodic vibrations in mechanical systems are possible.

Mechanical vibration is the term used to describe the continuing periodic motion of a solid body at any frequency. When the rate of vibration of the solid body ranges between 20 and 20,000 hertz (Hz), it may also be referred to as an acoustic vibration, for if these vibrations are transmitted to a human ear they will produce the sensation of sound. The vibration of such a solid body in contact with a fluid medium such as air or

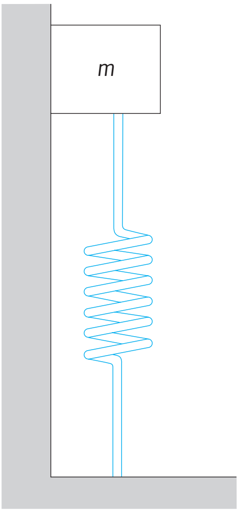

Fig. 1. Simple oscillator.

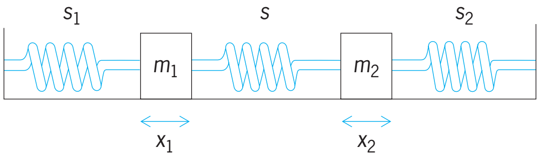

Fig. 2. Simple oscillator with two degrees of freedom. Masses m_1 and m_2, with displacements x_1 and x_2, are connected by springs s_1, s, and s_2.

water induces the molecules of the medium to vibrate in a similar fashion and thereby transmit energy in the form of an acoustic wave. Finally, when such an acoustic wave impinges on a material body, it forces the latter into a similar acoustic vibration. In the case of the human ear it produces the sensation of sound. *See* MECHANICAL VIBRATION; SOUND.

Systems with one degree of freedom are those for which one space coordinate alone is sufficient to specify the system's displacement from its normal configuration. An idealized example known as a simple oscillator consists of a point mass m fastened to one end of a massless spring and constrained to move back and forth in a line about its undisturbed position (Fig. 1). Although no actual acoustic vibrator is identical with this idealized example, the actual behavior of many vibrating systems when vibrating at low frequencies is similar and may be specified by giving values of a single space coordinate.

When the restoring force of the spring of a simple oscillator on its mass is directly proportional to the displacement of the latter from its normal position, the system vibrates in a sinusoidal manner called simple harmonic motion. This motion is identical with the projection of uniform circular motion on a diameter of a circle. *See* HARMONIC MOTION.

When two simple vibrating systems are interconnected by a flexible connection, the combined system has two degrees of freedom (Fig. 2). Such a system has two normal modes of vibration of two frequencies. Both of these frequencies differ from the respective natural frequencies of the individual uncoupled oscillators.

A vibrating system is said to have several degrees of freedom if many space coordinates are required to describe its motion. One example is n masses $m_1, m_2, \ldots, m_n$ constrained to move in a line and interconnected by $(n - 1)$ coupling springs with additional terminal springs leading from m_1 and m_n to rigid supports. This system has n normal modes of vibration, each of a distinct frequency. *See* DAMPING; VIBRATION DAMPING; VIBRATION ISOLATION. [L.E.K.]

Vibration damping

The processes and techniques used for converting the mechanical vibrational energy of solids into heat energy. While vibration damping is helpful under conditions of resonance, it may be detrimental in many instances to a system at frequencies above the resonant point. This is due to the fact that the relative motion between the base of the vibration isolator and the mounted body tends to become smaller as the isolator becomes more efficient at the higher frequencies. With damping present, the force transmitted by the elastic element is unable to overcome the damping force; this leads to a resulting increase in transmissibility. *See* DAMPING; VIBRATION; VIBRATION ISOLATION.

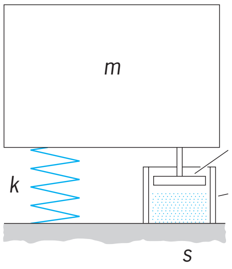

Fig. 1. Automobile shock absorber.

All metal springs which include structural members such as brackets and shelves have some damping. However, such damping is insufficient for vibration isolators and must be augmented by special damping devices. *See* SPRING (MACHINES).

Several different types of damping devices have been developed and used successfully. Probably the most familiar is that used on automobiles, which, although known as a shock absorber, is in reality a damper, and functions as a limiter to the spring system of spring constant k. The system is shown in Fig. 1. A piston p is attached to the body m and is arranged to move vertically through the liquid in a cylinder c which is secured to the support s. As the piston moves, the force required to cause the liquid to flow from one side of the piston to the other is approximately proportional to the velocity of the piston in the cylinder. This type of damping is known as viscous damping. The damping force is controlled by the viscosity of the liquid and by the size of the orifice in the piston. *See* SHOCK ABSORBER.

Some of the disadvantages of viscous damping may be overcome by using air instead of liquid as the damping medium. Air, being compressible, will add to the effective spring force with large displacements. If the air is housed within a flexible bellows, damping will be attainable horizontally as well as vertically. Such a system is illustrated in Fig. 2. This type of damping has proved very effective in vibration isolators.

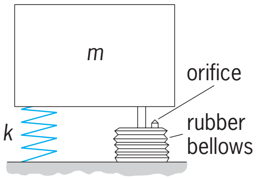

Fig. 2. System employing viscous damping with air.

Damping forces may be generated by causing one dry member to slide on another. This is known as dry friction or coulomb damping. Friction damping is used in several commercially available isolators because it provides a simple means to control the damping forces.

Magnetic damping is attainable as a result of the electric current induced in a conductor moving through a magnetic field. The damping force can be made proportional to the velocity of the conductor moving through the field. *See* ELECTROMAGNETIC INDUCTION. [K.W.J.]

Vibration isolation

The isolation, in structures, of those vibrations or motions that are classified as mechanical vibration. Vibration isolation involves the control of the supporting structure, the placement and arrangement of isolators, and control of the internal construction of the equipment to be protected.

The simplest kind of mechanical vibration has the waveform of sinusoidal motion. Vibrations in structures, although generally more complex in waveform, exist wherever movement takes place. Such movement may be caused, for example, by the engine in an automobile, by engines or wind buffeting in aircraft, or by a punch press in a building. Delicate electronic equipment and precision instruments must normally be isolated from these motions if accurate measurements are to be obtained. *See* MECHANICAL VIBRATION; VIBRATION.

Vibration, in most cases, may be effectively isolated by placing a resilient medium, or vibration isolator, between the source of vibration and its surrounding area to reduce the magnitude of the force transmitted from a structure to its support or, alternatively, to reduce the magnitude of motion transmitted from a vibrating support to the structure. Isolating vibration at its source is commonly termed active or source isolation; isolating an instrument from its surroundings is known as passive isolation.

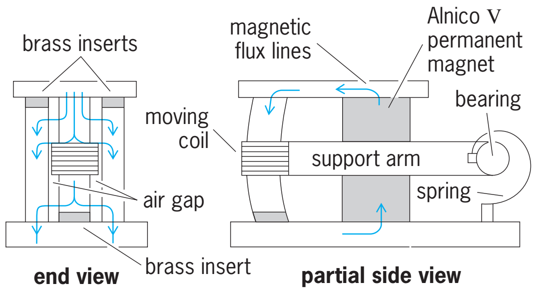
The vibration isolators may be positioned and arranged in many different ways, all variations of three basic types, each of which requires a definite amount of space: (1) isolators attached underneath equipment, known as an underneath mounting system; (2) isolators located in the plane of the center of gravity of the equipment, known as a center-of-gravity system; (3) mountings arranged four on each side in the plane of the radius of gyration, known as a double side-mounted system or radius-of-gyration system. *See* Center of gravity; Radius of gyration. [K.W.J.]

Vibration machine A device for subjecting a system to controlled and reproducible mechanical vibration. Vibration machines, commonly called shake tables, are widely used in vibration measurement and analysis. There are three types of vibration machines in general use. These are the mechanical direct-drive type, the mechanical reaction type, and the electrodynamic type. Other types, such as hydraulic excitation devices, resonant systems, piezoelectric vibration generators used for instrument calibration, and machines for testing packages, have only limited or specialized applications. *See* Mechanical vibration; Vibration. [K.W.J.]

Vibration pickup An electromechanical transducer capable of converting mechanical vibrations into electrical voltages. Depending upon their sensing element and output characteristics, such pickups are referred to as accelerometers, velocity pickups, or displacement pickups.

The accelerometer consists essentially of a mass which is seismically supported with respect to a surrounding case by means of a spring and guided to prevent motions other than those along the seismic direction of support. The mass exerts a force on the spring's support which is directly proportional to the acceleration being measured. This, in turn, is converted into an electrical voltage by means of stresses produced in a piezoelectric crystal. *See* Accelerometer.

The velocity pickup generates a voltage proportional to the relative velocity between two principal elements of the pickup, the two elements usually being a coil of wire and a source of magnetic field (see illustration).



Velocity pickup. The coil swings on one end of an arm which is supported by bearings at the opposite end. The case follows the motion of the structure to which it is attached. (*MB Manufacturing Co.*)

The displacement pickup is a device that generates an output voltage which is directly proportional to the relative displacement between two elements of the instrument. These pickups are similar in construction and behavior to velocity pickups. The only essential difference is the use of a frequency-weighting network, required to make them direct-reading. *See* Vibration. [L.E.K.]

Vibrotaction The response of tactile nerve endings to varying forces on the skin and to oscillatory motion of the skin. Grasping, holding, and tactile exploration of an object are part of everyday experience. The performance of all these activities is dependent on the dynamic response of specialized nerve endings located in the skin.

Knowledge of the neural and psychophysical processes involved in vibrotaction is necessary to develop effective tactile communication systems, such as vibrotactile pagers, and multipin vibrotactile stimulators used to produce images on an extended skin surface. Potential users range from business people to the visually and hearing impaired: potential applications range from activities involving visual and aural sensory saturation (such as pilots in high stress situations) to those requiring sensory stimulation (for example, virtual reality).

Small electrical impulses, or action potentials, generated by a single nerve ending can be recorded by inserting a microelectrode into the arm of an alert human subject and positioning the electrode tip in a nerve fiber. Studies of the action potentials produced when the skin is locally depressed at a fingertip have identified activity in four networks of distinctive nerve endings lying within 1–2 mm of the skin surface. These nerve endings, which transform skin motion into neural signals, consist of physically and functionally different mechanoreceptors.

Three types of mechanoreceptor in the fingertip have been implicated in vibrotaction. One of these is a population of slowly adapting mechanoreceptors (SA type I, or SAI); their action potentials persist for some time after a transient skin indentation. The two others are populations of rapidly adapting receptors (FAI and FAII types). Type I receptors respond only to skin indentation within a few millimeters of the nerve ending, whereas type II receptors also respond to stimuli at a greater distance from the nerve ending. A fourth mechanoreceptor type appears to respond primarily to skin stretch (denoted SAII). *See* Cutaneous sensation; Mechanoreceptors. [A.J.Br.]

Vicuna A rare animal whose fiber makes the world's most costly and most exquisite cloth, surpassing all others in fineness and beauty. It is found in an almost inaccessible area of the Andes Mountains.

A single animal yields only approximately $^1/_4$ lb (0.11 kg) of hair; thus 40 animals are required to provide enough hair for the average coat. The fiber of the vicuna is the softest and most delicate of the known animal fibers; yet it is strong for its weight, is resilient, and has a marked degree of elasticity and surface cohesion. *See* Alpaca; Camel's hair; Cashmere; Llama; Mohair; Natural fiber; Wool. [M.D.P.]

Video amplifier A low-pass amplifier having a bandwidth in the range from 2 to 100 MHz. Typical applications are in television receivers, cathode-ray-tube computer terminals, and pulse amplifiers. The function of a video amplifier is to amplify a signal containing high-frequency components without introducing distortion.

Modern video amplifiers use specially designed integrated circuits. With one chip and an external resistor to control the voltage gain, it is possible to make a video amplifier with a bandwidth between 50 and 100 MHz having voltage gains ranging from 20 to 500. *See* Amplifier; Integrated circuits. [H.F.K.]

Video disk A medium used to record, distribute, and play video information. The video disk exists in three major forms: the Digital Video Disk (DVD; sometimes also called the Digital Versatile Disk); the Laser Video disk (sometimes called the Laser Vision disk); and the Video CD. *See* Compact disk.

The advantages of DVD and Laser Video disks over videocassette tapes include very high video quality (because the signal-to-noise ratio is very high); use of a full television frame on playback; multiple audio channels, digital and analog; archival quality, since there is no disk deterioration over time; the possibility of interactivity, whereby cues, branches, and so forth can be programmed in; a freeze-frame option with no loss of quality; the ability to interface and interact with computers using digital cues;

the availability of rapid access to any point in the recording; the possibility of auto-stop, whereby a frame is preselected for freezing; frame-by-frame viewing, providing slow motion with no loss of quality; and programmability with certain systems. The Video CD does not possess these advantages, but is a lower-cost option with limited image quality and minimal interactivity.

All three types of video disks have basic elements in common, notably a solid-state laser a fraction of a square millimeter in size that emits a few milliwatts of coherent light focused to a micrometer-sized spot. This laser spot becomes essentially an optical stylus that performs various functions such as tracking, focusing, and reading the total integrated light. *See* LASER.

The laser spot follows a track on the rotating disk that is either the data itself or a groove. It does this by sensing the symmetry of the laser light reflected back to a split segmented detector; if the spot is not symmetric, the position of the head is jogged until it is back to a perfectly registered spot on the detector. The jogging movement is created by a small motor, often a voice coil motor, that is driven by an electronic servo system that "closes the loop" in an iterative manner. The laser spot and the disk are kept in focus through a similar servo-based controller that uses the image of the laser on the detector.

By adding up the total integrated light on the detector, it is possible to read the total light returned from the disk. While the laser light travels over the disk, differences in the intensity of the light, affected by the disk features that represent the data, are detected. These disk features can be pits in the surface (using the phase contrast of light coming off the disk) or the absorbed light in a dye or other material. This change in intensity is detected and the pulse train decoded by the system to produce a series of data bits that are then reconstructed to form a video image. This principle is used by all the above video disk applications. *See* OPTICAL RECORDING. [D.H.Da.]

Video games Entertainment systems in which a computer is used to drive a video display and interact with players using a variety of input devices. Video games can be divided into arcade systems, home computers, and game consoles. The distinction between a home computer and a game console is that a computer can be used for a variety of other applications such as word processing and Internet access while a game console is specifically designed for entertainment purposes.

Arcade systems are typically built for a particular game or set of related games. Everything from the choice of controls to the design on the sides and face of the unit are geared toward the game itself. The display is typically larger than that on a home computer, providing a greater sense of immersion. In some cases, specialized optics are used to further increase the sense of breadth and depth. In some racing simulations, for example, multiple screens are arranged side by side in an arc around the player in order to give an even greater feeling of being "in" the game. A combination of conventional arcade games and specialized high-end systems involve virtual reality gear, large rear-projection screens, motion platforms, and sophisticated input devices. *See* SIMULATION; VIRTUAL REALITY.

A game console typically does not include its own display, but is hooked up to a television set. This provides only limited resolution. The input devices on game consoles are limited to simple multipurpose controllers that are included with the console. Most consoles come with two controllers in order to support two-player competitive games. Consoles are much less expensive than the average home computer system and often have specialized hardware for fast graphics and high-quality sound. The games are distributed either as cartridges ("carts") or compact disks (CDs) that contain the game logic programmed into read-only memory (ROM). *See* COMPACT DISK.

Home computer systems have grown steadily more powerful to the point where they are more than capable of serving as game machines. Since they use an actual computer monitor rather than relying on a television set, the resolution and overall image quality is much higher than that of game consoles and often rivals or exceeds that of the arcade systems. A variety of controllers are available for the personal computer, ranging from simple analog joysticks to sophisticated input devices with full-force feedback. Production, packaging, and distribution costs for computer games are similar to those for game consoles that use CD-ROM. However, widespread Internet access allows game companies to make their games available for download. *See* COMPUTER GRAPHICS ; COMPUTER STORAGE TECHNOLOGY; INTERNET; MICROPROCESSOR.

Regardless of the platform (home computer, game console, arcade system), there are a number of basic genres of game. Some of these genres are more common on one type of platform than another, mostly due to technical limitations. Action games are popular on all platforms. Adventure games are mostly popular on home computers, though some game consoles do support them. Simulation games usually involve operating some sort of vehicle, such as an aircraft or a high-performance race car. Simulators can also be found on all popular platforms. Strategy games are based on planning and anticipating future events. There are two subcategories: war games and system simulators. War games are often based on reenacting historic battles of land, sea, or air. System simulators work by simulating a system such as a city, an ant colony, or an entire planet. Strategy games are found mostly on home computers and are not seen in arcade systems. [B.Roe.]

Video microscopy The use of a high-quality video camera or other fast camera (such as a charge-coupled device) attached to a research-quality light microscope for the purpose of real-time or high-speed imaging of samples on a microscope stage. These images are recorded at regular intervals (often at "video rate" of 30 images per second), and the time-lapse sequence can be played back in the form of a movie. The term "video microscopy" originally referred to microscope imaging using true video (30 frames per second) but now generally refers to rapid time-lapse imaging techniques. Video microscopy is used frequently to image small structures that move rapidly within cells as well as movement of whole cells. This motion can be quantitated, and in the case of fluorescence microscopy, changes in fluorescent intensity (reflecting the local chemical environment of the fluorescent molecule or the number of fluorescent molecules) can be quantitated as well. *See* CAMERA; CELL MOTILITY; CHARGE-COUPLED DEVICES; FLUORESCENCE; FLUORESCENCE MICROSCOPE; IMAGE PROCESSING; MICROSCOPE. [G.M.La.; J.F.Pr.]

Videotelephony A means of simultaneous, two-way communication comprising both audio and video elements. Participants in a video telephone call can both see and hear each other in real time. Videotelephony is a subset of teleconferencing, broadly defined as the various ways and means by which people communicate with one another over some distance. Initially conceived as an extension to the telephone, videotelephony is now possible using computers with network connections. *See* TELECONFERENCING.

Small residential video telephones, computer-based desktop video telephones, and small videoconferencing setups have been introduced to fulfill diverse needs. One such commercially available residential videophone is about as big as a typical office desk telephone with a small flip-up screen that has an eyeball camera above it. Although it will work with several standards, this phone is primarily designed for use over Integrated Services Digital Network (ISDN) lines in which a residence gets three circuits; one circuit is used for control and the other two for voice and video. *See* INTEGRATED SERVICES DIGITAL NETWORK (ISDN).

An example of a computer-based desktop videophone consists of a PCI (Peripheral Component Interconnect) video/audio CODEC board to add to a personal computer, a composite color camera, audio peripherals, and visual collaboration software.

Videotelephony software has been developed and made widely available that permits real-time collaboration and conferencing, including multipoint and point-to-point conferencing. Multipoint means, for example, that three people in three different locations could have a video telephone conference call in which each could see and hear the others. In addition to the basic audio and video capabilities, such software provides several other features such as a whiteboard, background file transfer, program sharing, and remote desktop sharing. [J.Bl.]

Vinegar

Vinegar A food condiment containing mainly acetic acid that is produced by the bacterial oxidative fermentation of various ethanolic solutions. Vinegar is one of the oldest fermented foods used by humans. Babylonian records indicate that vinegars prepared from wines and beer were widely used as early as 5000 B.C. *See* Acetic acid; Wine.

The names for the different vinegars are based on the substrates from which they are made. These include the juices from different fruits, starchy vegetables, cereals, and distilled ethanol (ethyl alcohol). In the United States, white distilled vinegar makes up over 80% of the annual production. Much of the white distilled vinegar is made from denatured synthetic ethanol. Nitrogen compounds, minerals, and other nutrients must be added to the alcohol medium to support the growth and metabolism of the acetic acid bacteria. Most other vinegars are made from ethanolic solutions generated by a yeast fermentation. Cider vinegar is produced from yeast-fermented apple juice, wine vinegar (such as Balsamic vinegar) from fermented grape juice. Other juices such as pineapple, orange, and pear, as well as sugarcane syrup and molasses, can serve as fermentation substrates. Vinegar is also produced from starchy vegetables such as potatoes and from cereals such as barley, corn, and rice. Malt vinegar is made from an infusion of barley malt and other cereals in which the enzymes in the malt have converted the starch to fermentable sugars. *See* Enzyme; Ethyl alcohol.

Vinegar sold in the United States must contain at least 4 g of acetic acid per 100 ml of solution (40-grain vinegar). Other federal specifications describe permitted color, odor, presence of trace metals, and alcohol content. Nondistilled vinegars possess distinctive colors and flavors that reflect the properties of the original substrate.

Bacteria belonging to the genus *Acetobacter* are primarily responsible for the vinegar fermentation. Four species are recognized; they are distinguished on the basis of nutrient requirements, production of brown pigments, and tolerance to ethanol. All acetic acid bacteria require oxygen for growth and metabolism. *See* Industrial microbiology.

A variety of methods are used for the production of vinegar. The simplest fermentations are slow and inefficient but are relatively foolproof and utilize inexpensive equipment. Submerged fermenters produce 120–150-grain vinegar in minimal time, but they are expensive and system failures can occur. *See* Fermentation. [D.F.Sp.]

Violales

Violales An order of flowering plants, division Magnoliophyta (Angiospermae), in the subclass Dilleniidae of the class Magnoliopsida (dicotyledons). The order consists of 24 families and more than 5000 species, including most of the families that have been referred to the Englerian order Parietales. The largest families are the Flacourtiaceae (about 800 species), Violaceae (about 800 species), Cucurbitaceae (about 900 species), Begoniaceae (about 1000 species), and Passifloraceae (about 650 species).

The most characteristic feature of this morphologically heterogeneous order is the unilocular, compound ovary with mostly parietal placentation. When the stamens are numerous they are initiated in centrifugal sequence. The more primitive members of the order, such as some of the Flacourtiaceae, are trees with stipulate, alternate leaves; perfect, polypetalous flowers with numerous centrifugal stamens; a compound pistil with free styles and parietal placentation; and seeds with a well-developed endosperm. Tendencies toward unisexuality, reduction in the number of stamens, fusion of filaments, development of a corona, reduction in the number of carpels, fusion of styles, and loss of endosperm from the seed can all be seen in the Flacourtiaceae. These are also some of the prominent characteristics used in combination to define many of the other families of the order. *See* Flower; Leaf; Seed.

Downy yellow violet (*Viola pubescens*). (*Photograph by Elsie M. Rodgers, National Audubon Society*)

Cucumbers and melons (species of *Cucumis*, in the Cucurbitaceae), pumpkins and squashes (species of *Cucurbita*), begonias, and violets (*Viola*; see illustration) are familiar members of the Violales. *See* Cantaloupe; Cucumber; Dilleniidae; Honey dew melon; Magnoliophyta; Magnoliopsida; Muskmelon; Persian melon; Plant taxonomy; Pumpkin; Squash; Watermelon. [A.Cr.; T.M.Ba.]

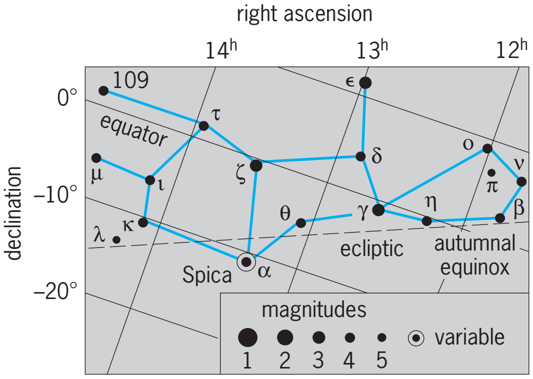
Viral inclusion bodies

Viral inclusion bodies Abnormal structures which appear within the cell nucleus, the cytoplasm, or both, during the course of virus multiplication. In general, the inclusion bodies are concerned with the developmental processes of the virus. In some virus infections, such as molluscum contagiosum, inclusion bodies may be simply masses of maturing virus particles. In other infections (herpes simplex), typical inclusion bodies do not appear until after the virus has multiplied. Such inclusions may be remnants of the process of virus multiplication.

The presence of inclusion bodies is often important in diagnosis. A cytoplasmic inclusion in nerve cells, the Negri body, is pathogenic for rabies. *See* Rabies; Virus. [J.L.Me.]

Virgo

Virgo In astronomy, a constellation handed down from antiquity, visible throughout the summer months. This sixth sign of



Line pattern of the constellation Virgo. The grid lines represent the coordinates of the sky. The apparent brightness, or magnitude, of the stars is shown by the sizes of the dots, which are graded by appropriate numbers as indicated.

the zodiac represents a maiden (see illustration). The brightest star in the constellation, Spica, is a spectroscopic binary with a massive dark companion. It is a fine first-magnitude star of the purest white tint, and also a navigational star. *See* CONSTELLATION; LIBRA. [C.S.Y.]

Virgo Cluster The nearest large cluster of galaxies, forming a conspicuous clump in the distribution of easily visible elliptical and spiral galaxies. The clump lies mostly in the constellation of Virgo but also extends into neighboring constellations, especially Coma Berenices. *See* CONSTELLATION; VIRGO.

Besides the 100 or so bright galaxies in Virgo, more than 2000 fainter galaxies show up in deeper searches of the cluster. Furthermore, the cluster includes the Southern Extension, where several dozen additional galaxies lie. G. de Vaucouleurs promoted the idea, now universally recognized, that the Virgo Cluster is so extensive in size that it includes a giant halo of many outlying groups, including the Local Group, to which the Milky Way Galaxy belongs. He called this structure the Local Supercluster. *See* LOCAL GROUP; UNIVERSE.

The Virgo Cluster is an example of a mixed-population cluster, with both early-type (elliptical and S0) and late-type (spiral and irregular) galaxies present. As the nearest large cluster, it provides a good testing ground for theories of how the dense cluster environment affects the properties of galaxies. The most obvious peculiarity of the Virgo galaxies is the limited extent of the disks of the spirals. The spiral galaxies have possibly been stripped of their outer gas by encounters with other galaxies in the cluster. A related phenomenon is the presence of anemic galaxies, spirals that have unusually low surface brightness and inconspicuous spiral arms.

Determining the distance to the Virgo Cluster has been an important task of twentieth-century astronomy. The Virgo Cluster forms an essential stepping stone for the cosmic distance scale, as it provides a connection between local distance criteria and the use of the Hubble law of gauging distances. The best measurements give a mean distance of 16 megaparsecs (5×10^7 light-years). When the infall velocity of the Milky Way Galaxy toward the center of the Virgo Cluster is taken into account, this distance indicates that the local cosmic value of the Hubble constant, which relates expansion velocity to distance, is about 70 kilometers per second per megaparsec. *See* COSMOLOGY; HUBBLE CONSTANT. [P.H.]

Virial equation An equation of state of gases that has additional terms beyond that for an ideal gas, which account for the interactions between the molecules. The pressure p can be expressed in terms of the molar volume $V_m = V/n$ (where n is the number of moles of gas molecules in a volume V), the absolute temperature T, and the universal gas constant $R = 8.3145$ J K^{-1} mol^{-1} or, in more commonly used practical units, 0.082058 L atm K^{-1} mol^{-1} [Eq. (1)]. In the equation the virial coefficients

$$\frac{V_m}{RT} = 1 + \frac{B_2(T)}{V_m} + \frac{B_3(T)}{V_m^2} + \frac{B_4(T)}{V_m^3} + \cdots \qquad (1)$$

$B_n(T)$ are functions only of the temperature and depend on the nature of the gas. In an ideal gas, in which all interactions between the molecules can be neglected because V_m is sufficiently large, only the first term, unity, survives on the right-hand side. *See* GAS.

The equation is important because there are rigorous relations between the coefficients B_2, B_3, and so on, as well as the interactions of the molecules in pairs, triplets, and so forth. It provides a valuable route to a knowledge of the intermolecular forces. Thus if the intermolecular energy of a pair of molecules at a separation r is $u(r)$, then the second virial coefficient can be expressed as Eq. (2). Here $N_A = 6.0221 \times 10^{23}$ mol^{-1} is the Avogadro constant, and $k = R/N_A$. In a gas mixture, B_n is a polynomial of order n in the mole fractions of the components. *See* INTERMOLECULAR FORCES.

$$B_2(T) = 2\pi N_A \int_0^\infty (1 - e^{-u(r)/kT}) r^2 \, dr \qquad (2)$$

The virial equation is useful in practice because it represents the pressure accurately at low and moderate gas densities, for example, up to about 4 mol L^{-1} for nitrogen at room temperature, which corresponds to a pressure of about 100 atm (10 MPa). It is not useful at very high densities, where the series may diverge, and is inapplicable to liquids. It can be rearranged to give the ratio pV_m/RT as an expansion in powers of the pressure instead of the density, which is equally useful empirically, but the coefficients of the pressure expansion are not usually called virial coefficients, and lack any simple relation to the intermolecular forces or, in a mixture, to the composition of the gas. *See* VAN DER WAALS EQUATION. [J.S.Row.]

Virial theorem A theorem in classical mechanics which relates the kinetic energy of a system to the virial of Clausius, as defined below. The theorem can be generalized to quantum mechanics and has widespread application. It connects the average kinetic and potential energies for systems in which the potential is a power of the radius. Since the theorem involves integral quantities such as the total kinetic energy, rather than the kinetic energies of the individual particles that may be involved, it gives valuable information on the behavior of complex systems. For example, in statistical mechanics the virial theorem is intimately connected to the equipartition theorem; in astrophysics it may be used to connect the internal temperature, mass, and radius of a star and to discuss stellar stability. The virial theorem makes possible a very easy derivation of the counterintuitive result that as a star radiates energy and contracts it heats up rather than cooling down. *See* STAR; STATISTICAL MECHANICS; STELLAR EVOLUTION.

The virial theorem states that the time-averaged value of the kinetic energy in a confined system (that is, a system in which the velocities and position vectors of all the particles remain finite) is equal to the virial of Clausius. The virial of Clausius is defined to equal $-\frac{1}{2}$ times the time-averaged value of a sum over all the particles in the system. The term in this sum associated with a particular particle is the dot product of the particle's position vector and the force acting on the particle. Alternatively, this term is the product of the distance, r, of the particle from the origin of coordinates and the radial component of the force acting on the particle.

In the common case that the forces are derivable from a power-law potential, V, proportional to r^k, where k is a constant, the virial is just $-k/2$ times the potential energy. Thus, in this case the virial theorem simply states that the kinetic energy is $k/2$ times the potential energy. For a system connected by Hooke's-law springs, $k = 2$, and the average kinetic and potential energies are equal. For $k = 1$, that is, for gravitational or Coulomb forces, the potential energy is minus twice the kinetic energy. *See* COULOMB'S LAW; GRAVITATION; HARMONIC MOTION. [A.G.P.]

Viroids The smallest known agents of infectious disease. Conventional viruses are made up of nucleic acid encapsulated in protein (capsid), whereas viroids are uniquely characterized by the absence of a capsid. In spite of their small size, viroid ribonucleic acids (RNAs) can replicate and produce characteristic disease syndromes when introduced into cells. Viroids thus far identified are associated with plants.

Nine different viroids have been described from widely separated geographical locations and from an assortment of herbaceous and woody plants. Viroid infections in some plant species produce profound disease symptoms ranging from stunting and leaf epinasty to plant death, whereas infections in other species produce few detectable symptoms compared to uninoculated control plants. Viroids generally have a restricted host range, although several viroids can infect the same hosts and cause similar symptoms in these hosts. Good controls are not available for diseases caused by these small infectious agents other than indexing procedures to provide viroid-free propagules. *See* PLANT VIRUSES AND VIROIDS; VIRUS. [R.K.Ho.]

Virtual acoustics The stimulation of the complex acoustic field experienced by a listener within an environment. The technology is also known as three-dimensional sound and auralization. Going beyond the simple left-right volume adjustment of normal stereo techniques, the goal is to process sounds so that they appear to come from particular locations in three-dimensional space. Although loudspeaker systems have been developed, much of the work in the field focuses on using headphones for playback and is the outgrowth of earlier analog techniques. For example, in binaural recording, the sound of an orchestra playing classical music is recorded through small microphones in the two imitation ear canals of an artificial or dummy head placed in the audience of a concert hall. When the recorded piece is played back over headphones, the listener passively experiences the illusion of hearing the violins on the left and the cellos on the right, along with all the associated echoes, resonances, and ambience of the original environment. Techniques use digital signal processing to synthesize the acoustical properties that people use to localize a sound source in space. Thus, they provide the flexibility of a kind of digital dummy head, allowing a more active experience in which a listener can both design and move around or interact with a simulated acoustic environment in real time. *See* BINAURAL SOUND.

The success of virtual acoustics is critically dependent on whether the acoustical cues used by humans to locate sounds have been adequately synthesized. There may be many cumulative effects on the sound as it makes its way to the eardrum, but all of these effects can be expressed as a single filtering operation much like the effects of a graphic equalizer in a stereo system. The exact nature of this filter can be measured by an experiment in which an impulse (a single, very short sound pulse or click) is produced by a loudspeaker at a particular location. The acoustic shaping by the two ears is then measured by recording the outputs of small probe microphones placed inside the ear canals of the individual or an artificial head. If the measurement of the two ears occurs simultaneously, the responses, when taken together as a pair of filters, include an estimate of the interaural differences as well. Thus, this technique makes it possible to measure all of the relevant spatial cues together for a given source location, for a given listener, and in a given room or environment. *See* EAR; EQUALIZER; HEARING; PSYCHOACOUSTICS; SOUND. [E.M.We.]

Virtual manufacturing The modeling of manufacturing systems using audiovisual or other sensory features to simulate or design alternatives for an actual manufacturing environment, or the prototyping and manufacture of a proposed product using computers. The motivation for virtual manufacturing is to enhance people's ability to predict potential problems and inefficiencies in product functionality and manufacturability before real manufacturing occurs. *See* MANUFACTURING ENGINEERING; MODEL THEORY.

The concepts underlying virtual manufacturing include virtual reality, high-speed networking and software interfaces, agile manufacturing, and rapid prototyping.

Virtual reality is broadly defined as the ability to create and interact in cyberspace, that is, a simulated space that represents an environment very similar to the actual environment. The subset of virtual reality that is used in virtual manufacturing is commonly known as virtual environment. The perceived visual space is three-dimensional rather than two-dimensional, the human-machine interface is multimodal, and the user is immersed in the computer-generated environment; the screen separating the user and the computer becomes invisible to the user. The virtual environment for virtual manufacturing is simulated through immersion in computer graphics coupled with an acoustic interface, domain-independent interacting devices such as wands, and domain-specific devices such as steering and brakes for cars or earthmovers or instrument clusters for airplanes. *See* VIRTUAL REALITY.

High-speed networking and software interfaces are concerned with computer-aided-design (CAD) model portability among systems, trade-offs of high-detail models versus real-time interaction and display, rapid prototyping, collaborative design using virtual reality over distance, use of the Web for small- or medium-business virtual manufacturing, use of qualitative information (illumination, sound levels, ease of supervision, handicap accessibility) to design manufacturing systems, use of intelligent and autonomous agents in virtual environments, and the validity of virtual reality versus reality.

Agile manufacturing integrates an organization's people and technologies through innovative management and organization, knowledgeable and empowered people, and flexible and intelligent technologies. Virtual manufacturing provides a model for making rapid changes in products and processes based on customer requirements, and an agile manufacturing system attempts to implement it.

Rapid prototyping is an area in which virtual manufacturing has made an impact in processes such as stereolithography, selective laser sintering, and fused deposition modeling. A CAD drawing of a part is processed to create a layered file of the part. The part is built one layer at a time, precisely depositing layer upon layer of material.

Global virtual manufacturing extends the definition of virtual manufacturing to include the use of the Internet and intranets (global communications networks) for virtual component sourcing, and the use of virtual collaborative design and testing environments by multiple organizations or sites. [P.Ba.]

Virtual reality A form of human-computer interaction in which a real or imaginary environment is simulated and users interact with and manipulate that world. Users travel within the simulated world by moving toward where they want to be, and interact with things in that world by grasping and manipulating simulated objects. In the most successful virtual environments, users feel that they are truly present in the simulated world and that their experience in the virtual world matches what they would experience in the environment being simulated. This sensation is referred to as engagement, immersion, or presence, and it is this quality that distinguishes virtual reality from other forms of human-computer interaction. *See* HUMAN-COMPUTER INTERACTION.

When a user interacts with a virtual environment, the computer-generated graphics display must be updated with each turn of the head or movement of the hand. The virtual environment must be able to generate and display realistic-looking views of the simulated world quickly enough that the interaction feels responsive and natural. *See* COMPUTER GRAPHICS.

Hardware. Virtual reality relies on a variety of specialized input and output devices to achieve this sense of natural interaction.

The most important of the input devices used in a virtual environment, a tracker is capable of reporting its location in space and its orientation. Tracking devices can be optical, magnetic, or acoustic. A tracker is sometimes combined with a traditional computer input device, such as a mouse or a joystick. *See* COMPUTER PERIPHERAL DEVICES.

An attempt to provide a truly natural input device, the data glove is outfitted with sensors that can read the angle of each of the finger joints in the hand. Wearing such a glove, users can interact with the virtual world through hand gestures, such as pointing or making a fist. *See* FIBER-OPTIC SENSOR; STRAIN GAGE.

The real-world visual experience is approximated in virtual environments by using stereoscopic displays. Two views of the simulated world are generated, one for each eye, and a stereoscopic display device is used to show the correct view to each eye.

Applications. Virtual reality can be applied in a variety of ways. In scientific and engineering research, virtual environments are used to visually explore whatever physical world phenomenon is under study. Training personnel for work in dangerous environments or with expensive equipment is best done through simulation. Airplane pilots, for example, train in flight simulators. Virtual reality can enable medical personnel to practice new surgical procedures on simulated individuals. As a form of entertainment, virtual reality is a highly engaging way to experience imaginary worlds and to play games. Virtual reality also provides a way to experiment with prototype designs for new products. *See* Aircraft design; Computer-aided design and manufacturing. [M.P.Ba.]

Virtual work principle The principle stating that the total virtual work done by all the forces acting on a system in static equilibrium is zero for a set of infinitesimal virtual displacements from equilibrium. The infinitesimal displacements are called virtual because they need not be obtained by a displacement that actually occurs in the system. The virtual work is the work done by the virtual displacements, which can be arbitrary, provided they are consistent with the constraints of the system. *See* Constraint.

The principle of virtual work is equivalent to the conditions for static equilibrium of a rigid body expressed in terms of the total forces and torques. That is, the principle of virtual work can be derived from these conditions, and conversely. *See* Equilibrium of forces; Statics.

One advantage of the principle of virtual work is that it can serve as a basis for all of statics. In the solution of problems the principle of virtual work is often useful for eliminating the need for consideration of the forces of constraint, since these forces often are perpendicular to the virtual displacements and consequently do no work. [P.W.S.]

Virulence The ability of a microorganism to cause disease. Virulence and pathogenicity are often used interchangeably, but virulence may also be used to indicate the degree of pathogenicity. Scientific understanding of the underlying mechanisms of virulence has increased rapidly due to the application of the techniques of biochemistry, genetics, molecular biology, and immunology. Bacterial virulence is better understood than that of other infectious agents.

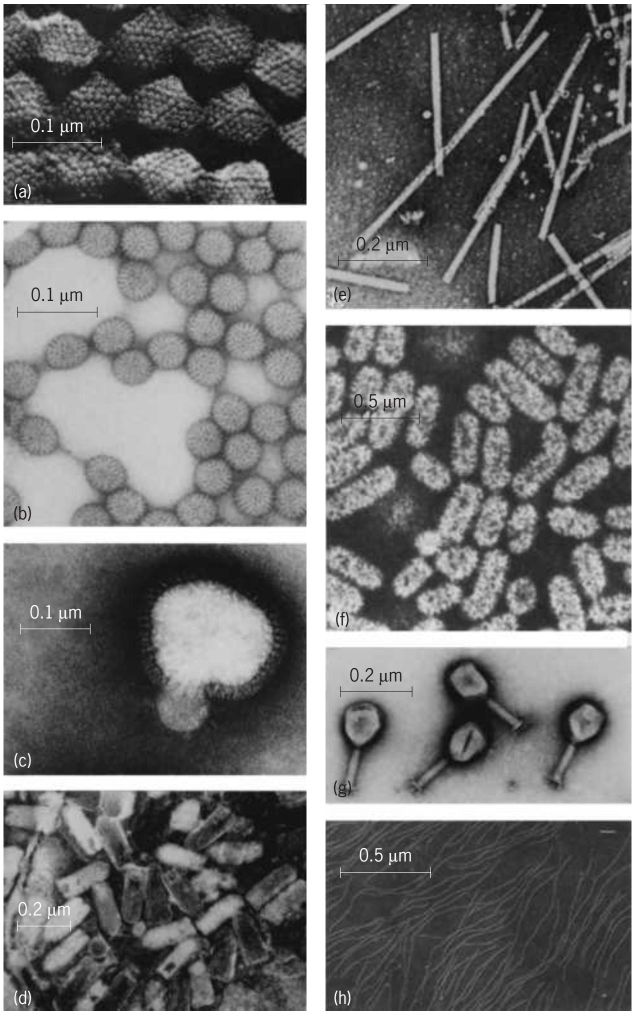
Virulence is often multifactorial, involving a complex interplay between the parasite and the host. Various host factors, including age, sex, nutritional status, genetic constitution, and the status of the immune system, affect the outcome of the parasite-host interaction. Hosts with depressed immune systems, such as transplant and cancer patients, are susceptible to microorganisms not normally pathogenic in healthy hosts. Such microorganisms are referred to as opportunistic pathogens. The attribute of virulence is present in only a small portion of the total population of microorganisms, most of which are harmless or even beneficial to humans and other animals. *See* Opportunistic infections.

The spread of an infectious disease usually involves the adherence of the invading pathogen to a body surface. Next, the pathogen multiplies in host tissues, resisting or evading various nonspecific host defense systems. Actual disease symptoms are from damage to host tissues caused either directly or indirectly by the microorganism's components or products.

Most genetic information in bacteria is carried in the chromosome. However, genetic information is also carried on plasmids, which are independently replicating structures much smaller than the chromosome. Plasmids may provide bacteria with additional virulence-related capabilities (such as pilus formation, iron transport systems, toxin production, and antibiotic resistance). In some bacteria, several virulence determinants are regulated by a single genetic locus. *See* Bacteria; Cellular immunology; Plasmid; Virus. [B.Wi.]

Virus Any of a heterogeneous class of agents that share three characteristics: (1) They consist of a nucleic acid genome surrounded by a protective protein shell, which may itself be enclosed within an envelope that includes a membrane; (2) they multiply only inside living cells, and are absolutely dependent on the host cells' synthetic and energy-yielding apparatus; (3) the initial step in multiplication is the physical separation of the viral genome from its protective shell, a process known as uncoating, which differentiates viruses from all other obligatorily intracellular parasites. In essence, viruses are nucleic acid molecules, that is, genomes that can enter cells, replicate in them, and encode proteins capable of forming protective shells around them. Terms such as "organism" and "living" are not applicable to viruses. It is preferable to refer to them as functionally active or inactive rather than living or dead.

The primary significance of viruses lies in two areas. First, viruses destroy or modify the cells in which they multiply; they are potential pathogens capable of causing disease. Many of the most important diseases that afflict humankind, including rabies, smallpox, poliomyelitis, hepatitis, influenza, the



Electron micrographs of highly purified preparations of some viruses. (*a*) Adenovirus. (*b*) Rotavirus. (*c*) Influenza virus (*courtesy of George Leser*). (*d*) Vesicular stomatitis virus. (*e*) Tobacco mosaic virus. (*f*) Alfalfa mosaic virus. (*g*) T4 bacteriophage. (*h*) M13 bacteriophage.

common cold, measles, mumps, chickenpox, herpes, rubella, hemorrhagic fevers, and the acquired immunodeficiency syndrome (AIDS) are caused by viruses. Viruses also cause diseases in livestock and plants that are of great economic importance. *See* ACQUIRED IMMUNE DEFICIENCY SYNDROME (AIDS); PLANT PATHOLOGY.

Second, viruses provide the simplest model systems for many basic problems in biology. Their genomes are often no more than one-millionth the size of, for example, the human genome; yet the principles that govern the behavior of viral genes are the same as those that control the behavior of human genes. Viruses thus afford unrivaled opportunities for studying mechanisms that control the replication and expression of genetic material. *See* HUMAN GENOME PROJECT.

Although viruses differ widely in shape and size (see illustration), they are constructed according to certain common principles. Basically, viruses consist of nucleic acid and protein. The nucleic acid is the genome which contains the information necessary for virus multiplication and survival, the protein is arranged around the genome in the form of a layer or shell that is termed the capsid, and the structure consisting of shell plus nucleic acid is the nucleocapsid. Some viruses are naked nucleocapsids. In others, the nucleocapsid is surrounded by a lipid bilayer to the outside of which “spikes” composed of glycoproteins are attached; this is termed the envelope. The complete virus particle is known as the virion, a term that denotes both intactness of structure and the property of infectiousness.

Viral genomes are astonishingly diverse. Some are DNA, others RNA; some are double-stranded, others single-stranded; some are linear, others circular; some have plus polarity, other minus (or negative) polarity; some consist of one molecule, others of several (up to 12). They range from 3000 to 280,000 base pairs if double-stranded, and from 5000 to 27,000 nucleotides if single-stranded. *See* VIRUS CLASSIFICATION.

Viral genomes encode three types of genetic information. First, they encode the structural proteins of virus particles. Second, most viruses encode enzymes capable of transcribing their genomes into messenger RNA molecules that are then translated by host-cell ribosomes, as well as nucleic acid polymerases capable of replicating their genomes; many viruses also encode nonstructural proteins with catalytic and other functions necessary for virus particle maturation and morphogenesis. Third, many viruses encode proteins that interact with components of host-cell defense mechanisms against invading infectious agents. The more successful these proteins are in neutralizing these defenses, the more virulent viruses are.

The two most commonly observed virus-cell interactions are the lytic interaction, which results in virus multiplication and lysis of the host cell; and the transforming interaction, which results in the integration of the viral genome into the host genome and the permanent transformation or alteration of the host cell with respect to morphology, growth habit, and the manner in which it interacts with other cells. Transformed animal and plant cells are also capable of multiplying; they often grow into tumors, and the viruses that cause such transformation are known as tumor viruses. *See* CANCER (MEDICINE); ONCOLOGY; RETROVIRUS; TUMOR VIRUSES.

There is little that can be done to interfere with the growth of viruses, since they multiply within cells, using the cells' synthetic capabilities. The process, interruption of which has met with the most success in preventing virus multiplication, is the replication of viral genomes, which is almost always carried out by virus-encoded enzymes that do not exist in uninfected cells and are therefore excellent targets for antiviral chemotherapy. Another viral function that has been targeted is the cleavage of polyproteins, precursors of structural proteins, to their functional components by virus-encoded proteases; this strategy is being used with some success in AIDS patients. *See* CHEMOTHERAPY; CYTOMEGALOVIRUS INFECTION; HERPES; INFLUENZA; RESPIRATORY SYNCYTIAL VIRUS; VIRUS CHEMOPROPHYLAXIS.

Antiviral agents on which much interest is focused are the interferons. Interferons are cytokines or lymphokines that regulate cellular genes concerned with cell division and the functioning of the immune system. Their formation is strongly induced by virus infection; they provide the first line of defense against viral infections until antibodies begin to form. Interferons interfere with the multiplication of viruses by preventing the translation of early viral messenger RNAs. As a result, viral capsid proteins cannot be formed and no viral progeny results.

By far the most effective means of preventing viral diseases is by means of vaccines. There are two types of antiviral vaccines, inactivated virus vaccines and attenuated active virus vaccines. Most of the antiviral vaccines currently in use are of the latter kind. The principle of antiviral vaccines is that inactivated virulent or active attenuated virus particles cause the formation of antibodies that neutralize a virulent virus when it invades the body. *See* ANIMAL VIRUS; PLANT VIRUSES AND VIROIDS; VACCINATION; VIRUS, DEFECTIVE. [W.K.J.]

Virus, defective A virus that by mutation has lost the ability to be replicated in the host cell without the aid of a helper virus. The virus particles (virions) contain all the viral structural components; they can attach, penetrate, and release their nucleic acid (RNA; DNA) within the host cell. However, since the mutation has destroyed an essential function, new virions will not be made unless the cell was simultaneously infected with the helper virus, which can provide the missing function. Only then will the cell produce a mixed population of new helper and defective viruses. Occasionally, when their nucleic acids become integrated in the DNA of the host cell, defective viruses persist in nature by propagation from mother cell to daughter cell. *See* ANIMAL VIRUS; MUTATION; VIRULENCE.

The most important group of defective viruses are deletion mutants. They are derived from their homologous nondefective (wild-type) virus through errors in the nucleic acid replication that result in the deletion of a fragment in the newly synthesized molecules. The defective nucleic acid must be capable of self-replication, at least in the presence of the wild-type virus, and must combine with other viral components to form a particle in order to exit the cell.

The defective RNA tumor viruses are deletion mutants. Mammalian and most avian sarcoma viruses require a nondefective leukemia virus as a helper virus. Usually the specificity for a certain type of host cell exhibited by the defective virion depends on the helper virus, indicating that one of the virion surface proteins has been furnished by the helper virus gene. These proteins are involved in interactions with cellular surface receptors, and thus determine whether a cell can serve as a host for viral infection. *See* ONCOLOGY; TUMOR VIRUSES. [M.E.Re.]

Virus classification There is no evidence that viruses possess a common ancestor or are in any way phylogenetically related. Nevertheless, classification along the lines of the Linnean system into families, genera, and species has been utilized. Based on the organisms they infect, the first broad division of viruses is into bacterial, plant, and animal viruses. Within these classes, other criteria for subdivision are used. Among these are general morphology; envelope or the lack of it; nature of the genome (DNA or RNA); structure of the genome (single- or double-stranded, linear or circular, fragmented or nonfragmented); mechanisms of gene expression and virus replication (positive- or negative-strand RNA); serological relationship; host and tissue susceptibility; pathology (symptoms, type of disease).

Animal viruses. The families of animal viruses are sometimes subdivided into subfamilies; the suffix -virinae may then be used. The subgroups of a family or subfamily are equivalent to the genera of the Linnean classification. *See* ANIMAL VIRUS.

The animal DNA viruses are divided into five families: Poxviridae, Herpesviridae, Adenoviridae, Papovaviridae, and Parvoviridae. RNA animal viruses may be either single-stranded or double-stranded. The single-stranded are further subdivided into positive-strand and negative-strand RNA viruses, depending on whether the RNA contains the messenger RNA (mRNA) nucleotide sequence or its complement, respectively. Further, the RNA genes may be located on one or several RNA molecules (nonfragmented or fragmented genomes, respectively). The positive-strand RNA animal viruses contain six families: Picornaviridae, Calciviridae, Coronaviridae, Togaviridae, Retroviridae, and Nodamuraviridae. The nucleocapsid of negative-strand RNA animal viruses contains an RNA-dependent RNA polymerase required for the transcription of the negative strand into the positive mRNAs. Virion RNA is neither capped nor polyadenylated. The group is divided into five families: Arenaviridae, Orthomyxoviridae, Paramyxoviridae, Rhabdoviridae, and Bunyaviridae. The double-stranded RNA animal viruses contain only one group, the Reoviridae.

Bacterial viruses. Bacterial viruses are also known as bacteriophages or phages. They may be tailed or nontailed. Nontailed phages are further subdivided into those with envelopes and those without. Tailed phages, which do not have envelopes, are divided into three families: Myoviridae, Styloviridae, and Pedoviridae. The group of nontailed DNA bacteriophages contains seven families, each with a distinctive morphology: Tectiviridae, Corticoviridae, Inoviridae, Microviridae, Leviviridae, Plasmaviridae, and Cystoviridae. Only the latter two families have envelopes. *See* BACTERIOPHAGE.

Plant viruses. Plant viruses are divided into groups, rather than families, except those which belong to families of rhabdo viridae and reoviridae. The group, and correspondingly subgroup and type, can be viewed as analogous to family, genus, and species, respectively. Most common among plant viruses are those with a single-stranded, capped but not polyadenylated, positive-strand RNA. *See* PLANT VIRUSES AND VIROIDS. [M.E.Re.]

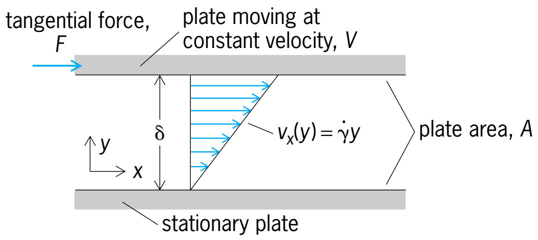
Virus interference

Inhibition of the replication of a virus by a previous infection with another virus. The two viruses may be unrelated, related, or identical. In some cases, virus interference may take place even if the first virus was inactivated. The term mutual exclusion has been applied to this phenomenon in bacterial viruses.

Several mechanisms of interference can be distinguished: (1) Inactivation of cell receptors by one virus may prevent subsequent adsorption and penetration by another virus. (2) The first virus may inhibit or modify cellular enzymes or proteins required for replication of the superinfecting virus. (3) The first virus may generate destructive enzymes or induce the cell to synthesize protective substances which prevent superinfection. (4) The first virus may generate defective interfering particles or mutants which may inhibit the replication of the infecting virus by competing with it for a protein (or enzyme) available in limited quantities; this type of viral interference has been called autointerference, and depends on a greater replicative efficiency of the defective interfering particles or mutants, compared to the infecting virus. *See* ANIMAL VIRUS; VIRULENCE; VIRUS; VIRUS, DEFECTIVE. [M.E.Re.]

Viscosity

The material property that measures a fluid's resistance to flowing. For example, water flows from a tilted jar more quickly and easily than honey does. Honey is more viscous than water, so although gravity creates nearly the same stresses in honey and water, the more viscous fluid flows more slowly.



Planar Couette flow. v_x = fluid velocity at distance y above the stationary plate, $\dot{\gamma}$ = velocity gradient or shear rate, δ = distance between plates.

The viscosity can be measured where the fluid of interest is sheared between two flat plates which are parallel to one another (see illustration). This is known as planar Couette flow. The shear stress is the ratio of the tangential force F needed to maintain the moving plate at a constant velocity V to the plate area A. The shear flow created between the plates has the velocity profile given by Eq. (1), where v_x is the velocity parallel to the plates

$$v_x = \dot{\gamma} y \tag{1}$$

at a perpendicular distance y above the stationary plate. The coefficient $\dot{\gamma}$, called the velocity gradient or shear rate, is given by V/δ, where δ is the distance between the plates. It is expected that the shear stress increases with increasing shear rate but that the ratio of these two quantities depends only on the fluid between the plates. This ratio is used to define the shear viscosity, η, as in Eq. (2). The shear viscosity may depend on temperature, pressure, and shear rate.

$$\eta \equiv \frac{\text{shear stress}}{\text{shear rate}} = \frac{F/A}{V/\delta} \tag{2}$$

Isaac Newton is credited with first suggesting a model for the viscous property of fluids in 1687. Newton proposed that the resistance to flow caused by viscosity is proportional to the velocity at which the parts of the fluid are being separated from one another because of the flow. Although Newton's law of viscosity is an empirical idealization, many fluids, such as low-molecular-weight liquids and dilute gases, are well characterized by it over a large range of conditions. However, many other fluids, such as polymer solution and melts, blood, ink, liquid crystals, and colloidal suspensions, are not described well by Newton's law. Such fluids are referred to as non-newtonian.

For planar Couette flow, Newton's law of viscosity is given mathematically by Eq. (3), where is the shear stress, and μ, a

$$\tau_{yx} = \mu \frac{dv_x}{dy} = \mu \dot{\gamma} \tag{3}$$

function of temperature and pressure, is the coefficient of viscosity or simply the viscosity. Therefore, by comparing Eqs. (2) and (3) the shear viscosity is equal to the coefficient of viscosity (that is, $\eta = \mu$) for a newtonian fluid. Because of this relation the shear viscosity is also often referred to as the viscosity. However, it should be clear that the two quantities are not equivalent; μ is a newtonian-model parameter, which varies only with temperature and pressure, while η is a more general material property which may vary nonlinearly with shear rate. *See* FLUID FLOW; NEWTONIAN FLUID.

From Eqs. (2) and (3), the units of viscosity are given by force per area per inverse time. If in planar Couette flow, for example, 1 dyne of tangential force is applied for every 1 cm^2 area of plate to create a velocity gradient of 1 s^{-1}, then the fluid between the plates has a viscosity of 1 poise (=1 dyne · s/cm^2). Several viscosity units are in common use (see table). Comparison of the viscosities of different fluids demonstrates some general trends. For example, the viscosity of gases is generally much less than that of liquids. Whereas gases tend to become more viscous as temperature is increased, the opposite is true of liquids. Other data also show that increasing pressure tends to increase the viscosity of dense gases, but pressure has only a small effect on the viscosity of dilute gases and liquids.

Whereas dilute gas molecules interact primarily in pairs as they collide, molecules in the liquid phase are in continuous interaction with many neighboring molecules. The concepts of average

Viscosity conversions

Unit	poise	cp	Pa · s	$lb_m/(ft \cdot s)$	$lb_f \cdot s/ft^2$

1 $lb_m/(ft \cdot s)$	14.88	1488	1.488	1	3.108×10^{-2}
1 $lb_f \cdot s/ft^2$	478.8	4.788×10^4	47.88	32.17	1

*1 poise = 1 dyne · s/cm^2 = 1 g/(cm · s).
†1 Pa · s = 1 kg/(m · s).

velocity and mean free path have little meaning for liquids. It is clear, however, that increasing temperature increases the mobility of molecules, thus allowing neighboring molecules to more easily overcome energy barriers and slip past one another. Such arguments lead to an exponential relation for the dependence of viscosity on temperature. *See* GAS; LIQUID.

Many non-newtonian fluids not only exhibit a viscosity which depends on shear rate (pseudoplastic or dilantant) but also exhibit elastic properties. These viscoelastic fluids require a large number of strain-rate-dependent material properties in addition to the shear viscosity to characterize them. The situation can become more complex when the material properties are time dependent (thixotropic or rheopectic). Fluids that are nonhomogeneous or nonisotropic require even more sophisticated analysis. The field of rheology attempts to deal with these complexities. *See* RHEOLOGY. [L.E.W.]

Vision The sense of sight, which perceives the form, color, size, movement, and distance of objects. Of all the senses, vision provides the most detailed and extensive information about the environment. In the higher animals, especially the birds and primates, the *eyes* and the visual areas of the central nervous system have developed a size and complexity far beyond the other sensory systems.

Visual stimuli are typically rays of light entering the *eyes* and forming images on the retina at the back of the eyeball (Fig. 1). Human vision is most sensitive for light comprising the visible spectrum in the range 380–720 nanometers in wavelength. In general, light stimuli can be measured by physical means with respect to their energy, dominant wavelength, and spectral purity. These three physical aspects of the light are closely related to the perceived brightness, hue, and saturation, respectively. *See* COLOR; LIGHT.

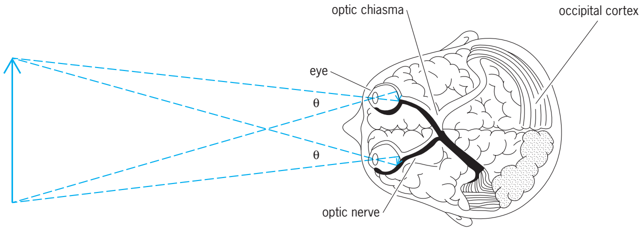

Fig. 1. Diagram showing the eyes and visual projection system. The visual angle θ is measured in degrees.

Anatomical basis for vision. The anatomical structures involved in vision include the *eyes*, optic nerves and tracts, optic thalamus, primary visual cortex, and higher visual areas of the brain. The *eyes* are motor organs as well as sensory; that is, each *eye* can turn directly toward an object to inspect it. The two *eyes* are coordinated in their inspection of objects, and they are able to converge for near objects and diverge for far ones. Each *eye* can also regulate the shape of its crystalline lens to focus the rays from the object and to form a sharp image on the retina. Furthermore, the *eyes* can regulate the amount of light reaching the sensitive cells on the retina by contracting and expanding the pupil of the iris. These motor responses of the *eyes* are examples of involuntary action that is controlled by various reflex pathways within the brain. *See* EYE (VERTEBRATE).

The process of seeing begins when light passes through the *eye* and is absorbed by the photoreceptors of the retina. These cells are activated by the light in such a way that electrical potentials are generated. These potentials serve to generate nerve responses in various successive neural cells in the vicinity of excitation. Impulses emerge from the *eye* in the form of repetitive discharges in the fibers of the optic nerve, which do not mirror exactly the excitation of the photoreceptors by light. Complex interactions within the retina serve to enhance certain responses and to suppress others. Furthermore, each *eye* contains more than a hundred times as many photoreceptors as optic nerve fibers. Thus it would appear that much of the integrative action of the visual system has already occurred within the retina before the brain has had a chance to act.

The optic nerves from the two *eyes* traverse the optic chiasma. Figure 1 shows that the fibers from the inner (nasal) half of each retina cross over to the opposite side, while those from the outer (temporal) half do not cross over but remain on the same side. The effect of this arrangement is that the right visual field, which stimulates the left half of each retina, activates the left half of the thalamus and visual cortex. Conversely the left visual field affects the right half of the brain. This situation is therefore similar to that of other sensory and motor projection systems in which the left side of the body is represented by the right side of the brain and vice versa.

The visual cortex includes a projection area in the occipital lobe of each hemisphere. Here there appears to be a point-for-point correspondence between the retina of each *eye* and the cortex. Thus the cortex contains a “map” or projection area, each point of which represents a point in visual space as seen by each *eye*. Other important features of an object such as its color, motion, orientation, and shape are simultaneously perceived. The two retinal maps are merged to form the cortical projection area. This allows the separate images from the two *eyes* to interact with each other in stereoscopic vision, binocular color mixture, and other phenomena. In addition to the projection areas on the right and left halves of the cortex, there are visual association areas and other brain regions that are involved in vision. Complex visual acts, such as form recognition, movement perception, and reading, are believed to depend on widespread cortical activity beyond that of the projection areas. *See* BRAIN.

Scotopic and photopic vision. Night animals have *eyes* that are specialized for seeing with a minimum of light. This type of vision is called scotopic. Day animals have predominantly photopic vision. They require much more light for seeing, but their daytime vision is specialized for quick and accurate perception of fine details of color, form, and texture, and location of objects. Color vision, when it is present, is also a property of the photopic system. Human vision is duplex; humans are in the fortunate position of having both photopic and scotopic vision. Some of the chief characteristics of human scotopic and photopic vision are enumerated in the table.

Scotopic vision occurs when the rod receptors of the *eye* are stimulated by light. The outer limbs of the rods contain a photosensitive substance known as visual purple or rhodopsin. This

Characteristics of human vision

Characteristic	Scotopic vision	Photopic vision
Photochemical substance	Rhodopsin	Cone pigments
Receptor cells	Rods	Cones
Speed of adaptation	Slow (30 min or more)	Rapid (8 min or less)
Color discrimination	No	Yes
Region of retina	Periphery	Center
Spatial summation	Much	Little
Visual acuity	Low	High
Number of receptors per eye	120,000,000	7,000,000
Cortical representation	Small	Large
Spectral sensitivity peak	505 nm	555 nm

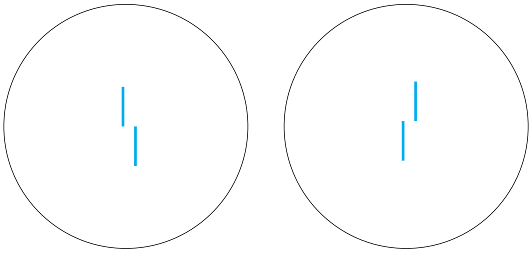
substance is bleached away by the action of strong light so that the scotopic system is virtually blind in the daytime. In darkness, however, the rhodopsin is regenerated by restorative reactions based on the transport of vitamin A to the retina by the blood. One experiences a temporary blindness upon walking indoors on a bright day, especially into a dark room. As the *eyes* become accustomed to the dim light the scotopic system gradually begins to function. This process is known as dark adaptation. Complete dark adaptation is a slow process during which the rhodopsin is restored in the rods. A 10,000-fold increase in sensitivity of is often found to occur during a half-hour period of dark adaptation. By this time some of the rod receptors are so sensitive that only one photon is necessary to trigger each rod into action. Faulty dark adaptation or night blindness is found in persons who lack rod receptors or have a dietary deficiency in vitamin A. This scotopic vision is colorless or achromatic. *See* VITAMIN A.

Normal photopic vision has the characteristics enumerated in the table. Emphasis is placed on the fovea centralis, a small region at the very center of the retina of each *eye*.

Foveal vision is achieved by looking directly at objects in the daytime. The image of an object falls within a region almost exclusively populated by cone receptors, closely packed together in the central fovea, each of which is provided with a series of specialized nerve cells that process the incoming pattern of stimulation and convey it to the cortical projection area. In this way the cortex is supplied with superbly detailed information about any pattern of light that falls within the fovea centralis.

Peripheral vision takes place outside the fovea centralis. Vision extends out to more than 90° from center, so that one can detect moving objects approaching from either side. This extreme peripheral vision is comparable to night vision in that it is devoid of sharpness and color.

There is a simple anatomical explanation for the clarity of foveal vision as compared with peripheral vision. The cones become less and less numerous in the retinal zones that are more and more remote from the fovea. In the extreme periphery there are scarcely any, and even the rods are more sparsely distributed. Furthermore, the plentiful neural connections from the foveal cones are replaced in the periphery by network connections in which hundreds of receptors may activate a single optic nerve fiber. This mass action is favorable for the detection of large or dim stimuli in the periphery or at night, but it is unfavorable for visual acuity (the ability to see fine details of an object) or color vision, both of which require the brain to differentiate between signals arriving from closely adjacent cone receptors.



left eye view

right eye view

Fig. 2. Vernier and stereoscopic discriminations of space.

Space and time perception. Vernier and stereoscopic discrimination are elementary forms of space perception. Here, the *eye* is required to judge the relative position of one object in relation to another (Fig. 2). The left *eye*, for example, sees the lower line as displaced slightly to the right of the upper. This is known as vernier discrimination. The *eye* is able to distinguish fantastically small displacements of this kind, a few seconds of arc under favorable conditions. If the right *eye* is presented with similar lines that are oppositely displaced, then the images for the two *eyes* appear fused into one and the subject sees the lower line as nearer than the upper. This is the principle of the stereoscope. Again it is true that displacements of a few seconds of arc are clearly seen, this time as changes in distance. The distance judgment is made not at the level of the retina but at the cortex where the spatial patterns from the separate *eyes* are fused together. The fineness of vernier and stereoscopic discrimination transcends that of the retinal mosaic and suggests that some averaging mechanism must be operating in space or time or both.

The spatial aspects of the visual field are also of interest. Good acuity is restricted to a narrowly defined region at the center of the visual field. Farther out, in the peripheral regions, area and intensity are reciprocally related for all small sizes of stimulus field. A stimulus patch of unit area, for example, looks the same as a patch of twice the same area and half the luminance. This high degree of areal summation is achieved by the convergence of hundreds of rod receptors upon each optic nerve fiber. It is the basis for the ability of the dark-adapted *eye* to detect large objects even on a dark night.

In daytime vision, spatial inhibition, rather than summation, is most noticeable. The phenomenon of simultaneous contrast is present at a border between fields of different color or luminance. This has the effect of heightening contours and making forms more noticeable against their background.

The temporal characteristics of vision are revealed by studying the responses of the *eye* to various temporal patterns of stimulation. When a light is first turned on, there is a vigorous burst of nerve impulses that travel from the *eye* to the brain. Continued illumination results in fewer and fewer impulses as the *eye* adapts itself to the given level of illumination. Turning the light off elicits another strong neural response. The strength of a visual stimulus depends upon its duration as well as its intensity. Below a certain critical duration, the product of duration and intensity is found to be constant for threshold stimulation. A flash of light lasting only a few milliseconds may stimulate the *eye* quite strongly, providing its luminance is sufficiently high. A light of twice of the original duration will be as detectable as the first if it is given half the original luminance.

Voluntary *eye* movements enable the *eyes* to roam over the surface of an object of inspection. In reading, for example, the *eyes* typically make four to seven fixational pauses along each line of print, with short jerky motions between pauses. An individual's vision typically takes place during the pauses, so that one's awareness of the whole object is the result of integrating these separate impressions over time.

A flickering light is one that is going on and off (or undergoing lesser changes in intensity) as a function of time. At a sufficiently high flash rate (called the critical frequency of fusion, cff) the *eye* fails to detect the flicker, and the light pulses seem to fuse to form a steady light that cannot be distinguished from a continuous light that has the same total energy per unit of time. As the flash rate is reduced below the cff, flicker becomes noticeable, and at very low rates the light may appear more conspicuous than flashes occurring at higher frequency. The cff is often used clinically to indicate a person's visual function as influenced by drugs, fatigue, or disease. *See* COLOR VISION; PERCEPTION.

[L.A.R.; C.E.Ste.]

Visual debugging Visualization of computer program state and program execution to facilitate understanding and, if necessary, alteration of the program. Debuggers are universal tools for understanding what is going on when a program is executed. Using a debugger, one can execute the program in a specific environment, stop the program under specific conditions, and examine or alter the content of the program variables or pointers. Traditional command-line oriented debuggers allowed only a simple textual representation of the program variables (program state).

Textual representation did not change even when modern debuggers came with a graphical user interface. Although variable names became accessible by means of menus, the variable values were still presented as text, including structural information, such as pointers and references. Likewise, the program execution is available only as a series of isolated program stops. (Pointers are variables that contain the "addresses" of other variables.) Compared to traditional debuggers, the techniques of visual debugging allow quicker exploration and understanding of what is going on in a program. *See* COMPUTER PROGRAMMING; PROGRAMMING LANGUAGES; SOFTWARE; SOFTWARE ENGINEERING.

The GNU Data Display Debugger (DDD), for example, is a graphical front-end to a command-line debugger, providing menus and other graphical interfaces that eventually translate into debugger commands. As a unique feature, DDD allows the visualization of data structures as graphs. The concept is simple: Double-clicking on a variable shows its value as an isolated graph node. By double-clicking on a pointer, the dereferenced value or the variable pointed is to shown as another graph node, with an edge relating pointer and dereferenced value. By subsequent double-clicking on pointers, the programmer can unfold the entire data structure.

If a pointer points to a value that is already displayed (for example, in a circular list), no new node is created; instead, the edge is drawn to the existing value. Using this alias recognition, the programmer can quickly identify data structures that are referenced by multiple pointers.

In principle, DDD can render arbitrary data structures by means of nodes and edges. However, the programmer must choose what to unfold, as the screen size quickly limits the number of variables displayed. Nonetheless, DDD is one of the most popular debugging tools under Unix and Linux. [A.Z.]

Visual impairment Abnormal visual acuity. The term is used to describe visual acuity substantially less than normal. The World Health Organization defines visual impairment as acuity less than 20/60 (normal being 20/20). The legal definition of blindness in the United States is visual acuity of 20/200 or worse (or severely restricted peripheral vision). The World Health Organization defines blindness as visual acuity worse than 20/400. Visual impairment and blindness increase substantially with age. The major causes of blindness differ substantially by race. Cataracts, which involve opacification of the normally clear lens, and diabetic retinopathy, which is an accumulation of fluid or the growth of abnormal blood vessels in the retina (most commonly in insulin-dependent diabetics), are important causes of blindness. A large proportion of people having blindness caused by cataracts can be treated by surgery.

A growing proportion of blindness caused by diabetic retinopathy can be prevented by laser surgery.

Other important causes of blindness are glaucoma and macular degeneration. Early detection of glaucoma requires routine, careful screening and examination, since many patients remain asymptomatic until much of the optic nerve is destroyed. Macular degeneration involves atrophy of that portion of the retina responsible for fine (reading) vision. People with macular degeneration rarely suffer the total blindness of advanced glaucoma or diabetic retinopathy. *See* DIABETES.

Visual problems are far more common in developing countries, where there are limited resources for dealing with problems that are otherwise readily treated, such as cataract, or prevented, such as trachoma or xerophthalmia ("blinding malnutrition" caused by vitamin A deficiency). *See* CATARACT; GLAUCOMA; VISION. [A.So.]

Vitamin An organic compound required in very small amounts for the normal functioning of the body and obtained mainly from foods. Vitamins are present in food in minute quantities compared to the other utilizable components of the diet, namely, proteins, fats, carbohydrates, and minerals.

Synthetic and natural vitamins usually have the same biological value. Different vitamins, which are often not related to each other chemically or functionally, are conventionally divided into a fat-soluble group (vitamins A, D, E, and K) and a water-soluble group [vitamin C (ascorbic acid) and the various B vitamins: thiamine, vitamin B, riboflavin, vitamin B_2, vitamin B_6, niacin, folic acid, vitamin B_{12}, biotin, and pantothenic acid]. The vitamins, particularly the water-soluble ones, occur almost universally throughout the animal and plant kingdoms individual articles on each vitamin.

The B vitamins function as coenzymes that catalyze many of the anabolic and catabolic reactions of living organisms necessary for the production of energy; the synthesis of tissue components, hormones, and chemical regulators; and the detoxification and degradation of waste products and toxins. On the other hand, vitamin C and the fat-soluble vitamins do not function as coenzymes. Vitamins C and E and β-carotene (a precursor of vitamin A) act as antioxidants, helping to prevent tissue injury from free-radical reactions. In addition, vitamin C functions as a cofactor in hydroxylation reactions. Vitamin D has hormone-like activity in calcium metabolism; vitamin A plays a critical role in night vision, growth, and maintaining normal differentiation of epithelial tissue; and vitamin K has a unique posttranscriptional role in the formation of active blood-clotting factors. *See* ANTIOXIDANT; CAROTENOID; COENZYME; NUTRITION. [L.J.M.]

Vitamin A A pale-yellow alcohol, soluble in fat but not in water. In pure form, it is readily destroyed by oxidation and light, which may cause losses during storage. Vitamin A is found in all animal tissues, although it is particularly concentrated in the liver. There are two different dietary sources for the vitamin: animal sources which contain vitamin A itself, mostly in the form of retinyl esters, and plant sources which contain carotenoids that are converted to vitamin A in animal tissues such as the absorptive cells in the intestine. The most vitamin A–enriched animal food source is fish liver oil. Plant carotenoids are found in green and yellow fruits and vegetables such as carrots, apricots, asparagus, broccoli, and green leafy vegetables. *See* CAROTENOID.

In vitamin A deficiency, the epithelial tissues of many organs are affected. Growth failure occurs, and young animals can suffer from neurological symptoms resulting from pressures on the central nervous system. Vitamin A deficiency is also strongly associated with depressed immune function and higher morbidity and mortality due to infectious diseases such as diarrhea, measles, and respiratory infections. A severe manifestation of vitamin A deficiency is night blindness and inflammation of the eyes (xerophthalmia), followed by irreversible blindness.

The symptoms seen in vitamin A deficiency reflect the multiple roles of this compound in animals. These roles are fulfilled by two compounds that are synthesized from vitamin A in the body: vitamin A aldehyde (retinaldehyde), which is critical for vision, and vitamin A acid (retinoic acid), which controls many physiological functions in both the embryo and the adult. *See* VISION.

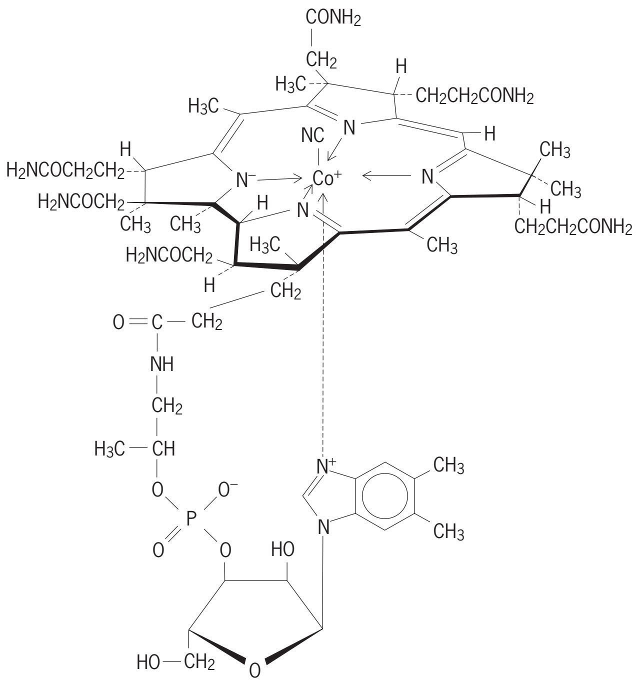
Studies of many mammalian species suggested that approximately 20 IU (6 μg) of vitamin A per kilogram of body weight will support growth and prevent symptoms of deficiency. The current intake recommendations of vitamin A in the United States is 3 mg/day and about 1 mg/day in the European Union. *See* VITAMIN. [S.N.G.; N.N.]

Vitamin B$_6$ A vitamin which exists as three chemically related and water-soluble forms found in food; pyridoxine, pyridoxal, and pyridoxamine. All three forms have equal activity for animals and yeast.

Vitamin B$_6$ deficiency is accompanied by poor growth, dermatitis, microcytic anemia, epileptiform convulsions, and kidney and adrenal lesions. There is evidence that some women in the third trimester of pregnancy may have a special requirement for vitamin B$_6$ in that its administration often relieves the nausea of pregnancy. Some types of human dermatitis respond to local application of this vitamin.

It is difficult to set requirements for vitamin B$_6$, since no single set of assay conditions or criteria has received universal acceptance. Adults probably require about 1.5–2 milligrams per day, and a dietary intake of 0.4 milligrams per day would probably be satisfactory for most infants. *See* VITAMIN. [S.N.G.]

Vitamin B$_{12}$ A group of closely related polypyrrole compounds, with the structure shown, containing trivalent cobalt; it is often called cobalamin, The vitamin is a dark-red crystalline compound; in aqueous solution and at room temperature it is most stable at pH 4–7.



Vitamin B$_{12}$ deficiency in animals is characterized primarily by anemia and neuropathy. In humans, this deficiency is called pernicious anemia. People suffering from this disease lack a factor secreted in gastric juice which, by affecting absorption directly and by protecting vitamin B$_{12}$ from intestinal destruction, enables the vitamin to be absorbed. *See* ANEMIA.

Requirements for vitamin B$_{12}$ are increased by reproduction or hyperthyroidism. Of the known vitamins B$_{12}$ is the most active biologically. A daily injection of 1 microgram of vitamin B$_{12}$ will prevent the recurrence of symptoms in people with pernicious anemia. For normal people a diet containing 3–5 μg per day (providing 1–1.5 μg absorbed) will satisfy vitamin B$_{12}$ requirements. *See* VITAMIN. [S.N.G.]

Vitamin D Either of two fat-soluble sterol-like compounds, ergocalciferol (vitamin D$_2$) and activated cholecalciferol (vitamin D$_3$). Vitamin D$_2$ is formed from the irradiation of ergosterol, a plant sterol. However, vitamin D$_3$ is normally manufactured in the skin, where ultraviolet light activates the compound 7-dehydrocholesterol. Vitamins D$_3$ and D$_2$ are about equal in activity in all mammals except New World monkeys and birds, in which vitamin D$_2$ is approximately one-tenth as active as vitamin D$_3$. *See* VITAMIN.

Vitamin D as acquired from the diet or produced in the skin is biologically inactive. It must be metabolized by the liver to produce 25-hydroxyvitamin D$_3$. However, this compound is also biologically inactive under physiological circumstances and must be activated by the kidney to produce the final vitamin D hormone, 1,25-dihydroxyvitamin D$_3$. This hormonal form of vitamin D plays an essential role in stimulating intestinal absorption of calcium and phosphorus, in the mobilization of calcium from bone, and in renal reabsorption of calcium. The function of vitamin D has been expanded beyond regulating plasma calcium and phosphorus levels, and hence healing the diseases of rickets and osteomalacia. It is now known that the vitamin D hormone controls parathyroid gland growth and production of the parathyroid hormone. It is an immunomodulator. Vitamin D hormone also appears to play a role in the regulation of insulin production or secretion. Finally, it is required for female reproduction. These new sites of action of vitamin D are under intense investigation. *See* HORMONE.

Vitamin D is largely absent from the food supply. It is found in large amounts in fish liver oils; cod liver oil has long been known to be an important source of vitamin D. Fortified foods are the major dietary source of vitamin D, but the major overall source is the production of vitamin D in skin by exposure to sunlight or ultraviolet irradiation. In winter months at temperate latitudes, insufficient amounts of vitamin D are produced in skin, and unless it is replaced by a dietary source, danger of insufficiency exists.

A deficiency of vitamin D in growing animals results in the disease rickets. A similar disease, osteomalacia, occurs in adult animals. By far the most serious disorder of vitamin D deficiency is the low-blood calcium levels which result in convulsions known as hypocalcemic tetany. Moderate deficiency of vitamin D may contribute to osteoporosis, especially in the elderly. *See* BONE; OSTEOPOROSIS.

The recommended daily requirement for vitamin D$_3$ is 10 micrograms or 400 international units (IU). Higher requirements are reported for the elderly and for rapidly growing adolescents: 20 μg or 800 IU per day. It is possible that the average requirement is lower than 10 μg per day. The exact absolute requirement has never been determined. [H.F.D.]

Vitamin E A group of compounds, α, β, γ, and δ tocopherols, that have a chromanol ring and phytyl side chain and are widely distributed in nature, especially in edible vegetable oils (wheat germ, sunflower, cottonseed, safflower, canola, soybean, and corn oil). Unprocessed grains, nuts, and vegetables are other sources. When used as supplements, there are two vitamin E products available: natural source RRR α-tocopherol and synthetic all-rac-α-tocopherol. The latter is a mixture of eight different stereoisomers, of which only one is RRR α-tocopherol. *See* VITAMIN.

The terms “vitamin E” and “α-tocopherol” are frequently used interchangeably in human nutrition, but it is imperative to distinguish between supplements of RRR α-tocopherol and of synthetic α-tocopherol because their biological activity is different. Since the major function of vitamin E is to serve as a chain-breaking antioxidant, protecting cell membranes against free-radical damage, the most potent form of the vitamin should be used as a supplement. Although gastrointestinal absorption of all forms of vitamin E is equivalent, the subsequent physiological steps are sharply in favor of the RRR form. This action is mediated by a cellular liver transfer protein that is specific for the RRR form of α-tocopherol. It maintains the plasma level by selectively choosing the RRR form and recycling it into plasma lipoproteins for distribution of the vitamin to every tissue and organ in the body.

When deficiencies of the vitamin occur in humans as a consequence of acquired malabsorption or genetic abnormalities of lipoproteins or of the transfer protein, the major symptoms that develop are in the nervous system. Ataxia (lack of muscular coordination) and other neurologic symptoms result in severe incoordination and subsequent musculoskeletal changes.

The recommended daily allowance for vitamin E is 15 milligrams, which is present in the usual Western diet. [H.J.K.]

Vitamin K A group of compounds derived from 2-methyl-1,4-naphthoquinone that prevent bleeding in mammals and birds. Vitamin K_1 (phylloquinone) is produced by green plants; a related form, vitamin K_2 (menaquinone), is produced by intestinal bacteria. Chemically synthesized forms include vitamin K_1, K_2, and menadione (vitamin K_3). All of these compounds are fat-soluble liquids at room temperature that become biologically inactive when exposed to light or alkali. *See* VITAMIN.

Vitamin K_1 (phylloquinone) is a photosynthesis cofactor in plants, and various forms of vitamin K_2 (menaquinones) participate in energy transfer reactions in bacteria. Mammals and many other animals need vitamin K hydroquinone (the active form) as a cofactor for the specific synthesis of the amino acid γ-carboxyglutamate (Gla) in certain proteins, which enable the proteins to bind calcium and phospholipids with high specificity. Gla is an essential part of coagulation factors and of other proteins that regulate blood clotting (hence the disruption of blood clotting and internal bleeding associated with vitamin K deficiency). *See* AMINO ACIDS; BLOOD; COENZYME; PROTEIN.

Humans depend on continuous vitamin K supplies, since storage is minimal. Good dietary sources of vitamin K_1 are green vegetables and fruits; certain fermented Asian foods, especially natto, have a high vitamin K_2 content.

Intestinal bacteria produce vitamin K_2, and under most circumstances enough is absorbed to prevent bleeding. However, spontaneous bleeding occurs if both dietary intake and production by intestinal bacteria are persistently low. Other health risks related to inadequate vitamin K intake may include accelerated loss of bone minerals and hardening of arteries. [M.Koh.]

Vivianite A mineral of the vivianite group, other important members of which are annabergite and erythrite.

Vivianite is a hydrated ferrous phosphate, $Fe_3(PO_4)_2 \cdot 8H_2O$; usually ferric iron is present as the result of oxidation. It crystallizes in the monoclinic system, with crystals generally prismatic. Vivianite also occurs in earthy form and as globular and encrusting masses of fibrous structure. Crystals are colorless and transparent when fresh. Oxidation changes the color progressively to pale blue, greenish blue, dark blue, or bluish black. [W.R.Lo.]

Vocal cords The pair of elastic, fibered bands inside the human larynx. The cords are covered with a mucous membrane and pass horizontally backward from the thyroid cartilage (Adam's apple) to insert on the smaller, paired arytenoid cartilages at the back of the larynx. The vocal cords act as sphincters for air regulation and may be vibrated to produce sounds. Separation, approximation, and alteration of tension are produced by action of laryngeal muscles acting on the pivoting arytenoids. Vibration of the cords produces fundamental sounds and overtones. These can be modified by the strength of the air current, the size and shape of the glottis (the opening between the cords), and tension in the cords. *See* LARYNX; SPEECH. [W.J.B.]

Voice response The generation of synthetic speech signals in order to convey information to listeners, usually based upon a verbal or textual request by the users. This speech synthesis typically employs a computer program and requires access to storage of portions of speech previously spoken by humans. The naturalness of the synthetic voice depends on several factors, including the vocabulary of words to pronounce, the amount of stored speech, and the complexity of the synthesis programs. The most basic voice response simply plays back appropriate short verbal responses, which are only copies of human speech signals stored using digital sampling technology. The most universal systems are capable of transforming any given text into comprehensible speech for a given language. These latter systems so far exist for only 20 or so of the world's major languages, and are flawed in producing speech that, while usually intelligible, sounds unnatural.

Voice response is also known as text-to-speech synthesis (TTS) because the task usually has as input a textual message (to be spoken by the machine). The text could be in tabular form (for example, reading aloud a set of numbers), or, more typically, formatted as normal sentences. Speech synthesizers are much more flexible and universal than their speech-recognition counterparts, for which human talkers must significantly constrain their verbal input to the machines in order to achieve accurate recognition. In TTS, a computer database usually determines the text to be synthetically spoken, following an automatic analysis of each user request. The user may pose the request in response to a menu of inquiries (for example, by an automated telephone dialogue, by pushing a sequence of handset keys, or by a series of brief verbal responses). Thus, the term "voice response" is used to describe the synthetic speech as an output to a user inquiry. The value of such a synthetic voice is the capability of efficiently receiving information from a computer without needing a computer screen or printer. Given the prevalence of telephones, as well as the difficulty of reading small computer screens on many portable computer devices, voice response is a convenient way to get data. *See* SPEECH RECOGNITION.

The simplest approach to voice response is to digitally sample natural speech and output the samples later as needed. A common Nyquist sampling rate is 10,000 samples per second, which preserves sound frequencies up to almost 5 kHz, allowing quite natural speech. High-frequency energy in fricative sounds is severely attenuated (but less so than on telephone lines), but this usually has little impact on intelligibility. Straightforward sampling requires 12 bits per sample, which requires memory at 120 kbits/s. Such high data rates are prohibitive except for applications with very small vocabularies. Even in cases with more limited bandwidth (for example, 8000 samples per second in telephone applications) and more advanced coding schemes, the straightforward playback approach is unacceptable for general TTS. Despite rapidly decreasing costs for computer memory, it will remain impossible to store all the necessary speech signals except for applications with very restricted vocabulary needs. *See* COMPACT DISK; DATA COMPRESSION; INFORMATION THEORY; PULSE MODULATION.

A voice response system which minimizes memory needs generates synthetic speech from sequences of brief basic sounds and has great flexibility. Since most languages have only 30–40 phonemes (distinct linguistic sounds), storing units of such size and number is trivial. However, the spectral features of these short concatenated sounds (lasting 50–200 ms) must be adjusted at their frequent boundaries to avoid severely discontinuous speech. Normal pronunciation of each phoneme in an utterance depends heavily on its phonetic context (for example, on neighboring phonemes, intonation, and speaking rate). The adjustment process and the need to calculate an appropriate intonation for each context lead to complicated synthesizers with correspondingly less natural output speech.

Current synthesizers usually compromise between the extremes of minimizing storage and complexity. One approach is to store thousands of speech units of varying size, which can be automatically extracted from natural speech. In contrast to automatic speech recognition, where segmentation of speech into pertinent units is very difficult, TTS training exploits prior knowledge of the text (the training speaker reads a furnished text).

Synthesizers that accept general text as input need a linguistic processor to convert the text into phonetic symbols in order to access the appropriate stored speech units. One task is to convert letters into phonemes. This may be as simple as a table look-up: a computer dictionary with an entry for each word in the chosen language, noting its pronunciation (including syllable stress), syntactic category, and possibly some semantic information. Many systems also have language-dependent rules, which examine the context of each letter in a word to determine how it is pronounced; for example, the letter [p] in English is pronounced /p/, except before the letter [h] (for example, in "telephone"; however, it has normal pronunciation in "cupholder"). English needs hundreds of such rules. TTS often employs these rules as a backup procedure to handle new words, foreign words, and typographical mistakes (that is, cases not in the dictionary). *See* PHONETICS.

The problem of determining an appropriate intonation for each input text continues to confound TTS. In simple voice response, the stored units are large (for example, phrases), and pitch and intensity are usually stored explicitly with the spectral parameters or implicitly in the signals of waveform synthesizers. However, when smaller units are concatenated, the synthetic speech sounds unnatural unless the intonation is adjusted for context. Intonation varies significantly among languages. Although automatic statistical methods show some promise, intonation analysis has mostly been manual.

Simple voice-response systems work equally well for all languages since they just play back previously stored speech units. For general TTS, however, major synthesizer components are highly language-dependent. The front end of TTS systems, dealing with letter-to-phoneme rules, the relationship between text and intonation, and different sets of phonemes, is language-dependent. The back end, representing simulation of the vocal track via digital filters, is relatively invariant across languages. Even languages with sounds (for example, clicks) other than the usual pulmonic egressives require only simple modifications.

Commercial synthesizers are widely available for about 10 languages. They often combine software, memory, and processing chips, and range from expensive systems providing close-to-natural speech to inexpensive personal computer programs. General digital signal processing chips are widely used for TTS. Current microprocessors can easily handle the speeds for synthesis, and indeed synthesizers exist entirely in software. Memory requirements can still be a concern, especially for some of the newer waveform concatenation systems. *See* MICROPROCESSOR; SPEECH. [D.O'S.]

Volatilization

The process of converting a chemical substance from a liquid or solid state to a gaseous or vapor state. Other terms used to describe the same process are vaporization, distillation, and sublimation. A substance can often be separated from another by volatilization and can then be recovered by condensation of the vapor. The substance can be made to volatilize more rapidly either by heating to increase its vapor pressure or by removal of the vapor using a stream of inert gas or a vacuum pump. Chemical reactions are sometimes utilized to produce volatile products. Volatilization methods are generally characterized by great simplicity and ease of operation, except when high temperatures or highly corrosion-resistant materials are needed. *See* CHEMICAL SEPARATION TECHNIQUES; DISTILLATION; SUBLIMATION; VAPOR PRESSURE. [L.Go./R.W.Mu.]

Volcanic glass

A natural glass formed by rapid cooling of magma. Magmas typically comprise crystals and bubbles of gas within a silicate liquid. On slow cooling, the liquid portion of the magma usually crystallizes, but if cooling is sufficiently rapid, it may convert to glass—an amorphous, metastable solid that lacks the long-range microscopic order characteristic of crystalline solids. *See* LAVA; MAGMA.

Silica-rich, rhyolitic magmas frequently quench to glass during explosive eruptions and make up the bulk of the solid material in many pyroclastic deposits (usually as shards, pumice lumps, and other fragments); but they also can erupt quiescently to form massive glassy rocks (known as obsidian, the most common source of volcanic glass on land) even in the slowly cooled interiors of flows tens of meters thick. In contrast, more basic, basaltic glasses (sometimes known as tachylite) are less common and rarely form in more than small quantities unless rapidly cooled in a volcanic eruption. Pele's hair is an example of basaltic glass formed in this way. *See* BASALT; OBSIDIAN; RHYOLITE. [E.M.St.]

Volcano

A mountain or hill, generally steep-sided, formed by accumulation of magma (molten rock with associated gas and crystals) erupted through openings or volcanic vents in the Earth's crust; the term volcano also refers to the vent itself. During the evolution of a long-lived volcano, a permanent shift in the locus of principal vent activity can produce a satellitic volcanic accumulation as large as or larger than the parent volcano, in effect forming a new volcano on the flanks of the old.

Planetary exploration has revealed dramatic evidence of volcanoes and their products on the Earth's Moon, Mars, Mercury, Venus, and the moons of Jupiter, Neptune, and Uranus on a scale much more vast than on Earth. However, only the products and landforms of terrestrial volcanic activity are described here. *See* MARS; MERCURY (PLANET); MOON; NEPTUNE; URANUS; VENUS; VOLCANOLOGY.

Volcanic vents. Volcanic vents, channelways for magma to ascend toward the surface, can be grouped into two general types: fissure and central (pipelike). Magma consolidating below the surface in fissures or pipes forms a variety of igneous bodies, but magma breaking the surface produces fissure or pipe eruptions. Fissures, most of them less than 10 ft (3 m) wide, may form in the summit region of a volcano, on its flanks, or near its base; central vents tend to be restricted to the summit area of a volcano. For some volcanoes or volcanic regions, swarms of fissure vents are clustered in swaths called rift zones.

Volcanic products. Magma erupted onto the Earth's surface is called lava. If the lava is chilled and solidifies quickly, it forms volcanic glass; slower rates of chilling result in greater crystallization before complete solidification. Lava may accrete near the vent to form various minor structures or may pour out in streams called lava flows, which may travel many tens of miles from the vents. During more violent eruption, lava torn into fragments and hurled into the air is called pyroclastic (fire-broken materials). *See* CRYSTALLIZATION; LAVA; MAGMA; PYROCLASTIC ROCKS; VOLCANIC GLASS.

Volcanic gases. Violent volcanic explosions may throw dust and aerosols high into the stratosphere, where it may drift across the surface of the globe for many thousands of miles. Most of the solid particles in the volcanic cloud settle out within a few days, and nearly all settle out within a few weeks, but the gaseous aerosols (principally sulfuric acid droplets) may remain suspended in the stratosphere for several years. Such stratospheric clouds of volcanic aerosols, if sufficiently voluminous and long-lived, can have an impact on global climate. *See* ACID RAIN; AEROSOL; AIR POLLUTION.

In general, water vapor is the most abundant constituent in volcanic gases; the water is mostly of meteoric (atmospheric) origin, but in some volcanoes can have a significant magmatic or juvenile component. Excluding water vapor, the most abundant gases are the various species of carbon, sulfur, hydrogen, chlorine, and fluorine.

Mudflows are common on steep-side volcanoes where poorly indurated or nonwelded pyroclastic material is abundant. Probably by far the most common cause, however, is simply heavy rain saturating a thick cover of loose, unstable pyroclastic material on the steep slope of the volcano, transforming the material into a mobile, water-saturated "mud," which can rush downslope at a speed as great as 50–55 mi (80–90 km) per hour. Such a dense, fast-moving mass can be highly destructive, sweeping up everything loose in its path.

Volcanic landforms. Much of the Earth's solid surface, on land and below the sea, has been shaped by volcanic activity. Landscape features of volcanic origin may be either positive (constructional) forms, the result of accumulation of volcanic materials, or negative forms, the result of the lack of accumulation or collapse.

Not all volcanoes show a graceful, symmetrical cone shape, such as that exemplified by Mount Fuji, Japan. Most volcanoes, especially those near tectonic plate boundaries, are more irregular, though of grossly conical shape. Such volcanoes, called stratovolcanoes or composite volcanoes, typically erupt explosively and are composed dominantly of andesitic, relatively viscous and short lava flows, interlayered with beds of ash and cinder that thin away from the principal vents. Volcanoes constructed primarily of fluid basaltic lava flows, which may spread great distances from the vents, typically are gentle-sloped, broadly upward convex structures. Such shield volcanoes, classic examples of which are Mauna Loa volcano, Hawaii, tend to form in oceanic intraplate regions and are associated with hot-spot volcanism. The shape and size of a volcano can vary widely between the simple forms of composite and shield volcanoes, depending on magma viscosity, eruptive style (explosive versus nonexplosive), migration of vent locations, duration and complexity of eruptive history, and posteruption modifications.

Some of the largest volcanic edifices are not shaped like the composite or shield volcanoes. In certain regions of the world, voluminous extrusions of very fluid basaltic lava from dispersed fissure swarms have built broad, nearly flat-topped accumulations. These voluminous outpourings of lava are known as flood basalts or plateau basalts. *See* BASALT.

Submarine volcanism. Deep submarine volcanism occurs along the spreading ridges that zigzag for thousands of miles across the ocean floor, and it is exposed above sea level only in Iceland. Because of the logistical difficulties in making direct observations posed by the great ocean depths, no deep submarine volcanic activity has been actually observed during eruption. However, evidence that deep-sea eruptions are happening is clearly indicated by (1) seismic and acoustic monitoring networks; (2) the presence of deep-ocean floor hydrothermal vents; (3) episodic hydrothermal discharges, measured and mapped as thermal and geochemical anomalies in the ocean water; and (4) the detection of new lava flows in certain segments of the oceanic ridge system. *See* HYDROTHERMAL VENT; MID-OCEANIC RIDGE.

Volcanic eruptions in shallow water are very similar in character to those on land but, on average, are probably somewhat more explosive, owing to heating of water and resultant violent generation of supercritical steam. Much of the ocean basin appears to be floored by basaltic lava. *See* OCEANIC ISLANDS.

Fumaroles and hot springs. Vents at which volcanic gases issue without lava or after the eruption are known as fumaroles. They are found on active volcanoes during and between eruptions and on dormant volcanoes, persisting long after the volcano itself has become inactive. Fumaroles grade into hot springs and geysers. The water of most, if not all, hot springs is predominantly of meteoric origin, and is not water liberated from magma. Some hot springs are of volcanic origin and the water may contain volcanic gases. *See* GEYSER.

Distribution of volcanoes. Over 500 active volcanoes are known on the Earth, mostly along or near the boundaries of the dozen or so lithospheric plates that compose the Earth's solid surface. Lithospheric plates show three distinct types of boundaries: divergent or spreading margins—adjacent plates are pulling apart; convergent margins (subduction zones)—plates are moving toward each other and one is being destroyed; and transform margins—one plate is sliding horizontally past another. All these types of plate motion are well demonstrated in the Circum-Pacific region, in which many active volcanoes form the so-called Ring of Fire. Some volcanoes, however, are not associated with plate boundaries, and many of these so-called intraplate volcanoes form roughly linear chains in the interior parts of the oceanic plates, for example, the Hawaiian-Emperor, Austral, Society, and Line archipelagoes in the Pacific Basin. Intraplate volcanism also has resulted in voluminous outpourings of fluid lava to form extensive plateau basalts, or of more viscous and siliceous pyroclastic products to form ash flow plains. [R.I.T.]

Volcanology The scientific study of volcanic phenomena, especially the processes, products, and hazards associated with active or potentially active volcanoes. It focuses on eruptive activity that has occurred within the past 10,000 years of the Earth's history, particularly eruptions during recorded history. Strictly speaking, it emphasizes the surface eruption of magmas and related gases, and the structures, deposits, and other effects produced thereby. Broadly speaking, however, volcanology includes all studies germane to the generation, storage, and transport of magma, because the surface eruption of magma represents the culmination of diverse physicochemical processes at depth. This article considers the activity of erupting volcanoes and the nature of erupting lavas. For a discussion of the distribution of volcanoes and the surface structures and deposits produced by them, *see* PLATE TECTONICS; VOLCANO.

On average, about 50 to 60 volcanoes worldwide are active each year. About half of these constitute continuing activity that began the previous year, and the remainder are new eruptions. Analysis of historic records indicates that eruptions comparable in size to that of Mount St. Helens or El Chichón tend to occur about once or twice per decade, and larger eruptions such as Pinatubo about once per one or two centuries. On a global basis, eruptions the size of that at Nevado del Ruiz in November 1985 are orders of magnitude more frequent.

Modern volcanology perhaps began with the founding of well-instrumented observations at Asama Volcano (Japan) in 1911 and at Kilauea Volcano (Hawaii) in 1912. The Hawaiian Volcano Observatory, located on Kilauea's caldera rim, began to conduct systematic and continuous monitoring of seismic activity preceding, accompanying, and following eruptions, as well as other geological, geophysical, and geochemical observations and investigations.

The eruptive characteristics, products, and resulting landforms of a volcano are determined predominantly by the composition and physical properties of the magmas involved in the volcanic processes (see table). Formed by partial melting of existing solid rock in the Earth's lower crust or upper mantle, the discrete blebs of magma consist of liquid rock (silicate melt) and dissolved gases. Driven by buoyancy, the magma blebs, which are lighter than the surrounding rock, coalesce as they rise toward the surface to form larger masses. *See* IGNEOUS ROCKS; LITHOSPHERE; MAGMA.

Magma consists of three phases: liquid, solid, and gas. Volcanic gases generally are predominantly water; other gases include various compounds of carbon, sulfur, hydrogen, chlorine, and fluorine. All volcanic gases also contain minor amounts of nitrogen, argon, and other inert gases, largely the result of atmospheric contamination at or near the surface.

Generalized relationships between magma composition, relative viscosity, and common eruptive characteristics

Magma composition	Relative viscosity	Common eruptive characteristics
Basaltic	Fluidal	Lava fountains, flows, and pools
Andesitic	Less fluidal	Lava flows, explosive ejecta, ashfalls, and pyroclastic flows
Dacitic-rhyolitic	Viscous	Explosive ejecta, ashfalls, pyroclastic flows, and lava domes

Temperatures of erupting magmas have been measured in lava flows and lakes, pyroclastic deposits, and volcanic vents by means of infrared sensors, optical pyrometers, and thermocouples. Reasonably good and consistent measurements have been obtained for basaltic magmas erupted from Kilauea and Mauna Loa volcanoes, Hawaii, and a few other volcanoes. Measured temperatures typically range between 2100 and 2200°F (1150 and 1200°C), and many measurements in cooling Hawaiian lava lakes indicate that the basalt becomes completely solid at about 1800°F (980°C). *See* GEOLOGIC THERMOMETRY.

The character of a volcanic eruption is determined largely by the viscosity of the liquid phase of the erupting magma and the abundance and condition of the gas it contains. Viscosity is in turn affected by such factors as the chemical composition and temperature of the liquid, the load of suspended solid crystals and xenoliths, the abundance of gas, and the degree of vesiculation. The subsequent violent expansion during eruption shreds the frothy liquid into tiny fragments, generating explosive showers of volcanic ash and dust, accompanied by some larger blocks (volcanic "bombs"); or it may produce an outpouring of a fluidized slurry of gas, semisolid bits of magma froth, and entrained blocks to form high-velocity pyroclastic flows, surges, and glowing avalanches. *See* PYROCLASTIC ROCKS; VISCOSITY.

Types of eruptions customarily are designated by the name of a volcano or volcanic area that is characterized by that sort of activity, even though all volcanoes show different modes of eruptive activity on occasion and even at different times during a single eruption.

Eruptions of the most fluid lava, in which relatively small amounts of gas escape freely with little explosion, are designated Hawaiian eruptions. Most of the lava is extruded as successive, thin flows that travel many miles from their vents. An occasional feature of Hawaiian activity is the lava lake, a pool of liquid lava with convectional circulation that occupies a preexisting shallow depression or pit crater. *See* LAVA.

Strombolian eruptions are somewhat more explosive eruptions of lava, with greater viscosity, and produce a larger proportion of pyroclastic material. Many of the volcanic bombs and lapilli assume rounded or drawn-out forms during flight, but commonly are sufficiently solid to retain these shapes on impact.

Generally still more explosive are the vulcanian type of eruptions. Angular blocks of viscous or solid lava are hurled out, commonly accompanied by voluminous clouds of ash but with little or no lava flow.

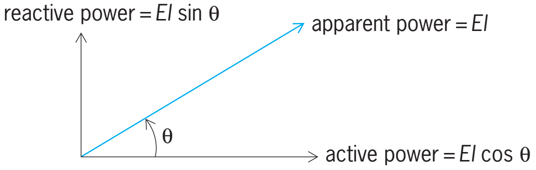
Peléean eruptions are characterized by the heaping up of viscous lava over and around the vent to form a steep-sided hill or volcanic dome. Explosions, or collapses of portions of the dome, may result in glowing avalanches (nuées ardentes).

Plinian eruptions are paroxysmal eruptions of great violence—named after Pliny the Elder, who was killed in A.D. 79 while observing the eruption of Vesuvius—and are characterized by voluminous explosive ejections of pumice and by ash flows. The copious expulsion of viscous siliceous magma commonly is accompanied by collapse of the summit of the volcano, forming a caldera, or by collapse of the broader region, forming a volcano-tectonic depression. *See* CALDERA.

A major component of the science of volcanology is the systematic and, preferably, continuous monitoring of active and potentially active volcanoes. Scientific observations and measurements—of the visible and invisible changes in a volcano and its surroundings—between eruptions are as important, perhaps even more crucial, than during eruptions. Measurable phenomena important in volcano monitoring include earthquakes; ground movements; variations in gas compositions; and deviations in local gravity, electrical, and magnetic fields. These phenomena reflect pressure and stresses induced by subsurface magma movements and or pressurization of the hydrothermal envelope surrounding the magma reservoir. The monitoring of volcanic seismicity and ground deformations before, during, and following eruptions has provided the most useful and reliable information. *See* EARTHQUAKE; SEISMOLOGY.

Volcanoes are in effect windows into the Earth's interior; thus research in volcanology, in contributing to an improved understanding of volcanic phenomena, provides special insights into the chemical and physical processes operative at depth. However, volcanology also serves an immediate role in the mitigation of volcanic and related hydrologic hazards (mudflows, floods, and so on). Progress toward hazards mitigation can best be advanced by a combined approach. One aspect is the preparation of comprehensive volcanic hazards assessments of all active and potentially active volcanoes, including a volcanic risk map for use by government officials in regional and local land-use planning to avoid high-density development in high-risk areas. The other component involves improvement of predictive capability by upgrading volcano-monitoring methods and facilities to adequately study more of the most dangerous volcanoes. An improved capability for eruption forecasts and predictions would permit timely warnings of impending activity, and give emergency-response officials more lead time for preparation of contingency plans and orderly evacuation, if necessary. [R.I.T.]

Volt-ampere The apparent-power index of drive level for sinusoidal alternating-current loads. A circuit branch with E volts across its two terminals, carrying I amperes from one to the other, is said to be receiving EI volt-amperes of apparent power, whatever may be the phase lag θ of current behind voltage. If such a load is driven through a transformer, the volt-amperes into the transformer primary is the same number as the volt-amperes into the load.



Apparent, active, and reactive power.

Practical computation of real power, reactive power, and apparent power is usually done with complex-number algebra using the geometrical diagram of the illustration. [M.G.F.]

Voltage amplifier An electronic circuit whose function is to accept an input voltage and produce a magnified, accurate replica of this voltage as an output voltage. The voltage gain of the amplifier is the amplitude ratio of the output voltage to the input voltage. Often, electronic amplifiers designed to operate in different environments are categorized by criteria other than their voltage gain, even though they are voltage amplifiers in fact. Many specialized circuits are designed to provide voltage amplification. *See* AUDIO AMPLIFIER; CASCODE AMPLIFIER; VIDEO AMPLIFIER.

Voltage amplifiers are distinguished from other categories of amplifiers whose ability to amplify voltages, or lack thereof, is of secondary importance. Amplifiers in other categories usually are designed to deliver power gain (power amplifiers, including push-pull amplifiers) or to isolate one part of a circuit from another (buffers and emitter followers). Power amplifiers may or may not have voltage gain, while buffers and emitter followers generally produce power gain without a corresponding voltage gain. *See* BUFFERS (ELECTRONICS); EMITTER FOLLOWER; POWER AMPLIFIER; PUSH-PULL AMPLIFIER.

Transistor amplifiers, such as the junction field-effect transistor (JFET) or the bipolar junction transistor (BJT) amplifier, will not operate properly without proper gate (JFET) or base (BJT) bias voltages applied in series with the signal voltage. These bias circuits can be modeled as ideal voltage sources. The bias and signal voltages are chosen so that the total input voltage—bias plus signal—will not cut off or saturate the amplifier for any value in the range of the input signal voltage. In addition to a bias voltage source, well-designed bipolar transistor amplifiers require negative feedback at dc to protect the transistor from thermal runaway. *See* BIAS (ELECTRONICS).

To obtain high gain, cascades of single amplifier circuits are used, usually with a coupling network, actually a simple filter, inserted between the stages of amplification. One such filter is a high-pass network formed by a coupling capacitor, the output resistances of the driving stage, and the input resistance of the driven stage. Since dc voltages are blocked by the capacitor, this ac coupling permits independently setting dc bias voltages for each amplifier stage in the cascade. The coupling network also rejects signals with ac frequency components below a cutoff. The capacitor must be sufficiently large not to attenuate any of the frequencies that are to be amplified. If dc is to be amplified, a direct-coupled amplifier is required, and the design is somewhat more complicated since dc bias voltages on each transistor now cannot be set independently. *See* DIRECT-COUPLED AMPLIFIER; ELECTRIC FILTER.

The amplifiers discussed above are called single-ended amplifiers, since their input and output voltages are referred to a common reference point which by convention is called ground. These single-ended circuits, while satisfactory for most noncritical applications, have several weaknesses which degrade their performance in high-gain, weak-signal applications. Their unbalanced construction and their use of a common ground point for return currents makes them susceptible to noise pickup.

To minimize noise on sensitive signal lines, special balanced differential amplifier circuits are often used in critical amplifier applications. Differential amplifiers are designed to have equal impedances to ground for each side of the signal line and to have an output voltage proportional to the difference of the voltages from each signal line to ground. This symmetry cancels common-mode noise voltages, voltages which tend to appear on each of the signal lines as equal voltages to ground. Proper circuit design, with attention to the symmetry of the input circuit construction, can ensure that the majority of undesired noise pickup will be common-mode noise and, hence, will be attenuated by the differential amplifier. *See* DIFFERENTIAL AMPLIFIER; INSTRUMENTATION AMPLIFIER.

In cases where a voltage amplifier is required for some special purpose, operational amplifiers are often used to fill the need. The operational amplifier is an integrated circuit containing a cascade of differential amplifier stages, usually followed by a push-pull amplifier acting as a buffer. The differential voltage gain of the operational amplifier is very high, about 100,000 at low frequencies, while its input impedance is in the megohm range and its output impedance is usually under 100 ohms. The amplifier is designed to be used in a negative-feedback configuration, where the desired gain is controlled by a resistive voltage divider feeding a fraction of the output voltage to the inverting input of the operational amplifier.

With needed amplification built into many integrated circuits and with the availability of operational amplifiers for special-purpose amplification needs, there is seldom a need to design and build a voltage amplifier from discrete components. *See* AMPLIFIER; OPERATIONAL AMPLIFIER. [P.V.L.]

Voltage measurement Determination of the difference in electrostatic potential between two points. The unit of voltage in the International System of Units (SI) is the volt, defined as the potential difference between two points of a conducting wire carrying a constant current of 1 ampere when the power dissipated between these two points is equal to 1 watt.

Direct-current voltage measurement. The chief types of instruments for measuring direct-current (constant) voltage are potentiometers, resistive voltage dividers, pointer instruments, and electronic voltmeters.

The most fundamental dc voltage measurements from 0 to a little over 10 V can now be made by direct comparison against Josephson systems. At a slightly lower accuracy level and in the range 0 to 2 V, precision potentiometers are used in conjunction with very low-noise electronic amplifiers or photo-coupled galvanometer detectors. Potentiometers are capable of self-calibration, since only linearity is important, and can give accurate measurements down to a few nanovolts. When electronic amplifiers are used, it may often be more convenient to measure small residual unbalance voltages, rather than to seek an exact balance. *See* AMPLIFIER; GALVANOMETER; JOSEPHSON EFFECT.

Voltage measurements of voltages above 2 V are made by using resistive dividers. These are tapped chains of wire-wound resistors, often immersed in oil, which can be self-calibrated for linearity by using a buildup method. Instruments for use up to 1 kV, with tappings typically in a binary or binary-coded decimal series from 1 V, are known as volt ratio boxes, and normally provide uncertainties down to a few parts per million. Another configuration allows the equalization of a string of resistors, all operating at their appropriate power level, by means of an internal bridge. The use of series-parallel arrangements can provide certain easily adjusted ratios.

Higher voltages can be measured by extending such chains, but as the voltage increases above about 15 kV, increasing attention must be paid to avoid any sharp edges or corners, which could give rise to corona discharges or breakdown. High-voltage dividers for use up to 100 kV with an uncertainty of about 1 in 10^5, and to 1 MV with an uncertainty of about 1 in 10^4, have been made. *See* CORONA DISCHARGE; ELECTRICAL BREAKDOWN.

For most of the twentieth century the principal dc indicating voltmeters have been moving-coil milliammeters, usually giving full-scale deflection with a current between 20 microamperes and 1 milliampere and provided with a suitable series resistor. Many of these will certainly continue to be used for many years, giving an uncertainty of about 1% of full-scale deflection.

The digital voltmeter has become the principal means used for voltage measurement at all levels of accuracy, even beyond one part in 10^7, and at all voltages up to 1 kV. Essentially, digital voltmeters consist of a power supply, which may be fed by either mains or batteries; a voltage reference, usually provided by a Zener diode; an analog-to-digital converter; and a digital display system. This design provides measurement over a basic range from zero to a few volts, or up to 20 V. Additional lower ranges may be provided by amplifiers, and higher ranges by resistive attenuators. The accuracy on the basic range is limited to that of the analog-to-digital converter. *See* ANALOG-TO-DIGITAL CONVERTER; ELECTRONIC POWER SUPPLY.

Most modern digital voltmeters use an analog-to-digital converter based on a version of the charge balance principle. In such converters the charge accumulated from the input signal during a fixed time by an integrator is balanced by a reference current of opposite polarity. This current is applied for the time necessary to reach charge balance, which is proportional to the input signal. The time is measured by counting clock pulses, suitably scaled and displayed. Microprocessors are used extensively in these instruments. *See* MICROPROCESSOR.

Alternating-current voltage measurements. Since the working standards of voltage are of the direct-current type, all ac measurements have to be referred to dc through transfer devices or conversion systems. A variety of techniques can be used to convert an ac signal into a dc equivalent automatically. All multimeters and most ac meters make use of ac-dc conversion to provide ac ranges. These are usually based on electronic circuits. Rectifiers provide the most simple example. *See* MULTIMETER.

In a commonly used system, the signal to be measured is applied, through a relay contact, to a thermal converter. In order to improve sensitivity, a modified single-junction thermal converter may be used in which there are two or three elements in a single package, each with its own thermocouple. The output of the thermal converter is measured by a very sensitive, high-resolution analog-to-digital converter, and the digital value memorized. When a measurement is required, the relay is operated, and the thermal converter receives its input, through a different relay contact, from a dc power supply, the amplitude of which is controlled by a digital and analog feedback loop in order to bring the analog-to-digital converter output back to the memorized level. The dc signal is a converted value of the ac input and can be measured. Modern versions of this type of instrument make use of microprocessors to control the conversion process, enhance the speed of operation, and include corrections for some of the errors in the device and range-setting components.

As in the dc case, digital voltmeters are now probably the instruments in widest use for ac voltage measurement. The simplest use diode rectification of the ac to provide a dc signal, which is then amplified and displayed as in dc instruments. This provides a signal proportional to the rectified mean. For most purposes an arithmetic adjustment is made, and the root-mean-square value of a sinusoidal voltage that would give the same signal is displayed. Several application-specific analog integrated circuits have been developed for use in instruments that are required to respond to the root-mean-square value of the ac input. More refined circuits, based on the logarithmic properties of transistors or the Gilbert analog multiplier circuit, have been developed for use in precision instruments. The best design, in which changes in the gain of the conversion circuit are automatically compensated, achieves errors less than 10 ppm at low and audio frequencies.

Sampling digital voltmeters are also used, in which the applied voltage is switched for a time very short compared with the period of the signal into a sample-and-hold circuit, of which the essential element is a small capacitor. The voltage retained can then be digitized without any need for haste. At low frequencies this approach offers high accuracy and great versatility, since the voltages can be processed or analyzed as desired. At higher frequencies, for example, in the microwave region, it also makes possible the presentation and processing of fast voltage waveforms using conventional circuits. *See* Oscilloscope.

Voltage measurements at radio frequencies are made by the use of rectifier instruments at frequencies up to a few hundred megahertz, single-junction converters at frequencies up to 500 MHz, or matched bolometers or calorimeters. At these higher frequencies the use of a voltage at a point must be linked to information regarding the transmission system in which it is measured, and most instruments effectively measure the power in a matched transmission line, usually of 50 ohms characteristic impedance, and deduce the voltage from it. *See* Bolometer; Microwave measurements; Microwave power measurement; Transmission lines.

Pulse voltage measurements are made most simply by transferring the pulse waveform to an oscilloscope, the deflection sensitivity of which can be calibrated by using low-frequency sine waves or dc. Digital sampling techniques may also be used. *See* Electrical measurements; Voltmeter. [R.B.D.K.]

Voltage-multiplier circuit

A circuit which produces a dc output voltage that is a fixed multiple of the input dc voltage or the peak voltage of an ac input waveform. This fixed multiple is approximately an integer ($\pm 2, \pm 3, \pm 4, \ldots$). Voltage multipliers are used to produce a high dc voltage where modest load current is required. The circuit can be implemented with diodes and capacitors or with switched capacitors.

A diode passes conventional current in only one direction. In the diode-capacitor voltage doubler, this current through one of the diodes charges one of the capacitors to approximately the peak value of the input voltage. The series combination of the input source and the capacitor generates a voltage across the diode that varies from approximately 0 to -2 times the peak input voltage. The diode is reverse biased except for short intervals to replace charge drained from the capacitor to supply the load current or leakage. A second diode and capacitor form another peak detecting circuit with the voltage across the first diode as the input. This results in a negative dc output voltage equal to twice the peak of the input waveform. The polarity of the output can be reversed by simply reversing both diodes. Another version of the voltage doubler produces two outputs, one equal to the peak input voltage and the other to its negative, using the same components. This is realized by connecting a positive and a negative peak detector across the input. *See* Capacitor; Diode.

A typical voltage-multiplier circuit that uses switched capacitors is a dc-to-dc converter that generates +10-V and −10-V dc sources from a single +5-V dc source. A common application for this circuit is to use a +5-V dc power supply to power integrated circuits which require positive and negative voltages. Such switched-capacitor applications are well suited to integrated circuits because the transistor switches and the associated control circuitry take up very little space and the added cost is negligible. *See* Electronic power supply; Integrated circuits; Switched capacitor; Transistor. [N.G.Di.]

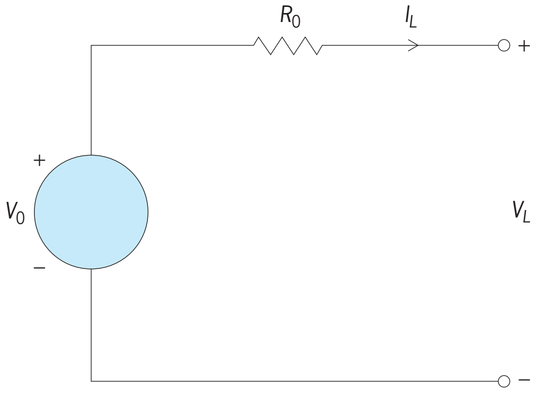
Voltage regulation

The change in voltage magnitude that occurs when the load (at a specified power factor) is reduced from the rated or nominal value to zero, with no intentional manual readjustment of any voltage control, expressed in percent of nominal full-load voltage. Voltage regulation is a convenient measure of the sensitivity of a device to changes in loading. *See* Generator; Transformer; Voltage regulator. [P.M.A.]

Voltage regulator

A device or circuit that maintains a load voltage nearly constant over a range of variations of input voltage and load current. Voltage regulators are used wherever the unregulated voltage would vary more than can be tolerated by the electrical equipment using that voltage. Alternating-current distribution feeders use regulators to keep the voltage supplied to the user within a prescribed range. Electronic equipment often has voltage regulators in dc power supplies.

Electronic regulator. A dc power supply is an essential component in any electronic system. The illustration shows a Thévenin equivalent circuit of a power supply voltage source having an open-circuit (no-load) voltage V_0 and output resistance R_0. When a load with resistance R_L is connected to the output of this supply, a load current $I_L = V_L/R_L$ flows through R_0, resulting in a drop in load voltage V_L as given by Eq. (1).



Equivalent circuit of a basic dc power supply.

$$V_L = V_0 - I_L R_0 \tag{1}$$

A basic power supply as modeled above exhibits two undersirable characteristics. The first is that the load voltage V_L decreases with increasing load current I_L. This effect can be severe in supplies with large effective output resistances. Such supplies are said to have poor load regulation. The second problem is that

V_L depends directly on the source V_0. In practice, V_0 might be derived from a relatively inaccurate source such as the ac line voltage (after suitable rectification and filtering) or a battery. Fluctuations in V_0 reflect directly onto the voltage experienced by the load. In this case, the supply is said to have poor line regulation. An ideal power supply would exhibit perfect load regulation (V_L independent of I_L) and perfect line regulation (V_L independent of V_0) and would provide an output voltage of the form of Eq. (2), where V_{ref} is a well-defined reference voltage and k is a constant scaling factor. The task of an electronic voltage regulator is to provide an output voltage characteristic that closely approximates the ideal of Eq. (2), given an unregulated supply voltage as an input.

$$V_L = kV_{\text{ref}} \qquad (2)$$

Feedback network. Typically, electronic voltage regulators employ a feedback network, where a high-gain amplifier compares a fraction of the load voltage V_L/k with a constant reference V_{ref}. Any difference between these two voltages is amplified and used to control a series pass device in a manner whereby this difference is minimized. For an ideal amplifier with zero offset and infinite voltage gain, the difference is reduced to zero and the ideal relationship of Eq. (2) is realized. *See* FEEDBACK CIRCUIT.

The wide range of applications for electronic voltage regulators has led to the development of these circuits in fully monolothic integrated circuit technology, where all or most of the required circuit components are realized on a single chip of silicon. Offering various output current and voltage ratings, and output voltages of either positive or negative polarity, several commercial regulator integrated circuits are now available to suit the requirements of most applications. The designs of these regulators have matured and have become rather sophisticated. In addition to implementation of the high-gain feedback amplifier, the series pass element, and an accurate voltage reference, all on a single silicon die, built-in protection against overload conditions (such as output short circuits and excessive operating temperature) is now standard. Novel circuit-design, processing, and packaging techniques have been developed and implemented to achieve increased accuracy, temperature stability, efficiency, reliability, and power-handling capability, while reducing package size and cost. *See* INTEGRATED CIRCUITS. [A.P.N.]

Power-system regulator. Voltage regulators are used on distribution feeders to maintain voltage constant, irrespective of changes in either load current or supply voltage. Voltage variations must be minimized for the efficient operation of industrial equipment and for the satisfactory functioning of domestic appliances, television in particular. Voltage is controlled at the system generators, but this alone is inadequate because each generator supplies many feeders of diverse impedance and load characteristics. Regulators are applied either in substations to control voltage on a bus or individual feeder or on the line to reregulate the outlying portions of the system. These regulators are variable autotransformers with the primary connected across the line. The secondary, in which an adjustable voltage is induced, is connected in series with the line to boost or buck the voltage. *See* AUTOTRANSFORMER; ELECTRIC DISTRIBUTION SYSTEMS; ELECTRIC POWER SUBSTATION. [D.D.MacC.]

Voltage regulators are used on rotating machines in power generation applications to automatically control the field excitation so as to maintain a desired machine output voltage. Rotating machines, both small (down to 1 kW) and large (up to 1,000,000 kW), are the predominant means of power generation throughout the world, and voltage regulators of varying design and sophistication are employed on most of them. Even ac generators (or alternators) in automotive applications employ voltage regulators utilizing similar principles. *See* DIRECT-CURRENT GENERATOR; ELECTRIC POWER GENERATION; ELECTRIC ROTATING MACHINERY; GENERATOR. [J.D.Hu.]

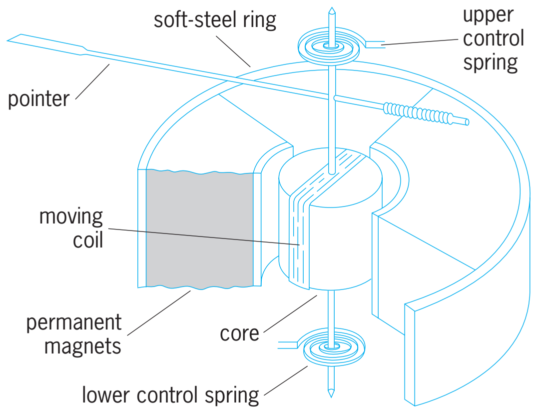
Voltmeter An instrument for the measurement of the electric potential difference between two conductors. Many different kinds of instruments are available to suit different purposes. Voltages of the order of picovolts (10^{-12} V) to megavolts (10^6 V) can be measured. Frequencies from zero (dc) to many megahertz and accuracies in the range from a fraction of part per million (ppm) to a few percent may be covered. *See* ELECTRICAL UNITS AND STANDARDS; VOLTAGE MEASUREMENT.

Analog voltmeters. Where no great accuracy is required, a voltage may be indicated by a mechanical displacement of a pointer against a scale. There is a wide variety of principles on which instruments of this type can be based. The d'Arsonval movement (see illustration) is one of the most popular constructions. This is basically a current-sensing instrument and is used in conjunction with a suitable resistance in series to measure voltage. A further variant, taut-band suspension, uses a pair of resilient strips under tension to carry the current to the coil, locate it, and provide the rotational restoring force. *See* AMMETER; MULTIMETER.

The permanent-magnet, moving-coil instrument is very sensitive, but by its nature is responsive only to the average value of the current flowing through the coil. It is therefore unsuitable for ac. A rectifier circuit can be used in order to combine the sensitivity of the movement with ac response. A transformer can be used to reduce the nonlinearity that results from the forward voltage drop of the diode rectifiers, at the expense of current drain. *See* RECTIFIER; TRANSFORMER.

Electronic voltmeters. The movements so far described require energy from the signal being measured to cause the deflection. The resulting current is liable to modify the voltage at the measurement point. To reduce this loading effect, active circuits are often used between the input terminals and the indicating movement. Once an independent source of power is available, electronic circuits can be used to provide other features, including a variety of kinds of signal processing and digital presentation of the results.

Digital voltmeters. Digital voltmeters (DVMs) are now the preferred instruments for ac and dc measurements at all levels of accuracy and at all voltages up to 1 kV. Essentially a digital voltmeter consists of a voltage reference, usually provided by a Zener diode, an analog-to-digital converter and digital display system, and a power supply, which may be derived from either the mains or a battery. The basic range of the instrument provides measurement from zero to 10 or 20 V. Additional lower ranges may be provided by amplifiers, whose gain is stabilized by precision resistors. These electronic input amplifiers often provide a very high input impedance, perhaps exceeding 10^{10} Ω. Since this impedance is obtained by active means, a much lower impedance may be found when the instrument is switched off. Higher voltage ranges are provided by the use of resistive



D'Arsonval moving-coil instrument. (*General Electric Co.*)

attenuators, usually limited to a value of 10 MΩ by economic restraints. The best accuracy is always obtained on the basic range, where it is limited to that of the analog-to-digital converter. *See* Amplifier; Analog-to-digital converter; Electronic power supply; Zener diode.

Sampling voltmeters. A sampling voltmeter is an instrument that uses sampling techniques and has advantages at very low frequencies, that is, below 1 Hz, and also at very high frequencies, where conventional measuring circuits become difficult or even impossible. Low-frequency sampling instruments achieve uncertainties as small as 50 ppm with 10-V signals; high-frequency instruments can achieve a few percent with frequencies as high as 12 GHz and amplitudes as small as 1 mV. Measurements are generally of rectified-mean or root-mean-square voltage. Modern digital sampling voltmeters may also be capable of calculating and displaying voltages or energy density as a function of frequency. Sampling voltmeters, like conventional voltmeters, may use scale and pointer meters, graphic recorders, cathode-ray tubes, or digital indicators for readout of measured quantities. *See* Waveform determination. [R.B.D.K.]

Volume control systems Systems that maintain proper audio signal levels in applications such as sound recording, public address systems, and broadcasting. Two types of electronic devices, compressors and limiters, perform this operation automatically without the need for human intervention, but differ in the way that they perform.

A compressor slowly varies its gain so as to maintain its output volume level at some constant average value. When used to process the audio signal from a microphone, a compressor equalizes the loudness of speech from different talkers. It compresses the dynamic range of the signal. A limiter controls the peak levels of an audio signal. Limiters are used to prevent overmodulation of transmitters in broadcast facilities, to prevent peak clipping in public address system audio amplifiers, and to prevent overload of audio recorders. A compressor followed by a limiter can be used to dramatically enhance the loudness of an audio signal without an increase in the peak level. This is a common practice in broadcasting to increase signal range and to maximize program loudness.

The input of a compressor or a limiter is applied to a variable-gain amplifier. A gain-control circuit monitors the level of the output and generates a voltage which controls the amplifier gain. Manual controls at the input and output allow setting the levels for proper interface to external devices. *See* Automatic gain control (AGC); Gain; Limiter circuit; Radio broadcasting; Sound recording; Sound-reinforcement system; Sound-reproducing system. [W.M.L.]

Volume unit (vu) A unit used to measure the strength of electrical waves produced by microphones. In sound recording, broadcasting, and public address systems, microphones convert acoustical signals into electrical waves that are nonperiodic and cannot be simply described in terms of voltage, current, power, or frequency. To provide a practical means of assigning a numerical value to the strength of such waves, the concept of “volume” is used. The volume of an audio program wave is the magnitude of the wave as measured with a standard volume indicator. This is a meter calibrated to read in volume units (vu, pronounced vee-you). [W.M.L.]

Volumetric efficiency In describing an engine or gas compressor, the ratio of volume of working substance actually admitted, measured at specified temperature and pressure, to the full piston displacement volume. For a liquid-fuel engine, such as a diesel engine, volumetric efficiency is the ratio of volume of air drawn into a cylinder to the piston displacement. For a gas-fuel engine, such as a gasoline engine with carburetor, throttle body, or port injection, volumetric efficiency is based on the charge of fuel and air drawn into the cylinder. *See* Compressor; Engine.

Volumetric efficiency of naturally aspirated automobile and aircraft reciprocating engines may be 85–90% at rated speed. Supercharging or turbocharging increases volumetric efficiency, giving values over 100%. Air compressors, refrigerator compressors, and dry vacuum pumps are generally specified for a volumetric efficiency of 60–90%. *See* Internal combustion engine; Reciprocating aircraft engine. [D.L.An.]

Volvocales A large order of green algae (Chlorophyceae) comprising all forms that normally are flagellate and motile. In zoological classification, it is called Volvocida, in the class Phytomastigophora. The cells are solitary or united into colonies of definite structure (coenobia), often with morphological and functional differentiation among the component cells. Some taxonomists place the unicellular forms in a separate order, Chlamydomonadales. Unicells that have volvocalean cytological features but are nonflagellate and sedentary in their vegetative phase are considered here to constitute the order Tetrasporales. Or these sedentary forms may be retained in the Chlamydomonadales or Volvocales. *See* Chlorophyceae.

Of the unicellular forms, *Chlamydomona*, which is presumed to be similar to ancestral Volvocales, has a very small cell body (usually 7–40 micrometers in greatest dimension) that is spherical, ellipsoid, or pyriform. The wall (or theca), which consists primarily of glycoproteins, is usually smooth, but may have blunt protuberances. The cell bears two smooth flagella of equal length at its apex, with contractile vacuoles and an eye-spot at the anterior end. Chloroplasts contain one or more pyrenoids. As in all Volvocales, the cells are uninucleate. Other genera with chlamydomonad features are distinguished on the basis of flagellar number, presence or absence of photosynthetic pigments, presence or absence of pyrenoids, and cell shape. Together with *Chlamydomonas* they constitute the family Chlamydomonadaceae. Two other families of unicellular Volvocales are recognized: Dunaliellaceae, in which the unicells are naked; and Phacotaceae, in which the unicells are surrounded by a lorica—a rigid, hyaline or dark brown, wall-like structure, which is often impregnated with compounds of calcium, iron, or manganese and which may be sculptured. Unicellular Volvocales are ubiquitous in fresh, brackish, and coastal marine waters and in such terrestrial habitats as soil, snow, and ice. They are especially abundant in organically enriched bodies of fresh water.

Most colonial (coenobial) Volvocales are placed in the family Volvocaceae. In this family, coenobia are composed of *Chlamydomonas*-like biflagellate cells embedded in a firm gelatinous matrix. Coenobia have the form of a slightly curved plate or are ellipsoid to spherical. The component cells are arranged according to a predetermined pattern. Asexual reproduction is by repeated bipartition of the protoplast of an ordinary or specialized cell to form a new coenobium (autocoenobium) that is a miniature of the parent. Sexual reproduction forms a phylogenetic series from isogamy through anisogamy to oogamy. The Volvocaceae are abundant in organically enriched bodies of fresh water, especially temporary pools. [P.C.Si.; R.L.Moe.]

Volvocida An order of the class Phytamastigophorea. The protozoans, also known as the Phytomonadida, are grass-green, but a few are colorless (*Polytoma*). Individual cells may be as small as 8 micrometers. They closely relate the flagellates to the algae. They have one, two, four, or eight flagella; plural flagella are usually equal. The group is large and about one-fourth of the approximately 100 genera form colonies, with flagella only in reproductive cells. Cell walls are of cellulose and often they are thick. Chromatophores contain the same chlorophylls as higher plants. Pyrenoids have the usual form commonly found with starch as the reserve material. *See* Cilia and flagella; Phytamastigophorea. [J.B.L.]

VOR (VHF omnidirectional range) A short-range air navigation aid, which provides azimuth aid by visual means of cockpit instruments. A VOR system provides properly equipped aircraft with bearing information relative to the VOR station and magnetic north. The VOR system is used for landing, terminal, and en route guidance. It also gives virtually static-free regular weather broadcasts, special flight instructions, and voice and code station identification. The VOR service operates in the very high frequency (VHF) band between 108 and 118 MHz, sharing alternate channels with the localizer in the instrument landing system. Typically, VOR stations are co-located with a distance measuring equipment (DME) system or a tactical are navigation (TACAN) system. The combined systems are referred to as VOR/DME or VORTAC stations and provide both azimuth and distance information. *See* Distance-measuring equipment; Instrument landing system (ILS); Tacan.

The VOR operates on the principle that the phase difference between two signals can be employed as a means of determining azimuth if one of the signals maintains a fixed phase through 360°, so it can be used as a reference, while the other is made to vary as a direct function of azimuth. The phase difference between these two signals will then equal the azimuth of the aircraft. In practice, two demodulated 30-Hz signals are used. These are called the reference-phase and variable-phase signals. *See* Electronic navigation systems.

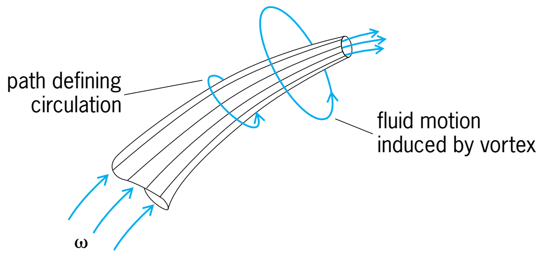
There are two types of VOR equipment. One employs a four-loop antenna array and is called conventional VOR. The other, Doppler VOR, having a 50-loop or larger antenna array located around a single-loop carrier antenna, is based on the Doppler principle and is designed for installation at locations which present especially difficult siting problems due to multipath conditions. Although the two types differ in design, from the standpoint of air navigation they function in essentially the same manner and can be received by the same equipment. Both types are used to define route intersections and most domestic airways. *See* Doppler effect; Doppler VOR.

As the United States national airspace is increasingly congested, serious consideration is being given to replacing or supplementing the VOR system with satellite-based navigation. It is believed that satellites will enable more flexible routing and that satellite positioning can be effectively integrated into air-traffic surveillance systems. However, VOR is expected to remain in place at least until the integrity of satellite-based services improves to the level of VOR services and until the costs of transitioning to satellite services are reduced to an acceptable level. *See* Satellite navigation systems. [W.I.Th.; R.B.F.]

Vortex In common usage, a fluid motion dominated by rotation about an isolated curved line in space, as in a tornado, a whirlpool, a hurricane, or a similar natural phenomenon. The importance of vortices is due to two characteristics: general fluid flows can be represented by a superposition of vortices; and vortices, once created, have a persistence that increases as the effects of viscosity are reduced. The aerodynamic lift forces and most other contributors to the forces and moments on aircraft and other bodies moving through fluids do not exist in the absence of vortices. *See* Aerodynamic force; Hurricane; Tornado; Waterspout.

The strength of rotation is measured by a vector called the vorticity, ω, defined as the curl of the velocity vector. A region of flow devoid of vorticity is known as irrotational. The spatial distribution of the vorticity vector provides a precise characterization of the rotation effects in fluids, and the nature of what subjectively and popularly would be called a vortex. *See* Calculus of vectors; Laplace's irrotational motion.

The vorticity vector field can be constructed by measuring the instantaneous angular velocity of small masses of fluid. The vorticity vector is twice the local angular velocity vector. Starting at any arbitrary point in the fluid, a line, called a vortex line, can be drawn everywhere parallel to the vorticity vector.



Vortex tube; ω is the vorticity.

A bundle of vortex lines defines a tubular region of space, called a vortex tube, with a boundary surface that no vortex line crosses.

Two simple rules follow from the definitions: (1) a vortex tube must either close on itself or end on a boundary of the fluid (including extending to "infinity" if the fluid is imagined to fill all space); and (2) at every cross section of a given vortex tube, the area integral of the normal vorticity has the same value at any given instant. The area integral is, by Stokes' theorem, equal to a line integral around the periphery of the tube, namely, the line integral of the velocity component parallel to the direction of the line integral. This quantity is also known as the circulation around the line, so at an instant of time a vortex tube has a unique value of the circulation applying to all cross sections (see illustration).

Vortex lines confined to a layer rather than a tube describe fluid motion of a different character. This is most easily visualized when the direction of the vorticity does not vary, so all of the vortex lines are straight and parallel. Assuming the vorticity has zero magnitude outside the layer, this vortex layer represents a flow with a different speed and direction on either side of the layer. Such a change in speed occurs at the edge of wakes produced by wind passing over an obstacle. Reducing the thickness of this layer of vorticity to zero leads to an idealization known as a vortex sheet, a surface in space across which there is a finite jump in velocity tangent to the surface. Vortex sheets have a tendency to roll up, because of self-induction. [S.Lei.]

Vorticity A vector proportional to the local angular velocity of a fluid flow. The vorticity, $\vec{\omega}$, is a derived quantity in fluid mechanics, defined, for a flow field with velocity $\vec{u}$, by Eq. (1). As the

$$\vec{\omega} = \nabla \times \vec{u} \qquad (1)$$

curl of the velocity vector, the vorticity is a vector with the dimensions of both a frequency and an angular velocity $[\vec{\omega}] = [\mathrm{s}^{-1}]$. The component of vorticity along a particular axis is related to the rate of rotation of the fluid about the axis. For this reason, flows for which $\vec{\omega} = 0$ are described as irrotational. *See* Calculus of vectors; Dimensional analysis; Velocity.

Circulation. Closely related to vorticity is the fluid circulation, Γ, defined, for any closed contour, C, in a fluid, by Eq. (2). In

$$\Gamma = \oint_C \vec{u} \cdot d\vec{l} = \iint_S \vec{\omega} \cdot \vec{n}\, dS \qquad (2)$$

this definition, $\oint_C$ indicates the conventional counterclockwise contour integral around the contour C, $\vec{l}$ is a unit vector tangent to the contour, and S is an arbitrary curved surface bounded by the contour C. [The equality of the two integrals in Eq. (2) may be deduced by the application of Stokes' theorem.] The circulation is thus a scalar quantity equal to the integrated component of vorticity normal to the surface around which Γ is taken. Circulation is important because the Kutta-Joukowski law of aerodynamics states that the lift generated by a two-dimensional airfoil is $L = \rho U \Gamma$. In this expression, ρ is the fluid density, U is the free-stream velocity, and Γ is the bound circulation of the airfoil, defined conventionally as the negative of the definition above. *See* AERODYNAMICS; AIRFOIL; STOKES' THEOREM; SUBSONIC FLIGHT.

Vortex line and vortex tube. A vortex line is defined as a line that is everywhere tangent to the local vorticity vector (analogous to a streamline). A series of adjacent vortex lines is referred to as a vortex tube. The first Helmholtz vortex law states that at any instant in time the circulation about all loops taken around the exterior of a vortex tube is the same. Thus, vortex tubes must either form loops entirely within a fluid or terminate at some fluid boundary. *See* VORTEX.

Kelvin's theorem. Kelvin's theorem considers how the circulation Γ around a material loop in a fluid (a loop that moves with the fluid) varies in time. Starting with the Navier-Stokes equations, Lord Kelvin showed that if (1) the fluid is inviscid along the loop, (2) the fluid is subject only to potential body forces, and (3) the fluid pressure is a function of density alone, then the rate of change of Γ is 0. In other words, the circulation around a material loop is time-independent. Kelvin's theorem may also be stated slightly differently: subject to the above three constraints, vortex lines are material lines, convected with the local fluid velocity. *See* KELVIN'S CIRCULATION THEOREM.

Generation. Kelvin's theorem can tell what happens when vorticity is already present in a flow, but it sheds no light on how vorticity is generated. To answer this question, it is useful to consider situations for which Kelvin's theorem is inapplicable: flow with viscosity, with nonpotential body forces, and for which the pressure is not solely a function of the density.

The action of viscosity has two effects on vorticity. One effect of viscosity is to cause the diffusion of vorticity in a fluid. A second effect of viscosity is the generation of vorticity at a wall where there is a pressure gradient at the wall. *See* VISCOSITY.

A common example of a nonpotential body force is the Coriolis force, which is present in a rotating frame of reference. This force generates vorticity in a fluid, and is a major cause of the large-scale circulation in the atmosphere and oceans. *See* CORIOLIS ACCELERATION.

There are many flows for which the pressure may not be solely a function of the density (so-called baroclinic flows), such as the flow of gas with heat addition and the flow of water with salinity variations. Pressure gradients in such flows generate vorticity. This source of vorticity is called baroclinic torque, and is important in atmospheric flow, buoyancy-driven flow, and oceanographic flow. *See* BAROCLINIC FIELD; DYNAMIC INSTABILITY; DYNAMIC METEOROLOGY. [S.I.G.]

W

Wake flow The flow downstream of a body immersed in a stream or the flow behind a body propagating through a fluid. Wakes are narrow elongated regions, filled with large and small eddies. The wake eddies of a bridge pier immersed in a river stream, or of a ship propelled through the water, are often visible on the surface. On windy days, similar wakes form downstream of smoke stacks or other structures, but the eddies in the air are not visible unless some smoke or dust is entrained in them.

Turbulence in the wake of bluff bodies consists of all sizes of eddies, which interact with each other in their unruly motion. Yet, out of this chaos emerges some organization, whereby large groups of eddies form a well-ordered sequence of vortices. The sense of rotation of these vortices alternates, and their spacing is quite regular. As a result, they can drive a structure that they encounter, or they can exert on the body that created them a force alternating in sign with the same frequency as that of the formation of the vortices. Such forces can impose on structures unwanted vibrations which often lead to serious damage. Flow-induced forces can be catastrophic if they are in tune with the frequency of vibration of the structure. *See* Fluid flow; Fluid-flow principles; Kármán vortex street; Turbulent flow.

Wakes are sustained for very large distances downstream of a body. Ship wakes retain their turbulent character for miles behind a vessel and can be detected by special satellites hours after their generation. Similarly, condensation in the wake of aircraft sometimes makes it look like a narrow braided cloud, traversing the sky. [D.P.T.]

Wall construction Methods for constructing walls for buildings. Walls are constructed in different forms and of various materials to serve several functions. Exterior walls protect the building interior from external environmental effects such as heat and cold, sunlight, ultraviolet radiation, rain and snow, and sound, while containing desirable interior environmental conditions. Walls are also designed to provide resistance to passage of fire for some defined period of time, such as a one-hour wall. Walls often contain doors and windows, which provide for controlled passage of environmental factors and people through the wall line.

Walls are designed to be strong enough to safely resist the horizontal and vertical forces imposed upon them, as defined by building codes. Such loads include wind forces, self-weight, possibly the weights of walls and floors from above, the effects of expansion and contraction as generated by temperature and humidity variations as well as by certain impacts, and the wear and tear of interior occupancy. *See* Loads, dynamic; Loads, transverse.

Modern building walls may be designed to serve as either bearing walls or curtain walls or as a combination of both in response to the design requirements of the building as a whole. Both types may appear similar when complete, but their sequence of construction is usually different.

Bearing-wall construction may be masonry, cast-in-place or precast reinforced concrete, studs and sheathing, and composite types. The design loads in bearing walls are the vertical loading from above, plus horizontal loads, both perpendicular and parallel to the wall plane. Bearing walls must be erected before supported building components above can be erected.

Curtain-wall construction takes several forms, including lighter versions of those used for bearing walls. These walls can also comprise assemblies of corrugated metal sheets, glass panels, or ceramic-coated metal panels, each laterally supported by light subframing members. The curtain wall can be erected after the building frame is completed, since it receives vertical support by spandrel beams, or relieving angles, at the wall line.

Masonry walls are a traditional, common, and durable form of wall construction used in both bearing and curtain walls. They are designed in accordance with building codes and are constructed by individual placement of bricks, blocks of stone, cinder concrete, cut stone, or combinations of these. The units are bonded together by mortar. *See* Concrete; Masonry; Mortar.

Reinforced concrete walls are used for both strength and esthetic purposes. Such walls may be cast in place or precast, and they may be bearing or curtain walls. Some precast concrete walls are constructed of tee-shaped or rectangular prestressed concrete beams, which are more commonly used for floor or roof deck construction. They are placed vertically, side by side, and caulked at adjacent edges. *See* Concrete beam; Reinforced concrete.

Stud and sheathing walls are a light type of wall construction, commonly used in residential or other light construction where they usually serve as light bearing walls. They usually consist of wood sheathing nailed to wood or steel studs, usually with the dimensions 2 × 4 in. (5 × 10 cm) or 2 × 6 in. (5 × 15 cm), and spaced at 16 in. (40 cm) or 24 in. (60 cm) on center—all common building module dimensions. The interior sides of the studs are usually covered with an attached facing material. This is often sheetrock, which is a sandwich of gypsum between cardboard facings. Composite walls are essentially a more substantial form of stud walls. They are constructed of cementitious materials, such as weatherproof sheetrock or precast concrete as an exterior sheathing, and sheetrock as an interior surface finish. *See* Gypsum; Precast concrete.

Prefabricated walls are commonly used for curtain-wall construction and are frequently known as prefab walls. Prefabricated walls are usually made of corrugated steel or aluminum sheets, although they are sometimes constructed of fiber-reinforced plastic sheets, fastened to light horizontal beams (girts) spaced several feet apart. Prefab walls are often made of sandwich construction: outside corrugated sheets, an inside liner of flat or corrugated sheet, and an enclosed insulation are fastened together by screws to form a thin, effective sandwich wall. These usually have tongue-and-groove vertical edges to permit sealed joints when the units are erected at the building site by being fastened to framing girts.

Glass, metal, or ceramic-coated metal panel walls are a common type of curtain wall used in high-rise construction. They are typically assembled as a sandwich by using glass, formed metal, or ceramic-coated metal sheets on the outside, and some form of liner, including possibly masonry, on the inside; insulation is enclosed.

Tilt-up walls are sometimes used for construction efficiency. Here, a wall of any of the various types is fabricated in a horizontal position at ground level, and it is then tilted up and connected at its edges to adjacent tilt-up wall sections. Interior partitions are a lighter form of wall used to separate interior areas in buildings. They are usually nonbearing, constructed as thinner versions of some of the standard wall types; and they are often designed for some resistance to fire and sound. Retaining walls are used as exterior walls of basements to resist outside soil pressure. They are usually of reinforced concrete; however, where the basement depth or exterior soil height is low, the wall may be constructed as a masonry wall. *See* BUILDINGS; RETAINING WALL; STRUCTURAL MATERIALS. [M.A.]

Walnut This name is applied to about a dozen species of large deciduous trees widely distributed over temperate North and South America, southeastern Europe, and central and eastern Asia. The genus (*Juglans*) is characterized by pinnately compound aromatic leaves and chambered or laminate pith. The staminate (male) flowers are borne in unbranched catkins on the previous season's growth, and the pistillate (female) flowers are terminal on the current season's shoots. The shells of the nuts of most species are deeply furrowed or sculptured.

Two species, the black walnut (*J. nigra*) and the Persian or English walnut (*J. regia*), are of primary importance for their timber and nuts. The butternut finds local use in the northeastern United States. The other species are sparingly used as shade trees, as grafting stocks, and as sources of nuts. *See* JUGLANDALES. [L.H.Mac.D.]

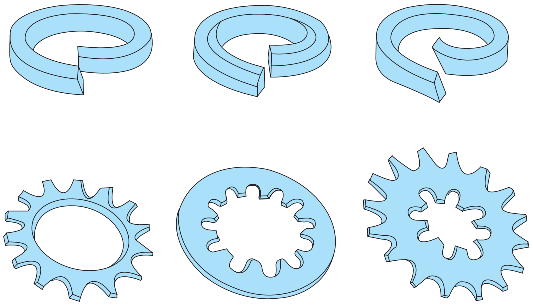
Warm-air heating system In a general sense, a heating system which circulates warm air. Under this definition both a parlor stove and a steam blast coil circulate warm air. Strictly speaking, however, a warm-air system is one containing a direct-fired furnace surrounded by a bonnet through which air circulates to be heated.

When air circulation is obtained by natural gravity action, the system is referred to as a gravity warm-air system. If positive air circulation is provided by means of a centrifugal fan (referred to in the industry as a blower), the system is referred to as a forced-air heating system.

Direct-fired furnaces are available for burning of solid, liquid, or gaseous fuels. Furnaces have also been designed which have air circulating over electrical resistance heaters. A completely equipped furnace-blower package consists of furnace, burner, bonnet, blower, filter, and accessories. The furnace shell is usually of welded steel. The burner supplies a positively metered rate of fuel and a proportionate amount of air for combustion. A casing, or jacket, encloses the furnace and provides a passage for the air to be circulated over the heated furnace shell. The casing is insulated and contains openings to which return-air and warm-air ducts can be attached. The blower circulates air against static pressure. The air filter removes dust particles from the circulating air. *See* OIL BURNER.

The complete forced-air heating system consists of the furnace-blower package unit; the return-air intake, or grille, together with return-air ducts leading from the grille to the return-air plenum chamber at the furnace; and the supply trunk duct and branch ducts leading to the registers located in the different spaces to be heated. *See* COMFORT HEATING. [S.Ko.]

Washer A flattened, ring-shaped device used to improve the tightness of a screw fastener. Three types of washer are in common use: plain, spring-lock, and antiturn (tooth-lock washers). Standard plain washers are used to protect a part from damage or to provide for a wider distribution of the load. Because a plain washer will not prevent a nut from turning, a locking-type washer should be used to prevent a bolt or nut from loosening under vibration (see illustration). Lock washers create a continuous pressure between the parts and the fastener. The antitum-type washers may be externally serrated, internally serrated, or both. The bent teeth bite into the bearing surface to prevent the nut from turning and the fastening from loosening under vibration. *See* SCREW FASTENER. [W.J.L.]



Lock washers. (***After W. J. Luzadder, Fundamentals of Engineering Drawing, 6th ed., Prentice-Hall, 1971***)

Watch A portable timepiece. Its operation may be described as mechanical, electromechanical, or electronic.

In the mechanical watch a mainspring in the barrel stores operating energy; the user retightens the spring daily by means of the winding stem. The wheel train advances at five increments per second under control by the escapement. From there the dial train turns the minute and hour hands across the watch face. *See* CLOCK; ESCAPEMENT; GEAR TRAIN; JEWEL BEARING; SPRING (MACHINES).

Among the variety of features incorporated into modern watches are: self-winding mechanisms, substitution of an electrochemical cell for the mechanical mainspring, and several forms of electromechanical escapement in place of the balance-and-hairspring mechanism.

When solid-state electronic integrated circuits became available in quantity, the all-electronic watch became a commercial reality. In it an electrochemical cell supplies the energy. A chain of binary dividers triggered from a crystal oscillator develops a train of seconds pulses. These pulses drive a digital counter or sealer, which develops minute and hour pulses to activate the digital display. *See* DIGITAL COUNTER; INTEGRATED CIRCUITS; OSCILLATOR; PIEZOELECTRICITY.

One form of readout uses a light-emitting diode (LED). Because illumination of the readout consumes most of the power in an electronic watch, a liquid crystal display (LCD) is used where low power consumption is a first consideration. *See* ELECTRONIC DISPLAY; HOROLOGY; LIGHT-EMITTING DIODE; LIQUID CRYSTALS. [F.H.R.]

Water The chemical compound with two atoms of hydrogen and one atom of oxygen in each of its molecules. It is formed by the direct reaction (1) of hydrogen with oxygen. The other

$$2H_2 + O_2 \rightarrow 2H_2O \qquad (1)$$

compound of hydrogen and oxygen, hydrogen peroxide, readily decomposes to form water, reaction (2). Water also is formed in

$$2H_2O_2 \rightarrow 2H_2O + O_2 \qquad (2)$$

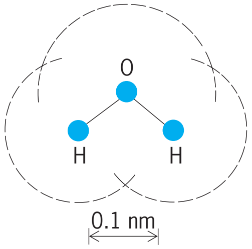
the combustion of hydrogen-containing compounds, in the pyrolysis of hydrates, and in animal metabolism. Some properties of water are given in the table.

Gaseous state. Water vapor consists of water molecules which move nearly independently of each other. The relative positions of the atoms in a water molecule are shown in the illustration. The dotted circles show the effective sizes of the isolated atoms. The atoms are held together in the molecule by chemical bonds which are very polar, the hydrogen end of each bond being electrically positive relative to the oxygen. When two molecules near each other are suitably oriented, the positive hydrogen of one molecule attracts the negative oxygen of the other,

Properties of water

Property	Value
Freezing point	0°C (32°F)
Density of ice, 0°C (32°F)	0.92 g/cm^3 (0.53 oz/in.^{3})
Density of water, 0°C (32°F)	1.00 g/cm^3 (0.578 oz/in.^{3})
Heat of fusion	80 cal/g (335 J/g)
Boiling point	100°C (212°F)
Heat of vaporization	540 cal/g (2260 J/g)
Critical temperature	347°C (657°F)
Critical pressure	217 atm (22.0 MPa)
Specific electrical conductivity at 25°C	1×10^{-7}/ohm-cm
Dielectric constant, 25°C (77°F)	78

and while in this orientation, the repulsion of the like charges is comparatively small. The net attraction is strong enough to hold the molecules together in many circumstances and is called a hydrogen bond. *See* Chemical bonding; Electronegativity; Gas; Valence.



The water molecule.

Solid state. Ordinary ice consists of water molecules joined together by hydrogen bonds in a regular arrangement. It appears that there is considerable empty space between the molecules. This unusual feature is a result of the strong and directional hydrogen bonds taking precedence over all other intermolecular forces in determining the structure of the crystal. *See* Crystal; Hydrogen bond.

Liquid state. The molecules in liquid water also are held together by hydrogen bonds. When ice melts, many of the hydrogen bonds are broken, and those that remain are not numerous enough to keep the molecules in a regular arrangement. As water is heated from 0°C (32°F), it contracts until 4°C (39°F) is reached and then begins the expansion which is normally associated with increasing temperature. This phenomenon and the increase in density when ice melts both result from a breaking down of the open, hydrogen-bonded structure as the temperature is raised. *See* Liquid.

Properties. The electrical conductivity of water is at least 1,000,000 times larger than that of most other nonmetallic liquids at room temperature. The current in this case is carried by ions produced by the dissociation of water according to reaction (3).

$$\mathrm{H_2O} \rightleftharpoons \mathrm{H^+} + \mathrm{OH^-} \qquad (3)$$

Water is an excellent solvent for many substances, but particularly for those which dissociate to form ions. Its principal scientific and industrial use as a solvent is to furnish a medium for purifying such substances and for carrying out reactions between them. *See* Solution; Solvent.

Water is not a strong oxidizing agent, although it may enhance the oxidizing action of other oxidizing agents, notably oxygen. Water is an even poorer reducing agent than oxidizing agent. One of the few substances that it reduces rapidly is fluorine. *See* Oxidation-reduction.

Substances with strong acidic or basic character react with water. For example, calcium oxide, a basic oxide, reacts in a process called the slaking of lime, reaction (4). Another type of substance with strong acidic character is an acid chloride. An example and its reaction with water is boron trichloride, reaction (5).

$$\mathrm{CaO} + \mathrm{H_2O} \rightarrow \mathrm{Ca(OH)_2} \qquad (4)$$

$$\mathrm{BCl_3} + 3\mathrm{H_2O} \rightarrow \mathrm{H_3BO_3} + 3\mathrm{HCl} \qquad (5)$$

This is termed hydrolysis, as is the reaction of an ester with water. *See* Hydrolysis.

Water also reacts with a variety of substances to form solid compounds in which the water molecule is intact, but in which it becomes a part of the structure of the solid. Such compounds are called hydrates. *See* Hydrate.

For various aspects of water, its uses, and occurrence *see* Heavy water; Hydrogen; Hydrology; Irrigation (agriculture); Nutrition; Oxygen; Plant-water relations; Precipitation (meteorology); Seawater; Triple point; Vapor pressure; Water analysis; Water conservation; Water microbiology; Water pollution; Water purification; Water softening; Water supply engineering; Water table; Water treatment; Waterpower. [H.L.F.]

Water-borne disease Disease acquired by drinking water contaminated at its source or in the distribution system, or by direct contact with environmental and recreational waters. Water-borne disease results from infection with pathogenic microorganisms or chemical poisoning.

These pathogenic microorganisms include viruses, bacteria, protozoans, and helminths. A number of microbial pathogens transmitted by the fecal-oral route are commonly acquired from water in developing countries where sanitation is poor. Viral pathogens transmitted via fecally contaminated water include hepatitis viruses A and E. Important bacterial pathogens transmitted via fecally contaminated water in the developing world are *Vibrio cholerae*, enterotoxigenic *Escherichia coli*, *Shigella*, and *Salmonella enterica* serotype Typhi. Water-borne protozoan pathogens in the developing world include *Giardia lamblia* and *Entamoeba histolytica*. The major water-borne helminthic infection is schistosomiasis; however, transmission is not fecal-oral. Another water-borne helmenthic infection is dracunculiasis (guinea worm infection).

In developed countries, fecal contamination of drinking water supplies is less likely. However, there have been outbreaks of diseases such as shigellosis and giardiasis associated with lapses in proper water treatment, such as cross-contamination of wastewater systems and potable water supplies. Animals are therefore more likely to play a role in water-borne disease in developed countries. Bacterial pathogens acquired from animal feces such as nontyphoid *S. enterica*, *Campylobacter jejuni*, and *E. coli* serotype O157:H7 have caused outbreaks of water-borne disease in developed countries where water is not properly chlorinated. Hikers frequently acquire *G. lamblia* infections from drinking untreated lake and stream water. *Giardia lamblia* may have animal reservoirs and can persist in the environment. A recently recognized pathogen apparently resistant to standard chlorination and filtration practices is the protozoan *Cryptosporidium parvum*. This organism is found in the feces of farm animals and may enter water supplies through agricultural runoff.

Chemical poisoning of drinking water supplies causes disease in both developing and developed countries. Lead, copper, and cadmium have been frequently involved. *See* Cholera; Escherichia; Medical parasitology; Schistosomiasis. [S.L.M.]

Water conservation The protection, development, and efficient management of water resources for beneficial purposes. Nearly every human activity—from agriculture to transportation to daily living—relies on water resources and affects the availability and quality of those resources. Water resource development has played a role in flood control, agricultural production, industrial and energy development, fish and wildlife resource management, navigation, and a host of other activities.

As a result of these impacts, natural hydrologic features have changed through time, pollution has decreased the quality of remaining water resources, and global climate change may affect the distribution of water in the future. *See* HYDROLOGY.

Water availability varies substantially between geographic regions, but it is also affected strongly by the population of the region. Asia, for example, has an extremely large total runoff but the lowest per-capita water availability. In addition, nearly 40% of the world's population lives in areas that experience severe to moderate water stress. Thus the combination of water and population distribution has resulted in a large difference in per-capita water use between countries.

Worldwide, nearly 4000 km^3 of water is withdrawn every year from surface and ground waters. This is a sixfold increase from the levels withdrawn in 1900 (since which time population has increased four times). Agriculture accounts for the greatest proportion of water use, with about two-thirds of water withdrawals and 85% of water consumption. It also accounts for a great proportion of the increase in water use, with irrigated cropland more than doubling globally since 1960. However, in Europe and North America particularly, industry consumes a large proportion of available water; industrial uses for water are anticipated to grow on other continents as well.

Land development has substantially affected the distribution of water resources. It is estimated that one-half of the natural wetlands in the world have been lost in the last century. In some areas, such as California, wetland loss is estimated to be greater than 90%. The vast majority of wetlands loss has been associated with agricultural development, but urban and industrial changes have reduced wetlands as well. River channels have also been altered to enhance irrigation, navigation, power production, and a variety of other human activities.

Ground-water resources have been depleted in the last century, with many aquifers or artesian sources being depleted more rapidly than they can be recharged. This is called ground-water overdraft. In the United States, ground-water overdraft is a serious problem in the High Plains from Nebraska to Texas and in parts of California and Arizona. *See* GROUND-WATER HYDROLOGY.

Streams have traditionally served for waste disposal. Towns and cities, industries, and mines provide thousands of pollution sources. Pollution dilution requires large amounts of water. Treatment at the source is safer and less wasteful than flushing untreated or poorly treated wastes downstream. However, sufficient flows must be released to permit the streams to dilute, assimilate, and carry away the treated effluents. *See* WATER POLLUTION.

The availability of fresh water is also likely to be affected by global climate change. There is substantial evidence that global temperatures have risen and will continue to rise. Although the precise effects of this temperature risk on water distribution are challenging to predict, most models of climate change do anticipate increased global precipitation. It is likely that some areas, particularly those at mid to high latitudes, will become wetter, but the increased precipitation will be more seasonal than current patterns. Other areas are likely to receive less precipitation than they do currently. In addition, many models predict increases in the intensity and frequency of severe droughts and floods in at least some regions. These changes will affect natural stream flow patterns, soil moisture, ground-water recharge, and thus the timing and intensity of human demands for fresh-water supplies. *See* GLOBAL CLIMATE CHANGE.

Land management vitally influences the distribution and character of runoff. Inadequate vegetation or surface organic matter; compaction of farm, ranch, or forest soils by heavy vehicles; frequent crop-harvesting operations; repeated burning; or excessive trampling by livestock or wild ungulates all expose the soil to the destructive energy of rainfall or rapid snowmelt. On such lands little water enters the soil, soil particles are dislodged and quickly washed into watercourses, and gullies may form. *See* LAND-USE PLANNING; SOIL CONSERVATION.

There are a variety of measures that can be taken to reduce water consumption. In the United States, for example, per-capita water usage dropped 20% from 1980 to 1995. In many cases, improvements to existing systems would contribute to additional water savings. In the United States, an average of 15% of the water in public supply systems (for cities with populations greater than 10,000) is unaccounted for, and presumably lost.

Improvements can also be achieved by changing industrial and agricultural practices. Agricultural water consumption has an estimated overall water use efficiency of 40%. More effective use of water in agricultural systems can be achieved, for example, with more efficient delivery methods such as drip irrigation. More accurate assessment of soil and plant moisture can allow targeted delivery of water at appropriate times. In industrial settings, recycling and more efficient water use has tremendous potential to reduce water consumption. Overall, industrial water usage dropped by 30% in California between 1980 and 1990, with some sectors achieving even greater reductions. Japan has achieved a 25% reduction in industrial water use since the 1970s. Additional potential to reduce this usage still exists even in locations where many conservation measures are already in place.

Residential water consumption can also be reduced through conservation measures. High-efficiency, low-flow toilets can reduce the water required to flush by 70% or more. Additional savings are possible with efficient faucet fixtures and appliances.

Water conservation in the United States faces a number of institutional as well as technological challenges. States must administer the regulatory provisions of their pollution-control laws, develop water quality standards and waste-treatment requirements, and supervise construction and maintenance standards of public service water systems. Some states can also regulate ground-water use to prevent serious overdrafts. Artesian wells may have to be capped, permits may be required for drilling new wells, or reasonable use may have to be demonstrated. Federal responsibilities consist largely of financial support or other stimulation of state and local water management. Federal legislation permits court action on suits involving interstate streams where states fail to take corrective action following persistent failure of a community or industry to comply with minimum waste-treatment requirements.

The watershed control approach to planning, development, and management rests on the established interdependence of water, land, and people. Coordination of structures and land-use practices is sought to prevent erosion, promote infiltration, and retard high flows (to prevent flooding). The Natural Resources Conservation and Forest Services of the Department of Agriculture administer the program. The Natural Resources Conservation Service cooperates with other federal and state agencies and operates primarily through the more than 2000 soil conservation districts.

Because watersheds often span political boundaries, many efforts to conserve and manage water require cooperation between states and countries. Many countries currently have international treaties addressing water allocation and utilization. In 1997, the United Nations adopted the Convention on the Law of the Non-navigational Uses of International Watercourses, which includes an obligation not to cause significant harm to other watercourse states, as well as provisions for dispute resolution. In addition, in 1996 the Global Water Partnership and the World Water Council were formed for the purpose of addressing ongoing international water concerns. [B.F.; M.McC.; G.Pr.]

The increasing utilization of the continental shelf for oil drilling and transport, siting of nuclear power plants, and various types of planned and inadvertent waste disposal, as well as for food and recreation, requires careful management of human activities in this ecosystem. Nearshore waters are presently subject to both atmospheric and coastal input of pollutants in the form of heavy metals, synthetic chemicals, petroleum hydrocarbons, radionuclides, and other urban wastes. Overfishing is an additional human-induced stress. Physical transport of pollutants, their modification by the coastal food web, and demonstration of transfer to humans are sequential problems of increasing complexity on the continental shelf.

One approach to quantitatively assess the above pollutant impacts is to construct simulation models of the coastal food web in a systems analysis of the continental shelf. Models of physical transport of pollutants have been the most successful, for example, as in studies of beach fouling by oil. Incorporation of additional biological and chemical terms in a simulation model, however, requires dosage response functions of the natural organisms to each class of pollutants, as well as a quantitative description of the "normal" food web interactions of the continental shelf. *See* ECOLOGICAL MODELING; FOOD WEB.

In addition to toxic materials introduced by oil spills, sewage, and agricultural and industrial run-off, coastal waters are vulnerable to thermal pollution. Thermal pollution is caused by the discharge of hot water from power plants or factories and from desalination plants. A large power installation may pump in 10^6 gal/min (63 m^3/s) of seawater to act as a coolant and discharge it at a temperature approximately 18°F (10°C) above that of the ambient water. In a shallow bay with restricted tidal flow, the rise in temperature can cause gross alterations to the natural ecology. Federal standards prohibit heating of coastal waters by more than 0.9°F (0.5°C). *See* THERMAL ECOLOGY.

Finally, dredging waters to fill wetlands for house lots, parking lots, or industrial sites destroys the marshes that provide sanctuary for waterfowl and for the young of estuarine fishes. As the bay bottom is torn up, the loosened sediments shift about with the current and settle in thick masses on the bottom, suffocating animals and plants. In this way, the marshes are eliminated and the adjoining bays are degraded as aquatic life zones. The northeast Atlantic states have lost 45,000 acres (182 km^2) of coastal wetlands in only 10 years, and San Francisco Bay has been nearly half obliterated by filling. Dredging to remove sand and gravel has the same disruptive effects as dredging for landfill or other purposes, whether the sand and gravel are sold for profit or used to replenish beach sand eroded away by storms. The dredging of boat channels adds to the siltation problem, and disposal of dredge spoils is being regulated in coastal areas. [J.J.W.]

Water desalination The removal of dissolved minerals (including salts) from seawater or brackish water. This may occur naturally as part of the hydrologic cycle, or as an engineered process. Engineered water desalination processes, which produce potable water from seawater or brackish water, have become important because many regions throughout the world suffer from water shortages caused by the uneven distribution of the natural water supply and by human use. *See* WATER SUPPLY ENGINEERING.

Seawater, brackish water, and fresh water have different levels of salinity, which is often expressed by the total dissolved solids (TDS) concentration. Seawater has a TDS concentration of about 35,000 mg/L, and brackish water has a TDS concentration of 1000–10,000 mg/L. Water is considered fresh when its TDS concentration is below 500 mg/L, which is the secondary (voluntary) drinking water standard for the United States. Salinity is also expressed by the water's chloride concentration, which is about half of its TDS concentration. *See* SEAWATER.

Water desalination processes separate feed water into two streams: a fresh-water stream with a TDS concentration much less than that of the feed water, and a brine stream with a TDS concentration higher than that of the feed water.

Distillation is a process that turns seawater into vapor by boiling, and then condenses the vapor to produce fresh water. Boiling water is an energy-intensive operation, requiring about 4.2 kilojoules of energy (or latent heat) to raise the temperature of 1 kg of water by 1°C. After water reaches its boiling point, another 2257 kJ of energy (or the heat of vaporization) is required to convert it to vapor. The boiling point depends on ambient atmospheric pressure—at lower pressure, the boiling point of water is lower. Therefore, keeping water boiling can be accomplished either by providing a constant energy supply or by reducing the ambient atmospheric pressure. *See* DISTILLATION.

Reverse osmosis, the process that causes water in a salt solution to move through a semipermeable membrane to the freshwater side, is accomplished by applying pressure in excess of the natural osmotic pressure to the salt solution. The operational pressure of reverse osmosis for seawater desalination is much higher than that for brackish water, as the osmotic pressure of seawater at a TDS concentration of 35,000 mg/L is about 2700 kJ while the osmotic pressure of brackish water at a TDS concentration of 3000 mg/L is only about 230 kJ.

Salts dissociate into positively and negatively charged ions in water. The electrodialysis process uses semipermeable and ion-specific membranes, which allow the passage of either positively or negatively charged ions while blocking the passage of the oppositely charged ions. An electrodialysis membrane unit consists of a number of cell pairs bound together with electrodes on the outside. These cells contain an anion exchange membrane and cation exchange membrane. Feed water passes simultaneously in parallel paths through all of the cells, separating the product (water) and ion concentrate. *See* DIALYSIS; ION EXCHANGE. [C.C.K.L.; J.W.P.]

Water hammer The propagation in a liquid of an acoustic wave that is caused by a rapid change in fluid velocity. Such relatively sudden changes in the liquid velocity are due to events such as the operation of pumps or valves in pipelines, the collapse of vapor bubbles within the liquid, underwater explosions, or the impact of water following the rapid expulsion of air from a vent or a partially open valve. Alternative terms such as pressure transients, pressure surge, hydraulic transients, and hydraulic shock are often employed. Although the physics and mathematical characterization of water hammer and underwater acoustics (employed in sonar) are identical, underwater sound is always associated with very small pressure changes compared to the potential of moderate to very large pressure differences associated with water hammer. *See* CAVITATION; SOUND; UNDERWATER SOUND.

A pressure change Δp is always associated with the rapid velocity change ΔV across a water hammer wave, as formulated from the basic physics of mass and momentum conservation by the Joukowsky equation, $\Delta p = -\rho a \Delta V$. Here ρ is the liquid mass density and a is the sonic velocity of the pressure wave in the fluid medium. In a pipe, this velocity depends on the ratio of the bulk modulus of the liquid to the elastic modulus of the pipe wall, and on the ratio of the inside diameter of the pipe to the wall thickness. In water in a very rigid pipe or in a tank, or even the sea, the acoustic velocity is approximately 1440 m/s (4720 ft/s), a value many times that of any liquid velocity.

Liquid-handling systems are designed so that water hammer does not result from sudden closure, but is limited to more gradual flow changes initiated by valves or other devices. The dramatic pressure rise (or drop) results can be significantly reduced by reflections of the original wave from pipe-area changes, tanks, reservoirs, and so forth. Although the Joukowsky equation applies across every wavelet, the effect of complete valve closure over a period of time greater than a minimum critical time can be quite beneficial. This critical time is the time required for an acoustic wave to propagate twice the distance along the pipe from the point of wave creation to the location of the first pipe-area change. *See* HYDRODYNAMICS; PIPE FLOW. [C.S.Ma.]

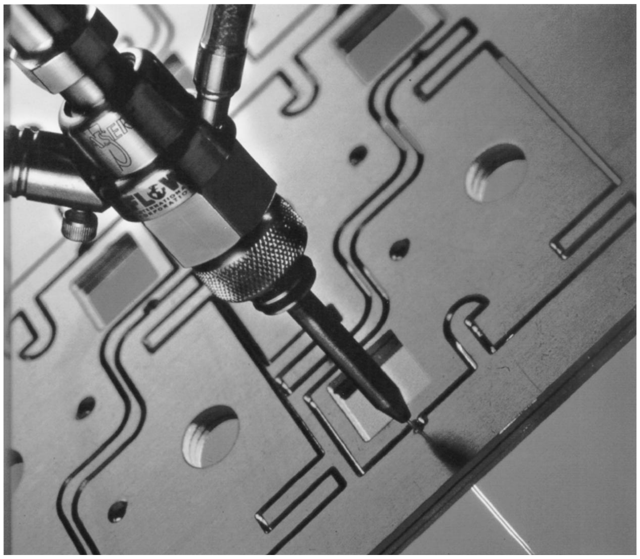
Water-jet cutting The use of high-pressure water jets, which may contain abrasive powder, for cutting and removing materials. For example, water accelerated up to twice the speed of sound [343 m/s (1125 ft/s) at 20°C (68°F)] can penetrate and cut rock in a few seconds.

Among the methods of cutting metal and nonmetallic materials, pure and abrasive water-jet cutting techniques have a distinct advantage because of their versatility and speed. They can cut all materials, including hard-to-machine materials such as superalloy, Kevlar, and boron carbide. They can also easily cut aerospace materials such as graphite composite and titanium, and brittle materials such as advanced ceramics, granite, marble, and glass (see illustration). The pure water jet is used by the food industry to cut candy and chocolate bars, meats, vegetables, and fruits. It is being tested for orthopedic surgery applications in bone cutting and scaling the flesh from bones. Other biomedical applications include a nonsurgical water-jet system for rapidly removing clots from blood vessels, and a water jet for corneal surgery.

The advantages of pure and abrasive water-jet cutting are (1) absence of thermal distortion and work hardening; (2) noncontact during cutting, thus eliminating tool wear and contact force; and (3) omnidirectional cutting, allowing the cutting of complex shapes and contours.

Although the use of the water-jet system is rapidly growing, the technique has some drawbacks and limitations. Water-jet technology has not yet developed fully for high-tolerance and -precision machining. The initial capital investment for the system, including the motion-control equipment and operating costs, is relatively high. The noise level (80 adjusted decibels) is somewhat high, but the system can be specially designed to isolate the noise source. *See* MACHINABILITY OF METALS.

The water-jet pump and its delivery system are designed to produce a high-velocity jet stream within a relatively short trajectory distance, since the kinetic energy of the water and abrasive particles is directly proportional to the square of the jet velocity. In abrasive jet cutting applications, the abrasives entrained in the jet stream usually attain approximately 80% of the water-droplet velocity at the nozzle tip. The jet cuts the material by a rapid erosion process, when its force exceeds the compressive strength of the material. Since the area eroded by the abrasive is also swept by the water stream, the heat generated during the cutting is dissipated immediately, resulting in a small rise in temperature (less than 90°F or 50°C) in the workpiece. Therefore, no thermal distortion or work hardening is associated with water-jet cutting. The cutting by rapid erosion also significantly reduces the actual force exerted on the material, enabling the water jet to cut fragile or deformable materials such as glass and honeycomb structures. *See* JET FLOW; METAL, MECHANICAL PROPERTIES OF; SHEAR. [T.J.K.]



Abrasive water-jet cutting of 0.5-in.-thick (12.5-mm) titanium at a pressure of 45,000 lb/in.^{2} (310 MPa). (*Flow International Corp.*)

Water pollution A change in the chemical, physical, biological, and radiological quality of water that is injurious to its existing, intended, or potential uses (for example, boating, waterskiing, swimming, the consumption of fish, and the health of aquatic organisms and ecosystems). The term “water pollution” generally refers to human-induced (anthropogenic) changes to water quality. Thus, the discharge of toxic chemicals from a pipe or the release of livestock waste into a nearby water body is considered pollution. Conversely, nutrients that originate from animals in the wild or toxins that originate from natural processes are not considered pollution.

The contamination of ground water, rivers, lakes, wetlands, estuaries, and oceans can threaten the health of humans and aquatic life. Sources of water pollution are generally divided into two categories. The first is point-source pollution, in which contaminants are discharged from a discrete location. Sewage outfalls and oil spills are examples of point-source pollution. The second category is non-point-source or diffuse pollution, referring to all of the other discharges that deliver contaminants to water bodies. Acid rain and unconfined runoff from agricultural or urban areas are examples of non-point-source pollution. The principal contaminants of water include toxic chemicals, nutrients and biodegradable organics, and bacterial and viral pathogens.

Water pollution can threaten human health when pollutants enter the body via skin exposure or through the direct consumption of contaminated food or drinking water. Priority pollutants, including dichlorodiphenyl trichloroethane (DDT) and polychlorinated biphenyls (PCBs), persist in the natural environment and bioaccumulate in the tissues of aquatic organisms. These persistent organic pollutants are transferred up the food chain (in a process called biomagnification), and they can reach levels of concern in fish species that are eaten by humans. Finally, bacteria and viral pathogens can pose a public health risk for those who drink contaminated water or eat raw shellfish from polluted water bodies. *See* ENVIRONMENTAL TOXICOLOGY; FOOD WEB.

Contaminants have a significant impact on aquatic ecosystems. for example, enrichment of water bodies with nutrients (principally nitrogen and phosphorus) can result in the growth of algae and other aquatic plants that shade or clog streams. If wastewater containing biodegradable organic matter is discharged into a stream with inadequate dissolved oxygen, the water downstream of the point of discharge will become anaerobic and will be turbid and dark. Settleable solids, if present, will be deposited on the streambed, and anaerobic decomposition will occur. Over the reach of stream where the dissolved-oxygen concentration is zero, a zone of putrefaction will occur with the production of hydrogen sulfide, ammonia, and other odorous gases. Because many fish species require a minimum of 4–5 mg of dissolved oxygen per liter of water, they will be unable to survive in this portion of the stream.

Direct exposures to toxic chemicals is also a health concern for individual aquatic plants and animals. Chemicals (e.g., pesticides) are frequently transported to lakes and rivers via runoff, and they can have unintended and harmful effects on aquatic life. Toxic chemicals have been shown to reduce the growth, survival, reproductive output, and disease resistance of exposed organisms. These effects can have important consequences for the viability of aquatic populations and communities. *See* INSECTICIDE.

Wastewater discharges are most commonly controlled through effluent standards and discharge permits. Under this system, discharge permits are issued with limits on the quantity and quality of effluents. Water-quality standards are sets of qualitative and quantitative criteria designed to maintain or enhance the quality of receiving waters. Receiving waters are divided into several classes depending on their uses, existing or intended, with different sets of criteria designed to protect uses such as drinking water supply, bathing, boating, fresh-water and shellfish harvesting, and outdoor sports for seawater. For toxic compounds, chemical-specific or whole-effluent toxicity studies are used to develop standards and criteria. In the chemical-specific approach, individual criteria are used for each toxic chemical detected in the wastewater. Criteria can be developed to protect aquatic life against acute and chronic effects and to safeguard humans against deleterious health effects, including cancer. In the whole-effluent approach, toxicity or bioassay tests are used to determine the concentration at which the wastewater induces acute or chronic toxicity effects. *See* HAZARDOUS WASTE; SEWAGE DISPOSAL; SEWAGE TREATMENT. [N.Sc.; G.Tc.]

Water softening The process of removing divalent cations, usually calcium or magnesium, from water. When a sample of water contains more than 120 mg of these ions per liter (0.016 oz/gal), expressed in terms of calcium carbonate ($CaCO_3$), it is generally classified as a hard water. Hard waters are frequently unsuitable for many industrial and domestic purposes because of their soap-destroying power and tendency to form scale in equipment such as boilers, pipelines, and engine jackets. Therefore it is necessary to treat the water either to remove or to alter the constituents for it to be fit for the proposed use.

The principal water-softening processes are precipitation, cation exchange, electrical methods, or combinations of these. The factors to be considered in the choice of a softening process include the raw-water quality, the end use of softened water, the cost of softening chemicals, and the ways and costs of disposing of waste streams. *See* ION EXCHANGE; WATER TREATMENT. [Y.H.M.]

Water supply engineering A branch of civil engineering concerned with the development of sources of supply, transmission, distribution, and treatment of water. The term is used most frequently in regard to municipal water works, but applies also to water systems for industry, irrigation, and other purposes.

Water obtained from subsurface sources, such as sands and gravels and porous or fractured rocks, is called ground water. Ground water flows toward points of discharge in river valleys and, in some areas, along the seacoast. The flow takes place in water-bearing strata known as aquifers. In an unconfined stratum the water table is the top or surface of the ground water. It may be within a few inches of the ground surface or hundreds of feet below. *See* AQUIFER; GROUND-WATER HYDROLOGY; WATER TABLE.

Wells are vertical openings, excavated or drilled, from the ground surface to a water-bearing stratum or aquifer. Pumping a well lowers the water level in it, which in turn forces water to flow from the aquifer. Thick, permeable aquifers may yield several million gallons daily with a drawdown (lowering) of only a few feet. Thin aquifers, or impermeable aquifers, may require several times as much drawdown for the same yields, and frequently yield only small supplies.

Dug wells, several feet in diameter, are frequently used to reach shallow aquifers, particularly for small domestic and farm supplies. They furnish small quantities of water, even if the soils penetrated are relatively impervious. Large-capacity dug wells or caisson wells, in coarse sand and gravel, are used frequently for municipal supplies. Drilled wells are sometimes several thousand feet deep.

The distance between wells must be sufficient to avoid harmful interference when the wells are pumped. In general, economical well spacing varies directly with the quantity of water to be pumped, and inversely with the permeability and thickness of the aquifer. It may range from a few feet to a mile or more.

Specially designed pumps, of small diameter to fit inside well casings, are used in all well installations, except in flowing artesian wells or where the water level in the well is high enough for direct suction lift by a pump on the surface (about 15 ft or 5 m maximum). Well pumps are set some distance below the water level, so that they are submerged even after the drawdown is established. *See* ARTESIAN SYSTEMS; WELL.

Natural sources, such as rivers and lakes, and impounding reservoirs are sources of surface water. Water is withdrawn from rivers, lakes, and reservoirs through intakes. The simplest intakes are pipes extending from the shore into deep water, with or without a simple crib and screen over the outer end. Intakes for large municipal supplies may consist of large conduits or tunnels extending to elaborate cribs of wood or masonry containing screens, gates, and operating mechanisms. Intakes in reservoirs are frequently built as integral parts of the dam and may have multiple ports at several levels to permit selection of the best water. *See* DAM; RESERVOIR; SURFACE WATER.

The water from the source must be transmitted to the community or area to be served and distributed to the individual customers. The major supply conduits, or feeders, from the source to the distribution system are called mains or aqueducts. The oldest and simplest type of aqueducts, especially for transmitting large quantities of water, are canals. Canals are used where they can be built economically to follow the hydraulic gradient or slope of the flowing water. If the soil is suitable, the canals are excavated with sloping sides and are not lined. Otherwise, concrete or asphalt linings are used. Gravity canals are carried across streams or other low places by wooden or steel flumes, or under the streams by pressure pipes known as inverted siphons. Tunnels are used to transmit water through ridges or hills; tunnels may follow the hydraulic grade line and flow by gravity or may be built below the grade line to operate under considerable pressure. Pipelines are a common type of transmission main, especially for moderate supplies not requiring large aqueducts or canals. *See* CANAL; PIPELINE; TUNNEL.

Included in the distribution system are the network of smaller mains branching off from the transmission mains, the house services and meters, the fire hydrants, and the distribution storage reservoirs. The network is composed of transmission or feeder mains, usually 12 in. (30 cm) or more in diameter, and lateral mains along each street, or in some cities along alleys between the streets. The mains are installed in grids so that lateral mains can be fed from both ends where possible. Valves at intersections of mains permit a leaking or damaged section of pipe to be shut off with minimum interruption of water service to adjacent areas.

Distribution reservoirs are used to supplement the source of supply and transmission system during peak demands, and to provide water during a temporary failure of the supply system. Ground storage reservoirs, if on high ground, can feed the distribution system by gravity, but otherwise it is necessary to pump water from the reservoir into the distribution system. Circular steel tanks and basins built of earth embankments, concrete, or rock masonry are used. Elevated storage reservoirs are tanks on towers, or high cylindrical standpipes resting on the ground. Storage reservoirs are built high enough so that the reservoir will maintain adequate pressure in the distribution system at all times. Elevated tanks are usually of steel plate, mounted on steel towers, but wood is sometimes used for industrial and temporary installations.

Pumps are required wherever the source of supply is not high enough to provide gravity flow and adequate pressure in the distribution system. The pumps may be high or low head depending upon the topography and pressures required. Booster pumps are installed on pipelines to increase the pressure and discharge, and adjacent to ground storage tanks for pumping water into distribution systems. Pumping stations usually include two or more pumps, each of sufficient capacity to meet demands when one unit is down for repairs or maintenance. The station must also include piping and valves arranged so that a break can be isolated quickly without cutting the whole station out of service. [R.H.]

Drinking water comes from surface and ground-water sources. Surface waters normally contain suspended matter, pathogenic organisms, and organic substances. Ground water normally contains dissolved minerals and gases. Both require treatment. Conventional water treatment processes include pretreatment, aeration, rapid mix, coagulation and flocculation, sedimentation, filtration, disinfection, and other unit processes to meet specific requirements. *See* FILTRATION; SEDIMENTATION (INDUSTRY); WATER TREATMENT.

Aeration (air or oxygen into water) and air stripping (water into air) primarily are used to remove dissolved gases, such as hydrogen sulfide which causes taste and odor, and to oxidize iron and manganese. [R.A.Cor.]

Water table The upper surface of the zone of saturation in permeable rocks not confined by impermeable rocks. It may also be defined as the surface underground at which the water is at atmospheric pressure. Saturated rock may extend a little above this level, but the water in it is held up above the water table by capillarity and is under less than atmospheric pressure; therefore, it is the lower part of the capillary fringe and is not free to flow into a well by gravity. Below the water table, water is free to move under the influence of gravity.

The position of the water table is shown by the level at which water stands in wells penetrating an unconfined water-bearing formation. Where a well penetrates only impermeable material, there is no water table and the well is dry. But if the well passes through impermeable rock into water-bearing material whose hydrostatic head is higher than the level of the bottom of the impermeable rock, water will rise approximately to the level it would have assumed if the whole column of rock penetrated had been permeable. This is called artesian water. *See* ARTESIAN SYSTEMS; GROUND-WATER HYDROLOGY; WELL. [A.N.S./R.K.L.]

Water treatment Physical and chemical processes for making water suitable for human consumption and other purposes. Drinking water must be bacteriologically safe, free from toxic or harmful chemicals or substances, and comparatively free of turbidity, color, and taste-producing substances. Excessive hardness and high concentration of dissolved solids are also undesirable, particularly for boiler feed and industrial purposes. The treatment processes of greatest importance are sedimentation, coagulation, filtration, disinfection, softening, and aeration.

Sedimentation occurs naturally in reservoirs and is accomplished in treatment plants by basins or settling tanks. Plain sedimentation will not remove extremely fine or colloidal material within a reasonable time, and the process is used principally as a preliminary to other treatment methods.

Fine particles and colloidal material are combined into masses by coagulation. These masses, called floc, are large enough to settle in basins and to be caught on the surface of filters.

Suspended solids, colloidal material, bacteria, and other organisms are filtered out by passing the water through a bed of sand or pulverized coal, or through a matrix of fibrous material supported on a perforated core. Soluble materials such as salts and metals in ionic form are not removed by filtration. *See* FILTRATION.

There are several methods of treatment of water to kill living organisms, particularly pathogenic bacteria; the application of chlorine or chlorine compounds is the most common. Less frequently used methods include the use of ultraviolet light, ozone, or silver ions. Boiling is the favored household emergency measure.

Municipal water softening is common where the natural water has a hardness in excess of 150 parts per million. Two methods are used: (1) The water is treated with lime and soda ash to precipitate the calcium and magnesium as carbonate and hydroxide, after which the water is filtered; (2) the water is passed through a porous cation exchanger which has the ability of substituting sodium ions in the exchange medium for calcium and magnesium in the water. For high-pressure steam boilers or some other industrial processes, almost complete deionization of water is needed, and treatment includes both cation and anion exchangers. *See* ION EXCHANGE.

Aeration is a process of exposing water to air by dividing the water into small drops, by forcing air through the water, or by a combination of both. Aeration is used to add oxygen to water and to remove carbon dioxide, hydrogen sulfide, and taste-producing gases or vapors. *See* WATER POLLUTION; WATER SUPPLY ENGINEERING. [R.H.]

Water-tube boiler A steam boiler in which water circulates within tubes and heat is applied from outside the tubes. The outstanding feature of the water-tube boiler is the use of small tubes [usually 1–3 in. (2.5–7.5 cm) outside diameter] exposed to the products of combustion and connected to steam and water drums which are shielded from these high-temperature gases. Thus, possible failure of boiler parts exposed to direct heat transfer is restricted to the small-diameter tubes and, in the event of failure, the energy released is reduced and explosion hazards are minimized.

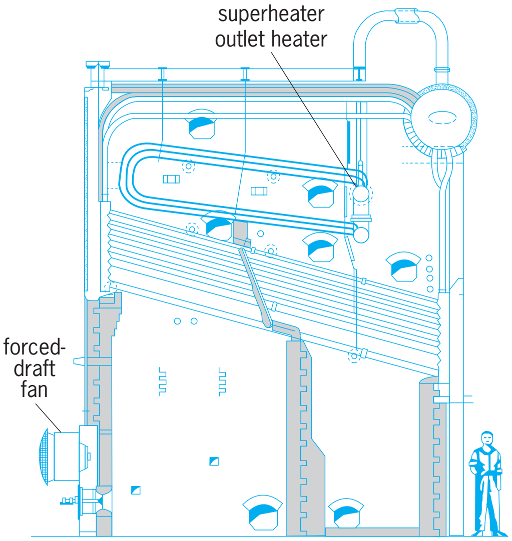


Diagram of a straight-tube-type boiler.

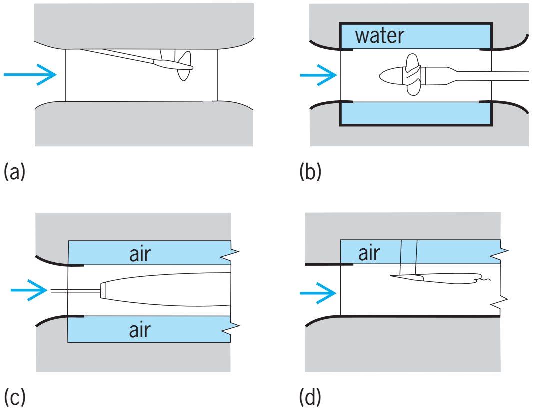
There are many types of water-tube boilers but, in general, they can be grouped into two categories: the straight-tube (see illustration) and the bent-tube types. In essence, both types consist of banks of parallel tubes which are connected to, or by, headers or drums. Most modern water-tube boilers utilize a water-cooled surface in the furnace, and this surface is an integral part of the boiler's circulatory system. Further, modern water-tube boilers generally incorporate the use of superheaters, economizers, or air heaters to utilize more efficiently the heat from the fuel and to provide steam at a high potential for useful work in an engine or turbine. *See* BOILER; STEAM; STEAM-GENERATING FURNACE; STEAM-GENERATING UNIT. [G.W.K.]

Water tunnel A hydrodynamic facility used for research, test, and evaluation, comprising a well-guided and controlled stream of water in which items for test are placed. The water tunnel is in many ways similar in appearance, arrangement, and operation to a subsonic wind tunnel. It is related to and complementary to the towing tank, in which the test item, usually a scale model of a ship or ship component, is towed through stationary water and evaluated through observation and measurement. In a water tunnel the test item is held stationary while the water is circulated around it. Many water tunnels are capable of operation with variable internal pressure to simulate the phenomenon of cavitation. *See* Cavitation; Towing tank; Wind tunnel.



Types of water-tunnel test sections with typical models. (*a*) Closed throat. (*b*) Open throat. (*c*) Free jet. (*d*) Free surface.

Water tunnels may be classified, in part, by the type of test section used. The most common section is the closed throat (illus. *a*) in which the test section flow has solid boundaries. The advantage of this arrangement is its simplicity and efficiency, but the model must be small relative to the tunnel cross section to avoid large wall effects. Small wall effects are theoretically correctable. In an open-throat test section (illus. *b*) the water jet passes through a water-filled chamber of larger diameter. This minimizes wall effects, and many tunnels dedicated to propeller testing use such an arrangement. When very low test section cavitation numbers are required, or for fully cavitating flows, a free jet (illus. *c*) in which the water jet passes through an air-filled chamber is useful. However, capture of the free jet and removal of excess entrained air prior to recirculation is not easily achieved over a broad range of test conditions. To study cavity flows on surface-piercing components or hydrofoils which operate near a free surface, a free-surface tunnel (illus. *d*) is required in which three sides of the water flow are bounded by solid walls and the upper surface is open to air at controlled pressure levels. This arrangement is often referred to as a water channel. *See* Hydrofoil craft; Open channel.

Another distinction among water tunnel types is whether or not they recirculate the flow. If the tunnel is nonrecirculating, water may "blow down" from a pressurized or elevated water tank or water may be diverted from a continuous source such as a waterfall or dam on a river. The blow-down tunnel has a limited test period proportional to the size of the storage tank. All water tunnels make use of transparent test-section viewing windows.

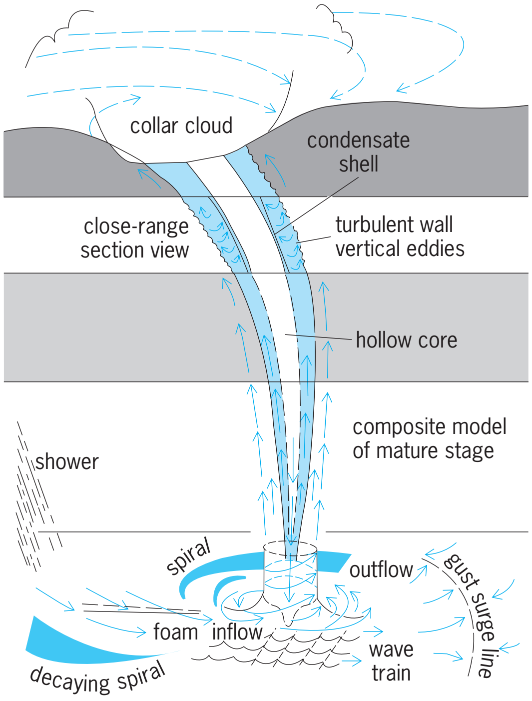
Water tunnels are used to investigate the dynamics, hydrodynamics, and cavitation of submerged and semisubmerged bodies such as propellers, ships, submarines, torpedoes, and hydrofoils and of turbomachinery. They are also indispensable to research on general flow phenomena in liquids. An application of great importance has been the acoustic characterization of propellers under both cavitating and noncavitating conditions. *See* Hydrodynamics; Propeller (marine craft). [R.S.Ro.; R.J.E.]

Watermelon The edible fruit of *Citrullus lanatus*, of the family Cucurbitaceae. The plant is an annual prostrate vine with multiple stems.

The numerous cultivars of watermelon are highly diverse in fruit size (5–85 lb; 2.3–38.3 kg), shape (round, oval, oblong-cylindrical), rind color (very light to very dark green and often striped or mottled), flesh color (red, pink, orange, yellow, white), and seed size and color. The flesh contains 6–12% sugar, depending upon variety and condition of growth, with 8% sugar being acceptable on most markets.

Watermelon juice of the sweet cultivars can be reduced to edible sugar and syrup. Watermelon seeds are relished as food in some Near East countries and in China. Fresh watermelon flesh has a unique melting quality that has proved impossible to preserve in palatable form through any processing technique. The flesh consists of water (91%), fiber, and sugar, and little else of obvious nutritional value, but may have some as yet unproved health-promoting value. It is said to have diuretic properties, and both frozen concentrate and canned juice have been available for the treatment of nephritis. The seeds also are said to contain substances effective in the control of hypertension. [C.F.A.]

Waterspout An intense columnar vortex (not necessarily containing a funnel-shaped cloud) of small horizontal extent, over water. Typical visible vortex diameters are of the order of 33 ft (10 m), but a few large waterspouts may exceed 330 ft (100 m) across. In the case of Florida waterspouts, only rarely does the visible funnel extend from parent cloudbase to sea surface. Like the tornado, most of the visible funnel is condensate. Therefore, the extension of the funnel cloud downward depends



Composite schematic model of a mature waterspout. For scaling reference, the maximum funnel diameters in this stage, just below the collar cloud, range from 10 to 460 ft (3 to 140 m).

upon the distribution of ambient water vapor, ambient temperature, and pressure drop due to the vortex circulation strength. These vortices are most frequently observed during the warm season in the oceanic tropics and subtropics.

All waterspouts undergo a regular life cycle composed of five discrete but overlapping stages. (1) The dark-spot stage signifies a complete vortex column extending from cloud-base to sea surface. (2) The spiral-pattern stage is characterized by development of alternating dark- and light-colored bands spiraling around the dark spot on the sea surface. (3) The spray ring (incipient spray vortex) stage is characterized by a concentrated spray ring around the dark spot, with a lengthening funnel cloud above. (4) The mature waterspout stage (see illustration) is characterized by a spray vortex of maximum intensity and organization. (5) The decay stage occurs when the waterspout dissipates (often abruptly).

Waterspouts and tornadoes are qualitatively similar, differing only in certain quantitative aspects: tornadoes are usually more intense, move faster, and have longer lifetimes—especially maxi-tornadoes. Tornadoes are associated with intense, baroclinic (frontal), synoptic-scale disturbances with attendant strong vertical wind shear, while waterspouts are associated with weak, quasibarotropic disturbances (weak thermal gradients) and consequent weak vertical wind shear. *See* TORNADO; WIND. [J.H.G.]

Watt-hour meter An electrical energy meter, that is, an electricity meter that measures and registers the integral, with respect to time, of the power in the circuit in which it is connected. This instrument can be considered as having two parts: a transducer, which converts the power into a mechanical or electrical signal, and a counter, which integrates and displays the value of the total energy that has passed through the meter. Either or both of these parts can be based on mechanical or electronic principles.

In its wholly mechanical form the transducer is an electric motor designed so that its torque is proportional to the electric power in the circuit. The motor spindle carries a conducting disk that rotates between the poles of one or more strong permanent magnets. These provide a braking torque that is proportional to the disk rotational speed, so the motor runs at a rate that accurately represents the circuit power. The integrating register is simply connected to the motor through a gear train that gives the required movement of the dials in relation to the passage of electrical energy. *See* MOTOR.

Mechanical meters can measure either dc or ac energy. Some form of commutator motor similar to those with a shunt field winding is commonly used for dc energy measurement. It is most convenient for the field to carry the circuit current, while the armature is fed with a signal from the circuit voltage. The Ferraris, or induction-type, meter is used for ac energy measurement. The stator carries two windings. An ordinary energy meter will easily achieve an accuracy of 2% over a wide range of loads; precision models may reach 0.1%. Ferraris meters are in very wide use and measure the consumption of the vast majority of domestic and industrial users of electric power throughout the world.

Electronic meters have an electronic watt transducer, which is a solid-state circuit that performs the multiplication of current and voltage signals, and delivers an output in the form of a pulse train at a rate proportional to power. The simplest solid-state watt-hour meter is completed by adding an electronic register to record the energy consumed. Precision electronic energy meters can give errors less than 0.005%. Electronic instruments are available in which six registers are provided, to record consumption at four different times of day and two levels of maximum demand. *See* TRANSDUCER; VOLTMETER.

Intelligent, or smart, meters can provide a wide variety of load and tariff-control functions, as well as remote reading of energy consumption.

Electronic and mechanical techniques can be combined in a variety of ways. Signals from a mechanical transducer may be used to operate electronic registers in order to obtain the advantages of the facilities that they can provide. A mechanical impulse register may be used in conjunction with an electronic transducer, where it is considered important to maintain a record without the need for batteries or nonvolatile memory elements.

Watt-hour meters that operate at potentials of 100–250 V and currents up to 100 A are widely manufactured. At higher levels, voltage or current transformers are used to reduce the signals handled by the meter to more convenient values, frequently 110 V and 5 A. By this means it is possible to carry out energy metering at any level required, including hundreds of kilovolts and tens of kiloamperes. *See* ELECTRIC POWER MEASUREMENT; ELECTRICAL ENERGY MEASUREMENT; INSTRUMENT TRANSFORMER; TRANSFORMER. [R.B.D.K.]

Wattmeter An instrument that measures electric power. *See* ELECTRIC POWER MEASUREMENT.

A variety of wattmeters are available to measure the power in ac circuits. They are generally classified by names descriptive of their operating principles. Determination of power in dc circuits is almost always done by separate measurements of voltage and current. However, some of the instruments described will also function in dc circuits, if desired.

Probably the most useful instrument in the measurement of ac power at commercial frequencies is the indicating (deflecting) electrodynamic wattmeter. It is similar in principle to the double-coil dc ammeter or voltmeter in that it depends on the interaction of the fields of two sets of coils, one fixed and the other movable. The moving coil is suspended, or pivoted, so that it is free to rotate through a limited angle about an axis perpendicular to that of the fixed coils. As a single-phase wattmeter, the moving (potential) coil, usually constructed of fine wire, carries a current proportional to the voltage applied to the measured circuit, and the fixed (current) coils carry the load current. This arrangement of coils is due to the practical necessity of designing current coils of relatively heavy conductors to carry large values of current. The potential coil can be lighter because the operating current is limited to low values. *See* AMMETER; VOLTMETER.

A thermal converter consists of a resistive heater in close thermal contact with one or more thermocouples. When current flows through the heater, the temperature rises. Thermocouples give an output voltage proportional to the temperature difference between their junctions, in this case proportional to the square of the current, and so make suitable transducers for the construction of thermal wattmeters. *See* ELECTRICAL RESISTANCE; THERMAL CONVERTERS; THERMOCOUPLE; THERMOELECTRICITY.

The electrostatic force between two conductors is proportional to the product of the square of the potential difference between them and the rate of change of capacitance with displacement. A differential electrostatic instrument may therefore be used to construct a quarter-squares wattmeter. In spite of the problems of matching the capacitance changes of the two elements and the small forces available, electrostatic wattmeters were used as standards for many years.

Digital wattmeters combine the advantages of electronic signal processing and a high-resolution, easily read display. Electrical readout of the measurement is also possible. A variety of electronic techniques for carrying out the necessary multiplication of the signals representing the current and voltage have been used. Usually the electronic multiplier is an analog system which gives as its output a voltage proportional to the power indication required. This voltage is then converted into digital form in one of the standard ways. Many of the multipliers were originally developed for use in analog computers. *See* ANALOG COMPUTER; ELECTRONIC DISPLAY.

The instruments described are designed for single-phase power measurement. In polyphase circuits, the total power is the algebraic sum of the power in each phase. This summation is assisted by simple modifications of single-phase instruments. *See* ALTERNATING CURRENT. [R.B.D.K.]

Wave (physics)

The general term applied to the description of a disturbance which propagates from one point in a medium to other points without giving the medium as a whole any permanent displacement.

Waves are generally described in terms of their amplitude, and how the amplitude varies with both space and time. The actual description of the wave amplitude involves a solution of the wave equation and the particular boundary conditions for the case being studied. *See* WAVE EQUATION; WAVE MOTION.

Acoustic waves, or sound waves, are a particular kind of the general class of elastic waves. Elastic waves are propagated in media having two properties, inertia and elasticity. Electromagnetic waves (for example, light waves and radio waves) are not elastic waves and therefore can travel through a vacuum. The velocity of the wave depends on the medium through which the wave travels. *See* ELECTROMAGNETIC WAVE. [W.J.G.]

Wave equation

The name given to certain partial differential equations in classical and quantum physics which relate the spatial and time dependence of physical functions. In this article the classical and quantum wave equations are discussed separately, with the classical equations first for historical reasons.

In classical physics the name wave equation is given to the linear, homogeneous partial differential equations which have the form of Eq. (1). Here υ is a parameter with the dimensions

$$\left[\nabla^2 - \frac{1}{\upsilon^2}\frac{\partial^2}{\partial t^2}\right] f(\mathbf{r},t) = 0 \qquad (1)$$

of velocity; $\mathbf{r}$ represents the space coordinates x, y, z; t is the time; and ∇^2 is Laplace's operator defined by Eq. (2). The function

$$\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \qquad (2)$$

$f(\mathbf{r},t)$ is a physical observable; that is, it can be measured and consequently must be a real function.

The simplest example of a wave equation in classical physics is that governing the transverse motion of a string under tension and constrained to move in a plane.

A second type of classical physical situation in which the wave equation (1) supplies a mathematical description of the physical reality is the propagation of pressure waves in a fluid medium. Such waves are called acoustical waves, the propagation of sound being an example. A third example of a classical physical situation in which Eq. (1) gives a description of the phenomena is afforded by electromagnetic waves. In a region of space in which the charge and current densities are zero, Maxwell's equations for the photon lead to the wave equations (3). Here $\mathbf{E}$ is

$$\begin{aligned}\left[\nabla^2 - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right] E(\mathbf{r},t) &= 0\\ \left[\nabla^2 - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right] B(\mathbf{r},t) &= 0\end{aligned} \qquad (3)$$

the electric field strength and $\mathbf{B}$ is the magnetic flux density; they are both vectors in ordinary space. The parameter c is the speed of light in vacuum. *See* ELECTROMAGNETIC RADIATION; MAXWELL'S EQUATIONS.

The nonrelativistic Schrödinger equation is an example of a quantum wave equation. Relativistic quantum-mechanical wave equations include the Schrödinger-Klein-Gordon equation and the Dirac equation. *See* QUANTUM MECHANICS; RELATIVISTIC QUANTUM THEORY. [D.L.We.]

Wave mechanics

The modern theory of matter holding that elementary particles (such as electrons, protons, and neutrons) have wavelike properties. In 1924 L. de Broglie postulated that the wave-particle duality which had been demonstrated for electromagnetic radiation also was a property of the elementary particles making up the atoms and molecules forming ordinary matter. In particular, de Broglie postulated that a particle has an associated wavelength obeying the same relation as was found to hold for photons, namely: the wavelength equals Planck's constant divided by the particle's momentum (as customarily defined in elementary mechanics). This hypothesis was verified in 1927 in an experiment in which a beam of electrons having known momentum is diffracted by a crystal into special directions. Such diffraction seems understandable only on the hypothesis that the electrons are waves. Furthermore, the wavelength of the electrons in the incident beam, computed via the same formula as was used to derive x-ray wavelengths in x-ray diffraction experiments, agreed precisely with the de Broglie relation. *See* ELECTRON DIFFRACTION; X-RAY DIFFRACTION.

Subsequent experiments have confirmed that not merely electrons but material particles in general, such as neutrons and neutral sodium atoms, manifest the wave-particle duality and obey the de Broglie relation. The de Broglie relation and the qualitative wave-particle duality concept have been incorporated into the highly successful modern theory of quantum mechanics. *See* ATOM OPTICS; DE BROGLIE WAVELENGTH; INTERFERENCE OF WAVES; QUANTUM MECHANICS. [E.G.]

Wave motion

The process by which a disturbance at one point in space is propagated to another point more remote from the source with no net transport of the material of the medium itself. For example, sound is a form of wave motion; wind is not. Wave motion can occur only in a medium in which energy can be stored in both kinetic and potential form. In a mechanical medium, kinetic energy results from inertia and is stored in the velocity of the molecules, while potential energy results from elasticity and is stored in the displacement of the molecules.

Media. In a free traveling wave (as distinguished from a stationary or standing wave) one part of the medium disturbs an adjacent part, thereby imparting energy to it. This portion of the medium, in turn, disturbs another part, thereby causing a flow of energy in a given direction away from the source. More technically, wave propagation is the result of kinetic energy at one point being transferred into potential energy at an adjacent point, and vice versa. The rate of travel of the disturbance, or velocity of propagation, is determined by the constants of the medium. A stationary wave is the combination of two waves of the same frequency and strength traveling in opposite directions so that no net transfer of energy away from the source takes place. A standing wave is the same but with the returning wave (toward the source) being of lesser intensity than the outwardly traveling wave so that a net transfer of energy away from the source does take place.

Wave motion can occur in a vacuum (electromagnetic waves), in gases (sound waves), in liquids (hydrodynamic waves), and in solids (vibration waves). Electromagnetic waves can also travel in gases, liquids, and solids provided that the electrical conductivity of the medium is not perfect or that the imaginary part of the dielectric constant is not infinitely great. By current usage, elastic waves propagated in gases, liquids, and solids, regardless of whether one can hear them or not, are called acoustic waves.

Fundamental relations. A wave is commonly referred to in terms of either its wavelength or its frequency. In any type of wave motion, these two quantities are related to a third quantity, velocity of propagation, by the simple relation $f\lambda = c$, where f = frequency, λ = wavelength, and c = velocity of propagation. The period T is the reciprocal of the frequency, and the amplitude A is the maximum magnitude taken on by the variable of the wave at a given point in space. It is a basic property of wave motion that the frequency of a wave remains constant under all circumstances except for a relative motion between the source of the wave and the observer. The velocity of propagation is dependent on the properties of the medium (and, sometimes, also on the frequency) and the wavelength will vary with the velocity in accordance with the equation above.

Electromagnetic waves. The media in which electromagnetic waves travel possess no elasticity or inertia, but rather the ability to store energy in the electric and magnetic fields. J. C. Maxwell recognized in about 1863 that the basic equations governing these fields could be combined to yield an equation resembling the wave equation for mechanical wave motion. Thus he predicted the existence of electromagnetic waves which had not been suspected theretofore. Later, electromagnetic waves proved to be identical with light waves. *See* ELECTROMAGNETIC RADIATION; LIGHT; MAXWELL'S EQUATIONS; WAVE EQUATION. [L.L.B.]

Motion in fluids. Wave motion within a fluid is generated by successive compression and expansion of adjacent volume elements. Because compression and expansion of an ordinary fluid can only proceed along the direction of propagation of the disturbance, waves within a fluid are mostly longitudinal waves.

Waves in a fluid can be classified as compression waves and expansion waves, according to whether the disturbance is a compression or an expansion. They can further be classified according to the amplitude of the disturbance and the chemical nature of the fluid. For example, waves of small amplitude are called acoustic (or sound) waves; compression waves propagating in chemically inert fluids are called shock waves; waves propagating in the Earth are seismic waves; and waves of large amplitude generated by rapid chemical reactions in explosive fluids are called detonation waves and can propagate much faster than sound waves. Waves in an electrically conducting fluid in the presence of strong magnetic fields are called magnetohydrodynamic waves. *See* MAGNETOHYDRODYNAMICS; SEISMOLOGY; SHOCK WAVE; SOUND. [S.C.Li.]

Motion in liquids. Disturbances propagated at a gas-liquid interface are primarily dependent upon the gravitational fluid property (surface tension and viscosity being of secondary importance). Wave motions which occur in confined fluids (either liquid or gaseous) are primarily dependent upon the elastic property of the medium.

Oscillatory waves may be generated in a rectangular channel by a simple harmonic translation of a vertical wall forming one end of the flume. A standing wave can be considered to be composed of two equal oscillatory wave trains traveling in opposite directions.

A solitary wave consists of a single crest above the original liquid surface which is neither preceded nor followed by another elevation or depression of the surface. Such a wave is generated by the translation of a vertical wall starting from an initial position at rest and coming to rest again some distance downstream. In practice, solitary waves are generated by a motion of barges in narrow waterways or by a sudden change in the rate of inflow into a river; they are therefore related to a form of flood wave. [D.R.F.H.]

Wave optics

The branch of optics which treats of light (or electromagnetic radiation in general) with explicit recognition of its wave nature. The counterpart to wave optics is ray optics or geometrical optics, which does not assume any wave character but treats the propagation of light as a straight-line phenomenon except for changes of direction induced by reflection or refraction. *See* ELECTROMAGNETIC RADIATION; GEOMETRICAL OPTICS; OPTICS.

Any optical phenomenon which is correctly describable in terms of geometrical optics can also be correctly described in terms of wave optics. However, the many phenomena of interference, diffraction, and polarization are incontrovertible evidence of the wave nature of light, and geometrical optics often gives an incomplete or incorrect description of the behavior of light in an optical system. This is especially true if changes of refractive index occur within a space which is of the order of several wavelengths of the light. *See* DIFFRACTION; INTERFERENCE OF WAVES; POLARIZED LIGHT. [R.C.L.]

Wave-shaping circuits

Electronic circuits used to create or modify specified time-varying electrical voltage or current waveforms using combinations of active electronic devices, such as transistors or analog or digital integrated circuits, and resistors, capacitors, and inductors. Most wave-shaping circuits are used to generate periodic waveforms. *See* INTEGRATED CIRCUITS; TRANSISTOR.

The common periodic waveforms include the square wave, the sine and rectified sine waves, the sawtooth and triangular waves, and the periodic arbitrary wave. The arbitrary wave can be made to conform to any shape during the duration of one period. This shape then is followed for each successive cycle. *See* FUNCTION GENERATOR; WAVEFORM.

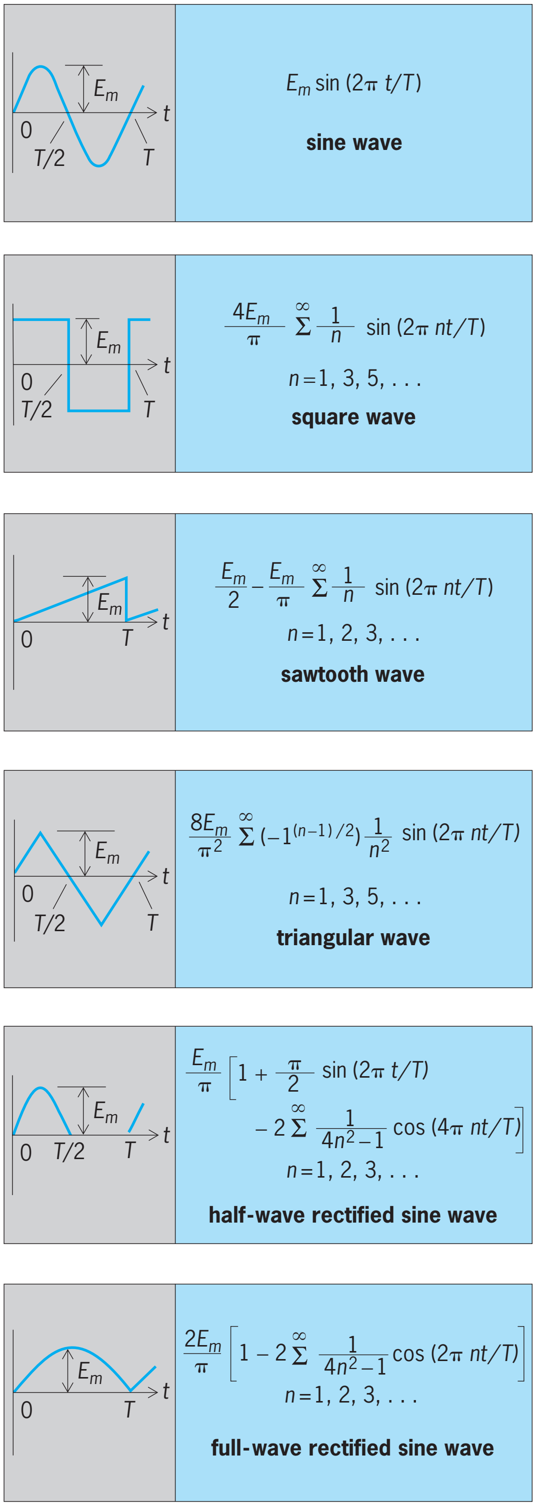
A number of traditional electronic and electromechanical circuits are used to generate these waveforms. Sine-wave generators and *LC*, *RC*, and beat-frequency oscillators are used to generate sine waves; rectifiers, consisting of diode combinations interposed between sine-wave sources and resistive loads, produce rectified sine waves; multivibrators can generate square waves; electronic integrating circuits operating on square waves create triangular waves; and electronic relaxation oscillators can produce sawtooth waves. *See* ALTERNATING CURRENT; DIODE; MULTIVIBRATOR; OPERATIONAL AMPLIFIER; OSCILLATOR; RECTIFIER.

In many applications, generation of these standard waveforms is now implemented using digital circuits. Digital logic or microprocessors generate a sequence of numbers which represent the desired waveform mathematically. These numerical values then are converted to continuous-time waveforms by passing them through a digital-to-analog converter. Digital waveform generation methods have the ability to generate waveforms of arbitrary shape, a capability lacking in the traditional approaches. *See* CIRCUIT (ELECTRONICS); DIGITAL-TO-ANALOG CONVERTER; LOGIC CIRCUITS; MICROPROCESSOR. [P.V.L.]

Waveform

The pictorial representation of the form or shape of a wave, obtained by plotting the amplitude of the wave with respect to time. There are an infinite number of possible waveforms (see illustration). One such waveform is the square wave, in which a quantity such as voltage alternately assumes two discrete values during repeating periods of time. Other waveforms of particular interest in electronics are the sine wave and rectified sine wave, the sawtooth wave and triangular wave, and the arbitrary wave—a recurrent waveform which takes on an arbitrary shape over one complete cycle; this shape is then repeated in successive cycles.

Each of these waveforms has a shape which repeats periodically in time. It is possible to characterize any of them mathematically by a Fourier series, a weighted sum of terms consisting of the basic periodic trigonometric functions: sines and cosines. A periodic waveform thus can be represented as a constant or dc term, plus a sum of harmonically related sine and cosine terms where the sine and cosine frequencies are integral multiples of the fundamental frequency. The Fourier series is given



Common electrical waveforms.

beside each waveform in the illustration as a function of time t, where E_m is the maximum value of the wave and T is the period. *See* FOURIER SERIES AND TRANSFORMS; NONSINUSOIDAL WAVEFORM; WAVE-SHAPING CIRCUITS. [P.V.L.]

Waveform determination The definition of a waveform, which describes the variation of a quantity with respect to time. The necessary measurements are normally carried out and presented in one of two ways: the amplitude may be presented as a function of time (time domain), or an analysis may be given of the relative amplitudes and phases of the frequency components (frequency domain). Although the simplest instruments measure and display the information in the same domain, it is possible to convert the data in either direction by mathematical processing.

Waveforms may be divided into two classes, depending on whether the signal is repeated at regular intervals or represents a unique event. The former signal is defined as a periodic or continuous wave, the latter as an aperiodic signal or transient. *See* ELECTRIC TRANSIENT; NONSINUSOIDAL WAVEFORM; WAVEFORM.

The oscilloscope is an example of an instrument that measures and displays directly in the time domain, by deflecting an electron beam in a vertical direction in accordance with the signal while scanning at a uniform rate in the horizontal direction. The position of the beam is revealed by a fluorescent screen. *See* OSCILLOSCOPE.

Several methods may be used to obtain the spectral content of a waveform. In the simplest, the signal is applied to a filter that is manually tuned in turn to each frequency that is expected to be present. In order to automate the measurement, the tuning of a filter may be varied by a linear, logarithmic, or other sweep and the resulting output displayed. However, there are important restrictions that limit the technique to continuous waveforms. A fleeting appearance of a signal at a frequency away from that to which the filter happens to be tuned at the instant will be completely missed. In order to provide high resolution, the tuned circuit must have high selectivity, or high Q. Its response to changes in amplitude is therefore slow, and the rate of sweeping has to be limited. By using this technique, it is possible to construct instruments that cover extremely wide frequency ranges. *See* ELECTRIC FILTER; HETERODYNE PRINCIPLE.

In order to overcome the limitations of the swept filter, an array of separate fixed tuned filters may be used, each adjusted to respond to a slightly different frequency. The amplitude of the signal in each filter is sampled in turn and displayed, giving a histogram of the frequency components of the waveform. The number of filters and their selectivities depend on the resolution required. Though simple in concept, such instruments are inclined to be bulky if high resolution is needed. They have the great advantage that all frequency components are taken into account throughout the measurement and their amplitudes can be examined continuously. Such instruments are useful for the analysis of music and speech.

Since the purpose of such instruments is to display the frequency components of the signal, they are often called spectrum or harmonic analyzers. *See* HARMONIC ANALYZER; SPECTRUM ANALYZER.

Many modern instruments use techniques in which the signal to be measured is sampled and digitized. In sampling oscilloscopes a sufficiently large number of samples is taken to define the waveform. The sampling rate is not necessarily high; where the waveform is repetitive, the Nyquist requirement that more than two samples should be available per cycle of the highest frequency of interest can be satisfied by obtaining the samples over a large number of periods of the signal. Each sample is digitized and stored. The waveform is then displayed by plotting the data on a cathode-ray tube or similar display in the correct order. As the data can be read out of digital storage at any convenient speed, this process can be relatively slow and low bandwidth display circuits are adequate. *See* ANALOG-TO-DIGITAL CONVERTER.

Once the data have been collected in digital form, they can be processed in many different ways. The application of a discrete Fourier transformation (DFT) to the amplitude data enables the information to be presented in the frequency domain. In this way, harmonic distortion which was invisible on a directly displayed waveform can be made obvious. *See* FOURIER SERIES AND TRANSFORMS. [R.B.D.K.]

Waveguide A device that constrains or guides the propagation of electromagnetic radiation along a path defined by the physical construction of the guide. Electromagnetic waves may propagate in space, as radio waves, but for many purposes waves need to be guided with minimum loss from the generating point to a point of application. Several guiding systems are of importance, including two-conductor transmission lines, various forms of striplines used in microwave integrated circuits, hollow-pipe waveguides, and dielectric waveguides. Hollow-pipe guides are used primarily in the microwave region of the spectrum, dielectric guides primarily in the optical region. *See* COAXIAL CABLE; ELECTROMAGNETIC WAVE TRANSMISSION; MICROWAVE; TRANSMISSION LINES.

Hollow-pipe waveguides consist of a dielectric region, usually air, surrounded by a closed good conductor such as silver, copper, aluminum, or brass. The cross-sectional shape is usually rectangular, but may be circular or of a variety of other shapes. Voltage and current concepts, so useful for transmission lines, are not so useful for waveguides. Distributions of electric and magnetic fields, obtained from Maxwell's equations, are needed. *See* MAXWELL'S EQUATIONS.

Solution of the field equations shows that there is an infinite number of modes for these guides, where a mode is a solution that maintains its transverse pattern but attenuates and shifts in phase as it propagates along the guide. These modal patterns may be likened to the resonant modes of a drumhead, with low-order modes having only a few transverse variations and high-order modes having many.

All modes in these guides have cutoff properties. Below a certain critical frequency, the mode will not propagate but only attenuates if excited; above the cutoff frequency, though, it may propagate with a finite phase velocity and small attenuation (zero attenuation for perfect dielectric and conductor). Higher-order modes usually have higher cutoff frequencies.

If the guiding pipe is perfectly conducting, the modes may be divided into transverse magnetic (TM) and transverse electric (TE) types. For the former, the magnetic field is confined to the transverse plane, while the electric field is so confined for the latter. These classifications remain useful for the practical metallic conductors used for such guides.

A variety of circuit elements is required for exciting desired modes, filtering, coupling to passive and active elements, and other necessary networking functions. Excitation of a particular mode may be by probes, along the direction of the mode's electric field, by loops normal to magnetic field lines, or by the charge streams of an active vacuum-tube or semiconductor device placed within the guide.

Other important waveguide elements are the directional coupler and isolator. In the directional coupler, there is coupling to an auxiliary guide in such a way that the output of one of its ports is proportional to the wave traveling in the forward direction, and the output of the other is proportional to the reverse wave. The isolator makes use of the nonreciprocal properties of ferrites with an applied magnetic field to pass the forward-traveling wave of the guide but to eliminate the reflected wave. *See* DIRECTIONAL COUPLER.

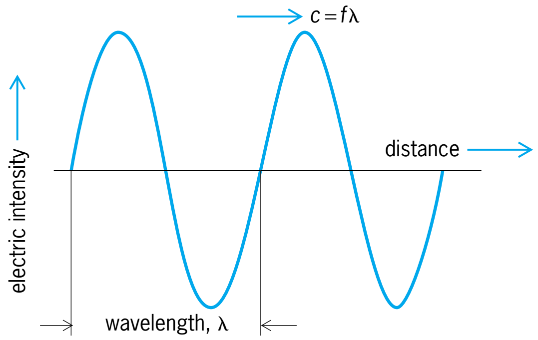
A dielectric waveguide consists of one dielectric material, called the core, surrounded by a different dielectric, called the cladding. The permittivity (dielectric constant), or refractive index, of the core is larger than that of the cladding, and under proper conditions electromagnetic energy is confined largely to the core through the phenomenon of total reflection at the boundary between the two dielectrics. *See* PERMITTIVITY; REFLECTION OF ELECTROMAGNETIC RADIATION; REFRACTION OF WAVES.

Early dielectric guides were so lossy that they could be used only over short distances. Dielectric light pipes found surgical and laboratory use. In 1969 silica fibers were developed with attenuations of 32 dB/mi (20 dB/km), low enough to be of use for optical communication applications. Since then, further improvements have reduced losses to as low as 0.3 dB/mi (0.2 dB/km). Fiber guides are now the basis for a worldwide optical communication network. *See* FIBER-OPTICS IMAGING.

Planar, rectangular, and thin-film forms of dielectric guides are also important in guiding optical energy from one device to another in optoelectronic and integrated optic devices, for example, from a semiconductor laser to an electrooptic modulator on a gallium arsenide substrate. Because of the simpler geometry, the planar forms will be used to explain the principle. *See* INTEGRATED OPTICS; LASER; OPTICAL MODULATORS.

By far the most important dielectric guide at present is the optical fiber used for optical communications. Here the round core is surrounded by a cladding of slightly lower refractive index. The combination is surrounded by a protective jacket to prevent corrosion and give added strength, but this jacket plays no role in the optical guiding. *See* OPTICAL FIBERS. [J.R.W.]

Wavelength The distance between two points on a wave which have the same value and the same rate of change of the value of a parameter, for example, electric intensity, characterizing the wave. The wavelength, usually designated by the Greek letter λ, is equal to the speed of propagation c of the wave divided by the frequency of vibration f; that is, $\lambda = c/f$ (see illustration). *See* WAVE (PHYSICS); WAVE MOTION. [W.J.G.]



Wavelength λ and related quantities.

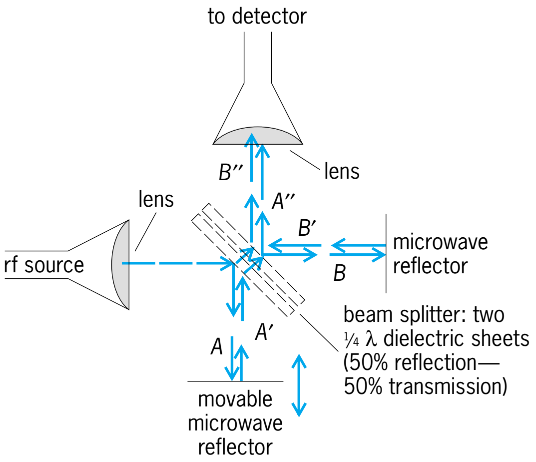
Wavelength measurement Determination of the distance between successive wavefronts of equal phase of a wave. *See* ELECTROMAGNETIC RADIATION; WAVE MOTION; WAVELENGTH.

From the relation $\lambda = c/f$ between wavelength λ, speed c, and frequency f, the wavelength of a wave motion can be calculated if the speed is known and its frequency is measured. The ease and accuracy of electronic counting and timing make frequency measurement the most precise of all physical measurements. This method of wavelength determination is thus one of the most accurate, but only if the speed (phase velocity) is known. In free space the speed of an electromagnetic wave c_0 is, through the 1983 definition of the meter, fixed at exactly 299,792,458 m/s (186,282.397 mi/s), or roughly 300,000 km/s. Unless otherwise specified, it is general practice to quote the wavelength of an electromagnetic wave as the free-space value λ_0, given by the equation below.

$$\lambda_0 = \frac{c_0}{f}$$

See FREQUENCY MEASUREMENT; PHASE VELOCITY.

Radio and microwave regions. The presence of any dielectric material (such as air) or any magnetic matter with a permeability greater then unity will cause the wave to travel at a velocity lower than its free-space value. The speed is also altered if the waves pass through an aperture, are focused by a lens or mirror, or are constrained by a wave-guide or transmission line. In such cases it may be more appropriate to measure



Wavelength measurement by the Michelson interferometer used at millimeter wavelengths.

the wavelength directly. In the pioneering experiments on radio waves, it was found that standing waves existed in space whenever reflections occurred and that these provided a convenient means of measuring the wavelength. It thus became the convention to characterize waves by their wavelength, rather than by their frequency as is now more commonly the case. Specifying the frequency is preferred because, unlike the wavelength, it is independent of the speed of propagation and does not change as the wave moves from one medium to another. *See* Electromagnetic wave transmission; Transmission lines; Waveguide.

In the microwave region the wavelengths are sufficiently short that it is convenient to measure them by using interferometer techniques directly analogous to those used with light.

In a typical interferometer used in the millimeter wavelength range (see illustration), a microwave beam is directed at a beam splitter, which splits the beam into two parts, A and B, by partial reflection. The A beam is reflected to a movable reflector and reflected again as A'. The beam splitter transmits part of this as A''. The transmitted part B of the original beam is reflected by a fixed microwave reflector as B'. This is partially reflected by the beam splitter as B''. The beams A'' and B'' combine to form standing waves, which are then detected. Movement of the movable reflector causes the position of the standing wave to move, which causes the detected signal to pass through successive points of maximum and minimum amplitude. The distance between points of successive maxima or minima is one-half wavelength. This distance may be determined from the motion of the movable reflector. *See* Interferometry.

Infrared and optical regions. The free-space wavelengths of monochromatic visible and infrared radiations can be derived directly, if their corresponding frequencies are known. The wavelengths of a few stabilized laser radiations have been precisely determined in this way, by reference to the cesium-133 primary frequency standard. These wavelength standards, with uncertainties between 4.5×10^{-10} and 3×10^{-12}, are used particularly for the practical realization of the unit of length, but they also serve as reference standards for interferometric wavelength measurements and for the calibration of wavelength comparators based on dispersion methods. *See* Length; Light; Physical measurement; Wavelength standards.

Wavelength values to an accuracy of 1 part in 10^5 can be determined with a spectrometer, spectrograph, or monochromator, in which a prism or diffraction grating is used as a dispersive element. Each wavelength forms a line image of the entrance slit at a particular angle. An unknown wavelength can be determined by interpolation with the pattern formed by a lamp emitting the tabulated characteristic wavelengths of a particular element. *See* Diffraction grating; Optical prism; Spectroscopy.

The most precise wavelength measurements use an interferometer to compare the unknown wavelength λ_1 with a standard wavelength λ_2. Usually either the two-beam Michelson form or the multiple-beam Fabry-Perot form of interferometer is used.

When a number of wavelengths are mixed together in the input to a moving-carriage two-beam interferometer, the output signal is the summation of the many separate sine-wave signals having different periods. A Fourier analysis of this composite signal enables the separate wavelengths to be identified. This Fourier transform method is particularly useful for the measurement of complex spectra in the infrared. *See* Fourier series and transforms; Infrared spectroscopy. [W.R.C.R.]

Wavelength standards Accurately known wavelengths of spectral radiation emitted from specified sources that are used to measure the wavelengths of other spectra. In the past, the radiation from the standard source and the source under study were superimposed on the slit of a spectrometer (prism or grating) and then the unknown wavelengths could be determined from the standard wavelengths by using interpolation. This technique has evolved into the modern computer-controlled photoelectric recording spectrometer. Accuracy of many more orders of magnitude can be obtained by the use of interferometric techniques, of which Fabry-Perot and Michelson interferometers are two of the most common. *See* Interferometry; Spectroscopy.

The newest definition of the meter is in terms of the second. The wavelength of radiation from the cesium atomic clock is not used to realize length because diffraction problems at this wavelength are severe. Instead, lasers at shorter wavelengths whose frequencies have been measured are used. Frequency measurements can now be made even into the visible spectral region with great accuracy. Hence, when the 1983 Conférence Général des Poids et Mesures redefined the meter, it also gave a list of very accurate wavelengths of selected stabilized lasers which may be used as wavelength standards; these are shown in the table. Nearly ten times better accuracy can be achieved by using these wavelengths than by using the radiation from the krypton lamp which provided the previous standard. *See* Frequency measurement; Hyperfine structure; Laser; Laser spectroscopy; Length; Molecular structure and spectra; Physical measurement.

The progress in laser frequency measurements since 1974 has established wavelength standards throughout the infrared spectral region. This has been accomplished with the accurate frequency measurement of rotational-vibrational transitions of selected molecules. The OCS molecule is used in the 5-micrometer spectral region. At 9–10 μm, the carbon dioxide (CO_2) laser itself with over 300 accurately known lines is used. From 10 to 100 μm, rotational transitions of various molecules are used; most are optically pumped laser transitions. The increased accuracy of frequency measurements makes this technique mandatory where ultimate accuracy is needed. *See* Wavelength. [D.A.J.]

Wavelets The elementary building blocks in a mathematical tool for analyzing functions. The functions can be very diverse; examples are solutions of a differential equation, and one- and two-dimensional signals. The tool itself, the wavelet transform, is the result of a synthesis of ideas from many different fields, ranging from pure mathematics to quantum physics and electrical engineering.

In many practical applications, it is desirable to extract frequency information from a signal—in particular, which frequencies are present and their respective importance. An example is the decomposition into spectral lines in spectroscopy. The tool that is generally used to achieve this is the Fourier transform. Many applications, however, concern nonstationary signals, in which the makeup of the different frequency components is constantly shifting. An example is music, where this shifting nature has been recognized for centuries by the standard notation, which tells a musician which note (frequency information) to play when and how long (time information). For signals of this nature, a time-frequency representation is needed. *See* FOURIER SERIES.

There exist many different mathematical tools leading to a time-frequency representation of a given signal, each with its own strengths and weaknesses. The wavelet transform is such a time-frequency analysis tool. Its strength lies in its ability to deal well with transient high-frequency phenomena, such as sudden peaks or discontinuities, as well as with the smoother portions of the signal. (An example is a crack in the sound from a damaged record, or the attack at the start of a music note.) The wavelet transform is less well adapted to harmonically oscillating parts in the signal, for which Fourier-type methods are more indicated.

Applications of wavelets include various forms of data compression (such as for images and fingerprints), data analysis (nuclear magnetic resonance, radar, seismograms, and sound), and numerical analysis (fast solvers for partial differential equations). *See* DIFFERENTIAL EQUATION; INTEGRAL TRANSFORM; NUMERICAL ANALYSIS. [I.D.]

Wavellite A hydrated phosphate of aluminum mineral with composition $A1_3(OH)_3(PO_4)_2 \cdot 5H_2O$, in which small amounts of fluorine and iron may substitute for the hydroxyl group (OH) and aluminum (Al), respectively. Wavellite crystallizes in the orthorhombic system. The crystals are stout to long prismatic, but are rare. Wavellite commonly occurs as globular aggregates of fibrous structure and as encrusting and stalactitic masses. Wavellite crystals range in color from colorless and white to different shades of blue, green, yellow, brown, and black. Wavellite is found at many places in Europe and North America; it is also abundant in tin veins at Llallagua, Bolivia. *See* PHOSPHATE MINERALS. [W.R.Lo.]

Wax, animal and vegetable Any of the substances containing esters of higher fatty acids and long-chain monohydric alcohols. From a practical standpoint, this definition is inadequate because it allows liquids such as sperm whale oil and jojoba oil to be called waxes, and it fails to indicate the complexity of waxes. While waxes do contain wax esters, they are seldom if ever pure. They are usually mixtures that may contain high-molecular-weight acids, alcohols, esters, ketones, hydrocarbons, sterols, diesters, hydroxyacids, and so forth, as well as the wax esters. *See* ESTER.

Practical wax formulators use physical, rather than chemical, properties to define waxes. Waxes must: be a solid at 68°F (20°C); be crystalline; melt above 140°F (40°C) without decomposition; have relatively low viscosity above the melting point; have consistency and solubility properties that are strongly dependent upon temperature; and be capable of being polished under slight pressure.

Wax sources are abundant. They have been isolated from the outer layers of bacteria, the roots, stems, leaves, fruit, and flowers of plants, the exudates of insects, the skin and hair of some animals, and the bodies of certain marine and land animals. Carnauba wax is extracted from an exudate on the leaves of the carnauba palm (*Copernicia prunifera*). Candelilla wax is obtained from a coating on the stem of *Euphorbia antisyphilitica*, a leafless desert shrub. Beeswax is an exudate of the honeybee. Wool wax is obtained from sheep wool. Many other waxes have been of commercial importance from time to time, but their availability or cost has forced them from the market. *See* CARNAUBA WAX; FAT AND OIL. [H.M.H.]

Wax, petroleum A substance produced primarily from the dewaxing of lubricating-oil fractions of petroleum. It may be of either the crystalline or microcrystalline type. Petroleum wax has a wide variety of uses. It is used to coat paper products, to blend with other waxes for the manufacture of candles, in the manufacture of electrical equipment and many polishes for home and industry, and as a source material for oxidized products. The softer waxes, such as petroleum jelly, after proper purification, are being used as medicinal products. *See* DEWAXING OF PETROLEUM; PETROLEUM PROCESSING; PETROLEUM PRODUCTS. [W.E.Ku.]

Weak nuclear interactions Fundamental interactions of nature that play a significant role in elementary particle and nuclear physics, and are distinguished from other such interactions by special properties such as participation of all the fundamental fermions and failure to conserve parity. The weak force has very short range (less than 10^{-17} m) and is extremely feeble compared to strong and electromagnetic forces, but can be distinguished from these two by its special character. For example, according to the present view, all of matter consists of certain fundamental spin-$^1/_2$ constituents, the quarks and leptons, collectively called the fundamental fermions. While only the quarks participate in strong interactions, and only the quarks and charged leptons e, μ, and τ participate in electromagnetic interactions, all of the fundamental fermions, including neutrinos, engage in weak interactions. Also, the strong and electromagnetic interactions respect spatial inversion symmetry (they conserve parity) and are also particle-antiparticle (charge conjugation) symmetric, whereas the weak interaction violates these two symmetries. *See* FUNDAMENTAL INTERACTIONS; LEPTON; PARITY (QUANTUM MECHANICS); QUARKS; SYMMETRY LAWS (PHYSICS).

Weak interactions are classified as "charged" or "neutral," depending on whether or not a particle participating in a weak reaction suffers a change of electric charge of one electronic unit. Observed charged weak interactions include nuclear beta decay and electron capture, muon capture on nuclei, and the slow decays of unstable elementary particles such as the μ and τ leptons, π, K, and charmed mesons, and hyperons and charmed baryons. Also, there are the charged neutrino-nucleon and neutrino-lepton scattering reactions. Neutral weak interactions include neutrino-nucleon and neutrino-lepton scattering as well as the electron-nucleon reaction which can also occur by electromagnetic interaction. *See* BARYON; ELEMENTARY PARTICLE; HYPERON; MESON.

The most important development in the study of weak interactions has been the creation of a successful theory based on the principles of local gauge invariance and spontaneous symmetry breaking. This theory proposes a single basis for the weak and electromagnetic interactions, and indeed, despite striking differences in the observed characteristics of strong, electromagnetic, and weak interactions, important theoretical ideas of a similar type suggest that all these interactions possess a common origin. [E.D.C.]

Weakly interacting massive particle (WIMP) A hypothetical elementary particle that might make up most of the matter in the universe, and that is also predicted to exist in supersymmetry theory. Most matter is detected only through its gravitational effects; this "dark matter" has not been observed to emit, absorb, or reflect light of any wavelength. The total amount of dark matter appears to be approximately ten times as great as all the ordinary matter in the universe, and about one hundred times as great as all the visible matter. The nature of the dark matter is not yet known, although many experiments are under way to try to discover it directly or indirectly. *See* COSMOLOGY; UNIVERSE.

Almost all the currently available data in elementary particle physics can be accounted for by a theory called the standard model, in which matter is made of quarks (the building blocks of protons and neutrons) and leptons (including electrons and neutrinos), while the strong, weak, and electromagnetic forces are transmitted by particles like the photon (the carrier of electromagnetic forces). However, the standard model does not predict the existence of any particle—say, X—that could be the dark matter. Most efforts to go beyond the standard model of particle physics have been based on the idea of supersymmetry, and most versions of supersymmetry predict that there will be a stable weakly interacting massive particle (WIMP) that would be a natural candidate for the X particles. Dark matter made of WIMPs would be "cold" dark matter (CDM), and a version of CDM theory has become the standard theory of structure formation in cosmology. *See* ELEMENTARY PARTICLE; STANDARD MODEL; SUPERSYMMETRY.

There is now abundant evidence for dark matter around galaxies and clusters of galaxies, and on larger scales in the universe. Gas and satellites at large distances from galaxies have orbital velocities similar to those at smaller distances from the center, which indicates that most of the mass in the galaxy must not be near the center, where most stars are, but in a roughly spherical dark matter halo that extends to perhaps ten times the optical size of the galaxy and has a mass at least ten times that of all the stars. Confirmation of the existence of such dark-matter halos has come from gravitational lensing observations, showing that light from more distant galaxies is bent by the gravity of nearer galaxies. *See* CELESTIAL MECHANICS; GALAXY, EXTERNAL; GRAVITATIONAL LENS; MILKY WAY GALAXY.

There is also much evidence for dark matter in clusters of galaxies. The astronomer Fritz Zwicky pointed out in 1933 that the galaxies in one nearby cluster were moving at such high speeds that they would not be held together gravitationally unless there was much more mass than was indicated by the light from their stars. This same was subsequently found to be true of other clusters. Later, similar conclusions were reached from x-ray observations and gravitational lensing observations of clusters. *See* X-RAY ASTRONOMY.

Supersymmetry is the hypothesis that there is a relationship between the two known classes of particles, bosons and fermions. According to supersymmetry, for every kind of boson in the universe, there must also be a corresponding fermion with the same electric charge and very similar interactions with other particles. Since these hypothetical sypersymmetric partner particles have not been discovered yet, if supersymmetry is right their masses must be too large for them to have been produced at current particle accelerators. Thus far, the evidence for supersymmetry is only indirect, but if the theory is right many supersymmetric partner particles should be produced at accelerators such as the Large Hadron Collider (LHC) being built in Geneva, Switzerland. *See* PARTICLE ACCELERATOR; QUANTUM STATISTICS.

Efforts to detect WIMPs directly are based on detecting their scattering from nuclei. WIMPs can also be detected indirectly, for example by looking for particles coming from their annihilation. WIMPs are also expected to be produced at accelerators such as the LHC from rapid decays of heavier supersymmetric partner particles, and this could be where they are discovered first if they are not seen before that in direct or indirect search experiments. Failure to see supersymmetric particles at LHC energies would mean that current ideas about supersymmetry are wrong. [J.R.Pr.]

Wear The removal of material from a solid surface as a result of sliding action. It constitutes the main reason why the artifacts of society (automobiles, washing machines, tape recorders, cameras, clothing) become useless and have to be replaced. There are a few uses of the wear phenomenon, but in the great majority of cases wear is a nuisance, and a tremendous expenditure of human and material resources is required to overcome the effects.

Adhesive wear is the only universal form of wear, and in many sliding systems it is also the most important. It arises from the fact that, during sliding, regions of adhesive bonding, called junctions, form between the sliding surfaces. If one of these junctions does not break along its original interface, then a chunk from one of the sliding surfaces will have been transferred to the other surface. In this way, an adhesive wear particle will have been formed. Initially adhering to the other surface, adhesive particles soon become loose and can disappear from the sliding system. *See* FRICTION.

Abrasive wear is produced by a hard, sharp surface sliding against a softer one and digging out a groove. The abrasive agent may be one of the surfaces (such as a file), or it may be a third component (such as sand particles in a bearing abrading material from each surface). Abrasive wear coefficients are large compared to adhesive ones. Thus, the introduction of abrasive particles into a sliding system can greatly increase the wear rate; automobiles, for example, have air and oil filters to catch abrasive particles before they can produce damage.

Corrosive wear arises when a sliding surface is in a corrosive environment, and the sliding action continuously removes the protective corrosion product, thus exposing fresh surface to further corrosive attack. *See* CORROSION.

Surface fatigue wear occurs as result of the formation and growth of cracks. It is the main form of wear of rolling devices such as ball bearings, wheels on rails, and gears. During continued rolling, a crack forms at or just below the surface and gradually grows until a large particle is lifted right out of the surface.

Most manifestations of wear are highly objectionable, but the phenomenon does have a few uses. Thus, a number of systems for recording information (pencil and paper, chalk and blackboard) operate via a wear mechanism. Some methods of preparing solid surfaces (filling, sandpapering, sandblasting) also make use of wear. *See* ABRASIVE. [E.R.]

Weasel The common name for at least 12 species of carnivores which are members of the family Mustelidae. They have a varied distribution in many regions of the world (see table).

Common names and distribution of 12 species of weasel

Scientific name	Common name	Distribution
Mustela rixosa	Pygmy weasel	North America
M. frenata	Long-tailed weasel	North and South America
M. nivalis	Common weasel	Europe, Asia, and Africa
M. altaica	Alpine weasel	Asia
M. sibirica	Siberian weasel	Asia
M. kathiah	Yellow-bellied weasel	Asia
M. strigidorsa	Back-striped weasel	Southern Asia
M. lutreolina	Java weasel	Java
M. nudipes	Bare-footed weasel	Malaysia
Lyncodon patagonicus	Patagonian weasel	South America
Poecilictis libyca	Libyan striped weasel	North Africa
Poecilogale albinucha	White-naped weasel	Africa

The common or European weasel is *Mustela nivalis*. This animal is a slim, voracious carnivore with a long body. The limbs are short and the body is muscular. Although the claws are nonretractile, these animals climb with agility. The gestation period is 5 weeks, and four to six young are born in a nest made in a hollow tree or rabbit burrow. One or two litters are born each year, and the life-span is about 8 years.

The common weasel has a wide distribution throughout Europe, North Africa, and Asia, and has managed to survive because of its size and ability to escape detection. It preys upon small rodents, such as mice, voles, and rats, and has been incriminated in attacking domestic animals, such as poultry. *See* GARNIVORA; FERRET; FISHER; MARTEN; MINK; OTTER; SKUNK; WOLVERINE. [C.B.C.]

Weather The state of the atmosphere, as determined by the simultaneous occurrence of several meteorological phenomena at a geographical locality or over broad areas of the Earth. When such a collection of weather elements is part of an interrelated physical structure of the atmosphere, it is termed a weather system, and includes phenomena at all elevations above the ground. More popularly, weather refers to a certain state of the atmosphere as it affects humans' activities on the Earth's surface. In this sense, it is often taken to include such related phenomena as waves at sea and floods on land.

A weather element is any individual physical feature of the atmosphere. At a given locality, at least seven such elements may be observed at any one time. These are clouds, precipitation, temperature, humidity, wind, pressure, and visibility. Each of these principal elements is divided into many subtypes. *See* WEATHER MAP.

The various forms of precipitation are included by international agreement among the hydrometeors, which comprise all the visible features in the atmosphere, besides clouds, that are due to water in its various forms. For convenience in processing weather data and information, this definition is made to include some phenomena not due to water, such as dust and smoke. Some of the more common hydrometeors include rain, snow, fog, hail, dew, and frost. *See* PRECIPITATION (METEOROLOGY).

Certain optical and electrical phenomena have long been observed among the weather elements. These include lightning, aurora, solar or lunar corona, and halo. *See* AIR MASS; ATMOSPHERE; AURORA; CLOUD; FRONT; LIGHTNING; METEOROLOGY; STORM; WEATHER OBSERVATIONS; WIND. [P.F.C.]

Weather forecasting and prediction Processes for formulating and disseminating information about future weather conditions based upon the collection and analysis of meteorological observations. Weather forecasts may be classified according to the space and time scale of the predicted phenomena. Atmospheric fluctuations with a length of less than 100 m (330 ft) and a period of less than 100 s are considered to be turbulent. The study of atmospheric turbulence is called micrometeorology; it is of importance for understanding the diffusion of air pollutants and other aspects of the climate near the ground. Standard meteorological observations are made with sampling techniques that filter out the influence of turbulence. Common terminology distinguishes among three classes of phenomena with a scale that is larger than the turbulent microscale: the mesoscale, synoptic scale, and planetary scale. *See* MICROMETEOROLOGY.

The mesoscale includes all moist convection phenomena, ranging from individual cloud cells up to the convective cloud complexes associated with prefrontal squall lines, tropical storms, and the intertropical convergence zone. Also included among mesoscale phenomena are the sea breeze, mountain valley circulations, and the detailed structure of frontal inversions. Most mesoscale phenomena have time periods less than 12 h. The prediction of mesoscale phenomena is an area of active research. Most forecasting methods depend upon empirical rules or the short-range extrapolation of current observations, particularly those provided by radar and geostationary satellites. Forecasts are usually couched in probabilistic terms to reflect the sporadic character of the phenomena. Since many mesoscale phenomena pose serious threats to life and property, it is the practice to issue advisories of potential occurrence significantly in advance. These "watch" advisories encourage the public to attain a degree of readiness appropriate to the potential hazard. Once the phenomenon is considered to be imminent, the advisory is changed to a "warning," with the expectation that the public will take immediate action to prevent the loss of life. *See* MESOMETEOROLOGY; SQUALL.

The next-largest scale of weather events is called the synoptic scale, because the network of meteorological stations making simultaneous, or synoptic, observations serves to define the phenomena. The migratory storm systems of the extratropics are synoptic-scale events, as are the undulating wind currents of the upper-air circulation which accompany the storms. The storms are associated with barometric minima, variously called lows, depressions, or cyclones. The synoptic method of forecasting consists of the simultaneous collection of weather observations, and the plotting and analysis of these data on geographical maps. An experienced analyst, having studied several of these maps in chronological succession, can follow the movement and intensification of weather systems and forecast their positions. This forecasting technique requires the regular and frequent use of large networks of data. *See* WEATHER MAP.

Planetary-scale phenomena are persistent, quasistationary perturbations of the global circulation of the air with horizontal dimensions comparable to the radius of the Earth. These dominant features of the general circulation appear to be correlated with the major orographic features of the globe and with the latent and sensible heat sources provided by the oceans. They tend to control the paths followed by the synoptic-scale storms, and to draw upon the synoptic transients for an additional source of heat and momentum. *See* ATMOSPHERE; METEOROLOGICAL INSTRUMENTATION; WEATHER OBSERVATIONS.

Numerical weather prediction is the prediction of weather phenomena by the numerical solution of the equations governing the motion and changes of condition of the atmosphere. Numerical weather prediction techniques, in addition to being applied to short-range weather prediction, are used in such research studies as air-pollutant transport and the effects of greenhouse gases on global climate change. *See* AIR POLLUTION; GREENHOUSE EFFECT; JET STREAM; UPPER-ATMOSPHERE DYNAMICS. [J.P.G.; J.R.G.]

The first operational numerical weather prediction model consisted of only one layer, and therefore it could model only the temporal variation of the mean vertical structure of the atmosphere. Computers now permit the development of multilevel (usually about 10–20) models that could resolve the vertical variation of the wind, temperature, and moisture. These multilevel models predict the fundamental meteorological variables for large scales of motion. Global models with horizontal resolutions as fine as 125 mi (200 km) are being used by weather services in several countries. Global numerical weather prediction models require the most powerful computers to complete a 10-day forecast in a reasonable amount of time.

Research models similar to global models could be applied for climate studies by running for much longer time periods. The extension of numerical predictions to long time intervals (many years) requires a more accurate numerical representation of the energy transfer and turbulent dissipative processes within the atmosphere and at the air-earth boundary, as well as greatly augmented computing-machine speeds and capacities.

Long-term simulations of climate models have yielded simulations of mean circulations that strongly resemble those of the atmosphere. These simulations have been useful in explaining the principal features of the Earth's climate, even though it is impossible to predict the daily fluctuations of weather for extended periods. Climate models have also been used successfully to explain paleoclimatic variations, and are being applied to predict future changes in the climate induced by changes in the atmospheric composition or characteristics of the Earth's surface due to human activities. *See* CLIMATE HISTORY; CLIMATE MODIFICATION; PALEOCLIMATOLOGY. [R.A.An.]

Surface meteorological observations are routinely collected from a vast continental data network, with the majority of these observations obtained from the middle latitudes of both hemispheres. Commercial ships of opportunity, military vessels, and moored and drifting buoys provide similar in-place measurements from oceanic regions. Information on winds, pressure, temperature, and moisture throughout the troposphere and into the stratosphere is routinely collected from (1) balloon-borne instrumentation packages (radiosonde observations) and commercial and military aircraft which sample the free atmosphere directly; (2) ground-based remote-sensing instrumentation such as wind profilers (vertically pointing Doppler radars), the National Weather Service Doppler radar network, and lidars; and (3) special sensors deployed on board polar orbiting or geostationary satellites. The remotely sensed observations obtained from meteorological satellites have been especially helpful in providing crucial measurements of areally and vertically averaged temperature, moisture, and winds in data-sparse (mostly oceanic) regions of the world. Such measurements are necessary to accommodate modern numerical weather prediction practices and to enable forecasters to continuously monitor global storm (such as hurricane) activity. *See* LIDAR; METEOROLOGICAL INSTRUMENTATION; RADAR METEOROLOGY.

Forecast products and forecast skill are classified as longer term (greater than 2 weeks) and shorter term. These varying skill levels reflect the fact that existing numerical prediction models such as the medium-range forecast have become very good at making large-scale circulation and temperature forecasts, but are less successful in making weather forecasts. An example is the prediction of precipitation amount and type given the occurrence of precipitation and convection. Each of these forecasts is progressively more difficult because of the increasing importance of mesoscale processes to the overall skill of the forecast. *See* PRECIPITATION (METEOROLOGY). [L.F.B.]

Nowcasting is a form of very short range weather forecasting. The term nowcasting is sometimes used loosely to refer to any area-specific forecast for the period up to 12 h ahead that is based on very detailed observational data. However, nowcasting should probably be defined more restrictively as the detailed description of the current weather along with forecasts obtained by extrapolation up to about 2 h ahead. Useful extrapolation forecasts can be obtained for longer periods in many situations, but in some weather situations the accuracy of extrapolation forecasts diminishes quickly with time as a result of the development or decay of the weather systems. *See* WEATHER. [K.A.B.]

Forecasts of time averages of atmospheric variables, for example, sea surface temperature, where the lead time for the prediction is more than 2 weeks, are termed long-range or extended-range climate predictions. Extended-range predictions of monthly and seasonal average temperature and precipitation are known as climate outlooks. The accuracy of long-range outlooks has always been modest because the predictions must encompass a large number of possible outcomes, while the observed single event against which the outlook is verified includes the noise created by the specific synoptic disturbances that actually occur and that are unpredictable on monthly and seasonal time scales. According to some estimates of potential predictability, the noise is generally larger than the signal in middle latitudes. [E.A.O'L.]

Weather map A map or a series of maps that is used to depict the evolution and life cycle of atmospheric phenomena at selected times at the surface and in the free atmosphere. Weather maps are used for the analysis and display of in-place observational measurements and computer-generated analysis and forecast fields derived from weather and climate prediction models by research and operational meteorologists, government research laboratories, and commercial firms. Similar analyses derived from sophisticated computer forecast models are displayed in map form for forecast periods of 10–14 days in advance to provide guidance for human weather forecasters. *See* METEOROLOGICAL INSTRUMENTATION; WEATHER OBSERVATIONS.

Rapid advances in computer technology and visualization techniques, as well as the continued explosive growth of the Internet distribution of global weather observations, satellite and radar imagery, and model analysis and forecast fields, have revolutionized how weather, climate, and forecast data and information can be conveyed to both the general public and sophisticated users in the public and commercial sectors. People and organizations with access to the Internet can access weather and climate information in a variety of digital or map forms in support of a wind range of professional and personal activities. *See* CLIMATOLOGY; METEOROLOGICAL SATELLITES; METEOROLOGY; RADAR METEOROLOGY; WEATHER FORECASTING AND PREDICTION. [L.F.B.]

Weather modification Human influence on the weather and, ultimately, climate. This can be either intentional, as with cloud seeding to clear fog from airports or to increase precipitation, or unintentional, as with air pollution, which increases aerosol concentrations and reduces sunlight. Weather is considered to be the day-to-day variations of the environment—temperature, cloudiness, relative humidity, wind-speed, visibility, and precipitation. Climate, on the other hand, reflects the average and extremes of these variables, changing on a seasonal basis. Weather change may lead to climate change, which is assessed over a period of years. *See* AIR POLLUTION; CLIMATE HISTORY; CLOUD PHYSICS.

Specific processes of weather modification are as follows: (1) Change of precipitation intensity and distribution result from changes in the colloidal stability of clouds. For example, seeding of supercooled water clouds with dry ice (solid carbon dioxide, CO_2) or silver iodide (AgI) leads to ice crystal growth and fallout; layer clouds may dissipate, convective clouds may grow. (2) Radiation change results from changes of aerosol or clouds (deliberately with a smoke screen, or unintentionally with air pollution from combustion), from changes in the gaseous constituents of the atmosphere (as with carbon dioxide from fossil fuel combustion), and from changes in the ability of surfaces to reflect or scatter back sunlight (as replacing farmland by houses.) (3) Change of wind regime results from change in surface roughness and heat input, for example, replacing forests with farmland. *See* PRECIPITATION (METEOROLOGY). [J.Hal.]

Weather observations The measuring, recording, and transmitting of data of the variable elements of weather. In the United States the National Weather Service (NWS), a division of the National Oceanic and Atmospheric Administration (NOAA), has as one of its primary responsibilities the acquisition of meteorological information. The data are sent by various communication methods to the National Meteorological Center.

At the Center, the raw data are fed into large computers that are programmed to plot, analyze, and process the data and also to make prognostic weather charts. The processed data and the forecast guidance are then distributed by special National Weather Service systems and conventional telecommunications to field offices, other government agencies, and private meteorologists. They in turn prepare forecasts and warnings based on both processed and raw data. *See* WEATHER MAP.

A wide variety of meteorological data are required to satisfy the needs of meteorologists, climatologists, and users in marine activities, forestry, agriculture, aviation, and other fields. This has led to a dual surface-observation program: the Synoptic Weather Program and the Basic Observations Program. *See* AERONAUTICAL METEOROLOGY; AGRICULTURAL METEOROLOGY; INDUSTRIAL METEOROLOGY.

The Synoptic Weather Program is designed to assist in the preparation of forecasts and to provide data for international exchange. Worldwide surface observations are taken at standard times [0000, 0600, 1200, and 1800 Universal Time Coordinated (UTC)] and sent in synoptic code.

The Basic Observations Program routinely provides meteorological data every hour. Special observations are taken at any intervening time to report significant weather events or changes. Observation sites are located primarily at airports; a few are in urban centers. At these sites, human observers report the weather elements.

Present weather consists of a number of hydrometers, such as liquid or frozen precipitation, fog, thunderstorms, showers, and tornadoes, and of lithometers, such as haze, dust, smog, dust devils, and blowing sand. The amount of cloudiness is also reported. *See* FOG; METEOROLOGICAL OPTICS; PRECIPITATION (METEOROLOGY); SMOG; THUNDERSTORM; TORNADO.

Pressure measurements are read from either a mercury or precision aneroid barometer located at the station. A microbarograph provides a continuous record of the pressure, from which changes in specific intervals of time are reported. Pressure changes are frequently quite helpful in short-range prediction of weather events. *See* Air pressure.

Temperature and humidity are measured by a hygrothermometer, located near the center of the runway complex at many airport stations. The readings are transmitted to the observation site. The temperature dial indicator is equipped with pointers to determine maximum and minimum temperature extremes. *See* Humidity; Hygrometer; Temperature measurement.

Wind speed and direction measurements are telemetered into most airport stations. The equipment, consisting of an anemometer and a wind vane, is located near the center of the runway complex at participating airports; elsewhere it is placed in an unsheltered area. *See* Wind measurement.

Various types of clouds and their heights are reported. The lowest height of opaque clouds covering half or more of the sky is known as the ceiling, and is normally measured by a ceilometer at first-order stations. *See* Cloud.

Upper-air observations have been made by the National Weather Service with radiosondes. The radiosonde is a small, expendable instrument package that is suspended below a 6-ft-diameter (2-m) balloon filled with hydrogen or helium. As the radiosonde is carried aloft, sensors on it measure profiles of pressure, temperature, and relative humidity. By tracking the position of the radiosonde in flight with a radio direction finder or radio navigation system, such as Loran or the Global Positioning System (GPS), information on wind speed and direction aloft is also obtained.

Understanding and accurately predicting changes in the atmosphere requires adequate observations of the upper atmosphere. Radiosonde observations, plus routine aircraft reports, radar, and satellite observations, provide meteorologists with a three-dimensional picture of the atmosphere. *See* Loran; Meteorological instrumentation; Satellite navigation systems; Weather observations; Wind measurement.

Weather radars distributed throughout the United States are used to observe precipitation within a radius of about 250 nmi (460 km), and associated wind fields (utilizing the Doppler principle) within about 125 nmi (230 km). The primary component of this set of weather radars is known as NEXRAD (Next Generation Weather Radar). These radars provide information on rainfall intensity, likelihood of tornadoes or severe thunderstorms, projected paths of individual storms (both ambient and within-storm wind fields), and heights of storms for short-range (up to 3 h) forecasts and warnings. *See* Doppler radar; Radar meteorology.

Geostationary weather satellites near 22,000 mi (36,000 km) above the Earth transmit pictures depicting the cloud cover over vast expanses of the hemisphere. Using still photographs and animated images, the meteorologist can determine, among other things, areas of potentially severe weather and the motion of clouds and fog. In addition, the satellite does an outstanding job of tracking hurricanes over the ocean where few other observations are taken. *See* Hurricane; Meteorological satellites.

Ground-based lightning detection systems detect the electromagnetic wave that emanates from the lightning path as the lightning strikes the ground. Lightning information has proven to be operationally valuable to a wide variety of users and as a supplement to other observing systems, particularly radar and satellites. *See* Lightning; Lightning and surge protection; Mesometeorology; Meteorology; Weather forecasting and prediction. [F.S.Z.; R.L.L.]

Weathering processes

The response of geologic materials to the environment (physical, chemical, and biological) at or near the Earth's surface. This response typically results in a reduction in size of the weathering materials; some may become as tiny as ions in solution.

The agents and energies that activate weathering processes and the products resulting therefrom have been classified traditionally as physical and chemical in type. In classic physical weathering, rock materials are broken by action of mechanical forces into smaller fragments without change in chemical composition, whereas in chemical weathering the process is characterized by change in chemical composition. In practice, however, the two processes commonly overlap.

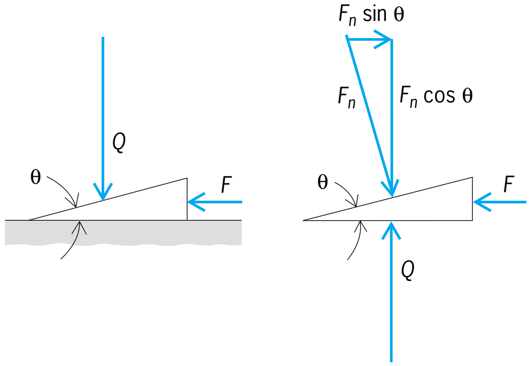
Specific agents of weathering may be recognized and correlated with the types of effects they produce. Important agents of weathering are water in all surface occurrences (rain, soil and ground water, streams, and ocean); the atmosphere (H_2O, O_2, CO_2, wind); temperature (ambient and changing, especially at the freezing point of water); insolation (on large bare surfaces); ice (in soil and glaciers); gravity; plants (bacteria and macroforms); animals (micro and macro, including humans). Human modifications of otherwise geologic weathering that have increased exponentially during recent centuries include construction, tillage, lumbering, use of fire, chemically active industry (fumes, liquid, and solid effluents), and manipulation of geologic water systems.

Products of physical weathering include jointed (horizontal and vertical) rock masses, disintegrated granules, frost-riven soil and surface rock, and rock and soil flows. Products of chemical weathering include the soil, and the clays used in making ceramic structural products, whitewares, refractories, various fillers and coating of paper, portland cement, absorbents, and vanadium. These are the relatively insoluble products of weathering; characteristically they occur in clays, siltstones, and shales. Sand-size particles resulting from both physical and chemical weathering may accumulate as sandstones.

After precipitation, the relatively soluble products of chemical weathering give rise to products and rocks such as limestone, gypsum, rock salt, silica, and phosphate and potassium compounds useful as fertilizers. [W.D.K.]

Wedge

A piece of resistant material whose two major surfaces make an acute angle. It is closely related to the inclined plane and is used to multiply the applied force and to change the direction in which it acts (see illustration). *See* Inclined plane.



Forces acting on a wedge.

Force F is the smaller applied force and Q is the larger force to be exerted. In the absence of friction, forces must act normal to their surfaces; thus the actual force on the inclined surface is not Q but a larger force F_n. Summing up forces in the horizontal and vertical directions gives Eqs. (1).

$$\begin{aligned} F_n \sin\theta - F &= 0 \\ Q - F_n \cos\theta &= 0 \end{aligned} \tag{1}$$

Combining the expressions for F and Q and solving for F gives Eq. (2).

$$F = Q \tan\theta \tag{2}$$

If angle θ is small, the reaction of Q against F is exceeded by the friction between the face of the wedge and the adjacent body on which it rests. Thus the wedge tends to remain in position even when loaded by a large force Q. *See* SIMPLE MACHINE. [R.M.Ph.]

Weeds Unwanted plants or plants whose negative values outweigh the positive values in a given situation. Weeds impact growers each year in reduced yield and quality of agricultural products. Especially in tropical areas, irrigation systems have become unusable because of clogging with weeds. Weeds can harbor deleterious disease organisms and insects that harm crops and livestock. In addition, weeds can cause allergic reactions and serious skin problems (poison ivy), break up pavement, slow or stop water flow in municipal water supplies, interfere with power lines, cause fire hazards around buildings and along railroad tracks, and produce poisonous plant parts. *See* ALLERGY.

The most serious weeds are those that succeed in invading new areas and surviving at the expense of other plants by monopolizing light, nutrients, and water or by releasing chemicals detrimental to the growth of surrounding vegetation (allelopathy). In the plant kingdom, dozens of species have been shown to release allelopathic chemicals from roots, leaves, and stems. *See* ALLELOPATHY.

Classification. Weeds can be classified as summer annuals, which germinate in the spring, set seed, and die in the fall (crabgrass); winter annuals, which germinate in the fall, set seed, and die in the spring (common chickweek); biennials, which germinate one year, overwinter, set seed, and die the following summer (wild carrot); simple perennials, which live for several years but spread only by seed (dandelion); and creeping perennials, which live for several years and can spread both by seed and by underground roots or rhizomes (field bindweed).

Control methods. Hand pulling, fire, flooding, and tillage are useful for controlling weeds. Insects and pathogens have also been introduced to control certain weed species. Techniques such as herbicides, computerization of spray and tillage technology, remote sensing for weed mapping and identification, and laser treatment have also been explored. Herbicides have resulted in large improvements in the availability and quality of food. They have increased the feasibility of no-till agriculture, leading to significant reductions in soil erosion. They commonly kill weeds by disrupting a physiological process that is not present in animals. Some, however, are moderately high in toxicity and must be used carefully. Rare individual weeds that are genetically resistant to the herbicide have flourished and reproduced, leading to populations of weeds resistant to that herbicide. *See* HERBICIDE. [A.P.A.]

Biological control. Biological control involves the use of natural enemies (parasites, pathogens, and predators) to control pest populations. In the case of weed pests, the primary natural enemy groups utilized are arthropods, fungal pathogens, and vertebrates. The two major approaches are classical and inundative biological control. Biocontrol can be a highly effective and cost-efficient means of controlling weeds without the use of chemical herbicides.

Classical biocontrol (also termed the inoculative or importation method) is based on the principle of population regulation by natural enemies. Most naturalized weeds leave behind their natural enemies when they colonize new areas, and so can increase to significant densities. Classical biocontrol involves the importation of natural enemies, usually from the area of origin of the weed (and preferably from a part of its native range that is a good climatic match with the intended control area), and their field release. Imported biocontrol agents must be host specific to the target weed.

Inundative control is the mass production and periodic release of large numbers of biocontrol agents to achieve controlling densities. It can be used where existing populations of agents are lacking or where existing populations that are not self-sustaining at high, controlling densities can be augmented. A chief advantage of this method is that it can be integrated with conventional fanning practices on cultivated croplands.

Arthropods, especially insects, are heavily utilized as imported biocontrol agents in uncultivated environments such as grasslands and aquatic systems.

Rusts (Uredinales) are the fungal group most frequently employed as imported agents in classical biocontrol programs. The rust *Puccinia chondrillina*, imported from Italy, controlled the narrow-leaf form of skeletonweed (*Chondrilla juncea*) in Australia. Formulations of spores of foreign and endemic pathogens can be used as mycoherbicides in inundative applications.

Vertebrate animal agents, such as goats, typically do not possess a high degree of host-plant specificity, and their feeding has to be carefully managed to focus it on the target weeds. *See* ARTHROPODA; FUNGI. [C.E.Tu.]

Weight The gravitational weight of a body is the force with which the Earth attracts the body. By extension, the term is also used for the attraction of the Sun or a planet on a nearby body. This force is proportional to the body's mass and depends on the location. Because the distance from the surface to the center of the Earth decreases at higher latitudes, and because the centrifugal force of the Earth's rotation is greatest at the Equator, the observed weight of a body is smallest at the Equator and largest at the poles. The difference is sizable, about 1 part in 300. At a given location, the weight of a body is highest at the surface of the Earth. Weight is measured by several procedures. *See* BALANCE; MASS; WEIGHT MEASUREMENT. [H.S.B.]

Weight measurement Weight is the resultant force acting on a mass (in a vacuum) due to the Earth's gravitational field corrected for the effect of the Earth's rotation. Units of weight are based upon an acceleration of gravity. When the weight of an unknown is determined by comparison with a known weight, there is no error in the readings due to gravity variations. The varying buoyant effect of the atmosphere is negligible when the density of the unknown is approximately the same as that of the standard. In precision weighing, the buoyant effect of air must be considered. *See* GRAVITY.

The equal-arm balance is probably the most common form of instrument for measuring weight. These balances are made in many designs and sizes; in some the knife-edge fulcrums are replaced with flexure plates; others have arms of unequal length. Conventionally, the unknown weight is placed on one pan, the known weight on the other. The final securing of a balance is done by adjusting the position of a rider, or small weight, on a bar of the balance arm bridge. The condition of balance is indicated when the pointer swings equal distances from its rest point. *See* BALANCE.

The mechanical-type industrial scale incorporates a number of levers with precisely located fulcrums to permit heavy objects to be balanced (weighed) with small, convenient counterweights or counterpoises.

The pendulum-type mechanical scale balances the force of the load by the rotation of a bent lever. With this construction, the deflection of the load on the scale moves the counterweights through the lever system so that their center of gravity is at a greater distance from the final fulcrum. Thus the increased lever arm of the counterweights automatically balances the load.

The spring scale utilizes the deflection of a spring to measure the load. If sensitive enough, such a scale can detect and indicate the effect of differences in the weight of a body due to changes in elevation.

In hydraulic systems, the load applied to the load cell piston is converted to hydraulic pressure. The effective area of the piston must be known. The pressure may be measured at a remote point by a pressure-gage, such as a Bourdon tube.

Pneumatic systems detect the load by a sensitive nozzle and flapper system and balance the load by modulating an air pressure in an opposing capsule.

Electrical weighing systems usually involve the electrical measurement of the elastic deformation of a mechanical element under stress. The strain gage is attached to the weighing element in a manner to produce the maximum resistance change per unit of load. The change in resistance with load is measured and amplified by electronic means, and the load is read on a potentiometer. *See* Weight. [H.S.B.]

Weightlessness A condition induced by the effective lack of resistance to gravitational force on an object or organism, sometimes known as free fall.

Newton proposed the law of universal gravitation, which states that two bodies of matter in the universe attract each other with a force that is directly proportional to the product of their masses and inversely proportional to the square of the distance between their centers. According to this law, even a small increase in the distance between bodies will produce a large decrease in the gravitational force, since the force decreases with the square of the distance. As a body moves from the Earth's surface to a location an infinite distance from the Earth, the gravitational force approaches zero and the body approaches weightlessness. In the true sense, a body can be weightless only when it is an infinite distance from all other objects.

Weightlessness is also defined as a condition in which no acceleration, whether of gravity or any other force, can be detected by an object or organism within the system in question. According to Albert Einstein's principle of equivalence, there is no way to distinguish between the forces of gravitational fields and the forces due to inertial motion. When a gravitational force on a body is opposed by an equal and opposite inertial force, a weightless state is produced. This is based on the fact that the mass that determines the gravitational force of a body is the same as the mass related to the acceleration produced by an inertial force of any kind. These inertial forces have no external physical origin, but are the consequences of an accelerated state of motion. Because of inertia, a moving object always tends to follow a straight line. When a person swings a bucket by the handle in a large circle, he or she feels a pull on his or her hand, because inertial force (also called centrifugal force in this case) tends to keep the bucket moving in a straight line, while the bucket holder exerts a counterforce constraining the bucket to move along the circle. A similar situation exists in a spaceship orbiting the Earth 200 mi (320 km) above the Earth's surface, where the gravitational field is only slightly weaker than at sea level. The ship, in free fall with negligible atmospheric drag, is pulled toward the Earth by the Earth's gravitational attraction force, while the inertial or centrifugal force of the moving ship is directed radially outward from the Earth; consequently, the force of gravity on the orbiting ship is opposed and nullified by the centrifugal force, and apparent weightlessness results. *See* Gravitation; Gravity; Inertia; Newton's laws of motion; Space flight; Space processing. [T.W.H.]

Welded joint The joining of two or more metallic components by introducing fused metal (welding rod) into a fillet between the components or by raising the temperature of their surfaces or edges to the fusion temperature and applying pressure (flash welding).

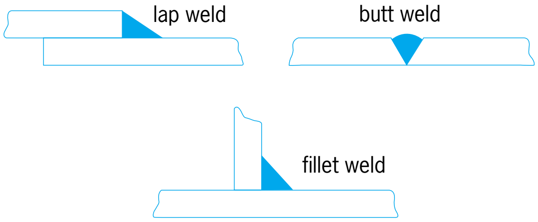


Fig. 1. Three types of welded joints.

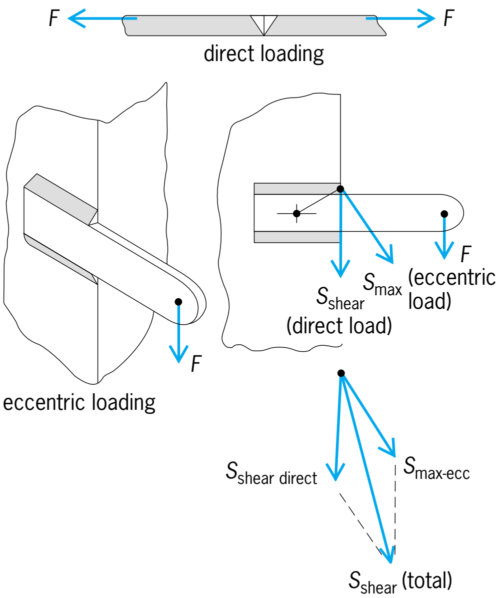

Fig. 2. Loading forces on a welded joint.

Figure 1 shows three types of welded joints. In a lap weld, the edges of a plate are lapped one over the other and the edge of one is welded to the surface of the other. In a butt weld, the edge of one plate is brought in line with the edge of a second plate and the joint is filled with welding metal or the two edges are resistance-heated and pressed together to fuse. For a fillet weld, the edge of one plate is brought against the surface of another not in the same plane and welding metal is fused in the corner between the two plates, thus forming a fillet. The joint can be welded on one or both sides.

Because welded joints are usually exposed to a complex stress pattern as a result of the high temperature gradients present when the weld is made, it is customary to design joints by use of arbitrary and simplified equations and generous safety factors. The force F of direct loading, and consequently the stress S, is applied directly along or across a weld. The stress-force equation is then simply $F = SA$, in which A is the area of the plane of failure (Fig. 2). For eccentric loading, the force F causes longitudinal and transverse forces of varying magnitudes along the weld. *See* Riveted joint; Structural connections; Welding and cutting of metals. [L.S.L.]

Welding and cutting of materials Processes based on heat to join and sever metals. Welding and cutting are grouped together because, in many manufacturing operations, severing precedes welding and involves the same production personnel. Welding is one of the joining processes, others being riveting, bolting, gluing, and adhesive bonding. *See* Bolted joint; Welded joint.

The American Welding Society's definition of welding is "a metal-joining process wherein coalescence is produced by heating to suitable temperatures with or without the application of pressure, and with or without the use of filler metal." Brazing is defined as "a group of welding processes wherein coalescence is produced by heating to suitable temperature and by using a filler metal, having a liquidus above 800°F (427°C) and below the solidus of the base metals. The filler metal is distributed between the closely fitted surfaces of the joint by capillary attraction." Soldering is similar in principle, except that the melting point of solder is below 800°F (427°C). The adhesion of solder depends not so much on alloying as on its keying into small irregularities in the surfaces to be joined. *See* Joint (structures); Brazing; Soldering.

Cutting is one of the severing and material-shaping processes, some others being sawing, drilling, and planning. Thermal cutting is defined as a group of cutting processes wherein the severing or removing of metals is effected by melting or by the chemical reaction of oxygen with the metal at elevated temperatures. Welding and cutting are widely used in building ships, machinery, boilers, spacevehicles, structures, atomic reactors, aircraft, railroad cars, missiles, automobiles, buses and trailers, and pressure vessels, as well as in constructing piping and storage tanks of steel, stainless steel, aluminum, nickel, copper, lead, titanium, tantalum, and their alloys. For many products, welding is the only joining process that achieves the desired economy and properties, particularly leak-tightness. *See* TORCH.

Nearly all industrial welding involves fusion. The edges or surfaces to be welded are brought to the molten state. The liquid metal bridges the gap between the parts. After the source of welding heat has been removed, the liquid solidifies, thus joining or welding the parts together. The principal sources of heat for fusion welding are electric arc, electric resistance, flame, laser, and electron-beam. *See* ARC WELDING; LASER WELDING; RESISTANCE WELDING. [M.M.S.]

Well An artificial excavation made to extract water, oil, gas, brine, or other fluid substance from the earth. Most wells are of the drilled type. Dug wells are almost obsolete, because of the greater speed of drilling and the greater efficiency of drilled wells. *See* ARTESIAN SYSTEMS; OIL AND GAS WELL DRILLING.

Drilled wells, commonly 2–36 in. (5–90 cm) in diameter, usually are fitted with a steel tube or casing inserted in the drilled hole to the desired depth. Where the water-bearing formation is competent to stand without support, the casing is set, or finished, at the top of solid rock. Where there is danger of caving, as in sand or gravel, the casing is carrried below the top of the water-bearing bed, and a perforated pipe or screen extends below the casing to the bottom of the hole. The construction includes a considerable period of pumping, surging, or other treatment (called well development), during which the finer particles of the formation are drawn into the well and removed. This process substantially increases the initial yield of the well.

Most wells of large capacity are equipped with pumps of the deep-well turbine type to lift the water to the surface. When a well is pumped, the pressure head at the well is lowered and a hydraulic gradient toward the well is established which causes water to flow toward the well. This lowering of head is called drawdown. *See* GROUND-WATER HYDROLOGY; PUMPING MACHINERY. [A.N.S./R.K.Li.]

Well logging The technique of making measurements in drill holes with probes designed to measure the physical and chemical properties of rocks and their contained fluids. Much information can be obtained from samples of rock brought to the surface in cores or bit cuttings, or from other clues while drilling, such as penetration rate; however, the greatest amount of information comes from well logs. *See* BOREHOLE LOGGING.

Well logs result from a probe lowered into the borehole at the end of an insulated cable. The resulting measurements are recorded graphically or digitally as a function of depth. These records are known as geophysical well logs, petrophysical logs, or more commonly well logs, or simply logs.

Although the most common uses of logs are for correlation of geological strata and location of hydrocarbon zones, there are many other important subsurface parameters that need to be detected or measured. Also, different borehole and formation conditions can require different tools to measure the same basic property. In petroleum engineering, logs are used to: identify potential reservoir rock; determine bed thickness; determine porosity; estimate permeability; locate hydrocarbons; estimate water salinity; quantify amount of hydrocarbons; estimate type and rate of fluid production; estimate formation pressure; identify fracture zones; measure borehole inclination and azimuth; measure hole diameter; aid in setting casing; evaluate quality of cement bonding; locate entry, rate, and type of fluid into borehole; and trace material injected into formations (such as artificial fractures). In geology and geophysics, they are used to: correlate between wells; locate faults; determine dip and strike of beds; identify lithology; deduce environmental deposition of sediments; determine thermal and pressure gradients; create synthetic seismograms; calibrate seismic amplitude anomalies to help identify hydrocarbons from surface geophysics; calibrate seismic with velocity surveys; and calibrate gravity surveys with borehole gravity meter. Other applications include: locating fresh-water aquifers; locating solid minerals; and studying soil and rock conditions for foundations of large structures.

Electrical devices employ instruments that generate data based on electrical measurements. The spontaneous potential, usually recorded along with resistivity curves, is a simple but valuable aid to help geologists correlate from one well to another and to assist them in inferring the depositional environment of the sediments. It defines permeable zones from surrounding non-permeable shales and can be used to estimate the salinity of formation water. Resistivity is one of the most important physical properties to record. A sand filled with salt water will conduct electricity much easier (and therefore has a lower resistivity) than a sand in which most of the salt water is replaced with a nonconducting oil or gas. The primary purpose of resistivity measurements is to determine hydrocarbon saturation.

Quantitative interpretation of hydrocarbon saturation requires a knowledge of porosity. One of the most widely used porosity logs is the acoustic log, also known as a sonic log, acoustilog, or velocity log. The acoustical log measures the shortest time for sound waves to travel through 1 ft (or 1 m) of formation. This log is used for many other purposes, including identification of lithology, prediction of pressures, and assisting with geophysical interpretation. In addition, information from the amplitude of the acoustic wave aids in detection of fractures and gas zones, determination of mechanical properties of rocks, and analysis of cement bond behind pipe.

Nuclear devices are instruments which generate data based on measurements of nuclear particles. In most cases the gamma-ray log may be considered as a shale log; that is, clays or shaly rocks will give a higher radioactive count than clean sands or carbonates. Like the spontaneous potential, this provides a good correlation curve, defines bed thicknesses, and aids interpretation of environmental deposition. Almost all the naturally occurring radioactivity that is detected by the gamma-ray log comes from three elements: potassium, thorium, and uranium.

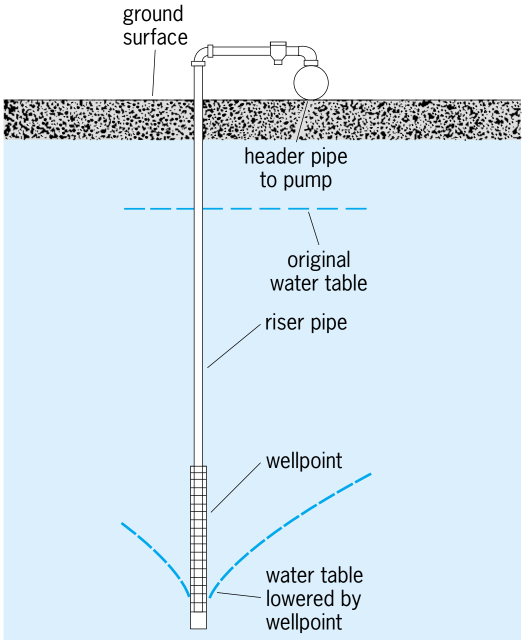
An important porosity tool is the density log, which emits a beam of gamma rays into the rock and these rays interact with electrons in the formation through Compton scattering. The tool provides a bulk density measurement. Another important device for determination of porosity is the neutron log. These logs respond primarily to hydrogen atoms. Therefore, in clean or shale-free formations the neutron log reflects the amount of liquid-filled porosity. A tool developed to distinguish hydrocarbon from salt water behind casing is the pulsed neutron capture tool which employs a neutron generator that repeatedly emits pulses of high-energy neutrons. After these neutrons are slowed down to the thermal state, they are captured by nuclei of the various atoms surrounding the tool. With each capture a corresponding emission of gamma rays occurs.

Production logging tools are designed to locate fluid movement behind the casing and into the well bore, to detect the type of fluid, and to determine the flow rate. Production logging tools include various types of flow meters, fluid density devices, sensitive thermometers, radioactive tracer devices, noise loggers, and capacitance logs. In addition, these tools usually record some correlation curve such as gamma-ray or collar locator to tie the production curves to the formation and casing. Closely related to production tools are logging devices that either magnetically or mechanically inspect the condition of the casing in the borehole.

Small but rugged and powerful computers designed for field operation record logs on magnetic tapes as they are run and mathematically manipulate them in the logging trucks at the well site. Detailed computations are made quickly on a foot by foot basis to give information on fluid and rock properties. The digital information from practically every curve can be incorporated into some type of analysis or interpretation program. [R.E.Wy.]

Wellpoint systems A method of keeping an excavated area dry by intercepting the flow of groundwater with pipe wells located around the excavation area. Intercepting the flow before it reaches the excavated area also improves the stability of the edge of the excavation, permitting steeper bank slopes and often eliminating the need for supporting or shoring the banks. *See* CONSTRUCTION METHODS; GROUND-WATER HYDROLOGY; WELL.

Wellpoint systems are most effective in coarse-grained soils, such as gravel or sand. They are not effective in fine soils, such as silts and clays, where the small size of the pores between grains restricts the flow of water.



Components of a wellpoint system.

The basic components of a wellpoint system are the wellpoint, the riser pipe, the header pipe or manifold, and the pump (see illustration). The wellpoint consists of a perforated pipe equipped with a ball valve to regulate the flow of water, a screen to prevent the entry of sand during pumping, and a jetting tip. The steel riser pipe brings the groundwater to the surface, where it is collected by the horizontal manifold pipe or header pipe. The pumps are located above the water table and collect the water from the header pipes for discharge away from the excavation area. *See* PUMP; PUMPING MACHINERY. [W.Her.]

Welwitschiales An order of the class Cycadopsida having one species, *Welwitschia mirabilis*. This plant is native to the very arid deserts of southwestern Africa. Its appearance is bizarre—it has a very short, unbranched, woody stem (sometimes to 3 ft or 1 m in diameter), which is cushion- or saucer-shaped and tapers quickly to a long taproot. There are only two leaves, and these persist throughout the life of the plant. The leaf is broadly strap-shaped, as wide as the stem, firm, and leathery, and gradually splits lengthwise between the veins. The leaf (of indefinite growth) develops from a meristem at this point of connection to the stem. The species is dioecious; the cones are borne on branched axes originating between the crown of the stem and the base of the leaf. The order is known only from the one living species and not from any fossils. *See* CYCADOPSIDA; PINOPHYTA; PLANT KINGDOM. [T.A.Z.]

Wentzel-Kramers-Brillouin method A special technique for obtaining an approximation to the solutions of the one-dimensional time-independent Schrödinger equation, valid when the wavelength of the solution varies slowly with position. It is named after G. Wentzel, H. A. Kramers, and L. Brillouin, who independently in 1926 contributed to its understanding in the quantum-mechanical application. It is also called the WKB method, BWK method, the classical approximation, the quasi-classical approximation, and the phase integral method. *See* QUANTUM MECHANICS; SCHRÖDINGER'S WAVE EQUATION. [R.H.Go.]

West Indies An archipelago, including the Bahamas, the Greater Antilles (including Cuba, Jamaica, Hispaniola—the Dominican Republic and Haiti—and Puerto Rico), the Lesser Antilles, and other islands, curving 2500 mi (4000 km) from Yucatan Peninsula and southeastern Florida to northern Venezuela and enclosing the Caribbean Sea. Situated between latitude 10° and 27°N and longitude 59° and 85°W, in the zone of the northeast trade winds, the West Indies have a subtropical and predominantly oceanic climate, with even warmth and steady breezes. Temperatures vary little from season to season, ranging from means of 80–85°F (27–29°C) in July to 70–78°F (21–26°C) in January at sea level. Freezing is unknown, and the hottest temperatures rarely exceed 90°F (32°C). Precipitation ranges from a low of 25–50 in. (64–127 cm) a year on low-lying islands and drier coasts up to 300 in. (7.6 m) on the highest peaks, which are almost perpetually cloud-capped. At lower elevations, rainfall is erratic from year to year and from season to season, but reaches a maximum in the summer and fall, when the northeast trades are replaced by light, variable winds. This is also the season of hurricanes, destructive tropical cyclones which sweep west and northwest across the Caribbean, sparing only the southernmost islands. The winter months are generally dry, and there is frequently a shorter dry season in July or August. *See* CARIBBEAN SEA; TROPICAL METEOROLOGY.

The West Indian flora is chiefly derived from Central and South America, but there are a number of endemic species, notably palms; many mainland plants failed to colonize the islands, which are floristically poor. The effect of isolation and small size is evident in the meager character of West Indian fauna. Animal species are limited; there are few mammals and no large ones, except for domesticated animals and, especially on Hispaniola, feral cattle, goats, pigs, and horses. [D.Low.]

Wetlands Ecosystems that form transitional areas between terrestrial and aquatic components of a landscape. Typically they are shallow-water to intermittently flooded ecosystems, which results in their unique combination of hydrology, soils, and vegetation. Examples of wetlands include swamps, fresh- and salt-water marshes, bogs, fens, playas, vernal pools and ponds, floodplains, organic and mineral soil flats, and tundra. As transitional elements in the landscape, wetlands often develop at the interface between drier uplands such as forests and farmlands, and deep-water aquatic systems such as lakes, rivers, estuaries, and oceans. Thus, wetland ecosystems are characterized by the presence of water that flows over, ponds on the surface of, or saturates the soil for at least some portion of the year.

Wetland soils can be either mineral (composed of varying percentages of sand, silt, or clay) or organic (containing 12–20% organic matter). Through their texture, structure, and landscape position, soils control the rate of water movement into and through the soil profile (the vertical succession of soil layers). Retention of water and organic carbon in the soil environment controls biogeochemical reactions that facilitate the functioning of wetland soils. *See* BIOGEOCHEMISTRY.

Vegetated wetlands are dominated by plant species, called hydrophytes, that are adapted to live in water or under saturated soil conditions. Adaptations that allow plants to survive in a water-logged environment include morphological features, such as pneumatophores (the "knees," or exposed roots, of the bald cypress), buttressed tree trunks, shallow root systems, floating leaves, hypertrophied lenticels, inflated plant parts, and adventitious roots. Physiological adaptations also allow plants to survive in a wetland environment. These include the ability of plants to transfer oxygen from the root system into the soil immediately surrounding the root (rhizosphere oxidation); the reduction or elimination of ethanol accumulation due to low concentrations of alcohol dehydrogenase; and the ability to concentrate malate (a nontoxic metabolite) instead of ethanol in the root system. *See* ROOT (BOTANY).

Wetlands differ with respect to their origin, position in the landscape, and hydrologic and biotic characteristics. For example, work has focused on the hydrology as well as the geomorphic position of wetlands in the landscape. This hydrogeomorphic approach recognizes and uses the fundamental physical properties that define wetland ecosystems to distinguish among classes of wetlands that occur in riverine, depressional, estuarine or lake fringe, mineral or organic soil flats, and slope environments.

The extent of wetlands in the world is estimated to be $2–3 \times 10^6$ mi^2 ($5–8 \times 10^6$ km^2), or about 4–6% of the Earth's land surface. Wetlands are found on every continent except Antarctica and in every clime from the tropics to the frozen tundra. Rice paddies, which comprise another 500,000–600,000 mi^2 ($1.3–1.5 \times 10^6$ km^2), can be considered as a type of domesticated wetland of great value to human societies worldwide. *See* BOG; MANGROVE; MUSKEG; PLAYA; SALT MARSH; TUNDRA.

Wetlands are often an extremely productive part of the landscape. They support a rich variety of waterfowl and aquatic organisms, and represent one of the highest levels of species diversity and richness of any ecosystem. Wetlands are an extremely important habitat for rare and endangered species.

Wetlands often serve as natural filters for human and naturally generated nutrients, organic materials, and contaminants. The ability to retain, process, or transform these substances is called assimilative capacity, and is strongly related to wetland soil texture and vegetation. The assimilative capacity of wetlands has led to many projects that use wetland ecosystems for wastewater treatment and for improving water quality. Wetlands also have been shown to prevent downstream flooding and, in some cases, to prevent ground-water depletion as well as to protect shorelines from storm damage. The best wetland management practices enhance the natural processes of wetlands by maintaining conditions as close to the natural hydrology of the wetland as possible. *See* GROUND-WATER HYDROLOGY.

The world's wetlands are becoming a threatened landscape. Loss of wetlands worldwide currently is estimated at 50%. Wetland loss results primarily from habitat destruction, alteration of wetland hydrology, and landscape fragmentation. Global warming may soon be added to this list, although the exact loss of coastal wetlands due to sea-level rise is not well documented. Worldwide, destruction of wetland ecosystems primarily has been through the conversion of wetlands to agricultural land.

Hydrologic modifications that destroy, alter, and degrade wetland systems include the construction of dams and water diversions, ground-water extraction, and the artificial manipulation of the amount, timing, and periodicity of water delivery. The primary impact of landscape fragmentation on wetland ecosystems is the disruption and degradation of wildlife migratory corridors, reducing the connectivity of wildlife habitats and rendering wetland habitats too small, too degraded, or otherwise irreversibly altered to support the critical life stages of plants and animals.

The heavy losses of wetlands in the world, coupled with the recognized values of these systems, have led to a number of policy initiatives at both the national and international levels.

Wetland restoration usually refers to the rehabilitation of degraded or hydrologically altered wetlands, often involving the reestablishment of vegetation. Wetland enhancement generally refers to the targeted restoration of one or a set of ecosystem functions over others, for example, the focused restoration of a breeding habitat for rare, threatened, or endangered amphibians. Wetland creation refers to the construction of wetlands where they did not exist before. Created wetlands are also called constructed or artificial wetlands. Restoring, enhancing, or creating a wetland requires a comprehensive understanding of hydrology and ecology, as well as engineering skills. *See* DAM; ECOSYSTEM; ESTUARINE OCEANOGRAPHY; HYDROLOGY; RIVER ENGINEERING; RESTORATION ECOLOGY. [W.J.M.; P.L.Fi.; L.C.Le.; S.R.St.]

Wheat A food grain crop. Wheat is the most widely grown food crop in the world, and is increasing in production. It ranks first in world crop production and is the national food staple of 43 countries. At least one-third of the world's population depends on wheat as its main staple. The principal food use of wheat is as bread, either leavened or unleavened. The United States is second to Russia in total production, but the average yield per acre in the United States is about twice that of Russia. Other major wheat-producing countries in the world are Canada, China, India, France, Argentina, and Australia.

Wheat is best adapted to a cool dry climate, but is grown in a wide range of soils and climates. Much of the world's wheat is seeded in the fall season and, after being dormant or growing very slowly during winter, it makes rapid growth in the spring and develops grain for harvest in early summer.

Wheat for milling is classified according to hardness, color, and best use. In the United States, there are seven official market classes of which the following five are the most important: (1) hard red winter, for bread; (2) hard red spring, for bread and rolls; (3) soft red winter, for cake and pastries; (4) white, for bread, breakfast foods, and pastries; and (5) durum, for macaroni products.

The wheat inflorescence is a spike bearing sessile spikelets arranged alternately on a zigzag rachis. Two, three, or more florets may develop in each spikelet and bear grains. The grain may be white, red (brown), or purple, and it may be hard or soft in texture. Size of the grain or caryopsis may be large, as in durum, or very small, as in shot wheat (*Triticum sphaerococcum*). Wheats vary in plant height and in the ability to produce tillers. The stems are usually hollow. The wheat grain is composed of the endosperm and embryo enclosed by bran layers. The endosperm portion is principally starch and is therefore used as energy food. Wheat is also an important protein source, especially for those people who use wheat as their main staple. *See* SEED.

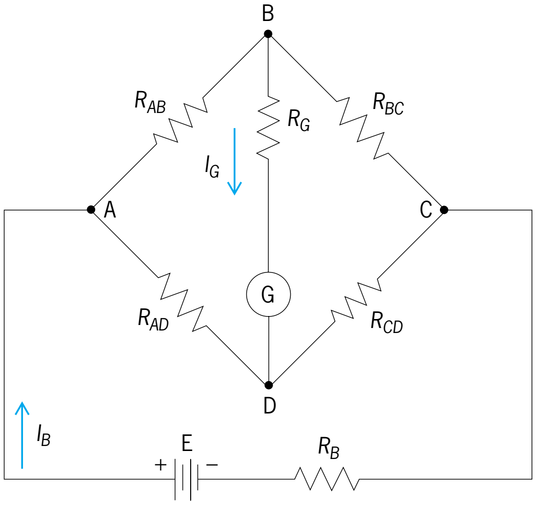
Botanically, wheat is a member of the grass family to which rice, barley, corn, and several other cereal grain crops also belong. The *Triticum* genus includes a wide range of wheat forms. Taxonomic studies place the goat grasses (*Aegilops*) and wheat (*Triticum*) in one genus, *Triticum*. Wheat has been crossed with rye (*Secale*) and with *Agropyron* (a grass). New forms, called *Triticale*, have been derived from crossing rye and wheat followed by doubling the chromosomes in the hybrid. *See* TRITICALE.

Most countries in which wheat is grown have wheat breeding programs in which the objective is to develop more productive and more stable varieties (cultivars). Many methods are combined in these programs, but in nearly all of them specially selected parent types are crossbred followed by pure-line selection among the progeny to develop new combinations of merit. Varieties and genetic types from all over the world become candidate parents to provide the desired recombinations of good quality, winter and drought hardiness, straw strength, yield, and disease resistance. Wheats must be bred for specific milling processes and to provide quality end-use products. Many new varieties have complex pedigrees. *See* BREEDING (PLANT); GRAIN CROPS. [L.P.R.]

Milling of wheat has evolved from rudimentary crushing or cracking to sophisticated separation and refining. The main purpose of milling is isolation of the starch-protein matrix, that is, separation of the endosperm from the high-fiber bran and high-lipid germ. Under optimal conditions, milling yields a high-quality, uniformly colored flour with a relatively stable shelf-life. The flours of hard wheats (11 to 13% protein) develop strong gluten complexes during mixing and are therefore suitable for making bread. Whole soft wheats (9 to 11% protein) yield flours that are used primarily for cakes, cookies, and pastries. Durum wheat is used to produce a relatively coarse flour, semolina, used for manufacture of pasta products. *See* FOOD MANUFACTURING. [M.A.U.]

Wheatstone bridge

Wheatstone bridge A device used to measure the electrical resistance of an unknown resistor by comparing it with a known standard resistance. This method was first described by S. H. Christie in 1833. Since 1843 when Sir Charles Wheatstone called attention to Christie's work, Wheatstone's name has been associated with this network.



Wheatstone bridge circuit.

The Wheatstone bridge network consists of four resistors R_{AB}, R_{BC}, R_{CD}, and R_{AD} interconnected as shown in the illustration to form the bridge. A detector G, having an internal resistance R_G, is connected between the B and D bridge points; and a power supply, having an open-circuit voltage E and internal resistance R_B, is connected between the A and C bridge points. *See* BRIDGE CIRCUIT.

If the network is adjusted so that Eq. (1) is satisfied, the detector

$$R_{BC}R_{AD} - R_{AB}R_{CD} = 0 \qquad (1)$$

current will be zero and this adjustment will be independent of the supply voltage, the supply resistance, and the detector resistance. Thus, when the bridge is balanced, Eq. (2) holds, and, if it is

$$R_{BC}R_{AD} = R_{AB}R_{CD} \qquad (2)$$

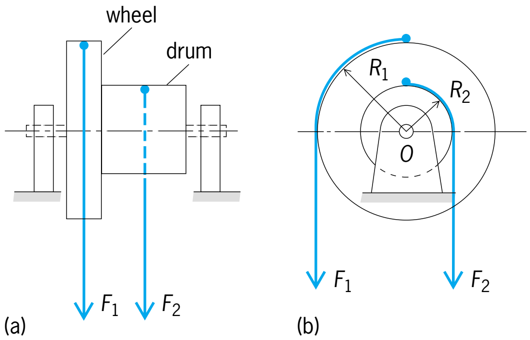
assumed that the unknown resistance is the one in the CD arm of the bridge, then it is given by Eq. (3).

$$R_{CD} = \left(\frac{R_{BC}}{R_{AB}}\right) \times R_{AD} \qquad (3)$$

See RESISTANCE MEASUREMENT. [C.E.A.]

Wheel and axle

Wheel and axle A wheel and its axle or, more generally, two wheels with different diameters or a wheel and drum, as in a windlass, rigidly connected together so that they rotate as a unit on a common axis. The principle of operation is the same as that of the lever in that, for static equilibrium, the summation of torques about the axis of rotation equals zero. Where flexible members, such as ropes, have been firmly attached to a wheel and drum (see illustration) and the machine is mounted on frictionless bearings, $F_1R_1 - F_2R_2 = 0$.



Wheel and axle. (*a*) Side view. (*b*) Front view.

The main difference between the lever and the wheel and axle is that the wheel and axle permits the forces to operate through a much greater distance. In the illustration the wheel and drum could be allowed to rotate any number of revolutions if the ropes were wrapped the required number of times around each before they were attached. *See* FORCE; SIMPLE MACHINE. [R.M.Ph.]

Wheel base

Wheel base The distance in the direction of travel from front to rear wheels of a vehicle, measured between centers of ground contact under each wheel. For a vehicle with two rear axles, the rear measuring point is on the ground midway between rear axles. Tread of a vehicle is the distance perpendicular to the direction of travel between front wheels, or between rear wheels, measured from centers of ground contact. [F.H.R.]

White dwarf star

White dwarf star The smallest kind of ordinary star, about the size of the Earth. In most white dwarf stars, an amount of matter equal to 60% of the Sun's mass is compressed into this small volume. One quarter liter (about 1 cup) of white dwarf material has a mass of 600 tons. Several thousand white dwarf stars have been discovered.

Some of the other properties of white dwarf stars reach extreme values. The hottest known stars are either white dwarfs or stars that are just about to become white dwarfs, and have temperatures of a few hundred thousand kelvins. A few white dwarf stars have very strong magnetic fields, with field strengths exceeding 10^8 gauss (10^4 teslas), many times stronger than can be generated in laboratories. Some white dwarf stars rotate every few minutes, and some others rotate so slowly that no spin has been detected over several decades. The coolest white dwarf stars emit less energy per second than any other type of visible star. *See* HIGH MAGNETIC FIELDS.

White dwarfs are the final stages in the life cycles of low-mass stars like the Sun, the most common types of stars. At present, the Sun is on the main sequence, fusing hydrogen to form helium in its core. Five billion years from now, the hydrogen in the center of the Sun will run out, and the Sun will become a red giant star as it turns to other nuclear reactions to provide its internal heat. Stars like the Sun will become only hot enough inside that they will fuse helium nuclei to form a mixture of carbon and oxygen. They will then reach the end of the nuclear fusion road, and will no longer be able to generate their own sources of energy. At this point in their life cycle, they will be on the way to becoming white dwarf stars, the most common types of stellar remnants. *See* NUCLEOSYNTHESIS; STELLAR EVOLUTION.

Just before a star becomes a white dwarf star, it will shed its outer layers as its stellar wind strengthens at the very end of the red giant stage of its life cycle. In many and perhaps all cases, the expelled gas will become visible as a glowing gas cloud called a planetary nebula. *See* PLANETARY NEBULA.

A star becomes a bona fide white dwarf when it contracts to a state where heat pressure plays a very small role in determining its internal structure. The material in white dwarf stars is a form of matter called degenerate matter. The electron clouds in degenerate matter actually touch each other, and this touching gives white dwarf matter a resistance to compression that balances the force of gravity.

White dwarf stars have no nuclear energy sources, so they simply cool. The hottest star to have compacted itself to the white dwarf state has a temperature of 190,000 K (350,000°F), while the coolest white dwarf stars have temperatures near 3800 K (6400°F), still hotter than the coolest main-sequence stars. The internal structure of these two stars is virtually the same.

However, the surface layers of white dwarfs are much more varied than is the case of other types of stars. For example, white dwarf stars come in two basic flavors, hydrogen-rich stars, whose hydrogen/helium ratios can exceed 10^7, and helium-rich stars, whose hydrogen/helium ratio can be less than 10^{-7}. (In virtually every other type of star, the hydrogen/helium ratio is near its cosmic value of approximately 10:1.) At least part of this extraordinary variation (over 14 orders of magnitude) probably comes from subtle differences in the way that white dwarfs form in the late stages of red giant life cycles. [H.L.Sh.]

Whooping cough An acute infection of the tracheobronchial tree caused by *Bordetella pertussis*, a bacteria species exclusive to infected humans. The disease (also known as pertussis) follows a prolonged course beginning with a runny nose, and finally develops into violent coughing, followed by a slow period of recovery. The coughing stage can last 2–4 weeks, with a whooping sound created by an exhausted individual rapidly breathing in through a narrowed glottis after a series of wrenching coughs. The classical disease occurs in children 1–5 years of age, but in immunized populations infants are at greatest risk and adults with attenuated (and unrecognized) disease constitute a major source of transmission to others. *Bordetella pertussis* is highly infectious, particularly following face-to-face contact with an individual who is coughing. The disease is caused by structural components and extracellular toxins elaborated by *B. pertussis*. Multiple virulence factors produced by the organism play important roles at various stages of pertussis.

A vaccine produced from whole *B. pertussis* cells and combined with diphtheria and tetanus toxoids has been used throughout the world for routine childhood immunization. Concern over vaccine morbidity has caused immunization rates to decline in some developed countries. These drops in immunization rates have often been followed by widespread outbreaks of disease, including deaths. Considerable effort has been directed toward the development of a vaccine which would minimize side effects but maintain efficacy. A new acellular vaccine is available and has fewer side effects than the whole-cell vaccine. *See* DIPHTHERIA; TETANUS; VACCINATION.

Although *B. pertussis* is susceptible to many antibiotics, their use has little effect once the disease reaches the coughing stage. Erythromycin is effective in preventing spread to close contacts and in the early stage. [K.J.R.]

Wide-area networks Communication networks that are regional, nationwide, or worldwide in geographic area, with a minimum distance typical of that between major metropolitan areas. Smaller networks include metropolitan and local-area networks. A communication network provides common transmission, multiplexing, and switching functions that enable users to transport data between many sources and many destinations. Under ideal circumstances, the data that arrive at the destination are identical to the data that were sent. The rate of arrival of bits at any point in the network is said to be the data rate at that point and is typically measured in bits per second. These bits may come from one source or from a multiplicity of sources. The capacity of a network to transmit at a cerain data rate is known as its bandwidth. *See* LOCAL-AREA NETWORKS.

There are several fundamental attributes and concepts that facilitate the accurate transmission of data within and between digital networks. To communicate between computers, a set of rules, formats, and delivery procedures known as protocols must be established.

Part of the communications protocol allows for definition of where the packets of digital data are to be routed. Each packet of data contains the unique address of a computer or other network as its destination. The routing of the data is known as packet switching since the nodes in the network can switch the packet to various transmission paths. Networks are interconnected by means of routers. *See* PACKET SWITCHING.

Another part of the communications protocol allows for including error detection and correction information in the data packets. The destination computer or network will verify the data in the packet utilizing the error control data, such as a checksum. Protocols are also used to implement flow control. This allows the receiving computer or network to communicate back to the sender when it can or cannot receive additional data. *See* DIGITAL COMPUTER.

Certain protocols have become standards for a majority of wide-area networks. Asynchronous Transfer Mode (ATM) is a protocol used in business-to-business (B2B) communications when high data rates are needed. Typically, one ATM port supports 45 megabits per second (Mbps). Frame Relay is another business-to-business protocol. The advantage of Frame Relay is that the data rate can be scaled to the individual company's needs. The third protocol, and the one having the most worldwide impact on both business and personal communications, is the Internet Protocol, or IP. *See* INTEGRATED SERVICES DIGITAL NETWORK (ISDN).

Wide-area networks may operate on a mix of transmission media for either fixed or mobile applications. Fixed applications mean that the receiver of digital data is stationary. Examples of wireline transmission media for fixed applications are fiber-optic cable, copper wire, and coaxial cable. For copper, a technique known as digital subscriber line (DSL) allows for transmission in excess of 1 Mbps over regular phone lines. In fiber, a technique known as wave division multiplexing (WDM) allows the simultaneous transmission of different streams of digital data over each spectral component of the light wave. This allows bundles of fiber-optic cable to transport billions of bits (gigabits) and even trillions of bits (terabits) of data per second. *See* COMMUNICATIONS CABLE; OPTICAL COMMUNICATIONS; OPTICAL FIBERS; TRANSMISSION LINES.

Wide-area networks also operate over a variety of wireless media. Wireless media can support either fixed or mobile applications. Another common distinction in wireless networks is whether it is point-to-point or point-to-multipoint. In point-to-point the originating transmission has one receiver, whereas in point-to-multipoint the originating transmission has multiple receivers. Examples of wireless media include radio-wave, microwave, cellular, and satellite. *See* COMMUNICATIONS SATELLITE; MOBILE RADIO; RADIO SPECTRUM ALLOCATIONS; RADIO-WAVE PROPAGATION.

There are many different types of content transmitted over WANs. Examples of content are data, voice, video, audio, paging messages, and fax. By virtue of the ability to digitize all of this content, the major difference in transmission requirements is the bandwidth, or capacity, required to transmit digital packets of any type of content. *See* DATA COMMUNICATIONS; ELECTRICAL COMMUNICATIONS; FACSIMILE.

In order to utilize the bandwidth capacity of WANs more efficiently, digital compression techniques are now used in many applications. Fundamentally, digital compression reduces the amount of bits in data packets by removing repetitive strings of bits and replacing them with shorter packets that numerically describe the amount of repetitive data. *See* DATA COMPRESSION.

With massive amounts of information being transmitted over WANs using both public and private infrastructure, data security is increasingly important. In order to secure digital data transmitted over networks, encryption techniques have been developed. Encryption of digital data involves using hardware and software to manipulate the bits in a data packet, making it unrecognizable and unusable to anyone not authorized to use the data. *See* COMMUNICATIONS SCRAMBLING; COMPUTER SECURITY; CRYPTOGRAPHY.

The Internet, using the IP, has become by far the most ubiquitous WAN in the world. Internet users are able to transmit video clips, electronic mail (e-mail), telephone calls (called Voice Over IP), to digitized x-rays over the Internet. There are three basic variations of IP networks. First is the overall Internet itself which encompasses all personal and business users of the Internet. The second type of IP-based networks is intranets. An intranet is usually deployed within a specific organization or company. A company intranet may be used to manage human resources and financial processes and keep employees updated on company news. The third type of IP-based networks is extranets. Typically, extranets are used to link multiple organizations or companies for some common business purpose. In both intranets and extranets, a technology known as a firewall is employed to prevent unauthorized access to the network or unauthorized URL (Uniform Resources Locator) from the network. The URL is the basic unique address or location for any Web site or other Internet service. *See* ELECTRONIC MAIL; INTERNET. [R.L.Je.]

Wiedemann-Franz law An empirical law of physics which states that the ratio of the thermal conductivity of a metal to its electrical conductivity is a constant times the absolute temperature, as given by the equation below. Here K_c is the thermal

$$K_c = L_0 \sigma T$$

conductivity due to the conduction electrons, σ is the electrical conductivity, T is the absolute temperature, and L_0 is known as the Lorentz number. The Wiedemann-Franz law provides an important check on theories of electrical and thermal conductivity. *See* CONDUCTION (HEAT); THERMAL CONDUCTION IN SOLIDS. [F.J.B.]

Willemite A rare nesosilicate mineral, composition Zn_2SiO_4, crystallizing in the hexagonal system. It is usually massive or granular with a vitreous luster; crystals are rare. The mineral may be variously colored, most commonly green, red, or brown. Hardness is $5^1/_2$ on Mohs scale; specific gravity is 3.9–4.2. Willemite forms a valuable ore of zinc at Franklin, New Jersey. At this famous zinc deposit Willemite fluoresces a yellow-green. *See* SILICATE MINERALS. [C.S.Hu.]

Willow A deciduous tree and shrub of the genus *Salix*, order Salicales, common along streams and in wet places in the United States, Europe, and China. The twigs are often yellow-green and bear alternate leaves which are characteristically long, narrow, and pointed, usually with fine teeth along the margins. Flowers occur in catkins. The fruit contains several silky seeds. *See* SALICALES.

Willow lumber is used for fuel and in making charcoal, excelsior, ball bats, boxes, crates, boats, waterwheels, and wicker furniture. The tough, pliable shoots of many species are used to make baskets; the bark of other species is used for tanning. Willows are of great value in checking soil erosion. A few species are ornamental shade trees. [J.F.F.]

Wind The motion of air relative to the Earth's surface. The term usually refers to horizontal air motion, as distinguished from vertical motion, and to air motion averaged over a chosen period of 1–3 min. Micrometeorological circulations (air motion over periods of the order of a few seconds) and others small enough in extent to be obscured by this averaging are thereby eliminated.

The direct effects of wind near the surface of the Earth are manifested by soil erosion, the character of vegetation, damage to structures, and the production of waves on water surfaces. At higher levels wind directly affects aircraft, missile and rocket operations, and dispersion of industrial pollutants, radioactive products of nuclear explosions, dust, volcanic debris, and other material. Directly or indirectly, wind is responsible for the production and transport of clouds and precipitation and for the transport of cold and warm air masses from one region to another. *See* ATMOSPHERIC GENERAL CIRCULATION; WIND MEASUREMENT.

Cyclonic and anticyclonic circulation are each a portion of the pattern of airflow within which the streamlines (which indicate the pattern of wind direction at any instant) are curved so as to indicate rotation of air about some central point of the cyclone or anticyclone. The rotation is considered cyclonic if it is in the same sense as the rotation of the surface of the Earth about the local vertical, and is considered anticyclonic if in the opposite sense. Thus, in a cyclonic circulation, the streamlines indicate counterclockwise (clockwise for anticylonic) rotation of air about a central point on the Northern Hemisphere or clockwise (counterclockwise for anticyclonic) rotation about a point on the Southern Hemisphere. When the streamlines close completely about the central point, the pattern is denoted respectively a cyclone or an anticyclone. Since the gradient wind represents a good approximation to the actual wind, the center of a cyclone tends strongly to be a point of minimum atmospheric pressure on a horizontal surface. Thus the terms cyclone, low-pressure area, or low are often used to denote essentially the same phenomenon. *See* GRADIENT WIND.

Convergent or divergent patterns are said to occur in areas in which the (horizontal) wind flow and distribution of air density is such as to produce a net accumulation or depletion, respectively, of mass of air. The horizontal mass divergence or convergence is intimately related to the vertical component of motion. For example, since local temporal rates of change of air density are relatively small, there must be a net vertical export of mass from a volume in which horizontal mass convergence is taking place. Only thus can the total mass of air within the volume remain approximately constant.

The horizontal mass divergence or convergence is closely related to the circulation. In a convergent wind pattern the circulation of the air tends to become more cyclonic; in a divergent wind pattern the circulation of the air tends to become more anticyclonic. A convergent surface wind field is typical of fronts. As the warm and cold currents impinge at the front, the warm air tends to rise over the cold air, producing the typical frontal band of cloudiness and precipitation. *See* FRONT.

Zonal surface winds patterns result from a longitudinal averaging of the surface circulation. This averaging typically reveals a zone of weak variable winds near the Equator (the doldrums) flanked by northeasterly trade winds in the Northern Hemisphere and southeasterly trade winds in the Southern Hemisphere, extending poleward in each instance to about latitude 30°. The doldrum belt, particularly at places and times at which it is so narrow that the trade winds from the two hemispheres impinge upon it quite sharply, is designated the intertropical convergence zone, or ITCZ. The resulting convergent wind field is associated with abundant cloudiness and locally heavy rainfall. *See* MONSOON METEOROLOGY.

Local winds commonly represent modifications by local topography of a circulation of large scale. They are often capricious and violent in nature and are sometimes characterized by extremely low relative humidity. Examples are the mistral which blows down the Rhone Valley in the south of France, the bora which blows down the gorges leading to the coast of the Adriatic Sea, the foehn winds which blow down the Alpine valleys, the williwaws which are characteristic of the fiords of the Alaskan coast and the Aleutian Islands, and the chinook which is observed on the eastern slopes of the Rocky Mountains. *See* CHINOOK. [F.S.; H.B.B.]

Wind measurement The determination of three parameters: the size of an air sample, its speed, and its direction of motion. Air movement or wind is a vector that is specified by speed and direction; meteorological convention indicates wind direction is the direction from which the wind blows (for example, a southeast wind blows toward the northwest). Anemometers measure wind speed, while wind vanes indicate direction. On average, the wind blows horizontally over flat terrain; however, gusts, thermals, cloud outflows, and many other conditions have associated with them significant short-term vertical wind components. While research wind instruments typically measure both horizontal and vertical air movement, operational and personal wind sensors measure only the horizontal component. *See* ANEMOMETER.

There are many types of wind measurement instruments. In situ devices measure characteristics of air in contact with the instrument; often they are referred to as immersion sensors because they are immersed in the fluid (air) they measure. Remote wind sensors make measurements without physical contact with the portion of the atmosphere measured. Active remote sensors emit electromagnetic (for example, light or radio waves) or sound waves into the atmosphere and measure the amount and nature of the electromagnetic or acoustic power returned from the atmosphere. *See* LIDAR; METEOROLOGICAL INSTRUMENTATION; METEOROLOGICAL RADAR; WIND. [W.F.D.]

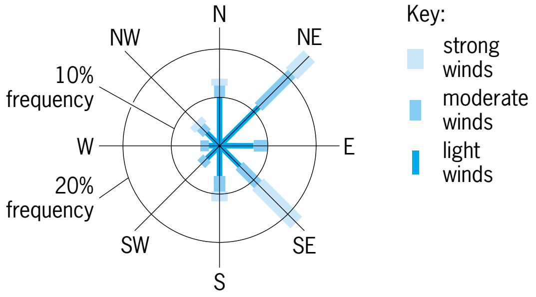
Wind power The extraction of kinetic energy from the wind and conversion of it into a useful type of energy: thermal, mechanical, or electrical. Wind power has been used for centuries.

It has been estimated that the total wind power in the atmosphere averages about 3.6×10^{12} kW, which is an annual energy of about 107,000 quads (1 quad = 2.931×10^{11} kWh). Only a fraction of this wind energy can be extracted, estimated to be a maximum of 4000 quads per year. According to what is commonly known as the Betz limit, a maximum of 59% of this power can be extracted by a wind machine. Practical machines actually extract from 5 to 45% of the available power. Because the available wind power varies with the cube of wind speed, it is very important to find areas with high average wind speeds to locate wind machines. *See* WIND.

Most research on wind power has been concerned with producing electricity. Wind power is a renewable energy source that has virtually no environmental problems. However, wind power has limitations. Wind machines are expensive and can be located only where there is adequate wind. These high-wind areas may not be easily accessible or near existing high-voltage lines for transmitting the wind-generated energy. Another disadvantage occurs because the demand for electricity varies with time, and electricity production must follow the demand cycle. Since wind power varies randomly, it may not be available when needed. The storage of electrical energy is difficult and expensive, so that wind power must be used in parallel with some other type of generator or with nonelectrical storage. Wind power teamed with hydroelectric generators is attractive because the water can be used for energy storage, and operation with underground compressed-air storage is another option. *See* ELECTRIC POWER GENERATION; ENERGY SOURCES; ENERGY STORAGE.

The most common type of wind turbine for producing electricity has a horizontal axis, with two or more aerodynamic blades mounted on the horizontal shaft. With a horizontal-axis machine, the blade tips can travel at several times the wind speed, which results in a high efficiency. The blade shape is designed by using the same aerodynamic theory as for aircraft. *See* PROPELLER (AIRCRAFT); TURBINE. [G.Th.]

Wind rose A diagram in which statistical information concerning the direction and speed of the wind at a particular location may be conveniently summarized. In the standard wind rose a line segment is drawn in each of perhaps eight compass directions from a common origin (see illustration). The length of a particular segment is proportional to the frequency with which winds blow from that direction. Parts of a given segment are given various thicknesses, indicating frequencies of occurrence of various classes of wind speed from the given direction. *See* WIND MEASUREMENT. [F.S.]



Standard wind rose.

Wind stress The drag or tangential force per unit area exerted on the surface of the Earth by the adjacent layer of moving air. Erosion of ground surfaces and the production of waves on water surfaces are manifestations of wind stress. Surface wind stress determines the exchange of momentum between the Earth and the atmosphere and exerts a strong influence on the typical variation of wind through the lowest kilometer of the atmosphere. Estimated values of the surface wind stress range up to several dynes per square centimeter (0.1 pascal), depending on the nature of the surface and the character of the adjacent airflow. *See* METEOROLOGY.

Significant stresses arise within the lower atmosphere because of the strong shear of the wind between the slowly moving air near the ground and the more rapidly moving air a kilometer above and because of the turbulent nature of the airflow in this region. The turbulent eddies referred to here have characteristic dimensions ranging up to a few hundreds of meters.

Wind pressure is the force exerted by the wind per unit area of solid surface exposed normal to the wind direction and is also known as dynamic pressure. In contrast to shearing stresses, the wind pressure arises from the difference in pressure between the windward and lee sides of the exposed surface. Wind pressure thus represents a substantial force when the wind speed is high. *See* WIND. [F.S.]

The drag or tangential force of the wind on the sea is expressed in units of dynes per square centimeter or micronewtons per square meter but is normally taken to represent the mean drag over an undefined area, perhaps several kilometers square, containing many waves. It is usually related to an appropriate time and space average of the wind near the sea surface (at 10 m above the mean level, for example).

The drag coefficient over the sea is an important quantity in both meteorology and oceanography since it relates the wind speed to the drag, which generates ocean waves, drives the ocean currents, and sets the scale of the atmospheric turbulence that transfers water vapor and heat from the ocean to the atmosphere to provide the energy for clouds and weather systems. The drag coefficient of the sea surface depends on the wave field and on the turbulent structure of the flow in the air and the water. Present knowledge of the complicated fluid mechanics involved is not sufficient to allow theoretical calculation of it. *See* ATMOSPHERIC GENERAL CIRCULATION; MARITIME METEOROLOGY; OCEAN CIRCULATION; OCEAN WAVES.

There is substantial agreement that the drag of the wind on the sea is small relative to that of a fixed soil surface with the same geometry. It is largely independent of the fetch and so seems to depends less on the larger waves than on the short waves and ripples. Surface-active agents, which affect the shortest waves, may therefore be important. [H.C.]

Wind tunnel A duct in which the effects of airflow past objects can be determined. The steady-state forces on a body held still in moving air are the same as those when the body moves through still air, given the same body shape, speed, and air properties. Scaling laws permit the use of models rather than full-scale objects, such as aircraft or automobiles. Models are less costly and may be modified more easily, and conditions may be simulated in the wind tunnel that would be impossible or dangerous in full scale.

Most data are secured from wind tunnels through measurement of forces and moments, surface pressures, changes produced in the airstream by the model, local temperatures, and motions of dynamically scaled models, and by visual studies.

A balance system separates and measures the six components of the total force. The three forces taken parallel and perpendicular to a flight path are lift, drag, and side force. The three moments about these axes are yawing moment, rolling moment, and pitching moment, respectively.

Surface pressures are measured by connecting orifices flush with the model surface to pressure-measuring devices. Local air load, total surface load, moment about a control surface hinge line, boundary-layer characteristics, and local Mach number may be obtained from pressure data.

Measurements of stream changes produced by the model may be interpreted in terms of forces and moments on the model. In two-dimensional tunnels, where an aircraft model spans the tunnel, it is possible to determine the lift and center of pressure by measuring the pressure changes on the floor and ceiling of the tunnel. The parasite drag of a wing section may be determined by measuring the total pressure of the air which has passed over the model and calculating its loss of momentum.

Measurements of surface temperatures indicate the rate of heat transfer or define the amount of cooling that may be necessary.

In elastically and dynamically scaled models used for flutter testing, measurements of amplitude and frequency of motion are made by using accelerometers and strain gages in the structure. In free-flight models, such as bomb or missile drop tests, data are frequently obtained photographically.

At low speeds, smoke and tufts are often used to show flow direction. A mixture of lampblack and kerosine painted on the model shows the surface streamlines. A suspension of talcum powder and a detergent in water is also used.

For aircraft at velocities near or above the speed of sound, some flow features may be made visible by optical devices. *See* INTERFEROMETRY; SCHLIEREN PHOTOGRAPHY; SHADOWGRAPH.

The V/STOL wind tunnel is a newer development of low-speed wind tunnels having a large very-low-speed section to permit testing of aircraft designed for vertical or short takeoff and landing (V/STOL) while operating in the region between vertical flight and cruising flight. [R.G.Jo.]

Windings in electric machinery Windings can be classified in two groups: armature windings and field windings. The armature winding is the main current-carrying winding in which the electromotive force (emf) or counter-emf of rotation is induced. The current in the armature winding is known as the armature current. The field winding produces the magnetic field in the machine. The current in the field winding is known as the field or exciting current. *See* ELECTRIC ROTATING MACHINERY; GENERATOR; MOTOR.

The location of the winding depends upon the type of machine. The armature windings of dc motors and generators are located on the rotor, since they must operate in conjunction with the commutator, and the field windings are mounted on stator field poles. *See* DIRECT-CURRENT GENERATOR; DIRECT-CURRENT MOTOR.

Alternating-current synchronous motors and generators are normally constructed with the armature winding on the stator and the field winding on the rotor. There is no clear distinction between the armature and field windings of ac induction motors or generators. One winding may carry the main current of the machine and also establish the magnetic field. It is customary to use the terms stator winding and rotor winding to identify induction motor windings. The word armature, when used with induction motors, applies to the winding connected to the power source (usually the stator). *See* ALTERNATING-CURRENT GENERATOR; ALTERNATING-CURRENT MOTOR; SYNCHRONOUS MOTOR. [A.R.E.]

Wine Alcoholic beverages made by fermentation of the juice of fruits or berries, essentially grape juice. Wines from other materials are always required to show their source on the label, for example, apple wine, berry wine, and cherry wine. California produces the largest percentage of the grape wine made in the United States, and well over a hundred varieties of the cultivated grape (*Vitis vinifera*) are used.

Classification of wine depends on the color, relative sweetness, alcoholic content, presence of carbon dioxide, the variety of grape, and the region where the grapes are grown. Wines may be red or white. The terms dry and sweet refer to the relative sugar content of a wine. Table wines contain less than 14% alcohol by volume, and dessert wines contain over 14%, usually 20%, alcohol. The higher alcohol content of dessert wines is obtained by the addition of brandy, which is called fortification. Sparkling wines such as champagne and sparkling Burgundy contain carbon dioxide.

Grapes are harvested and go through a crusher-stemmer, which crushes the berries, but not the seeds, and removes the stems. The must, still containing seeds and skins, is pumped to fermentation tanks where it receives sulfur dioxide gas. This controls, to a large extent, the growth of bacteria and wild yeasts, whereas the various strains of wine yeast are adapted to this amount of SO_2. A pure yeast starter is then added. In the production of white wines, the juice is separated from the skins and seeds at an early stage of fermentation. *See* FERMENTATION.

After the initial fermentation, the wine is transferred to the storage cellar for completion of fermentation, clarification, aging, stabilization, and bottling. These operations are called cellar practices. The sediment of yeast and other insoluble matter is called lees. The new wine is drawn off, or racked, from the lees to avoid picking up undesirable flavors from the lees. Aging is then continued. Wines are often chilled to precipitate excess cream of tartar, the potassium acid tartrate from the grape, which otherwise might precipitate upon chilling of bottled wine. Champagne is made by allowing a secondary fermentation to occur with a special flocculating type of yeast. either in bottles, by the original French procedure, or in bulk, using pressure tanks followed by bottling. The carbon dioxide, CO_2, of sparkling wines is produced by yeast fermentation. *See* ALCOHOLIC BEVERAGES. [E.M.M.; H.J.P.]

Wing A lifting surface of a heavier-than-air object, either bird or airplane. Lift is created by a pressure difference between the upper and lower surfaces of the wing, the average pressure on the upper surface being lower. The average velocity on the upper surface is larger than on the lower surface, resulting in the lifting pressure difference in accordance with Bernoulli's theorem. The velocity difference is caused by having a greater curvature on the wing upper surface, or a positive wing angle of attack (that is, leading edge up), or both. The amount of lift is proportional to the angle of attack, the wing area, the air density, and the square of the velocity. *See* AERODYNAMIC FORCE; BERNOULLI'S THEOREM; SUBSONIC FLIGHT.

The important physical characteristics of a wing are wing area, measured in the plan or top view, the span or distance from the left wing tip to the right wing tip, the aspect ratio, the taper ratio, and the thickness ratios of the airfoils. The aspect ratio is the ratio of the span to the average chord. The chord of a wing is the distance from the leading edge to the trailing edge. In all but the simplest airplanes, the chord varies along the span, being largest at the root. The taper ratio is the ratio of the tip chord to the root chord. Airfoils are the cross-sectional shapes of wings as defined by the intersections with planes parallel to the oncoming airstream and perpendicular to the plane of the wing surface. The thickness ratio is the ratio of the maximum thickness of an airfoil to the chord and often varies between the root and tip. If an airfoil has greater curvature on the upper surface than on the lower surface, the mean line midway between the upper and lower surfaces is curved. The amount of this curvature is called camber. All of these wing characteristics affect flight efficiency and must be carefully chosen. *See* AIRCRAFT DESIGN; AIRFOIL.

There is a particular angle of attack of a wing that provides the necessary lift with the least drag. Wing area selection attempts to have the airplane fly at this angle of attack at the desired speed and within the range of desirable altitudes. Of course, takeoff and landing fields are important in area selection. A larger wing area permits slower flight, which is associated with shorter takeoff acceleration distances and shorter stopping distances after landing.

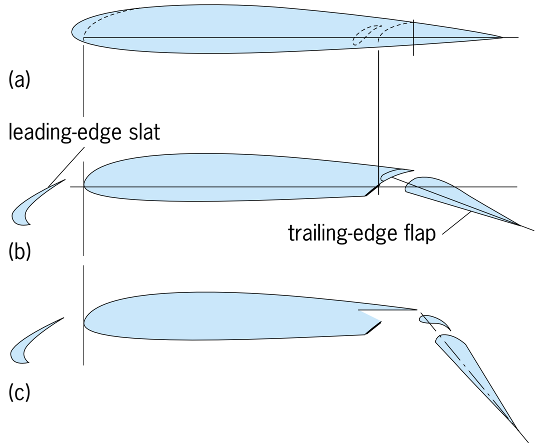
Wings must be designed to stall safely. Above the maximum angle of attack at which the flow will remain smoothly attached to the wing surface, there is a sharp loss of lift and a large increase in drag. This is known as the stall, a condition that is normally avoided. Wings are designed to stall near the root first so that the tendency to roll sharply is minimized and the ailerons on the outer wing remain effective. This is done by varying the airfoil sections and thickness ratios across the span in a careful manner.

The flight of airplanes is controlled primarily by varying the magnitude and direction of the wing lift and by varying the thrust or power contributed by the engines. An important aspect of flight is the speed, which is controlled by adjusting the wing angle of attack with respect to the oncoming airstream. The angle of attack is adjusted by varying the angle of the elevator, a control surface usually located on the horizontal tail. After adjusting the flight speed by using the elevators, the angle of the flight path, zero for level flight, is controlled by setting the engine thrust. *See* ELEVATOR (AIRCRAFT).

The direction of flight is basically controlled by the angle of bank of the wing. When the wing is level and the resultant force, or lift, is vertical, the airplane flies in a straight line. Ailerons are trailing-edge flaps on the outer part of the wing that deflect in opposite directions on the left and right sides of the airplane. When the airplane banks or rolls because of the deflection of ailerons, the lift force is tilted toward the side since it remains perpendicular to the banked wing. This provides a sidewise force which accelerates the airplane in a direction perpendicular to the flight path and thereby curves the flight path. Application of the rudder keeps the airplane pointed into the wind during the turn, although the vertical tail will do much of that job even without rudder deflection *See* AILERON; ELEVON.

High-speed aircraft also use spoilers, essentially plates ahead of the flaps, to lose lift on only one side to roll the airplane. These spoilers are also used symmetrically to slow down an airplane and increase the rate of descent. Spoilers are also used after touchdown to quickly reduce lift and dump the weight on the braked wheels, thereby greatly improving the stopping effectiveness.

Wings also carry moving elements that serve lift-increase functions. Trailing-edge flaps (see illustration) inboard of the ailerons increase the lift that can be carried before the stall. Thus the minimum flight speed can be decreased. Leading-edge flaps and slats (see illustration) are used to increase the angle of attack for stall and further reduce the minimum flight speed. The primary purpose of increasing the lift capability and obtaining the lowest flight speed is to reduce the required field lengths for takeoff and landing or to reduce the necessary wing area. *See* AILERON; ELEVATOR (AIRCRAFT); ELEVON; FLIGHT CONTROLS.



Trailing-edge flaps and leading-edge slats in (*a*) cruise, (*b*) takeoff, and (*c*) landing settings.

Wings also serve as fuel tanks, a function that sometimes sets the minimum wing area—especially on small aircraft such as executive jets. Wing thickness ratio is important in determining the volume available for fuel within the wing. Wings often house all or part of the landing gear. Engines are mounted on the wing of many aircraft. *See* AIRCRAFT ENGINE; AIRPLANE; LANDING GEAR; WING STRUCTURE. [R.S.Sh.]

Winged bean A plant (*Psophocarpus tetragonolobus*), also known as four-cornered bean, asparagus pea, goa bean, and manila bean, in the family Leguminosae. It is a climbing perennial that is usually grown as an annual. It has been suggested that it originated either in East Africa or Southeast Asia, but there is more evidence to support an African origin. However, Southeast Asia and the highlands of Papua New Guinea represent two foci of its domestication.

Traditionally, winged bean is grown as a backyard vegetable in Southeast Asia and a few islands of the Pacific. It is grown as a field crop in Burma and Papua New Guinea. However, between 1980 and 1990 winged bean was introduced throughout the tropical world.

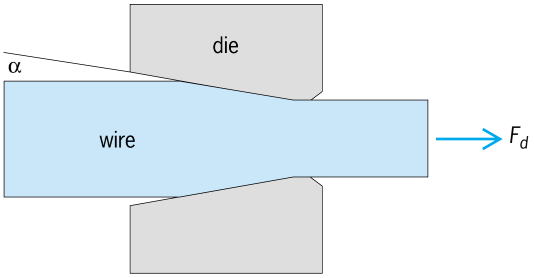
Almost all parts of this plant are edible and are rich sources of protein. The green pods, tubers, and young leaves can be used as vegetables, and the flowers can be added to salads. The dry seeds are similar to soybeans and can be used for extracting edible oil, feeding animals, and making milk and traditional Southeast Asian foods such as tempeh, tofu, and miso. Flour from the winged bean can also be used as a protein supplement in bread making.

A number of diseases and insect pests may limit winged bean yield. The most widespread and damaging disease appears to be false rust or orange gall (caused by *Synchytrium psophocarpi*). *See* BREEDING (PLANT); PLANT PATHOLOGY; ROSALES. [T.N.K.]

Wire A thread or slender rod of metal. Wire is usually circular in cross section and is flexible. If it is of such a diameter or composition that it is fairly stiff, it is termed rod. The wire may be of several small twisted or woven strands, but if used for lifting or in a structure, it is classed as cable. Wire may be used structurally in tension, as in a suspension bridge, or as an electrical conductor, as in a power line. The working of metal into wire greatly increases its tensile strength. Thus, a cable of stranded small-diameter wires is stronger as well as more flexible than a corresponding solid rod. *See* MAGNET WIRE. [F.H.R.]

Wire bonding An interconnect technique widely used in microchip manufacturing to provide electrical continuity between the metal pads of an integrated circuit (IC) chip and the electrical leads of the package housing the chip. The two common methods of wire bonding are thermocompression and ultrasonic bonding. In these, a fine aluminum or gold wire is bonded at one end to the metal pad of the IC, and at the other to the electrical lead of the package. In ultrasonic bonding, the metallurgical bond is achieved through a combination of ultrasonic energy and pressure to break the few surface layers of the material and form the bond between the contamination-free surfaces. In thermocompression bonding, the metallurgical bond is formed by applying heat and pressure without melting. Thermocompression bonding has higher throughput and speed than ultrasonic bonding. *See* Circuit (electronics); Electronic packaging; Integrated circuits; Ultrasonics. [L.M.]

Wire drawing The reduction of the diameter of a metal rod or wire by pulling it through a die. The working region of dies are typically conical (see illustration). The tensile stress on the drawn wire, that is, the drawing stress, must be less than the wire's yield strength. Otherwise the drawn section will yield and fail without pulling the undrawn wire though the die. Because of this limitation on the drawing stress, there is a maximum reduction that can be achieved in a single drawing pass. After large drawing reductions, wires or rods develop crystallographic textures or preferred orientations of grains. The textures are characteristic of the crystal structure of the metal. *See* Alloy; Crystal structure; Metal; Metal, mechanical properties of; Metallurgy. [W.F.Ho.]



Wire being drawn through a die.

Wiring A system of electric conductors, components, and apparatus for conveying electric power from source to the point of use. In general, electric wiring for light and power must convey energy safely and reliably with low power losses, and must deliver it to the point of use in adequate quantity at rated voltage. Electric wiring systems are designed to provide a practically constant voltage to the load within the capacity limits of the system. There are a few exceptions, notably series street-lighting circuits which operate at constant current. The building wiring system originates at a source of electric power, conventionally the distribution lines or network of an electric utility system. *See* Electrical codes.

Systems and service. Wiring systems are generally three-phase to conform to the supply systems. Energy is transformed to the desired voltage levels by a bank of three single-phase transformers. The transformers may be connected in either a delta or Y configuration.

Service provided at the primary voltage of the utility distribution system, typically 13,800 or 4160 volts, is termed primary service. Service provided at secondary or utilization voltage, typically 120/208 or 277/480 volts, is called secondary service.

Service at primary voltage levels is often provided for large industrial, commercial, and institutional buildings, where the higher voltage can be used to advantage for power distribution within the buildings. Where primary service is provided, power is distributed at primary voltage from the main switchboard through feeders to load-center substations installed at appropriate locations throughout the building.

Most secondary services in the United States are 120/208 volts, three-phase, four-wire, or 120/240 volts, single-phase, three-wire serving both light and power. For relatively large buildings where the loads are predominantly fluorescent lighting and power (as for air conditioning), the service is often 277/480 volts, three-phase, four-wire, supplying 480 volts for power and 277 volts, phase-to-neutral, for the lighting fixtures.

From the service entrance, power is carried in feeders to the main switchboard, then to distribution panelboards. Smaller feeders extend from the distribution panelboards to light and power panelboards. Branch circuits then carry power to the outlets serving the various lighting fixtures, plug receptacles, motors, or other utilization devices.

Methods. Methods of wiring in common use for light and power circuits are as follows: (1) insulated wires and cables in raceways; (2) nonmetallic sheathed cables; (3) metallic armored cables; (4) busways; (5) copper-jacketed, mineral-insulated cables; (6) aluminum-sheathed cables; (7) nonmetallic sheathed and armored cables in cable support systems; and (8) open insulated wiring on solid insulators (knob and tube).

The selection of the wiring method or methods is governed by a variety of considerations, which usually include code rules limiting the use of certain types of wiring materials; suitability for structural and environmental conditions; installation (exposed or concealed); accessibility for changes and alterations; and costs.

Circuit design. The design of a particular wiring system is developed by considering the various loads, establishing the branch-circuit and feeder requirements, and then determining the service-entrance requirements. Outlets for lighting fixtures, motors, portable appliances, and other utilization devices are indicated on the building plans and the load requirement of each outlet noted in watts or horsepower. Lighting fixtures and plug receptacles are then grouped on branch circuits and connections to the lighting panelboard indicated.

Lighting branch circuits may be loaded to 80% of circuit capacity. However, there is a reasonable probability that the lighting equipment will be replaced at some future time by equipment of higher output and greater load. Therefore, in modern practice, lighting branch circuits are loaded only to about 50% capacity. Lighting branch circuits are usually rated at 20 A. Smaller 15-A branch circuits are used mostly in residences. [W.T.S./J.F.McP.]

Wiring diagram A drawing illustrating electrical and mechanical relationships between parts of a component between which electrical wiring must be connected.

A wiring diagram is distinguished from an electrical schematic in that the arrangement of the schematic bears no necessary relationship to the mechanical arrangement of the electrical elements in the component. The wiring diagram provides an accurate picture of how the wiring on the components and between components should appear in order that the electrical wiring technician can install the wiring in the manner that will best contribute to the optimum performance of the device.

Wiring diagrams also include such information as type of wire, color coding, methods of wire termination, and methods of wire and cable clamping. *See* Schematic drawing. [R.W.M.]

Witherite The mineral form of barium carbonate. Witherite has orthorhombic symmetry and the aragonite structure type. Crystals, often twinned, may appear hexagonal in outline. It may be white or gray with yellow, brown, or green tints. Its hardness is 3.5 and its specific gravity 4.3.

Witherite may be found in veins with barite and galena. It is found in many places in Europe, and large crystals occur at Rosiclare, Illinois. *See* Barium; Carbonate minerals; Hardness scales. [R.I.Ha.]

Wolf-Rayet star A type of hot, luminous star that is distinguished by its extremely dense and fast wind. The spectacularly bright, discrete bands of atomic emission from these winds greatly facilitated their discovery with the aid of a visual spectroscope by the French astronomers Charles Wolf and Georges Rayet at the Paris Observatory in 1867. *See* ASTRONOMICAL SPECTROSCOPY.

The Wolf-Rayet phenomenon is a typical phase in the advanced evolution of a massive star (about 20–100 times the Sun's mass), or sometimes among lower-mass stars in the planetary nebula stage. The first fusion process in the core of a massive star involves the conversion of hydrogen into helium via the carbon-nitrogen-oxygen (CNO) cycle, in which helium and nitrogen are enhanced at the expense of the initially abundant hydrogen and traces of carbon and oxygen. When such fusion products are visible in the winds, a WN-type Wolf-Rayet star is seen, whose spectrum is dominated by Doppler-broadened atomic lines of helium and nitrogen in various stages of ionization. Later, when the second fusion process occurs, helium is converted mainly into carbon and oxygen, with nitrogen being virtually destroyed. A WC-type Wolf-Rayet star is then seen with lines mainly of carbon and helium. A brief oxygen-rich phase may occur (WO), after which all other phases are so rapid that the chances of seeing them are negligible. At that point, it is believed that the Wolf-Rayet star will explode as a supernova, resulting in the collapse to a black hole in most cases. *See* BLACK HOLE; DOPPLER EFFECT; NUCLEOSYNTHESIS; PLANETARY NEBULA; SUPERNOVA.

Beneath the dense winds that often hide the stellar surface, massive Wolf-Rayet stars have surface temperatures ranging from 30,000 to 150,000 (54,000 to 270,000°F), radii of 1 to 15 solar units, and luminosities of 10^5 to 10^6 times that of the Sun. They are losing matter at a rate that is typically 10^9 times that of the Sun's wind, at speeds ranging from 1000 to 3000 km/s (600 to 1800 mi/s). Although massive Wolf-Rayet stars appear to be rare (only 200 are known so far in the Milky Way Galaxy, out of an estimated total population of 1000–2000), all massive stars likely pass through a Wolf-Rayet stage toward the end of their relatively short lives. *See* SOLAR WIND; STAR; STELLAR EVOLUTION. [A.F.J.M.]

Wolframite A mineral with composition $(Fe,Mn)WO_4$, intermediate between ferberite and huebnerite, which form a complete solid solution series. Wolframite occurs commonly in short, brownish-black, monoclinic, prismatic, bladed crystals. It is probably the most important tungsten mineral. China is the major producer of wolframite. Tungsten minerals of the wolframite series occur in many areas of the western United States; the major producing district is Boulder and northern Gilpin counties in Colorado. *See* HUEBNERITE. [E.C.T.C.]

Wollastonite A mineral inosilicate with composition $CaSiO_3$. Commonly it is massive, or in cleavable to fibrous aggregates. Hardness is $5\text{–}5^1/_2$ on Mohs scale; specific gravity is 2.85. On the cleavages the luster is pearly or silky; the color is white to gray.

Wollastonite is found in large masses in the Black Forest of Germany; Brittany, France; Chiapas, Mexico; and Willsboro, New York, where it is mined as a ceramic material. *See* SILICATE MINERALS. [C.S.H.]

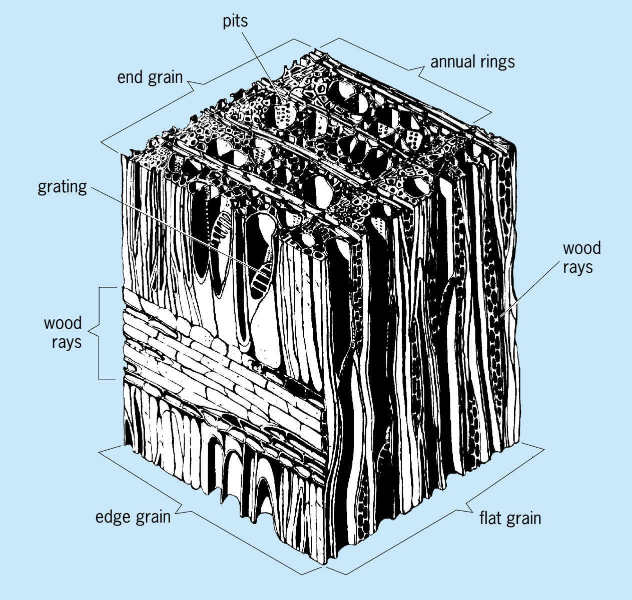
Wolverine A carnivorous mammal, *Gulo gulo*, also known as the glutton, which is the largest and most vicious member of the family Mustelidae, to which the ferrets, minks, martens, weasels, badgers, otters, and skunks belong. It ranges throughout northern Europe, Asia, and North America, where it is found in coniferous forests during the winter and on the tundras during summer.

The wolverine (*Gulo gulo*), a stoutly built carnivore with strong teeth and claws.

This animal is about 40 in. (100 cm) long and weighs about 40 lb (18 kg) (see illustration). It feeds primarily on mice, lemmings, and birds but will attack large animals when they are sick or trapped and exhausted in deep snow. It is a solitary animal, and the male remains with the female only during the courtship period, after which the female is left to rear the cubs. The wolverine lives in a den or burrow and does not hibernate. *See* BADGER; CARNIVORA; FISHER; MARTEN; OTTER; SKUNK; WEASEL. [C.B.C.]

Wood anatomy Wood is composed mostly of hollow, elongated, spindle-shaped cells that are arranged parallel to each other along the trunk of a tree. The characteristics of these fibrous cells and their arrangement affect strength properties, appearance, resistance to penetration by water and chemicals, resistance to decay, and many other properties.

Just under the bark of a tree is a thin layer of cells, not visible to the naked eye, called the cambium. Here cells divide and eventually differentiate to form bark tissue to the outside of the cambium and wood or xylem tissue to the inside. This newly formed wood (termed sapwood) contains many living cells and conducts sap upward in the tree. Eventually, the inner sapwood cells become inactive and are transformed into heartwood. This transformation is often accompanied by the formation of extractives that darken the wood, make it less porous, and sometimes provide more resistance to decay. The center of the trunk is the pith, the soft tissue about which the first wood growth takes place in the newly formed twigs. *See* STEM.



Structure of a typical hardwood. (*USDA*)

In temperate climates, trees often produce distinct growth layers. These increments are called growth rings or annual rings when associated with yearly growth; many tropical trees, however, lack growth rings. These rings vary in width according to environmental conditions.

Many mechanical properties of wood, such as bending strength, crushing strength, and hardness, depend upon the density of wood; the heavier woods are generally stronger. Wood density is determined largely by the relative thickness of the cell wall and the proportions of thick- and thin-walled cells present. *See* WOOD PROPERTIES.

In hardwoods (for example, oak or maple), these three major planes along which wood may be cut are known commonly as end-grain, quarter-sawed (edge-grain) and plain-sawed (flat-grain) surfaces (see illustration).

Hardwoods have specialized structures called vessels for conducting sap upward. Vessels are a series of relatively large cells with open ends, set one above the other and continuing as open passages for long distances. In most hardwoods, the ends of the individual cells are entirely open; in others, they are separated by a grating. On the end grain, vessels appear as holes and are termed pores. The size, shape, and arrangement of pores vary considerably between species, but are relatively constant within a species.

Most smaller cells on the end grain are wood fibers which are the strength-giving elements of hardwoods. They usually have small cavities and relatively thick walls. Thin places or pits in the walls of the wood fibers and vessels allow sap to pass from one cavity to another. Wood rays are strips of short horizontal cells that extend in a radial direction. Their function is food storage and lateral conduction. *See* PARENCHYMA; SECRETORY STRUCTURES (PLANT).

The rectangular units that make up the end grain of softwood are sections through long vertical cells called tracheids or fibers. Because softwoods do not contain vessel cells, the tracheids serve the dual function of transporting sap vertically and giving strength to the wood. The wood rays store and distribute sap horizontally.

The principal compound in mature wood cells is cellulose, a polysaccharide of repeating glucose molecules which may reach 4 μm in length. These cellulose molecules are arranged in an orderly manner into structures about 10–25 nm wide called microfibrils. The microfibrils wind together like strands in a cable to form macrofibrils that measure about 0.5 μm in width and may reach 4 μm in length. These cables are as strong as an equivalent thickness of steel.

This framework of cellulose macrofibrils is cross-linked with hemicelluloses, pectins, and lignin. Lignin, the second most abundant polymer found in plants, gives the cell wall rigidity and the substance that cements the cells together. *See* CELL WALLS (PLANT); CELLULOSE; LIGNIN; PECTIN; PLANT ANATOMY; TREE. [R.B.M.]

Wood chemicals

Wood chemicals Substances derived from wood. Woody plants comprise the greatest part of the organic materials produced by photosynthesis on a renewable basis, and were the precursors of the fossil coal deposits. The derivation of chemicals from wood is carried out wherever technical utility and economic conditions have combined to make it feasible.

Wood is a mixture of three natural polymers—cellulose, hemicelluloses, and lignin—in an approximate abundance of 50:25:25. In addition to these polymeric cell wall components which make up the major portion of the wood, different species contain varying amounts and kinds of extraneous materials called extractives. The nature of the chemicals derived from wood depends on the wood component involved. *See* CELLULOSE; HEMICELLULOSE.

Chemicals derived from wood include: bark products, cellulose, cellulose esters, cellulose ethers, charcoal, dimethyl sulfoxide, ethyl alcohol, fatty acids, furfural, hemicellulose extracts, kraft lignin, lignin sulfonates, pine oil, rayons, rosin, sugars, tall oil, turpentine, and vanillin. Most of these are either direct products or by-products of wood pulping, in which the lignin that cements the wood fibers together and stiffens them is dissolved away from the cellulose. High-purity chemical cellulose or dissolving pulp is the starting material for such polymeric cellulose derivatives as viscose rayon and cellophane, cellulose esters such as the acetate and butyrate for fiber, film, and molding applications, and cellulose ethers such as carboxymethylcellulose, ethylcellulose, and hydroxyethylcellulose for use as gums. *See* CELLOPHANE; DIMETHYL SULFOXIDE; ETHYL ALCOHOL; FURFURAL; ROSIN; TURPENTINE; VANILLA; WAX, ANIMAL AND VEGETABLE; WOOD PRODUCTS. [I.S.G.]

Wood degradation

Wood degradation Decay of the components of wood. Despite its highly integrated matrix of cellulose, hemicellulose, and lignin, which gives wood superior strength properties and a marked resistance to chemical and microbial attack, a variety of organisms and processes are capable of degrading wood. The decay process is a continuum, often involving a number of organisms over many years. Wood degrading agents are both biotic and abiotic, and include heat, strong acids or bases, organic chemicals, mechanical wear, and sunlight (uv degradation).

Abiotic degradation. Heat degrades both cellulose and hemicellulose, reducing strength and causing the wood to darken. At temperatures above 451°F (219°C), combustion occurs. Strong acids eventually degrade the carbohydrate portion of wood, reducing its strength. Strong bases attack the lignin, leaving the wood appearance bleached and white. Other chemicals, such as concentrated organics or salt solutions, can also disrupt the lignocellulosic matrix, reducing material properties of the wood. Sunlight, primarily through the action of ultraviolet light, also degrades wood through the creation of free radicals which then degrade the wood polymers. Mechanical wear of wood can occur in a variety of environments.

Biotic degradation. Biotic damage can occur from a variety of agents, including bacteria, fungi, insects, marine borers, and birds and animals. Birds and animals generally cause mechanical damage in isolated instances. All biotic agents have four basic requirements: adequate temperature (32–104°F or 0–40°C) with most optima between 77–90°F (25–32°C), oxygen (or other suitable terminal election acceptor), water, and a food source. Water is a critical element for biotic decay agents: it serves as reactant in degradative reactions, a medium for diffusion of enzymes into wood and degradative products back to the organism, and a wood swelling agent.

Bacteria are not major degraders of wood products, but they can damage pit membranes, thereby increasing permeability, and some are capable of cell wall degradation. *See* BACTERIA.

Fungi are among the most important wood-degrading organisms because they play an important role in terrestrial carbon cycling. Wood-degrading fungi can be classified as molds, stainers, soft rotters, brown rotters, and white rotters on the basis of the attack patterns. Molds, stainers, and soft rotters are members of the ascomycetes and the deuteromycetes (Fungi Imperfecti). *See* ASCOMYCOTA; DEUTEROMYCOTINA; FUNGI.

A number of insects have evolved to attack wood, including termites (Isoptera), beetles (Coleoptera), and bees and ants (Hymenoptera). Termites are the most important wood-degrading insects in most environments, and their activity causes severe economic losses. *See* COLEOPTERA; HYMENOPTERA; ISOPTERA.

In saline environments, marine borers can cause significant wood losses. Three groups of marine borers—shipworms, pholads, and gribbles (*Limnoria*)—cause most wood damage in these areas. *See* BORING BIVALVES; SHIPWORM.

Wood protection. Protecting wood from degradation can take a number of forms. By far the simplest method is to employ designs which limit wood exposure to moisture. In some cases, however, water exclusion is not possible and alternative methods must be employed. The simplest of these methods is the use of heartwood from naturally durable species. Decay- or insect-resistant species include redwood (*Sequoia sempervirens*), western red cedar (*Thuja plicata*), and ekki (*Lophira alata*), while marine-borer-resistant heartwoods include greenheart (*Ocotea rodiaei*) and ekki. Most marine-borer-resistant woods contain high levels of silica which discourages marine borer attack, while species resistant to terrestrial decay agents often contain toxic phenolics. Wood can also be protected from degradation by spraying, dipping, soaking, or pressure treatment with preservatives. *See* WOOD PROPERTIES. [J.J.Mo.]

Wood engineering design The process of creating products, components, and structural systems with wood and wood-based materials. Wood engineering design applies concepts of engineering in the design of systems and products that must carry loads and perform in a safe and serviceable fashion. Examples include structural systems such as buildings or electric power transmission structures, components such as trusses or prefabricated stressed-skin panels, and products such as furniture or pallets and containers. The design process considers the shape, size, physical and mechanical properties of the materials, type and size of the connections, and the type of system response needed to resist both stationary and moving (dynamic) loads and to function satisfactorily in the end-use environment. *See* ENGINEERING DESIGN; STRUCTURAL DESIGN.

Wood is used in both light frame structures and heavy timber structures. Light frame structures consist of many relatively small wood elements such as lumber covered with a sheathing material such as plywood. The lumber and sheathing are connected to act together as a system in resisting loads; an example is a residential house wood floor system where the plywood is nailed to lumber bending members or joists. In this system, no one joist is heavily loaded because the sheathing spreads the load out over many joists. Service factors such as deflections or vibration often govern the design of floor systems rather than strength. Light frame systems are often designed as diaphragms or shear walls to resist lateral forces resulting from wind or earthquake. *See* FLOOR CONSTRUCTION; WOOD PROCESSING.

In heavy timber construction, such as bridges or industrial buildings, there is less reliance on system action and, in general, large beams or columns carry more load transmitted through decking or panel assemblies. Strength, rather than deflection, often governs the selection of member size and connections. There are many variants of wood construction using poles, wood shells, folded plates, prefabricated panels, logs, and combinations with other materials. *See* WOOD PRODUCTS. [T.E.McL.]

Wood processing Peeling, slicing, sawing, and chemically altering hardwoods and softwoods to form finished products such as boards or veneer; particles or chips for making paper, particle, or fiber products; and fuel. *See* PAPER; VENEER.

A high percentage of the weight of freshly cut or green wood is water. Green wood contains free water in the cell cavities and bound water in the cell walls. When all the free water has been extracted and before any of the bound water has been removed, the wood is said to be at the fiber saturation point. As the moisture content falls below the fiber saturation point, the bound water leaves the cell walls and the wood shrinks. During the drying process, differential shrinkage can cause internal stresses in the wood. If not controlled, this can result in defects such as cracks, splits, and warp. Below the fiber saturation point, wood takes on and gives off water molecules depending on the relative humidity of the air around it and swells and shrinks accordingly.

Wood is machined to bring it to a specific size and shape for fastening, gluing, or finishing. With the exception of lasers, which have a limited application at this time, all machining is based on a sharpened wedge that is used to sever wood fibers. Tools for sawing, boring holes, planing, and shaping, as well as the particles in sandpaper, use some version of the sharpened wedge. *See* WOOD ENGINEERING.

Wood is ground to fibers for hardboard, medium-density fiberboard, and paper products. It is sliced and flaked for particleboard products, including wafer boards and oriented strand boards. Whether made from waste products (sawdust, planer shavings, slabs, edgings) or roundwood, the individual particles generally exhibit the anisotropy and hygroscopicity of larger pieces of wood. The negative effects of these properties are minimized to the degree that the three wood directions (longitudinal, tangential, and radial) are distributed more or less randomly. *See* WOOD PRODUCTS. [C.J.Ga.]

Wood products Materials developed from use of the hard fibrous substance (wood) which makes up the greater part of the trunks and limbs of trees.

Solid wood products include lumber, veneer and plywood, furniture, poles, piling, mine timbers, and posts; and composite wood products such as laminated timbers, insulation board, hard-board, and particle board. *See* PLYWOOD.

Fiber wood products can be referred to as those which develop initially from the various processes for pulping wood. All are intended to separate the cellulose fibers one from another in relatively pure form to be recombined into layers of pulp, paper sheets, or paperboards. *See* PAPER.

Chemical wood products result from the chemical modification or conversion of cellulose, lignin, and extractives. Chief among these products are textile fibers such as rayon, and many cellulose plastics products such as cellophane, nitrocellulose, photographic film, telephone parts, and plastic housewares and toys. *See* CELLULOSE; TEXTILE; WOOD CHEMICALS. [W.S.Br.]

Wood properties Physical and mechanical characteristics of wood which are controlled by specific anatomy, moisture content, and to a lesser extent, mineral and extractive content. The properties are also influenced by wood's directional nature, which results in markedly different properties in the longitudinal, tangential, and radial directions or axes. Wood properties within a species vary greatly from tree to tree and within a single axis.

Physical properties. The physical properties (other than appearance) are moisture content, shrinkage, density, permeability, and thermal and electrical properties.

Moisture content is a major factor in the processing of wood because it influences all physical and mechanical properties, and durability and performance during use. Normal in-use moisture content of processed wood that has been dried ranges 8–13%. Moisture content for wood is expressed on either a fractional or percentage basis. Moisture content is defined as the ratio of the mass of water contained in the wood to the mass of the same sample of dry wood.

Shrinkage occurs when wood loses moisture below the fiber saturation point. Above that point, wood is dimensionally stable. The amount of the shrinkage depends on its direction relative to grain orientation and the amount of moisture lost below the fiber saturation point. Wood shrinks significantly more in the radial and tangential directions than in the longitudinal direction.

The density of wood is determined by the amount of cell wall substance and the volume of voids caused by the cell cavities (lumens) of the fibers. Density can vary widely across a growth or annual ring. The percentage of earlywood and latewood in each growth ring determines the overall density of a wood sample.

Permeability is a measure of the flow characteristics of a liquid or gas through wood as a result of the total pressure gradient. Permeability is influenced by the anatomy of the wood cells, the direction of flow (radial, tangential, and longitudinal), and the properties of the fluid being measured. Permeability is also affected by the species, by whether the wood is sapwood or heartwood, and by the chemical and physical properties of the fluid.

The primary thermal properties of wood are conductivity, specific heat, and coefficient of thermal expansion. The conductivity of wood is determined by density, moisture content, and direction of conduction. Thermal conductivity in the transverse directions (radial and tangential) is approximately equal. Conductivity in the longitudinal direction is greater than in the transverse directions. For most processing operations, the dominant heating direction is transverse. Thermal conductivity is important to wood processing because heating—whether for drying, curing, pressing, or conditioning—is an integral step. Specific heat of wood is dependent on moisture content and, to less extent, on temperature. *See* SPECIFIC HEAT.

Dry wood is an excellent insulator. By measuring wood's electrical resistance, electrical moisture meters accurately determine the moisture content of wood in the 5–25% range. Two other electrical properties of interest are the dielectric constant and the dielectric power factor for alternating current. These dielectric properties are dependent on density, moisture content, frequency of current, grain orientation, and temperature. The power factor is a measure of the stored energy that is converted to heat.

Mechanical properties. The mechanical properties of wood include elastic, strength, and vibration characteristics. These properties are dependent upon species, grain orientation, moisture content, loading rate, and size and location of natural characteristics such as knots.

Wood is both an elastic and plastic material. Elasticity manifests itself during loading and at moisture contents and temperatures that occur in most service uses of wood. The elastic stiffness or modulus of elasticity of wood is dependent on grain orientation, moisture content, species, temperature, and rate of loading. The stiffness of wood in the longitudinal (fiber) direction is utilized in the manufacture of composite products such as oriented strand board, in which the grain or fiber direction is controlled. *See* ELASTICITY.

The strength of wood, like its elastic properties, is dependent upon rate of loading, species, moisture content, orientation, temperature, size and location of natural characteristics such as knots, and specimen size. The strength of individual wood fibers in the longitudinal direction can be significantly greater than that of larger samples with their complex anatomy and many defects. As with stiffness, the excellent strength characteristics of wood in the direction of the fiber can be maximized during the manufacture of wood composites by controlling fiber alignment.

Damping and sound velocity are two primary vibration phenomena of interest in structural applications. Damping occurs when internal friction dissipates mechanical energy as heat. The velocity of a sound wave through wood can be used to estimate mechanical stiffness and strength: the higher the velocity, the higher the stiffness and strength. Like other properties of wood, the velocity of sound along the three principal axes differs. Sound velocity in the longitudinal direction is two to four times greater than in the transverse directions. *See* WOOD ANATOMY. [J.B.Wi.]

Woodward-Hoffmann rule

A concept which can predict or explain the stereochemistry of certain types of reactions in organic chemistry. It is also described as the conservation of orbital symmetry, and is named for its developers, R. B. Woodward and Roald Hoffmann. The rule applies to a limited group of reactions, called pericyclic, which are characterized by being more or less concerted (that is, one-step, without a distinct intermediate between reactants and products) and having a cyclic arrangement of the reacting atoms of the molecule in the transition state. Most pericyclic reactions fall into one of three major classes: electrocyclic, cycloaddition, or sigmatropic. *See* STEREOCHEMISTRY. [D.L.D.]

Woodworking

The shaping and assembling of wood and wood products into finished articles such as mold patterns, furniture, window sashes and frames, and boats. The pronounced grain of wood requires modifications in the working techniques when cutting with the grain and when cutting across it. Five principal woodworking operations are sawing, planing, steam bending, gluing, and finishing. To shape round pieces, wood is worked on a lathe. *See* TURNING (WOODWORKING).

Wood is sawed by cutting or splitting its fibers by the continuous action of a series of uniformly spaced teeth alternately staggered to move in closely parallel work planes. Action of the cutting teeth produces a path or kerf of uniform width through the workpiece from which the fibers have been severed and removed. Sawing across the grain or cell structure of the wood is called crosscutting. Cutting parallel with the grain of the piece is referred to as ripping. Saw teeth are bent alternately to the left and right to provide clearance for the blade. Some blades include straight raker teeth for cleaning fibers from the cut.

Flat or uniformly contoured surfaces of wood are roughed down, smoothed, or made level by the shaving and cutting action of a wide-edged blade or blades. Planing may be accomplished either manually or by power-operated tools.

Wooden members are bent or formed to a desired shape by pressure after they have been softened or plasticized by heat and moisture. If thick pieces of wood are to be bent to a permanent shape without breaking, some form of softening or plasticizing such as steaming is necessary. When a piece of wood is bent, its outer or convex side is actually stretched in tension while its concave side is simultaneously compressed. Actually, plasticized wood can be stretched but little. It can, however, be compressed a considerable amount. When a piece of plasticized wood is successfully bent, the deformation is chiefly compression distributed almost uniformly over the curved portion. Curvature results from many minute folds, wrinkles, and slippages in the compressed area.

Wood pieces may be fastened together by the adhesive qualities of a substance that sets or hardens into a permanent bond. Adhesives for wood are of two principal types, synthetic and natural-origin. The term glue was first applied to bonding materials of natural origin, while adhesive has been used to describe those of synthetic composition. *See* ADHESIVE.

The finishing operation is the preparation and sealing or covering of a surface with a suitable substance in order to preserve it or to give it a desired appearance. The preparation and conditioning of a surface may include cleaning, sanding, use of steel wool, removing or covering nails and screws, gluing or fastening loose pieces, filling cracks and holes with putty or crack filler, shellacking, and dusting. An inconsequential item with a painted surface does not require the thorough surface preparation that a piece of fine furniture does. The quality of surface conditioning directly affects the end result. *See* WOOD PROPERTIES. [A.H.T.]

Wool

A textile fiber made of the undercoat of various animals, especially sheep. Wool provides warmth and physical comfort that cotton and linen fabrics cannot give. These qualities, combined with its soft resiliency, make wool a necessity for apparel and for rugs and blankets.

Sheep are generally shorn of their fleeces in the spring, but the time of shearing varies in different parts of the world. Each fleece contains different grades, or sorts, of wool, and the raw stock must be carefully graded and segregated according to length, diameter, and quality of fiber. Wool from different parts of the body of the lamb differs greatly. The shoulders and sides generally yield the best quality of wool, because the fibers from those parts are longer, softer, and finer.

Wool's major physical characteristics include fiber diameter (fineness or grade), staple length, and clean wool yield. Also significant are soundness, color, luster, and content of vegetable matter. Grade refers specifically to mean fiber diameter and its variability. Fiber diameter is the most important manufacturing characteristic. Fleeces are commercially graded visually through observation and handling by men of long experience in the industry. Degree of crimp and relative softness of the fleece are important deciding factors employed by the graders.

The inherent advantages of wool have been exploited, and its limitations as a textile fiber have been overcome by the application of technology to manufacturing processes. The use of the insecticide dieldrin as a dye renders wool mothproof for life. Permanent pleats have been imparted to garments which are shrinkproofed and can be home laundered. Each such technological advance enables wool to hold its competitive place in the field of textile manufacture and use. *See* Textile. [T.D.W.]

Word processing The use of a computer and specialized software to write, edit, format, print, and save text. In addition to these basic capabilities, the latest word processors enable users to perform a variety of advanced functions. Although the advanced features vary among the many word processing applications, most of the latest software facilitates the exchange of information between different computer applications, allows easy access to the World Wide Web for page editing and linking, and enables groups of writers to work together on a common project. *See* Computer; Software; World Wide Web.

Writing is accomplished by using the computer's typewriterlike keyboard. The characters appear on the computer screen as they are typed. A finite number of characters can be typed across the computer screen. The word processor "knows" when the user has reached this limit and automatically moves the cursor to the next line for uninterrupted typing. The position on the computer screen where a character can be typed is marked by a blinking cursor. The cursor can be positioned anywhere on the screen by using the mouse, or the keys marked with arrows on the keyboard. *See* Computer peripheral devices; Electronic display.

In addition to writing, the latest word processors provide tools to create and insert drawings anywhere in the document. Typical features allow users to draw lines, rectangles, circles, and arrowheads, and to add text.

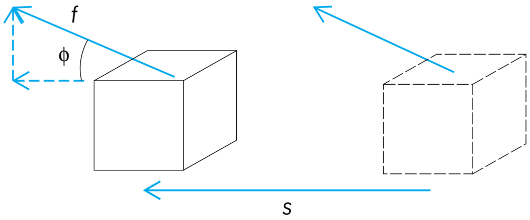
Editing allows users to correct typographical errors, add new sentences or paragraphs, move entire blocks of text to a different location, delete portions of the document, copy text and paste it somewhere else in the document, or insert text or graphics from an entirely different document. Most word processing programs can automatically correct many basic typographical errors, such as misspelled words, two successive capital letters in a word, and failure to capitalize the first letter of the names of days and of the first word in a sentence. Some other helpful editing tools commonly found in word processors include an automatic spelling checker, a thesaurus, and a grammar checker.

Formatting enables users to define the appearance of the elements in a document, such as the font and type size of all headings and text, the left, right, top, and bottom margins of each page, and the space before and after sentences and paragraphs. Most word processors allow all the elements in a document to be formatted at once. This is accomplished by applying a "style."

Word processors are approaching the formatting power of full-featured desktop publishing applications. The formatted page can be viewed on the computer screen exactly as it will be printed. This is referred to as "what you see is what you get" (WYSIWYG).

The latest word processors have many features for allowing groups of people to work together on the same document. For instance, multiple versions of a document can be saved to a single file for version control; access levels can be assigned so that only a select group of people can make changes to a document; edits can be marked with the date, time, and editor's name; and text colors can be assigned to differentiate editors. In addition, some word processors have editing features that include highlighting text, drawing lines through text to represent deleted text, and using red underscoring to identify changed text. [C.Qui.]

Work In physics, the term work refers to the transference of energy that occurs when a force is applied to a body that is moving in such a way that the force has a component in the direction of the body's motion. Thus work is done on a weight that is being lifted, or on a spring that is being stretched or compressed, or on a gas that is undergoing compression in a cylinder.



Work of constant force *f* is *fs* cos ϕ.

When the force acting on a moving body is constant in magnitude and direction, the amount of work done is defined as the product of just two factors: the component of the force in the direction of motion, and the distance moved by the point of application of the force. Thus the defining equation for work W is given below, where f and s are the magnitudes of the force and

$$W = f\cos\phi \cdot s$$

displacement, respectively, and ϕ is the angle between these two vector quantities (see illustration). Because $f\cos\phi\cdot s = f\cdot s\cos\phi$, work may be defined alternatively as the product of the force and the component of the displacement in the direction of the force.

The work done is positive in sign whenever the force or any component of it is in the same direction as the displacement; one then says that work is being done by the agent exerting the force and *on* the moving body. The work is said to be negative whenever the direction of the force or force component is opposite to that of the displacement; then work is said to be done *on* the agent and *by* the moving body. From the point of view of energy, an agent doing positive work is losing energy to the body on which the work is done, and one doing negative work is gaining energy from that body.

The work principle, which is a generalization from experiments on many types of machines, asserts that, during any given time, the work of the forces applied to the machine is equal to the work of the forces resisting the motion of the machine, whether these resisting forces arise from gravity, friction, molecular interactions, or inertia.

The work done by any conservative force, such as a gravitational, elastic, or electrostatic force, during a displacement of a body from one point to another has the important property of being path-independent: Its value depends only on the initial and final positions of the body, not upon the path traversed between these two positions. On the other hand, the work done by any nonconservative force, such as friction due to air, depends on the path followed and not alone on the initial and final positions, for the direction of such a force varies with the path, being at every point of the path tangential to it. *See* Energy; Force. [L.N.]

Work function (electronics) A quantity with the dimensions of energy which determines the thermionic emission of a solid at a given temperature. For metals, the work function may also be determined by measuring the photoemission as a function of the frequency of the incident electromagnetic radiation: the work function is then equal to the minimum (threshold) frequency for which electon emission is observed times Planck's constant h (= 6.63×10^{-34} joule second). The work function of a solid is usually expressed in electronvolts.

The work function of metals varies from one crystal plane to another and also varies slightly with temperature. For a metal, the work function has a simple interpretation. At absolute zero, the energy of the most energetic electrons in a metal is referred to as the Fermi energy; the work function of a metal is then equal to the energy required to raise an electron with the Fermi energy to the energy level corresponding to an electron at rest in vacuum. The work function of a semiconductor or an insulator has the same interpretation, but in these materials the Fermi level is in general not occupied by electrons and thus has a more abstract meaning. *See* FIELD EMISSION; PHOTOEMISSION; THERMIONIC EMISSION. [A.J.D.]

Work function (thermodynamics) The thermodynamic function better known as the Helmholtz energy, $A = U - TS$, where U is the internal energy, T is the thermodynamic (absolute) temperature, and S is the entropy of the system. At constant temperature, the change in work function is equal to the maximum work that can be done by a system ($\Delta A = w_{\max}$). *See* FREE ENERGY. [P.W.A.]

Work measurement The determination of a set of parameters associated with a task. There are four reasons, common to most organizations whether profit seeking or not, why time, effort, and money are spent to measure the amount of time a job takes. These are cost accounting, evaluation of alternatives, acceptable day's work, and scheduling. The fifth, pay by results, is used only by a minority of organizations.

There are three common ways to determine time per job: stopwatch time study (sequential observations), occurrence sampling (nonsequential observations), and standard data.

Stopwatch time study can be used for almost any existing job. It is reasonable in cost and gives reasonable accuracy. However, it does require the worker to be rated. Once the initial cost of standard data system has been incurred, standard data may be the lowest-cost, most accurate, and most accepted technique.

Occurrence sampling is also called work sampling or ratio-delay sampling. If time study is a "movie," then occurrence sampling is a "series of snapshots." The primary advantage of this approach may be that occurrence sampling standards are obtained from data gathered over a relatively long time period, so the sample is likely to be representative of the universe. That is, the time from the study is likely to be representative of the long-run performance of the worker.

Reuse of previous times (standard data) is an alternative to measuring new times for an operation. There are three levels of detail: micro, elemental, and macro (see table). Micro-level systems have times of the smallest component ranging from about 0.01 to 1 s. Components usually come from a predetermined time system such as methods-time-measurement (MTM) or Work-Factor. Elemental level systems have the time of the smallest component, ranging from about 1 to 1000 s. Components come from time study or micro-level combinations. Macro-level systems have times ranging upward from about 1000 s. Components come from elemental-level combinations, from time studies, and from occurrence sampling. *See* METHODS ENGINEERING; PERFORMANCE RATING; PRODUCTIVITY. [S.A.K.]

Three levels of detail for standard time systems

Micro system (typical component time range from 0.01 to 1 s; MTM nomenclature)

Element	*Code*	*Time*
Reach	R10C	12.9 TMU*
Grasp	G4B	9.1
Move	M10B	12.2
Position	P1SE	5.6
Release	RL1	2.0

Elemental system (typical component time range from 1 to 1000 s)

Element	*Time*
Get equipment	1.5 min
Polish shoes	3.5
Put equipment away	2.0

Macro system (typical component times vary upward from 1000 s)

Element	*Time*
Load truck	2.5 h
Drive truck 200 km	4.0
Unload truck	3.4

*27.8 TMU = 1 s; 1 s = 0.036 TMU.

Work standardization The establishment of uniformity of technical procedures, administrative procedures, working conditions, tools, equipment, workplace arrangements, operation and motion sequences, materials, quality requirements, and similar factors which affect the performance of work. It involves the concepts of design standardization applied to the performance of jobs or operations in industry or business. *See* DESIGN STANDARDS; WORK MEASUREMENT.

Work standardization is part of methods engineering and, where it is practiced, usually precedes the setting of time standards. The objectives of work standardizations are lower costs, greater productivity, improved quality of workmanship, greater safety, and quicker and better development of skills among workers. *See* METHODS ENGINEERING; PRODUCTIVITY.

One of the best known of the more formal techniques of work standardization is group technology. This is the careful description of a heterogeneous lot of machine or other piece parts with a view to discovering as many common features in materials and dimensions as can be identified. It is then possible to start a rather large lot of a basic part through the production process, doing the common operations on all of them. Any changes or additional operations required to produce the final different parts can then be made at a later stage. The economy is realized in being able to do the identical jobs at one time.

There has been considerable progress in computerized systems to facilitate group technology. The techniques are closely linked to computer-aided design and to formalized codes that permit the detailed description of many operations. *See* COMPUTER-AIDED DESIGN AND MANUFACTURING. [J.E.U.]

World Wide Web A part of the Internet that contains linked text, image, sound, and video documents. Before the World Wide Web (WWW), information retrieval on the Internet was text-based and required that users know basic UNIX commands. The World Wide Web has gained popularity largely because of its ease of use (point-and-click graphical interface) and multimedia capabilities, as well as its convenient access to other types of Internet services (such as e-mail, Telnet, and Usenet). *See* INTERNET.

Improvements in networking technology, the falling cost of computer hardware and networking equipment, and increased bandwidth have helped the Web to contain richer content. The Web is the fastest medium for transferring information and has universal reach (crossing geographical and time boundaries). It is also easy to access information from millions of Web sites using search engines (systems that collect and index Web pages, and store searchable lists of these pages). The Web's unified networking protocols make its use seamless, transparent, and portable. As the Web has evolved, it has incorporated complementary new technologies for developing online commerce and video on demand, to name a few.

Individual documents are called Web pages, and a collection of related documents is called a Web site. All Web documents are assigned a unique Internet address called a Uniform Resource Locator (URL) by which they can be accessed by all Web browsers. A URL (such as http://www.hq.nasa.gov/office/procurement/index.html) identifies the communication protocol used by the site (http), its location [domain name or server (www.hq.nasa.gov)], the path to the server (office/procurement), and the type of document (html).

The language used to create and link documents is called Hypertext Markup Language (HTML). Markup is the process of adding information to a document that is not part of the content but identifies the structure or elements. Markup languages are not new. HTML is based on the Standard Generalized Markup Language (SGML).

Though the initial format for creating a Web site was pure HTML, new and extended HTML has the ability to include programming language scripts such as common gateway interface (CGI), active server page (ASP), and Java server page (JSP), which can be used to create dynamic and interactive Web pages as opposed to just static HTML text. Dynamic Web pages allow users to create forms for transactions and data collection; perform searches on a database or on a particular Web site; create counters and track the domain names of visitors; customize Web pages to meet individual user preferences; create Web pages on the fly; and create interactive Web sites.

XML, developed by the World Wide Web Consortium, is another derivative of SGML and is rapidly becoming the standard information protocol for all commercial software such as office tools, messaging, and distributed databases. XML is a flexible way to create common information formats and share both the format and the data on the World Wide Web, intranets, and other Web-based services. [A.V.]

Wrought iron As defined by the American Society for Testing and Materials, "a ferrous material, aggregated from a solidifying mass of pasty particles of highly refined metallic iron, with which, without subsequent fusion, is incorporated a minutely and uniformly distributed quantity of slag." This slag is a ferrous silicate resulting from the oxidizing reactions of refining, and it varies in amount from 1 to 3% in various types of final product. It is in purely mechanical association with the iron base metal, as contrasted with the alloying relationships of the metalloids present in steel. *See* STEEL.

A distinguishing characteristic of wrought iron is a fragmented or irregular fracture, as contrasted with a fibrous or crystalline type in steel. Metallographic analysis shows that this results from the fiberlike slag inclusions. Although wrought iron once held competitive merit in certain uses, notably where corrosion- and shock-resistance were important, very little wrought iron is produced at present. *See* IRON ALLOYS. [J.As./J.F.W.]

Wulfenite A mineral consisting of lead molybdate, $PbMoO_4$. Wulfenite occurs commonly in yellow, orange, red, and grayish-white crystals, with a luster from adamantine to resinous. Wulfenite may also be massive or granular. Its fracture is uneven. Its hardness is 2.7–3 on Mohs scale and its specific gravity 6.5–7. Its streak is white.

Wulfenite is found in numerous localities in the western and southwestern United States. Brilliant orange tabular wulfenite crystals up to 2 in. (5 cm) in size have been found from the Red Cloud and Hamburg mines in Yuma County, Arizona. *See* MOLYBDENUM. [E.C.T.C.]

Wurtzilite A black, infusible carbonaceous substance occurring in Uinta County, Utah. It is insoluble in carbon disulfide, has a density of about 1.05, and consists of 79–80% carbon, 10.5–12.5% hydrogen, 4–6% sulfur, 1.8–2.2% nitrogen, and some oxygen. Wurtzilite is derived from shale beds deposited near the close of Eocene (Green River) time. The material was introduced into the calcareous shale beds as a fluid after which it polymerized to form nodules or veins. *See* ASPHALT AND ASPHALTITE; ELATERITE; IMPSONITE. [I.A.B.]

Wurtzite A mineral with composition ZnS (zinc sulfide). It exists most commonly in fibrous or columnar aggregates and banded crusts with resinous luster and brownish-black color. Hardness is $3^1/_2$ on Mohs scale and its specific gravity 4.0. Zinc sulfide is dimorphous, crystallizing as both the high-temperature form wurtzite, α-ZnS, and the low-temperature form sphalerite, β-ZnS. Wurtzite is the rarer and at room temperature the less stable form and, unlike sphalerite, is rarely mined as an ore of zinc. Wurtzite usually contains iron and cadmium, and a complete solid solution series extends to greenockite, CdS. *See* GREENOCKITE; SPHALERITE. [C.S.Hu.]

X

X-ray astronomy The study of x-ray emission from extrasolar sources, including virtually all types of astronomical objects from stars to galaxies and quasars. The x-ray region of the electromagnetic spectrum extends from wavelengths of about 10 picometers to a few tens of nanometers, with shorter wavelengths corresponding to higher-energy photons (1 nm corresponds to about 1000 eV). X-ray astronomy is traditionally divided into broad bands—soft and hard—depending on the energy of the radiation being studied. Observations in the soft band (below about 10 keV) must be carried out above the atmosphere from rockets or satellites, while hard x-ray observations can be made at high altitudes achievable by balloons. *See* Electromagnetic radiation; Rocket astronomy; Satellite astronomy; X-rays.

Most observations have been in the soft band. Sky surveys, particularly the *ROSAT* all-sky survey, have located tens of thousands of sources at a sensitivity of about 1/100,000 of the strength of the brightest source, Sco X-1. Some of these sources are concentrated along the galactic equator. Such a concentration corresponds to objects in the Milky Way Galaxy, particularly in the disk, which contains most of the galactic stars and the spiral arms. Other x-ray sources are uniformly spread over the sky, associated mainly with extragalactic objects, such as individual galaxies, clusters of galaxies, and quasars. *See* Milky Way Galaxy.

Galactic sources. Galactic x-ray sources have been identified with different types of unusual objects. The Crab Nebula, which was the first nonsolar x-ray source to be identified with a specific celestial object, is a supernova remnant left over from the explosive death of a star. It contains a rapidly rotating neutron star at its center as well as a nebula consisting of hot gas and energetic particles. About 10% of the x-ray emission from the Crab is pulsed radiation from the neutron star; the rest is extended emission associated with the nebula. Many other galactic supernova remnants have been detected as x-ray sources, and there have also been detections of supernova remnants in the nearest neighboring galaxies, especially in the Large Magellanic Cloud. *See* Crab Nebula; Neutron star; Pulsar; Supernova.

While normal stars radiate some energy in the x-ray band, most of their luminosity is output in the visible region of the spectrum. X-ray surveys have discovered a class of objects where the majority of energy is radiated in the x-ray portion of the electromagnetic spectrum. These are known as x-ray stars. With accurate locations, it has been possible to identify them with binary star systems. The combination of x-ray and optical data leads to the conclusion that these systems usually consist of a relatively normal visible star and one subluminous star in a gravitationally bound orbit about each other. The x-ray star is often a collapsed object, such as a white dwarf, neutron star, or even a black hole. Such compact sources form the majority of galactic emitters.

The theoretical model for x-ray emission in these systems consists of matter being transferred from the normal star to the compact object. This process, known as accretion, usually leads to the creation of a disk of infalling material spiraling down toward the surface of the compact star. During infall the matter reaches very high temperatures as gravitational energy is converted to heat, which is then radiated as x-rays. It is believed that similar processes are involved regardless of whether the compact object is a white dwarf, neutron star, or black hole. However, different types of detailed behavior are expected for each of these objects. Rotating neutron stars lead to x-ray pulsars. For white dwarfs, there appear to be fluctuations in x-ray intensity on time scales of hours to days that might be indicative of changes at the surface of the star where accreted material is collecting, and then flashing in a burst of thermonuclear energy release. In the case of black hole candidates, there are variations in x-ray intensity at extremely short time scales that indicate very small regions of x-ray emission.

Another type of time behavior is represented by the so-called bursters. These sources emit at some constant level, with occasional short bursts or flares of increased brightness. These outbursts may well be instabilities in the x-ray emission processes associated with this type of source. *See* Binary star; Black hole; Cataclysmic variable; Stellar evolution; White dwarf star.

Extragalactic sources. Among the more interesting types of objects detected have been apparent normal galaxies, galaxies with active nuclei, radio galaxies, clusters of galaxies, and quasars.

In active nuclei galaxies (those with strong optical emission lines and nonthermal continuum spectra), x-ray emission is usually orders of magnitude in excess of that from normal galaxies. In most cases the emission comes from the galactic nucleus, and must be confined to a relatively small region on the basis of variability and lack of structure at the current observational limits of a few seconds of arc. Many astrophysicists believe that galactic nuclei are the sites of massive black holes, at least 10^6–10^9 times the mass of the Sun, and that the radiation from these objects is due to gravitational energy released by infalling material. The broad range of properties, such as x-ray luminosity, may reflect the size of the black hole and availability of infalling matter. Quasars may represent the extreme case of this mechanism. Many of the observable properties depend on the viewing angle of the observer as well as the size of the nuclear black hole. *See* Quasar.

Clusters of galaxies are collections of hundreds to thousands of individual galaxies which form a gravitationally bound system. The space between galaxies in such clusters has been found to contain hot (approximately 10^7–10^8 K) tenuous gas which glows in x-rays, and whose mass is equal to (or exceeds) the mass of the visible galaxies. *See* Astrophysics, high-energy; Galaxy, external. [S.S.M.]

X-ray crystallography The study of crystal structure by x-ray diffraction techniques. For the experimental aspects of x-ray diffraction *See* X-ray diffraction.

Structurally, a crystal is a three-dimensional periodic arrangement in space of atoms, groups of atoms, or molecules. If the periodicity of this pattern extends throughout a given piece of material, one speaks of a single crystal. The exact structure of any given crystal is determined if the locations of all atoms making up the three-dimensional periodic pattern called the unit cell are known. The very close and periodic arrangement of the atoms in a crystal permits it to act as a diffraction grating for x-rays. *See* Crystallography. [L.F.D.]

X-ray diffraction The scattering of x-rays by matter with accompanying variation in intensity in different directions due to interference effects. X-ray diffraction is one of the most important tools of solid-state chemistry, since it constitutes a powerful and readily available method for determining atomic arrangements in matter. X-ray diffraction methods depend upon the fact that x-ray wavelengths of the order of 1 nanometer are readily available and that this is the order of magnitude of atomic dimensions. When an x-ray beam falls on matter, scattered x-radiation is produced by all the atoms. These scattered waves spread out spherically from all the atoms in the sample, and the interference effects of the scattered radiation from the different atoms cause the intensity of the scattered radiation to exhibit maxima and minima in various directions. *See* DIFFRACTION.

Uses. Some of the uses of x-ray diffraction are: (1) differentiation between crystalline and amorphous materials; (2) determination of the structure of crystalline materials (crystal axes, size and shape of the unit cell, positions of the atoms in the unit cell); (3) determination of electron distribution within the atoms, and throughout the unit cell; (4) determination of the orientation of single crystals; (5) determination of the texture of polygrained materials; (6) identification of crystalline phases and measurement of the relative proportions; (7) measurement of limits of solid solubility, and determination of phase diagrams; (8) measurement of strain and small grain size; (9) measurement of various kinds of randomness, disorder, and imperfections in crystals; and (10) determination of radial distribution functions for amorphous solids and liquids.

Techniques. The techniques employed in the study of crystalline substances, gases, and liquids are discussed below.

Laue method. The Laue pattern uses polychromatic x-rays provided by the continuous spectrum from an x-ray tube operated at 35–50 kV. The different diffracted beams have different wavelengths, and their directions are determined solely by the orientations of the set of planes with Miller indices *hkl*. Transmission Laue patterns were once used for structure determinations, but their many disadvantages have made them practically obsolete. On the other hand, the back-reflection Laue pattern is used a great deal in the study of the orientation of crystals.

Rotating crystal method. The original rotating crystal method was employed in the Bragg spectrometer. A sufficiently monochromatic beam, of wavelength of the order of 1 Å, is collimated by a system of slits and then falls on the large extended face of a single crystal as shown by Fig. 1. The Bragg spectrometer has been used extensively in obtaining quantitative measurements of the integrated intensity from planes parallel to the face of the crystal. The chamber is set at the correct 2θ angle with a slit so wide that all of the radiation reflected from the crystal can enter and be measured. The crystal is turned at constant angular speed through the Bragg law position, and the total diffracted energy received by the ionization chamber during this process is measured. Similar readings with the chamber set on either side of the peak give a background correction.

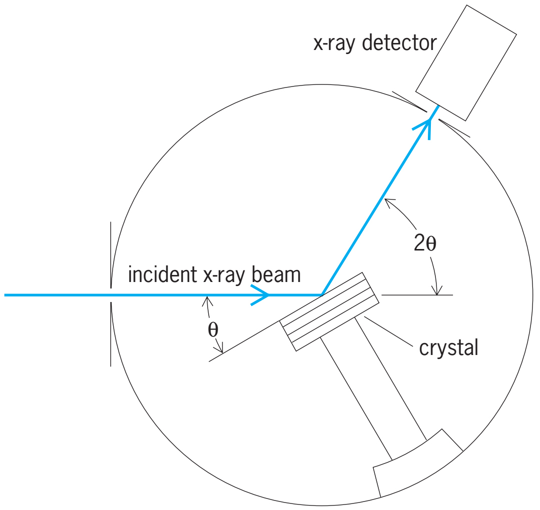

Fig. 1. Schematic of Bragg spectrometer.

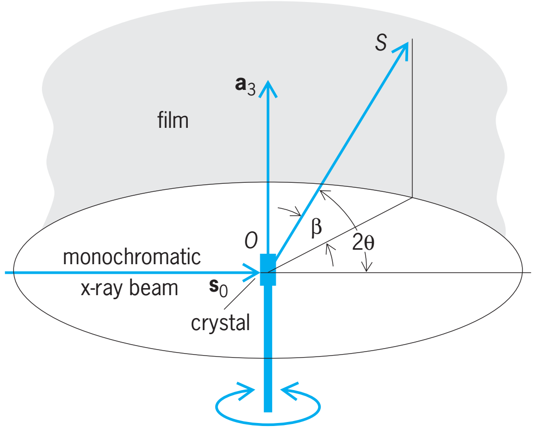

Fig. 2. Schematic of rotation camera.

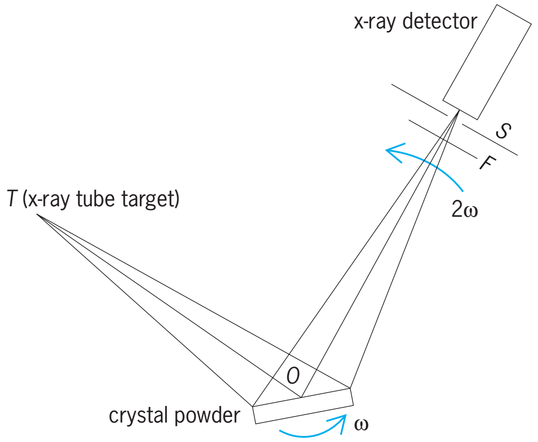

Fig. 3. Schematic representation of the Geiger counter diffractometer for powder samples.

The rotation camera, which is frequently used for structure determinations, is illustrated in Fig. 2. The monochromatic primary beam $\mathbf{s}_0$ falls on a small single crystal at *O*. The crystal is mounted with one of its axes (say, $\mathbf{a}_3$) vertical, and it rotates with constant velocity about the vertical axis during the exposure. The various diffracted beams are registered on a cylindrical film concentric with the axis of rotation.

Powder method. The powder method involves the diffraction of a collimated monochromatic beam from a sample containing an enormous number of tiny crystals having random orientation. Powder pattern studies are made with Geiger counter, or proportional counter, diffractometers. The apparatus is shown schematically in Fig. 3. X-rays diverging from a target at *T* fall on the sample at *O*, the sample being a flat-faced briquet of powder. Diffracted radiation from the sample passes through the receiving slit at s and enters the Geiger counter. During the operation the sample turns at angular velocity ω and the counter at 2ω. The distances *TO* and *OS* are made equal to satisfy approximate focusing conditions. A filter *F* before the receiving slit gives the effect of a sufficiently monochromatic beam. A chart recording of the amplified output of the Geiger counter gives directly a plot of intensity versus scattering angle 2θ. [B.E.W.]

Gases. Gases and liquids are found to give rise to x-ray diffraction patterns characterized by one or more halos or interference rings which are usually somewhat diffuse. These diffraction patterns, which are similar to those for glasses and amorphous solids, are due to interference effects depending both upon the electronic distribution of each of the individual atoms or molecules and upon their relative positions in the system.

For monatomic gases the only appreciable interference effects giving rise to a distribution of scattered intensities are those produced by the electronic distribution about each nucleus. These interference effects giving rise to so-called coherent intensities are the result of the interference of the individual waves scattered by electrons in different parts of the atom. The electronic distribution of an atom is described in terms of a characteristic atomic scattering factor which is defined as the ratio of the resultant amplitude scattered by an atom to the amplitude that a free electron would scatter under the same conditions.

Liquids. One cannot, as in the cases of dilute gases and crystalline solids, derive unambiguous, detailed descriptions of liquid structures from diffraction data. Nevertheless, diffraction studies of liquids do provide most useful information. Instead of comparing the experimental intensity distributions with theoretical distributions computed for various models, the experimental results are usually provided in the form of a radial distribution function which specifies the density of atoms or electrons as a function of the radial distance from any reference atom or electron in the system without any prior assumptions about the structure. From the radial distribution function one can obtain (1) the average interatomic distances most frequently occurring in the structure corresponding to the positions of the first, second, and possibly third nearest neighbors; (2) the distribution of distances; and (3) the average coordination number for each interatomic distance. [L.F.D.]

X-ray fluorescence analysis A nondestructive physical method used for chemical elemental analysis of materials in the solid or liquid state. The specimen is irradiated by photons or charged particles of sufficient energy to cause its elements to emit (fluoresce) their characteristic x-ray line spectra. The detection system allows the determination of the energies of the emitted lines and their intensities. Elements in the specimen are identified by their spectral line energies or wavelengths for qualitative analysis, and the intensities are related to their concentrations for quantitative analysis. Computers are widely used in this field, both for automated data collection and for reducing the x-ray data to weight-percent and atomic-percent chemical composition or area-related mass (of films). *See* FLUORESCENCE.

The materials to be analyzed may be solids, powders, liquids, or thin foils and films. The crystalline state normally has no effect on the analysis, nor has the state of chemical bonding, except for very light elements. All elements above atomic number 12 can be routinely analyzed in a concentration range from 0.1 to 100 wt %. Special techniques are required for the analysis of elements with lower atomic numbers (4–11) or of lower concentrations, and for trace analysis. The counting times required for analysis range from a few seconds to several minutes per element, depending upon specimen characteristics and required accuracy; but they may be much longer for trace analysis and thin films. The results are in good agreement with wet chemical and other methods of analysis. The method is generally nondestructive for most inorganic materials in that a suitably prepared specimen is not altered by the analytical process.

There are two general methods for producing x-ray spectra for fluorescence analysis excitation by photons and excitation by charged particles. The most common method is to expose the specimen to the entire spectrum emitted from a standard x-ray tube. It is sometimes modified by using a secondary target material (or monochromator) outside the x-ray tube to excite fluorescence. This has the advantage of selecting the most efficient energy close to the absorption edge of the element to be analyzed and reducing or not exciting other interfering elements, but the intensity is reduced by two or three orders of magnitude. Further alternatives are radioactive sources and synchrotron radiation.

The other method, used in electron microscopes and the electron microprobe, uses an electron beam directly on the specimen, and each element generates its own x-ray spectrum, under electron bombardment, as in an x-ray tube. *See* ELECTRON MICROSCOPE.

The output signals from a detector are fed into the analyzer, where the photon counts are stored in memory locations (1024–8192 channels are generally used) that are related to the energies of these photons. This also allows visual observation on a cathode-ray-tube screen of the accumulated spectrum and of the simultaneous counting process. Analyzers are usually provided with cursor markers to easily identify the peaks in the spectrum. Computer memories can be used for storage of the spectral counts, thus providing efficient access to computer routines for further data evaluation.

The electron microprobe is widely used for elemental analysis of small areas. An electron beam of 1 micrometer (or smaller) is used, and the x-ray spectrum is analyzed with a focusing (curved) crystal spectrometer or with an energy dispersive solid-state detector. Usually two or three spectrometers are used to cover different spectral regions. Light elements down to beryllium, boron, and carbon can be detected. An important use of the method is in point-to-point analysis with a few cubic micrometers of spatial resolution. *X-Y* plots of any element can be made by moving the specimen to determine the elemental distribution. *See* ELECTRON-PROBE MICROANALYSIS. [W.P.; M.Man.]

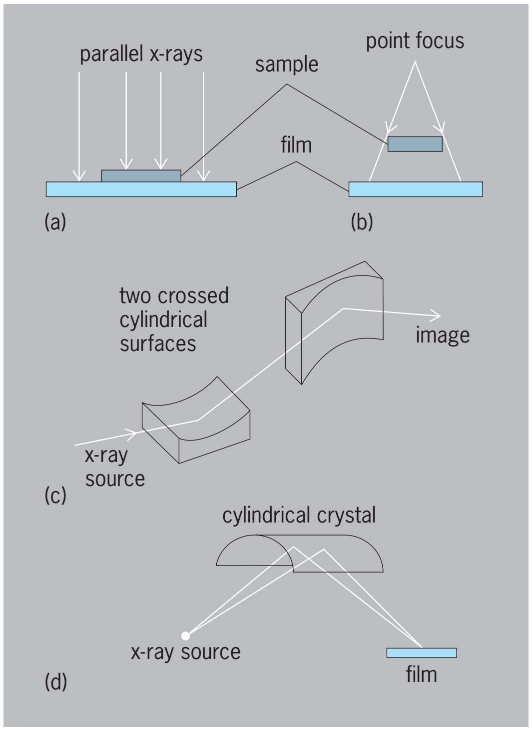
X-ray microscope A technique and an instrument or combination of instruments which utilize x-radiation for chemical analysis and for magnification of 100–1000 diameters. The resolution possible is about 0.25 micrometer. The contrast in the x-ray microscopic image is caused by the varying x-ray attenuation in the specimen. The advantage of x-ray microscopy is that it yields quantitative chemical information, besides structural information, about objects, including those which are opaque to light. It is a reliable ultramicrochemical analytical technique by which amounts of elements and weights of samples as small as 10^{-12} to 10^{-14} g can be analyzed with an error of only a few percent. *See* MICRORADIOGRAPHY.

There are four general principles of image formation in x-ray microscopy: (1) contact microradiography (illus. *a*), (2) projection x-ray microscopy (illus. *b*), (3) reflection x-ray microscopy (illus. *c*), and (4) x-ray image spectrography (illus. *d*).

In contact microradiography the thin specimen is placed in close contact with an extremely fine-grained photographic emulsion which has a resolution of more than 25, 000 lines/in. (1000 lines/mm), and radiographed with x-rays of suitable wavelength. Thus an absorption image in scale 1:1 is obtained, and this image is subsequently viewed in a light microscope. The maximal resolution is that of the optical microscope (0.25 μm), but the image has more information, which can be obtained by examining the microradiogram in the electron microscopes. *See* ELECTRON MICROSCOPE.

Projection x-ray microscopy, or x-ray shadow microscopy, is based on the possibility of producing an extremely fine x-ray focal spot. This is achieved by an electronic lens system similar to that in the electron microscope. The fine focal spot is produced on a very thin metal foil which serves as a transmission target. The x-rays are generated on the target by the impact of the electrons. The sample is placed near the target, and the primary magnification depends on the ratios of the distances from focal spot to sample and sample to film. Resolution is of the same order as the size of the focal spot; the best value is about 0.1 μm in favorable objects.

The method of reflection x-ray microscopy is based on the fact that the refractive index for x-rays in solids is a very small amount less than 1. Thus at grazing incidence (that is, incidence at very



Principles for x-ray microscopy. (*a*) Contact microradiography; (*b*) projection x-ray microscopy; (*c*) reflection x-ray microscopy; and (*d*) x-ray image spectrography.

small angles), the x-rays are totally reflected, and if the reflecting surface is made cylindrical, there will be a focusing action in one dimension. By crossing two such surfaces a true image formation can be obtained, although with some astigmatism, which can be corrected by giving the surfaces a complicated optical shape. The resolution by this procedure is about 0.5–1μm.

X-ray image spectrography utilizes Bragg reflections in a cylindrically bent crystal and produces slightly enlarged emission images; this technique is best classified as a micromodification of x-ray fluorescence analysis. The resolution is about 50 μm. *See* X-RAY DIFFRACTION; X-RAY FLUORESCENCE ANALYSIS.

In biology, x-ray microscopy has been utilized for the quantitative determination of the dry weight, water content, and elementary composition of many tissues, especially mineralized tissues. [A.E.]

X-ray optics By analogy with the science of optics, those aspects of x-ray physics in which x-rays exhibit properties similar to those of light waves. X-ray optics may also be defined as the science of manipulating x-rays with instruments analogous to those used in visible-light optics. These instruments employ optical elements such as mirrors to focus and deflect x-rays, zone plates to form images, and diffraction gratings to analyze x-rays into their spectral components. X-ray optics is important in many fields, including x-ray astronomy, biology, medical research, thermonuclear fusion, and x-ray microlithography. It is essential to the construction of instruments that manipulate and analyze x-rays from synchrotrons and particle storage rings for synchrotron radiation research. *See* GEOMETRICAL OPTICS; OPTICS; PHYSICAL OPTICS; X-RAYS.

When W. C. Roentgen discovered x-rays in 1895, he unsuccessfully attempted to reflect, refract, and focus them with mirrors, prisms, and lenses of various materials. The reason for his lack of success became evident after it was established that x-rays are electromagnetic waves of very short wavelength for which the refractive index of all materials is smaller than unity by a only a small decrement. In addition, x-rays are absorbed by materials. The refractive index can be written as a complex quantity, as in Eq. (1), where $1 - \delta$ represents the real part, n, of the refractive index and β is the absorption index. These quantities are strongly dependent on the wavelength of the x-rays and the material. X-rays of wavelength about 0.1 nanometer or less are called hard x-rays and are relatively penetrating, while x-rays of wavelength 1–10 nm are less penetrating and are called soft x-rays. Radiation in the wavelength range 10– 50 nm, called the extreme-ultraviolet (EUV) region, is very strongly absorbed by most materials. Values of δ remain very small throughout the x-ray and extreme-ultraviolet regions with the consequence that radiation is very weakly refracted by any material. Thus lenses for x-rays would have to be very strongly curved and very thick to achieve an appreciable focusing effect. However, because the absorption index, β, is so high in comparison, such thick lenses would absorb most of the incident radiation, making such lenses impractical. *See* ABSORPTION OF ELECTROMAGNETIC RADIATION; REFRACTION OF WAVES; ULTRAVIOLET RADIATION.

$$\tilde{n} = 1 - \delta - i\beta \qquad (1)$$

If radiation is incident normally (that is, perpendicular) to a surface between two media of differing refractive index, the fraction of the energy that is reflected is $^1/_4(\delta^2 + \beta^2)$. This is clearly impractically small for a normal-incidence mirror for x-rays. However, useful mirrors can be constructed by using the principle of total reflection. If electromagnetic waves are incident on the boundary between one material of refractive index n_1 and another of lower refractive index n_2, there exists an angle of incidence I_c, called the critical angle, given by Eq. (2). If the angle of incidence (the angle of incident radiation with respect to the normal to the surface) is greater than this critical angle, all the wave energy is reflected back into the first medium. This phenomenon can be seen when looking upward into an aquarium tank; objects in the tank are reflected in the surface of the water, which acts as a perfect mirror. An analogous situation occurs for x-rays. Since the refractive index for all materials is slightly less than 1, x-rays incident from vacuum (or air) on a polished surface of, say, a metal encounter a lower refractive index and there exists a critical angle given by $\sin I_c = 1 - \delta$. Since δ is very small, I_c is very close to 90°. In this case the angle of incidence is customarily measured from the tangent to the surface rather than from the normal, and the angle $\theta_c = 90^\circ - I_c$ is termed the angle of glancing (or grazing) incidence. This angle is typically in the range 0.1–1.0°. *See* REFLECTION OF ELECTROMAGNETIC RADIATION.

$$\sin I_c = \frac{n_2}{n_1} \qquad (2)$$

Although the reflectivity of surfaces at glancing angles greater than the critical angle is very small, this reflectivity can be enhanced by depositing a stack of ultrathin films having alternately high and low values of δ on the surface. The individual thicknesses of these films is adjusted so that the reflections from each interface add in phase at the top of the stack in exact analogy to the multilayer mirrors used for visible light. However, whereas visible multilayers require film thicknesses of hundreds of nanometers, in the x-ray region the thickness of each film must be between 1 and 100 nm. Such ultrathin films can be made by a variety of vacuum deposition methods, commonly sputtering and evaporation. The response of these artificial multilayers is strongly wavelength-selective. *See* X-RAY DIFFRACTION.

As a coating for glancing-incidence optics, multilayers allow a mirror to be used at a shorter wavelength (higher x-ray energy) for a given glancing angle, increasing the projected area and thus the collection efficiency of the mirror. At wavelengths longer than 3 or 4 nm, multilayer mirrors can be used to make normal-incidence mirrors of relatively high reflecting power. For example, stacks consisting of alternating layers of molybdenum and silicon can have reflectivities as high as 65% at wavelengths of 13 nm and longer. These mirrors have been used to construct optical systems that are exact analogs of mirror optics used for visible light. For example, normal-incidence x-ray telescopes have photographed the Sun's hot outer atmosphere at wavelengths of around 18 nm. Multilayer optics at a wavelength of 13.5 nm can be used to perform x-ray microlithography by the projection method to print features of dimensions less than 100 nm.

Crystals are natural multilayer structures and thus can reflect x-rays. Many crystals can be bent elastically (mica, quartz, silicon) or plastically (lithium fluoride) to make x-ray focusing reflectors. These are used in devices such as x-ray spectrometers, electron-beam microprobes, and diffraction cameras to focus the radiation from a small source or specimen on a film or detector. Until the advent of image-forming optics based on mirrors and zone plates, the subject of x-ray diffraction by crystals was called x-ray optics. *See* X-RAY CRYSTALLOGRAPHY; X-RAY SPECTROMETRY.

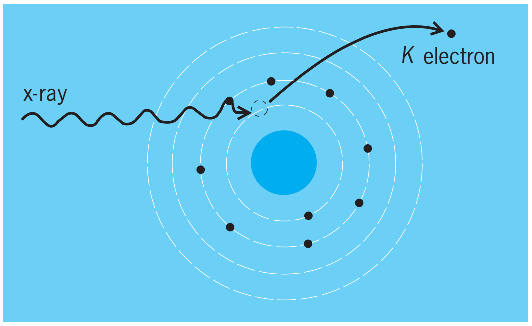
Zone plates are diffraction devices that focus x-rays and form images. They are diffracting masks consisting of concentric circular zones of equal area, and are alternately transparent and opaque to x-rays. Whereas mirrors and lenses focus radiation by adjusting the phase at each point of the wavefront, zone plates act by blocking out those regions of the wavefront whose phase is more than a half-period different from that at the plate center. Thus a zone plate acts as a kind of x-ray lens. Zone-plate microscopy is the most promising candidate method for x-ray microscopy of biological specimens. *See* DIFFRACTION. [J.H.U.]

X-ray powder methods Physical techniques used for the identification of substances, and for other types of analyses, principally for crystalline materials in the solid state. In these techniques, a monochromatic beam of x-rays is directed onto a polycrystalline (powder) specimen, producing a diffraction pattern that is recorded on film or with a diffractometer. This x-ray pattern is a fundamental and unique property resulting from the atomic arrangement of the diffracting substance. Different substances have different atomic arrangements or crystal structures, and hence no two chemically distinct substances give identical diffraction patterns. Identification may be made by comparing the pattern of the unknown substance with patterns of known substances in a manner analogous to the identification of people by their fingerprints. The analytical information is different from that obtained by chemical or spectrographic analysis. X-ray identification of chemical compounds indicates the constituent elements and shows how they are combined.

The x-ray powder method is widely used in fundamental and applied research; for instance, it is used in the analysis of raw materials and finished products, in phase-diagram investigations, in following the course of solid-state chemical reactions, and in the study of minerals, ores, rocks, metals, chemicals, and many other types of material. The use of x-ray powder diffraction methods to determine the actual atomic arrangement, which has been important in the study of chemical bonds, crystal physics, and crystal chemistry, is described in related articles. *See* X-RAY CRYSTALLOGRAPHY; X-RAY DIFFRACTION.

There are many types of powder diffractometer available ranging from simple laboratory instruments to versatile and complex instruments using a synchrotron source. Specialized instruments allow recording of diffraction patterns under nonambient conditions, including variable temperature, pressure, and atmosphere. Completely automated equipment for x-ray analysis is available. Most laboratory instruments consist of a high-voltage generator which provides stabilized voltage for the x-ray tube, so that the x-ray source intensity varies by less than 1%. A diffractometer goniometer is mounted on a table in front of the x-ray tube window. Electronic circuits use an x-ray detector to convert the diffracted x-ray photons to measurable voltage pulses, and to record the diffraction data. [R.Je.]

X-ray spectrometry A rapid and economical technique for quantitative analysis of the elemental composition of specimens. It differs from x-ray diffraction, whose purpose is the identification of crystalline compounds. It differs from spectrometry in the visible region of the spectrum in that the x-ray photons have energies of thousands of electronvolts and come from tightly bound inner-shell electrons in the atoms, whereas visible photons come from the outer electrons and have energies of only a few electronvolts.



Removal of a *K* election from an atom by a primary x-ray photon. (*After L. S. Birks, X-Ray Spectrochemical Analysis, 2d ed., Wiley-Interscience, 1969*)

In x-ray spectrometry the irradiation of a sample by high-energy electrons, protons, or photons ionizes some of the atoms, which then emit characteristic x-rays whose wavelength depends on the atomic number of the element, and whose intensity is related to the concentration of that element. Generally speaking, the characteristic x-ray lines are independent of the physical state (solid or liquid) and of the type of compound (valence) in which an element is present, because the x-ray emission comes from inner, well-shielded electrons in the atom. The illustration shows the removal of one of the innermost, *K*-shell, electrons by a high-energy photon. The photon energy must be greater than the binding energy of the electron; the difference in energy appears as the kinetic energy of the ejected electron. The *K* ionized atom is unstable, and one of the *L*- or *M*-shell electrons drops into the *K*-shell vacancy. As this transition occurs, a characteristic x-ray photon is emitted with an energy equal to the difference in energy between the *K* and the *L* (or *M*) shell, or an additional electron, called an Auger electron, is ejected from the atom. Either the x-rays or the Auger electrons may be used for analysis. *See* AUGER EFFECT.

X-ray spectrometry generally does not require any separation of elements before measuring, because the x-ray lines are easily resolved. However, preconcentration methods are sometimes useful as a means for improving the limit of detection. One limitation of x-ray spectrometry is the progressive difficulty of measurement below atomic number 11. *See* SPECTROSCOPY. [L.S.B.]

X-ray telescope An instrument designed to collect and detect x-rays emitted from a source outside the Earth's atmosphere and to resolve the x-rays into an image. Absorption by the atmosphere requires that x-ray telescopes be carried to high altitudes. Balloons are used for detection systems designed for higher-energy (hard) x-ray observations, whereas rockets and satellites are required for softer x-ray detectors. *See* X-RAY ASTRONOMY; X-RAYS.

Image formation. An image-forming telescope lens for x-ray wavelengths can be based either on the phenomenon of total external reflection at a surface where the index of refraction changes (grazing-incidence telescope) or on the principles of constructive interference (multilayer telescope).

In the case of x-rays, the index of refraction in matter is slightly less than unity. By application of Snell's law, the condition for total external reflection is that the radiation be incident at small grazing angles, less than a critical angle of about 1°, to the reflecting surface. Based on these properties, x-ray mirrors have been constructed which focus an image in two dimensions.

Various configurations of surfaces are possible. *See* Reflection of electromagnetic radiation; Refraction of waves.

A second type of x-ray telescope is based on the principles of constructive interference in extremely thin layers of material deposited on a mirror surface. Unlike the grazing-incidence telescope, multilayer telescopes do not require the x-rays to strike at shallow angles in order to be reflected. Instead these mirrors are similar to normal optical telescope mirrors where the incoming radiation strikes the mirror at nearly normal incidence to be reflected and focused. *See* Interference of waves.

The advantage of a multilayer mirror is that all of the mirror area is used in collecting the x-ray radiation, whereas the grazing-incidence telescopes have only a small projected area of the actual mirror surface collecting radiation. There is an offsetting disadvantage, as the multilayer mirror reflects x-rays only within a very narrow range of energy while the grazing-incidence mirror reflects over a broad range of energies. The effect is similar to using a narrow-band filter with an optical telescope, and in some cases this can be very useful. The first astronomical use of multilayer, normal-incidence x-ray telescopes was in photographing the Sun.

Image detection. The high angular resolution of the grazing-incidence telescope requires a camera that has correspondingly good spatial resolution. One type of detector uses microchannel plates and yields about 20 micrometers resolution for x-rays in the soft energy band (about 100–10,000 eV). The microchannel plate is an array of small hollow tubes or channels (about 10–15 μm in diameter) which are processed to have high secondary electron yield from their inner walls.

The charge-coupled device (CCD) has been developed for x-ray imaging applications. This solid-state detector consists of microscopic silicon picture elements (pixels) in which electronic charges produced by the passage of an x-ray photon are collected. Typical charge-coupled devices have pixels that are 15–25 μm on a side, and there are up to 4096×4096 pixels on one such device. The charge-coupled device not only records the position of an event but can also yield information on the energy of the photon. *See* Charge-coupled devices.

A position-sensitive proportional counter is a gas-filled counter in which x-rays are photoelectrically absorbed, yielding an electron which is detected by the ionization it produces in the gas. By operation of the counter in the proportional mode and use of planes of wires to localize the electrical signals, the position and amplitude of each event can be recorded. These detectors generally have lower spatial resolution (about 200 μm) than do microchannel plate or charge-coupled-device detectors, but they can be made larger in size and provide better energy resolution than microchannel plate detectors. *See* Ionization chamber.

Another class of detectors consists of very low-temperature devices that detect the heat deposited in an absorber when an x-ray is stopped. These devices promise improved energy resolution and efficiency over a broad range of energies. *See* Telescope. [S.S.M.]

X-ray tube An electronic device used for the generation of x-rays. X-rays are produced in the x-ray tube by accelerating electrons to a high velocity by an electrostatic field and then suddenly stopping them by collision with a solid body, the so-called target, interposed in their path. The x-rays radiate in all directions from the spot on the target where the collisions take place. The x-rays are due to the mutual interaction of the fast-moving electrons with the electrons and positively charged nuclei which constitute the atoms of the target. Depending upon the method used in generating the electrons, x-ray tubes may all be classified in two general groups, gas tubes and high-vacuum tubes. *See* X-rays.

In gas tubes electrons are freed from a cold cathode by positive ion bombardment. For the existence of the positive ions a certain gas pressure is required without which the tube will allow no current to pass. Metals, such as platinum and tungsten, are placed in the path of the electron beam to serve as the target. Concave metal cathodes are used to focus the electrons on a small area of the metal target and increase the sharpness of the resulting shadows on the fluorescent screen or the photographic film. Many designs of gas tubes have been built for useful application, particularly in the medical field.

The operational difficulties and erratic behavior of gas x-ray tubes are inherently associated with the gas itself and the positive ion bombardment that takes place during operation. The high-vacuum x-ray tube eliminates these difficulties by using other means of emitting electrons from the cathode. The original type of high-vacuum x-ray tube had a hot tungsten-filament cathode and a solid tungsten target. This tube permitted stable and reproducible operation with relatively high voltages and large masses of metals. A modern commercial hot-cathode high-vacuum x-ray tube is built with a liquid-cooled, copper-backed tungsten target. [E.E.C]

X-rays X-rays, or roentgen rays, are electromagnetic waves in which periodically variable electric and magnetic fields are perpendicular to each other and to the direction of propagation. Thus they are identical in nature with visible light and all the other types of radiation that constitute the electromagnetic spectrum. In general, x-rays are generated as the result of energy transitions of atomic electrons caused by the bombardment of a material of high atomic weight by high-energy electrons. *See* Electromagnetic radiation.

Following W. R. Röntgen's discovery of "a new kind of ray" in 1895, other scientists found the essential experimental conditions to prove that x-rays can be polarized, diffracted by crystals, refracted in prisms and in crystals, reflected by mirrors, and diffracted by ruled gratings. *See* X-ray optics.

The range of x-rays in the electromagnetic spectrum, as excited in x-ray tubes by the bombardment of anode targets by cathode electrons under a high accelerating potential, overlaps the ultraviolet range on the order of 100 nanometers on the long-wavelength side, and the shortest-wavelength limit moves downward as voltages increase. An accelerating potential of 10^9 volts, now readily generated, produces a wavelength of 10^{-15} m (10^{-6} nm). An average wavelength used in research is 0.1 nm, or about 1/6000 the wavelength of yellow light. *See* X-ray tube.

In diffraction, refraction, polarization, and interference phenomena, x-rays, together with all other related radiations, appear to act as waves. In other phenomena—such as the appearance of sharp spectral lines, a definite short-wavelength limit of the continuous "white" spectrum, the shift in wavelength of x-rays scattered by electrons in atoms (Compton effect), and the photoelectric effect—the energy seems to be propagated and transferred in quanta, called photons. *See* Compton effect; Electron diffraction; Neutron diffraction; Photoemission; Quantum mechanics.

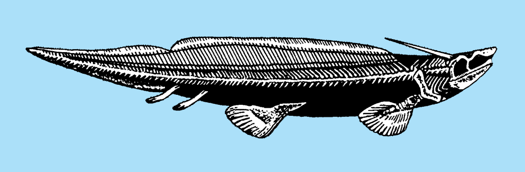
Important uses have been found for x-rays in many fields of scientific endeavor, for example, roentgen spectrometry and roentgen diffractometry. Extensive tables of the wavelengths of x-ray emission lines in series (*K, L, M*, and so on) and so-called absorption edges, characteristic of the chemical elements, afford the necessary information for chemical analyses, exactly as in the case of optical emission spectra and for derivation of theories of atomic structure to account for the origin of spectra. *See* Historadiography; Microradiography; Radiation biology; Radiography; Radiology; X-ray crystallography; X-ray diffraction; X-ray fluorescence analysis; X-ray microscope; X-ray powder methods. [G.L.Cl.]

Xanthophyceae A class of plants, comprising the yellow-green algae, in the chlorophyll *a–c* phylectic line (Chromophycota). Alternate names are Tribophyceae, derived from *Tribonema*, a filamentous member of the class, and Heterokontae, referring to the presence of two kinds of flagella on each motile cell. The absence of starch is an important characteristic in distinguishing yellow-green algae from green algae, which they may resemble superficially in form and color. *See* ALGAE; CHROMOPHYCOTA.

Motile cells have two unequal flagella borne apically or laterally. One (usually the longer) is directed forward and is pleuronematic (hairy); the other is directed backward and is acronematic (smooth). The compound zoospore (synzoospore) of *Vaucheria* is exceptional in having numerous pairs of slightly unequal smooth flagella. There are usually two chloroplasts in each motile cell, the ventral one with a reddish refractile eyespot at its anterior end. One or two contractile vacuoles occur at the anterior end of a motile cell. Cells in most Xanthophyceae are uninucleate, but in some genera they are multinucleate. The mitochondria have tubular cristae. Each vegetative cell contains one to many yellow-green, laminate or discoid, parietal chloroplasts.

Most Xanthophyceae occur in fresh water, especially soft water. Frequently, they are epiphytic on aquatic plants. The chief exception is *Vaucheria*, which has fresh-water, brackish-water, and marine species. Xanthophyceae also occur in and on soil and mud, in snow and ice, and on tree trunks and damp walls. [P.C.Si.; R.L.Moe]

Xenacanthida An order of Paleozoic sharklike fishes abundant in fresh-water deposits of the Carboniferous and Early Permian. Although primitive in cranial structures, the pleuracanths differ notably from other sharks in several regards (see illustration). The teeth are two-pronged; there is a long spine projecting upward and backward from the posterior part of the braincase; the tail extends directly backward, in contrast with the upturned heterocercal caudal fin of other sharks; and the paired fins have the archipterygial skeletal pattern of a central axis and side branches, in contrast with a fan-shaped arrangement in typical sharks. *See* ELASMOBRANCHII. [A.S.R.]



Xenacanthus **(*Pleuracanthus*), Carboniferous and Permian sharklike form; perhaps $2^1/_2$ft (75 cm) long. (*After Fritsch*)**

Xenolith A rock fragment enclosed in another rock, and of varying degrees of foreigness. Cognate xenoliths, for example, are pieces of rock that are genetically related to the host rock that contains them, such as pieces of a border zone in the interior of the same body. Included blocks of unrelated rocks are more deserving of the xenolith label. Such foreign rocks help establish the once molten condition of invading magma capable of incorporating and mixing an assemblage of unrelated rock inclusions. *See* LAVA; MAGMA.

Xenoliths tend to react with the enclosing magma, so that their constituent minerals become like those in equilibrium with the melt. Reaction is rarely complete, however. Even completely equilibrated xenoliths may be conspicuous because the equilibration process does not require either the texture or the proportions of the minerals in the xenolith to match those in the enclosing rock. *See* PLUTON.

Xenoliths may be angular to round, millimeters to meters in diameter, aligned or haphazard, and sharply or gradationally bounded. Xenoliths are present in most bodies of igneous rock. *See* IGNEOUS ROCKS. [A.T.A.]

Xenon A chemical element, Xe, atomic number 54. It is a member of the family of noble gases, group 18 in the periodic table. Xenon is colorless, odorless, and tasteless; it is a gas under ordinary conditions (see table). *See* INERT GASES; PERIODIC TABLE.

Xenon is the only one of the nonradioactive noble gases which forms chemical compounds that are stable at room temperature. Xenon also forms weakly bonded clathrates with such substances as water, hydroquinone, and phenol. *See* CLATHRATE COMPOUNDS.

Physical properties of xenon

Property	Value
Atomic number	54
Atomic weight (atmospheric xenon only)	131.30
Melting point (triple point)	−111.8°C (−169.2°F)
Boiling point at 1 atm pressure	−108.1°C (−162.6°F)
Gas density at 0°C and 1 atm pressure, g/liter	5.8971
Liquid density at its boiling point, g/ml	3.057
Solubility in water at 20°C, ml xenon (STP) per 1000 g water at 1 atm partial pressure of xenon	108.1

The three fluorides, XeF_2, XeF_4, and XeF_6, are thermodynamically stable compounds at room temperature, and they may be prepared simply by heating mixtures of xenon and fluorine at 300–400°C (570–750°F).

The reaction of XeF_6 with water gives $XeOF_4$; if the reaction is allowed to continue, XeO_3 is formed. XeO_3 is a colorless, odorless, and dangerously explosive white solid of low volatility. Gaseous xenon tetroxide, XeO_4, is formed by the reaction of sodium perxenate, Na_4XeO_6, with concentrated H_2SO_4. The vapor pressure of XeO_4 is about 3.3 kPa at 0°C (32°F). It is unstable and has a tendency to explode.

Xenon is produced commercially in an air-separation plant. The air is liquefied and distilled. The oxygen is redistilled; the least volatile portion contains small amounts of xenon and krypton, which are adsorbed on silica gel directly from the liquid oxygen. The crude xenon and krypton thus obtained are separated and further purified by distillation and selective absorption, at controlled low temperatures, on activated carbon. Remaining impurities are removed by passing the xenon over hot titanium, which reacts with all but the inert gases. *See* AIR SEPARATION.

Xenon is used to fill a type of flashbulb used in photography and called an electronic speed light. These bulbs produce a white light with a good balance of all the colors in the visible spectrum, and can be used 10,000 times or more before burning out.

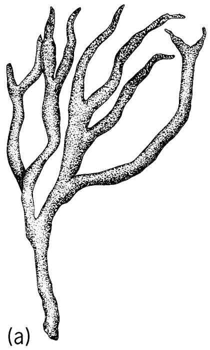
A xenon-filled arc lamp gives a light intensity approaching that of the carbon arc; it is particularly valuable in projecting motion pictures. *See* VAPOR LAMP.

An important development in high-energy physics was the detection of nuclear radiation, such as gamma rays and mesons, by bubble chambers, in which a liquid is kept at a temperature just above its boiling point. Nucleation by the radiation results in bubble formation along the path of the particle. The tracks made by the particles are then photographed. Liquid xenon is one of the liquids used in these bubble chambers.

Xenon is used to fill neutron counters, x-ray counters, gas-filled thyratrons, and ionization chambers for cosmic rays; it is also used in high-pressure arc lamps to produce ultraviolet radiation.

Between 3 and 5% of the fissions in a nuclear reactor using uranium as fuel lead to the formation of xenon-135. [A.W.F.]

Xenophyophorida An order of Protozoa in the subclass Granuloreticulosia. The group includes deep-sea forms which are multinucleate at maturity. They develop as discoid to fan-shaped or algalike branching forms (illus. *a* and *b*) covered with a hyaline organic layer and sometimes measuring 2 mm or more overall. The aggregate contains many tubes which vary in diameter and form netlike or branching patterns. The lack of detailed information makes the taxonomic status of these



Xenophyophorids. ***(a) Stanomma dendroides. (b) Stannophyllum zonarium.***

organisms somewhat uncertain. The genera included are *Psammetta, Stanomma*, and *Stannophyllum*. *See* GRANULORETICULOSIA. [R.P.H.]

Xenungulata An order of large, primitive, digitigrade, hoofed, tapirlike mammals with relatively short, slender limbs and five-toed feet with broad, flat phalanges. They are restricted to the Paleocene deposits of Brazil and Argentina. Only one genus (*Carodnia*) constitutes the single family (Carodniidae) in the order. The dentition is complete with strong, procumbent, chisel-shaped incisors, strong sharp-pointed canines, and low-crowned cheek teeth with bilophodont molars. *See* DENTITION; EUTHERIA.

The affinities of the Xenungulata remain uncertain. Affinities with the Dinocerata are strongly supported by the dental characteristics, but the structure of the tarsus suggests that the xenungulates had common ancestry with the Pyrotheria, to which they were tentatively assigned originally. *See* DINOCERATA; PYROTHERIA. [G.T.J.; E.C.O.]

Xiphosurida An order of the subclass Xiphosura in the class Merostomata. These "sword-tailed" arthropods have three distinct body divisions: a prominent horseshoe-shaped, fused head and thorax, the prosoma; a segmented "abdomen," or opisthosoma; and a spikelike terminal segment, the telson. The Xiphosurida have an extensive fossil record. The two suborders, Synziphosurina and Limulina, span over 500,000,000 years of evolution. The Synziphosurina usually lacked compound eyes. Some species had a distinct axial, or cardiac, region, free segments in the opisthosoma, and a broad, short telson. Superfamilies Belinuracea and Limulacea of the Limulina have the clearly recognizable horseshoe "crab" form.

The carapace (test or shell) is composed of chitin, strengthened internally in the adults by bridgelike struts within the shell margins. Sensory structures on the carapace include chemoreceptors for taste on the bases of the legs and a pair of simple eyes, or ocelli. The multilensed compound eyes form mosaic images and are sensitive to polarized light. The organ systems, except the peripheral blood vessels and nerves, digestive, and reproductive glands, which branch extensively into the lateral portions of the prosoma, are mainly within the prominent axial region. This region contains the musculature of the paired appendages, hinge, and telson, the digestive tube, the coxal (excretory) gland, and the respiratory, central circulatory, and nervous structures. The dorsally situated tubular heart lies within a sinus which receives venous blood from the book gills, the respiratory structures, and the body. The central nervous system and the major nerve branches are sheathed by arteries. A plate of "cartilaginous" chitin, the endocranium, forms a roof over the brain. *See* MEROSTOMATA. [C.N.Sh.]

Xylem The principal water-conducting tissue and the chief supporting system of higher plants. This tissue and the associated phloem constitute the vascular system of vascular plants. Xylem is composed of various kinds of cells, living or nonliving. The structure of these cells differs in their functions, but characteristically all have a rigid and enduring cell wall that is well preserved in fossils.

In terms of their functions, the kinds of cells in xylem are those related principally to conduction and support, tracheids; to conduction, vessel members; to support, fibers; and to food storage, parenchyma. Vessel members and tracheids are often called tracheary elements. The cells in each of the four categories vary widely in structure. *See* PARENCHYMA.

Xylem tissues arise in later stages of embryo development of a given plant and are added to by differentiation of cells derived from the apical meristems of roots and stems. Growth and differentiation of tissues derived from the apical meristem provide the primary body of the plant, and the xylem tissues formed in it are called primary. Secondary xylem, when present, is produced by the vascular cambium. *See* LATERAL MERISTEM.

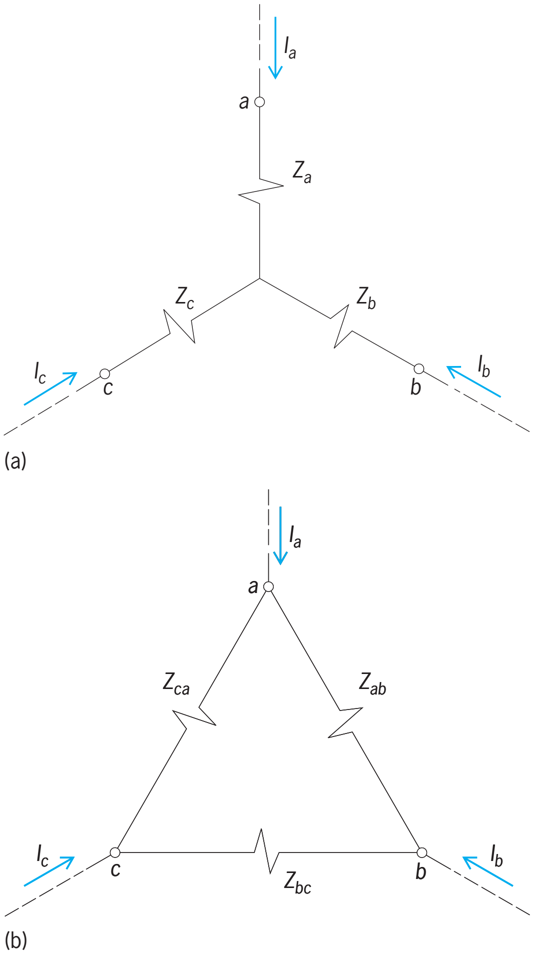
In the trade, softwood is a name for xylem of gymnosperms (conifers) and hardwood for xylem of angiosperms. The terms do not refer to actual hardness of the wood. Woods of gymnosperms are generally composed only of tracheids, wood parenchyma, and small rays, but differ in detail. Resin ducts are present in many softwoods. Woods of angiosperms show extreme variation in both vertical and horizontal systems, but with few exceptions have vessels. [V.I.C.; K.E.]

Xylose A pentose sugar, referred to in the early literature as L-xylose. It is present in many woody materials. The polysaccharide xylan, which is closely associated with cellulose, consists practically entirely of D-xylose. Corncobs, cottonseed hulls, pecan shells, and straw contain considerable amounts of this sugar. This pentose sugar is also a component of the hemicelluloses and the rare disaccharide, primeverose. *See* CARBOHYDRATE; POLYSACCHARIDE. [W.Z.H.]

Y

Y-delta transformations Electrically equivalent networks with three terminals, one being connected internally by a Y configuration and the other being connected internally by a Δ configuration.

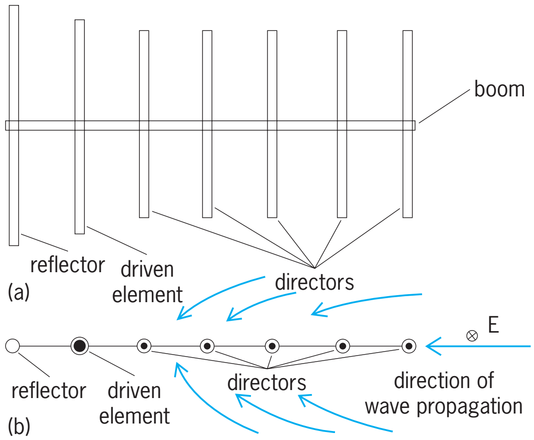
If a network connects three terminals with one another, it is called a three-terminal network. The simplest configurations of three-terminal networks are the Y or star (illus. *a*) and the Δ or mesh (illus. *b*).



Three-terminal networks: (*a*) Y or star, (*b*) Δ or mesh.

If a given three-terminal network, passive and linear, has a Y configuration, it is possible to determine an equivalent Δ network that could be substituted for the Y without changing the relations of voltage and current at the network terminals, or elsewhere external to the network. Similarly, if a Δ network is given, an equivalent Y network can be found. Impedances of equivalent networks are usually functions of frequency, and realization of these impedances by use of physically possible elements is usually limited to a single frequency. [H.H.Sk.]

Yagi-Uda antenna An antenna in which the gain of a single dipole element is enhanced by placing a reflector element behind the dipole (the driver) and one or more director elements in front of it (see illustration). It was invented in 1926 by H. Yagi and S. Uda in Japan. The gain is slightly increased by the reflector and further enhanced by the first director element. Additional director elements further increase the gain and improve the front-to-back ratio, up to a point of diminishing returns. This type of antenna has traditionally been used for local television reception. Its variants have found applications in the more modern communication systems at higher frequencies and smaller sizes, and have even been adapted to printed-circuit techniques in some applications. The same electromagnetic induction principle used in such linear elements can be applied to loop and disk elements as well with similar results. *See* DIRECTIVITY; ELECTROMAGNETIC INDUCTION; GAIN; PRINTED CIRCUIT.



Yagi-Uda antenna. Typical radiation patterns are shown. (*a*) Side view with radiation pattern in the E plane (the plane containing the electric field). (*b*) Top view with radiation pattern in the H plane (the plane containing the magnetic field).

Since these antennas can be made highly directive with good radiation efficiency, they have found new applications and new manufacturing techniques with miniaturization. They can be printed on microwave circuit substrates with high dielectric constants, which reduces their size even further. The parasitic electromagnetic coupling demonstrated in the Yagi-Uda antenna has been adapted to many new types of miniaturized antennas applicable to mobile communication devices in wide use, and will be used in future wireless Internet devices. *See* ANTENNA (ELECTROMAGNETISM); INTERNET; MICROWAVE SOLID-STATE DEVICES; MOBILE RADIO. [J.S.I.]

Yak A heavily built mammal, *Poephagus grunniens*, of the order Artiodactyla that has been domesticated but still exists in the wild state in Tibet and high areas of China, living at elevations of 13,000–20,000 ft (about 4–6 km). It is related to the bison, which it resembles anatomically in having 14 pairs of ribs instead of the 13 pairs more usual of the order. Economically, it is probably the most important animal in Tibet, being used as a beast of burden and for its excellent milk. The dung is used as fuel, the hair is used for making cloth, and the flesh is eaten. Calving occurs in the autumn after a gestation period of about 10 months. *See* ARTIODACTYLA; BISON. [C.B.C.]

Yaw indicator An aircraft instrument that provides a measure of the sideslip or yaw of the aircraft, defined as the angular measure of the relative wind in relation to a vertical plane passing through the longitudinal center of the aircraft. This device is not common to production aircraft, being found in only a few vertical takeoff and landing (VTOL) aircraft which operate in the low-speed regime. The measurement of yaw is accomplished either by a balanced vane which aligns with the wind, or through a set of pressure sensors that determine the difference in static pressure on each side of the vertical plane and hence the sideslip. The device provides equivalent information in the lateral-directional (yaw and roll) axis to the angle of attack in the longitudinal (pitch) axis. *See* AIRCRAFT INSTRUMENTATION; VERTICAL TAKEOFF AND LANDING (VTOL). [G.W.W.]

Yaws An infectious disease of humans caused by the spirochete *Treponema pertenue*. It is also known as frambesia and is largely confined to the tropics. Usually yaws is contracted in childhood by direct contact or from small flies feeding in succession on infected lesions and open wounds. No race or age possesses natural immunity. [T.B.T.]

Year The period of the Earth's revolution around the Sun. This period can be measured in several ways.

The most commonly used type of year, known as the tropical year, is the mean period for the Sun to go around the sky from one vernal equinox to the next. The tropical year varies slightly over time. Tropical year 2000 was approximately 365.242190 mean solar days, or 365 d 5 h 48 m 45.2 s. Seasons repeat with intervals of a tropical year.

The sidereal year is the average period of the Earth's revolution around the Sun until the Earth-Sun line returns to the same direction in space as measured by the star background. A sidereal year is approximately 365.25636 mean solar days long, or 365 d 6 h 9 m 10 s.

The anomalistic year is the average period of the Earth's return to perihelion in its orbit around the Sun. An anomalistic year is approximately 365.25964 days, or 365 d 6 h 13 m 53 s.

An eclipse year is the duration between alternate eclipse seasons, measured as the interval between the Moon passing alternate nodes. An eclipse year lasts only 346.62005 days, or 346 d 14 h 52 m 52 s.

A Gaussian year, defined as the period derived from Kepler's law for 1 astronomical unit, is 365.25690 days, or 365 d 6 h 9 m 56 s. *See* ASTRONOMICAL UNIT; KEPLER'S LAWS.

The term "year" is also used for the period of the orbit of other planets, both inside the solar system and around other stars. For example, a Jupiter year is 5.2 Earth years long. *See* TIME. [J.M.P.]

Yeast A collective name for those fungi which possess, under normal conditions of growth, a vegetative body (thallus) consisting, at least in part, of simple, single cells. The cells making up the thallus occur in pairs, in groups of three, or in straight or branched chains consisting of as many as 12 or more cells. Vegetative reproduction is characterized by budding or fission. Sexual reproduction also occurs in yeast, and is differentiated from that of other fungi by sexual states that are not enclosed in a fruiting body. Yeasts are a phylogenetically diverse group of organisms that occur in two divisions of fungi (Ascomycotina and Basidiomycotina) and 100 genera. The 700 or more species that have been described possibly represent only 1% of the species in nature, so the majority of the yeasts have yet to be discovered. Yeast plays a large part in industrial fermentation processes such as the production of industrial enzymes and chemicals, food products, industrial ethanol, and malt beverage and wine; in diseases of humans, animals and plants; in food spoilage; and as a model of molecular genetics. *See* DISTILLED SPIRITS; FOOD MICROBIOLOGY; GENETIC ENGINEERING; MALT BEVERAGE; MEDICAL MYCOLOGY; WINE.

The shape and size of the individual cells of some species vary slightly, but in other species the cell morphology is extremely heterogeneous. The shape of yeast cells may be spherical, globose, ellipsoidal, elongate to cylindrical with rounded ends, more or less rectangular, pear-shaped, apiculate or lemon-shaped, ogival or pointed at one end, or tetrahedral. The diameter of a spherical cell may vary from 2 to 10 micrometers. The length of cylindrical cells is often 20–30 μm and, in some cases, even greater.

The asexual multiplication of yeast cells occurs by a budding process, by the formation of cross walls or fission, and sometimes by a combination of these two processes. Yeast buds are sometimes called blastospores or blastoconidia. When yeast reproduces by a fission mechanism, the resulting cells are termed arthrospores or arthroconidia.

Yeasts are categorized into two groups, based on their methods of sexual reproduction: the ascomycetous (Division Ascomycotina) and basidiomycetous (Division Basidiomycotina) yeasts.

The sexual spores of the ascomycetous yeasts are termed ascospores, which are formed in simple structures, often a vegetative cell. Such asci are called naked asci because of the absence of an ascocarp, which is a more complex fruiting body found in the higher Ascomycetes. If the vegetative cells are diploid, a cell may transform directly into an ascus after the $2n$ nucleus undergoes a reduction or meiotic division. *See* ASCOMYCOTA.

Certain yeasts have been shown to be heterothallic; that is, sporulation occurs when strains of opposite mating type (usually indicated by "a" and α) are mixed on sporulation media. However, some strains may be homothallic (self-fertile), and reduction division and karyogamy (fusion of two haploid nuclei) take place during formation of the sexual spore. Yeasts that produce sporogenous cells represent the teleomorphic form of the life cycle. In cases, in which sexual cycles are unknown, the yeast represents the asexual or anamorphic form. A species of yeast may be originally discovered in the anamorphic form and named accordingly; subsequently, the sexual state may be found and a name applied to represent the teleomorph. Consequently, the anamorphic and teleomorphic names will differ.

Basidiospores and teliospores are the sexual spores that are produced in the three classes of basidiomycetous yeasts: Urediniomycetes, Hymenomycetes, and Ustilaginomycetes. Sexual reproduction and life cycle in these yeasts is typical of other basidiomycetes in that it can include both unifactorial (bipolar) and bifactorial (tetrapolar) mating systems. *See* BASIDIOMYCOTA.

Some yeasts have the ability to carry out an alcoholic fermentation. Other yeasts lack this property. In addition to the fermentative type of metabolism, fermentative yeasts as a rule have a respiratory type of metabolism, whereas nonfermentative yeasts have only a respiratory, or oxidative, metabolism. Both reactions produce energy, with respiration producing by far the most, which is used in part for synthetic reactions, such as assimilation and growth. Part is lost as heat. In addition, small or sometimes large amounts of by-products are formed, including organic acids, esters, aldehydes, glycerol, and higher alcohols. When a fermenting yeast culture is aerated, fermentation is suppressed and respiration increases. This phenomenon is called the Pasteur effect. *See* FERMENTATION.

Yeasts are ubiquitous in nature. They exist on plants and animals; in waters, sediments, and soils; and in terrestrial, aquatic, and marine habitats. Yeasts require oxygen for growth and reproduction; therefore they do not inhabit anaerobic environments such as anoxic sediments. Many species have highly specific habitats, whereas others are found on a variety of substrates in nature. [J.W.Fe.; H.J.P.]

Yeast infection An infection mainly caused by fungi of the genus *Candida*. Although members of the genus *Candida* continue to be the most common agents of yeast infections, numerous nosocomial (related to medical treatment) factors have altered this etiologic pattern over the last 20 years. Reports in professional publications have described over 200 species in 25 yeast genera as being associated with human infections. *See* FUNGAL INFECTIONS; FUNGI; YEAST.

Etiologic agents. *Candida*, species particularly *C. albicans*, cause almost 70% of all yeast infections. However, recent changes in medical practices such as the use of broad-spectrum antibiotics, steroids, and immunosuppressive drugs, along with the recognition of new and highly debilitating diseases [for example, acquired immune deficiency syndrome (AIDS)], have increased the diversity of the agents of these infections. Species that were once rarely encountered in patient specimens (for example, *C. parapsilosis*, *C. krusei*, and *C. guilliermondii*) are being isolated with increased frequency. Equally important is the fact that yeasts that have never been described as the cause of human infections, (for example, *Blastoschizomyces capitatus*, *C. dubliniensis*, and *Trichosporon cutaneum*) are now being associated, albeit rarely, with human disease. *See* ACQUIRED IMMUNE DEFICIENCY SYNDROME (AIDS); MEDICAL MYCOLOGY; OPPORTUNISTIC INFECTIONS.

Predisposing factors. Since yeasts are not as adept as other microbial pathogens at evading or overwhelming the body's immune defenses, they generally require some disruption in the natural protective mechanisms of humans to initiate an infection. Minor breaks in the skin (such as those caused by a cut or scrape) to more significant disruptions in the integrity of the skin (as created by the delivery of medications or nutrients through intravenous catheters) can provide the means by which the yeasts on human skin may enter the body and potentially initiate an infection. The use of broad-spectrum antibacterial agents eliminates a large portion of the normal bacterial flora, allowing the yeasts in the mouth and intestines to grow rapidly and seed the blood to create a temporary benign infection or a chronic, potentially life-threatening infection. Natural hormonal imbalances as created by pregnancy or diabetes mellitus, as well as those caused by the use of medications such as corticosteroids, depress the immune system and predispose the individual to possible yeast infections. The common use of immunosuppressive drugs, and the depressed immunity associated with newer human diseases such as AIDS cause a decrease in the immune system's ability to prevent and eliminate yeast infections. Finally, the longer human life expectancy created by modern medical practices has contributed to an ever-increasing population of senior citizens with naturally lowered resistance to all forms of microbial infections. *See* IMMUNOSUPPRESSION.

Clinical symptomology. Although yeast infections usually affect the skin and mucous membranes, the illness can take several different forms, each with different symptoms. For example, in newborns and infants, candidiasis can appear as reddening and blisterlike lesions of skin infections (diaper rash), or it can present as white-gray lesions on the mucosal tissue lining the oral cavity (thrush). The symptoms observed in the vast majority of yeast infections mimic those of other microbial pathogens and thus are generally of little value in establishing their etiology. The diagnosis of most yeast infections involves obtaining detailed medical histories from patients, conducting extensive physical examinations, analyzing clinical laboratory data, and utilizing the education, training, and experience of the attending physicians and infectious disease specialists. *See* CLINICAL MICROBIOLOGY.

Treatment. The introduction of the first clinically effective antifungal antibiotic (nystatin) closely followed the use of antibacterial drugs (penicillin). However, nystatin was found to be effective only when brought into direct contact with the infectious agent. The broad-spectrum and fungicidal (killing fungi) activity of amphotericin B, another member of the same chemical family, maintains its use as the drug of choice for several yeast infections and as the antifungal of last resort when all other antibiotics have failed. Two closely related families of drugs, the azoles and triazoles, were introduced in the early 1970s and quickly established themselves as the first-line antibiotics for yeast infections. However, the newer triazoles are fungistatic (limiting growth) rather than fungicidal. As a result, recurrences of infection happen frequently once therapy is discontinued. Although new antifungal antibiotics continue to be introduced, the perfect drug with broad-spectrum and fungicidal activity, easy delivery, and limited side effects has yet to be found. *See* ANTIBIOTIC; ANTIMICROBIAL AGENTS; FUNGISTAT AND FUNGICIDE; PENICILLIN. [I.F.S.]

Yellow fever An acute, febrile, mosquito-borne viral disease characterized in severe cases by jaundice, albuminuria, and hemorrhage. Inapparent infections also occur.

The agent is a flavivirus, an arbovirus of group B. The virus multiplies in mosquitoes, which remain infectious for life. After the mosquito ingests a virus-containing blood meal, an interval of 12–18 days (called the extrinsic incubation period) is required for it to become infectious. *See* ANIMAL VIRUS; ARBOVIRAL ENCEPHALITIDES.

The virus enters the body through a mosquito bite and multiplies in lymph nodes, circulates in the blood, and localizes in the liver, spleen, kidney, bone marrow, and lymph glands. The severity of the disease and the major signs and symptoms which appear depend upon where the virus localizes and how much cell destruction occurs. The incubation period is 3–6 days. At the onset, the individual has fever, chills, headache, and backache, followed by nausea and vomiting. A short period of remission often follows. On about the fourth day, the period of intoxication begins with a slow pulse relative to a high fever and moderate jaundice. In severe cases, there are high levels of protein in the urine, and manifestations of bleeding appear; the vomit may be black with altered blood; and there is an abnormally low number of lymphocytes in the blood. When the disease progresses to the severe stage (black vomit and jaundice), the mortality rate is high. However, the infection may be mild and go unrecognized. Diagnosis is made by isolation of the virus from the serum obtained from an individual as early as possible in the disease, or by the rise in serum antibody. *See* ANTIBODY; COMPLEMENT-FIXATION TEST; NEUTRALIZATION REACTION (IMMUNOLOGY).

There are two major epidemiological cycles of yellow fever: classical or urban epidemic yellow fever, and sylvan or jungle yellow fever. Urban yellow fever involves person-to-person transmission by *Aedes aegypti* mosquitoes in the Western Hemisphere and West Africa. This mosquito breeds in the accumulations of water that accompany human settlement. Jungle yellow fever is primarily a disease of monkeys. In South America and Africa, it is transmitted from monkey to monkey by arboreal mosquitoes (*Haemagogus* and *Aedes* species) that inhabit the moist forest canopy. The infection in animals ranges from severe to inapparent. Persons who come in contact with these mosquitoes in the forest can become infected. Jungle yellow fever may also occur when an infected monkey visits a human habitation and is bitten by *A. aegypti*, which then transmits the virus to a human.

Vigorous mosquito abatement programs have virtually eliminated urban yellow fever. However, with the speed of modern air travel, the threat of a yellow fever outbreak exists where *A. aegypti* is present. An excellent attenuated live-virus vaccine is available. *See* VACCINATION. [J.L.Me.]

Yersinia A genus of bacteria in the Enterobacteriaceae family. The bacteria appear as gram-negative rods and share many physiological properties with related *Escherichia coli*. Of the 11 species of *Yersinia, Y. pestis, Y. enterocolitica*, and *Y. pseudotuberculosis* are etiological agents of human disease. *Yersinia pestis* causes flea-borne bubonic plague (the black death), an extraordinarily acute process believed to have killed over 200 million people during human history. Enteropathogenic *Y. pseudotuberculosis* and *Y. enterocolitica* typically cause mild chronic enteric infections. The remaining species either promote primary infection of fish (*Y. ruckeri*) or exist as secondary invaders or inhabitants of natural environments (*Y. aldovae, Y. bercovieri, Y. frederiksenii, Y. intermedia, Y. kristensenii, Y. mollaretii*, and *Y. rohdei*). *See* MEDICAL BACTERIOLOGY; PLAGUE. [R.R.B.]

Yew A genus of evergreen trees and shrubs, *Taxus*, with a fruit containing a single seed surrounded by a scarlet, fleshy, cuplike envelope (aril). The leaves are flat and acicular (needle-shaped), green below, with stalks extending downward on the stem. The only native American species of commercial importance is the Pacific yew (*T. breuifolia*), a medium-sized tree of the Pacific Coast and northern Rocky Mountain regions. Although it is not a common tree, its wood is sometimes used for poles, paddles, bows, and small cabinetwork.

The English yew (*T. baccata*), native in Europe, North Africa, and northern Asia, and the Japanese yew (*T. cuspidate*) are much cultivated in the United States as evergreen ornamentals. *See* TAXALES. [A.H.G./K.P.D.]

Ylide A variety of organic compounds that contain two adjacent atoms bearing formal positive and negative charges, and in which both atoms have full octets of electrons. Heteroatoms most commonly utilized as the positive atom are phosphorus, nitrogen, sulfur, selenium and oxygen, and the negative atom usually involves carbon, nitrogen, oxygen, or sulfur. The ylide may be in an alicyclic or cyclic environment, and in the latter the ylide function may be endocyclic or exocyclic. Ylides most useful in organic synthesis are those containing phosphorus or sulfur and an adjacent carbanion.

A phosphorus ylide is known as a phosphorane. Ylides of this type are highly reactive. Sulfur-containing ylides (π-sulfuranes) are of two types, sulfonium ylides and oxosulfonium ylides, which differ in having an oxygen atom attached to the sulfur in the latter. *See* REACTIVE INTERMEDIATES.

The ylide function may also be incorporated into heterocyclic systems. For example, the meso-ionic sydnone molecule contains an azomethine imine ylide, and the mesomeric betaine derived from 3-hydroxypyridine contains an azomethine ylide. These ylides are often referred to as masked ylides. [K.T.P.]

Yolk sac An extraembryonic membrane which extends through the umbilicus in vertebrates. In some elasmobranchs, birds, and reptiles, it is laden with yolk which serves as the nutritive source of embryonic development.

In mammals, as in birds, the yolk sac generally develops from extraembryonic splanchnopleure, and extends beneath the developing embryo. A blood vessel network develops in the mammalian yolk sac lining. Though these blood vessels are empty, they play an important role in absorbing nourishing food and oxygen from the mother. Thus, although the yolk sac in higher mammals may be considered an evolutionary vestige from its yolky-egged ancestors, it still serves important functions in the young embryo. As the embryo ages, the yolk sac shrinks in size, and the allantois takes over the role of nutrition. *See* ALLANTOIS. [S.B.O.]

Young's modulus A constant designated E, the ratio of stress to corresponding strain when the material behaves elastically. Young's modulus is represented by the slope $E = \Delta S/\Delta\varepsilon$ of the initial straight segment of the stress-strain diagram. More correctly, E is a measure of stiffness, having the same units as stress: pounds per square inch or pascals. When stress and strain are not directly proportional, E may be represented as the slope of the tangent or the slope of the secant connecting two points on the stress-strain curve. The modulus is then designated as tangent modulus or secant modulus at stated values of stress. The modulus of elasticity applying specifically to tension is called Young's modulus. *See* ELASTICITY; HOOKE'S LAW; STRESS AND STRAIN. [W.J.K./W.G.B.]

Ytterbium A chemical element, Yb, atomic number 70, and atomic weight 173.04. Ytterbium is a metal element of the rare-earth group. There are 7 naturally occurring stable isotopes. *See* PERIODIC TABLE.

The common oxide, Yb_2O_3, is colorless and dissolves readily in acids to form colorless solutions of trivalent salts which are paramagnetic. Ytterbium also forms a series of divalent compounds. The divalent salts are soluble in water but react very slowly with water to liberate hydrogen.

The metal is best prepared by distillation. It is a silvery soft metal which corrodes slowly in air and resembles the calcium-strontium-barium series more than the rare-earth series. For a discussion of the properties of the metal and its salts *see* RARE-EARTH ELEMENTS. [F.H.Sp.]

Yttrium A chemical element, Y, atomic number 39, and atomic weight 88.905. Yttrium resembles the rare-earth elements closely. The stable isotope ^{89}Y constitutes 100% of the natural element, which is always found associated with the rare earths and is frequently classified as one. *See* PERIODIC TABLE.

Yttrium metal absorbs hydrogen, and in alloys up to a composition of YH_2 they resemble metals very closely. In fact, in certain composition ranges, the alloy is a better conductor of electricity than the pure metal.

Yttrium forms the matrix for the europium-activated yttrium phosphors which emit a brilliant, clear-red light when excited by electrons. The television industry uses these phosphors in manufacturing television screens.

Yttrium is used commercially in the metal industry for alloy purposes and as a "getter" to remove oxygen and nonmetallic impurities in other metals. For properties of the metal and its salts *see* RARE-EARTH ELEMENTS. [F.H.Sp.]

Z

Z transform The preferred operational-calculus tool for analysis and design of discrete-time systems. (It should not be confused with the z transformation.) The role of the z transform with regard to discrete-time systems is similar to that of the Laplace transform for continuous systems. In fact, the Laplace transform is a specialized case of the z transform. The z transform is by far the more insightful tool, and the Laplace transform is just the limiting case of the z transform in a practical as well as a conceptual way. *See* Control systems; Digital filter; Laplace transform; Linear system analysis.

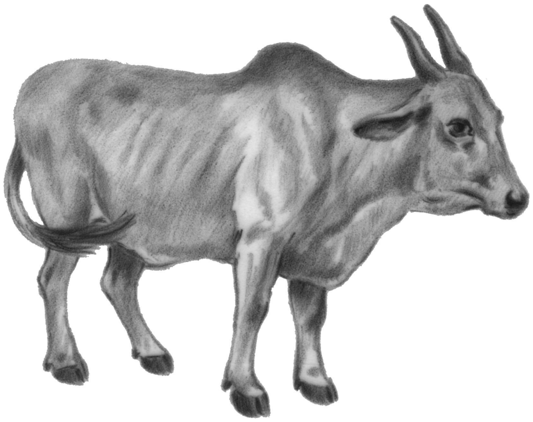
It is useful to consider a band-limited real continuous signal, $x(t)$, with no significant amount of energy above a frequency, fc. This signal is sampled at uniformly spaced intervals of time, T, $2T$, $3T$, ..., nT, ..., where the sampling interval, T, and the sampling frequency, f_s, are reciprocals of one another, and where f_s is greater than $2f_c$, a condition necessary for unambiguous interpretation of the sampled signal. If the common shorthand notation $x(nT) = x_n$ is used, the definition of the z transform of $x(t)$ is given by the equation

$$X(z) = x_0 + x_1z^{-1} + x_2z^{-2} + x_3z^{-3} + \cdots$$

The coefficient of z^{-p} is therefore the value of the pth sample of the time signal. This gives a great deal of physical insight to the use of the z transform, a feature not shared by the Laplace transform. The Laplace transform can be found by evaluating the limit of the z transform as T approaches zero. *See* Analog-to-digital converter; Information theory. [S.A.Wh.]

Zebra Three species belonging to the family Equidae and indigenous to Africa. These animals are odd-toed ungulates (order Perissodactyla) which are monodactyl; that is, the middle digit is functional while the second and fourth digits are vestigial. The striped coat is considered to be an example of protective coloration since they live on open plains. Zebras are sociable and graze with other animals, such as deer, gnu, and ostriches. The gestation period is 13 months and a single young is born. The maximum life-span is 30 years. *See* Perissodactyla. [C.B.C.]

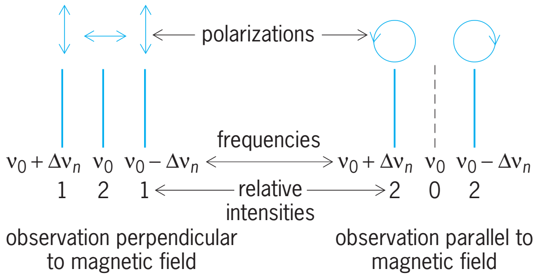
Zebu A domestic breed of cattle, indigenous to India, belonging to the family Bovidae in the order Artiodactyla. This animal, *Bos indicus*, known as the Brahman in the United States, is protected as the sacred cow in India, where it is used as a draft animal as well as for milk. The ears are long and drooping (see illustration); the color is quite variable, One of the most notable cross breeds is the Santa Gertrudis, in which Brahman bulls are crossed with short-horn cows. This produces one of the heaviest beef breeds. *See* Artiodactyla. [C.B.C.]



The zebu, or Brahman, characterized by a dorsal hump between the shoulders and loose skin which forms a dewlap under the chin.

Zeeman effect A splitting of spectral lines when the light source being studied is placed in a magnetic field. Discovered by P. Zeeman in 1896, the effect furnishes information of prime importance in the analysis of spectra. Each kind of spectral term has its characteristic mode of splitting, and the types of terms are most definitely identified by this property, Furthermore, the effect allows an evaluation of the ratio of charge to mass of the electron and an evaluation of its precise magnetic moment.

The normal Zeeman effect is a splitting into two or three lines, depending on the direction of observation, as shown in the illustration. The light of these components is polarized in ways indicated in the illustration. The normal effect is observed for all lines belonging to singlet systems, those for which the spin quantum number $S = 0$. The change of frequency of the shifted components can be evaluated on classical electromagnetic principles.



Triplet observed in normal Zeeman effect. ν_0 = unshifted frequency; $\Delta\nu_n$ = frequency shift.

The anomalous Zeeman effect is a more complicated type of line splitting, so named because it did not agree with the predictions of classical theory. It occurs for any spectral line arising from a combination of terms of multiplicity greater than one. Since multiplicity in spectral lines is caused by the presence of a resultant spin vector S of the electrons, the anomalous effect must be attributed to a nonclassical magnetic behavior of the electron spin.

The quadratic Zeeman effect, which depends on the square of the field strength, is of two kinds. The first results from second-order terms, and the second from the diamagnetic reaction of the electron when revolving in large orbits.

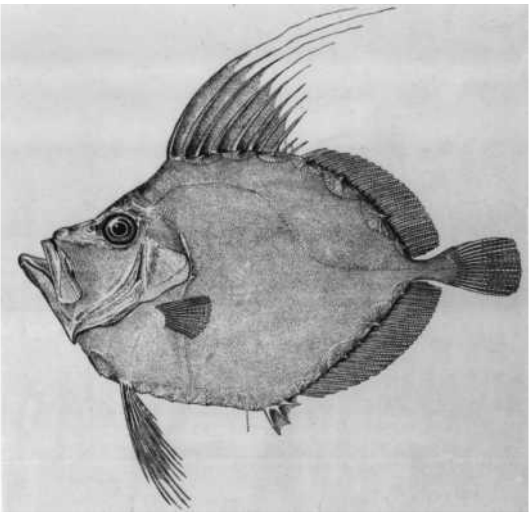
The inverse Zeeman effect is the Zeeman effect of absorption lines. It is closely related to the Faraday effect, the rotation of plane-polarized light by matter situated in a magnetic field. *See* Faraday effect.

The Zeeman effect in molecules is, in general, so small as to be unobservable, even for molecules which have a permanent magnetic moment. An exception occurs for some light molecules where the magnetic moment is coupled so lightly to the frame of the molecule that it can orient itself freely in the magnetic field just as for atoms.

A clear Zeeman effect also can be observed in many crystals with sharp spectrum lines in absorption or fluorescence. Such crystals are found particularly among rare-earth salts.

The magnetic moment of the nucleus causes a Zeeman splitting in atomic spectra which is of an order of magnitude a thousand times smaller than the ordinary Zeeman effect. This Zeeman effect of the hyperfine structure usually is modified by a nuclear Paschen-Back effect. *See* Paschen-Back effect. [F.A.J.; G.H.Di./W.W.W.]

Zeiformes A small order of teleost fishes, structurally intermediate between the Beryciformes and the Perciformes. This group is also known as the Zeomorphi or Zeoidea; commonly the fish are known as dories. There is no orbitosphenoid bone; the pelvic fin has a spine and from five to nine soft rays; and there is a more or less distinct anterior, spinous anal fin of one to four spines, as well as a spinous dorsal fin (see illustration).

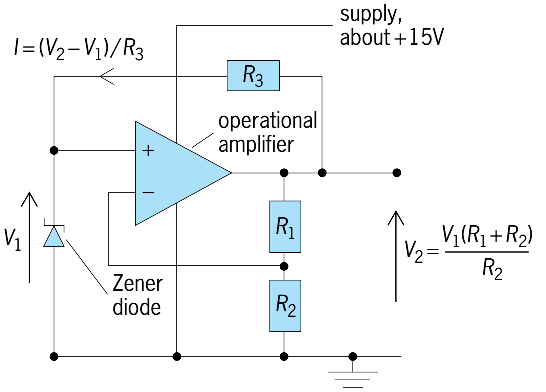


John dory (*Zenopsis ocellata*). (*After G. B. Goode, Fishery Industries of the United States, sect. 1, 1884*)

The zeiform fishes, which are known from the Paleocene on, are grouped into 6 families, perhaps 12 genera, and fewer than 50 species. All are marine, living in shore waters and chiefly at moderate depths off tropical and temperate coasts. Most are of small size and of minor economic importance. *See* Actinopterygii; Beryciformes; Perciformes. [R.M.B.]

Zener diode A two-terminal semiconductor junction device with a very sharp voltage breakdown as reverse bias is applied. The device is used to provide a voltage reference. It is named after C. Zener, who first proposed electronic tunneling as a mechanism of electrical breakdown in insulators. *See* Semiconductor; Tunneling in solids.

A classic circuit to define a very stable current uses an operational amplifier and three stable resistors (see illustration). The voltage across the Zener itself defines a higher level from which the current is drawn. Thus, a stable noise-free Zener defines its own stable noise-free current. *See* Operational amplifier.



Zener diode circuit to define a very stable current, *I*, using an operational amplifier and three stable resistors, R_1, R_2, and R_3. The voltage V_1 across the Zener itself defines a higher level V_2 from which the current *I* is drawn.

The effect of temperature on the breakdown voltage can be nulled by having a second forward-biased junction, which has a small negative temperature coefficient, in series with the Zener junction. Such a device is called compensated Zener and has a breakdown voltage of 6.2 V rather than the normal 5.6 V (for the smallest possible temperature coefficient). Alternatively, a Zener junction can be part of an integrated circuit which adds a whole temperature controller to keep the silicon substrate at a constant temperature. For the very best performance, only four components are integrated into the silicon: the Zener, a heater resistor, a temperature-sensing transistor, and a current-sensing transistor. A separate selected dual operational amplifier then completes the current-and-temperature-control circuit. Such a circuit sets the chip temperature at, say 122°F (50°C), and the junction condition is then largely independent of ambient temperature. *See* Integrated circuits.

The compact, robust Zener diode, with the circuits described to set its current and temperature, makes a fine portable voltage standard. This is used to disseminate the voltage level from national or accredited calibration laboratories to industry and to research laboratories. *See* Junction diode; Semiconductor diode; Voltage measurement; Voltage regulator. [P.J.Sp.]

Zenith The point in the sky directly above an observer. If the observer is at a pole, then the observer's zenith is a celestial pole; but for observers at midlatitudes the zenith is a point in the sky that corresponds to a changing right ascension but a constant declination as the sky rotates overhead. The point directly below the observer is the observer's nadir, and is 180° in longitude and in latitude from the observer's zenith.

The zenith distance of an object in the sky is the angle across the sky from the zenith to the object. The zenith distance is 90° minus the altitude of an object above the horizon. *See* Astronomical coordinate systems; Celestial sphere. [J.M.P.]

Zeolite Any mineral belonging to the zeolite family of minerals and synthetic compounds characterized by an aluminosilicate tetrahedral framework, ion-exchangeable large cations, and loosely held water molecules permitting reversible dehydration. The general formula can be expressed as $X_y{}^{1+,2+}Al_x{}^{3+}Si_{1-x}{}^{4+}O_2 \cdot nH_2O$. The amount of large cations (X) present is conditioned by the aluminum/silicon (Al:Si) ratio and the formal charge of these large cations. Typical large cations are the alkalies and alkaline earths such as sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), strontium (Sr^{2+}), and barium (Ba^{2+}). The large cations, coordinated by framework oxygens and water molecules, reside in large cavities in the crystal structure; these cavities and channels may even permit the selective passage of organic molecules. Thus, zeolites are extensively studied from theoretical and technical standpoints because of their potential and actual use as molecular sieves, catalysts, and water softeners. *See* Molecular sieve; Silicate minerals; Water softening.

Zeolites are low-temperature and low-pressure minerals and commonly occur as late minerals in amygdaloidal basalts, as devitrification products, as authigenic minerals in sandstones and other sediments, and as alteration products of feldspars and nepheline. Phillipsite and laumontite occur extensively in sediments on the ocean floor. Stilbite, heulandite, analcime, chabazite, and scolecite are common as large crystals in vesicles and cavities in various basalts.

Zeolites are usually white, but often may be colored pink, brown, red, yellow, or green by inclusions; the hardness is moderate (3–5) and the specific gravity low (2.0–2.5) because of their rather open framework structures. [P.B.M.]

The porous, yet crystalline nature of zeolites has been exploited commercially in three main areas—as sorbents, as cation-exchange materials, and as catalysts.

Most aluminosilicate zeolites have an extremely high (yet reversible) affinity for water and are widely used as desiccants. The discrimination between molecules on the basis of their size as compared to the zeolite pore size is the basis of several extremely important separation processes in a procedure known as molecular sieving. *See* CHEMICAL SEPARATION TECHNIQUES.

The major commodity use of zeolites takes advantage of their cation-exchange ability and leads to their use in low-phosphate detergents. Mineral zeolites have found utility in agricultural and wastewater treatment applications, where they either ion-exchange harmful metal ions out of the stream being treated or absorb ammonia by reacting, as their acidic form, to produce the absorbed ammonium ion. *See* ION EXCHANGE.

The most important and expanding area of application for zeolites is as heterogeneous catalysts. By combining the properties of excellent thermal stability (>800°C or 1500°F), a pore size of molecular dimensions, and the ready introduction of a wide assortment of cations via ion exchange, numerous very selective catalysts can be prepared. *See* HETEROGENEOUS CATALYSIS. [N.Her.]

Zero In mathematics, the concept zero is used in two ways: as a number and as a value of a variable. The positional system of number notation, developed first by the Babylonians (about 500 B.C.) with the base 60, and a millennium later by the Hindus and the Chinese with the base 10, required for greater clarity a special marker of the empty, nonoccupied position.

The zero as a number, however, is a new concept, introduced by the Hindus and Chinese about the same time (6th century). Brahmagupta (born A.D. 598) remarked that the number 0 has special properties: $a \pm 0 = a$, and $a \cdot 0 = 0$, where a may be any number (integer).

In a modern way, zero can be called the identity element of the infinite Abelian additive group of integers. If in an integral domain a product is equal to zero, then at least one factor of the product is zero. In the second concept zero is the value of a variable for which a function is equal to zero. [H.R.; E.Gr.]

Zinc A chemical element, Zn, atomic number 30, and atomic weight 65.38. Zinc is a malleable, ductile, gray metal. Because of chemical similarities among zinc, cadmium, and mercury, these three metals are classed together in a transition-elements subgroup of the periodic table. *See* METAL; PERIODIC TABLE; TRANSITION ELEMENTS.

Fifteen isotopes of zinc are known, of which five are stable, having atomic masses of 64, 66, 67, 68, and 70. About half of ordinary zinc occurs as the isotope of atomic mass 64. The half-lives of the radioactive isotopes range from 88 s for ^{61}Zn to 244 days for ^{65}Zn.

Zinc is a fairly active metal chemically. It can be ignited with some difficulty to give a blue-green flame in air and to discharge clouds of zinc oxide smoke. Zinc ranks above hydrogen in the electrochemical series, so that metallic zinc in an acidic solution will react to liberate hydrogen gas as the zinc passes into solution to form dipositively charged zinc ions, Zn^{2+}. This reaction is slow with very pure zinc, but the presence of small amounts of impurities, addition of a trace of copper sulfate, or contact between the zinc surface and such metals as nickel or platinum facilitates formation of gaseous hydrogen and speeds the reaction. The combination of zinc and dilute acid is often used to generate small quantities of hydrogen in the laboratory. Zinc also dissolves in strongly alkaline solutions, such as sodium hydroxide, to liberate hydrogen and form dinegatively charged tetrahydroxozincate ions, $Zn(OH)_4{}^{2-}$, sometimes written as $ZnO_2{}^{2-}$ in the formulas of the zincate compounds. Zinc also dissolves in solutions of ammonia or ammonium salts. The common soluble zinc compounds undergo to some extent the process of hydrolysis, which makes their solutions slightly acidic. The ion Zn^{2+} is colorless, so that the relatively few zinc compounds that are not colorless in large crystals, or white as powders, receive their color through the influence of the other constituents. Some of the atomic and ionic properties of zinc are shown in the table. *See* ELECTROCHEMICAL SERIES; HYDROLYSIS.

Atomic and ionic properties of zinc

Property	Value
Electronic configuration	$1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^{10}, 4s^2$
Ionization potentials	
1st electron loss	9.39 eV
2d electron loss	17.9 eV
Ionic radius, Zn^{2+}	0.072 nm
Covalent radius (tetrahedral)	0.131 nm
Oxidation potentials	$Zn \rightleftharpoons Zn^{2+} + 2e^-, E^\circ = 0.76$ V $Zn + 4OH^- \rightleftharpoons ZnO_2{}^{2-} + 2H_2O + 2e^-, E^\circ = 1.22$ V

Zinc also forms many coordination compounds. The zincates are actually coordination compounds, or complexes, in which hydroxide ions, OH^-, are bound to the zinc ions. Ammonia, NH_3, forms complexes with zinc, such as the typical tetrammine zinc ion, $[Zn(NH_3)_4]^{2+}$. Zinc cyanide, usually given the simple formula $Zn(CN)_2$, is a coordination compound in which many alternating zinc and cyanide ions are three-dimensionally bound together in a very large molecule. This compound is still widely used in zinc plating, but concern over environmental pollution has led to increasing use of zinc chloride plating baths. In most coordination compounds of zinc, the fundamental structural unit is a central zinc ion surrounded by four coordinated groups arranged spatially at the corners of a regular tetrahedron. *See* COORDINATION CHEMISTRY; COORDINATION COMPLEXES.

Pure, freshly polished zinc is bluish-white, lustrous, and moderately hard (2.5 on Mohs scale). Moist air brings about a superficial tarnish to give the metal its usual grayish color. Pure zinc is malleable and ductile enough to be rolled or drawn, but small amounts of other metals present as contaminants may render it brittle. Malleability of even pure zinc is improved by heating zinc to 100–150°C (212–300°F). If heated zinc is mechanically worked; it does not embrittle on cooling. Zinc melts at 420°C (788°F) and boils at 907°C (1665°F). Its density is 7.13 times that of water, so that 1 ft^3 (0.028 m^3) of zinc weighs 445 lb (200 kg).

As a conductor of heat and of electricity, zinc ranks fairly high. However, its electrical resistivity (5.92 microhm-cm at 20°C or 68°F) is almost four times that of silver, the best conductor. As a conductor of heat, zinc is likewise only about one-fourth as efficient as silver. At 0.91 K zinc is an electrical superconductor. Pure zinc is not ferromagnetic, but the alloy compound $ZrZn_2$ displays ferromagnetism below 35 K.

The most important uses of zinc are in its alloys and as a protective coating on other metals. Coating iron or steel with zinc is known as galvanizing, and it may be done by immersing the article in melted zinc (hot-dip process), depositing zinc electrolytically onto the article in a plating bath (electrogalvanizing), exposing the article to powdered zinc near its melting point (sherardizing), or spraying the article with melted zinc (metallizing). The mere physical presence of the zinc coat prevents corrosion of iron, and even if breaks in the coat expose portions of the iron, the greater chemical activity of the zinc causes it to be consumed in preference to the iron. Adding small amounts of other metals to galvanizing baths has been found to improve the adhesion and weathering qualities of the coating. *See* ELECTROPLATING OF METALS; GALVANIZING.

Even such nonstructural materials as cardboard can be zinc-coated by low-temperature flame spraying. Other important uses of zinc are in brass and zinc die-casting alloys, in zinc sheet and strip, in electrical dry cells, in making certain zinc compounds, and as a reducing agent in chemical preparations.

A so-called tumble-plating process coats small metal parts by applying zinc powder to them with an adhesive, then tumbling them with glass beads to roll out the powder into a continuous coat of zinc. Rechargeable nickel-zinc batteries offer higher energy densities than conventional dry cells. Foamed zinc metal has been suggested for use in lightweight structures such as aircraft and spacecraft. Some other uses of zinc are in dry cells, roofing, lithographic plates, fuses, organ pipes, and wire coatings. Zinc dust, a flammable material when dry, is used in fireworks and as a chemical catalyst and reducing agent. Radioactive ^{65}Zn is used medically in the study of metabolism of zinc, and also in determining rates of wear for zinc-containing alloys. *See* METAL COATINGS; ZINC ALLOYS. [W.E.C.]

Zinc is believed to be needed for normal growth and development of all living species, including humans; actually, life without zinc would be impossible. Zinc is a common element that is present in virtually every type of human food, and zinc deficiency is therefore not considered to be a common problem in humans. Zinc is a trace element; that is, it is present in biological fluids at a concentration below 1 ppm, and only a small amount (normally <25 mg) is required in the daily diet. (The recommended daily allowance for zinc is 15 mg/day for adults and 10 mg/day for growing children.) It is relatively nontoxic, without noticeable side effects at intake levels of up to 10 times the normal daily requirement. [J.F.Ri.; K.H.F.]

Zinc alloys Combinations of zinc with one or more other metals. If zinc is the primary constituent of the alloy, it is a zinc-base alloy. Zinc also is commonly used in varying degrees as an alloying component with other base metals, such as copper, aluminum, and magnesium. A familiar example of the latter is the association of varying amounts of zinc (up to 45%) with copper to produce brass. *See* BRASS; COPPER ALLOYS.

Zinc-base alloys have two major uses: for casting and for wrought applications. Casting includes both die casting and gravity casting, which differs from die casting primarily in that no pressure is applied, except the force of gravity, in forcing the molten metal into the mold. *See* METAL CASTING.

The great bulk of zinc die casting is carried out with two alloys, commonly identified as alloys 3 and 5. A third alloy has been added and is commonly designated as alloy 7. The entire group in the United States is often spoken of by its original trade name as Zamak alloys, and in England as the Mazak alloys.

Aluminum, the major alloying constituent in alloys 3 and 5, is added in amounts of about 4%, which has proved to be the optimum composition from the standpoint of strength, ductility, and stability. The aluminum content also sharply reduces the rate of attack of molten zinc on iron containers. Aluminum also avoids “soldering,” or sticking of the casting to the die. This permits the casting of these zinc alloys in the more productive hot-chamber (plunger) type of die-casting machine. *See* ALUMINUM.

Alloys 3 and 5 differ primarily in their copper content. Copper additions increase strength and hardness and improve corrosion resistance. The copper content of alloys is held to a specified maximum of 1.25% (in alloy 5) to avoid making the alloy unstable through aging and to avoid reducing the impact strength to a very low value.

Alloy 7 is considered a modification of alloy 3. It has a lower magnesium content, and iron, lead, tin, and cadmium are also held to lower levels. A small amount of nickel is added. When the alloys are compared, alloy 7 exhibits improved casting properties, making it easier to secure high-quality surfaces for finishing (mostly chromium plating) and to obtain higher production rates.

In the wrought zinc area, numerous compositions and alloys are used, depending on ultimate product requirements. Alloying metals can be used to improve various properties, such as stiffness, for special applications. The zinc-copper-titanium alloy has become the dominant wrought-zinc alloy for applications demanding superior performance. *See* ZINC; ZINC METALLURGY. [A.L.P.]

Zinc metallurgy Separating and extracting zinc from ores, refining it, and preparing it into usable forms. Ordinarily, after being mined, ores must first be separated into a concentrated mineral and a waste rock. This concentrate then is reduced to the metal in a metallurgical works. Finally, the metal may be further refined and alloyed to commercially usable form. Commonly, these three extractive metallurgical operations are conducted at separate locations and are broadly categorized as concentrating, smelting, and refining, respectively.

Zinc sulfide ores are usually beneficiated (concentrated or ore-dressed) adjacent to the mine site. First, the ore must be crushed and ground in order to free the mineral lattices from those of the waste rock (gangue). Next, the finely divided ore is mixed into a slurry with water and the mineral and gangue particles are separated utilizing the effect of gravity. The most common means of separation is the froth flotation process. *See* FLOTATION; ORE DRESSING.

The second operation, smelting, involves first the chemical or physical changes required in the source material to prepare it into a crude zinc oxide form and a specified particle size (depending upon the particular smelting method contemplated). Such process steps variously entail the operations of roasting, sintering, or pyroconcentration. The other basic part of smelting is the reduction step, wherein the zinc is reduced from its oxide to its elemental form. Several very successful and varied processes accomplish this function, including horizontal retort, vertical retort, electrothermic furnace, and blast furnace (all of which are pyrometallurgical and use carbon as a reducing agent). *See* PYROMETALLURGY; SINTERING.

Purity of zinc produced by the various smelting processes is largely dependent upon controls and operating procedures practiced during the preparation steps. The quality produced is variously suitable for hot-dip galvanizing, continuous-line galvanizing, and in some cases for brass manufacture and rolled (wrought) zinc; however, for the sizable usage in die-casting alloys, output from this type of smelter must undergo a refining step. Fractional distillation in reflux refining columns is the leading method of upgrading the lower-purity zinc metal. *See* ZINC ALLOYS. [C.H.Co.]

Zincite A mineral with composition ZnO (zinc oxide). It crystallizes in the hexagonal system with a wurtzite-type structure. Thus its principal axis is polar and different forms appear at top and bottom of crystals. Such crystals are rare and the mineral is usually massive. Its hardness is 4 and its specific gravity 5.6. The mineral has a subadamantine luster and a deep-red to orange-yellow color. Zincite is rare except at the zinc deposits at Franklin and Sterling Hill, N.J. There, associated with franklinite and willemite, it is mined as a valuable ore of zinc. *See* FRANKLINITE; WILLEMITE; ZINC. [C.S.Hu.]

Zingiberales An order of flowering plants, division Magnoliophyta, in the monocots, consisting of eight families and about 1800 species. Zingiberales (also known as Scitamineae or Scitaminales) are morphologically well defined and clearly circumscribed in DNA sequence analyses. The largest families are Zingiberaceae (about 1000 species), Marantaceae (about 400 species), Costaceae (about 150 species), and Heliconiaceae (about 100 species). Zingiberales are most closely related to Commelinales.

Zingiberales are herbs or scarcely branched trees or shrubs with pinnately veined leaves and irregular flowers that have well-differentiated sepals and petals, an inferior ovary, septal or septa-derived nectaries, and usually either one or five functional stamens. The economic crops, ginger (*Zingiber officinale*) in Zingiberaceae and banana (*Musa*) in Musaceae, and the ornamentals, bird of paradise flower (*Strelitzia*) in Strelitziaceae and *Canna* in Cannaceae, are familiar members of Zingiberales. *See* Banana; Commelinales; Flower; Fruit; Ginger; Liliopsida; Magnoliophyta. [M.F.F.]

Zingiberidae A subclass of Liliopsida (monocotyledons) of the division Magnoliophyta (Angiospermae), the flowering plants, containing two orders (Bromeliales and Zingiberales), with nine families and about 3800 species. The subclass has been associated with the Commelinidae and the Liliidae, sharing some features with each but aberrant in either, and it differs from both in usually having four or more supporting cells around each stomate. The flowers are usually epigynous, usually bisexual, and often irregular, and they are usually showy and adapted to pollination by insects or other animals. The pistil consists of three united carpels, often with septal nectaries opening at the top of the ovary. The seeds usually have well-developed, mealy or starchy endosperm. *See* Bromeliales; Liliopsida; Magnoliophyta; Plant kingdom; Secretory structures (plant); Zingiberales. [T.M.Ba.]

Zircon A mineral with the idealized composition $ZrSiO_4$, one of the chief sources of the element zirconium. Structurally, zircon is a nesosilicate, with isolated SiO_4 groups. *See* Silicate minerals; Zirconium.

Zircon often occurs as well-formed crystals. The color is variable, usually brown to reddish brown, but also colorless, pale yellowish, green, or blue. The transparent colorless or tinted varieties are popular gemstones. Hardness is $7^1/_2$ on Mohs scale; specific gravity is 4.7, decreasing in metamict types. *See* Metamict state.

Because of its chemical and physical stability, zircon resists weathering and accumulates in residual deposits and in beach and river sands, from which it has been obtained commercially in Florida and in India, Brazil, and other countries. *See* Heavy minerals. [C.Fr.]

Zirconium A chemical element, Zr, atomic number 40, atomic weight 91.22. Its naturally occurring isotopes are 90, 91, 92, 94, and 96. Zirconium is one of the more abundant elements, and is widely distributed in the Earth's crust. Being very reactive chemically, it is found only in the combined state. Under most conditions, it bonds with oxygen in preference to any other element, and it occurs in the Earth's crust only as the oxide, ZrO_2, baddeleyite, or as part of a complex of oxides as in zircon, elpidite, and eudialyte. Zircon is commercially the most important ore. Zirconium and hafnium are practically indistinguishable in chemical properties, and occur only together. *See* Hafnium; Periodic table; Zircon.

Most of the zirconium used has been as compounds for the ceramic industry: refractories, glazes, enamels, foundry mold and core washes, abrasive grits, and components of electrical ceramics, The incorporation of zirconium oxide in glass significantly increases its resistance to alkali. The use of zirconium metal is almost entirely for cladding uranium fuel elements for nuclear power plants. Another significant use has been in photo flashbulbs.

Zirconium is a lustrous, silvery metal, with a density of 6.5 g/cm^3 (3.8 oz/in.^{3}) at 20°C (68°F). It melts at about 1850°C (3362°F). Estimates of the boiling point from appropriate data have commonly been of the order of 3600°C (6500°F), but observations suggest about 8600°C (15,500°F). The free energies of formation of its compounds indicate that zirconium should react with any nonmetal, other than the inert gases, at ordinary temperatures. In practice, the metal is found to be nonreactive near room temperature because of an invisible, impervious oxide film on its surface. The film renders the metal passive, and it remains bright and shiny in ordinary air indefinitely. At elevated temperatures it is very reactive to the non-metallic elements and many of the metallic elements, forming either solid solutions or compounds.

Zirconium generally has normal covalency of 4, and commonly exhibits coordinate covalencies of 5, 6, 7, and 8. Zirconium is at oxidation number 4 in nearly all of its compounds, Halides in which its oxidation numbers are 3 and 2 have been prepared. While zirconium is often part of cationic or anionic complexes, there is no definite evidence for a monatomic zirconium ion in any of its compounds.

Most handling and testing of zirconium compounds have indicated no toxicity. There has generally been no ill consequence of contact of zirconium compounds with the unabraded skin. However, some individuals appear to have allergic sensitivity to zirconium compounds, characteristically manifested by appearance of nonmalignant granulomas. Inhalation of sprays containing some zirconium compounds and of metallic zirconium dusts have had inflammatory effects. [W.B.B.]

Zoantharia A subclass of the Anthozoa. Zoantharians are monomorphic anthozoans, most of which have retractile, simple, tubular tentacles. The tentacles vary from six to several hundred. The mesenteries are six or some multiple of six and may be complete or incomplete in the Actiniaria and Scleractinia, while in other groups they are not constant. When a skeleton is present, it is secreted by ectodermal cells, and free spicules are found. Actiniaria and Scleractinia embrace many species, whereas the other orders, notably the Ceriantheria, include only a few. *See* Anthozoa; Zoanthidea. [K.At.]

Zoanthidea An order of the subclass Zoantharia. These animals are mostly colonial, sedentary, skeletonless, anemone-like anthozoans. They live in warm, shallow waters or on coral reefs. The body is in the form of a polyp. The pedal disk is indistinguishable. The column, bearing tubercles, is often encrusted with sand grains, sponge spicules, formaniferous shells, and other detritus. The tentacles are arranged in two cycles. The life cycle is incompletely known. Daughter polyps arise by budding from the stolon or the polyp base, or by longitudinal fission. *See* Zoantharia. [K.At.]

Zodiac The band of sky through which the Sun, Moon, and planets apparently move in the course of the year. The Babylonians, about 2500 years ago, divided the zodiac into 12 parts, which correspond to constellations. These zodiacal constellations, in order around the sky, are Aries, the Ram; Taurus, the Bull; Gemini, the Twins; Cancer, the Crab; Leo, the Lion; Virgo, the Virgin; Libra, the Scales; Scorpius, the Scorpion; Sagittarius, the Archer, Capricornus, the Sea Goat; Aquarius, the Water Carrier; and Pisces, the Fish. These constellations are based on Greek myths.

Because of the precession of the equinoxes, the positions of the constellations in the sky have drifted from the dates of the year with which they were associated thousands of years ago. Thus the popular astrological "signs" of the zodiac are not actually those that currently correspond to the sky. Though the vernal equinox is often called the first point of Aries, precession has moved it into Pisces, not far from Aquarius. *See* Precession of equinoxes.

The Sun actually passes through parts of 13 constellations, as currently defined. Also, if the zodiac is defined as the region within latitudes ±8°, which accommodates the eight planets through Neptune, it contains all or part of 24 constellations. *See* Constellation; Ecliptic. [J.M.P.]

Zodiacal light A diffuse, night-sky luminosity easily seen at low to middle geographic latitudes in the absence of moonlight. It is caused by sunlight scattered and absorbed by interplanetary (solar system) dust particles. Zodiacal light extends over the entire sky, but it is brightest toward the Sun and in the zodiacal band. It is best seen in the west after evening twilight and in the east before morning twilight when the ecliptic is close to the vertical. In the Northern Hemisphere this corresponds to spring evenings and autumn mornings. *See* ECLIPTIC; INTERPLANETARY MATTER.

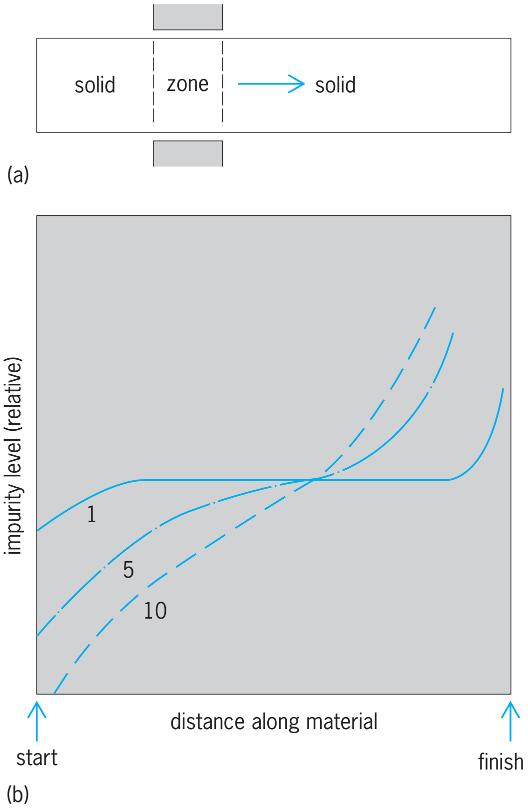
The density of particles responsible for the zodiacal light falls off somewhat faster than 1/R, where *R* is heliocentric distance. The particles are primarily in the size range of tens to hundreds of micrometers in diameter, and are believed to originate primarily from comets. *See* COMET.

The visual zodiacal light brightness decreases monotonically with elongation (angular distance from the Sun) to a relatively flat minimum in the ecliptic at 120 to 140°, after which it gradually increases out to the antisolar point at 180°. The enhanced brightness near the antisolar point is called the Gegenschein or counterglow. It is barely above the visible threshold and is described by visual observers as being oval in appearance, 6 by 10° or larger, with the long axis in the ecliptic. Space observations have shown the Gegenschein to be an intrinsic part of the zodiacal light; that is, the zodiacal dust particles have an increased scattering efficiency near backscattering.

Although the Earth's atmosphere complicates attempts to observe zodiacal light closer than approximately 30° to the Sun, eclipse and space observations have shown the brightness to increase smoothly all the way in to the F-corona. The F-corona or inner zodiacal light and the "primary" zodiacal light seen at larger elongations come primarily from dust particles located relatively close to the Sun. *See* SOLAR CORONA; SUN. [J.L.Wei.]

Zone refining One of a number of techniques used in the preparation of high-purity materials. The technique is capable of producing very low impurity levels, namely, parts per million or less in a wide range of materials, including metals, alloys, intermetallic compounds, semiconductors, and inorganic and organic chemical compounds. In principle, zone refining takes advantage of the fact that the solubility level of an impurity is different in the liquid and solid phases of the material being purified; it is therefore possible to segregate or redistribute an impurity within the material of interest. In practice, a narrow molten zone is moved slowly along the complete length of the specimen in order to bring about the impurity segregation. *See* SOLUTION; SOLVENT.

Impurity atoms either raise or lower the melting point of the host material. There is also a difference in the concentration of the impurity in the liquid phase and in the solid phase when the liquid and solid exist together in equilibrium. In zone refining, advantage is taken of this difference, and the impurity atoms are gradually segregated to one end of the starting material. To do this, a molten zone is passed from one end of the impure material to the other, as in illus. *a*, and the process is repeated several times. The end to which the impurities are segregated depends on whether the impurity raises or lowers the melting point of the pure material; a lowering of the melting point is more common, in which case impurities are moved in the direction of travel of the molten zone. The effect of multiple zone passes (in the same direction) on impurity content along the material is illustrated in illus. *b*. *See* METALLURGY. [A.La.]



Zone refining. (*a*) Passage of a molten zone along the material to be purified. (*b*) Effect of 1, 5, and 10 zone passes on the impurity distribution along the material.

Zooarcheology Zooarcheology or archeozoology is the study of animal remains from archeological sites. Most such remains derive from people's meals. In other words, zooarcheology is essentially the study of ancient garbage, mainly bones and teeth of mammals, as well as birds, fish, mollusks, and even insects. Zooarcheology helps to provide a more complete picture of people's environment and way of life, especially their economy, as reflected in the relationship between people and animals 100,000 or even just 100 years ago. It is a multidisciplinary endeavor requiring knowledge of anatomy and biometry as well as an appreciation of the archeological questions that need to be addressed. Unlike most paleontological collections, zooarcheological collections are usually well dated and comprise large numbers of bones. They provide excellent opportunities to study microevolution. However, much remains to be explored in this relatively new science. *See* ANTHROPOLOGY; ARCHEOLOGY; FOSSIL HUMANS; ZOOLOGY. [S.J.M.D.]

Zoogeography The subdivision of the science of biogeography that is concerned with the detailed description of the distribution of animals and how their past distribution has produced present-day patterns. Scientists in this field attempt to formulate theories that explain the present distributions as elucidated by geography, physiography, climate, ecological correlates (especially vegetation), geological history, the canons of evolutionary theory, and an understanding of the evolutionary relationships of the particular animals under study.

The field of zoogeography is based upon five observations and two conclusions. The observations are as follows. (1) Each species and higher group of animals has a discrete nonrandom distribution in space and time (for example, the gorilla occurs only in two forest areas in Africa). (2) Different geographical regions have an assemblage of distinctive animals that coexist (for example, the fauna of Africa south of the Sahara with its monkeys, pigs, and antelopes is totally different from the fauna of Australia with its platypuses, kangaroos, and wombats). (3) These differences (and similarities) cannot be explained by the amount of distance between the regions or by the area of the region alone [for example, the fauna of Europe and eastern Asia is strikingly similar although separated by 6900 mi (11,500 km) of land, while the faunas of Borneo and New Guinea are extremely different although separated by a tenth of that distance across land and water]. (4) Faunas strikingly different from those found today previously occurred in all geographical regions (for example, dinosaurs existed over much of the world in the Cretaceous). (5) Faunas resembling those found today or their antecedents previously occurred, sometimes at sites far distant from their current range (for example, the subtropical-warm temperate fauna of Eocene Wyoming, including many fresh-water fishes, salamander, and turtle groups, is now restricted to the southeastern United States).

The conclusions are as follows. (1) There are recognizible recurrent patterns of animal distribution. (2) These patterns represent faunas composed of species and higher groups that have evolved through time in association with one another.

Two rather different approaches have dominated the study of zoogeography since the beginning of the nineteenth century: ecological and historical. Ecological zoogeography attempts to explain current distribution patterns principally in terms of the ecological requirements of animals, with particular emphasis on environmental parameters, physiological tolerances, ecological roles, and adaptations. The space and time scales in this approach are narrow, and emphasis is upon the statics and dynamics of current or very recent events. Historical zoogeography recognizes that each major geographical area has a different assemblage of species, that certain systematic groups of organisms tend to cluster geographically, and that the interaction of geography, climate, and evolutionary processes over a long time span is responsible for the patterns or general tracks. Emphasis in this approach is upon the statics and dynamics of major geographical and geological events ranging across vast areas and substantial time intervals of up to millions of years. The approach is based on concordant evolutionary association of diverse groups through time. *See* ECOLOGY. [J.M.S.]

Zoological nomenclature

Zoological nomenclature The system of naming animals that was adopted by zoologists and detailed in the International Code of Zoological Nomenclature, which applies to both living and extinct animals. The present system is founded on the 10th edition of C. Linnaeus's *Systema Naturae* (1758) and has evolved through international agreements culminating in the Code adopted in 1985. The primary objective of the Code is to promote the stability of the names of taxa (groups of organisms) by providing rules concerning name usage and the activity of naming new taxa. The rules are binding for taxa ranked at certain levels and nonbinding on taxa ranked at other levels. *See* ANIMAL SYSTEMATICS.

Zoological nomenclature is built around four basic features. (1) The correct names of certain taxa are either unique or unique combinations. (2) These names are formed and treated as Latin names and are universally applicable, regardless of the native language of the zoologist. (3) The Code for animals is separate and independent from similar codes for plants and bacteria. (4) No provisions of the Code are meant to restrict the intellectual freedom of individual scientists to pursue their own research.

There are four common reasons why nomenclature may change. (1) New species are found that were once considered parts of other species. (2) Taxonomic revisions may uncover older names or mistakes in identification of types. (3) Taxa may be combined, creating homonyms that require replacement. (4) Concepts of the relationships of animals change. Stability is subservient to progress in understanding animal diversity.

The articles in the Code are directed toward the names of taxa at three levels. The family group includes taxa ranked as at the family and tribe levels (including super- and subfamilies). The genus group includes taxa below subtribe and above species. The species group includes taxa ranked as species or subspecies. Taxa above the family group level are not specifically treated, and their formation and use are not strictly regulated. For each group, provisions are made that are either binding or recommended.

Binominal nomenclature. The basis for naming animals is binominal nomenclature, that is, a system of two-part names. The first name of each species is formed from the generic name, and the second is a trivial name, or species epithet. The two names agree in gender unless the specific epithet is a patronym (named for a person). The combination must be unique; no other animal can have the same binominal. The formal name of a species also includes the author, so the formal name for humans is *Homo sapiens* Linnaeus. The genus, as a higher taxon, may have one or many species, each with a different epithet. *Homo* includes *H. sapiens, H. erectus, H. habilis*, and so forth. One feature of the Linnaean binominal system is that species epithets can be used over and over again, so long as they are used in different genera. *Tyrannosaurus rex* is a large dinosaur, and *Percina rex* is a small fresh-water fish. The epithet *rex* is not the species name of *Percina rex* because all species names are binominal in form. It is recommended that names of genera and species be set in a different typeface from normal text; italics is conventional. Different names for the same species are termed synonyms, and the senior synonym is usually correct (principle of priority). Modern species descriptions are accompanied by a description that attempts to show how the species is different from others, and the designation of one or more type specimens.

Higher taxa. All higher taxonomic names have one part (uninominal) and are plural. Names of taxa of the family and genus groups must be unique. The names of genera are in Latin or latinized, are displayed in italics, and may be used alone. The names of the family group are formed by a root and an ending specific to a particular hierarchical level: family Hominidae (root + idae), subfamily Homininae (root + inae). The endings of superfamilies (root + oidea) and tribes (root + ini) are recommended but not mandated. The endings of taxa higher than the family group vary. For example, orders of fishes are formed by adding -iformes to the root (Salmoniformes), while in insects the ending is usually -ptera (Coleoptera). *See* CLASSIFICATION, BIOLOGICAL; TAXONOMIC CATEGORIES. [E.O.W.]

Zoology

Zoology The science that deals with knowledge of animal life. With the great growth of information about animals, zoology has been much subdivided. Some major fields are anatomy, which deals with gross and microscopic structure; physiology, with living processes in animals; embryology, with development of new individuals; genetics, with heredity and variation; parasitology, with animals living in or on others; natural history, with life and behavior in nature; ecology, with the relation of animals to their environments; evolution, with the origin and differentiation of animal life; and taxonomy, with the classification of animals. *See* ANATOMY, REGIONAL; DEVELOPMENTAL BIOLOGY; GENETICS; PARASITOLOGY; PHYLOGENY; PLANT EVOLUTION; TAXONOMY. [T.I.S.]

Zoom lens

Zoom lens A system of lenses in which two or more parts are moved with respect to each other to obtain a continuously variable focal length and hence magnification, while the image is kept in the same image plane.

The system must be constructed so that the errors do not vary too much in the shifting. Thus the designer must strive for a design in which the image errors are small, at least for the beginning and end positions of the "zooming" procedure, and do not become too large for intermediate positions.

Some early variable-focal-length lenses contained 15 or more separated elements, but this number has been reduced to as few as 4. The zoom ratio (the ratio of maximum to minimum power) is in general 3:1, but it has been possible in some designs to increase the range to 4:1 or even more. *See* LENS (OPTICS). [M.J.H.]

Zoomastigophorea

Zoomastigophorea A class of protozoans of the subphylum Sarcomastigophora. Zoomastigophorea, also known as Zoomastigina, are flagellates. Some are simple, some are specialized; some have pseudopodia besides flagella. One group engulfs solid food at any body point; another shows localized ingestive areas. All are colorless. None produce starch or paramylum, and lipids and glycogen are assimilation products. Cells are naked or have delicate membranes. Colony formation is common. Colonies differ greatly in form and may be amorphous, linear, spherical, arboroid, or plane. Flagella vary from none to many.

Nine orders are included in this class: the Choanoflagellida, Bicosoecida, Rhizomastigida, Kinetoplastida, Retortomonadida, Diplomonadida, Oxymonadida, Trichomonadida, and Hypermastigida. See articles on these classes. *See also* SARCOMASTIGOPHORA. [J.B.L.]

Zoonoses Infections of humans caused by the transmission of disease agents that naturally live in animals. People become infected when they unwittingly intrude into the life cycle of the disease agent and become unnatural hosts. Zoonotic helminthic diseases, caused by parasitic worms, involve many species of helminths, including nematodes (roundworms), trematodes (flukes), cestodes (tapeworms), and acanthocephalans (thorny-headed worms). Helminthic zoonoses may be contracted from domestic animals such as pets, from edible animals such as seafood, or from wild animals. Fortunately, most kinds of zoonotic helminthic infections are caused by rare human parasites.

The best-recognized example of a food-borne zoonotic helminthic disease is trichinosis, caused by the trinchina worm, *Trichinella spiralis*, a tiny nematode. People commonly become infected by eating inadequately prepared pork, but a sizable proportion of victims now contract the worms by eating the meat of wild carnivores, such as bear. Trichinosis is usually a mild disease, manifested by symptoms and signs of intestinal and muscular inflammation, but in heavy infections damage done by the larvae to the heart and central nervous system can be life threatening. Because of public awareness about properly cooking pork and federal regulations about feeding pigs, trichinosis has become uncommon in the United States. People who eat inadequately prepared marine fish may become infected with larval nematodes. Of the many potential (and rare) helminthic zoonoses from wild animals in the United States, *Baylisascaris procyonis* is particularly dangerous. The nematode is highly prevalent in raccoons, the definitive host. *See* CESTODA; FOOD SAFETY; MEDICAL PARASITOLOGY; NEMATA; TREMATODA. [D.E.No.]

Zooplankton Animals that inhabit the water column of oceans and lakes and lack the means to counteract transport currents. Zooplankton inhabit all layers of these water bodies to the greatest depths sampled, and constitute a major link between primary production and higher trophic levels in aquatic ecosystems. Many zooplankton are capable of strong swimming movements and may migrate vertically from tens to hundreds of meters; others have limited mobility and depend more on water turbulence to stay afloat. All zooplankton, however, lack the ability to maintain their position against the movement of large water masses.

Zooplankton can be divided into various operational categories. One means of classification is based on developmental stages and divides animals into meroplankton and holoplankton. Meroplanktonic forms spend only part of their life cycles as plankton and include larvae of benthic worms, mollusks, crustaceans, echinoderms, coral, and even insects, as well as the eggs and larvae of many fishes. Holoplankton spend essentially their whole existence in the water column. Examples are chaetognaths, pteropods, larvaceans, siphonophores, and many copepods. Nearly every major taxonomic group of animals has either meroplanktonic or holoplanktonic members.

Size is another basis of grouping all plankton. A commonly accepted size classification scheme includes the groupings: picoplankton (<2 micrometers), nanoplankton (2–20 μm), microplankton (20–200 μm), mesoplankton (0.2–20 mm), macroplankton (20–200 mm), and megaplankton (>200 mm).

The classic description of the trophic dynamics of plankton is a food chain consisting of algae grazed by crustacean zooplankton which are in turn ingested by fishes. This model may hold true to a degree in some environments such as upwelling areas, but it masks the complexity of most natural food webs. Zooplankton have an essential role in linking trophic levels, but several intermediate zooplankton consumers can exist between the primary producers (phytoplankton) and fish. Thus, food webs with multiple links to different organisms indicate the versatility of food choice and energy transfer and are a more realistic description of the planktonic trophic interactions.

Size is of major importance in planktonic food webs. Most zooplankton tend to feed on organisms that have a body size smaller than their own. However, factors other than size also modify feeding interactions. Some phytoplankton are noxious and are avoided by zooplankton, and others are ingested but not digested. Furthermore, zooplankton frequently assume different feeding habits as they grow from larval to adult form. They may ingest bacteria or phytoplankton at one stage of their life cycle and become raptorial feeders later. Other zooplankton are primarily herbivorous but also ingest heterotrophic protists and can opportunistically become carnivorous. Consequently, omnivory, which is considered rare in terrestrial systems, is a relatively common trophic strategy in the plankton. In all food webs, some individuals die without being consumed and are utilized by scavengers and ultimately by decomposers (bacteria and fungi). *See* ECOLOGY; ECOSYSTEM; MARINE ECOLOGY; PHYTOPLANKTON. [R.W.Sa.]

Zoraptera An order of insects which is related to the termites and psocids. Zoraptera are about 0.08–0.1 in. (2–2.5 mm) long and not important economically. They are of great interest because of their rarity, relatively recent discovery in 1913, and intriguing habits and relationships.

Zoraptera live sheltered from light, in decaying wood, usually in logs and stumps, except during the emergence of winged adults. The winged adults are well pigmented, have eyes, and often shed their wings. In the southeastern United States they occur especially on slabs buried in old sawdust piles. They apparently scavenge, mainly on microscopic molds. Most individuals are of the wingless caste, pale in color, and blind. Metamorphosis is gradual.

Zoraptera are distributed nearly worldwide in warm countries. The best known of the two United States species, *Zorothpus hubbardi*, occurs from Pennsylvania to Florida, west to Iowa, Kansas, Missouri, and Texas. Approximately 23 species are known; all are in the genus *Zorotypus* of the family Zorotypidae. *See* INSECTA. [A.B.Gu.]

Zosterophyllopsida An extinct class of the division Lycophyta, comprising primitive vascular land plants that evolved from the rhyniophytes and reached a relatively brief peak in the late Early Devonian, when they were an ecologically important and widely distributed element of the exclusively herbaceous terrestrial flora.

The Zosterophyllopsida consists of approximately 18 genera, although few of these include species that have been fully reconstructed from their disarticulated organs. All genera exhibited rhizomatous growth. The rhizomes produced adventitious roots and upright aerial branches, which were typically densely crowded. The group is united by the key lycophyte characters of exarch protoxylem maturation and laterally borne, vascularized, kidney-shaped sporangia with multilayered walls and complete distal dehiscence.

The most primitive generally accepted lycophyte is *Zosterophyllum*. *Sawdonia* and *Gosslingia* are more advanced zosterophyllopsids, possessing characters that are absent from the lycopsids. Although briefly successful as dense stands on floodplains and channel margins, these more sophisticated zosterophyllopsids were virtually extinct by the end of the Devonian. *See* LYCOPHYTA; LYCOPSIDA. [R.M.Ba.; W.A.DiM.]

Zygnematales A large order of green algae (Chlorophyceae) that is characterized by the lack of flagellate cells. Sexual reproduction is effected by the fusion of ameboid or passive gametes in conjugation tubes, which give rise to the alternate name Conjugates. Biochemical and ultrastructural features indicate that the Zygnematales are more closely related to charophytes than they are to most other green algae. Members of this order are essentially restricted to fresh-water and subaerial habitats. They are sometimes placed in their own class, with each family elevated to the rank of order. The order Zygnematales is frequently divided into two suborders, Zygnematineae and Desmidiineae. [P.C.Si.; R.L.Moe]

Zygomycetes A class of terrestrial fungi in the phylum Zygomycota, comprising organisms commonly known as the bread molds. Sexual reproduction is by the formation of zygospores. Asexual reproduction is by endospores (sporangiospores) produced in sporangia, or uni- or multispored sporangiola or merosporangia, conidia, yeast cells, chlamydospores, or arthrospores. These fungi occur as haustorial (having food-absorbing cells in the host) or nonhaustorial parasites of fungi, plants, or animals (including humans), or as saprobes, especially in soil or dung; but other substrates with soluble nutrients may also contain Zygomycetes. Some taxa are endo- or ectomycorrhizal on vascular plants.

The mature spore-bearing structures are dry and readily dispersed by air currents, or are wet and are distributed by direct contact with small animals or are ingested by animals and disseminated in their feces. Water droplets also may disperse the spores or the intact spore-bearing structures.

Classification is based on mode of nutrition, morphology of the zygospore (if formed), type of asexual reproduction, branching pattern of sporophores, and frequency of septa (if formed) and septal morphology. Zygomycetes are currently placed in seven orders: Dimargaritales, Endogonales, Entomophthorales, Glomales, Kickxellales, Mucorales, and Zoopagales. Zygomycetes are distributed worldwide, although many taxa are rarely encountered; they may be relatively common on a particular host or substrate. *See* EUMYCOTA; FUNGI; ZYGOMYCOTINA. [G.L.Be.]

Zygomycotina Subdivision of fungi characterized by distinctive sexual and asexual reproductive stages. The sexual zygospore results from fusion of two gametangia. Asexual reproduction may be sporangial (containing one to many, always nonmotile, sporangiospores) to conidial. The various asexual forms found in different taxa are interpreted as representing evolutionary development from sporangial to conidial. Asexual reproduction is more common than sexual; in fact, sexual reproduction is unknown in many species and within certain orders. Zygomycotina are cosmopolitan. Many are free-living saprobes. Others, even entire orders, are saprophytic, parasitic, or obligate symbionts, especially in arthropods. There are two classes (Zygomycetes and Trichomycetes), but it is uncertain whether they are naturally related or appear similar through convergent evolution. [D.J.S.B.]

Zygophyllales An order of flowering plants in the eurosid I group of the rosid eudicots. This order comprises just two small families of distant relationship (as evidenced by DNA sequence studies) to all other rosid eudicots: Krameriaceae and Zygophyllaceae. Krameriaceae (25 species) are photosynthetic parasitic plants (“hemiparasites”) found from the southwestern United States to South America, whereas Zygophyllaceae (240 species) are free-living and widely distributed in arid to semiarid zones throughout the warmer regions of the world. Some species of the latter family produce especially hard woods such as lignumvitate (*Bulnesia* and *Guaiacum*), and a few others produce medicinal compounds, such as the creosote bush (*Larrea*). *See* FLOWER; LIGNUMVITAE; MAGNOLIOPHYTA; MAGNOLIOPSIDA; POLYGALALES; ROSIDAE; SAPINDALES. Measurement systems

U.S. Customary System and the metric system

Over the past 200 years or so, scientists and engineers have used two major systems of units in measurement. These are commonly called the U.S. Customary System (inherited from the British Imperial System) and the metric system (developed at the time of the French Revolution).

In the U.S. Customary System the units yard and pound with their divisions, such as the inch, and multiples, such as the ton, are basic. The metric system has been adopted for general use by most countries. It is used nearly everywhere for precise measurements in science. The meter and kilogram with their multiples, such as the kilometer, and fractions, such as the gram, are basic to the metric system. Until the second half of the twentieth century, most of the base units in these systems were defined in terms of specific physical artifacts, such as the International Prototype Kilogram, a platinum-iridium cyclinder maintained in Sèvres, France.

In the U.S. Cutomary System, units of the same kind are related almost at random. For example, there are the units of length, the inch, yard, and mile. In the metric system the relationships between units of the same kind are strictly decimal (millimeter, meter, and kilometer).

However, in technical writing there is no uniformity within each of these two systems as to the choice of units for the same quantities. For example, the hour or the second, the foot or the inch, and the centimeter or the millimeter could be chosen as the unit of measurement for the quantities time and length.

International System

To simplify matters and to make communication more understandable, an internationally accepted system of units came into use in 1960. This is termed the International System of Units, which is abbreviated SI in all languages (from the French Système International d'Unités).

Fundamentally the system is metric, with base units whose definitions have been modified from time to time in order to allow for their more accurate realization as techniques of measurement have evolved. In several instances, artifact standards have been replaced by physically invariant quantities, such as atomic transition frequencies and fundamental physical constants. For example, the meter in the SI is defined as the length of the path traveled by light in vacuum during a time interval of l/299 792 458 of a second. The effect of this definition, which was adopted in 1983, is to fix the speed of light at exactly 299 792 458 meters per second.

The second in the SI is defined as the duration of 9 192 631 770 periods of the radiation corresponding to the transition between two hyperfine levels of the ground state of the cesium-133 atom.

Interestingly, the kilogram, the SI unit of mass, is still the mass of the kilogram kept at Sèvres. However, it is probable that eventually the unit will be redefined in terms of atomic mass or through a definition that will fix the value of the Planck constant h.

Although the SI is increasingly used by scientists and engineers, there are some other units in everyday use which will probably remain, for example, minute, hour, day, degree (angle), and liter. The point should be made, however, that these terms will not be employed in a scientific context if the SI is fully adopted. Because of their extremely common use among scientists, several units are still permitted in conjunction with SI units, for example, the electronvolt, rad, roentgen, barn, and curie. In time their usage might be phased out.

One futher point is that in October 1967 the Thirteenth General Conference of Weights and Measures decided to name the SI unit of thermodynamic temperature "kelvin" (symbol K) instead of "degree Kelvin" (symbol °K). For example, the notation is 273 K and not 273°K.

The base units and derived units of the SI are shown in **Table 1** and **2**.

In the SI the prefixes differ from a unit in steps of 10^3. A list of prefix terms, symbols, and their factors is given in **Table 3**. Some examples of the use of these prefixes follow:

$$\begin{aligned} 1000\ \mathrm{m} &= 1\ \text{kilometer} &&= 1\ \mathrm{km} \\ 1000\ \mathrm{V} &= 1\ \text{kilovolt} &&= 1\ \mathrm{kV} \\ 1\,000\,000\ \Omega &= 1\ \text{megohm} &&= 1\ \mathrm{M\Omega} \\ 0.000\,000\,001\ \mathrm{s} &= 1\ \text{nanosecond} &&= 1\ \mathrm{ns} \end{aligned}$$

Only one prefix is to be employed for a unit. For example:

$$\begin{aligned} 1000\ \mathrm{kg} &= 1\ \mathrm{Mg} && \text{not } 1\ \mathrm{kkg} \\ 10^{-9}\ \mathrm{s} &= 1\ \mathrm{ns} && \text{not } 1\ \mathrm{m}\mu\mathrm{s} \\ 1\,000\,000\ \mathrm{m} &= 1\ \mathrm{Mm} && \text{not } 1\ \mathrm{kkm} \end{aligned}$$

Also, when a unit is raised to a power, the power applies to the whole unit including the prefix. For example:

$$\mathrm{km}^2 = (\mathrm{km})^2 = (1000\ \mathrm{m})^2 = 10^6\ \mathrm{m}^2$$
$$\text{not } 1000\ \mathrm{m}^2$$

Some common units defined in terms of SI units are given in **Table 4** (the definitions in the fourth column are exact).

Conversion factors for the measurement systems

This Encyclopedia has retained the U.S. Customary and metric systems, but has incorporated SI units in many cases. Conversion factors between the three measurement systems are given in **Table 5** for some prevalent units; in each of the subtables the user proceeds as follows:

To convert a quantity expressed in a unit in the left-hand column to the equivalent in a unit in the top row of a subtable, multiply the quantity by the factor common to both units. For example, to convert 7 ft to the equivalent in meters, go to subtable A, "Units of length." and find 1 ft in the left-hand column and m in the top row. The conversion factor common to these units is 0.3048. Therefore, 7 ft = 7 × 0.3048 = 2.1336 m.

The conversion factors have been carried out to seven significant figures, as derived from the fundamental constants and the definitions of the units. However, this does not mean that the factors are always known to that accuracy. Numbers followed by ellipses are to be continued indefinitely with repetition of the same pattern of digits. Factors written with fewer than seven significant digits are exact values. Numbers followed by an asterisk are definitions of the relation between the two units.

TABLE 1. Base units of the International System

Quantity	Name of unit	Unit symbol
length	meter	m
mass	kilogram	kg
time	second	s
electric current	ampere	A
temperature	kelvin	K
luminous intensity	candela	cd
amount of substance	mole	mol

TABLE 2. Derived units of the International System*

Quantity	Name of unit	Unit symbol, or unit expressed in terms of other SI units	Unit expressed in terms of SI base units
plane angle	radian	rad	m/m = 1
solid angle	steradian	sr	m^2/m^2 = 1
area	square meter		m^2
volume	cubic meter		m^3
frequency	hertz	Hz	s^{-1}
density	kilogram per cubic meter		kg/m^3
velocity	meter per second		m/s
angular velocity	radian per second	rad/s	m/(m $\cdot$ s) = s^{-1}
acceleration	meter per second squared		m/s^2
angular acceleration	radian per second squared	rad/s^2	m/(m $\cdot$ s^2) = s^{-2}
volumetric flow rate	cubic meter per second		m^3/s
force	newton	N	kg $\cdot$ m/s^2
surface tension	newton per meter, joule per square meter	N/m, J/m^2	kg/s^2
pressure	pascal, newton per square meter	Pa, N/m^2	kg/(m $\cdot$ s^2)
viscosity, dynamic	pascal-second, newton-second per square meter	Pa $\cdot$ s, N $\cdot$ s/m^2	kg/(m $\cdot$ s)
viscosity, kinematic	meter squared per second		m^2/s
work, torque, energy, quantity of heat	joule, newton-meter, watt-second	J, N $\cdot$ m, W $\cdot$ s	kg $\cdot$ m^2/s^3
power, heat flux	watt, joule per second	W, J/s	kg $\cdot$ m^2/s^3
heat flux density	watt per square meter	W/m^2	kg/s^3
volumetric heat release rate	watt per cubic meter	W/m^3	kg/(m $\cdot$ s^3)
heat transfer coefficient	watt per square meter kelvin	W/(m^2 $\cdot$ K)	kg/(s^3 $\cdot$ K)
heat capacity (specific)	joule per kilogram kelvin	J/kg $\cdot$ K)	m^2/(s^2 $\cdot$ K)
capacity rate	watt per kelvin	W/K	kg $\cdot$ m^2/(s^3 $\cdot$ K)
thermal conductivity	watt per meter kelvin	W/(m $\cdot$ K), $\frac{J \cdot m}{s \cdot m^2 \cdot K}$	kg $\cdot$ m/(s^3 $\cdot$ K)
quantity of electricity	coulomb	C	A $\cdot$ s
electromotive force	volt	V, W/A	kg $\cdot$ m^2/(A $\cdot$ s^3)
electric field strength	volt per meter	V/m	kg $\cdot$ m/(A $\cdot$ s^3)
electric resistance	ohm	Ω, V/A	kg $\cdot$ m^2/(A^2 $\cdot$ s^3)
electric conductance	siemens	S, A/V	A^2 $\cdot$ s^3/(kg $\cdot$ m^2)

TABLE 4. Some common units defined in terms of SI units

Quantity	Name of unit	Unit symbol	Definition of unit
length	inch	in.	2.54×10^{-2} m
mass	pound (avoirdupois)	lb	0.45359237 kg
force	kilogram-force	kgf	9.80665 N
pressure	atmosphere	atm	101325 Pa
pressure	torr	torr	(101325/760) Pa
pressure	conventional millimeter of mercury*	mmHg	$13.5951 \times 980.665 \times 10^{-2}$ Pa
energy	kilowatt-hour	kWh	3.6×10^{6} J
energy	thermochemical calorie	cal	4.184 J
energy	international steam table calorie	cal_{IT}	4.1868 J
thermodynamic temperature (T)	degree Rankine	°R	(5/9) K
customary temperature (t)	degree Celsius	°C	$t(°\text{C}) = T(\text{K}) - 273.15$
customary temperature (t)	degree Fahrenheit	°F	$t(°\text{F}) = [1.8 \times t(°\text{C})] + 32 = T(°\text{R}) - 459.67$
radioactivity	curie	Ci	3.7×10^{10} Bq
energy†	electronvolt	eV	$\text{eV} = 1.60218 \times 10^{-19}$ J
mass†	unified atomic mass unit	u	$\text{u} = 1.66054 \times 10^{-27}$ kg

*The conventional millimeter of mercury, symbol mmHg (not mm Hg), is the pressure exerted by a column exactly 1 mm high of a fluid of density exactly 13.5951 g cm^{-3} in a place where the gravitational acceleration is exactly 980.665 cm · s^{-2}. The mmHg differs from the torr by less than 2×10^{-7} torr.

†These units defined in terms of the best available experimental values of certain physical constants may be converted to SI units. The factors for conversion of these units are subject of change in the light of new experimental measurements of the constants involved.

Units of temperature in measurement systems

Temperature is a basic physical quantity. It is a measure of the thermal energy of random motion of particles in a system. As such it has been chosen as one of the base quantities in the SI. It is to be treated as are the units of length, mass, time, electric current, and luminous intensity. In the SI the unit of length is the meter, the unit of time the second, and so on. The question arises as to the choice of the unit of temperature in the SI.

In the past it was customary to refer to scales of temperature, for example, the Celsius and Fahrenheit scales. On the Celsius scale, 0 designates the freezing point (ice point) and 100 the boiling point (steam point) of water. Corresponding numbers on the Fahrenheit scale are 32 and 212. There are 100 units between the ice point and steam point on the Celsius scale, and 180 units between these points in the Fahrenheit system.

By measuring the volume changes of a gas within the 100-unit interval for the ice point and steam point of water on the Celsius scale, it was found that a numerical value could be assigned for a basic unit of temperature. Careful measurement of this ice-steam interval in a gas thermometer determined that the ice point of water should be assigned the value of 273.15 kelvins. The unit of temperature was thus called the kelvin with the symbol K. Further experiments led to the decision to define the kelvin in the SI along the same lines but in terms of the triple point of water. This is the temperature and pressure at which ice, liquid water, and water vapor coexist at equilibrium. The triple point was chosen because it was a more reproducible value than the ice point.

This change led to the SI definition of temperature in terms of the temperature of the triple point of water, which contains exactly 273.16 kelvins.

It follows that the Celsius temperture (°C) is an intermediate scale. It is useful in defining Kelvin temperature in the SI. Celsius temperature (t) is related to Kelvin temperature (K) as follows:

$$t_{\text{ice point}} = 0^\circ\text{C}$$
$$t_{\text{steam point}} = 100^\circ\text{C}$$
$$0\,\text{K} = -273.15^\circ\text{C}$$

A summary of the conventions in the SI as proposed in the Thirteenth General Conference of Weights and Measures pertaining to temperature units is given below.

1. The unit of SI temperature is the kelvin, symbol K.
2. The word “scale” is not to be used except in terms of measurement of temperature between certain fixed points on the Celsius scale.
3. The terms “thermodynamic scale” or “absolute scale” are not to be used to describe temperature. The degree sign is to be eliminated with the symbol K.
4. When Celsius temperatures are used (°C), it is understood that the temperature unit is the kelvin.

Not all scientists and engineers have adopted the SI of temperature terminology. Furthermore, many engineers in the United States still use the Fahrenheit system in discussing practical engineering systems.

In converting Fahrenheit (°F) to Celsius (°C) the following formula applies.

$$^\circ\text{C} = \frac{^\circ\text{F} - 32^\circ}{1.8}$$

In converting Celsius to Fahrenheit the following formula can be used.

$$^\circ\text{F} = (^\circ\text{C} \times 1.8) + 32^\circ$$

In changing from Celsius terminology (t) to kelvin units (K) the following formula can be used.

$$\text{K} = \text{t} + 273.15$$

Chemistry

Symbols for the chemical elements

The mass number, atomic number, number of atoms, and ionic charge of an element are often indicated by means of four indices placed around the symbol. The positions occupied are left upper index, mass number; left lower index, atomic number; right upper index, ionic charge; and right lower index, number of atoms of an element in a molecule or formula unit of a given species: for example, ${}^{12}_{6}\text{C}$, Ca^{2+}, O_2, and Al_2O_3. The atomic number, which is redundant, is omitted in most cases: that is, ${}^{12}_{6}\text{C}$ can be written as ${}^{12}\text{C}$.

Ionic charge is indicated by a plus or minus superscript following the symbol of the ion; for multiple charges an arabic superscript numeral precedes the plus or minus sign, for example, Na^{+}, $\text{NO}_3{}^{-}$, Ca^{2+}, $\text{PO}_4{}^{3+}$.

An alphabetical list of the elements, their symbols, and their atomic numbers is shown in **Table 6**. Elements 111 and 112 have been reported, but no official names have been assigned.

Chemical nomenclature

The International Union of Pure and Applied Chemistry (IUPAC) has established definitive rules for chemical nomenclature. Chemical species are identified in the Dictionary by a systematic name, frequently accompanied by a formula. Occasionally common names are used.

For inorganic compounds, systematic names of compounds are formed by identifying the constituents and their proportions in a specific order, for example, dinitrogen oxide (N_2O). Also accepted by IUPAC is Stock's system, in which the proportions of the constituents are indicated indirectly, and roman numerals are used to represent the oxidation number or stoichiometric valence of an element, for example, iron(II) chloride (FeCl_2). Complex compounds are also named according to rules specified by IUPAC; an example is potassium oxodichloroimidophosphate, $\text{K[POCl}_2\text{(NH)]}$. Examples of accepted trivial names are diborane (B_2H_6), silane (SiH_4), and ammonia (NH_3).

There also are definitive rules for naming organic compounds. Because of the infinite variety of disciplines and industrial applications involving organic compounds, the rules encompass different types of names. Sometimes a single compound can correctly be identified by a number of names; for example, chloral hydrate is also known as 2,2,2-trichloro-1,1-ethanediol and trichloroacetaldehyde monohydrate.

Samarium	Sm	62
Scandium	Sc	21
Seaborgium	Sg	106
Selenium	Se	34
Silicon	Si	14
Silver	Ag	47
Sodium	Na	11
Strontium	Sr	38
Sulfur	S	16
Tantalum	Ta	73
Technetium	Tc	43
Tellurium	Te	52
Terbium	Tb	65
Thallium	Tl	81
Thorium	Th	90
Thulium	Tm	69
Tin	Sn	50
Titanium	Ti	22
Tungsten	W	74
Uranium	U	92
Vanadium	V	23
Xenon	Xe	54
Ytterbium	Yb	70
Yttrium	Y	39
Zinc	Zn	30
Zirconium	Zr	40

*This element does not have an official name or symbol.

Symbols in scientific writing

Symbols commonly encountered in scientific writing are listed in **Table 7**. Symbols following the ellipses and separated by commas are alternatives that are used only when there is some reason for not using the symbol given first. The letters of the Greek alphabet, frequently used to represent terms, are shown in **Table 8**.

Some frequently encountered symbols for particles and quanta are as follows:

neutron	n	pion	π
proton	p	muon	μ
deuteron	d	electron	e
triton	t	neutrino	ν
alpha particle	α	photon	γ

The meaning of abbreviated notations for nuclear reactions should be the following:

initial nuclide (incoming particle(s) or quanta,
outgoing particle(s) or quanta) final nuclide

Some examples are:

$^{14}\mathrm{N}(\alpha, p)^{17}\mathrm{O}$ $^{59}\mathrm{Co}(n, \gamma)^{60}\mathrm{Co}$

$^{23}\mathrm{Na}(\gamma, 3n)^{20}\mathrm{Na}$ $^{31}\mathrm{P}(\gamma, pn)^{29}\mathrm{Si}$

TABLE 7. Commonly used symbols in scientific writing

Space, time, mass, and related quantities

length	l
height	h
radius	r
diameter	d
path, length of arc	s
plane angle	$\alpha, \beta, \gamma, \theta, \phi, \psi$
solid angle	ω
area	A, S
volume	$V \ldots v$
specific volume	v
wavelength	λ
wavenumber	σ, ν
time	t
period or other characteristic interval	T, τ
frequency	v, f
angular frequency ($2\pi\nu$)	ω
velocity	$\nu \ldots u, w$
angular velocity	ω
acceleration	a
acceleration of free fall	g
mass	m
moment of inertia	I
density	ρ
relative density	d

Molecular and related quantities

molecular mass	m
molar mass	M
Avogadro's number	N_0, L, N
number of molecules	N
number of moles	n
mole fraction	$x \ldots X, y$
molality	m
concentration	c
molar concentration of substance B	c_{B}, [B], c(B)
molecular concentration	C
partition function	Q
statistical weight	$g \ldots p$
symmetry number	σ
characteristic temperature	θ
diameter of molecule	$\sigma \ldots D$
mean free path	l
diffusion coefficient	D
osmotic pressure	Π
surface concentration	Γ

Mechanical and related quantities

force	F
force due to gravity (weight)	$G \ldots W$
moment of force	M
power	P
pressure	p, P
traction	σ
shear stress	τ
modulus of elasticity	E
shear modulus	G
compressibility	κ
compression modulus ($1/\kappa$)	K
viscosity	η
fluidity	ϕ
kinematic viscosity	v
friction coefficient	f
surface tension	$\gamma \ldots \sigma$
angle of contact	θ

Thermodynamic and related quantities

temperature	$\theta \ldots t$
temperature, absolute	T
gas constant	R
Boltzmann constant	k
heat	q, Q
work	w, A
energy (Gibbs ε)	$E \ldots U$
entropy (Gibbs η)	S
*Helmholtz free energy (Gibbs Ψ)	A
enthalpy (Gibbs χ)	H
*Gibbs function (ζ)	$G \ldots F$
heat capacity	C
specific heat at constant pressure	c_p
specific heat at constant volume	c_v
ratio of specific heats c_p/c_v	γ, κ
chemical potential	μ
activity, absolute	λ
activity, relative	a
activity coefficient	f, γ
osmotic coefficient	g, ϕ
thermal conductivity	γ
Joule-Thomson coefficient	μ

---

*The terms for the Helmholtz and Gibbs energies were modified by action of the IUPAC Council. Montreal, August 1961, as follows:
Helmholtz energy (Gibbs $\Psi = E_2TS$): A Gibbs energy (Gibbs $\zeta = H_2TS$): G

TABLE 7. Commonly used symbols in scientific writing (cont.)

Chemical reactions

stoichiometric number of molecules (negative for reactants, positive for products) ν
standard equation of chemical reaction $\Sigma\nu_B B = 0$
affinity ($-\Sigma\nu_{B}\mu_{B}$) of a reaction A
equilibrium constant K
equilibrium quotient or equilibrium product (of molalities) Q
extent of reaction ($dn_B = \nu_B d\xi$) ξ
degree of reaction (e.g., degree of dissociation) α
rate constant k
collision number (collisions per unit volume and unit time) Z
rate constant corresponding to the rate Z z
rate of reaction $v \ldots r, s, J$

Light

Planck's constant h
Planck's constant divided by 2π $\hbar$
quantity of light q
radiant power, flux of light (dQ/dt) Φ
illumination ($d\Phi/dS$) E
luminance L,B
luminous emittance H
absorption factor (fraction of incident radiant power which is absorbed) α
reflection factor (fraction of incident radiant power which is reflected) ρ
transmission factor (fraction of incident radiant power which is transmitted) τ
transmittance ($T = I/I_0$) T
absorption (extinction) coefficient [$\kappa/c = \ln(1/T)$] κ
absorbance (extinction) [$A = \log(1/T)$] $A \ldots E$
absorptivity (specific absorbance) [decadic absorption or extinction coefficient] a
molar absorptivity (molar decadic absorption or extinction coefficient) [$\varepsilon/c = A$] ϵ
refraction index n
refractivity r
angle of optical rotation α

Electricity and magnetism

elementary change e
quantity of electricity Q
change density p
surface change density σ
electric current $I \ldots i$
electric current density J
electric potential V
electric field strength E
electric displacement D
electrokinetic potential ζ
capacitance C
permittivity (dielectric constant) ϵ
dielectric polarization P
dipole moment μ
electric polarizability of a molecule α, γ
magnetic field strength H
magnetic induction B
magnetic permeability μ
magnetization M
magnetic susceptibility χ
resistance R
resistivity ρ
self inductance L
mutual inductance M, L_{12}
reactance X
impedance Z
admittance Y

Electrochemistry

Faraday's constant (the faraday) F
charge number of an ion, plus or minus z
degree of electrolytic dissociation α
ionic strength $I \ldots \mu$
electrolytic conductivity (specific conductance) κ
equivalent or molar conductance of electrolyte or ion A
transport number t, T
electromotive force E
overpotential η

TABLE 8. Greek alphabet

Upper and lower cases	Name	Upper and lower cases	Name
Α α	Alpha	Ν ν	Nu
Β β	Beta	Ξ ξ	Xi
Γ ξ	Gamma	Ο ο	Omicron
Δ δ ∂	Delta	Π π	Pi
Ε ϵ ε	Epsilon	Ρ ρ	Rho
Ζ ζ	Zeta	Σ σ	Sigma
Η η	Eta	Τ τ	Tau
Θ θ	Theta	Υ υ	Upsilon
Ι ι	Iota	Φ ϕ φ	Phi
Κ κ	Kappa	Χ χ	Chi
Λ λ	Lambda	Ψ ψ	Psi
Μ μ	Mu	Ω ω	Omega

Mathematics

Mathematical signs and symbols

Symbol	Definition
$+$	plus (sign of addition)
$+$	positive
$-$	minus (sign of subtraction)
$-$	negative
$\pm$ ($\mp$)	plus or minus (minus or plus)
$\times$	times, by (multiplication sign)
$\cdot$	multiplied by
$\div$	sign of division
$/$	divided by
$:$	ratio sign, divided by, is to
$::$	equals, as (proportion)
$<$	less than
$>$	greater than
$\ll$	much less than
$\gg$	much greater than
$=$	equals
$\equiv$	identical with
$\sim$	similar to
$\approx$	approximately equals
$\cong$	approximately equals, congruent
$\leq$	equal to or less than
$\geq$	equal to or greater than

Symbol	Definition
ǂ $\neq$	not equal to
$\rightarrow$ $\doteq$	approaches
$\propto$	varies as
∞	infinity
$\sqrt{\ }$	square root of
$\sqrt[3]{\ }$	cube root of
$\therefore$	therefore
$\Vert$	parallel to
( ) [ ] { }	parentheses, brackets and braces; quantities enclosed by them to be taken together in multiplying dividing, etc.
$\overline{AB}$	length of line from A to B
π	(pi) = 3.14159 +
$^\circ$	degrees
$'$	minutes
$''$	seconds
$\angle$	angle
dx	differential of x
Δ	(delta) difference
Δx	increment of x

Symbol	Definition
$\partial u/\partial x$	partial derivative of u with respect to x
$\int$	integral of
$\int_b^a$	integral of, between limits a and b
$\oint$	line integral around a closed path
Σ	(sigma) summation of
$f(x)$, $F(x)$	functions of x
∇	del or nabla, vector differential operator
∇^2	Laplacian operator
£	Laplace operational symbol
$4!$	factorial $4 = 1 \times 2 \times 3 \times 4$
$\lvert x\rvert$	absolute value of x
$\dot{x}$	first derivative of x with respect to time
$\ddot{x}$	second derivative of x with respect to time
$\mathbf{A} \times \mathbf{B}$	vector product; magnitude of **A** times magnitude of **B** times sine of the angle from **A** to **B**; $AB \sin \overline{AB}$
$\mathbf{A} \cdot \mathbf{B}$	scalar product of **A** and **B**; magnitude of **A** times magnitude of **B** times cosine of the angle from **A** to **B**; $AB \cos \overline{AB}$

Mathematical notation

Mathematical logic

p, q, $P(x)$	Sentences, propositional functions, propositions
$\neg p$, $\sim p$, non p, Np	Negation, read "not p" ($\neq$: read "not equal")
$p \vee q$, $p + q$, Apq	Disjunction, read "p or q," "p, q," or both
$p \wedge q$, $p \cdot q$, $p\&q$, Kpq	Conjunction, read "p and q"
$p \rightarrow q$, $p \supset q$, $p \Rightarrow q$, Cpq	Implication, read "p implies q" or "if p then q"
$p \leftrightarrow q$, $p \equiv q$, $p \Leftrightarrow q$, Epq, p iff q	Equivalence, read "p is equivalent to q" or "p if and only if q"
n.a.s.c.	Read "necessary and sufficient condition"
( ), [ ], { }, . . .	Parentheses
V, $\forall$, Σ	Universal quantifier, read "for all" or "for every"
∃, $\exists$, Π	Existential quantifier, read "there is a" or "there exists"
$\vdash$	Assertion sign ($p \vdash q$: read "q follows from p"; $\vdash p$: read "p is or follows from an axiom," or "p is a tautology")
0, 1	Truth, falsity (values)
$=$	Identity
$\overset{\text{Df}}{=}$, $\overset{\text{df}}{=}$, $\underset{\text{df}}{=}$, $\equiv$	Definitional identity
■	"End of proof"; "QED"

Set theory, relations, functions

X, Y	Sets
$x \in X$	x is a member of the set X
$x \notin X$	x is not a member of X
$A \subset X$, $A \subseteqq X$	Set A is contained in set X
$A \not\subset X$, $A \nsubseteqq X$	A is not contained in X
$X \cup Y$, $X + Y$	Union of sets X and Y
$X \cap Y$, $X \cdot Y$	Intersection of sets X and Y
$+$, $\dot{+}$, $\bigcirc$	Symmetric difference of sets
$\cup X_i$, ΣX	Union of all the sets X_i
$\cap X_i$, ΠX_i	Intersection of all the sets X_i
$\varnothing$, 0, Λ	Null set, empty set
X', $\complement X$, CX	Complement of the set X
$X - Y$, $X \backslash Y$	Difference of sets X and Y
$\hat{x}(P(x))$, $\{x \mid P(x)\}$, $\{x{:}P(x)\}$	The set of all x with the property P
(x,y,z), (x, y, z)	Ordered set of elements x, y, and z; to be distinguished from (x,z,y), for example
$\{x,y,z\}$	Unordered set, the set whose elements are x, y, z, and no others
$\{a_1, a_2, \ldots, a_n\}$, $\{a_i\}_{i=1,2,\ldots,n}$, $\{a_i\}_{i=1}^{n}$	The set whose members are a_i, where i is any whole number from 1 to n
$\{a_1, a_2, \ldots\}$, $\{a_i\}_{i=1,2,\ldots}$, $\{a_i\}_{i=1}^{\infty}$	The set whose members are a_i, where i is any positive whole number
$X \times Y$	Cartesian product, set of all (x,y) such that $x \in X$, $y \in Y$

$\{a_i\}_{i \in I}$	The set whose elements are a_i, where $i \in I$
xRy, $R\{x,y\}$	Relation
$\equiv, \cong, \sim, \simeq$	Equivalence relations, for example, congruence
$\geqq, \geq, >, \varepsilon, \gg, \leqq, \leq, <$	Transitive relations, for example, numerical order
$f{:}X \to Y$, $X \xrightarrow{f} Y$, $X \to Y$, $f \in Y^X$	Function, mapping, transformation
f^{-1}, $\overset{-1}{f}$, $X \xleftarrow{f-1} Y$	Inverse mapping
$g \circ f$	Composite functions: $(g \circ f)(x) = g(f(x))$
$f(X)$	Image of X by f
$f^{-1}(X)$	Inverse-image set, counter image
1-1, one-one	Read "one-to-one correspondence"
$\begin{tikzcd} X \arrow[r, "f"] \arrow[d, "\phi"'] & Y \arrow[d, "\psi"] \\ W \arrow[r, "g"] & Z \end{tikzcd}$	Diagram: the diagram is commutative in case $\psi \circ f = g \circ \phi$
$f \mid A$	Partial mapping, restriction of function f to set A
$\overset{=}{X}$, card X, $\lvert X \rvert$	Cardinal of the set A
$\aleph_0$, d	Denumerable infinity
$\mathfrak{c}$, c, $2^{\aleph_0}$	Power of continuum
ω	Order type of the set of positive integers
σ-	Read "countably"

Number, numerical functions

1.4; 1,4; 1·4	Read "one and four-tenths"
1(1)2(10)100	Read "from 1 to 20 in intervals of 1, and from 20 to 100 in intervals of 10"
const	Constant
$A \geqq 0$	The number A is nonnegative, or the matrix A is positive definite, or the matrix A has nonnegative entries
$x \mid y$	Read "x divides y"
$x \equiv y \bmod p$	Read "x congruent to y modulo p"
$a_0 + \frac{1}{a_1} + \frac{1}{a_2} + \cdots,$ $a_0 + \frac{1 \rvert}{\lvert a_1} + \cdots$	Continued fractions
$[a,b]$	Closed interval
$[a,b)$, $[a,b[$	Half-open interval (open at the right)
(a,b), $]a,b[$	Open interval
$[a,\infty)$, $[a,\to[$	Interval closed at the left, infinite to the right
$(-\infty, \infty)$, $[\leftarrow,\to[$	Set of all real numbers
$\max_{x \in X} f(x)$, $\max\{f(x) \mid x \in X\}$	Maximum of $f(x)$ when x is in the set X
min	Minimum
sup, l.u.b.	Supremum, least upper bound
inf, g.l.b.	Infimum, greatest lower bound
$\lim_{x \to a} f(x) = b$, $\lim_{x=a} f(x) = b$, $f(x) \to b$ as $x \to a$	b is the limit of $f(x)$ as x approaches a
$\lim_{x \to a-} f(x)$, $\lim_{x=a-0} f(x)$, $f(a-)$	Limit of $f(x)$ as x approaches a from the left
lim sup, $\overline{\lim}$	Limit superior
lim inf, $\underline{\lim}$	Limit inferior
l.i.m.	Limit in the mean
$z = x + iy = re^{i\theta}$, $\zeta = \xi + i\eta$, $w = u + iv = \rho e^{i\phi}$	Complex variables
z^*	Complex conjugate
Re, $\Re$	Real part
Im, $\Im$	Imaginary part
arg	Argument
$\frac{\partial(u,v)}{\partial(x,y)}$, $\frac{D(u,v)}{D(x,y)}$	Jacobian, functional determinant
$\int_E f(x)\, d\mu(x)$	Integral (for example, Lebesgue integral) of function f over set E with respect to measure μ
$f(n) \sim \log n$ as $n \to \infty$	$f(n)/\log n$ approaches 1 as $n \to \infty$
$f(n) = O(\log n)$ as $n \to \infty$	$f(n)/\log n$ is bounded as $n \to \infty$
$f(n) = o(\log n)$	$f(n)/\log n$ approaches zero
$f(x) \nearrow b, f(x) \uparrow b$	$f(x)$ increases, approaching the limit b
$f(x) \downarrow b, f(x) \searrow b$	$f(x)$ decreases, approaching the limit b

a.e., p.p.	Almost everywhere
ess sup	Essential supremum
C^0, $C^0(X)$, $C(X)$	Space of continuous functions
C^k, $C^k[a,b]$	The class of functions having continuous kth derivative (on $[a,b]$)
C'	Same as C^1
Lip_α, Lip α	Lipschitz class of functions
L^p, L_p, $L^p[a,b]$	Space of functions having integrable absolute pth power (on $[a,b]$)
L'	Same as L^1
(C,α), (C,p)	Cesàro summability

Special functions

$[x]$	The integral part of x
$\binom{n}{k}$, ${}^nC_k$, ${}_nC_k$	Binomial coefficient $n!/k!(n-k)!$
$\left(\frac{n}{p}\right)$	Legendre symbol
e^x, exp x	Exponential function
sinh x, cosh x, tanh x	Hyperbolic functions
sn x, cn x, dn x	Jacobi elliptic functions
$\wp(x)$	Weierstrass elliptic function
$\Gamma(x)$	Gamma function
$J_\nu(x)$	Bessel function
$\chi_X(x)$	Characteristic function of the set X: $\chi_X(x) = 1$ in case $x \in X$, otherwise $\chi_X(x) = 0$
sgn x	Signum: sgn $0 = 0$, while sgn $x = x/\lvert x \rvert$ for $x \neq 0$
$\delta(x)$	Dirac delta function

Algebra, tensors, operators

$+, \cdot, \times, \circ, \mathrm{T}, \tau$	Laws of composition in algebraic systems
e, 0	Identity, unit, neutral element (of an additive system)
e, I, I	Identity, unit, neutral element (of a general algebraic system)
e, e, E, P	Idempotent
a^{-1}	Inverse of a
Hom(M,N)	Group of all homomorphisms of M into N
G/H	Factor group, group of cosets
$[K{:}k]$	Dimension of K over k
$\oplus$, $+$	Direct sum
$\otimes$	Tensor product, Kronecker product
$\wedge$	Exterior product, Grassmann product
$\vec{x}$, $\mathbf{x}$, $\mathfrak{x}$, x	Vector
$\vec{x} \cdot \vec{y}$, $\mathbf{x} \cdot \mathbf{y}$, $(\mathfrak{x}, \mathfrak{y})$	Inner product, scalar product, dot product
$\mathbf{x} \times \mathbf{y}$, $[\mathfrak{x},\mathfrak{y}]$, $\mathbf{x} \wedge \mathbf{y}$	Outer product, vector product, cross product
$\lvert x \rvert$, $\lvert x \rvert$, $\lVert x \rVert$, $\lVert x \rVert_p$	Norm of the vector x
Ax, xA	The image of x under the transformation A
δ_{ij}	Kronecker delta: $\delta_{ii} = 1$, while $\delta_{ij} = 0$ for $i \neq j$
A', tA, A^t, ${}^tA$	Transpose of the matrix A
A^*, $\bar{A}$	Adjoint, Hermitian conjugate of A
tr A, Sp A	Trace of the matrix A
det A, $\lvert A \rvert$	Determinant of the matrix A
$\Delta^n f(x)$, $\Delta_k{}^n f$, $\underset{h}{\Delta^n} f(x)$	Finite differences
$[x_0,x_1]$, $[x_0,x_1,x_2]$, $\underset{x_1}{\Delta} u_{x_0}$, $[x_0,x_1]_f$	Divided differences
∇f, grad f	Read "gradient of f"
$\nabla \cdot$ v, div v	Read "divergence of **v**"
$\nabla \times$ v, curl v, rot **v**	Read "curl of **v**"
∇^2, Δ, div grad	Laplacian
$[X,Y]$	Poisson bracket, or commutator, or Lie product
GL(n,R)	Full linear group of degree n over field R
O(n,R)	Full orthogonal group
SO(n,R), O$^+(n,R)$	Special orthogonal group

Topology

E^n	Euclidean n space
S^n	n sphere
$\rho(p,q)$, $d(p,q)$	Metric, distance (between points p and q)
$\bar{X}$, X^-, cl X, X^c	Closure of the set X
FrX, fr$X$, ∂X, bdry X	Frontier, boundary of X
int X, $\mathring{X}$	Interior of X
T_2 space	Hausdorff space
F_σ	Union of countably many closed sets
G_δ	Intersection of countably many open sets
dim X	Dimensionality, dimension of X
$\pi_1(X)$	Fundamental group of the space X
$\pi_n(X)$, $\pi_n(X,A)$	Homotopy groups
$H_n(X)$, $H_n(X,A;G)$, $H_*(X)$	Homology groups
$H^n(X)$, $H^n(X,A;G)$, $H^*(X)$	Cohomology groups

Probability and statistics

X, Y	Random variables
$P(X \leqq 2)$, $\Pr(X \leqq 2)$	Probability that $X \leqq 2$
$P(X \leqq 2 \mid Y \geqq 1)$	Conditional probability
$E(X)$, $E(X)$	Expectation of X
$E(X \mid Y \geqq 1)$	Conditional expectation
c.d.f.	Cumulative distribution function
p.d.f.	Probability density function
c.f.	Characteristic function
$\bar{x}$	Mean (especially, sample mean)
σ, s.d.	Standard deviation
σ^2, Var, var	Variance
μ_1, μ_2, μ_3, μ_i, μ_{ij}	Moments of a distribution
ρ	Coefficient of correlation
$\rho_{12\cdot 34}$	Partial correlation coefficient

Fundamental constants

Recommended values (2002) of selected fundamental constants of physics and chemistry[a]

Quantity	Symbol	Numerical value[b]	Unit[c]	Relative uncertainty (standard deviation)
UNIVERSAL CONSTANTS				
Speed of light in vacuum	c, c_0	299 792 458	m s^{-1}	(exact)
Magnetic constant	μ_0	$4\pi \times 10^{-7}$ = 12.566 370 614 . . . × 10^{-7}	N A^{-2} N A^{-2}	(exact)
Electric constant, $1/\mu_0 c^2$	ε_0	8.854 187 817 . . . × 10^{-12}	F m^{-1}	(exact)
Characteristic impedance of vacuum, $\sqrt{\mu_0/\varepsilon_0} = \mu_0 c$	Z_0	376.730 313 461 . . .	Ω	(exact)
Newtonian constant of gravitation	G	6.6742(10) × 10^{-11}	m^3 kg^{-1} s^{-2}	1.5 × 10^{-4}
	$G/\hbar c$	6.7087(10) × 10^{-39}	(GeV/c^2)$^{-2}$	1.5 × 10^{-4}
Planck constant	h	6.626 0693(11) × 10^{-34}	J s	1.7 × 10^{-7}
in eV s		4.135 667 43(35) × 10^{-15}	eV s	8.5 × 10^{-8}
hc in eV m		1.239 841 91(11) × 10^{-6}	eV m	8.5 × 10^{-8}
$h/2\pi$	$\hbar$	1.054 571 68(18) × 10^{-34}	J s	1.7 × 10^{-7}
in eV s		6.582 119 15(56) × 10^{-16}	eV s	8.5 × 10^{-8}
$\hbar c$ in eV m		197.326 968(17) × 10^{-9}	eV m	8.5 × 10^{-8}
Planck mass, $(\hbar c/G)^{1/2}$	m_{p}	2.176 45(16) × 10^{-8}	kg	7.5 × 10^{-5}
Planck length, $\hbar/m_{\mathrm{p}}c = (\hbar G/c^3)^{1/2}$	l_{p}	1.616 24(12) × 10^{-35}	m	7.5 × 10^{-5}
Planck time, $l_{\mathrm{p}}/\mathrm{c} = (\hbar G/c^5)^{1/2}$	t_{P}	5.391 21(40) × 10^{-44}	s	7.5 × 10^{-5}
ELECTROMAGNETIC CONSTANTS				
Elementary charge	e	1.602 176 53(14) × 10^{-19}	C	8.5 × 10^{-8}
Magnetic flux quantum, $h/2e$	Φ_0	2.067 833 72(18) × 10^{-15}	Wb	8.5 × 10^{-8}
Josephson constant[d], $2e/h$	K_{J}	483 597.879(41) × 10^{9}	Hz V^{-1}	8.5 × 10^{-8}
von Klitzing constant[e], $h/e^2 = \mu_0 \mathrm{c}/2\alpha$	R_{K}	25 812.807 449(86)	Ω	3.3 × 10^{-9}
Bohr magneton, $e\hbar/2m_e$	μ_{B}	927.400 949(80) × 10^{-26}	J T^{-1}	8.6 × 10^{-8}
in eV T^{-1}		5.788 381 804(39) × 10^{-5}	eV T^{-1}	6.7 × 10^{-9}
	μ_{B}/h	13.996 2458(12) × 10^{9}	Hz T^{-1}	8.6 × 10^{-8}
	μ_{B}/hc	46.686 4507(40)	m^{-1} T^{-1}	8.6 × 10^{-8}
	$\mu_{\mathrm{B}}k$	0.671 7131(12)	K T^{-1}	1.8 × 10^{-6}
Nuclear magneton, $e\hbar\, 2m_{\mathrm{p}}$	μ_{N}	5.050 783 43(43) × 10^{-27}	J T^{-1}	8.6 × 10^{-8}
in eV T^{-1}		3.152 451 259(21) × 10^{-8}	eV T^{-1}	6.7 × 10^{-9}

	μ_{N}/hc	2.542 623 58(22) × 10^{-2}	m^{-1}T^{-1}	8.6 × 10^{-8}
	μ_{N}/k	3.658 2637(64) × 10^{-4}	K T^{-1}	1.8 × 10^{-6}
ATOMIC AND NUCLEAR CONSTANTS				
General				
Fine-structure constant, $e^2/4\pi\varepsilon_0\hbar c$	α	7.297 352 568(24) × 10^{-3}		3.3 × 10^{-9}
Inverse fine-structure constant	α^{-1}	137.035 999 11(46)		3.3 × 10^{-9}
Rydberg constant, $\alpha^2 m_e c/2h$	R_∞	10 973 731.568 525(73)	m^{-1}	6.6 × 10^{-12}
	$R_\infty c$	3.289 841 960 360(22) × 10^{15}	Hz	6.6 × 10^{-12}
$R_\infty hc$ in eV		13.605 6923(12)	eV	8.5 × 10^{-8}
Bohr radius, $\alpha/4\pi R_\infty = 4\pi\varepsilon_0\hbar^2/m_e e^2$	a_0	0.529 177 2108(18) × 10^{-10}	m	3.3 × 10^{-9}
Hartree energy, $e^2/4\pi\varepsilon_0 a_0 = 2R_\infty he = \alpha^2 m_e c^2$	E_{h}	4.359 744 17(75) × 10^{-18}	J	1.7 × 10^{-7}
in eV		27.211 3845(23)	eV	8.5 × 10^{-8}
Electroweak				
Fermi coupling constant[f]	$G_{\mathrm{F}}/(\hbar c)^3$	1.166 39(1) × 10^{-5}	GeV^{-2}	8.6 × 10^{-6}

[a] Footnotes are at table end.

Recommended values (2002) of selected fundamental constants of physics and chemistry[a] (cont.)

Quantity	Symbol	Numerical value[b]	Unit[c]	Relative uncertainty (standard deviation)
		ATOMIC AND NUCLEAR CONSTANTS (cont.)		
		Electron, e^-		
Electron mass	m_e	$9.109\,3826(16) \times 10^{-31}$	kg	1.7×10^{-7}
in u		$5.485\,799\,0945(24) \times 10^{-4}$	u	4.4×10^{-10}
Energy equivalent in MeV	$m_e c^2$	$0.510\,998\,918(44)$	MeV	8.6×10^{-8}
Electron charge to mass quotient	$-e/m_e$	$-1.758\,820\,12(15) \times 10^{11}$	$\mathrm{C\ kg^{-1}}$	8.6×10^{-8}
Compton wavelength, $h/m_e c$	λ_C	$2.426\,310\,238(16) \times 10^{-12}$	m	6.7×10^{-9}
$\lambda_c/2\pi = \alpha a_0 = \alpha^2/4\pi R_\infty$	$\bar{\lambda}_C$	$386.159\,2678(26) \times 10^{-15}$	m	6.7×10^{-9}
Classical electron radius, $\alpha^2 a_0$	r_e	$2.817\,940\,325(28) \times 10^{-15}$	m	1.0×10^{-8}
Thomson cross section, $(8\pi/3)r^2{}_e$	σ_e	$0.665\,245\,873(13) \times 10^{-28}$	$\mathrm{m^2}$	2.0×10^{-8}
Electron magnetic moment	μ_e	$-928.476\,412(80) \times 10^{-26}$	$\mathrm{J\ T^{-1}}$	8.6×10^{-8}
Electron magnetic moment anomaly, $\lvert\mu_e\rvert/\mu_B - 1$	a_e	$1.159\,652\,1859(38) \times 10^{-3}$		3.2×10^{-9}
Electron gyromagnetic ratio, $2\lvert\mu_e\rvert/\hbar$	γ_e	$1.760\,859\,74(15) \times 10^{11}$	$\mathrm{s^{-1}\ T^{-1}}$	8.6×10^{-8}
	$\gamma_e/2\pi$	$28\,024.95\,32(24)$	$\mathrm{MHz\ T^{-1}}$	8.6×10^{-8}
		Muon, μ^-		
Muon mass	m_μ	$1.883\,531\,40(83) \times 10^{-28}$	kg	1.7×10^{-7}
in u		$0.113\,428\,9264(30)$	u	2.6×10^{-8}
Energy equivalent in MeV	$m_\mu c^2$	$105.658\,3692(94)$	MeV	8.9×10^{-8}
Muon-electron mass ratio	m_μ/m_e	$206.768\,2838(54)$		2.6×10^{-8}
Muon Compton wavelength, $h/m_\mu c$	$\lambda_{C,\mu}$	$11.734\,441\,05(30) \times 10^{-15}$	m	2.5×10^{-8}
$\lambda_{C,\mu}/2\pi$	$\bar{\lambda}_{C,\mu}$	$1.867\,594\,298(47) \times 10^{-15}$	m	2.5×10^{-8}
Muon magnetic moment	μ_μ	$-4.490\,447\,99(40) \times 10^{-26}$	$\mathrm{J\ T^{-1}}$	8.9×10^{-8}
Muon magnetic moment anomaly, $\lvert\mu_\mu\rvert/(e\hbar/2m_\mu) - 1$	a_μ	$1.165\,919\,81(62) \times 10^{-3}$		5.3×10^{-7}
		Tau, τ^-		
Tau mass[g]	m_τ	$3.167\,77(52) \times 10^{-27}$	kg	1.6×10^{-4}
in u		$1.907\,68(31)$	u	1.6×10^{-4}
Energy equivalent in Mev	$m_\tau c^2$	$1776.99(29)$	MeV	1.6×10^{-4}
Tau-electron mass ratio	m_τ/m_e	$3\,477.48(57)$		1.6×10^{-4}
		Proton, p		
Proton mass	m_p	$1.672\,621\,71(29) \times 10^{-27}$	kg	1.7×10^{-7}
in u		$1.007\,276\,466\,88(13)$	u	1.3×10^{-10}
Energy equivalent in MeV	$m_p c^2$	$938.272\,029(80)$	MeV	8.6×10^{-8}
Proton-electron mass ratio	m_p/m_e	$1836.152\,672\,61(85)$		4.6×10^{-10}
Proton charge to mass quotient	e/m_p	$9.578\,833\,76(82) \times 10^{7}$	$\mathrm{C\ kg^{-1}}$	8.6×10^{-8}
Proton Compton wavelength, $h/m_p c$	$\lambda_{C,p}$	$1.321\,409\,8555(88) \times 10^{-15}$	m	6.7×10^{-9}
$\lambda_{c,p}/2\pi$	$\lambda_{C,p}$	$0.210\,308\,9104(14) \times 10^{-15}$	m	6.7×10^{-9}
Proton magnetic moment	μ_p	$1.410\,606\,71(12) \times 10^{-26}$	$\mathrm{J\ T^{-1}}$	8.7×10^{-8}
to nuclear magneton ratio	μ_p/μ_N	$2.792\,847\,351(28)$		1.0×10^{-8}
Shielded proton magnetic moment[h]	μ'_p	$1.410\,570\,47(12) \times 10^{-26}$	$\mathrm{J\ T^{-1}}$	8.7×10^{-8}
to nuclear magneton ratio	μ'_p/μ_N	$2.792\,775\,604(30)$		1.1×10^{-8}
Proton gyromagnetic ratio, $2\mu_p/\hbar$	γ_p	$2.675\,222\,05(23) \times 10^{8}$	$\mathrm{s^{-1}\ T^{-1}}$	8.6×10^{-8}
	$\gamma_p/2\pi$	$42.577\,4813(37)$	$\mathrm{MHz\ T^{-1}}$	8.6×10^{-8}
Shielded proton gyromagnetic ratio[h], $2\mu'_p/\hbar$	γ'_p	$2.675\,153\,33(23) \times 10^{8}$	$\mathrm{s^{-1}\ T^{-1}}$	8.6×10^{-8}
	$\gamma'_p/2\pi$	$42.576\,3875(37)$	$\mathrm{MHz\ T^{-1}}$	8.6×10^{-8}
		Neutron, n		
Neutron mass	m_n	$1.674\,927\,28(29) \times 10^{-27}$	kg	1.7×10^{-7}
in u		$1.008\,664\,915\,60(55)$	u	5.5×10^{-10}
Energy equivalent in MeV	$m_n c^2$	$939.565\,360(81)$	MeV	8.6×10^{-8}
Neutron magnetic moment	μ_n	$-0.966\,236\,45(24) \times 10^{-26}$	$\mathrm{J\ T^{-1}}$	2.5×10^{-7}
to nuclear magneton ratio	μ_n/μ_N	$-1.913\,042\,73(45)$		2.4×10^{-7}
		Deuteron, d		
Deuteron mass	m_d	$3.343\,583\,35(57) \times 10^{-27}$	kg	1.7×10^{-7}
in u		$2.013\,553\,212\,70(35)$	u	1.7×10^{-10}
Energy equivalent in MeV	$m_d c^2$	$1\,875.612\,82(16)$	MeV	8.6×10^{-8}
Deuteron magnetic moment	μ_d	$0.433\,073\,482(38) \times 10^{-26}$	$\mathrm{J\ T^{-1}}$	8.7×10^{-8}
to nuclear magneton ratio	μ_d/μ_N	$0.857\,438\,2329(92)$		1.1×10^{-8}

[a] Footnotes are at table end.

Recommended values (2002) of selected fundamental constants of physics and chemistry[a] (cont.)

Quantity	Symbol	Numerical value[b]	Unit[c]	Relative uncertainty (standard deviation)
PHYSICOCHEMICAL CONSTANTS				
Avogadro constant	N_A, L	$6.022\,1415(10) \times 10^{23}$	mol^{-1}	1.7×10^{-7}
Atomic mass constant,				
$m_u = \frac{1}{12}m(^{12}\mathrm{C}) = 1\ \mathrm{u}$	m_u	$1.660\,538\,86(28) \times 10^{-27}$	kg	1.7×10^{-7}
$= 10^{-3}\ \mathrm{kg\ mol}^{-1}/N_A$				
Energy equivalent in MeV	m_uC^2	$931.494\,043(80)$	MeV	8.6×10^{-8}
Faraday constant[i], N_Ae	F	$96\,485.3383(83)$	$\mathrm{C\ mol}^{-1}$	8.6×10^{-8}
Molar Planck constant	N_Ah	$3.990\,312\,716(27) \times 10^{-10}$	$\mathrm{J\ s\ mol}^{-1}$	6.7×10^{-9}
	N_Ahc	$0.119\,626\,565\,72(80)$	$\mathrm{J\ m\ mol}^{-1}$	6.7×10^{-9}
Molar gas constant	R	$8.314\,472(15)$	$\mathrm{J\ mol}^{-1}\ \mathrm{K}^{-1}$	1.7×10^{-6}
Boltzmann constant, R/N_A	k	$1.380\,6505(24) \times 10^{-23}$	$\mathrm{J\ K}^{-1}$	1.8×10^{-6}
in $\mathrm{eV\ K}^{-1}$		$8.617\,343(15) \times 10^{-5}$	$\mathrm{eV\ K}^{-1}$	1.8×10^{-6}
	k/h	$2.083\,6644(36) \times 10^{10}$	$\mathrm{Hz\ K}^{-1}$	1.7×10^{-6}
	k/hc	$69.503\,56(12)$	$\mathrm{m}^{-1}\mathrm{K}^{-1}$	1.7×10^{-6}
k^{-1} in $\mathrm{K\ eV}^{-1}$		$11\,604.505(20)$	$\mathrm{K\ eV}^{-1}$	1.8×10^{-6}
Molar volume of ideal gas, RT/p, for				
$T = 273.15$ K, $p = 101.325$ kPa	V_m	$22.413\,996(39) \times 10^{-3}$	$\mathrm{m}^3\ \mathrm{mol}^{-1}$	1.7×10^{-6}
Loschmidt constant, N_A/V_m	n_o	$2.686\,7773(47) \times 10^{25}$	m^{-3}	1.8×10^{-6}
Stefan-Boltzmann constant,				
$(\pi^2/60)k^4/\hbar^3c^2$	σ	$5.670\,400(40) \times 10^{-8}$	$\mathrm{W\ m}^{-2}\ \mathrm{K}^{-4}$	7.0×10^{-6}
First radiation constant, $2\pi hc^2$	c_1	$3.741\,771\,38(64) \times 10^{-16}$	$\mathrm{W\ m}^2$	1.7×10^{-7}
Second radiation constant, hc/k	c_2	$1.438\,7752(25) \times 10^{-2}$	m K	1.7×10^{-8}
Wien displacement law constant,				
$b = \lambda_{\max} T = c_2/4.965\,114\,231\ldots$	b	$2.897\,7685(51) \times 10^{-3}$	m K	1.7×10^{-6}
NON-SI UNITS ACCEPTED FOR USE WITH THE SI				
Electronvolt: (e/C) J	eV	$1.602\,176\,53(14) \times 10^{-19}$	J	8.5×10^{-8}
(Unified) atomic mass unit:				
$1\ \mathrm{u} = m_u = \frac{1}{12}m(^{12}\mathrm{C})$	u	$1.660\,538\,86(28) \times 10^{-27}$	kg	1.7×10^{-7}

[a] This table presents a selection of the values of the fundamental constants recommended by the Committee on Data for Science and Technology (CODATA). These "2002 CODATA recommended values" form a self-consistent set based on the data available through December 31, 2002, and are generally recognized for use in all fields of science and technology. A detailed description of the data and analysis that led to these results will be published in 2004. The 2002 adjustment was carried out under the auspices of the CODATA Task Group on Fundamental Constants. The recommended values are available on the World Wide Web at http://physics.nist.gov/cuu/Constants/index.html.

[b] The digits in parentheses represent one-standard-deviation uncertainties in the final two digits of the quoted values.

[c] A = ampere, C = coulomb, F = farad, Hz = hertz, J = joule, K = kelvin, kg = kilogram, m = meter, mol = mole, N = newton, Pa = pascal, s = second, T = tesla, W = watt, Wb = weber, Ω = ohm, eV = electronvolt, u = (unified) atomic mass unit. Prefixes: k = 10^3, M = 10^6, G = 10^9.

[d] The conventional value of the Josephson constant, adopted internationally for realizing representations of the volt using the Josephson effect, is $K_{\mathrm{J-90}} = 483\,597.9\ \mathrm{GHz\ V}^{-1}$.

[e] The conventional value of the von Klitzing constant, adopted internationally for realizing representations of the ohm using the quantum Hall effect, is $R_{\mathrm{k-90}} = 25\,812.807\ \Omega$.

[f] Value recommended by the Particle Data Group in the 2002 Review of Particle Physics [K. Hagiwara et al. (Particle Data Group), *Physical Review D*, vol. 66, Paper 010001, 2002 (http://pdg.lbl.gov)].

[g] This and all other values involving m_τ are based on the value of $m_\tau c^2$ in MeV recommended by the Particle Data Group in the 2002 Review of Particle Physics (*ibid.*), but with a standard uncertainty of 0.29 MeV rather than the quoted uncertainty of −0.26 MeV, + 0.29 MeV.

[h] Based on nuclear magnetic resonance (NMR) frequency of protons in a sphere of pure water (H_2O) at 25°C surrounded by vaccum.

[i] The numerical value of F to be used in coulometric chemical measurements is 96 485.336(16) [relative uncertainty = 1.7×10^{-7}] when the relevant current is measured in terms of representations of the volt and ohm based on the Josephson and quantum Hall effects and the conventional values of the Josephson and von Klitzing constants, $K_{\mathrm{J-90}}$ and $R_{\mathrm{k-90}}$.

The fundamental particles[a]

Gauge bosons $J_C^P = 1_-^-$ Self-conjugate except $\overline{W^+} = W^-$.

Name	Symbol	Charge[b]	Mass and width, GeV	Couplings
Photon	γ	0	0	$A \Rightarrow \gamma A$
Gluon[c]	g	0	0	$A \Rightarrow gA'$
Weak bosons				
Charged[d]	$W^\pm$	±1	80.4, 2.1	$U \Rightarrow W^+D$
Neutral[e]	Z^0	0	91.2, 2.5	$A \Rightarrow Z^0A$

Fermions[f] $J = {}^1/_2$ All have distinct antiparticles, except perhaps the neutrinos.

Name	Charge[b]	Symbol and mass, GeV		Symbol and mass, GeV		Symbol and mass, GeV	
Leptons							
Neutrinos	0	ν_e	$<3 \times 10^{-9}$	ν_μ	$<.0002$	ν_τ	$<.02$
Charged leptons[g]	–1	e	.00051	μ	.106[h]	τ	1.78[h]
Quarks[c]							
Up type	${}^2/_3$	u	.0015–.004	c	1.55–1.35	t	170–180[i]
Down type	$-{}^1/_3$	d	.004–.008	s	.08–.13	b	4.1–4.4

---

[a] The graviton, with $J_C^P = 2_+^+$, has been omitted, since it plays no role in high-energy particle physics.

[b] In units of the proton charge.

[c] The gluon is a color SU_3 octet (8); each quark is a color triplet (3). These colored particles are confined constituents of hadrons; they do not appear as free particles.

[d] The branching ratios (%) of the decay modes of the W^+ are:

$u\bar{d}$, $c\bar{s}$	34 each
$\nu_e e^+$, $\nu_\nu \mu^+$, $\nu_\tau \tau^+$	11 each

[e] The branching ratios (%) of the decay modes of the Z^0 are:

$d\bar{d}$, $s\bar{s}$, $b\bar{b}$	16.6 each
$u\bar{u}$, $c\bar{c}$	10.1 each
$\nu_e\bar{\nu}_e$, $\nu_\mu\bar{\nu}_\mu$, $\nu_\tau\bar{\nu}_\tau$	6.7 each
e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$	3.4 each

[f] The three known families (generations) of fermions are displayed in three columns.

[g] Any further charged leptons have mass greater than 40 GeV.

[h] The μ and τ leptons are unstable, with the following mean life and principal decay modes (branching ratios in %):

μ	$\tau_\mu = 2.2 \times 10^{-6}$ s	$e\bar{\nu}_e\nu_\mu$ 100
τ	$\tau_\tau = 2.9 \times 10^{-13}$ s	$\mu\bar{\nu}_\mu\nu_\tau$ 17, $e\bar{\nu}_e\nu_\tau$ 18, (hadrons)$\bar{\nu}_\tau$ 63

[i] The t quark has a width ≈ 1.4 GeV, with dominant decay to Wb.

Geologic time scale and related aspects

Eon	Era	Period (Interval length, × 10^6 years)	Epoch	Beginning of epoch, × 10^6 years ago	Forms of life	Other features
Phanerozoic	Cenozoic "Age of Mammals"	Quaternary (1.8)	Recent	0.01	Modern humans	Extensive glaciation during portions of Quaternary Formation of most present mountain ranges
			Pleistocene	1.8	Early humans	
		Tertiary (63.2)	Pliocene	5.3	Large carnivores	
			Miocene	23.8	Whales, apes, grazing animals	
			Oligocene	33.7	Large browsing animals	
			Eocene	54.8	Rise of modern floras	
			Paleocene	65	First placental mammals	
	Mesozoic "Age of Reptiles"	Cretaceous (79)	Upper (Base Santonian)		Last of dinosaurs	Widespread seas over much of present-day Europe, North Africa, and North America
			Middle (Base Albian)		Last of ammonites	
			Lower	144	Rise of flowering plants	
		Jurassic (62)	Upper (Base Callovian)		Toothed birds	Beginning of formation of Atlantic Ocean
			Middle (Base Bajocian)		Flying reptiles	
			Lower	206	First primitive mammals	
		Triassic (44)	Upper		Rise of dinosaurs	
			Middle		Rise of ammonites	
			Lower	250	Rise of cycads	
	Paleozoic "Age of Invertebrates"	Permian (40)	Upper (Base Ochoan)		Primitive reptiles	Mountain building during late Paleozoic
			Middle (Base Guadalupian)		Last of trilobites	
			Lower	290	Glossopteris flora	
		Carboniferous[a]: Pennsylvanian (32)	Upper		Spread of amphibians	Widespread coal swamps
			Middle		Great coal forests	
			Lower	322	Climax of spore-forming plants	
		Carboniferous[a]: Mississippian (32)	Upper		Abundant sharks	
			Middle		Climax of crinoids and blastoids	
			Lower	354		
		Devonian (63)	Upper		First forests	
			Middle		Rise of ferns	
			Lower	417	Earliest known amphibians	
		Silurian (26)	Upper		Appearance of land plants	
			Middle		First known scorpions	
			Lower	443	Expansion of brachiopods and corals	
		Ordovician (47)	Upper		Appearance of primitive fishes	
			Middle		Climax of trilobites	
			Lower	490	Rise of cephalopods	
		Cambrian (53)	Upper (Base Croixian)		Abundant trilobites	
			Middle		Many kinds of shelled invertebrates	
			Lower	543		
Proterozoic	Precambrian		Neoproterozoic (357[b])	900	Marine algae, wormlike organisms, other simple forms	Extensive glaciation Oldest dated rocks (Greenland)
			Mesoproterozoic (700[b])	1600		
			Paleoproterozoic (900[b])	~2500		
Archean[c]			Late (500[b])	3000	Blue-green algae (cyanobacteria)	Abundant dark sediments Formation of earliest known rocks
			Middle (400[b])	3400		
			Early (>400[b])	>3800	Bacteria	

[a] The period known as Carboniferous in Europe is divided into two periods in North American usage.
[b] Length of epoch, × 10^6 years.
[c] The beginning of the Archean corresponds to the age of the oldest preserved continental crust.

Biographical Listing

Abbe, Ernst (1840–1905), German physicist. Developed optical instruments, such as an apochromatic objective and a crystal refractometer.

Abel, Frederick Augustus (1827–1902), English chemist. Expert on the chemistry of explosives; originated the Abel test for determination of the flash point of petroleum.

Abel, John Jacob (1857–1938), American pharmacologist and physiologist. Isolated epinephrine, and insulin in crystal form.

Abel, Niels Henrik (1802–1829), Norwegian mathematician. Contributed to the theory of elliptical functions.

Abell, George Ogden (1927–1983), American astronomer. Research in problems relating to organization, structure, and distribution of galaxies; observational cosmology; and planetary nebulae.

Abney, William de Wiveleslie (1843–1920), English photographic chemist and physicist. Photographed the infrared solar spectrum.

Abrikosov, Alexei A. (1928–), Russian-born American physicist. Applied the Ginzburg-Landau theory to explain the behavior of type II superconductors. Nobel Prize, 2003.

Adams, John Couch (1819–1892), English astronomer. Discovered, independently of U. J. J. Leverrier, Neptune.

Adanson, Michel (1727–1806), French naturalist. Classified plants in his *Les Familles Naturelles des Plantes.*

Addison, Thomas (1793–1860), English physician. Identified pernicious anemia and Addison’s disease of the adrenal cortex.

Adler, Alfred (1870–1937), Austrian psychiatrist and psychologist. Founded the school of individual psychology.

Adrian of Cambridge, Edgar Douglas Adrian, Baron (1889–1977), English physiologist. Investigated physiology of nervous system; showed that change in electric potential in electroencephalograph is due to electrical activity of cortex; Nobel Prize, 1932.

Afzelius, Adam (1750–1837), Swedish botanist. Founded the Linnaean Institute.

Agassiz, Jean Louis Rudolphe (1807–1873), Swiss-born American naturalist. Wrote books on ichthyology, especially relating to classification.

Agnesi, Maria Gaetana (1718–1799), Italian mathematician. Author of *Instituzioni Analitiche*, a complete treatment of algebra and analysis; shared in the discovery of a cubic curve (“witch of Agnesi”).

Agre, Peter (1949–), American medical doctor and scientist. Discovered water channels in cell membranes; Nobel Prize, 2003.

Agricola, Georgius, real name Georg Bauer (1494–1555), German physician and mineralogist. Known as the father of systematic mineralogy.

Ahlfors, Lars Valerian (1907–1996), Finnish-American mathematician. Did research on covering surfaces related to Riemann surfaces of inverse functions of entire and meromorphic functions; opened up new fields of analysis; Fields Medal, 1936.

Airy, George Biddell (1801–1892), English astronomer. Discovered inequality in the motions of Venus and the Earth; determined the mass of the Earth.

Aitken, John (1839–1919), Scottish physicist. Studied dust particles in the atmosphere, known as Aitken nuclei.

Aitken, Robert Grant (1864–1951), American astronomer. Discovered more than 3000 binary stars.

Alder, Kurt (1902–1958), German chemist. Codeveloper of the Diels-Alder reaction for diene synthesis; contributed to stereochemistry; Nobel Prize, 1950.

Alembert, Jean le Rond d’ (1717–1783), French mathematician. Developed d’Alembert’s principle and the calculus of partial differences.

Alferov, Zhores Ivanovich (1930–), Russian physicist and electronics engineer. Developed semiconductor heterostructures used in high-speed and opto-electronics, including fast transistors, laser diodes, and light-emitting diodes; Nobel Prize, 2000.

Alfvén, Hannes Olof Gösta (1908–1995), Swedish physicist. Studies in magnetohydrodynamics, planetary physics, antiferromagnetism, and ferrimagnetism; Nobel Prize, 1970.

Alhazen (965–1038), Arab mathematician and astronomer. Provided the first accounts of atmospheric refraction and reflection from concave surfaces; constructed spherical and parabolic mirrors.

al-Khwarizmi (780–?850), Arab mathematician. Wrote treatises on arithmetic and algebra, which were important in the mathematical knowledge of medieval Europe.

Allen, Edgar (1892–1943), American biologist. Discovered estrogen; investigated hormonal mechanisms controlling female reproductive cycle.

Allen, Willard Myron (1904–1993), American physician. With G. W. Corner, discovered progesterone, and proved it necessary for development of embryo in early pregnancy; with O. Wintersteiner, synthesized crystalline progesterone.

Altman, Sidney (1939–), American chemist. Discovered an unusual enzyme that contains ribonucleic acid (RNA) in addition to a protein, leading to the discovery that RNA molecules have catalytic properties similar to those of enzymes; Nobel Prize, 1989.

Alvarez, Luis Walter (1911–1988), American physicist. Pioneer in building liquid hydrogen bubble chambers, and in developing measurement devices and computer systems to analyze data from these chambers; discovered large numbers of short-lived elementary particles; Nobel Prize, 1968.

Amagat, Émile (1841–1915), French physicist. Investigated relationship of pressure, density, and temperature in gases and liquids, particularly at high pressure.

Amici, Giovanni Battista (1786–1863), Italian astronomer, optician, and naturalist. Invented the Amici microscope; designed parabolic mirrors for reflecting telescopes.

Ampère, André Marie (1775–1836), French physicist and mathematician. Founder of electrodynamics; formulated Ampère’s law; invented the astatic needle.

Anaximander (611–547 B.C.), Greek astronomer and mathematician. Reputed inventor of geographical maps; formulated the concept of the universe as infinite (apeiron).

Anderson, Carl David (1905–1991), American physicist. Discovered the meson in cosmic rays; discovered the positron; Nobel Prize, 1936.

Anderson, Philip Warren (1923–), American physicist. Demonstrated existence of electronic localization in disordered solids, and of localized magnetism in metals; Nobel Prize, 1977.

Andrade, Edward Neville da Costa (1887–1971), English physicist. Discovered Andrade’s creep law and a law governing variation of viscosity of liquids with temperature.

Andrews, Roy Chapman (1884–1960), American naturalist. Discovered many plant and animal fossils.

Anfinsen, Christian Boehmer (1916–1995). American biochemist. Discovered how three-dimensional structures of ribonuclease and other proteins are formed; Nobel Prize, 1972.

Angström, Anders Jonas (1814–1874), Swedish physicist. Mapped the solar spectrum; discovered hydrogen in the solar atmosphere.

Apollonius of Perga (247–205 B.C.), Greek mathematician. Wrote about conic sections; coined the terms parabola, ellipse, and hyperbola.

Appleton, Edward Victor (1892–1965), English physicist. Demonstrated the existence of the ionosphere and discovered its region known as the Appleton layer; contributed to the development of radar; Nobel Prize, 1947.

Arago, Dominique François (1786–1853), French astronomer and physicist. Discovered the magnetic properties of nonferrous materials, and the production of magnetism by electricity.

Arber, Werner (1929–), Swiss molecular biologist. Determined the molecular mechanism of host-controlled restriction modification of bacterial viruses and discovered the restriction enzymes; Nobel Prize, 1978.

Archimedes (287–212 B.C.), Greek physicist and mathematician. Formulated Archimedes’ principle; invented the compound pulley and Archimedes’ screw.

Argand, Jean Robert (1768–1822), Swiss mathematician. Developed the Argand diagram.

Argelander, Friedrich Wilhelm August (1799–1875), German astronomer. Prepared a star catalog; introduced decimal division of stellar magnitudes.

Aristarchus of Samos (310–250 B.C.), Greek astronomer. Invented the hemispherical sundial; determined the movement of the Earth around the stationary Sun; added a correction factor of 1/1623 of a day to the length of the year.

Aristotle (384–322 B.C.), Greek philosopher. Exponent of the methodology and division of sciences; contributed to physics, astronomy, meteorology, psychology, and biology.

Arkwright, Richard (1732–1792). English inventor. Developed the first practical mechanized spinning frame, utilizing rollers.

Arrhenius, Svante August (1859–1927), Swedish physicist and chemist. Developed theory of electrolytic dissociation; investigated osmosis and viscosity of solutions; Nobel Prize, 1903.

Arsonval, Jacques Arsène d’ (1851–1940), French physicist and physiologist. Pioneered in electrotherapy; invented d’Arsonvalgalvanometer.

Aston, Francis William (1877–1945), English physicist and chemist. Discovered isotopes in nonradioactive elements by using the mass spectrograph he invented; Nobel Prize, 1922.

Atiyah, Michael Francis (1929–), British mathematician. Work centered on the interaction between geometry and analysis; developed K theory in collaboration with F. Hirzebruch; with I. M. Singer, proved the index theorem concerning elliptic differential operators on compact differentiable manifolds, which was later seen to have applications to theoretical physics; Fields Medal, 1966; Abel Prize, 2004.

Atwood, George (1746–1807), English mathematician. Invented the Atwood machine.

Audubon, John James (1785–1851), Haitian-born American ornithologist and artist. Made drawings and paintings of birds and animals.

Auger, Pierre Victor (1899–1993), French physicist. Discovered the Auger effect.

Avicenna (979–1037), Arab physician. Wrote the medical text *Canon Medicinae*.

Avogadro, Amedeo (1776–1856), Italian physicist. Formulated Avogadro’s law.

Axel, Richard (1946–), American molecular biologist. Recognized along with Linda Buck for pioneering research of the olfactory system, which led to the discovery of the genes and proteins involved in the transmission of olfactory information. Later independent work clarified the cellular and molecular mechanisms underlying the olfactory system. Nobel Prize, 2004.

Axelrod, Julius (1912–), American biochemist and pharmacologist. Showed that many drugs act by modifying storage of neurotransmitters at nerve terminals; made discoveries concerning metabolism, and mechanisms for formation and inactivation of norepinephrine; Nobel Prize, 1970.

Ayrton, William Edward (1847–1908), English physicist and electrical engineer. Invented the ammeter, voltmeter, and other electrical measuring instruments.

Baade, Walter (1893–1960), German-born American astronomer. Formulated concept of stellar populations; increased distance scale of universe by factor of 2.

Babbage, Charles (1792–1851), English mathematician. Devised a primitive computer to calculate and print mathematical and astronomical tables.

Babcock, Harold Delos (1882–1968) and **Horace Welcome** (1912–2003), American astronomers. Invented the Babcock magnetograph, observed weak solar magnetic fields, and discovered stellar magnetic fields.

Babcock, Stephen Moulton (1843–1931), American agricultural chemist. Pioneer in nutrition; devised the Babcock test to measure fat content in milk.

Babinet, Jacques (1794–1872), French physicist. Invented a polariscope and a goniometer.

Back, Ernst E. A. (1881–1959), German physicist. Developed improved spectrographs; made spectroscopic observations leading to Paschen-Back effect.

Badger, Richard McLean (1896–1974), American physical chemist and spectroscopist. Studied structures of polyatomic molecules; formulated Badger's rule concerning molecular bonds.

Baekeland, Leo Hendrik (1864–1944), Belgian-born, American chemist. Invented the phenol-formaldehyde polymer, Bakelite, the first commercial synthetic polymer.

Baer, Karl Ernst von (1792–1876), Estonian embryologist. Discovered the mammalian ovum and the notochord; developed the theory of embryonic germ layers.

Baeyer, Johann Friedrich Wilhelm Adolf von (1835–1917), German chemist. Synthesized indigo and hydroaromatic compounds; Nobel Prize, 1905.

Baily, Francis (1774–1844), English astronomer. A founder of the Royal Astronomical Society; first observed phenomenon of Baily's beads.

Baire, René Louis (1874–1932), French mathematician. Contributed to theory of functions of real variables; introduced concept of Baire functions.

Baker, Alan (1939–), British mathematician. Proved a generalization of the Gelfond-Schneider theorem; from this work, generated transcendental numbers not previously identified and solved problems in the theory of Diophantine equations; Fields Medal, 1970.

Balfour, Francis Maitlant (1851–1882), English biologist. Founder of comparative embryology.

Balmer, Johann Jakob (1825–1898), Swiss physicist. Expressed the mathematical formula for frequencies of hydrogen lines in the visible spectrum.

Baltimore, David (1938–), American virologist. Investigated interaction between ribonucleic acid tumor viruses and genetic material; independently of H. M. Temin, discovered reverse transcriptase; Nobel Prize, 1975.

Banach, Stefan (1892–1945), Polish mathematician. Laid foundations of contemporary functional analysis; introduced concept of Banach space and discovered its fundamental properties.

Bang, Bernhard Laurits Frederik (1848–1932), Danish veterinarian. Discovered method of eradicating bovine tuberculosis; discovered *Brucella abortus*, the agent of contagious abortion (Bang's disease) and brucellosis.

Banting, Frederick Grant (1891–1941), Canadian physician. With J. J. R. Macleod and C. H. Best, discovered insulin and its role in diabetes; Nobel Prize. 1923.

Bárány, Robert (1876–1936), Austrian physician. Developed new methods of diagnosing ear diseases; Nobel Prize, 1914.

Bardeen, John (1908–1991), American physicist. With L. N. Cooper and J. R. Schrieffer, formulated a theory of superconductivity; invented the transistor; Nobel Prize, 1956 and 1972.

Barkhausen, Heinrich Georg (1881–1956), German electronic engineer and physicist. Contributed to theory and application of electron tubes; with K. Kurz, developed Barkhausen-Kurz oscillator; discovered Barkhausen effect.

Barkla, Charles Glover (1877–1944), English physicist. Described characteristics of x-rays and other short-wave emissions of elements.

Barnard, Edward Emerson (1857–1923), American astronomer. Discovered 16 comets, the fifth satellite of Jupiter, and dark nebulae; contributed to celestial photography.

Barnett, Samuel Jackson (1873–1956), American physicist. Discovered Barnett effect and used it to measure the gyromagnetic ratio of ferromagnetic materials; gave experimental proof of existence of ionosphere.

Barr, Murray Llewellyn (1908–1995), Canadian anatomist. Discovered the Barr body on the X chromosome of the human female.

Bartholin, Kaspar (1655–1738), Danish physician. Discovered Bartholin's glands of the vagina and a sublingual duct.

Bartholin, Thomas (1616–1680), Danish physician. Discovered lymphatic glands; described the lymphatic system.

Bartlett, James Holly (1904–2000), American physicist. Introduced concept of Bartlett force; did research on nuclear shell model, electrochemical potentiostat, and restricted three-body problem.

Barton, Derek Harold Richard (1918–1998), British chemist. Developed and expanded concept of conformation to include large molecules with complex ring systems; Nobel Prize, 1969.

Basov, Nicolai Gennediyevich (1922–2001), Soviet physicist. Conducted fundamental studies in quantum electronics; with A. M. Prokhorov, developed quantum optical generators; Nobel Prize, 1964.

Bassham, James Alan (1922–), American chemist. Helped to elucidate basic photosynthetic carbon cycle.

Bates, Henry Walter (1825–1892), English naturalist. Discovered Batesian mimicry among butterflies and moths.

Baudot, Èmile (1845–1903), French engineer. Invented an improved telegraph transmitter.

Baumé, Antoine (1728–1804), French chemist. Invented a graduated hydrometer which utilizes the Baumé scale.

Bautz, Laura Patricia (1940–), American astronomer. Collaborated with W. W. Morgan in developing Bautz-Morgan classification of galaxy clusters.

Bayer, Johann (1572–1624), German astronomer. Charted 12 constellations; first to use Greek letters to designate the order of brightness of stars in a constellation.

Bayes, Thomas (1702–1761), English mathematician. Formulated a basis for statistical inference.

Bayliss, William Maddock (1860–1924), English physiologist. Did research on electrophysiology of heart action; discovered the hormone secretin.

Beadle, George Wells (1903–1989), American geneticist. With E. L. Tatum, proved that genes affect heredity by controlling cell chemistry; Nobel Prize, 1958.

Beams, Jesse Wakefield (1898–1977), American physicist. Developed vacuum-type ultracentrifuges, used in purification and molecular weight determination of large-molecular-weight substances, isotope separation, and determination of the gravitational constant.

Beattle, James Alexander (1895–1981), American chemist and physicist. Studied ionic theory and thermodynamics; with P. W. Bridgman, proposed Beattie and Bridgman equation for gases.

Beaufort, Francis (1774–1857), English hydrographer. Devised scale of wind velocity.

Beaumont, William (1785–1853), American physician. Did pioneering studies of digestion and gastric juices.

Béchamp, Pierre Jacques Antoine (1816–1908), French chemist. Discovered a method of preparing aniline.

Beckmann, Ernst Otto (1853–1923), German chemist. Discovered Beckmann molecular transformation; invented the Beckmann thermometer.

Becquerel, Antoine César (1788–1878), French physicist. Pioneer in electrochemistry; first to extract metals from ore by electrolysis.

Becquerel, Antoine Henri (1852–1908), French physicist. A discoverer of radioactivity in uranium.

Bednorz, Johannes Georg (1950–), German physicist. With K. A. Müller, discovered high-temperature superconductivity in copper oxide ceramic materials; Nobel Prize, 1987.

Beebe, Charles William (1877–1962), American naturalist. Pioneer in deep-sea exploration; made ornithological collections.

Beer, August (1825–1863), German physicist. Discovered Beer's law of light absorption.

Behring, Emil Adolph von (1854–1917), German bacteriologist. Produced diphtheria and tetanus antitoxins; Nobel Prize, 1901.

Békésy, Georg von (1889–1972), Hungarian-born American physicist. Studied hearing processes, especially inner-ear mechanics; Nobel Prize, 1961.

Bell, Alexander Graham (1847–1922), Scottish-born American inventor. Invented the telephone, pho-tophone, graphophone, and one of the earliest gramophones.

Bell, Charles (1774–1842), Scottish anatomist. Discovered that sensory and motor nerves are anatomically and functionally distinct.

Bellman, Richard Ernest (1920–1984), American mathematician. Research in analytic number theory, differential equations, stochastic processes, dynamic programming, and mathematical biosciences; discovered Bellman's principle of optimality.

Benacerraf, Baruj (1920–), American immunologist. Discovered immune-response (Ir) genes that control specific immune responses to thymus-dependent antigens; Nobel Prize, 1980.

Benioff, Hugo (1899–1968), American geophysicist. Investigated earthquakes, particularly through instrumental seismology.

Bentham, George (1800–1884), English botanist. With J. Hooker, wrote *Genera Plantarum*.

Berg, Paul (1926–), American biochemist. Investigated the biochemistry of deoxyribonucleic acid (DNA) and designed a technique for gene splicing; Nobel Prize, 1980.

Bergey, David Hendricks (1860–1937), American bacteriologist. Authority on classification of bacteria.

Bergius, Friedrich (1884–1949), Polish-born German chemist. Developed Bergius process for hydrogenation of coal to a petroleumlike oil; Nobel Prize, 1931.

Bergström, Sune Carl (1916–2004), Swedish biochemist and medical scientist. Studied the metabolism of unsaturated fatty acids and determined the chemical structure of prostaglandins; Nobel Prize, 1982.

Bernard, Claude (1813–1878), French physiologist. Studied digestion; discovered that glycogen is produced by the liver.

Berners-Lee, Tim (1955–), British-born physicist and software engineer. Proposed the World Wide Web, and then invented hypertext markup language (HTML), HyperText Transfer Protocol (HTTP), the Internet addressing scheme (Universal Resource Locator or URL), and the first Web browser.

Bernoulli, Daniel (1700–1782), Swiss mathematician born in the Netherlands. Founder of mathematical physics; worked on hydrodynamics and differential equations; formulated the Bernoulli equation.

Bernoulli, Jacques or Jacob (1654–1705), Swiss mathematician. Contributed to mathematics of curves, calculus, and probability; developed the Bernoulli number.

Bernoulli, Jean or Johann (1667–1748), Swiss mathematician. A founder of calculus of variations; contributed to exponential calculus, complex numbers, geodesics, and trigonometry.

Berthelot, Pierre Eugène Marcellin (1827–1907), French chemist. Founder of thermochemistry; first to synthesize organic compounds; demonstrated nitrogen fixation.

Bertrand, Joseph Louis Francois (1822–1900), French mathematician. Contributed to analysis, differential geometry, and probability theory.

Berzelius, Jons Jakob (1779–1848), Swedish chemist. Discovered the elements cerium, selenium, thorium, and silicon; developed a system for classification and nomenclature of compounds.

Bessel, Friedrich Wilhelm (1784–1846), German astronomer and mathematician. Developed Bessel functions; determined parallax of the star 61 Cygni; postulated existence of Neptune and dark stars.

Bessemer, Henry (1813–1898), English engineer. Invented the Bessemer process, the first method for manufacturing steel on a large scale.

Best, Charles Herbert (1899–1978), Canadian physiologist and medical researcher. Associated with F. G. Banting and J. J. R. Macleod in the discovery of insulin.

Bethe, Hans Albrecht (1906–), German-born American physicist. Formulated the theory of energy production in stars; research on nuclear physics; Nobel Prize, 1967.

Bhabha, Homi Jehangir (1909–1966), Indian physicist. With W. Heitler, developed theory of cascade showers of cosmic rays; observed slowing of decay rate of high-velocity mesons.

Bianchi, Luigi (1856–1928), Italian mathematician. Contributed to differential geometry and study of noneuclidean geometries; discovered Bianchi identity.

Bichat, Marie François Xavier (1771–1802), French anatomist and physiologist. Founder of animal histology; originated the term "tissues," and distinguished 21 types in his particular scheme.

Bieberbach, Ludwig (1886–1982), German mathematician. Research on complex function theory, differential equations, geometry, and algebra; postulated Bieberbach's conjecture.

Bienaymé, Irénée Jules (1796–1878), French mathematician. Studied calculus of probabilities and its application to financial science; with P. L. Chebyshev, discovered Bienaymé-Chebyshev inequality.

Billet, Felix (1808–1882). French physicist, Invented Billet split lens.

Binet, Alfred (1857–1911), French psychologist. Investigated development and measurement of intelligence.

Binnig, Gerd (1947–), German physicist. With H. Rohrer, developed scanning tunneling microscope; Nobel Prize, 1986.

Biot, Jean Baptiste (1774–1862), French mathematician and physicist. Discovered circular polarization of light; invented a polariscope; with D. Brewster, discovered biaxial crystals; helped formulate Biot-Savart law.

Birkhoff, George David (1884–1944), American mathematician. Investigated differential equations, dynamical systems, ergodic theory, mechanics of fluids, and foundations of relativity and quantum mechanics.

Bishop, John Michael (1936–), American virologist and biochemist. With H. Varmus, researched the genetic basis of human cancers; their work led to the identification of over 50 cellular genes that can become oncogenes; Nobel Prize, 1989.

Bjerknes, Vilhelm Fremann Doren (1862–1951), Norwegian physicist. Research on electric waves; originated the polar-front theory in meteorology.

Black, James (1924–), British pharmacologist. Developed the first beta blocker drug, propranolol; also credited with the discovery of another important class of drugs, the H2 antagonists; Nobel Prize, 1988.

Black, Joseph (1728–1799) Scottish physicist and chemist. Established the concepts of latent heat and specific heat, and discovered carbon dioxide.

Blackett, Patrick Maynard Stuart (1897–1974), English physicist. Built an improved cloud chamber used to photograph tracks of a nuclear disintegration and of a cosmic-ray shower; discovered the positron; Nobel Prize, 1948.

Blobel, Günter (1936–), German-born American cell and molecular biologist. Discovered that proteins carry signals that help direct their movement among the organelles of the cell; Nobel Prize, 1999.

Bloch, Felix (1905–1983), Swiss-born American physicist. Discovered a technique for studying magnetism of atomic nuclei in normal matter; Nobel Prize, 1952.

Bloch, Konrad Emil (1912–2000), German-born American biochemist. Traced the transformations of fat and carbohydrate metabolites to cholesterol; Nobel Prize, 1964.

Blodgett, Katharine Burr (1898–1979), American chemical physicist. Studied surface science, and is best know for her work with Irving Langmuir and the development of the Langmuir-Blodgett film.

Bloembergen, Nicholaas (1920–), Netherlands-born American physicist. Contributed to development of maser; made extensive contributions to theoretical and experimental development of nonlinear optics; Nobel Prize, 1981.

Blumberg, Baruch Samuel (1925–), American physician and biologist. Research leading to a test for hepatitis viruses in blood and to an experimental hepatitis vaccine; Nobel Prize, 1976.

Boas, Franz (1858–1942), American anthropologist. Pioneered in physical anthropology; contributed to stratigraphic archeology in Mexico; emphasized importance of linguistic analysis.

Bobillier, Étienne (1798–1840), French mathematician and physicist. Contributed to geometry and statics; discovered Bobillier's law.

Bode, Johann Elert (1747–1826), German astronomer. Prepared a celestial atlas showing about 17,000 stars; formulated Bode's law.

Boerhaave, Hermann (1668–1738), Dutch physician. A great teacher at the University of Leyden; wrote the physiology textbook *Institutiones Medicae*.

Bohm, David (1917–1992), American-born British physicist. Research in quantum theory and new modes of description in physics.

Bohr, Aage (1922–), Danish physicist. With B. R. Mottelson, developed theory which unifies shell and liquid-drop models of the atomic nucleus, and which explains nonspherical nuclei; Nobel Prize, 1975.

Bohr, Niels (1885–1962), Danish physicist. Devised an atomic model; codeveloped the quantum theory, applying it to atomic structure in Bohr's theory; Nobel Prize, 1922.

Boltzmann, Ludwig Eduard (1844–1906), Austrian physicist. An authority on the kinetic theory of gases; demonstrated the Stefan-Boltzmann law of blackbody radiation, Boltzmann's law of energy, and the Boltzmann constant.

Bolyai, János (1802–1860), Hungarian mathematician. Independently of K. F. Gauss and N. I. Lobachevski, originated a system of noneuclidean geometry.

Bolzano, Bernard (1781–1848), Czechoslovakian philosopher, logician, and mathematician. Contributed to theory of real functions; proved Bolzano's theorem and Bolzano-Weierstrass theorem.

Bombieri, Enrico (1940–), Italian mathematician. Made major contributions to the study of prime numbers, partial differential equations and minimal surfaces, univalent functions and the local Bieberbach conjecture, and functions of several complex variables; Fields Medal, 1974.

Bond, George Phillips (1825–1865), American astronomer. Introduced concept of Bond albedo; pioneered astronomical photography.

Boole, George (1815–1864), English mathematician and logician. Developed new system of mathematical logic, which is known as Boolean algebra.

Borcherds, Richard Ewan (1959–), British mathematician. Worked in algebra and geometry; proved the moonshine conjecture, which relates the so-called monster group and elliptical curves, using methods borrowed from string theory in theoretical physics; Fields Medal, 1998.

Borda, Jean Charles (1733–1799), French physicist and mathematician. Introduced Borda mouthpiece; developed instruments for navigation, geodesy, and determination of weights and measures.

Bordet, Jules Jean Baptiste Vincent (1870–1961), Belgian physiologist. Made discoveries in immunology; with O. Gengou, developed the technique of the complement fixation reaction; Nobel Prize. 1919.

Borel, Félix Edouard Émile (1871–1956), French mathematician. Work in infinitesimal calculus and the calculus of probabilities.

Born, Max (1882–1970), German-born British theoretical physicist. Pioneered in the development of quantum mechanics; Nobel Prize, 1954.

Bosch, Carl (1874–1940), German chemist. Developed chemical high-pressure methods, and the Haber-Bosch process for ammonia synthesis; Nobel Prize, 1931.

Bose, Jagadis Chandra (1858–1937), Indian plant physiologist and physicist. Founded the Bose Research Institute in Calcutta; investigated photosynthesis, "nervous mechanism" of plants, and other plant subjects.

Bose, Satyendra Nath (1894–1974), Indian physicist. Originated Bose-Einstein statistics to describe photons.

Bothe, Walter (1891–1957), German physicist. Devised the coincidence method for the investigation of nuclear reactions and cosmic radiation; Nobel Prize, 1954.

Bouguer, Pierre (1698–1758), French geodesist, hydrographer, and physicist. Laid foundations of photometry; discovered Bouguer-Lambert law of light intensity.

Bourdon, Eugène (1808–1884), French inventor. Invented Bourdon pressure gage.

Bourgain, Jean (1954–), Belgian mathematician. Worked in several areas of mathematical analysis, including the geometry of Banach spaces, convexity in high dimensions, harmonic analysis, ergodic theory, and nonlinear partial differential equations; Fields Medal, 1994.

Boussinesq, Joseph Valentin (1842–1929), French mathematical physicist. Research in hydrodynamics; introduced Boussinesq approximation.

Bovet, Daniel (1907–1992), Swiss-born Italian pharmacologist. Research on synthetic compounds that inhibit the action of the vascular system and skeletal muscles; Nobel Prize, 1957.

Bowditch, Nathaniel (1773–1838), American navigator and mathematician. Produced navigation guide; translated and improved P. S. de Laplace's *Mécanique céleste*.

Bowen, Norman Levi (1887–1956), Canadian-born American geologist. Studied physical chemistry of geological processes and phase equilibria of silicates; discovered significance of reaction principle in petrogenesis.

Boyer, Paul D. (1918–), American chemist. Made major contributions toward elucidating the enzymatic mechanism underlying the synthesis of adenosine triphosphate (ATP) by proposing the binding change mechanism; Nobel Prize, 1997.

Boyle, Robert (1627–1691), British physicist and chemist. Conducted experiments on properties of the air pump; his law concerning gases is named for him; advanced the atomistic theory of matter.

Bradley, James (1693–1762), English astronomer. Discovered aberration of light due to the Earth's motion, and nutation of the Earth's axis; prepared astronomical tables and star catalogs.

Bragg, William Henry (1862–1942), English physicist. Codeveloper, with W. L. Bragg, of the x-ray spectrometer; used x-ray diffraction to determine crystal structure; Nobel Prize, 1915.

Bragg, William Lawrence (1890–1971), British physicist. With W. H. Bragg, developed x-ray analysis of the atomic arrangement in crystalline structures; Nobel Prize, 1915.

Brahe, Tycho or Tyge (1546–1601), Danish astronomer. Made painstaking observations of the planetary system; wrote *Astronomiae Instauratae Progymnasmata*.

Brattain, Walter Houser (1902–1987), American physicist. Investigated properties of semiconductors; research on surface properties of solids; Nobel Prize, 1956.

Braun, Karl Ferdinand (1850–1918), German physicist. Research on cathode rays and wireless telegraphy; Nobel Prize, 1909.

Bravais, Auguste (1811–1863), French physicist. Studied relationship between crystal form and structure; derived Bravais lattices.

Breit, Gregory (1899–1981), Russian-born American physicist. Research on quantum theory, quantum electrodynamics, hyperfine structure, and ionosphere.

Brenner, Sydney (1927–), South African-born British molecular biologist. Established the nematode *Caenorhabditis elegans* as an experimental model system for studying genetic regulation of cell division, cell specialization, and organ development in multicellular animals. Also credited with the identification of messenger ribonucleic acid (mRNA). Nobel Prize, 2002.

Breuer, Josef (1842–1925), Austrian neurologist. Evolved abreaction method for treatment of neuroses.

Brewster, David (1781–1868), Scottish physicist. Formulated Brewster's law on polarization of light; codiscoverer, with J. B. Biot, of biaxial crystals.

Brianchon, Charles Julien (1783–1864), French mathematician. Proved Brianchon's theorem.

Bridgman, Percy Williams (1882–1961), American physicist. Worked in high-pressure physics and thermodynamics of liquids; Nobel Prize, 1946.

Briggs, Henry (1561–1631), English mathematician. Prepared logarithmic tables (later known as common logarithms); devised sophisticated interpolation techniques.

Bright, Richard (1789–1858), English physician. Made biochemical study of disease; researched Bright's disease of the kidneys.

Brillouin, Leon (1889–1969), French physicist. With G. Wentzel and H. A. Kramers, developed Wentzel-Kramers-Brillouin method; originated concept of Brillouin zones.

Brillouin, Louis Marcel (1854–1948), French physicist. Work on crystal structure, viscosity of liquids and gases, radiotelegraphy, and relativity.

Brinell, Johann August (1849–1925), Swedish engineer. Invented the Brinell machine to measure the hardness of alloys and metals in terms of the Brinell number.

Brockhouse, Bertram Neville (1918–2003), Canadian physicist. Developed slow neutron spectroscopy technique for studying dynamics of atoms in solids and liquids; Nobel Prize, 1994.

Broglie, Louis Victor de (1892–1987), French physicist. Worked in nuclear physics; first to link wave and corpuscular theory; Nobel Prize, 1929.

Bromwich, Thomas John I'Anson(1875–1929), English mathematician. Showed how the Heaviside calculus could be developed in a manner acceptable to pure mathematicians through use of contour integrals.

Brönsted, Johannes Nicolaus (1879–1947), Danish chemist. Researched kinetic properties of ions, catalysis, and nitramide; formulated the Brönsted theory of acid-base reactions.

Brown, Herbert Charles (1912–), British-born American chemist. Developed methods for chemical synthesis of diborane and organoboranes; Nobel Prize, 1979.

Brown, Michael S. (1941–), American biochemist and geneticist. With Joseph L. Goldstein, discovered low-density lipoprotein receptors and their function in cholesterol metabolism; Nobel Prize, 1985.

Browning, John Moses (1855–1926), American inventor. Invented the Browning machine gun.

Brun, Viggo (1885–1978), Norwegian mathematician. Worked in number theory, introducing what is now known as the Brun's sieve, which made some progress in the resolution of such problems as Goldbach's conjecture and the twin prime problem.

Brunauer, Stephen (1903–1986), Hungarian-born American chemist. Contributed to surface and colloid chemistry; with P. H. Emmett and E. Teller, developed Brunauer-Emmett-Teller equation for surface area determinations.

Brunel, Isambard Kingdom (1806–1859), English engineer. Constructed great bridges in England; designed important steamships.

Buchner, Eduard (1860–1917), German chemist. Studied alcoholic fermentation of sucrose; Nobel Prize, 1907.

Buck, Linda (1947–), American molecular biologist. Recognized along with Richard Axel for pioneering research of the olfactory system, which led to the discovery of the large gene family encoding the different odorant receptors located on the membrane of olfactory receptor cells. Later independent work clarified the olfactory system, from the molecular level to the organization of the cells. Nobel Prize, 2004.

Buckingham, Edgar (1867–1940), American physicist. Worked on thermodynamics and dimensional analysis; derived Buckingham's π theorem.

Buffon, Georges Louis Leclerc, Comte de (1707–1788), French naturalist. Compiled *Histoire Narurelle*, a monumental work on natural history.

Bullen, Keith Edward (1906–1976), Australian applied mathematician. Carried out mathematical studies of earthquake waves; with H. Jeffreys, prepared the Jeffreys-Bullen tables on seismic travel time.

Bunsen, Robert Wilhelm (1811–1899), German chemist. Discovered, with G. R. Kirchhoff, spectrum analysis; invented the Bunsen burner, Bunsen cell, and Bunsen ice calorimeter; formulated law of reciprocity with H. E. Roscoe.

Burbank, Luther (1849–1926), American horticulturist. Experimented on crossing and in-breeding of plant varieties.

Burnet, Frank Macfarlane (1899–1985), Australian immunologist. With P. B. Medawar, studied the body's tolerance of antigenic substances; Nobel Prize, 1960.

Bush, Vannevar (1890–1974), American electrical engineer. Originated the concept of hypertext.

Butenandt, Adolph Friedrich Johann (1903–1995), German chemist. Researched sex hormones; Nobel Prize (declined), 1939.

Buys-Ballot, Christoph Hendrik Didericus (1817–1890), Dutch meteorologist. Devised a system of storm signals; formulated Buys-Ballot's law for determination of wind direction.

Byron, Augusta Ada, Countess of Lovelace (1815–1852), English mathematician. Daughter of the poet Lord Byron; wrote the first program for Charles Babbage's analytical engine; often described as the first computer programmer.

Cailletet, Louis Paul (1832–1913), French chemist. Researched liquefaction of gases; first to obtain liquid oxygen, hydrogen, nitrogen, and air.

Callendar, Hugh Longbourne (1863–1930), English physicist and engineer. Developed platinum resistance thermometer and continuous-flow calorimeter.

Callow, John Michael (1867–1940), English-born American mining engineer and metallurgist. Invented Callow flotation cell and Callow screen.

Calvin, Melvin (1911–1997), American chemist. With J. A. Bassham, traced the path of carbon in photosynthesis; Nobel Prize, 1961.

Cannizzaro, Stanislao (1826–1910), Italian chemist. Promulgated Avogadro's work as related to atomic weights; discovered Cannizzaro's reaction in organic chemistry.

Cantor, Georg (1845–1918), Russian-born German mathematician. Founded set theory; introduced fundamental concepts in topology; worked on the theory and representations of real numbers.

Carathéodory, Constantin (1873–1950), German mathematician. Developed calculus of variations for curves with corners; introduced Carathéodory outer measure; gave mathematical formulation of second law of thermodynamics (Carathéodory's principle).

Cardano, Geronimo, or Jerome Cardan (1501–1576), Italian physician and mathematician. Wrote on algebra, medicine, and astronomy; invented the Cardan shaft.

Carlsson, Arvid (1923–), Swedish pharmacologist. Did research on dopamine, leading to the discovery of its role as a key neurotransmitter in the brain and in the control of movement; the development of L-dopa, a precursor of dopamine, into a drug to treat Parkinson's disease; the elucidation of the mode of action of antipsychotic drugs, which affect synaptic transmission by blocking dopamine receptors; did work (along with that of Paul Greengard and Eric Kandel) leading to the elucidation of the molecular mechanisms involved in slow synaptic transmission in the nervous system; Nobel Prize, 2000.

Carnot, Nicolas Léonard Sadi (1796–1832), French physicist. Formulated Carnot's theorems in thermodynamics.

Carrel, Alexis (1873–1944), French surgeon and biologist. Worked on transplanting organs, suturing blood vessels, treating deep wounds, and prolonging tissue life; Nobel Prize, 1912.

Carrington, Richard Christopher (1826–1875), English astronomer. Investigated motions of sunspots.

Carver, George Washington (1864–1943), American botanist. Did research on industrial uses of the peanut.

Cassegrain, N. (17th century), French physician. Designed the Cassegrain reflecting telescope.

Cassini, Jean Dominique (1625–1712), Italian-born French astronomer. Director of the Paris Observatory; discovered four new satellites of Saturn and the Cassini division in Saturn's ring; conducted pendulum experiments related to the shape of the Earth.

Castigliano, Carlo Alberto (1847–1884), Italian structural engineer. Proved Castigliano's theorem.

Cauchy, Augustin Louis, Baron (1789–1857), French mathematician. Wrote extensively on wave propagation, calculus, and elasticity.

Cavendish, Henry (1731–1810), English physicist and chemist. Determined the density of the Earth and the composition of the atmosphere; studied properties of carbon dioxide and hydrogen.

Cayley, Arthur (1821–1895), English mathematician. Proposed the theory of matrices; developed the theory of invariants and covariants; worked on quantics and the theory of groups.

Cech, Thomas R. (1947–), American chemist. By studying the single-cell organisms *Tetrahymena* and *Thermophila*, discovered that molecules of ribonucleic acid (RNA) have catalytic properties similar to those of enzymes; Nobel Prize, 1989.

Celsius, Anders (1701–1744), Swedish astronomer. Constructed the thermometer using the Celsius (centigrade) scale.

Cerenkov, Pavel Alexeyevich (1904–1990), Soviet physicist. Discovered the Cerenkov effect of radiation; devised the Cerenkov counter for particle detection; Nobel Prize, 1958.

Cerf, Vinton G. (1943–), American computer scientist. Co-invented (with Robert E. Kahn) Transmission Control Protocol/Internet Protocol (TCP/IP).

Cesalpino, Andrea (1519–1603), Italian physician and botanist. First to attempt to classify plants according to characteristics of fruit and seed in his *De Plantis*.

Cesàro, Ernesto (1859–1906), Italian mathematician. Formulated an intrinsic geometry; introduced the Cesàro summation.

Ceva, Giovanni (1647?–1734), Italian mathematician. Formulated a theorem on the concurrency of straight lines passing through the vertices of a triangle.

Chadwick, James (1891–1974), English physicist. Established experimentally the existence of the neutron; Nobel Prize, 1935.

Chain, Ernst Boris (1906–1979), German-born British biochemist. With H. W. Florey, worked on the chemical structure of penicillin and its first clinical trials; Nobel Prize, 1945.

Chamberlain, Owen (1920–), American physicist. With E. G. Segrè, demonstrated the existence of the antiproton; Nobel Prize. 1959.

Chamberlin, Thomas Chrowder (1843–1928), American geologist. Studied the fundamental geology of the solar system.

Chandler, Seth Carlo (1846–1913), American astronomer. Discovered the Chandler wobble.

Chandrasekhar, Subrahmanyan (1910–1995), Indian astrophysicist. Developed a theory of white dwarf stars; Nobel Prize, 1983.

Chaplygin, Sergel Alekseevich (1869–1942), Russian physicist, engineer, and mathematician. Made contributions to fluid mechanics, particularly aerodynamics.

Chapman, Sydney (1888–1970), English mathematician and physicist. Discovered (independently of D. Enskog) gaseous thermal diffusion; studied the daily variations of the geomagnetic field and magnetic storms.

Chaptal, Jean Antoine Claude, Comte de Chanteloup (1756–1832), French chemist. Wrote on technical chemistry; introduced the metric system after the Revolution.

Charcot, Jean Martin (1825–1893), French neurologist. Director of the Salpetrière clinic, where he made systematic clinical studies of chronic nervous disorders, including cerebrospinal disease.

Charles, Jacques Alexandre César (1746–1823), French physicist, chemist, and inventor. Formulated Charles' law, relating gas volume to pressure.

Charpak, Georges (1924–), French physicist. Invented the multiwire proportional chamber, used as a detector in high-energy physics experiments; Nobel Prize, 1992.

Chebyshev, Pafnuti Lvovich (1821–1894), Russian mathematician. Research on convergence of Taylor series, prime numbers, probability theory, quadratic forms, and integral theory.

Chladini, Ernst Florenz Friedrich (1756–1827), German physicist. Discovered Chladini's figures and used them to study vibrations of solid plates.

Christoffel, Elwin Bruno (1829–1900), Swiss mathematician. Worked in higher analysis, geometry, mathematical physics, and geodesy.

Chu, Ching-Wu (1941–), Chinese-born American physicist. Discovered superconductivity at temperatures over 90 K (−298°F) in yttrium-barium-copper-oxygen compounds.

Chu, Steven (1948–), American physicist. Developed a system of opposed laser beams to cool atoms to extremely low temperatures, and a magnetooptical trap to capture them; Nobel Prize, 1997.

Ciechanover, Aaron (1947–), Israeli medical doctor and scientist. Discovered ubiquitin-mediated protein degradation; Nobel Prize, 2004.

Clairaut, Alexis Claude (1713–1765), French mathematician. Studied the shape of the Earth, evolving Clairaut's theorem; made astronomical calculations concerning Halley's comet.

Claisen, Ludwig (1851–1930), German organic chemist. Developed Claisen condensation; contributed to understanding of tautomerism; worked on rearrangement of allyl aryl ethers into phenols.

Clapeyron, Benoit Paul Émile (1799–1864), French engineer. Developed N. L. S. Carnot's concept of a universal function of temperature.

Clarke, Alexander Ross (1828–1914), British geodesist. Worked on the triangulation of the British Isles; proposed Clarke ellipsoids as geodetic standards.

Claude, Albert (1899–1983), American cytologist, born in Luxembourg. Pioneered in applying electron microscopy to cell studies and in using centrifuge to separate cell components; Nobel Prize. 1974.

Clausius, Rudolf Julius Emmanuel (1822–1888), German physicist. A founder of thermodynamics: worked out the Clausius-Clapeyron equation for the universal temperature function.

Clebsch, Rudolf Friedrich Alfred (1833–1872), German mathematician. Contributions to theory of invariants and algebraic geometry.

Cockcroft, John Douglas (1897–1967), English physicist. With E. T. S. Walton, split nuclei by bombarding them with accelerated protons.

Cohen, Paul Joseph (1934–), American mathematician. Proved that the axiom of choice is independent of the other axioms of set theory, and that the continuum hypothesis is independent of the axiom of choice, a result with profound implications for the foundations of mathematics; Fields Medal, 1966.

Cohen, Stanley (1922–), American biochemist. With R. Levi-Montalcini, made landmark studies of nerve growth factor and its functions; Nobel Prize, 1986.

Cohen-Tannoudji, Claude (1933–), French physicist. Helped develop methods to cool and trap atoms with laser light, and explained how atoms could be cooled to temperatures lower than the previously calculated theoretical limits; Nobel Prize, 1997.

Cohn, Ferdinand Julius (1828–1898), German botanist. A founder of bacteriology; did research in plant pathology; first to classify bacteria according to genus and species.

Cole, Kenneth Stewart (1900–1984), American biophysicist. Research on structure and function of living cell membranes and nerve membranes in particular, concentrating on electrical approach; with brother, R. H. Cole, introduced Cole-Cole plot of dielectric behavior.

Cole, Robert Hugh (1914–1990), American chemist and physicist. Research on dielectric properties of matter and intermolecular forces; with brother, K. S. Cole, introduced Cole-Cole plot of dielectric behavior.

Collins, Samuel Cornette (1898–1984), American engineer. Invented Collins helium liquefier.

Compton, Arthur Holly (1892–1962), American physicist. Discovered the Compton effect of x-rays; studied cosmic rays; helped develop the atomic bomb; Nobel Prize, 1927.

Conant, James Bryant (1893–1978), American chemist. Researched free radicals, hemoglobin, and chlorophyll; contributed to atomic energy development.

Condon, Edward Uhler (1902–1974). American physicist. Contributed to the Franck-Condon principle, by extending and giving quantum-mechanical treatment to J. Franck's concept of nuclear motion to molecules in transition from one energy level to another.

Connes, Alain (1947–), French mathematician. Did fundamental work on the theory and application of operator algebras, particularly von Neumann algebras; Fields Medal, 1982.

Coolidge, William David (1873–1975), American physicist. Invented Coolidge tube; discovered method for making tungsten strong and ductile.

Cooper, Leon N. (1930–), American physicist. Showed that electrons could form Cooper pairs; with J. R. Schrieffer and J. Bardeen. formulated a theory of superconductivity; Nobel Prize, 1972.

Copernicus, Nicolaus (1473–1543), Polish (or Prussian) astronomer. Proposed the Copernican system, with the Sun as the center of planetary orbits.

Corey, Elias James (1928–), American chemist. Developed theories and methods of organic chemical synthesis that have made possible the production of a wide variety of complex biologically active substances and useful chemicals; Nobel Prize, 1990.

Cori, Carl Ferdinand (1896–1984), and **Cori, Gerty Theresa Radnitz** (1896–1957). Czechoslovakian-born American biochemists. Discovered the enzymatic mechanism of glucose-glycogen interconversion and the effects of hormones on this mechanism; Nobel Prize, 1947.

Coriolis, Gaspard Gustave de (1792–1843), French physicist. Contributed to theoretical and applied mechanics; clarified and supplied concepts of work and kinetic energy; derived Coriolis acceleration.

Cormack, Allan MacLeod (1924–1998), American physicist. Contributed to the development of computerized axial tomography; Nobel Prize, 1979.

Cornell, Eric Allin (1961–), American physicist. With C. E. Wieman, succeeded for the first time in producing Bose-Einstein condensates in a dilute gas of alkali (rubidium) atoms, and carried out fundamental studies of their properties, including studies of collective excitations and vortex formation in condensates; Nobel Prize, 2001.

Corner, George Washington (1889–1981), American medical biologist. Contributed to understanding of anatomical details of menstrual cycle and functions of estrogen and progesterone.

Cornforth, John Warcup (1917–), Australian-born British chemist. Investigated stereochemistry of enzyme-catalyzed reactions; Nobel Prize, 1975.

Cornu, Marie Alfred (1841–1902), French physicist. Used Cornu spiral for determination of intensities in interference phenomena.

Coster, Dirk (1889–1950), Dutch physicist. Work in x-ray spectroscopy; with G. von Hevesy, discovered hafnium; with R. Kronig, discovered Coster-Kronig transitions.

Cottreli, Frederick Gardner (1877–1948), American chemist. Invented the Cottrell process for precipitation of particles from gas; researched nitrogen fixation, liquefaction of gases, and recovery of helium.

Coulomb, Charles Augustin de (1736–1806), French physicist. Formulated Coulomb's law of electric charges.

Courant, Richard (1888–1972), German-born American mathematician. Research in geometric function theory, differential equations of mathematical physics, and transition by limiting processes from finite difference equations to differential equations.

Cournand, André Frédéric (1895–1988), French-born American physician. Studied normal and abnormal human cardiovascular and pulmonary functions; Nobel Prize, 1956.

Cowan, Clyde L., Jr. (1919–1974), American physicist. With F. Reines, made first detection of the neutrino, a fundamental particle.

Crafts, James Mason (1839–1917), American chemist. With C. Friedel, discovered the Freidel-Crafts reaction, wherein anhydrous aluminum chloride acts as a catalyst.

Cram, Donald J. (1919–2001), American chemist. Expanded the field of crown ether chemistry by using crown ethers to synthesize structures that mimic the action of biological molecules; Nobel Prize, 1987.

Cramer, Gabriel (1704–1752), Swiss mathematician. Contributed to Cramer's rule for solving linear equations.

Crick, Francis Harry Compton (1916–2004), English molecular biologist. With J. D. Watson, proposed a double-helix structure for the deoxyribo-nucleic acid molecule; Nobel Prize, 1962.

Cronin, James Watson (1931–), American physicist. Collaborated with V. L. Fitch on experiment showing that the principle of time-reversal invariance is violated in the decay of neutral K mesons; Nobel Prize, 1980.

Cronstedt, Axel Fredrik, Baron (1722–1765), Swedish mineralogist. Discovered nickel; developed a chemical classification system for minerals.

Crookes, William (1832–1919), English physicist and chemist. Invented Crookes tube to study electrical discharges in high vacuum, and a radiometer; discovered thallium.

Crutzen, Paul J. (1933–), Dutch chemist. Demonstrated that nitrogen oxides react catalytically with ozone, thus accelerating the rate of reduction of the ozone layer; Nobel Prize, 1995.

Curie, Marie, born Marya Sklodowska (1867–1934), Polish physical chemist in France. Explored nature of radioactivity; codiscoverer of radium, and first to separate polonium; Nobel Prize, 1903 and 1911.

Curie, Pierre (1859–1906), French chemist and physicist. Codiscoverer of radium; formulated the Curie point, relating magnetic properties and temperature; discovered the piezoelectric effect; Nobel Prize, 1903.

Curl, Robert F., Jr. (1933–), American chemist. Made major contributions toward the discovery of fullerenes; Nobel Prize, 1996.

Cushing, Harvey (1869–1930), American surgeon. Innovator in neurosurgical techniques; research on function and diseases of the pituitary gland.

Cuvier, Georges Léopold Chrétien Frédéric Dagobert, Baron (1769–1838), French naturalist. Made a detailed classification of the animal kingdom; wrote on comparative anatomy.

Daguerre, Louis Jacques Mandé (1787–1851), French inventor. Invented the daguerreotype photographic process.

Dale, Henry Hallett (1875–1968), British pharmacologist and physiologist. Isolated acetylcholine and recognized its effect to be similar to that brought about by parasympathetic nerves; Nobel Prize, 1936.

Dalén, Nils Gustaf (1869–1937), Swedish physicist. Invented automatic gas lighting for unsupervised lighthouses and railroad signals; Nobel Prize, 1912.

Dalitz, Richard Henry (1925–), Australian-born British theoretical physicist. Research on properties of mesons and baryons and nuclear interactions of the lambda hyperon; proposed models for elementary particles; introduced the Dalitz plot.

Dalton, John (1766–1844), English chemist and physicist. Proposed the atomic theory of chemical reactions; developed the law of partial pressures of gases; studied color-blindness.

Dam, Carl Peter Henrik (1895–1976), Danish biochemist and nutritionist. Discovered vitamin K and studied its role in human hemorrhagic disease; Nobel Prize, 1943.

Danckwerts, Peter Victor (1916–1984), British chemical engineer. Proposed the surface-renewal model of liquids.

Daniell, John Frederic (1790–1845), English physicist and chemist. Invented the Daniell cell.

Darwin, Charles Robert (1809–1882), English naturalist. Proposed far-reaching theory of evolution of species and theory of natural selection in his *Origin of Species*.

Darwin, George Howard (1845–1912), English mathematician and astronomer. Applied detailed dynamical analysis to cosmological and geological problems.

Dausset, Jean (1916–), French biologist and medical scientist. Studied antigen in human leukocytes and their role in transplant acceptance or rejections; Nobel Prize, 1980.

Davis, Raymond, Jr. (1914–), American physicist. Developed pioneering experiments to detect solar neutrinos, and observed deficit in their number. Nobel Prize, 2002.

Davisson, Clinton Joseph (1881–1958), American physicist. Studied magnetism, radiant energy, and electricity; independent of G. P. Thomson, discovered electron diffraction by crystals; Nobel Prize, 1937.

Davy, Humphry (1778–1829), English chemist. Discovered potassium and sodium; invented the Davy safety lamp for use in coal mines; proposed theoretical explanations of electrolysis and voltaic action.

Debye, Peter Joseph William (1884–1966), American physical chemist born in the Netherlands. Worked on dipole moments and the diffraction of x-rays in gases; formulated Debye-Hückel theory on the behavior of strong electrolytes; Nobel Prize, 1936.

Dedekind, Julius Wilhelm Richard (1831–1916), German mathematician. Worked in number theory and analysis, particularly with algebraic integers, algebraic functions, and ideals; defined real numbers by Dedekind cuts.

de Duve, Christian René (1917–), Belgian biochemist and cytologist. Refined centrifuge technique for studying cell components; discovered lysosomes; Nobel Prize, 1974.

De Forest, Lee (1873–1961), American inventor. Pioneer in radio technology; invented audio amplifier and the four-electrode valve; incorporated the grid into the thermionic valve.

de Gennes, Pierre-Gilles (1932–), French physicist. Applied physical principles to the study of complex systems, including liquid crystals and polymers; Nobel Prize, 1991.

de Haas, Wander Johannes (1878–1960), Dutch physicist. Demonstrated the Einstein-de Haas effect; worked on production of extremely low temperatures by adiabatic demagnetization; with P. Van Alphen, discovered de Haas-Van Alphen effect.

Dehmelt, Hans Georg (1922–), German-born American physicist. Developed the Penning trap, which uses magnetic and electric fields to hold ions in a small volume; used the traps to isolate a single electron and carry out extremely accurate measurements of atomic properties; Nobel Prize, 1989.

Deisenhofer, Johann (1943–), German chemist. With R. Huber and M. Hartmut, elucidated the structure of a bacterial protein that performs photosynthesis; Nobel Prize, 1988.

Delbruck, Max (1906–1981), German-born American biologist. Pioneered in molecular biology; research on bacterial viruses; Nobel Prize, 1969.

Deligne, Pierre René (1944–), Belgian mathematician. Solved three conjectures of A. Weil concerning generalizations of the Riemann hypothesis to finite fields—work which brought together algebraic geometry and algebraic number theory; Fields Medal, 1978.

Demoivre, Abraham (1667–1754), French-born English mathematician. Originated two theorems on expansions of trigonometrical expansions; proposed methods to approximate functions of large numbers, and the concept of the normal distribution curve.

De Morgan, Augustus (1806–1871), English mathematician. Wrote textbooks and treatises on arithmetic, algebra, and trigonometry; formulated the De Morgan theorem.

Desargues, Gérard (1593–1662), French mathematician. A founder of modern geometry; proposed the theory of involution and transversals.

Descartes, René (1596–1650), French mathematician. Originated cartesian, or coordinate, geometry.

de Sitter, Willem (1872–1934), Dutch astronomer. Worked on the application of Einstein's theory to the problems of the universe; computed the size of the universe.

De Vries, Hugo (1848–1935), Dutch botanist. Formulated the mutation theory of evolution.

Dewar, James (1842–1923), British chemist. Made pioneering studies of matter at low temperatures; first to liquefy hydrogen; invented the Dewar vacuum flask.

Dick, George Frederick (1881–1967), American physician and bacteriologist. Isolated scarlet fever streptococci, developed scarlet fever streptococcus antitoxin, and developed Dick test.

Dicke, Robert Henry (1916–1997), American physicist. Developed new relativistic theory of gravitation with C. Brans; investigated cosmic blackbody radiation; worked on development of radar.

Diels, Otto Paul Hermann (1876–1954), German chemist. Codiscoverer of the Diels-Alder reaction (diene synthesis); worked on sterol chemistry; discovered carbon suboxide; Nobel Prize, 1950.

Diesel, Rudolf (1858–1913), German inventor. Designed and built the diesel engine.

Deisenhofer, Johann (1943–), German chemist. With R. Huber and M. Hartmut, elucidated the structure of a bacterial protein that performs photosynthesis; Nobel Prize, 1988.

Diocles (2d century B.C.), Greek mathematician. Contributions to theory of conics and geometry.

Diophantus of Alexandria (3d century), Greek mathematician. Known as the father of algebra; the first to use conventional algebraic notation.

Dirac, Paul Adrien Maurice (1902–1984), English physicist. Worked in quantum mechanics; his theory of negative-energy holes predicted existence of the positron; Nobel Prize, 1933.

Dirichlet, Peter Gustave Lejeuné (1805–1859), German mathematician. Applied higher analysis to the theory of numbers; work on definite integrals.

Djerassi, Carl (1923–), Austrian-born, American chemist. Synthesized the first oral contraceptive.

Dobzhansky, Theodosius (1900–1975), Russian-born American biologist. Elucidated the mechanisms of heredity and variation through studies of *Drosophila*.

Doherty, Peter C. (1940–), Australian-born American immunologist. Collaborated with R. M. Zinkerngagel in the discovery of specificity of cell-mediated immune defense; Nobel Prize, 1996.

Dolsy, Edward Adelbert (1893–1986), American biochemist. Isolated pure crystalline compounds important to human health, such as sex hormones and vitamins; Nobel Prize, 1943.

Domagk, Gerhard (1895–1964), German biochemist. Discovered sulfamidocrysoidin, the first synthetic microbial of broad clinical usefulness. Nobel Prize (declined), 1939.

Donaldson, Simon Kirwan (1957–), British mathematician. Worked on topology of four-manifolds and showed that there exist exotic four-spaces, that is, four-dimensional differentiable manifolds that are topologically but not differentiably equivalent to the standard Euclidean four-space; Fields Medal, 1986.

Donati, Giovanni Battista (1826–1873), Italian astronomer. Studied stellar spectra; discovered six comets.

Donnan, Frederick George (1870–1956), Irish chemist born in Ceylon. Research in chemical kinetics; originated the Donnan theory of membrane equilibrium.

Doppler, Christian Johann (1803–1853), Austrian physicist and mathematician. Formulated Doppler's principle, relating the frequency of wave motion to velocity; described the Doppler effect.

Douglas, Jesse (1897–1965), American mathematician. Solved the Plateau problem (the problem of determining the existence of a minimal surface with a given space curve as its boundary) about the same time as T. Radó and studied generalizations of this problem; Fields Medal, 1936.

Drake, Frank Donald (1930–), American astronomer. Research on solar system, 21-centimeter radio line, search for extraterrestrial intelligence (introduced Drake equation), and radio telescope development.

Draper, Henry (1837–1882), American scientist. Research in spectroscopy; the Draper catalog is named in his honor.

Drinfeld, Vladimir Gershonovich (1954–), Ukrainian mathematician. Worked in algebraic geometry, number theory, and the theory of quantum groups; proved a special case of the Langlands conjecture; Fields Medal, 1990.

Drude, Paul Karl Ludwig (1863–1906), German physicist. Attempted to correlate and account for optical, electrical, thermal, and chemical properties of substances; developed theory of properties of metals based on free electrons treated as a gas.

Duane, William (1872–1935), American physicist and radiologist. Developed treatment of cancer by radioisotopes and x-rays; with F. L. Hunt, discovered Duane-Hunt law of x-rays.

Du Bois-Reymond, Emil (1818–1896), German physiologist. Pioneer work in electrical properties of living tissues, especially nerves.

DuBridge, Lee Alvin (1901–1994), American physicist. Developed Fowler-DuBridge theory of photoelectric emission.

Ducrey, Augusto (1860–1940), Italian dermatologist. Discovered *Hemophilus ducreyi*, the agent of chancroid.

Dufay, Charles François de Cisternay (1698–1739), French chemist. Discovered positive and negative types of electricity.

Dulbecco, Renato (1914–), Italian-born American virologist. Developed techniques for studying animal viruses; investigated interaction between deoxyribonucleic acid tumor viruses and genetic material; Nobel Prize, 1975.

Dulong, Pierre Louis (1785–1838), French chemist and physicist. With A. T. Petit, formulated the law of the constancy of atomic heats; developed the Dulong formula for heat value of fuels.

Dumas, Jean Baptiste André (1800–1884), French chemist. Research on organic compounds; determined many atomic weights.

Dürer, Albrecht (1471–1528), German painter, graphic artist, and mathematician. Work on scientific perspective and mathematical proportion.

du Vigneaud, Vincent (1901–1978), American biochemist. Synthesized a polypeptide hormone, oxytocin: worked on other biologically important sulfur compounds; Nobel Prize, 1955.

Eccles, John Carew (1903–1997), Australian physiologist. Elucidated the action of nerve impulses across zones of close contact between nerve cells; Nobel Prize, 1963.

Eddington, Arthur Stanley (1882–1944), English astronomer and writer. Theoretical research on stellar movements and internal makeup of stars; wrote on theory of relativity.

Edelman, Gerald Maurice (1929–), American biochemist. Worked to determine chemical structure of immunoglobulins; Nobel Prize, 1972.

Edison, Thomas Alva (1847–1931), American electrician and inventor. Invented the gramophone, carbon transmitter for the telephone, incandescent electric lamp, moving pictures, and the diplex method of telegraphy.

Ehrenfest, Paul (1880–1933), Austrian-born Dutch theoretical physicist. Contributed to statistical mechanics and quantum mechanics; developed Ehrenfest's principle; proved Ehrenfest's theorem.

Ehrlich, Paul (1854–1915), German bacteriologist. Research in chemotherapy, notably the discovery of Salvarsan for treatment of syphilis; pioneered in the study of hematology and immunity; Nobel Prize, 1908.

Eigen, Manfred (1927–), German chemist. Devised relaxation techniques to study high-speed chemical reactions; Nobel Prize, 1967.

Eijkman, Christiaan (1858–1930), Dutch physician. Studied dietary deficiency disease, in particular beriberi; Nobel Prize, 1929.

Einstein, Albert (1879–1955), German-born American physicist. Proposed the theory of relativity; extended the application of quantum theory; Nobel Prize, 1921.

Einthoven, Willem (1860–1927), Dutch physiologist born in Java. Used the string galvanometer to record electrical activity of the heart, thereby inventing the electrocardiograph; Nobel Prize, 1924.

Elion, Gertrude Belle (1918–1999), American biochemist. With G. H. Hitchings, pioneered research that led them to the development of drugs for the treatment of leukemia, malaria, gout, herpes, bacterial and fungal infections, and autoimmune diseases and organ-transplant rejection; Nobel Prize, 1988.

Elsasser, Walter Maurice (1904–1991), German-born American geophysicist. Formulated the dynamo theory of the Earth's permanent terrestrial magnetic force.

Elster, Johann Philipp Ludwig Julius (1854–1920), German experimental physicist. With H. F. Geitel, studied atmospheric electricity, radioactivity, and photoelectricity, and invented photocell.

Emmett, Paul Hugh (1900–1985), American chemist. Worked on catalysts for ammonia synthesis and the water-gas conversion reaction; with S. Brunauer and E. Teller, formulated Brunauer-Emmett-Teller equation for surface area determinations.

Encke, Johann Franz (1791–1865), German astronomer. Determined period of revolution of Encke's comet, discovered by J. L. Pons; measured the distance of the Sun from the Earth.

Enders, John Franklin (1897–1985), American microbiologist. With F. C. Robbins and T. H. Weller, discovered the capacity of poliomyelitis virus to grow in various tissue cultures; Nobel Prize, 1954.

Enskog, David (1884–1947), Swedish physicist. With S. Chapman, developed the Chapman-Enskog theory for solving the Boltzmann transport equation.

Eötvös, Roland, Baron (1848–1919), Hungarian physicist. Research on gravitation and terrestrial magnetism; formulated a law which relates surface tension to temperature of liquids; designed the Eötvös torsion balance.

Erasistratus (3d century B.C.), Greek physician and anatomist. Founder of physiology; distinguished between the cerebrum and cerebellum, and sensory and motor nerves.

Eratosthenes (3d century B.C.), Greek astronomer. Suggested an extra day in the calendar every fourth year; made a determination of the size of the Earth; measured obliquity of the ecliptic.

Erdös, Paul (1913–1996), Hungarian mathematician. Did wide-ranging work in algebra, analysis, combinatorial theory, geometry, topology, number theory, and graph theory; with A. Selberg, gave an elementary proof of the prime number theorem.

Erlanger, Joseph (1874–1965), American physiologist. With H. S. Gasser, created new methods for amplifying and recording electrical impulses in nerves; research on the function of the synapse; Nobel Prize, 1944.

Erlenmeyer, Richard August Carl Emil (1825–1909), German organic chemist. Research on synthesis and constitution of aliphatic compounds; introduced modern structural notation; invented Erlenmeyer flask.

Ernst, Richard R. (1933–). Swiss chemist. Developed methods that transformed nuclear magnetic resonance (NMR) spectroscopy from a tool with a narrow application to a key analytical technique in chemistry as well as many other fields: Nobel Prize, 1991.

Esaki, Leo (1925–), Japanese physicist. Discovered a new negative-resistance characteristic in semiconductor *pn* junctions, leading to the discovery of the tunnel, or Esaki. diode; Nobel Prize, 1973.

Euclid (ca. 330-ca. 275 B.C.), Greek mathematician. Wrote geometry textbooks; euclidean geometry is named after him.

Eudoxus of Cnidus (ca. 408-ca. 355 B.C.). Greek astronomer and mathematician. Expounded theory of motion of planets based on homocentric spheres; developed theory of proportions and methods of measuring areas and volumes of geometrical figures.

Euler, Leonhard (1707–1783), Swiss mathematician. Contributed to algebraic series and differential and integral calculus; realized the significance of coefficients (Euler numbers) of certain trigonometrical expansions.

Euler-Chelpin, Hans Karl August Simon von (1873–1964), German-Swedish chemist. Research on enzyme action and fermentation of sugars; Nobel Prize, 1929.

Ewald, Paul Peter (1888–1985), German-born. American physicist. Developed dynamic theory of x-ray interference in crystals.

Ewing, William Maurice (1906–1974), American geophysicist. Made fundamental contributions to seismology, geodesy, oceanography, and submarine geology.

Eyring, Henry (1901–1981), Mexican-born American chemist. Pioneered in the application of quantum and statistical mechanics to chemistry; conceived the theory of absolute reaction rates and the significant structures theory of liquids.

Fabricius, Hieronymus, or Girolamo Fabrizio (ca. 1533–1619), Italian anatomist. Made painstaking descriptions of valves in veins; did comparative research in animal embryology.

Fabry, Charles (1867–1945), French physicist. With A. Pérot, invented Fabry-Perot interferometer; experimentally verified Doppler broadening and Doppler effect.

Fahrenheit, Gabriel Daniel (1686–1736), German physicist. Constructed thermometers; invented the Fahrenheit temperature scale.

Fallopio, Gabriele (1523–1562), Italian anatomist. Discovered Fallopian tubes; gave first clear description of organs of inner and middle ear.

Faltings, Gerd (1954–), German mathematician. Used methods of arithmetic algebraic geometry to prove the Mordell conjecture, which states that there are only finitely many rational points on a curve of genus greater than 1; this was a step toward the later proof of Fermat's last theorem by A. Wiles; Fields Medal, 1986.

Fanning, John Thomas (1837–1911), American civil engineer. Designed water works and water supply systems.

Faraday, Michael (1791–1867), English chemist and physicist. Discovered electromagnetic induction; formulated two laws of electrolysis; invented the dynamo.

Fechner, Gustav Theodor (1801–1887), German psychologist. Founded psychophysics; developed the Fechner law concerning intensity of sensation produced by a stimulus.

Fefferman, Charles Louis (1949–), American mathematician. Worked in Fourier analysis, partial differential equations, and the theory of functions of several complex variables; discovered the dual of the Hardy space H^1; Fields Medal, 1978.

Feit, Walter (1930–2004), Austrian-born American mathematician. Worked in group theory; with J. G. Thompson, proved that all noncyclic finite simple groups have even order.

Fenn, John B. (1917–), American chemist. Developed soft desorption ionization method for mass spectrometric analyses of biological macromolecules; Nobel Prize, 2002.

Fermat, Pierre de (1601–1665), French mathematician. Founder of the modern theory of numbers; originated Fermat's last theorem, and Fermat's principle in optics.

Fermi, Enrico (1901–1954), Italian-born American physicist. Research on producing radioactive isotopes by neutron bombardment; directed construction of the first atomic pile; Nobel Prize, 1938.

Feynman, Richard Phillips (1918–1988), American physicist. Proposed a theory to eliminate difficulties that had arisen in the study of the interaction of electrons, positrons, and radiation; Nobel Prize, 1965.

Fibiger, Johannes Andreas Grib (1867–1928), Danish pathologist. First to produce cancer experimentally; Nobel Prize, 1926.

Finsen, Niels Ryberg (1860–1904), Danish physician. Originated ultraviolet light therapy for certain diseases; Nobel Prize, 1903.

Fischer, Edmond H. (1920–), American biochemist. With E. G. Krebs, discovered phosphorylation processes that play a critical role in cell-protein regulation; they isolated the first protein kinase, a class of enzymes that transfer phosphate from adenosinetriphosphate to proteins; Nobel Prize, 1992.

Fischer, Emil Hermann (1852–1919), German chemist. Synthesized many natural substances, including purines, D-glucose and other sugars, and the first nucleotide; studied polypeptides and proteins; Nobel Prize, 1902.

Fischer, Ernst Otto (1918–), German chemist. Studied how metals and organic molecules combine to form unique molecules with sandwichlike structures; Nobel Prize, 1973.

Fischer, Hans (1881–1945), German organic chemist. Investigated and synthesized pyrrole pigments; studied structure of chlorophylls; Nobel Prize, 1930.

Fisher, Ronald Aylmer (1890–1962), English geneticist and statistician. Developed statistical techniques for analysis of variance, and for use and validation of small samples; developed theory of the evolution of dominance.

Fitch, Val Logsdon (1923–), American physicist. Collaborated with J. W. Cronin on experiment showing that the principle of time-reversal invariance is violated in the decay of neutral K mesons; Nobel Prize, 1980.

FitzGerald, George Francis (1851–1901), Irish physicist. Proposed Lorentz-FitzGerald contraction, relating to a material moving through an electromagnetic fieid.

Fizeau, Armand Hippolyte Louis (1819–1896), French physicist. First to accurately measure the velocity of light; conducted experiments on the velocity of electricity, use of light wavelength to measure length, and measurement of diameter of stars through the method of interference.

Flamsteed, John (1646–1719), English astronomer. Made a trustworthy catalog of stars; invented conical projection in mapmaking.

Fleming, Alexander (1881–1955), British bacteriologist. Discovered lysozyme and penicillin; Nobel Prize, 1945.

Fleming, John Ambrose (1849–1945), English electrical engineer. Invented the thermionic valve; contributed to widespread application of electric lighting and heating.

Florey, Howard Walter (1898–1968), British pathologist born in Australia. Contributed, with E. B. Chain, to development of penicillin as a chemotherapeutic agent; Nobel Prize, 1945.

Flory, Paul John (1910–1985), American physical chemist. Developed analytic techniques to explore properties and molecular structures of long-chain molecules; Nobel Prize, 1974.

Fock (Fok), Vladimir Alexandrovitch (1898–1974), Soviet theoretical physicist. Contributions to quantum electrodynamics, quantum field theory, electromagnetic diffraction and propagation, and general relativity; developed Hartree-Fock approximation of wave functions.

Forbush, Scott Ellsworth (1904–1984), American geophysicist. Discovered the worldwide decrease in cosmic-ray intensity associated with some magnetic storms.

Forssmann, Werner Theodor Otto (1904–1979), German physician. Developed the technique of cardiac catheterization; Nobel Prize, 1956.

Foucault, Jean Bernard Léon (1819–1868), French physicist. Accurately determined the velocity of light; constructed the Foucault pendulum and the Foucault prism; determined experimentally the rotation of the Earth.

Fourier, Jean Baptiste Joseph, Baron (1768–1830), French geometrician and physicist. Proposed the Fourier series on arbitrary functions; formulated the law of heat propagation.

Fowler, Ralph Howard (1889–1944), English physicist. Applied statistical mechanics to matter at high temperatures and high pressures; explained structure of white dwarf stars; with E. A. Guggenheim, R. F. Peierls, and others, developed Ising model.

Fowler, William Alfred (1911–1995), American physicist. Fundamental contributions to understanding of nuclear reactions that generate the energy of stars and synthesize the elements of the universe; Nobel Prize, 1983.

Franck, James (1882–1964), German physicist. With G. Hertz, studied energy transfer in collisions of molecules; formulated Franck-Condon principle of transition from one energy state to another; Nobel Prize, 1925.

Frank, llya Milkhallovich (1908–1990), Soviet physicist. With I. Y. Tamm, proposed a theoretical interpretation of Cerenkov radiation; Nobel Prize, 1958.

Franklin, Benjamin (1706–1790), American physicist, oceanographer, meteorologist, and inventor. Formulated a theory of general electrical “action”; introduced principle of conservation of charge; showed that lightning is an electrical phenomenon; invented lighting rod.

Fraunhofer, Joseph von (1787–1826), German optician and physicist. First to study the dark lines in the solar spectrum (Fraunhofer lines); invented a heliometer; improved the spectroscope.

Fredholm, Eric Ivar (1866–1927), Swedish mathematician. Developed the theory of integral equations (Fredholm equations).

Freedman, Michael Hartley (1951–), American mathematician. Developed new methods for topological analysis of four-manifolds and applied them to prove the Poincaré conjecture for dimension 4; Fields Medal, 1986.

Frenet, Jean Frédéric (1816–1900), French mathematician. Helped to develop Frenet-Serret formulas.

Frenkel, Yakov llyich (1894–1954), Soviet physicist. Pioneered in modern atomic theory of solids; developed quantum-mechanical explanations for electron mean free path in metals, and for paramagnetism and ferromagnetism; postulated excitons, Frenkel excitons, and Frenkel defects.

Fresnel, Augustin Jean (1788–1827), French physicist. Investigated effects (Fresnel’s fringes) due to the interference of light; developed a wave theory of light; originated Fresnel’s reflection formula.

Freud, Sigmund (1856–1939), Austrian psychoanalyst. Founder of psychoanalysis, with emphasis on dream interpretation and free association; developed a theory of personality involving id, ego, and superego, and stressing importance of the libido.

Friedel, Charles (1832–1899), French chemist and mineralogist. With J. M. Crafts, described the Friedel-Crafts reaction; work on artificial production of minerals; studied crystals, ketones, and aldehydes.

Friedman, Jerome Isaac (1930–), American physicist. Collaborated in experiments that demonstrated that protons, neutrons, and similar particles are made up of quarks; Nobel Prize, 1990.

Frisch, Karl von (1886–1982), Austrian zoologist. Discovered means by which bees communicate information about the distance and direction of food; Nobel Prize, 1973.

Frobenius, Georg Ferdinand (1849–1917), German mathematician. Developed representation theory of finite groups and method for solving linear homogeneous ordinary differential equations.

Froude, William (1810–1879), English engineer. Discovered the Froude law of comparison, concerning the towing of an object in a liquid.

Fubini, Guido (1879–1943), Italian mathematician. Worked in algebra, analysis, and differential projective geometry; proved Fubini’s theorem.

Fukui, Kenichi (1918–1998), Japanese chemist. Developed frontier orbital theory, a quantum-mechanical model useful in prediction of the combinative properties of molecules; Nobel Prize, 1981.

Fuller, R. Buckminster (1895–1983), American engineer and architect. Designed geodesic dome; the carbon molecular form C_{60} was named buckminsterfullerene because of its structured resemblance to the geodesic dome, and the name fullerene was given to any closed-cage molecule containing an even number of carbon atoms.

Furchgott, Robert F. (1916–), American pharmacologist. Discovered endothelium-derived relaxing factor (EDRF), a signaling molecule in the cardiovascular system that makes vascular smooth muscle cells relax (Louis J. Ignarro, working independently and with Furchgott, later concluded that EDRF was nitric oxide); Nobel Prize, 1998.

Gabor, Dennis (1900–1979), Hungarian-born British physicist and engineer. Invented holography; Nobel Prize, 1971.

Gajdusek, Daniel Carleton (1923–), American physician and virologist. Discovered causal virus and transmission mechanism of kuru; Nobel Prize, 1976.

Galen (2d century), Greek physician and medical writer. Wrote treatises long used as textbooks; experimented on animal nervous systems; made anatomical descriptions of structure and functions of body parts.

Galileo Galilei (1564–1642), Italian astronomer. First to use the telescope for observational purposes; made many discoveries related to the planets and the Sun; did theoretical work on classical physics.

Galois, Evariste (1811–1832), French mathematician. Developed Galois theory of polynomials.

Gamow, George (1904–1968), Russian-born American physicist. Made theoretical contributions to nuclear physics, astronomy, and biology; with E. Teller, formulated the selection rule for beta emission: proposed theoretically the genetic code.

Garvey, Gerald Thomas (1935–), American physicist. Research in experimental nuclear physics, particularly nuclear reactions, isobaric spin studies, and weak interactions in nuclear systems.

Gasser, Herbert Spencer (1888–1963), American physiologist. With J. Erlanger, provided a new method for recording electrical impulses of nerves; studied functions of nerve fibers; Nobel Prize, 1944.

Gatterman, Friedrich August Ludwig (1860–1920), German chemist. Originated Gatterman-Koch synthesis of aldehydes; isolated and analyzed nitrogen trichloride; synthesized aromatic carboxylic acids, thionaphthalene, and thioanilide.

Gauss, Karl Friedrich (1777–1855), German mathematician, astronomer, and physicist. Formulated the Gauss theorem in the mathematics of electricity; made many contributions to pure and applied mathematics; determined orbits of planets and comets from observational data.

Gay-Lussac, Joseph Louis (1778–1850), French chemist and physicist. Discovered the law of expansion of gases by heat, and the law of combining volumes of gases; studied chemistry of iodine and cyanogen.

Geiger, Hans Wilhelm (1882–1945), German physicist and inventor. Invented the Geiger counter to detect alpha particles; investigated properties of alpha particles, cosmic rays, and artificial radiation.

Geissler, Johann Heinrich Wilhelm (1815–1879), German instrument maker. Developed Geissler pump and Geissler tube.

Geitel, Hans Friedrich (1855–1923), German experimental physicist. With J. Elster, studied atmospheric electricity, radioactivity, and photoelectricity, and invented photocell.

Gell-Mann, Murray (1929–), American physicist. Proposed law of conservation of strangeness; used unitary symmetry to classify and explain elementary particles; postulated concept of quarks; Nobel Prize, 1969.

Gesner, Konrad von (1516–1565), Swiss naturalist. Wrote *Historia Animalium*, beginning zoology as a science.

Giacconi, Riccardo (1931–), Italian-born American astrophysicist. Pioneered the field of x-ray astronomy, working out the principles of an x-ray telescope and leading the development of the early x-ray telescopes. Nobel Prize, 2002.

Giaever, Ivar (1929–), Norwegian-born American physicist. Discovered that current-voltage characteristics of an electron tunneling across a thin insulating film separating two metals, one or both of which is in a superconducting state, can be used to obtain electron density of states of superconductors; Nobel Prize, 1973.

Giauque, William Francis (1895–1982), Canadian-born American chemist. Developed adiabatic demagnetization technique for production of extremely low temperatures; collaborated in discovery of isotopes of oxygen; Nobel Prize, 1949.

Gibbs, Josiah Willard (1839–1903), American mathematician and physicist. Made a mathematical treatment of chemical subjects, notably thermodynamics; worked on statistical mechanics, leading to the basis for the phase rule of heterogeneous equilibria.

Gilbert, Walter (1932–), American biochemist. Developed methods for determining nucleotide sequence (independently of F. Sanger), advancing the technology of DNA recombination; Nobel Prize, 1980.

Gilman, Alfred G. (1941–), American pharmacologist. With M. Rodbell, discovered G-proteins and their role in cellular signal transduction; Nobel Prize, 1994.

Ginzburg, Vitaly Lazarevich (1916–), Soviet physicist. Developed Ginzburg-Landau and Ginzburg-London theories of superconductivity; Nobel Prize, 2003.

Giorgi, Giovanni (1871–1950), Italian electrical engineer, physicist, and mathematician. Developed the meter-kilogram-second-ampere system of units.

Glaser, Donald Arthur (1926–), American physicist. Invented the bubble chamber for detecting the paths of high-energy atomic particles; Nobel Prize, 1960.

Glashow, Sheldon Lee (1932–), American physicist. Contributed to development of theory uniting electromagnetism and weak nuclear interactions; postulated existence of charmed particles; Nobel Prize, 1979.

Glauber, Johann Rudolf (1604–1670), German chemist. Discovered Glauber’s salt (sodium sulfate) and hydrochloric acid; conducted experiments on compounds of mercury, arsenic, and antimony.

Gmelin, Leopold (1788–1853), German chemist. Wrote *Handbuch der Chemie*, first systematic treatment of chemical knowledge; devised

Gmelin's test for presence of bile pigments; studied cyanides.

Goldbach, Christian (1690–1764), German-born Russian mathematician. Research on number theory and analysis; proposed the Goldbach conjecture.

Goldhaber, Maurice (1911–), Austrian-born American physicist. With J. Chadwick, discovered photodisintegration and disintegration of light elements by slow neutrons; with L. Grodzins and A. W. Sunyar, discovered that the neutrino has left-handed spin.

Goldstein, Joseph L. (1940–), American biochemist and geneticist. With M. S. Brown, discovered low-density lipoprotein receptors and their function in cholesterol metabolism; Nobel Prize, 1985.

Golgi, Camillo (1843–1926), Italian physician. Pioneered in the study of histology of the nervous system; discovered the Golgi bodies; Nobel Prize, 1906.

Gordan, Paul Albert (1837–1912), German mathematician. Worked on the theory of invariants and on solutions of algebraic equations and their groups of substitutions.

Gordon, Walter (1893–1940), German-born Swedish physicist. Contributed to relativistic quantum theory; with O. B. Klein, originated the Klein-Gordon equation.

Goudsmit, Samuel Abraham (1902–1978), Dutch-born American physicist. With G. E. Uhlenbeck, discovered electron spin.

Gowers, William Timothy (1963–), British mathematician. Contributed to functional analysis, in particular, to the theory of Banach spaces, using methods of combinatorial theory; Fields Medal, 1998.

Gram, Hans Christian Joachim (1853–1938), Danish physician. Developed the Gram method for staining and differentiating bacteria.

Gram, Jorgen Pedersen (1850–1916), Danish mathematician. Worked in number theory and analysis; with E. Schmidt, originated Gram-Schmidt process for obtaining orthogonal set of vectors.

Granit, Rangar Arthur (1900–1991), Finnish-born Swedish physiologist. Research on vision and on motor control by afferent neurons; Nobel Prize, 1967.

Grashof, Franz (1826–1893), German mechanical engineer. Applied mathematics and physics to engineering problems; derived fundamental equations in the theory of elasticity; introduced Grashof number.

Gray, Henry (1825–1861), English anatomist. Wrote *Anatomy of the Human Body*.

Green, George (1793–1841), English mathematician. Worked in analysis; derived Green's theorem and Green's identities; introduced Green's function.

Greengard, Paul (1925–), American neurobiologist. Discovered the mechanism by which dopamine and other chemical neurotransmitters (such as norepinephrine and serotonin) affect the nervous system—work contributing to the elucidation of the molecular mechanisms involved in slow synaptic transmission in the nervous system; Nobel Prize, 2000.

Gregory, James (1638–1675), Scottish geometer. Provided first proof of the theorem of calculus; gave first description of the reflecting telescope; discovered the series from which π can be calculated.

Grignard, François Auguste Victor (1871–1935), French chemist. Discovered organomagnesium compounds, or Grignard reagents, useful in synthesis of organic and organometallic compounds; Nobel Prize, 1912.

Gross, David J. (1941–), American physicist. Discovered asymptotic freedom in the strong interactions (in collaboration with F. Wilczek, and independent of H. D. Politzer). Nobel Prize, 2004.

Grothendieck, Alexander (1928–), German-born French mathematician. Made fundamental advances in algebraic geometry and related fields, providing unifying themes in geometry, number theory, topology, and complex analysis; introduced the idea of K theory; revolutionized homological algebra; developed theory of schemes, allowing conjectures in number theory to be solved; Fields Medal, 1966.

Gruneisen, Eduard (1877–1949), German physicist. Formulated laws relating specific heat and other properties of solids.

Guillaume, Charles Édouard (1861–1938), Swiss-born French physicist. Studied nickel-steel alloys and invented Invar; Nobel Prize, 1920.

Guillemin, Ernst Adolph (1898–1970), American electrical engineer. Worked on network analysis and synthesis problems; invented Guillemin line; developed network to produce loran pulses.

Guillemin, Roger Charles Louis (1924–), French-born American physiologist. With A. V. Schally, isolated and analyzed peptide hormones secreted in hypothalamic region of brain which control anterior pituitary hormone secretion; Nobel Prize, 1977.

Gullstrand, Allvar (1862–1930), Swedish ophthalmologist. Discovered intracapsular accommodation of the eye lens; improved techniques for studying eye structure; Nobel Prize, 1911.

Gunn, John Battiscombe (1928–), Egyptian-born American physicist. Discovered Gunn effect and used it to develop Gunn oscillator.

Gunter, Edmund (1581–1626), English mathematician and astronomer. Invented Gunter's chain used in surveying, and the logarithmic scale (Gunter's scale) which is the principle of the slide rule.

Gutenberg, Johann (ca. 1397–1468), German inventor. Invented the movable-type printing press.

Haar, Alfred (1885–1933), Hungarian mathematician. Studied orthogonal systems of functions, complex functions, partial differential equations, and calculus of variations; introduced the Haar measure on groups.

Haber, Fritz (1868–1934), German chemist. Developed the Haber-Boch process for synthesis of ammonia; made electrochemical studies; Nobel Prize, 1918.

Hadamard, Jacques (1865–1963), French mathematician. Proved theorem on the asymptotic behavior of the function giving the number of prime numbers less than a given number; introduced concept of "the problem correctly posed" in the solution of partial differential equations.

Haeckel, Ernst Heinrich (1834–1919), German biologist. Studied various invertebrates; classified animals as uni- and multicellular organisms; proposed the theory of recapitulation: ontogeny repeats phylogeny.

Hagen, Carl Ernst Bessel (1851–1923), German physicist. With H. Rubens, conducted experiments confirming Maxwell's electromagnetic theory of light, permitting determination of electrical conductivity of metals by optical measurements alone.

Hagen, Gotthilf Heinrich Ludwig (1797–1884), German hydraulic engineer. Discovered Hagen-Poiseuille law independently of J. L. M. Poiseuille; directed construction of dikes, harbor installations, and dune fortifications.

Hahn, Hans (1879–1934), Austrian mathematician. With S. Banach, proved the Hahn-Banach theorem of linear functionals.

Hahn, Otto (1879–1968), German chemist. With L. Meitner and F. Strassman, discovered that fission of heavy nuclei was possible by irradiation with neutrons; discovered protactinium with Meitner; Nobel Prize, 1944.

Hahnemann, Christian Friedrich Samuel (1775–1843), German physician. Founder of homeopathy.

Haldane, John Bourdon Sanderson (1892–1964), British geneticist and physiologist. Pioneered in mathematical treatment of population genetics; studied respiration in humans; wrote about enzymes.

Haldane, John Scott (1860–1936), British physiologist. Research on respiration, particularly the effects of high and low atmospheric pressures.

Hale, George Ellery (1868–1938), American astronomer. Established the Mount Wilson and Mount Palomar observatories; proved existence of magnetic fields in sunspots; invented the spectroheliograph.

Hall, Charles Martin (1863–1914), American commercial chemist. Discovered Hall process for extracting aluminum.

Hall, Edwin Herbert (1855–1938), American physicist. Discovered Hall effect and conducted studies of this and other galvanomagnetic and thermomagnetic effects.

Halley, Edmond (1656–1742), English astronomer. Published a southern star catalog; computed orbits of 24 comets; discovered Halley's comet.

Hamel, Georg Karl Wilhelm (1877–1954), German mathematician. Research on analysis and applied mathematics; introduced Hamel basis of vectors.

Hamilton, William Rowan (1805–1865), Irish mathematician and mathematical physicist. Discovered quaternions; developed mathematical theories encompassing wave and particle optics and mechanics; introduced Hamilton's principle and a form of the Hamilton-Jacobi theory.

Hankel, Hermann (1839–1873), German mathematician. Studied complex and hypercomplex numbers, theory of functions, and Hankel functions; proved that no hypercomplex number system can satisfy all the laws of ordinary arithmetic.

Hansen, Armauer (1841–1912), Norwegian bacteriologist. Discovered the bacillus of leprosy, or Hansen's disease.

Harden, Arthur (1865–1940), English chemist. Research on enzymes and alcoholic fermentation; Nobel Prize, 1929.

Hardy, Godfrey Harold (1877–1947), English mathematician. With S. Ramanujan, discovered formula for number of ways of writing a positive integer as the sum of positive integers; proved that the Riemann zeta function has an infinite number of zeros with real part equal to 1/2.

Harker, David (1906–1991), American crystallographer. Completed development of Patterson-Harker method of x-ray diffraction analysis of crystal structure.

Hartley, Ralph Vinton Lyon (1888–1970), American electrical engineer. Invented Hartley oscillator; developed Hartley principle in information theory.

Hartline, Haldan Keffer (1903–1983), American biophysicist. Elucidated cellular electrical activity in the eye and optic nerve; Nobel Prize, 1967.

Hartmann, Johannes Franz (1865–1936), German astronomer. Derived Hartmann dispersion formula relating index of refraction and wavelengths; devised Hartmann test for telescope mirrors; gave first observational proof of interstellar matter.

Hartree, Douglas Rayner (1897–1958). English mathematician and mathematical physicist. Developed methods of numerical analysis which made it possible to apply Hartree method to calculation of atomic wave functions.

Hartwell, Leland H. (1939–), American geneticist. Discovered more than 100 genes that control the cell cycle and introduced the concept of cell cycle checkpoints, ordered groups of genes and protein which halt progress through the cell cycle if DNA is damaged, allowing time for DNA repair; Nobel Prize, 2001.

Harvey, William (1578–1657), English anatomist and physician. Described the true circulation of blood and the action of the heart.

Hassel, Odd (1897–1981), Norwegian chemist. Developed concept of conformation by studying three-dimensional structure of cyclohexane molecule, and explaining the orientation of attached atoms or functional groups: Nobel Prize, 1969.

Hauptman, Herbert A. (1917–), American chemist. With J. Karle, developed computer-aided mathematical techniques for use in x-ray crystallography to determine three-dimensional structures of molecules: Nobel Prize, 1985.

Hausdorff, Felix (1868–1942), German mathematician. Founded and advanced general topology and the general theory of metric spaces.

Haüy, Réné Just, Abbé (1743–1822), French mineralogist. Formulated the geometrical law of crystallization; pioneer in the science of crystallography.

Havers, Clopton (1665–1702), English osteologist. Provided the first full discussion of Haversian lamellae and Haversian canals.

Haworth, Walter Norman (1883–1950), English chemist. Synthesized ascorbic acid; studied carbohydrates, including the structure of sugars; Nobel Prize, 1937.

Heaviside, Oliver (1850–1925), English physicist. Proposed the Heaviside layer in the upper atmosphere.

Heeger, Alan J. (1936–), American physicist. Discovered and developed conductive polymers with Alan MacDiarmid and Hideki Shirakawa; Nobel Prize, 2000.

Hefner-Alteneck, Friedrich Franz von (1845–1904), German engineer. Invented Hefner candle as a standard of luminous intensity.

Heine, Heinrich Eduard (1821–1881), German mathematician. Formulated concept of uniform continuity.

Heisenberg, Werner (1901–1976), German physicist. Founder of quantum mechanics; studied structure of the atom and the Zeeman effect; formulated the principle of indeterminancy in nuclear physics; Nobel Prize, 1932.

Heitler, Watler Heinrich (1904–1981), German-born Swiss theoretical physicist. Developed Heitler-London covalence theory of chemical bonding.

Helmholtz, Hermann Ludwig Ferdinand von (1821–1894), German physicist. anatomist, and physiologist. Physiological research on the nervous system and the human eye and ear, and theoretical work on conservation of force in physics; invented the ophthalmoscope.

Hench, Philip Showalter (1896–1965), American physiologist. Discovered that ACTH and cortisone could be used to treat rheumatoid arthritis; Nobel Prize, 1950.

Henle, Friedrich Gustav Jacob (1809–1885), German pathologist and anatomist. Wrote *Handbuch der Rationellen Pathologie*, integrating the study of physiology and pathology; discovered looped portion of the kidney tubules, and the epithelium.

Henry, Joseph (1797–1878), American physicist. Studied electromagnetic induction, solar phenomena, meteorology, and acoustics.

Henry, William (1775–1836), English chemist and physician. Formulated Henry's law of solubility of gases in liquid.

Henyey, Louis George (1910–1970), American astronomer. Research on reflection nebulae, interstellar matter, stellar atmospheres and evolution, and optical design.

Hermite, Charles (1822–1901), French mathematician. First to solve a fifth-degree equation; investigated *e*, the base of natural logarithms.

Hero of Alexandria (3d century or earlier), Greek mathematician. Wrote on the geometry of plane and solid figures, mechanics, and simple machines; showed that the angle of incidence equals the angle of reflection.

Héroult, Paul Louis Toussaint (1863–1914), French metallurgist. Designed the Héroult furnace for electric steel; developed the Héroult process for aluminum extraction.

Herschbach, Dudley R. (1932–), American chemist. With Y. T. Lee, developed crossed molecular-beam technique for tracing chemical reactions; Nobel Prize, 1986.

Herschel, John Frederick William (1792–1871), English mathematician, physicist, and astronomer. Discovered many nebulae and clusters; pioneered in celestial photography.

Herschel, William or Friedrich Wilhelm (1738–1822), German-born English astronomer. Discovered Uranus, two of its satellites, and two satellites of Saturn; discovered the Sun's intrinsic motion; proposed the concept of the form of the Milky Way.

Hershey, Alfred Day (1908–1997), American biologist. With M. Chase, experimented with bacteriophage, confirming earlier indications that the material basis of heredity is contained in nucleic acids; Nobel Prize, 1969.

Hershko, Avram (1937–), Israeli medical doctor and scientist. Discovered ubiquitin-mediated protein degradation; Nobel Prize, 2004.

Hertz, Gustav (1887–1975), German physicist. With J. Franck, studied effects of electron impacts on atoms; Nobel Prize, 1925.

Hertz, Heinrich Rudolph (1857–1894), German physicist. Discovered Hertzian waves in the ether; proved experimentally Maxwell's theories of electricity and magnetism.

Hertzsprung, Ejnar (1873–1967), Danish astronomer. Discovered method of spectroscopic parallax for measuring stellar distances; determined relation between color and luminosity of stars; with H. N. Russell, developed Hertzsprung-Russell diagram.

Herzberg, Gerhard (1904–1999), German-born Canadian physicist. Determined electronic structure and geometry of diatomic and polyatomic molecules, particularly free radicals; Nobel Prize, 1971.

Hess, Victor Franz (1883–1964), Austrian physicist. Studied alpha particles from radium; discovered cosmic rays; Nobel Prize, 1936.

Hess, Walter Rudolf (1881–1973), Swiss physiologist. Discovered the organizer function of the middle brain in coordinating activity of internal organs; developed technique of using electrodes to stimulate localized brain areas; Nobel Prize, 1949.

Hevelius or Hewel, Johannes (1611–1687), Danzig-born astronomer. Discovered four comets; charted surface of the Moon; cataloged numerous stars.

Hevesy, George von (1886–1966), Hungarian chemist. Experimented with radioisotope indication, leading to the technique of isotope tracing of biological and chemical processes; Nobel Prize, 1943.

Hevroský, Jaroslav (1890–1967), Czechoslovakian physical chemist. Developed the technique of polarographic analysis; Nobel Prize, 1959.

Hewish, Antony (1924–), British astronomer. Pioneered in discovery of pulsars, by means of radio telescopes; Nobel Prize, 1974.

Heymans, Corneille (1892–1968), French-Belgian physiologist. Investigated the carotid sinus in connection with the mechanism of breathing; Nobel Prize, 1938.

Hilbert, David (1862–1943), German mathematician. Contributed to theory of numbers and theory of invariants; applied integral equations to physical problems.

Hill, Archibald Vivian (1886–1977), English physiologist. Worked on heat loss and oxygen consumption in muscle contraction; Nobel Prize, 1922.

Hinshelwood, Cyril Norman (1897–1967), British chemist. Elucidated chain reaction and chain branching mechanisms; Nobel Prize, 1956.

Hippias of Elis (5th century B.C.), Greek philosopher and mathematician. Discovered quadratrix.

Hipparchus of Rhodes (fl. 130 B.C.), Greek astronomer. Calculated the inclination of the ecliptic and the precession of the equinoxes; invented trigonometry; made the first star catalog.

Hippocrates (460?–377 B.C.), Greek physician. Known as the father of medicine; writings attributed to him contain clinical observations of diseases, descriptions of surgical practice, and the Hippocratic doctrine of the four humors.

Hironaka, Heisuke (1931–), Japanese-American mathematician. Worked in algebraic geometry; solved the problem of the resolution of singularities on an algebraic variety for algebraic varieties of any dimension over a field of characteristic 0, generalizing work of O. Zariski; Fields Medal, 1970.

Hirzebruch, Friedrich Ernst Peter (1927–), German mathematician. Collaborated with M. F. Atiyah in the development of K theory.

Hitchings, George Herbert (1905–1998), American biochemist. With G. B. Elion, pioneered research that led them to the development of drugs for the treatment of leukemia, malaria, gout, herpes, bacterial and fungal infections, and autoimmune diseases and organ-transplant rejection; Nobel Prize, 1988.

Hittorf, Johann Wilhelm (1824–1914), German physicist. Described effects of Hittorf rays in vacuum tubes; studied electrolysis, and electrical discharge in rarefied gases with the Hittorf tube.

Hodgkin, Alan Lloyd (1914–1998), British biophysicist. With A. Huxley, devised a system of mathematical equations describing the nerve impulse; presented evidence for the sodium theory of nervous conduction; Nobel Prize, 1963.

Hodgkin, Dorothy Crowfoot (1910–1994), Egyptian-born British chemist. Determined the structure of the vitamin B_{12} molecule through x-ray crystallographic analysis; Nobel Prize, 1964.

Hodgkin, Thomas (1798–1866), English physician. First to describe Hodgkin's disease, a glandular disorder.

Hoffmann, Roald (1937–), Polish-born American chemist. Developed methods for predicting whether a chemical reaction is possible based on molecular orbital models; Nobel Prize, 1981.

Hofmann, August Wilhelm von (1818–1892), German chemist. Studied reactions of derivatives; developed the Hofmann reaction for preparing primary amines.

Hofmeister, Wilhelm Friedrich Benedict (1824–1877), German botanist. Did fundamental work on plant embryology; explained the alternating life cycles of mosses and ferns.

Hofstadter, Robert (1915–1990), American physicist. Investigated the properties and behavior of the proton and neutron; determined the size and shape of many nuclei; discovered the construction scheme of fundamental atomic nuclei; Nobel Prize, 1961.

Hölder, Otto Ludwig (1859–1937), German mathematician. Contributed to analysis and group theory; introduced Hölder condition; proved Hölder inequality and Jordan-Hölder theorem.

Holley, Robert William (1922–1993), American biochemist. With coworkers, made first determination of a nucleotide sequence of a nucleic acid; Nobel Prize, 1968.

Holmberg, Erik Bertil (1908–2000), Swedish astronomer. Investigations of galaxies, especially photometry of galaxies.

Hooke, Robert (1635–1703), English inventor. Invented the compound microscope, wheel barometer, universal (Hooke's) joint, and the reflecting telescope; formulated theories on light and on the motion of the Earth.

Hooker, Joseph Dalton (1817–1911), English botanist. With G. Bentham, wrote *Genera Plantarum*; prepared works on the flora of New Zealand, Antarctica, and India.

Hopkins, Frederick Gowland (1861–1947), English biochemist. Discovered the amino acid tryptophan and the tripeptide glutathione; did experimental work leading to the discovery of vitamins; Nobel Prize, 1929.

Hopper, Grace (1906–1992), American mathematician and computer scientist. Pioneered in the development of computer software, including the invention of the first compiler. Credited with having discovered the first computer "bug," a moth that literally had to be removed from the wiring of an early computer.

Hörmander, Lars (1931–), Swedish mathematician. Worked on partial differential equations; in particular, made major contributions to the general theory of linear differential operators; Fields Medal, 1962.

Horvitz, H. Robert (1947–), American geneticist and neurobiologist. Identified and characterized the genes controlling programmed cell death in the nematode *Caenorhabditis elegans*. Showed that these genes interact with each other in cell death and correspond to existing genes in humans. Nobel Prize, 2002.

Houdry, Eugene J. (1892–1962), French-born American engineer. Devised catalytic method of producing oil.

Hounsfield, Godfrey Newbold (1919–2004), British electronics engineer. Invented computerized axial tomography; Nobel Prize, 1979.

Houssay, Bernardo Alberto (1887–1971), Argentine physiologist. Research on the functions and effects of the hypophysis, including its relationship to carbohydrate metabolism; Nobel Prize, 1947.

Howell, William Henry (1860–1945), American physiologist. Discovered heparin; isolated thrombin and thromboplastin; discovered Howell-Jolly bodies; proved that blood platelets are formed in lungs.

Hubble, Edwin Powell (1889–1953), American astronomer. Studied nebulae; formulated Hubble's law of extragalactic nebulae.

Hubel, David Hunter (1926–), American neurobiologist. Contributed to the study of the processing of visual information in the brain; Nobel Prize, 1981.

Huber, Robert (1937–), German chemist. With J. Deisenhofer and M. Hartmut, elucidated the structure of a bacterial protein that performs photosynthesis; Nobel Prize, 1988.

Hückel, Erich (1896–1980), German chemist. With P. J. W. Debye, formulated Debye-Hückel theory of strong electrolytes; devised theoretical explanation of electron properties of aromatic hydrocarbons.

Huggins, Charles Brenton (1901–1997), Canadian-born American surgeon and cancer researcher. Developed treatment of cancers using endocrinologic methods; Nobel Prize, 1966.

Hughes, David Edward (1831–1900), English-born American inventor. Invented the Hughes electromagnet, a printing telegraph, microphone, and induction balance.

Hugoniot, Pierre Henry (1851–1887), French physicist. Developed theory of shock waves.

Hulse, Russell A. (1950–), American astronomer and physicist. With J. H. Taylor, discovered the binary pulsar and studied it to observe phenomena predicted by general relativity; worked in plasma physics; Nobel Prize, 1993.

Humboldt, Friedrich Heinrich Alexander, Baron von (1769–1859), German naturalist. Founder of physical geography; made scientific explorations of South America and Central Asia.

Hume-Rothery, William (1899–1968), English metallurgist and chemist. Discovered Hume-Rothery rule concerning electron compounds.

Hunt, Franklin Livingston (1883–1973), American physicist. Research on x-ray spectroscopy; with W. Duane, discovered and applied Duane-Hunt law.

Hunt, R. Timothy (1943–), British biologist who discovered cyclins, proteins that regulate cyclin-dependent kinase activity, and found that their periodic degradation is an important general control mechanism of the cell cycle; Nobel Prize, 2001.

Hurwitz, Adolf (1859–1919), German-born Swiss mathematician. Worked on modular functions, number theory, Riemann surfaces, complex function theory, and analytic number theory; formulated condition satisfied by Hurwitz polynomials.

Huxley, Andrew Fielding (1917–), British physiologist. With A. L. Hodgkin, discovered the ionic mechanism involved in excitation in the cell membrane of peripheral nerves; Nobel Prize, 1963.

Huygens, Christiaan (1629–1695), Dutch mathematician, physicist, and astronomer. Discovered Saturn's rings; contributed to dynamics and optics; proposed the wave theory of light.

Hylleraas, Egil Andersen (1898–1965), Norwegian physicist. Applied quantum theory to helium atom, negative hydrogen ion, and other atoms, molecules, and crystals; developed variational method and other methods for mathematical solution of quantum-mechanical problems.

Ignarro, Louis J. (1941–), American pharmacologist. Working independently and with Robert Furchgott, he concluded that endothelium-derived relaxing factor was identical to nitric oxide; Nobel Prize, 1998.

Ingenhousz, Jan (1730–1799), Dutch physician and naturalist. Demonstrated the cycle of photosynthesis in plants.

Ising, Ernest (1900–1998), German-born American physicist. Introduced Ising model of ferromagnetic material; research in solid-state physics and ferromagnetism.

Itō, Kiyosi (1915–), Japanese mathematician. Studied stochastic processes; introduced Itō's integral and Itō's formula.

Jacob, François (1920–), French biologist. Discovered episomes, a class of genetic elements; with J. Monod, proposed the concepts of messenger ribonucleic acid and of the operon; Nobel Prize, 1965.

Jacobi, Karl Gustav Jacob (1804–1851), German mathematician. Worked on elliptic functions and differential equations; developed the theory of determinants.

Jacquard, Joseph Marie (1752–1834), French inventor. Designed and built the Jacquard loom for figured weaving.

Jaeger, Frans Maurits (1877–1945), Dutch crystallographer and physical chemist. Measured physical properties of molten salts and silicates at extremely high temperatures.

James, William (1842–1910), American psychologist and writer. Coformulator of James-Lange theory that emotions are the perception of physiological changes.

Janet, Pierre Marie Félix (1859–1947), French psychologist. Studied hysteria, obsession, and neurosis; wrote a textbook on the theory of hysteria.

Jeans, James Hopwood (1877–1946), English physicist and astronomer. Worked in stellar dynamics; proposed the tidal theory of the origin of planets.

Jenner, Edward (1749–1823), English physician. Discovered vaccination.

Jensen, J. Hans D. (1906–1973), German physicist. With M. G. Mayer, formulated the nuclear shell model; Nobel Prize, 1963.

Jerne, Niels Kaj (1911–1994), Swiss immunologist. Formulated three important theories involving the immune system: how the body produces specific antibodies, how the immune system develops and matures, and how the various interrelated aspects of the immune response are coordinated by the body; Nobel Prize, 1984.

Johnson, Harold Lester (1921–1980), American astronomer. Research in astrophysics, astronomical photometry, infrared astronomy, applications of electronics to astronomy, and Fourier transform spectroscopy; collaborated with W. W. Morgan in developing Johnson-Morgan system of stellar magnitudes.

Joliot-Curie, Irène (1897–1956), French physicist. With M. Curie, discovered projection of atomic nuclei by neutrons; with J. F. Joliot-Curie, discovered artificial radiation; Nobel Prize, 1935.

Joliot-Curie, Jean Frédéric (1900–1958), French physicist. With I. Joliot-Curie, produced an artificial radioactive substance by bombarding boron with fast alpha particles; Nobel Prize, 1935.

Jones, Vaughn Frederick Randal (1952–), New Zealand-American mathematician. Proved an index theorem for von Neumann algebras, discovered a relationship between these algebras and geometric topology, and discovered a new polynomial invariant for knots; this work provided a connecting link for widely separated areas of mathematics and physics; Fields Medal, 1990.

Jordan, Camille (1838–1921), French mathematician. Discovered many fundamental results in group theory; gave a proof of the Jordan curve theorem (later shown to be incorrect).

Jordan, Pascual (1902–1980), German physicist. Contributed to formulation of quantum mechanics; introduced Jordan algebra in an attempt to generalize quantum mechanics.

Josephson, Brian David (1940–), British physicist. Predicted the Josephson effect concerning electron pairs; Nobel Prize, 1973.

Joukowski, Nikolai Jegorowitch (1847–1921), Russian applied mathematician and aerodynamicist. Helped to introduce concept of Kutta-Joukowski airfoil and to prove Kutta-Joukowski theorem.

Joule, James Prescott (1818–1889), English physicist. Formulated a mechanical theory of heat; demonstrated Joule-Thomson effect relating to the fall in temperature of a gas; first to estimate the velocity of a gas molecule.

Jung, Carl Gustav (1875–1961), Swiss psychologist and psychiatrist. Evolved a theory of complexes; founded the analytical school of psychoanalysis and psychotherapy.

Jussieu, Antoine Laurent de (1748–1836), French botanist. Wrote *Genera Plantarum*, the basis of modern natural botanical classification.

Kahn, Robert E. (1938–), American electrical engineer. Co-invented (with Vinton G. Cerf) Transmission Control Protocol/Internet Protocol (TCP/IP).

Kalman, Rudolf Emil (1930–), Hungarian born American mathematician and electrical engineer. Worked on mathematical theory of control systems; developed the Kalman filter; introduced concepts of controllability and observability.

Kaluza, Theodor Franz Eduard (1885–1954), German mathematical physicist. Developed theory which attempted to unify gravitation and electromagnetism.

Kamerlingh Onnes, Heike (1853–1926), Dutch physicist. Research on cryogenics, critical phenomena, and low temperatures; discovered the phenomenon of superconductivity; Nobel Prize, 1913.

Kandel, Eric R. (1929–), Austrian-born American neurobiologist. Discovered that protein phosphorylation plays an important role in the molecular mechanisms underlying learning and memory formation; his work contributed to the elucidation of the molecular mechanisms involved in slow synaptic transmission in the nervous system; Nobel Prize, 2000.

Kapitza, Pjotr Leonidovich (1894–1984), Russian physicist. Studied magnetism and low temperature; designed hydrogen and helium liquefaction plants; Nobel Prize, 1978.

Kapteyn, Jacobus Cornelius (1851–1922), Dutch astronomer. Studied the proper motion of stars; with P. J. van Rhijn, evolved a theory of the universe.

Karle, Jerome (1918–), American crystallographer. With H. A. Hauptman, developed computer-aided mathematical techniques for use in x-ray crystallography to determine three-dimensional structures of molecules; Nobel Prize, 1985.

Karrer, Paul (1889–1971), Swiss chemist. Pioneering research on vitamins A and B_2 and on the flavins and carotenoids; Nobel Prize, 1937.

Kastler, Alfred (1902–1984). French physicist. Developed a double-resonance method to study energy levels of atoms in excited states; Nobel Prize, 1966.

Kater, Henry (1777–1835), English geodesist. Developed Kater's reversible pendulum to obtain accurate values of acceleration of gravity.

Katz, Bernard (1911–2003), German-born British physiologist. Made discoveries concerning mechanism for release of transmitter substances at nerve-muscle junction; Nobel Prize, 1970.

Keesom, Willem Hendrik (1876–1956), Dutch physicist. Worked in low-temperature physics; first to solidify helium; studied molecular structure of liquids and compressed gases.

Kekulé von Stradonitz, Friedrich August (1829–1896), German chemist. A founder of structural organic chemistry; made theoretical proposal of the structure of benzene.

Kelvin, William Thomson, 1st Baron (1824–1907), British mathematician and physicist. Invented the Kelvin balance; formulated Kelvin's laws concerning electric cables; contributed to thermodynamics.

Kendall, Edward Calvin (1886–1972), American biochemist. Chemical investigation of the adrenal cortex, leading to the isolation of crystalline cortical hormones, especially cortisone; Nobel Prize, 1950.

Kendall, Henry Way (1926–1999), American physicist. Collaborated in experiments that demonstrated that protons, neutrons, and similar particles are made up of quarks; Nobel Prize, 1990.

Kendrew, John Cowdery (1917–1997), British molecular biologist. First to successfully determine the structure of a protein; Nobel Prize, 1962.

Kennelly, Arthur Edwin (1861–1939), American electrical engineer. Discovered the ionized layer in the atmosphere, independently of O. Heaviside; proposed the theory of alternating currents.

Kepler, Johannes (1571–1630), German astronomer. Proposed Kepler's three laws of planetary motion; worked in optics.

Kerr, John (1824–1907), Scottish physicist. Discovered the Kerr magnetooptic effect.

Ketterle, Wolfgang (1957–), German physicist. Produced Bose-Einstein condensates in a dilute gas of sodium atoms (independent of the work of E. A. Cornell and C. E. Wieman) and carried out fundamental studies of their properties, including the production of interference patterns and atom lasers; Nobel Prize, 2001.

Khorana, Har Gobind (1922–), Indian-born American biochemist. Synthesized complicated nucleic acids: proved that genetic code consists of nonoverlapping triplets of bases without gaps between triplets; Nobel Prize, 1968.

Kilby, Jack St. Clair (1923–), American physicist, electronics engineer, and inventor. Participated in the invention of the integrated circuit; Nobel Prize, 2000.

Kirchhoff, Gustav Robert (1824–1887), German physicist. With R. W. Bunsen, discovered method of spectrum analysis; formulated Kirchhoff's law of electric currents and electromotive forces in a network.

Kirkwood, Daniel (1814–1895), American astronomer. Discovered Kirkwood gaps; studied nature, origin, and evolution of solar system, particularly role of asteroids, comets, meteors, and meteorites.

Kitasato, Shibasaburo (1852–1931), Japanese bacteriologist. Independently of A. E. J. Yersin, discovered the bacillus of bubonic plague; isolated bacilli of symptomatic anthrax, dysentery, and tetanus.

Klebs, Edwin (1834–1913), German pathologist. Described diphtheria (Klebs-Löffler) bacillus; studied bacteriology of malaria, anthrax, and tuberculosis.

Klein, Christian Felix (1849–1925), German mathematician. Contributed to function theory, noneuclidean geometry, group therapy, and applied mathematics; introduced Klein bottle.

Klein, Oskar Benjamin (1894–1977), Swedish physicist. Codeveloper of Klein-Gordon equation. Klein-Nishina formula, and Klein-Rydberg method; proposed theory of overall structure of the universe.

Kleinrock, Leonard (1934–), American electrical engineer. Developed the basic principles of packet switching for communication networks, the underlying technology of the Internet.

Klitzing, Klaus von (1943–), German physicist. Discovered quantum Hall effect; Nobel Prize, 1985.

Klug, Aaron (1926–), South African-born British biochemist. Developed crystallographic electron microscopy and elucidated biologically important nucleic acid-protein complexes; Nobel Prize, 1982.

Knowles, William S. (1917–), American chemist. Developed chirally catalyzed hydrogenation reactions; Nobel Prize, 2001.

Knudsen, Martin Hans Christian (1871–1949), Danish physicist and hydrographer. Studied flow and diffusion of gases at low pressure; developed Knudsen cell and Knudsen gage; developed methods to measure the properties of seawater.

Koch, Robert (1843–1910), German physician and bacteriologist. Studied cholera, tuberculosis, and bubonic plague; showed a specific bacillus to be the cause of anthrax; discovered the tubercle bacillus; Nobel Prize, 1905.

Kocher, Emil Theodor (1841–1917), Swiss surgeon. Studied the functions and malfunctions of the thyroid gland; Nobel Prize, 1909.

Kodaira, Kunihiko (1915–1997), Japanese mathematician. Did research on harmonic integrals and harmonic forms with applications to Kählerian and more specifically algebraic varieties; demonstrated, by sheaf cohomology, that such varieties are Hodge manifolds; Fields Medal, 1954.

Köhler, Georges J. F. (1946–1995), Swiss immunologist. With C. Milstein, discovered a laboratory technique for producing monoclonal antibodies, highly uniform immune bodies that are selective in responding to target substances; Nobel Prize, 1984.

Kohn, Walter (1923–), Austrian-born American physicist. Developed density-functional theory, which solves equations for electron density rather than positions of individual electrons; it is one of the developments that has significantly sped up computational quantum chemistry; Nobel Prize, 1998.

Kolbe, Adolf Wilhelm Hermann (1818–1884), German chemist. Contributed to the synthesis concept of compound formation, doing much to eliminate the division of chemistry into two branches: organic and inorganic.

Kolmogorov, Andrei Nikolaevich (1903–1987), Soviet mathematician. Formulated set-theoretic basis of probability theory.

Kontsevich, Maxim (1964–), Russian mathematician and mathematical physicist. Worked in algebraic geometry, algebraic topology, string theory, and quantum field theory; demonstrated equivalence of two models of quantum gravitation; discovered an invariant for classifying knots; Fields Medal, 1998.

Kornberg, Arthur (1918–), American biochemist. Discovered deoxyribonucleic acid polymerase, providing the first rational enzymatic mechanism for the replication of genetic material of the cell; Nobel Prize, 1959.

Korteweg, Diederik Johannes (1848–1941), Dutch mathematician. Work in applied mathematics, mechanics, and hydrodynamics; with G. de Vries, proposed equation of wave motion with soliton solution.

Kosiba, Masatoshi (1926–), Japanese physicist. Developed large water detectors (Kamiokande and Super Kamiokande) that observed solar and atmospheric neutrinos and neutrinos from Supernova 1987A, and found evidence for neutrino oscillations. Nobel Prize, 2002.

Kossel, Albrecht (1853–1927), German chemist. Investigated the chemistry of cells and of proteins; Nobel Prize, 1910.

Krafft-Ebing, Richard, Baron von (1840–1902), German neurologist. Authority on psychological disorders and their forensic implications; wrote *Psychopathia Sexualis*, a collection of case histories.

Kramers, Hendrik Anthony (1894–1952), Dutch physicist. Developed quantum theory of dispersion, establishing Kramers-Kronig relation; with G. Wentzel and L. Brillouin, developed Wentzel-Kramers-Brillouin method.

Krebs, Edwin Gerhard (1918–), American biochemist. With E. H. Fischer, discovered phosphorylation processes that play a critical role in cell-protein regulation; they isolated the first protein kinase, a class of enzymes that transfer phosphate from adenosine triphosphate to proteins; Nobel Prize, 1992.

Krebs, Hans Adolf (1900–1981), German-born British biochemist. Elucidated metabolic pathways, including the tricarboxytic acid cycle; Nobel Prize, 1953.

Kroemer, Herbert (1928–), German-American physicist and electronics engineer. Developed semiconductor heterostructures used in high-speed and opto-electronics, including fast transistors, laser diodes, and light-emitting diodes; Nobel Prize, 2000.

Krogh, Schack August Steenberg (1874–1949), Danish physiologist. Discovered the regulation of the vasomotor mechanism of capillaries; devised the nitrous oxide method for measuring human circulation; Nobel Prize, 1920.

Kronecker, Leopold (1823–1891), German mathematician. Contributed to theory of elliptical functions, algebra, and number theory, and attempted to unify these disciplines; attempted to base all mathematics on integers and finite processes.

Kroto, Harold W. (1939–), British chemist. Studied long-chain molecules found in radioastronomy by using microwave spectroscopy, which ultimately led to the discovery of fullerenes; Nobel Prize, 1996.

Kruskal, Martin David (1925–), American mathematician and physicist. Research in plasma physics, asymptotic phenomena, relativity, and minimal surfaces.

Kuhn, Richard (1900–1967), German chemist. Research on the structures and synthesis of vitamins and carotenoids; Nobel Prize, 1938 (declined).

Kundt, August Adolph (1839–1894), German physicist. Used Kundt tube to determine speed of sound in gases; determined ratio of specific heats of monatomic gases; with W. K. Röntgen, demonstrated Faraday effect in gases.

Kurchatov, Igor Vasilievich (1903–1960), Soviet physicist. Discovered nuclear isomers; studied nuclear reactions; developed nuclear weapons and nuclear power.

Kusch, Polykarp (1911–1993), German-born American physicist. Precisely determined the magnetic moment of the electron; Nobel Prize, 1955.

Kutta, Wilhelm Martin (1867–1944), German applied mathematician. Helped introduce concept of Kutta-Joukowski airfoil, prove Kutta-Joukowski theorem, and develop Runge-Kutta method.

Kwolek, Stephanie (1923–), American polymer chemist. Developed Kevlar, poly(*p*-phenylene terephthalamide), a lightweight synthetic fiber that is stronger than steel.

Lacaille, Nicolas Louis de (1713–1762), French astronomer and geodesist, Determined positions of nearly 10,000 stars in southern skies; measured lunar and solar parallax; showed that Earth has equatorial bulge.

Lafforgue, Laurent (1966–), French mathematician. Proved the global Langlands correspondence for function fields, a major advance toward the realization the Langlands program, which deals with deep connections between number theory, analysis, and group representation. Fields Medal, 2002.

Lagrange, Joseph Louis, Count (1736–1813), French geometer and astronomer. Invented the calculus of variations; studied the mathematics of sound; wrote *Mécanique Analytique*, concerning statics and dynamics.

Laguerre, Édmond Nicolas (1834–1886), French mathematician. Discovered Laguerre's differential equations and Laguerre polynomials.

Lamarck, Jean Baptiste Pierre Antoine de Monet, Chevailer de (1744–1829), French naturalist. Proposed theory that changes in animal and plant structure are caused by changes in environment; classified animals into vertebrates and invertebrates.

Lamb, Willis Eugene, Jr. (1913–), American physicist. Made precise atomic measurements leading to a new understanding of the theory of electron interactions and electromagnetic radiation; Nobel Prize, 1955.

Lambert, Johann Heinrich (1728–1777), German physicist. Formulated the Lambert theorem concerning the illumination of a surface.

Lamé, Gabriel (1795–1870), French mathematician, physicist, and engineer. Introduced curvilinear coordinates and applied them to differential equations, elasticity, thermodynamics, and number theory.

Landau, Lev Davydovich (1908–1968), Soviet physicist. Made theoretical explanation of the nature and properties of liquid helium; investigated condensed matter; Nobel Prize, 1962.

Landé, Alfred (1888–1975), German-born American physicist. Introduced Landé g factor; discovered Landé interval rule and Landé Γ-permanence rule.

Landsteiner, Karl (1868–1943), Austrian-born American pathologist. Discovered human blood groups and factors M and N; with A. S. Weiner, discovered the Rh factor; Nobel Prize, 1930.

Lange, Carl Georg (1834–1900), Danish physician and psychologist. With W. James, proposed the James-Lange theory of emotion.

Langerhans, Paul (1847–1888), German pathologist and anatomist. Studied human and animal microscopical anatomy, particularly structures of skin and pancreas; discovered islets of Langerhans.

Langevin, Paul (1872–1946), French physicist. Developed quantitative theories of paramagnetism and diamagnetism; helped to elucidate the theory of relativity; contributed to the development of sonar.

Langley, Samuel Pierpont (1834–1906), American astronomer and airplane pioneer. Studied infrared solar spectrum; constructed in 1896 the first mechanical heavier-than-air machine to fly.

Langmuir, Irving (1881–1957), American chemist. With G. N. Lewis, proposed the Lewis-Langmuir atomic theory; studied surface chemistry and thermionic emission; Nobel Prize, 1932.

Laplace, Pierre Simon, Marquis de (1749–1827), French astronomer and mathematician. Contributed to celestial mechanics, especially to the study of the Moon, Saturn, and Jupiter; formulated the theory of probability; discovered the Laplace differential equation.

Larmor, Joseph (1857–1942), British physicist. Developed electron theory which fused electromagnetic and optical concepts; introduced Larmor precession and derived Larmor formula.

Latimer, Louis Howard (1848–1928), American inventor. A collaborator of Alexander Graham Bell and Thomas Edison, this self-educated son of an escaped slave is best known for key inventions in the field of electric lighting.

Laue, Max Theodor Felix von (1879–1960), German physicist. Proposed the theory of x-ray diffraction by crystals; developed the Laue method of investigating crystal structure; Nobel Prize, 1914.

Laughlin, Robert Betts (1950–), American physicist. Provided a theoretical explanation for the fractional quantum Hall effect by showing how electrons acting together in strong magnetic fields can form new types of quasiparticles with charges that are fractions of electron charges; Nobel Prize, 1998.

Laurent, Pierre Alphonse (1813–1854), French mathematician and physicist. Introduced Laurent series; research on wave theory of light.

Lauterbur, Paul C. (1929–), American chemist. Discovered that it was possible to create a two-dimensional image of the body with magnetic resonance by introducing gradations in the external magnetic field, providing the basis for the development of magnetic resonance as a useful medical imaging technique. Nobel Prize, 2003.

Laveran, Charles Louis Alphonse (1845–1922), French physician. Discovered the malaria parasite; researched sleeping sickness; Nobel Prize, 1907.

Lavoisier, Antoine Laurent (1743–1794), French chemist. The founder of modern chemistry; studied combustion and respiration; published a table of the elements.

Lawrence, Ernest Orlando (1901–1958), American physicist. Discovery, development, and use of the cyclotron; Nobel Prize, 1939.

Lebesgue, Henry Léon (1875–1941), French mathematician. Developed theory of measure and integration; studied trigonometric series.

Le Chatelier, Henry Louis (1850–1936), French chemist and metallurgist. Research on cement chemistry, gas combustion, blast furnace reactions, chemical equilibria, alloy properties, and chemistry and metallurgy of iron and steel; formulated Le Chatelier's principle.

Leclanché, Georges (1839–1882), French chemist and electrician. Invented the Leclanché galvanic cell.

Lederberg, Joshua (1925–), American geneticist. With E. L. Tatum, discovered genetic recombination in bacteria and organization of genetic material; Nobel Prize, 1958.

Lederman, Leon Max (1922–), American physicist. Collaborated in experiment that demonstrated the existence of two types of neutrino; led an experiment that discovered the upsilon particle; Nobel Prize, 1988.

Lee, David Morris (1931–), American physicist. With D. D. Osheroff and R. C, Richardson, discovered superfluidity in helium-3; Nobel Prize, 1996.

Lee, Tsung-Dao (1926–), Chinese-born American physicist. With C. N. Yang disproved the parity principle; worked on statistical mechanics, astrophysics, nuclear and subnuclear physics, and field theory; Nobel Prize, 1957.

Lee, Yuan Tseh (1936–), American chemist. With Dudley R. Herschbach, developed crossed molecular-beam technique for tracing chemical reactions; Nobel Prize, 1986.

Legendre, Adrien Marie (1752–1833), French mathematician. Worked on elliptic functions, the theory of numbers, and the method of least squares.

Leggett, Anthony J. (1938–), British and American physicist. Developed a theory explaining the complex behavior of superfluid helium-3. Nobel Prize, 2003.

Lehn, Jean-Marie (1939–), French chemist. Studied crown ethers and developed the synthesis of related structures known as cryptands; Nobel Prize, 1987.

Leibniz, Gottfried Wilhelm, Baron von (1646–1716), German mathematician. Contributed to the development of differential calculus.

Leloir, Luis Federico (1906–1987), French-born Argentine biochemist. Discovered sugar nucleotides and their role in carbohydrate biosynthesis; Nobel Prize, 1970.

Lenard, Phillipp Eduard Anton (1862–1947), Hungarian-born German physicist. Studied cathode rays outside the discharge tube; worked on photoelectricity; Nobel Prize, 1905.

L'Enfant, Pierre Charles (1754–1825), French engineer. Designed Washington, D.C.

Lennard-Jones, John Edward (1894–1954), English physicist and chemist. Proposed Lennard-Jones potential for interatomic forces; contributed to quantum theory of molecular structure and statistical mechanics of liquids, gases, and surfaces.

Lenz, Heinrich Friedrich Emil (1804–1865), German physicist. Formulated Lenz's law governing induced current.

Leverrier, Urbain Jean Joseph (1811–1877), French astronomer. Studied Mercury, Uranus, and Neptune; credited, with J. C. Adams in England, as discoverer of Neptune.

Levi-Civita, Tullio (1873–1941), Italian mathematician and mathematical physicist. With G. Ricci-Curbastro, developed tensor analysis; introduced concept of parallelism in curved spaces.

Levi-Montalcini, Rita (1909–), Italian biologist. With S. Cohen, made landmark studies of nerve growth factor and its functions; Nobel Prize, 1986.

Lewis, Edward B. (1918–2004), American geneticist. Shared in discoveries showing the genetic involvement of early embryonic development with C. Nusselin-Volhard and E. F. Wieschaus; Nobel Prize, 1995.

Lewis, Gilbert Newton (1875–1946), American chemist. Collaborated in developing the Lewis-Langmuir atomic theory; worked on the electronic theory of valency and chemical thermodynamics.

Leydig, Franz von (1821–1908), German histologist and anatomist. Founder of comparative histology; promoted use of microscope in anatomical study; described cells in testes believed to secrete male hormones.

l'Hospital (l'Hôpital), Guillaume Françöis Antoine de, Marquis de Sainte-Mesme, Compte d'Entremont (1661–1704), French mathematician. Wrote first textbook on differential calculus, which gives l'Hospital's rule.

Libby, Willard Frank (1908–1980), American chemist. Developed the method of radiocarbon dating; Nobel Prize, 1960.

Lie, Marius Sophus (1842–1899), Norwegian mathematician. Originated the theory of tangential transformations.

Liebig, Justus, Baron von (1803–1873), German chemist. Discovered chloroform and chloral; founded agricultural chemistry; invented the Liebig condenser.

Linnaeus, Carolus, real name Carl von Linné (1707–1778), Swedish botanist. Developed the Linnaean system of biological classification.

Lions, Pierre-Louis (1956–), French mathematician. Made important contributions to the theory of nonlinear partial differential equations; Fields Medal, 1994.

Liouville, Joseph (1809–1882), French mathematician. Proved existence of transcendental functions; developed concept of geodesic curvature; originated theory of doubly periodic functions.

Lipmann, Fritz Albert (1899–1986), German-born American biochemist. Formulated general rules for the biotechnology of energy transmission; discovered coenzyme A; Nobel Prize, 1953.

Lippmann, Gabriel (1845–1921), French physicist. Produced the first colored photograph of the light spectrum; invented the Lippmann capillary electrometer; Nobel Prize, 1908.

Lipscomb, William Nunn, Jr. (1919–), American physical chemist. Studied structure and bonding of boranes, providing insight into nature of chemical bonding; Nobel Prize, 1976.

Lissajous, Jules Antoine (1822–1880), French physicist. Invented the vibration microscope, involving Lissajous figures.

Lister, Joseph, 1st Baron (1827–1912), English surgeon. Introduced antiseptics to surgery; pioneered in bacteriology.

Littlewood, John Endensor (1885–1977), British mathematician. Work on diophantine approximation, Tauberian theorems, Fourier series and associated function theory, the zeta function, additive number theory, and inequalities.

Littrow, Joseph Johann von (1781–1840), Austrian astronomer. Studied light refraction; worked on telescope construction.

Lloyd, Humphrey (1800–1881), Irish physicist. Discovered Lloyd's mirror interference; verified W. R. Hamilton's prediction of conical refraction.

Lobachevski, Nikola Ivanovich (1793–1856), Russian mathematician. Originated the first comprehensive system of noneuclidean geometry.

Loewi, Otto (1873–1961), German pharmacologist. Investigated nerve impulses; proved the role of ace-tylcholine in nerve impulse transmission; Nobel Prize, 1936.

Löffler, Friedrich August Johannes (1852–1915). German bacteriologist. Isolated the diphtheria (Klebs-Löffler) bacillus; developed protective serum against foot-and-mouth disease.

London, Fritz (1900–1954), German-born American physicist. Developed, with W. Heitler, theory of covalent bonding; with H. London, theory of superconductivity; and theory of superfluidity.

London, Heinz (1907–1970), German-born English physicist. Research on electrodynamic and ther-modynamic behavior of superconductors and properties of superfluid helium.

Lorentz, Hendrik Antoon (1853–1928), Dutch physicist. Proposed the electron theory to explain electromagnetic properties of materials; proposed the Lorentz-FitzGerald contraction and the Lorentz transformation, contributing to the theory of relativity; studied Zeeman effect; Nobel Prize, 1902.

Lorenz, Konrad Zacharias (1903–1989), Austrian zoologist. Pioneered in study of animal behavior patterns; discovered imprinting in birds; Nobel Prize, 1973.

Loschmidt, Johann Joseph (1821–1895), Austrian physicist and chemist, born in Bohemia. Worked on graphical and structural molecular formulas; attempted to estimate size of air molecules and number of air molecules per unit volume.

Lowry, Thomas Martin (1874–1936), British chemist. Simultaneously with Johannes Brønsted, defined acid-base theory in terms of proton transfer—the Brønsted-Lowry theory (of acids and bases).

Lummer, Otto Richard (1860–1925), German physicist. Codeveloper of Lummer-Brodhun sight box and Lummer-Gehrcke plate; constructed an improved bolometer.

Luria, Salvador Edward (1912–1991), Italian-born American biologist. Devised fluctuation test to demonstrate and study spontaneous mutations in bacteria and viruses; Nobel Prize, 1969.

Lwoff, André Michael (1902–1994), French biologist. Explained the phenomenon of lysogeny in bacteria; Nobel Prize, 1965.

Lyapunov, Aleksandr Mikhailovich (1857–1918), Soviet mathematician and physicist. Determined in what cases linear approximations can be used to solve the problem of stability of a mechanical system with a finite number of degrees of freedom; proved existence of various figures of equilibrium for a rotating liquid.

Lyell, Charles (1797–1875), British geologist. Wrote *Principles of Geology*, refuting catastrophic theory of geological changes.

Lyman, Theodore (1874–1954), American physicist. Observed ultraviolet spectra; clarified nature of Lyman ghosts; discovered Lyman series.

Lynen, Feodor (1911–1979), German biochemist. Research on the formation of the cholesterol molecule; discovered chemistry of biotin; Nobel Prize, 1964.

Lyot, Bernard Ferdinand (1879–1952), French astronomer. Invented the coronagraph and developed monochromatic filters that greatly extended knowledge of the solar corona.

MacDiarmid, Alan G. (1927–), New Zealand-born American chemist. Discovered and developed conductive polymers with Hideki Shirakawa and Alan Heeger; Nobel Prize, 2000.

Mach, Ernst (1838–1916), Austrian physicist. Research on supersonic flight, leading to Mach angle and Mach number; studied airflow over objects at high speeds.

MacKinnon, Roderick (1956–), American medical doctor and scientist. Determined structure and mechanism of ion channels in cell membranes; Nobel Prize, 2003.

Maclaurin, Colin (1698–1746), Scottish mathematician. Systematized and developed Newton's calculus; introduced Maclaurin series and Maclaurin-Cauchy test.

Macleod, John James Rickard (1876–1935), Scottish physiologist. Shared in discovery of insulin with F. G. Banting and C. H. Best; Nobel Prize, 1923.

Magnus, Heinrich Gustav (1802–1872), German physicist and chemist. Made first quantitative analysis of blood gases; showed that arterial blood has higher oxygen content than venous blood; discovered Magnus effect.

Majorana, Ettore (1906–1938), Italian physicist. Studied properties of elementary particles; postulated Majorana force.

Maksutov, Dmitry Dmitrievich (1896–1964), Soviet physicist and astronomer. Developed general theory of aplanatic optical systems; developed Maksutov system.

Malpighi, Marcello (1628–1694), Italian anatomist. Discovered the capillaries; made microscopic studies in embryology; discovered the Malpighian layer of the epidermis and the Malpighian corpuscles in the kidney.

Malus, Étienne Louis (1775–1812), French engineer and physicist. Formulated Malus' cosine-squared law concerning polarized light and Malus' law of rays.

Mandelstam, Stanley (1928–), American physicist, born in South Africa. Research in theoretical physics of elementary particles; introduced Mandelstam plane and Mandelstam representation.

Mansfield, Peter (1933–), British physicist. Developed mathematical techniques for capturing, analyzing, and processing magnetic resonance signals more efficiently, making it possible to produce three-dimensional images of internal organs. Nobel Prize, 2003.

Marconi, Guglielmo, Marquis (1874–1937), Italian electrician and inventor. Developed commercial wireless telegraphy; Nobel Prize, 1909.

Margulis, Gregori Aleksandrovich (1946–), Russian mathematician. Worked in combinatorics, differential geometry, ergodic theory, dynamical systems, and Lie groups; developed innovative analysis of the structure of Lie groups, describing their discrete subgroups; Fields Medal, 1978.

Mariotte, Edmé (?-1684), French physicist and physiologist. Discovered blind spot; studied circulation of sap in plants, collisions of bodies, properties of air, refraction and color of light, hydrostatics, hydraulics, and meteorology.

Marcus, Rudolph Arthur (1923–), Canadian-born American chemist. Developed the mathematical analysis for electron transfer reactions in chemical systems; Nobel Prize, 1992.

Mark, Herman Francis (1895–1992), Austrian-born American chemist. Elucidated molecular structures of natural and synthetic polymers; developed theory of polymerization; studied relation between structure and properties of macromolecular systems.

Markov, Andrei Andreevich (1856–1922), Russian mathematician. Formulated rigorous proofs of law of large numbers and central-limit theorem; introduced Markov chain.

Martin, Archer John Porter (1910–2002), English chemist. With R. L. M. Synge, developed partition chromatography; Nobel Prize, 1952.

Mascheroni, Lorenzo (1750–1800), Italian mathematician. Calculated Euler's constant; proved that all plane construction problems that can be solved with a ruler and compass can also be solved with a compass alone.

Mathieu, Emile Leonard (1835–1890), French mathematician and physicist. Worked on solution of partial differential equations; research in celestial and analytical mechanics; studied Mathieu equation and introduced Mathieu functions.

Matthias, Bernd Teo (1919–1980), German-born American physicist. Tested metals and alloys for superconductivity; developed empirical rules to predict new superconducting materials.

Maunder, Edward Walter (1851–1928), British astronomer. Observations of the sun, sunspots and eclipses.

Maupertuis, Pierre Louis Moreau de (1698–1759), French mathematician and astronomer. Discovered the principle of least action: mathematical writings on the properties of curves.

Maxwell, James Clerk (1831–1879), Scottish physicist. Formulated the electromagnetic theory of light and the Maxwell distribution of molecular velocities of gases; invented the Maxwell disk concerning color vision.

Mayall, Nicholas Ulrich (1906–1993), American astronomer. Research on nebulae, globular star clusters, and external galaxies.

Mayer, Julius Robert von (1814–1878), German physicist. Discovered the principle of conservation of energy.

Mayer, Maria Goeppert (1906–1972), German-born American nuclear physicist. With J. H. D. Jensen, discovered nuclear shell structure; Nobel Prize, 1963.

McClintock, Barbara (1902–1992), American geneticist. Discovered mobile genetic elements known as jumping genes; Nobel Prize, 1983.

McCoy, Elijah (1844–1929), Canadian-born American inventor. Educated in Scotland as a mechanical engineer, this son of former slaves is best known for inventing automatic lubricating systems for steam engines and industrial machines, greatly advancing the Industrial Revolution; the popularity of his products is believed to have led to the American expression "the real McCoy."

McMillan, Edwin Mattison (1907–1991), American physicist. Discovered element 93 (neptunium), which led to the creation of element 94 (plutonium); conceived the theory of phase stability; Nobel Prize, 1951.

McMullen, Curtis Tracy (1958–), American mathematician. Worked in hyperbolic geometry and in complex dynamics, also known as chaos theory; Fields Medal, 1998.

Meckel, Johann Friedrich (1781–1833), German anatomist and embryologist. Gave first comprehensive description of birth defects; described Meckel's cartilage; discovered Meckel's diverticulum.

Medawar, Peter Brian (1915–1987), Brazilian-born British biologist and medical scientist. Discovered acquired immunological tolerance; Nobel Prize, 1960.

Meissner, Alexander (1883–1958), Austrian-born German radio engineer. Helped develop improved electrical insulators and continuous-wave transmission; invented Meissner oscillator.

Meissner, Walther (1882–1974), German physicist. Research in low-temperature physics; discovered Meissner effect.

Meitner, Lise (1878–1968), German physicist. With O. Hahn, discovered protactinium; found evidence of four other radioactive elements; with Hahn and F. Strassmann, accomplished fission of uranium.

Mendel, Gregor Johann (1822–1884), Austrian botanist. Formulated Mendel's laws of heredity, the foundation of genetics.

Mendeleev, Dmitri Ivanovich (1834–1907), Russian chemist. Formulated Mendeleev's periodic law and table of the elements; research on interatomic and intermolecular forces.

Menelaus of Alexandria (1st century), Greek mathe matician and astronomer. Founded spherical trigonometry.

Mercator, Gerhardus, real name Gerhard Kremer (1512–1594), Flemish geographer. Created a chart of the world (Mercator projection); made surveying instruments.

Mercer, John (1791–1866), English chemist. Invented the mercerizing process for cotton.

Merrifield, Robert Bruce (1921–), American biochemist. Developed methods of protein synthesis, including solid-phase peptide synthesis that produces proteins by assembling amino acids sequentially into peptide chains; Nobel Prize, 1984.

Mersenne, Marin (1588–1648), French physicist. Showed that pitch is proportional to frequency and calculated frequencies of musical notes; discovered Mersenne's law for vibrating strings, and similar relations for wind and percussion instruments.

Messier, Charles (1730–1817), French astronomer. Credited with discovering 21 comets; compiled a catalog of nebulae.

Metchnikoff, Élie (1845–1916), Russian-born French zoologist and bacteriologist. Work on cholera and immunology; Nobel Prize, 1908.

Meusnier de la Place, Jean Baptiste Marie Charles (1754–1793), French mathematician, physicist, and chemist. Derived Meusnier's theorem of curvature of surface curve; with A. L. Lavoisier, did research on analysis and synthesis of water.

Meyerhof, Otto Fritz (1884–1951), German physiologist. Studied the glycogen-lactic acid cycle of muscles; Nobel Prize, 1923.

Michaelis, Leonor (1875–1949), German-born American biochemist. Developed theory of kinetics of enzyme-catalyzed reactions.

Michel, Hartmut (1948–), German chemist. With J. Deisenhofer and R. Huber, elucidated the structure of a bacterial protein that performs photosynthesis; Nobel Prize, 1988.

Michelson, Albert Abraham (1852–1931), American physicist. Experimented on the velocity of light with S. Newcomb; invented the Michelson interferometer; performed, with E. W. Morley, an experiment to determine the Earth's motion through the ether; Nobel Prize, 1907.

Mie, Gustav (1868–1957), German physicist. Carried out rigorous electrodynamic calculation of Mie scattering; attempted to formulate theory of matter.

Miller, William Hallowes (1801–1880), British crystallographer and mineralogist. Introduced Miller indices for identifying crystallographic planes.

Millikan, Robert Andrews (1868–1953), American physicist. Determined an accurate value for Planck's constant; originated the "oil drop" experiment to measure electronic charge; work on x-rays and cosmic rays; Nobel Prize, 1923.

Milnor, John Willard (1931–), American mathematician. Proved that a seven-dimensional sphere can have several differential structures, opening up the new field of differential topology; contributions to algebraic K theory, differential geometry, and algebraic topology; Fields Medal, 1962.

Milstein, César (1927–2002), British immunologist. With Georges J. F. Köhler, discovered a laboratory technique for producing monoclonal antibodies, highly uniform immune bodies that are selective in responding to target substances; Nobel Prize, 1984.

Minkowski, Hermann (1864–1909), Russian-born German mathematician. Studied the mathematical basis of relativity, notably the concept of the space-time continuum.

Minot, George Richards (1885–1950), American physician. With W. P. Murphy, first to recognize the value of liver therapy for pernicious anemia; studied arthritis, cancer, and vitamin B deficiency; Nobel Prize, 1934.

Mitchell, Peter (1920–1992), British chemist. Explained how plant and animal cells store and transfer energy by creating protonic gradients in the oxidative and photosynthetic phosphorylation processes; Nobel Prize, 1978.

Möbius, August Ferdinand (1790–1868), German mathematician and astronomer. Founder of topology; developed the Möbius strip.

Mohl, Hugo von (1805–1872), German botanist. Worked on the anatomy and physiology of higher plant forms; discovered protoplasm.

Mohorovičić, Andrija (1857–1936), Yugoslav meteorologist and seismoiogist. Discovered Mohorovičić seismic discontinuity.

Mohr, Carl Friedrich (1806–1879), German chemist. Developed titration procedures, including use of Mohr's salt.

Mohr, Christian Otto (1835–1918), German civil engineer. Studied stresses and strains of bodies, and failure of materials; introduced Mohr's stress circle.

Mohs, Friedrich (1773–1839), German mineralogist. Developed Mohs scale of hardness.

Moissan, Ferdinand Frédéric Henri (1852–1907), French chemist. First to isolate fluorine; invented an electric furnace and used it to produce synthetic metal compounds and samples of less common metals; Nobel Prize, 1906.

Molina, Mario J. (1943–), American chemist. Demonstrated that chemically inert chlorofluorocarbon (CFC) could be transported up to the ozone layer and could react with ultraviolet light and deplete the ozone layer; Nobel Prize, 1995.

Mollier, Richard (1863–1935), German physicist and engineer. Presented properties of thermodynamic media in form of charts and diagrams; introduced concept of enthalpy and Mollier diagram.

Moniz, Antonio Egas (1874–1955), Portuguese neurosurgeon. Developed cerebral angiography; introduced the prefrontal lobotomy; Nobel Prize, 1949.

Monod, Jacques (1910–1976), French biologist. With F. Jacob, proposed the concepts of messenger ribonucleic acid and of the operon; Nobel Prize, 1965.

Moody, Lewis Ferry (1880–1953), American hydraulic engineer. Made improvements in hydraulic turbines, pumps, and accessories.

Moore, Stanford (1913–1982), American biochemist. With W. H. Stein, developed technique for determining amino acid sequence in proteins, and applied it to ribonuclease; Nobel Prize, 1972.

Mordell, Louis Joel (1888–1972), American-born British mathematician. Worked in number theory; proved the finite basis theorem concerning the finite generation of the group of rational points on an elliptic curve; conjectured that there are only finitely many rational points on a curve of genus greater than 1 (the Mordell conjecture).

Morgagni, Giovanni Battista (1682–1771), Italian anatomist. Founded pathological anatomy; first to describe liver cirrhosis.

Morgan, Thomas Hunt (1866–1945), American geneticist, embryologist, and zoologist. Proposed the chromosome theory of heredity; Nobel Prize, 1933.

Morgan, William Wilson (1906–1994), American astronomer. Developed methods for investigating more precisely the structure of the Milky Way Galaxy and of other galaxies; collaborated in developing the Johnson-Morgan system of stellar magnitudes (with H. L. Johnson) and Bautz-Morgan classification of galaxy clusters (with L. P. Bautz).

Mori, Shigefumi (1951–), Japanese mathematician. Worked in algebraic geometry, particularly on the classification of algebraic varieties of dimension three; Fields Medal, 1990.

Morley, Edward Williams (1838–1923), American chemist and physicist. Associated with A. A. Michelson in an experiment on ether drift; research on variations of atmospheric oxygen content.

Morse, Samuel Finley Breese (1791–1872), American inventor. Invented the receiving and sending instruments for the telegraph, and a code for sending messages.

Moseley, Henry Gwyn Jeffries (1887–1915), English physicist. Discovered Moseley's law for frequency of x-ray spectral lines.

Mössbauer, Rudolf Ludwig (1929–), German physicist. Discovered the property of recoilless resonance absorption, the ability of some nuclei to emit and absorb gamma rays without energy loss; Nobel Prize, 1961.

Mossotti, Ottaviano Fabrizio (1791–1863), Italian physicist. Developed theory of dielectrics, from which he derived the Clausius-Mossotti equation.

Mott, Nevill Francis (1905–1996), British physicist. Applied quantum mechanics to study of charged particle scattering; with R. W. Gurney, developed Gurney-Mott theory of photographic process; introduced fundamental concepts elucidating electronic properties of disordered materials; Nobel Prize, 1977.

Mottelson, Ben Roy (1926–), American-born Danish physicist. With A. Bohr, developed theory which unifies shell and liquid-drop models of atomic nucleus, and which explains nonspherical nuclei; Nobel Prize, 1975.

Muller, Hermann Joseph (1890–1967), American geneticist. Studied genetic mutation rates under natural and artificial conditions; discovered the effect of x-rays on mutation rate; Nobel Prize, 1946.

Müller, Johannes Peter (1801–1858), German physiologist and anatomist. Proposed the principle of specific nerve energies, concerning stimuli to sense organs; discovered the Müllerian duct, an early embryonic structure.

Müller, Karl Alex (1927–), Swiss physicist. With J. G. Bednorz, discovered high-temperature superconductivity in copper oxide ceramic materials; Nobel Prize, 1987.

Müller, Paul Hermann (1899–1965), Swiss chemist. Discovered the insecticidal properties of DDT; Nobel Prize, 1948.

Mulliken, Robert Sanderson (1896–1986), American chemist. Applied principles of quantum mechanics to study of chemical bonding; with F, Hund, systematized electronic states of molecules in terms of molecular orbitals; Nobel Prize, 1966.

Mullis, Kary B. (1944–), American chemist. Invented the polymerase chain reaction (PCR) method used for studying DNA molecules; Nobel Prize, 1993.

Mumford, David Bryant (1937–), American mathematician. Worked in algebraic geometry, especially on problems of the existence and structure of varieties of moduli and on the theory of algebraic surfaces; Fields Medal, 1974.

Murad, Ferid (1936–), American pharmacologist. Analyzed the action of nitroglycerin and related vasodilating compounds, leading to the discovery that they release nitric oxide, which relaxes smooth muscle cells; his work, along with the research of Robert F. Furchgott and Louis J. Ignarro, led to the discovery of nitric oxide as a signaling molecule in the cardiovascular system; Nobel Prize, 1998.

Murchison, Roderick Impey (1792–1871), British geologist. Studied the order of rock formations in Great Britain; with A. Sedgwick, differentiated the Silurian and Devonian.

Murphy, William Parry (1892–1987), American physician. With G. R. Minot, first to suggest liver diet as a treatment for pernicious anemia; Nobel Prize, 1934.

Murray, Joseph (1919–), American physician. Performed the first successful transplant of a human organ, a kidney; with E. D. Thomas, helped define and then overcome the immunological mechanisms behind organ rejection; Nobel Prize, 1990.

Napier or Neper, John, Laird of Merchiston (1550–1617), Scottish mathematician. Invented the theory of logarithms and developed methods to compute them.

Nathans, Daniel (1928–1999), American biologist. Pioneered in the use of restriction enzymes to study the structure and functions of deoxyribonucleic acid (DNA) molecules; Nobel Prize, 1978.

Natta, Giulio (1903–1979), Italian chemist. Discovered stereospecific polymerization, making possible the production of new classes of macromolecules from inexpensive raw materials; Nobel Prize, 1963.

Navier, Claude Louis Marie Henri (1785–1836), French physicist and engineer. Studied analytical mechanics and its application to strength of materials, machines, and motion of solid and liquid bodies; formulated Navier-Stokes equations.

Néel, Louis Eugène Félix (1904–2000), French physicist. Proposed the theory of behavior of antiferromagnetic and other ferrimagnetic materials in which the cyrstal lattice is divided into one or more sublattices; Nobel Prize, 1970.

Neher, Erwin (1944–), German biophysicist. With B. Sakmann, using the "patch clamp" technique they developed, showed how individual ion channels control the passage of charged ions into and out of cells; Nobel Prize, 1991.

Nernst, Hermann Walther (1864–1941), German chemist. Proposed the heat theorem (third law of thermodynamics); determined the specific heat of solids at low temperatures; proposed the chain reaction theory in photochemistry; Nobel Prize, 1920.

Neumann, Carl Gottfried (1832–1925), German mathematician. Believed to be founder of logarithmic potentials; developed the potential theory.

Newcomb, Simon (1835–1909), American astronomer. With A. A. Michelson, determined the velocity of light; studied the motions of the Moon and planets.

Newton, Isaac (1642–1727), English mathematician. Proposed a dynamical theory of gravitation; discovered three basic laws of motion which are the foundation of practical mechanics; made discoveries in optics and mathematics.

Neyman, Jerzy (1894–1981), Russian-born American statistician. Developed methodology for making decisions based only on results of experiments or observations subject to chance.

Nicholson, Seth Barnes (1891–1963), American astronomer. Discovered four satellites of Jupiter; with E. Petit, invented a thermocouple to measure surface temperature of planets.

Nicol, William (1763–1851), Scottish physicist. Invented the Nicol prism for investigating the polarization of light.

Nicolle, Charles Jules Henri (1866–1936), French physician. Discovered the louse to be the transmission vector of typhus; Nobel Prize, 1928.

Nicomedes (3d century B.C.), Greek mathematician. Discovered the conchoid.

Nirenberg, Marshall Warren (1927–), American biochemist. Pioneered in deciphering genetic code; Nobel Prize, 1968.

Nishina, Yoshio (1890–1951), Japanese physicist. Pioneer in study of cosmic rays; with O. B. Klein, originated the Klein-Nishina formula.

Nobel, Alfred Bernhard (1833–1896), Swedish chemist and engineer. Invented dynamite and a blasting gelatin containing nitroglycerin; established the annual Nobel prizes.

Noguchi, Hideyo (1876–1928), Japanese bacteriologist. First to produce pure cultures of syphilis spirochetes; discovered the parasite of yellow fever.

Norrish, Ronald George Wreyford (1897–1978), British physical chemist. With G. Porter and colleagues, developed methods of flash photolysis and kinetic spectroscopy for the study of very fast reactions; Nobel Prize, 1967.

Northrop, John Howard (1891–1987), American biochemist. Isolated several enzymes and proved them to be proteins; isolated the first bacterial virus; established the chemical nature of enzymes and viruses; Nobel Prize, 1946.

Novikov, Sergi Petrovich (1938–), Russian mathematician. Worked in algebraic topology; proved the topological invariance of the Pontryagin classes of a differentiable manifold; studied the cohomology and homotopy of Thom spaces; Fields Medal, 1970.

Noyce, Robert Norton (1927–1990), American physicist, electronics engineer, and inventor. Participated in the invention of the integrated circuit.

Noyori, Ryoji (1938–), Japanese chemist. Developed chirally catalyzed hydrogenation reactions; Nobel Prize, 2001.

Nurse, Paul M. (1949–), British biologist. Identified, cloned, and characterized a key regulator of the cell cycle, cyclin-dependent kinase; Nobel Prize, 2001.

Nusselt, Ernst Kraft Wilhelm (1882–1957), German mechanical engineer and physicist. Used dimensional analysis to derive functional form of solutions to equations for heat flux in a flowing fluid.

Nüsslein-Volhard, Christiane (1942–), German developmental biologist. Using *Drosophila*, she and Eric Wieschaus identified and classified a small number of genes that are important in determining the body plan and the formation of body segments; their work, along with that of American development biologist Edward B. Lewis, led to the discovery of important genetic mechanisms which control early embryonic development; Nobel Prize, 1995.

Nyquist, Harry (1889–1976), Swedish-born American physicist and engineer. Discovered conditions necessary to keep feedback control circuits stable; determined Nyquist rate for communications channels.

Ochoa, Severe (1905–1993), Spanish-born American biochemist. Discovered a bacterial enzyme that synthesizes ribonucleic acid from nucleoside diphosphates; first to synthesize a ribonucleic acid; Nobel Prize, 1959.

Ockham, William of (ca. 1284–1347), English philosopher and theologian. Developed nominalist school of thought; postulated Ockham's razor.

Oersted, Hans Christian (1777–1851), Danish physicist, chemist, and electromagnetist. Discovered a fundamental principle of electromagnetism: a magnetic needle turns at right angles to an electric current.

Ohm, Georg Simon (1787–1854), German physicist. Discovered Ohm's law relating electrical resistance to voltage and current.

Olah, George A. (1927–), American chemist. Made fundamental contributions in carbocation chemistry; Nobel Prize, 1994.

Olbers, Heinrich Wilhelm Matthias (1758–1840), German astronomer. Devised new method for computing cometary orbits; proposed Glbers' paradox.

Onsager, Lars (1903–1976), Norwegian-born American chemist. Laid the foundation of irreversible thermodynamics; contributed to theories of dielectrics, electrolytes, and cooperative phenomena; Nobel Prize, 1968.

Oort, Jan Hendrik (1900–1992), Dutch astronomer. Research on the structure and dynamics of the galactic system; investigated the origin of comets.

Oppenheimer, J. Robert (1904–1967), American physicist. Research on nuclear disintegration, quantum theory, cosmic rays, and relativity; directed production of the atomic bomb.

Orr, John Boyd, Baron (1880–1971). Scottish physiologist and nutritionist. Work on animal nutrition; pioneer in science of human nutrition; Nobel Peace Prize, 1949.

Osheroff, Douglas D. (1945–), American physicist. With D. M. Lee and R. C. Richardson, discovered superfluidity in helium-3; Nobel Prize, 1996.

Ostwald, Friedrich Wilhelm (1853–1932), German chemist born in Latvia. Researches on affinity and mass action; discovered the Ostwald dilution law; worked on the catalytic oxidation of ammonia; Nobel Prize, 1909.

Otto, Nikolaus August (1832–1891), German inventor. Built the first four-stroke internal combustion engine.

Paget, James (1814–1899), English surgeon and pathologist. Studied pathology of tumors and bone and joint diseases; described osteitis deformans (Paget's disease).

Palade, George Emil (1912–), Rumanian born American cytologist. Applied electron microscope and centrifuge techniques to study of ultrastructure of cells; discovered ribosomes; Nobel Prize, 1974.

Papanicolaou, George Nicholas (1883–1962), Greek-born American cytologist and anatomist. Developed the Papanicolaou test for diagnosis of uterine cervical and endometrial cancer.

Pappus, Alexandrinus (ca. 3d–4th century), Greek mathematician. Wrote *Mathematical Collection*, an account of Greek geometry; formulated Pappus' theorems.

Paracelsus, Philippus Aureolus, real name Theophrastus Bombastus von Hohenheim (1493–1541), Swiss physician. Emphasized use of chemicals in medicine; advocated that diseases are specific and require specific remedies.

Paré, Ambroise (1509–1590), French surgeon. Advocated the treatment of wounds by tying arteries with ligatures rather than by cauterization; proposed improvements in operating methods.

Parkinson, James (1755–1824), English physician and paleontologist. Described parkinsonism.

Parseval des Chenes, Marc Antoine (1755–1836), French mathematician. Introduced an equation from which the theorem now known as Parseval's theorem is derived.

Pascal, Blaise (1623–1662), French mathematician and physicist. Contributed to the geometry of conies; formulated Pascal's law, relating to the pressure of a liquid at rest; applied Pascal's triangle to the calculation of probabilities.

Paschen, Louis Carl Heinrich Friedrich (1865–1947), German physicist. Established Paschen's law; with E. Back, discovered Paschen-Back effect; verified predictions of relativistic fine structure made by Bohr-Sommerfeld theory.

Pasteur, Louis (1822–1895), French biologist. Founder of microbiology; discovered the role of bacteria in fermentation; discovered anaerobic bacteria; developed the pasteurization process; demonstrated the efficacy of vaccination, especially for rabies.

Patterson, Arthur Lindo (1902–1966), New Zealand-born American physicist and crystallographer. Developed Patterson-Harker method of x-ray diffraction analysis of crystal structure.

Paul, Wolfgang (1913–1993), German physicist. Invented the Paul trap, which uses radio-frequency radiation to hold ions in a small volume; Nobel Prize, 1989.

Pauli, Wolfgang (1900–1958), Austrian-born American physicist. Worked on quantum theory; formulated the Pauli exclusion principle; contributed to matrix mechanics; Nobel Prize, 1945.

Pauling, Linus Carl (1901–1994), American chemist. Applied quantum theory to chemistry; research on molecular structure and chemical bonds; contributed to electrochemical theory of valency; Nobel Prize, 1954; Nobel Peace Prize, 1963.

Pavlov, Ivan Petrovich (1849–1936), Russian pathologist. Discovered the nerve fibers affecting heart action and the secretory nerves of the pancreas; research on the physiology of digestive glands; studied conditioned reflexes; Nobel Prize, 1904.

Peano, Giuseppe (1858–1932), Italian mathematician. Pioneer in symbolic logic and foundations of mathematics; promoted axiomatic method in mathematics; formulated postulates for natural numbers.

Pearl, Raymond (1879–1940), American biologist and statistician. Applied statistics to the study of population changes; introduced logistic curve describing population growth.

Pearson, Karl (1857–1936), English applied mathematician, statistician, and biometrician. Pioneered in application of statistics to biology; introduced chi-square test.

Pedersen, Charles J. (1904–1989), American chemist. Developed the synthesis of cyclic polyethers known as crown ethers; Nobel Prize, 1987.

Peierls, Rudolf Ernst (1907–1995). German-born British physicist. Developed theory of heat conduction in nonmetallic crystals; with O. R. Frisch, calculated critical mass of uranium-235.

Peirce, Charles Santiago Sanders (1839–1914), American mathematician, logician, and physicist. Laid foundation for logical analysis of mathematics; contributed to probability theory.

Pelletier, Pierre Joseph (1788–1842), French chemist. Discovered quinine, strychnine, and other alkaloids.

Peltier, Jean Charles Athanase (1785–1845), French physicist. Discovered the Peltier effect in thermoelectricity.

Penrose, Roger (1931–), British mathematician and physicist. Developed twistor theory of space-time geometry; studied singularities in classical general relativity theory.

Penzias, Arno A. (1933–), American astrophysicist. With R. W. Wilson, discovered cosmic background radiation, confirming the big bang theory of the origin of the universe; Nobel Prize, 1978.

Perl, Martin L. (1927–), American physicist. Discovered the tau lepton, a fundamental particle; Nobel Prize, 1995.

Pérot, Jean Baptiste Gaspard Gustav Alfred (1863–1925), French physicist. With C. Fabry, developed Fabry-Pérot interferometer.

Perrin, Jean Baptiste (1870–1942), French physicist. Research on the particle nature of cathode rays; found values for Avogadro's number, thereby proving the existence of molecules; Nobel Prize, 1926.

Perutz, Max Ferdinand (1914–2002), Austrian-born British crystallographer and molecular biologist. Worked on the structure of hemoglobin; introduced the method of isomorphous replacement with heavy atoms into protein crystallography; Nobel Prize, 1962.

Petit, Alexis Thérèse (1791–1820), French physicist. With P. L. Dulong, formulated the law of constancy of atomic heats; devised methods for determining thermal expansion and specific heats of solids.

Pettit, Edison (1890–1962). American astronomer. Studied the Sun and formulated laws alleged to govern the movement of prominences; constructed the interference polarizing monochromator; with S. B. Nicholson, devised a sensitive thermocouple to measure the surface temperatures of planets.

Pfaff, Johann Friedrich (1765–1825), German mathematician. Developed theory of Pfaffian differential equations, which is basic to general solution of partial differential equations.

Pfeiffer, Richard Friedrich Johann (1858–1945), German bacteriologist. Discovered Pfeiffer's bacillus in influenza; described Pfeiffer's reaction for determination of cholera.

Phillips, William Daniel (1948–), American physicist. Developed a method of slowing and trapping atoms in an atomic beam by using an opposed laser beam and a magnetic trap, and cooled these atoms to temperatures lower than the previously calculated theoretical limits: Nobel Prize, 1997.

Piaget, Jean (1896–1980), Swiss psychologist. Elucidated development of cognitive functions in the child.

Picard, Charles Émile (1856–1941), French mathematician. Formulated Picard's theorem relating to functions.

Piccard, Auguste (1884–1962), Swiss physicist. Conducted a data-collecting exploration of the stratosphere in an airtight gondola of a balloon; constructed and tested a bathysphere for deep-sea exploration.

Pickering, Edward Charles (1846–1919), American astronomer. Invented the meridian photometer; pioneered in stellar spectroscopy.

Pierce, George Washington (1872–1956). American physicist and electronic engineer. Developed theoretical basis of electrical communications: developed Pierce oscillator; with A. E. Kennelly, discovered concept of motional impedance.

Pitzer, Kenneth Sanborn (1914–1997), American chemist. Pioneered in the development of useful approximations which made possible the calculation of chemical thermodynamic properties of broad classes of chemical substances.

Planck, Max Karl Ernst Ludwig (1858–1947), German physicist. Presented the quantum theory; introduced Planck's constant, or quantum of action.

Planté, Gaston (1834–1889), French physicist. Constructed a storage battery, the first primitive accumulator.

Plateau, Joseph Antoine Ferdinand (1801–1883), Belgian physicist. Experimented with soapy films bounded by wires, noting that the surfaces formed were minimal surfaces; from this he formulated the Plateau problem (the problem of determining the existence of a minimal surface with a given space curve as its boundary).

Podolsky, Boris (1896–1966), Russian-born American physicist. Collaborated in formulation of Einstein-Podolsky-Rosen paradox; research on quantum electrodynamics.

Poggendorff, Johann Christian (1796–1877), German physicist. Introduced the small mirror on a suspended system to magnify small deflections of a light beam; invented the galvanometer.

Poincaré, Jules Henri (1854–1912), French mathematician. Worked on the theory of functions, on differential equations, and on the theory of orbits in astronomy.

Poinsot, Louis (1777–1859), French mathematician. Originated theory of couples.

Poiseuille, Jean Léonard Marie (1797–1869), French physiologist and physicist. Studied physiology of arterial circulation; invented improved methods for measuring blood pressure; discovered Hagen-Poiseuille law independently of G. H. L. Hagen.

Poisson, Siméon Denis (1781–1840), French mathematician. Worked on mathematical physics; contributed to the wave theory of light; formulated the Poisson ratio concerning the elasticity of materials.

Politzer, H. David (1949–), Discovered asymptotic freedom in the strong interactions (independent of D. J. Gross and F. Wilczek). Nobel Prize, 2004.

Polonyi, John C. (1929–), Canadian chemist. Studied chemiluminescence, a phenomenon in which the energy states of excited molecules are revealed by their emission of light; Nobel Prize, 1986.

Pomeranchuk, Isaak Yakolevich (1913–1966), Soviet physicist. Showed that energy of cosmic-ray electrons reaching the atmosphere is limited by their radiation in Earth's magnetic field; proved the Pomeranchuk theorem for scattering cross sections.

Pons, Jean Louis (1761–1831), French astronomer. Discovered 37 comets, including Encke's comet.

Pople, John A. (1925–2004), British-born chemist. Developed computational methods in quantum chemistry; Nobel Prize, 1998.

Porro, Ignazio (1801–1875), Italian topographer, geodesist, and physicist. Invented optical surveying instruments, Porro prism erecting system, and modern prism binoculars.

Porter, George (1920–2002), British chemist. With R. G. W. Norrish, developed the technique of flash photolysis to initiate and record very fast chemical reactions; Nobel Prize, 1967.

Porter, Rodney Robert (1917–1985), British biochemist. Research to determine chemical structure of immunoglobulins; Nobel Prize, 1972.

Powell, Cecil Frank (1903–1969), British physicist. Made practical the use of photographic emulsions in nuclear research; with G. P. S. Occhialini and others, discovered and investigated production of pions from cosmic radiation in the Earth's atmosphere; Nobel Prize, 1950.

Poynting, John Henry (1852–1914), English physicist. Determined the constant of gravitation and explained why a comet's tail points away from the Sun.

Prandtl, Ludwig (1875–1953), German physicist. Contributed to fluid mechanics, particularly aerodynamics; introduced concept of boundary layer.

Pregl, Fritz (1869–1930), Austrian chemist. Developed microchemical methods of analysis; Nobel Prize, 1923.

Prelog, Vladimir (1906–1998), Yugoslavian-born Swiss chemist. Investigated stereochemistry of organic molecules and reactions; Nobel Prize, 1975.

Prevost, Pierre (1751–1839), Swiss physicist. Developed theory of exchanges, explaining nature of heat.

Priestley, Joseph (1733–1804), English chemist and physicist. Discovered oxygen, ammonia, oxides of nitrogen, hydrochloric acid gas, nitrogen, carbon monoxide, and sulfur dioxide.

Prigogine, Ilya (1917–2003), Soviet-born Belgian chemist. Contributed to nonequilibrium thermodynamics, particularly the theory of dissipative structures; Nobel Prize, 1977.

Prokhorov, Aleksandr Mikhailovich (1916–2002), Soviet physicist. With N. G. Basov, devised a new method for amplifying electromagnetic radiation; Nobel Prize, 1964.

Prout, William (1785–1850), English physician and chemist. Formulated Prout's hypothesis concerning atomic weights.

Prusiner, Stanley B. (1942–), American neurologist. Discovered prions, a new biological agent of infection; Nobel Prize, 1997.

Ptolemy (2d century), Greco-Egyptian astronomer, geographer, and geometer at Alexandria. Proposed the Ptolemaic system, with the Earth as the center of the universe.

Pupin, Michael (1858–1935), Yogoslavian-born American physicist and electrical engineer. Developed inductance coils for telephone lines; contributed to x-ray fluoroscopy, design of radio transmitters, and network theory.

Purcell, Edward Mills (1912–1997), American physicist. Developed the method of nuclear resonance absorption; Nobel Prize, 1952.

Purkinje, Johannes Evangelista (1787–1869), Czech physiologist. Discovered the Purkinje effect in eye physiology and Purkinje cells in the cerebral cortex.

Pythagoras (6th century B.C.), Greek mathematician. Originated a system of geometry, including the Pythagorean theorem.

Quételet, Lambert Adolphe Jacques (1796–1874), Belgian statistician. Did pioneer work on statistics; applied the calculus of probabilities to sociological studies.

Quillen, Daniel Gray (1940–), American mathematician. Developed algebraic K-theory, an extension of ideas of A. Grothendieck to commutative rings, which employed geometric and topological methods and ideas to formulate and solve major problems in algebra, particularly ring theory and module theory; Fields Medal, 1978.

Rabi, Isidor Isaac (1898–1988), Austrian-born American physicist. Research on neutrons, magnetism, quantum mechanics, and nuclear physics; Nobel Prize, 1944.

Radô, Tibor (1895–1965), Hungarian-American mathematician. Solved the Plateau problem (the problem of determining the existence of a minimal surface with a given space curve as its boundary) about the same time as J. Douglas.

Radon, Johann (1887–1956), Bobemian-born Austrian mathematician. Work in calculus of variations and integration theory.

Rainwater, Leo James (1917–1986), American physicist. Suggested that shell-model potentials of certain atomic nuclei are not spherical but are deformed into spheroids, and proposed mechanism for this distortion; Nobel Prize, 1975.

Raman, Chandrasekhara Venkata (1888–1970), Indian physicist. Research on diffraction and oscillation; discovered the Raman effect; Nobel Prize, 1930.

Ramón y Cajal, Santiago (1852–1934), Spanish histologist. Isolated the neuron and made discoveries concerning nerve cells in gray matter and the spinal cord; Nobel Prize, 1906.

Ramsay, William (1852–1916), British chemist. With J. W. S. Rayleigh, discovered argon; with M. W. Travers, discovered neon, krypton, and xenon; Nobel Prize, 1904.

Ramsden, Jesse (1735–1800), English mathematical-instrument maker. Invented an eyepiece containing cross-wires as a measuring scale; introduced equatorial mounting for telescopes.

Ramsey, Norman Foster (1915–), American physicist. Invented an accurate method of measuring differences between atomic energy levels that formed the basis for the cesium atomic clock; worked on the hydrogen maser; Nobel Prize, 1989.

Rankine, William John Macquorn (1820–1872), Scottish civil engineer. Contributed to thermodynamics and theories of elasticity and waves; wrote textbooks on the steam engine and civil engineering.

Raoult, François Marie (1830–1901), French chemist. Formulated Raoult's law concerning vapor pressure of a solution.

Rathke, Martin Heinrich (1793–1860), German biologist. Discovered gill slits and gill arches in embryo birds and mammals, and Rathke's pocket in developing vertebrates.

Ray or Wray, John (1627?–1706), English naturalist. Identified the difference between mono- and dicotyledons; arranged plants according to their natural form, the foundation of the natural system of classification.

Rayleigh, John William Strutt, 3d Baron (1842–1919), English physicist. Worked on the theory of sound and on physical optics; with W. Ramsay, discovered argon; Nobel Prize, 1904.

Réaumur, René Antoine Ferchault de (1683–1757), French entomologist. Worked in biology and metallurgy; invented the Réaumur thermometer scale.

Regge, Tullio (1931–), Italian physicist. Played a role in introducing the idea of complex angular momenta into elementary particle physics.

Regiomontanus, real name Johann Müller (1436–1476), German astronomer. Erected the first European observatory, in 1471 in Nürnberg; produced mathematical tables.

Reichstein, Tadeus (1897–1996), Polish-born Swiss organic chemist. Isolated about 30 of the 40 substances produced by the adrenal cortex; synthesized and described the structure and properties of many of these substances; Nobel Prize, 1950.

Reines, Frederick (1918–1998), American physicist. With C. L. Cowan, made first detection of the neutrino, a fundamental particle; Nobel Prize, 1995.

Reynolds, Osborne (1842–1912), British engineer and physicist. Demonstrated streamline and turbulent flow in pipes, and showed that transition between them occurs at a critical velocity determined by Reynolds' number; introduced Reynolds' analogy.

Riccati, Jacopo Francesco (1676–1754), Italian mathematician. Research on analysis, particularly differential equations, and geometry.

Ricci-Curbastro, Gregorio (1853–1924), Italian mathematician and mathematical physicist. Developed theory of tensor analysis, providing mathematical foundation for general relativity.

Richards, Dickinson Woodruff (1895–1973), American physician. With A. F. Cournand, uitlized the technique of cardiac catheterization and proved its value as a diagnostic tool; Nobel Prize, 1956.

Richards, Theodore William (1868–1928), American chemist. Worked on atomic weights; experimentally confirmed the existence of isotopes of lead from uranium and thorium; Nobel Prize, 1914.

Richardson, Owen Willans (1879–1959), English physicist. Studied the emission of electricity from hot bodies and the electron theory of matter; Nobel Prize, 1928.

Richardson, Robert Coleman (1937–), American physicist. With D. M. Lee and D. D. Osheroff, discovered superfluidity in helium-3; Nobel Prize, 1996.

Richet, Charles Robert (1850–1935), French physiologist. Studied serum therapy and discovered anaphylaxis; Nobel Prize, 1913.

Richter, Burton (1931–), American physicist. Independently of S. C. C. Ting, discovered a new heavy elementary particle, which he named the psi particle; Nobel Prize, 1976.

Richter, Jeremias Benjamin (1762–1807), German chemist. Discovered the law of equivalent proportions.

Riemann, Georg Friedrich Bernhard (1826–1866), German mathematician. Originated Riemannian geometry, a noneuclidean system.

Riesz, Frigyes or Frederic (1880–1956), Hungarian mathematician. Did research on abstract and general theories related to mathematical analysis, particularly functional analysis; independently of E. Fischer, discovered Riesz-Fisher theorem.

Righi, Augusto (1850–1920), Italian physicist. Discovered magnetic hysteresis and Righi-Leduc effect, independently of S. A. Leduc; demonstrated that microwaves have all properties characteristic of light waves.

Ritchey, George Wills (1864–1945), American astronomer. Made important astronomical observations, particularly on the Andromeda nebula; with H. Chrétien, developed Ritchey-Chrétien optics.

Ritz, Walter (1878–1909), Swiss-born German physicist. Introduced Ritz combination principle; developed Ritz method for numerical solution of boundary-value problems.

Robbins, Frederick Chapman (1916–2003), American microbiologist. Discovered that poliomyelitis virus can be grown in various human tissue cultures; Nobel Prize, 1954.

Roberts, Richard J. (1943–), British geneticist. Independently of P. Sharp, discovered split genes; Nobel Prize, 1993.

Robinson, Robert (1886–1975), English chemist. Worked on plant pigments, alkaloids, and phenanthrene derivatives; Nobel Prize, 1947.

Roche, Edouard Adelbert (1820–1883), French physicist, mathematician, and meteorologist. Studied the internal structure and free-surface form of the celestial bodies; applied results to study of cosmogonic hypotheses.

Rodbell, Martin (1925–1998), American pharmacologist. With A. Gilman, discovered G-proteins and the role of these proteins in cellular signal transduction; Nobel Prize, 1994.

Rohrer, Heinrich (1933–), Swiss physicist. With G. Binnig, developed scanning tunneling microscope; Nobel Prize, 1986.

Rolle, Michel (1652–1719), French mathematician. Worked on Diophantine analysis and algebra of equations.

Röntgen, Wilhelm Konrad (1845–1923), German physicist. Discovered x-rays; Nobel Prize, 1901.

Roscoe, Henry Enfield (1833–1915), English chemist. With R. W. Bunsen, evolved the law of reciprocity and invented the actinometer; first to isolate metallic vanadium.

Rose, Irwin (1926–), American biochemist. Discovered ubiquitin-mediated protein degradation; Nobel Prize, 2004.

Rosen, Nathan (1909–1995), American-born Israeli physicist. Collaborated in formulation of Einstein-Podolsky-Rosen paradox; research on general relativity and gravitational waves.

Ross, Ronald (1857–1932), British physician. Proved that malaria is transmitted by the female *Anopheles* mosquito; Nobel Prize, 1902.

Rossby, Carl Gustaf Arvid (1898–1957), Swedish-born American meteorologist. Formulated theories of large-scale air movements; derived the Rossby formula, relating speed of propagation of perturbations to airflow and wavelengths of perturbations; devised the Rossby diagram, used to plot air mass properties.

Roth, Klaus Friedrich (1925–), German-born British mathematician. Solved a problem previously studied by A. Thue and C. Siegel concerning the approximation to algebraic numbers by rational numbers; proved that a sequence with no three numbers in arithmetic progression has zero density; Fields Medal, 1958.

Rous, Francis Peyton (1879–1970), American physician and virologist. Produced cancer in chickens by inoculating them with filterable virus procured from tissue of chickens with tumors; Nobel Prize, 1966.

Routh, Edward John (1831–1907), British mathematical physicist. Made contributions to classical mechanics, including procedure for eliminating cyclic coordinates from equations of motion.

Roux, Pierre Paul Emile (1853–1933), French physician and bacteriologist. Helped develop modern serum therapeutics, especially concerning diphtheria.

Rowland, F. Sherwood (1927–), American chemist. Demonstrated that chemically inert chlorofluorocarbon (CFC) could be transported up to the ozone layer and could react with ultraviolet light and deplete the ozone layer; Nobel Prize, 1995.

Rowland, Henry Augustus (1848–1901), American physicist. Developed the Rowland grating in spectroscopy; studied electromagnetism and heat.

Rubbia, Carlo (1934–), Italian physicist. Principal architect of experiment that first detected intermediate vector bosons, an important step in confirming theory uniting electromagnetic and weak nuclear interactions; Nobel Prize, 1984.

Rubens, Heinrich (1865–1922), German physicist. With E. B. Hagen, conducted electromagnetic experiments; built new types of galvanometer and bolometer.

Rumford, Benjamin Thompson, Count (1753–1814), British physicist. Carried out research on heat.

Runge, Carl David Tolme (1856–1927), German mathematician and physicist. Research on theoretical and experimental spectroscopy, particularly data reduction and development of series formulas; developed methods for numerical and graphical computation, including Runge-Kutta method.

Ruska, Ernst (1906–1988), German electronic engineer. Developed the electron microscope; Nobel Prize, 1986.

Russell Bertrand Arthur William (1872–1970), English mathematician and philosopher. With A. N. Whitehead, pioneered in study of mathematical logic.

Russell, Henry Norris (1877–1957), American astronomer and physicist. Analyzed eclipsing binary stars: with E. Hertzsprung, introduced Hertzsprung-Russell diagram; determined abundance of chemical elements in solar atmosphere; with F. A. Saunders, devised theory of Russell-Saunders coupling.

Rutherford, Ernest, 1st Baron (1871–1937), British physicist. Discovered alpha, beta, and gamma rays; suggested the divisible nuclear atom; effected the transmutation of an atom: Nobel Prize, 1908.

Ružička, Leopold (1887–1976), Swiss chemist born in Croatia. Research on many-membered rings and higher terpenes (including male sex hormones); Nobel Prize, 1939.

Rydberg, Johannes Robert (1854–1919), Swedish physicist. Developed a formula for series of spectral lines, involving Rydberg's constant.

Ryle, Martin (1918–1984), British astronomer. Devised aperture synthesis method in radiotelescopy; designed equipment and made observations in radio astronomy; Nobel Prize, 1974,

Sabatier, Paul (1854–1941), French chemist. Discovered, with J. B. Senderens, the process for catalytic hydrogenation of oils to solid fat; Nobel Prize, 1912.

Sabin, Albert Bruce (1906–1993), Polish-born American physician and virologist. Studied nature, mode of transmission, and epidemiology of human poliomyelitis; developed oral polio virus vaccine.

Sabine, Edward (1788–1883), British physicist and astronomer. Headed a magnetic survey of the world which discovered a connection between sunspots and terrestrial magnetic disturbances.

Sabine, Wallace Clement Ware (1868–1919), American physicist. Pioneered in architectural acoustics; discovered law determining reverberation time in acoustics.

Sachs, Julius von (1832–1897), German botanist. Studied the connection between sunlight and chlorophyll; worked on heliotropism and geotropism.

Saha, Meghnad (1894–1956), Indian physicist. Developed theory for degree of ionization of hot gases, a basic component of modern astrophysics.

Sakmann, Bert (1942–), German physiologist. With E. Neher, using the "patch clamp" technique they developed, showed how individual ion channels control the passage of charged ions into and out of cells: Nobel Prize, 1991.

Salam, Abdus (1926–1996), Pakistani physicist. Independently of S. Weinberg, developed theory uniting two of the basic forces of nature, electromagnetism and the weak nuclear interactions; Nobel Prize, 1979.

Salk, Jonas Edward (1914–1995), American physician. Produced killed-virus vaccine effective in preventing poliomyelitis.

Salpeter, Edwin Ernest (1924–), Austrian-born American physicist. Research in quantum theory of atoms, quantum electrodynamics, nuclear theory, energy production of stars, and theoretical astrophysics; with H. A. Bethe, introduced Bethe-Salpeter equation.

Samuelsson, Bengt Ingemar (1934–), Swedish biochemist and medical scientist. Studied prostaglandin metabolism and the formation of prostaglandin from arachidonic acid; Nobel Prize, 1982.

Sanctorius, real name Santorio Santorio (1561–1636), Italian physician. Invented the clinical thermometer; experimented with metabolism.

Sanger, Frederick (1918–), English chemist. Determined the exact order of amino acids in insulin; first to establish amino acid sequence for a protein; developed methods for determining nucleotide sequences (independently of W. Gilbert), advancing the technology of DNA recombination; Nobel Prizes. 1958 and 1980.

Savart, Félix (1791–1841), French physicist. Helped formulate the Biot-Savart law in electromagnetism.

Schally, Andrew Victor (1926–), Polish-born American physiologist. With R. Guillemin, isolated and analyzed peptide hormones secreted in hypothalmic region of brain which control anterior pituitary hormone secretion; Nobel Prize, 1977.

Schawlow, Arthur Leonard (1921–1999), American physicist. Contributed to invention of laser; made numerous contributions to laser spectroscopy, particularly the development of Doppler-free spectroscopy; Nobel Prize, 1981.

Scheele, Karl Wihelm (1742–1786), Swedish chemist. Made many discoveries, including oxygen (independently of J. Priestley), chlorine, and glycerin; synthesized many organic acids.

Schiaparelli, Glovanni Virginio (1835–1910), Italian astronomer. Discovered the connection between comets and meteorites, and the "canals" of Mars.

Schiff, Hugo Josef (1834–1915). German-born Italian organic chemist. Discovered Schiff bases; devised Schiff test; devised an improved nitrometer.

Schmidt, Bernhard Voldemar (1879–1935), Estonian-born German astronomer. Invented Schmidt system for astronomical telescopes.

Schmidt, Erhard (1876–1959), German mathematician. Extended D. Hilbert's work on integral equations; formalized and developed concept of Hilbert space.

Schoenflies, Arthur Moritz (1853–1928), German mathematician and crystallographer. Classified the 230 crystallographic space groups.

Schottky, Walter (1886–1976), Swiss-born German physicist. Discovered Schottky effect; invented screen grid and tetrode; developed Schottky theory of semiconductor-metal junctions.

Schrieffer, John Robert (1931–), American physicist. With J. Bardeen and L. N. Cooper, formulated a theory of superconductivity: Nobel Prize, 1972.

Schrödinger, Erwin (1887–1961), German physicist. Proposed concept of atomic structure based on wave mechanics; contributed to quantum theory and color theory; Nobel Prize, 1933.

Schur, Issai (1875–1941), Russian-born German mathematician. Contributed to representation theory of groups; research on group theory, matrices, algebraic equations, and number theory.

Schwartz, Laurent (1915–2002), French mathematician. Developed the theory of distributions, which provided an abstract and rigorous mathematical foundation for methods of formal calculation such as the Dirac delta function, and greatly extended their range of application; Fields Medal, 1950.

Schwartz, Melvin (1932–), American physicist. Collaborated in an experiment that demonstrated the existence of two types of neutrino; Nobel Prize, 1988.

Schwarz, Hermann Amandus (1843–1921), German mathematician. Introduced Schwarz-reflection principle and Schwarz's lemma while proving the Riemann mapping theorem.

Schwarzschild, Karl (1873–1916), German astronomer. Developed photographic methods for measuring brightness of stars; discovered Schwarzschild solution of equations of general relativity.

Schwarzschild, Martin (1912–1997), German-born American astronomer. Numerical studies of the internal structure and evolution of stars; astronomical observations with balloon-borne telescopes.

Schwinger, Julian Seymour (1918–1994), American physicist. Made fundamental contributions to the quantum theory of radiation; worked out the mathematical formalism of interaction between charged particles and an electromagnetic field; Nobel Prize, 1965.

Seaborg, Glenn Theodore (1912–1999), American chemist. Synthesized and identified eight transuranium elements and over a hundred isotopes; Nobel Prize, 1951.

Secchi, Pietro Angelo (1818–1878), Italian astronomer. Originated the spectroscopic survey of the heavens; made the first classification of stars according to spectral type.

Sedgwick, Adam (1785–1873), English geologist. With R. I. Murchison, established the Devonian system.

Seebeck, Thomas Johann (1770–1831), German physicist. Investigated thermoelectricity and invented the thermocouple.

Segrè, Emilio Gino (1905–1989), Italian-born American physicist. Codiscovered the elements technetium, astatine, and plutonium, slow neutrons, and the antiproton; Nobel Prize, 1959.

Seidel, Philipp Ludwig von (1821–1896), German astronomer and mathematician. Developed theory of aberrations; made first accurate photometric measurements of stars and planets, and evaluated them with probability theory.

Selberg, Atle (1917–), Norwegian-American mathematician. Worked on generalizations of the sieve methods of V. Brun; proved major results on zeros of the Riemann zeta function; with P. Erdös, gave an elementary proof of the prime number theorem, with a generalization to numbers in an arbitrary arithmetic progression; Fields Medal, 1950.

Semenov, Nikolai Nikolaevich (1896–1986), Soviet chemist. Elucidated the mechanisms of chemical reactions, especially the chain mechanism; Nobel Prize, 1956.

Senderens, Jean Baptiste (1856–1937), French chemist. With P. Sabatier, discovered hydrolysis of oils by catalysis.

Serber, Robert (1909–1997), American physicist. Laid foundations of orbit theory of high-energy particle accelerators; introduced Serber potential to describe nuclear forces.

Serre, Jean-Paul (1926–), French mathematician. Applied spectral sequences to discover fundamental connections between the homology groups and homotopy groups of a space and to prove important results on the homotopy groups of spheres; reformulated and extended some of the main results of complex variable theory in terms of sheaves; Fields Medal, 1954; Abel Prize, 2003.

Serret, Joseph Alfred (1819–1885), French mathematician and astronomer. Helped develop Frenet-Serret formulas in the theory of space curves.

Servetus, Michael (1511–1553), Spanish physician. Discovered the pulmonary circulation and the purification of the blood by the lungs.

Shannon, Claude Elwood (1916–2001), American mathematician. Developed mathematical theory of communication, making use of analogy between concepts of entropy and information.

Shapley, Harlow (1885–1972), American astronomer. Worked on a theory to explain cepheid variables; made an estimate of the size of the universe: provided a description of the universe's form of construction.

Sharp, Phillip A. (1944–), American geneticist. Independently of R. Roberts, discovered split genes; Nobel Prize, 1993.

Sharpless, K. Barry (1941–), American chemist. Developed chirally catalyzed oxidation reactions; Nobel Prize, 2001.

Sherrington, Charles Scott (1861–1952), English physiologist. Studied the neuron and its function and other aspects of the nervous system; Nobel Prize, 1932.

Shirakawa, Hideki (1936–), Japanese polymer scientist. Discovered and developed conductive polymers with Alan Heeger and Alan MacDiarmid; Nobel Prize, 2000.

Shockley, William (1910–1989), English-born American physicist. Discovered the transistor effect for electronic amplification by means of solid-state semiconductors; Nobel Prize, 1956.

Shor, Peter (1959–), American mathematician. Worked in combinatorial analysis and the theory of quantum computing; developed a computational method for factorizing large numbers on quantum computers, which, theoretically, could be used to break many of the coding systems currently employed.

Shubnikov, Aleksei Vasilevich (1887–1970), Soviet crystallographer. Classified Shubnikov groups; developed techniques for growing crystals, including synthetic rubies used in lasers.

Shull, Clifford G. (1915–2001), American physicist. Developed the neutron diffraction technique for studying the atomic structure of solids and liquids; Nobel Prize, 1994.

Siegbahn, Kai Manne Börje (1918–), Swedish physicist. Pioneered the development of high-resolution electron spectroscopy; Nobel Prize, 1981.

Siegbahn, Karl Manne Georg (1886–1978), Swedish physicist. Studied x-ray spectroscopy, in which he discovered the M series; Nobel Prize, 1924.

Siegel, Carl Ludwig (1896–1981), German mathematician. Worked on number theory, functions of one or several complex variables, and differential equations.

Siemens, Ernst Werner von (1816–1892), German engineer and electrician. Developed telegraphy and self-acting dynamo.

Siemens, William or Karl Wilhelm (1823–1883), German inventor in London. Made many inventions, including a differential governor, bathometer, dynamometer, and electric furnace.

Simpson, Thomas (1710–1761), English mathematician. Formulated the Simpson rule for finding the area of a figure, given only a limited number of data.

Singer, Isadore Manual (1924–), American mathematician. Worked in global analysis, especially the theory of elliptic operators and their applications to topology and geometry, and in mathematical physics; collaborated with M. F. Atiyah in proving the index theorem; Abel Prize, 2004.

Skou, Jens C. (1918–), Dutch chemist. Discovered an ion-transporting enzyme—sodium, potassium-stimulated adenosine triphosphatase (Na^+ , K^+-ATPase)—maintaining the balance of sodium and potassium ions in the living cell; Nobel Prize, 1997.

Slater, John Clarke (1900–1976), American physicist. Introduced Slater determinant describing many-electron systems; developed theory of magnetrons.

Smale, Stephen (1930–), American mathematician. Worked in differential topology, differential equations, and dynamical systems; proved that the sphere can be turned inside out and that the generalized Poincaré conjecture is valid for dimensions greater than 4; discovered strange attractors that lead to chaotic dynamical systems; Fields Medal, 1966.

Smalley, Richard E. (1943–), American chemist. Designed and built a special laser-supersonic cluster beam apparatus that was used in the discovery of fullerenes; Nobel Prize, 1996.

Smith, Hamilton Othanel (1931–), American geneticist. Isolated a restriction enzyme that cleaves deoxyribonucleic acid (DNA) molecules at a specific site; Nobel Prize, 1978.

Smith, Michael (1927–2000), Canadian chemist. Made fundamental contribution toward oligonucleotide-based, site-directed mutagenesis and its development for protein studies within DNA-based chemistry; Nobel Prize, 1993.

Smith, Robert (1689–1768), English physicist. Developed a particulate theory of light; developed geometric propositions for computing properties of optical systems; derived a special case of the Smith-Helmholtz law.

Snell, George Davis (1903–1996), American immunogeneticist. Demonstrated the x-ray induction of mutational changes in a mammal; contributed to the study of immunological systems and to the development of transplant immunology; Nobel Prize, 1980.

Snell, Willebrod van Roijen (1591–1626), Dutch mathematician. Formulated Snell laws concerning angles of incidence and refraction; conceived the idea of measuring the Earth by triangulation.

Soddy, Frederick (1877–1956), English chemist. With E. Rutherford, developed theory of atomic disintegration of radioactive substances; research on isotopes; Nobel Prize, 1921.

Solvay, Ernest (1838–1922), Belgian industrial chemist. Developed the Solvay process for production of sodium carbonate.

Sommerfeld, Arnold (1868–1951), German physicist. Developed quantum theory, especially in its application to sprectral lines and the Bohr atomic model.

Sörensen, Sören Peter Lauritz (1868–1939), Danish biochemist. Did pioneer work on hydrogen ion concentration; invented the symbol pH.

Spemann, Hans (1869–1941), German zoologist. Studied embryonic development and discovered the organizer function of certain tissues; Nobel Prize, 1935.

Sperry, Roger Wolcott (1913–1994), American neuroscientist. Discovered the functional split between the left and right hemispheres of the brain; Nobel Prize, 1981.

Spörer, Gustav Friedrich Wilhelm (1822–1895), German astronomer. Observations of the sun and sunspots.

Stanley, Wendell Meredith (1904–1971), American biochemist. Discovered that a virus is a nucleoprotein and can be crystallized; Nobel Prize, 1946.

Stanton, Thomas Ernest (1865–1931), English engineer. Studied surface friction of fluids; built wind tunnel for wind velocity investigations; studied strength of materials, heat transmission, and lubrication.

Stark, Johannes (1874–1957), German physicist. Studied radiation and atomic theory; discovered the Stark effect on spectrum lines and the Doppler effect in canal rays; Nobel Prize, 1919.

Staudinger, Hermann (1881–1965), German chemist. Conceived and elaborated the explanation of phenomenon of polymerization; Nobel Prize, 1953.

Steenrod, Norman Earl (1910–1971), American mathematician. Worked in topology; introduced Steenrod algebra.

Stefan, Josef (1835–1893), Austrian physicist. Originated Stefan's (or Stefan-Boltzmann) law of blackbody radiation; proposed theory of diffusion of gases; studied gas conductivity.

Stein, William Howard (1911–1980), American biochemist. With S. Moore, developed technique for determining amino acid sequence in proteins, and applied it to ribonuclease; Nobel Prize, 1972.

Steinberger, Jack (1931–), German-born American physicist. Collaborated in an experiment that demonstrated the existence of two types of neutrino; Nobel Prize, 1988.

Steinmetz, Charles Proteus (1865–1923), German-born American electrical engineer. Developed complex number technique for analyzing alternating-current circuits; made numerous electrical inventions; applied mathematical methods to solution of electrical engineering problems.

Stern, Otto (1888–1969), German-born American physicist. Developed the molecular beam method and used it to prove directly the existence of the magnetic moment of atoms and nuclei and to measure their magnitudes; Nobel Prize, 1943.

Stieltjes, Thomas Jan (1856–1894), Dutch-born French mathematician. Developed analytic theory of continued fractions, and Stieltjes integral as a tool for their study.

Stirling, James (1692–1770), British mathematician. Discovered Stirling's formula and Stirling's interpolation formula.

Stokes, George Gabriel (1819–1903), British mathematician and physicist. Originated the idea of determining the chemical composition of the Sun and stars from their spectra; studied double refraction and electromagnetic waves.

Stone, Marshall Harvey (1903–1989), American mathematician. Studied structural aspects of mathematical situations having origins in classic problems of analysis, geometry, and logic.

Störmer, Carl Fredrik Mülertz (1874–1957), Norwegian mathematician and geophysicist. Studied atmospheric phenomena; discovered the Stormer cone concerning cosmic rays.

Störmer, Horst Ludwig (1949–), German-American physicist. With D. C. Tsui, discovered the fractional quantum Hall effect, a manifestation of a new form of quantum fluid with fractionally charged excitations; Nobel Prize, 1998.

Strassman, Fritz (1902–1980), German chemist. With O. Hahn and L. Meitner, discovered nuclear fission; research on uranium and thorium isotopes.

Strömgren, Bengt Georg Daniel (1908–1987), Swedish-born American astronomer. Developed theory of neubulae consisting of hydrogen ionized by hot stars.

Struve, Friedrich Georg Wilhelm von (1793–1864), German-born Russian astronomer. Authority on double stars and nebulae; one of the first to measure a stellar parallax.

Struve, Otto Wilhelm von (1819–1905), Russian astronomer. Discovered some 500 new double stars; calculated the constant of precession.

Sturgeon, William (1783–1850), English electrician and inventor. Constructed the first useful electromagnet and the first moving-coil galvanometer.

Sturm, Jacques Charles François (1803–1855), French mathematician. Formulated the Sturm theorems, concerning real roots of an equation.

Suhl, Harry (1922–), German-born American physicist. Discovered Suhl effect; invented Suhl amplifier; studied resonance in magnetic materials, superconductivity, and general theory of magnetism.

Sulston, John E. (1942–), British geneticist. Using the nematode *Caenorhabditis elegans* as a model system, discovered that specific cells in the cell lineage always die through programmed cell death. Described the visible steps in the cellular death process and demonstrated the first mutations of genes participating in programmed cell death. Nobel Prize, 2002.

Sumner, James Batcheller (1887–1955), American biochemist. First to isolate an enzyme in pure, crystalline form and characterize it as a protein; Nobel Prize, 1946.

Sutherland, Earl Wilbur, Jr. (1915–1974), American physiologist. Uncovered intermediary role of cyclic adenylic acid in the mechanism of hormone control over human metabolic activities; Nobel Prize, 1971.

Svedberg, Theodor (1884–1971), Swedish chemist. An authority on colloid chemistry (dispersed phase); developed a centrifuge for colloidal particles and protein molecules; Nobel Prize, 1926.

Sydenham, Thomas (1624–1689), English physician. Gave classic descriptions of gout, venereal disease, fevers, hysteria, and Sydenham's chorea.

Synge, Richard Laurence Millington (1914–1994), English chemist. Developed partition chromatography with A. J. P. Martin; Nobel Prize, 1952.

Szent-Györgyi, Albert von Nagyrapolt (1893–1986), Hungarian biochemist. Isolated vitamin C; research on combustion processes in plant and animal tissues, muscular contraction, and cell division; Nobel Prize, 1937.

Talbot, William Henry Fox (1800–1877), English inventor and mathematician. Invented the calotype photographic process.

Tamm, Igor Yevgenevich (1895–1971), Soviet physicist. With I. M. Frank, formulated the mathematical theory explaining the physical origin and properties of Cerenkov radiation; Nobel Prize, 1958.

Tanaka, Koichi (1959–), Japanese engineer. Developed soft desorption ionization method for mass spectrometric analyses of biological macromolecules; Nobel Prize, 2002.

Tatum, Edward Lawrie (1909–1975), American biochemist and geneticist. Researched the relation of genes to biochemical reactions in bacterial, yeast, and mold cells; with G. W. Beadle, discovered the phenomenon of genetic recombination in bacteria; Nobel Prize, 1958.

Taube, Henry (1915–), American chemist. Elucidated the mechanisms of electron transfer reactions, especially in metal complexes; Nobel Prize, 1983.

Taylor, Brook (1685–1731), English mathematician. Formulated Taylor's theorem and worked on mathematics of physical problems.

Taylor, Geoffrey Ingram (1886–1975), British mathematician. Work in theoretical hydrodynamics, particularly turbulence and effect of rotation on fluid flow.

Taylor, Joseph Hooten, Jr. (1941–), American astronomer. With R. A. Hulse, discovered a binary pulsar and studied it to observe phenomena predicted by general relativity; Nobel Prize, 1993.

Taylor, Richard Edward (1929–), American physicist. Collaborated in experiments that demonstrated that protons, neutrons, and similar particles are made up of quarks; Nobel Prize, 1990.

Taylor, Richard Lawrence (1962–), British mathematician. Assisted A. Wiles in the proof of Fermat's last theorem; collaborated with C. Breuil, B. Conrad, and F. Diamond in extending this work by proving the Taniyama-Shimura conjecture on elliptic curves.

Teisserenc de Bort, Léon Philippe (1855–1913), French meteorologist. Discovered the stratosphere.

Teller, Edward (1908–2003), Hungarian-born American physicist. With associates, developed the concept which led to the construction of the first hydrogen bomb; with G. Gamow, proposed the Gamow-Teller interaction and Gamow-Teller selection rules.

Temin, Howard Martin (1934–1994), American virologist. Proposed that genetic information is transferred from ribonucleic acid tumor viruses to deoxyribonucleic acid; independently of D. Baltimore, discovered reverse transcriptase; Nobel Prize, 1975.

Tesla, Nikola (1856–1943), American inventor born in what is now Croatia of Serbian parents. Invented the induction motor, a high-frequency electric coil; improved design of dynamos, transformers, and electric bulbs.

Thales (ca. 640-ca. 546 B.C.), Greek mathematician and astronomer. First to scientifically predict an eclipse of the Sun; discovered static electricity; credited with formulating several theorems.

Theiler, Max (1899–1972), South African physician and virologist. Developed a vaccine to prevent human yellow fever; Nobel Prize, 1951.

Theorell, Axel Hugo Teodor (1903–1982), Swedish biochemist. Made discoveries concerning the nature and mode of action of oxidative enzymes; Nobel Prize, 1955.

Thiele, F. K. Johannes (1865–1918), German chemist. Research on nitrogen compounds and the theory of unsaturated organic molecules.

Thom, René (1923–2002), French mathematician. Invented and developed the theory of cobordism in algebraic topology, a classification of manifolds that used homotopy theory in a fundamental way; developed catastrophe theory; Fields Medal, 1958.

Thomas, Edward Donnall (1920–), American physician. Performed the first successful transfer of bone marrow from one individual to another; with J. Murray, helped define and then overcome the immunological mechanisms behind organ rejection; Nobel Prize, 1990.

Thomas, Llewellyn Hilleth (1903–1992), English-born American physicist. Discovered Thomas precession; with E. Fermi, developed Thomas-Fermi atomic model; developed basic theory for Thomas cyclotron.

Thompson, John Griggs (1932–), American-British mathematician. Worked on theory of finite groups; with W. Feit, proved that all noncyclic finite simple groups have even order; determined the finite simple groups whose proper subgroups are solvable (minimal simple groups); Fields Medal, 1970.

Thomson, George Paget (1892–1975), English physicist. Discovered, independently of C. J. Davisson, the diffraction of electrons by crystals; Nobel Prize, 1937.

Thomson, Joseph John (1856–1940), English physicist. Discovered that cathode rays consist of negatively charged particles, or electrons; Nobel Prize, 1906.

't Hooft, Gerardus (1946–), Dutch physicist. With M. J. G. Veltman, elucidated the quantum structure of the electroweak interactions, placing the theory of these interactions and similar particle physics theories on a firmer mathematical foundation by showing how they may be used for precise calculations of physical quantities; Nobel Prize, 1999.

Thouless, David James (1934–), British physicist. Studied many-body problem and its applications to nuclear and condensed matter physics, including phase transitions in superfluid helium films and electrons in disordered systems.

Thue, Axel (1863–1922), Norwegian mathematician. Worked on number theory, especially algebraic numbers and Diophantine equations.

Thurston, William Paul (1946–), American mathematician. Advanced the study of topology in two and three dimensions, showing relationships between analysis, topology, and geometry; suggested that a very large class of closed three-manifolds carry a hyperbolic structure; Fields Medal, 1982.

Tinbergen, Nikolaas (1907–1988), Dutch-born British zoologist. Pioneered in study of social behavior of animals and their responses to complex stimuli; conducted experimental studies of the effects of selection pressures and evolutionary response to them; Nobel Prize, 1973.

Ting, Samuel Chao Chung (1936–), American physicist. Independently of B. Richter, discovered a new heavy elementary particle, which he named the J particle; Nobel Prize, 1976.

Tiselius, Arne Wilhelm Kaurin (1902–1971), Swedish biochemist. Research on electrophoresis and absorption analysis; made discoveries concerning the complex nature of serum proteins; Nobel Prize, 1948.

Todd of Trumpington, Alexander Robertus Todd, Baron (1907–1997), British chemist. Worked on the structure and synthesis of nucleotides, and nucleotide coenzymes, and the related problem of phosphorylation; Nobel Prize, 1957.

Tomlinson, Ray (1941–), American computer engineer. Invented electronic mail, including the use of @ in the address.

Tomonaga, Sin-Itiro (1906–1979), Japanese physicist. Showed the modern theory of quantum electrodynamics to be quantitatively consistent with observed physical phenomena; Nobel Prize, 1965.

Tonegawa, Susumu (1939–), Japanese immunologist. Discovered how a limited number of genes are capable of producing a vast number of diverse antibodies, each designed for a specific invading foreign substance; Nobel Prize, 1987.

Torricelli, Evangelista (1608–1647), Italian physicist. Invented the mercury barometer.

Townes, Charles Hard (1915–), American physicist. Invented the maser; Nobel Prize, 1964.

Townsend, John Sealy Edward (1868–1957), British physicist. Developed collision theory of ionization of gases in an electric field.

Travers, Morris William (1872–1961), English chemist. Discovered, with W. Ramsay, krypton, xenon, and neon; investigated low-temperature phenomena.

Ts'ai Lun (fl. 105), Chinese inventor. Invented paper.

Tsui, Daniel Chee (1939–), Chinese-born American physicist. With H. L. Störmer, discovered the fractional quantum Hall effect, a manifestation of a new form of quantum fluid with fractionally charged excitations; Nobel Prize, 1998.

Turing, Alan Mathison (1912–1954), English mathematician. Developed concept of Turing machine; research on mathematical logic, group theory, and computer technology.

Tychonoff (Tikhonov), Andrei Nikolaevich (1906–1993), Soviet mathematician and geophysicist. Proved Tychonoff theorem in topology and introduced concept of Tychonoff space.

Tyndall, John (1820–1893), British physicist. Studied temperature waves in metals and diathermancy of gases; discovered the effect of atmospheric density on sound transmission.

Uhlenbeck, George Eugene (1900–1988), Javanese-born American physicist. With S. Goudsmit, developed hypothesis of electron spin.

Urey, Harold Clayton (1893–1981), American chemist. Isolated heavy water and thus discovered the heavy isotope of hydrogen; Nobel Prize, 1934.

Urysohn, Pavel Samuilovich (1898–1924), Soviet mathematician. Proved Urysohn's lemma in topology.

Van Allen, James Alfred (1914–), American physicist. Discovered that the Earth is circled by two high-energy radiation belts, leading to major revisions in concepts of the Earth's atmosphere and magnetic field.

Van de Graaff, Robert Jemison (1901–1967), American physicist. Contributed to the development of the direct particle accelerator and invented the electrostatic belt generator.

van der Meer, Simon (1925–), Dutch physicist. Devised method to ensure frequent and efficient collision of accelerated protons and antiprotons in the superproton synchrotron at CERN, contributing to discovery of intermediate vector bosons; Nobel Prize, 1984.

Vandermonde, Alexandre Théophile (1735–1796), French mathematician. Gave first logical exposition of theory of determinants; developed methods to test solvability of algebraic equations.

van der Waals, Johannes Diderik (1837–1923), Dutch physicist. Formulated van der Waals equation; investigated van der Waals forces, concerning intermolecular attraction; Nobel Prize, 1910.

Vane, John Robert (1927–), English pharmacologist. Discovered prostaglandin X (prostacyclin) and the role of aspirinlike drugs as blocking agents in the prostaglandin synthesis; Nobel Prize, 1982.

van Rhijn, Pieter Johannes (1886–1960), Dutch astrophysicist. With J. C. Kapetyn, evolved a theory of the universe.

van't Hoff, Jacobus Hendricus (1852–1911), Dutch chemist. Pioneered in the study of stereochemistry; studied reaction rates, thermodynamics applied to chemistry, and the theory of dilute solutions; Nobel Prize, 1901.

Van Vleck, Jan Hasbrouck (1899–1980), American mathematical physicist. Pioneer in the development of the modern quantum-mechanical theory of magnetism; Nobel Prize, 1977.

Varmus, Harold (1939–), American researcher in molecular virology and oncogenesis. With J. M. Bishop, researched the genetic basis of human cancers; their work led to the identification of over 50 cellular genes that can become oncogenes; Nobel Prize, 1989.

Vauquelin, Louis Nicola (1763–1829), French chemist. Discovered chromium and its compounds and beryllium compounds.

Vega, George, Baron von (1756–1802), Austrian mathematician. Prepared logarithmic tables.

Veltman, Martinus J. G. (1931–), Dutch physicist. With G. 't Hooft, elucidated the quantum structure of the electroweak interactions, placing the theory of these interactions and similar particle physics theories on a firmer mathematical foundation by showing how they may be used for precise calculations of physical quantities; Nobel Prize, 1999.

Verdet, Marcel Emile (1824–1866), French physicist. Determined dependence of Faraday effect on magnetic field strength, wavelength of the light, and index of refraction of the material.

Vernier, Pierre (1580–1637), French technician. Invented the Vernier scale.

Vesalius, Andreas (1514–1564), Belgian anatomist in Italy. Known as the father of modern anatomy; corrected many of Galen's mistaken doctrines.

Viète, François, or Franciscus Vieta (1540–1603), French mathematician. Worked on the solution of equations up to the fourth degree and laid the foundation of modern algebra.

Virtanen, Artturi Ilmari (1895–1973), Finnish biochemist. Research on problems of human nutrition and agriculture; investigated acidity (pH) and biological nitrogen fixation; Nobel Prize, 1945.

Voevodsky, Vladimir (1966–), Russian mathematician. Developed a new cohomology theory for algebraic varieties, which represented an important advance in number theory and algebraic geometry. Fields Medal, 2002.

Vogel, Hermann Wilhelm (1834–1898), German photochemist. Invented the orthochromatic photographic plate and designed a photometer.

Voigt, Woldemar (1850–1919), German physicist. Introduced transformation equations (later known as Lorentz transformations).

Volta, Alessandro, Count (1745–1827), Italian physicist. Invented the voltaic pile; developed the theory of current electricity.

Volterra, Vito (1860–1940), Italian mathematician. Developed method of solving Volterra equations; pioneered in developing functional analysis.

Von Braun, Wernher (1912–1977), German-born American rocket engineer. Directed development of the German V-2 and Wassefall missiles; instrumental in launch of *Explorer 1*, first American artificial satellite; supervised development of Saturn rockets for the Apollo program.

Von Euler, Ulf Svante (1905–1983), Swedish physiologist. Identified norepinephrine as neurotransmitter of sympathetic nervous system; isolated and characterized norepinephrine storage granules in nerves; Nobel Prize, 1970.

von Kármán, Theodore (1881–1963), American aerodynamicist. Theoretical contributions to aerodynamics; formulated von Kármán's theory of vortex streets, an early step in the mathematical treatment of turbulent motion.

von Neumann, John (1903–1954), Hungarian-born American mathematician. Research in logic, theory of quantum mechanics, theory of high-speed computing machines, and mathematical theory of games and strategy.

Wagner von Jauregg (Wagner-Jauregg), Julius (1857–1940), Austrian psychiatrist. Developed use of malarial infection to treat general paresis; Nobel Prize, 1927.

Waksman, Selman Abraham (1888–1973), Russian-born American bacteriologist. Isolated the antibiotic streptomycin; Nobel Prize, 1952.

Wald, George (1906–1997), American biologist and biochemist. Discovered the role of vitamin A in vision; Nobel Prize, 1967.

Walker, John E. (1941–), British chemist. Made major contributions toward elucidating the enzymatic mechanism underlying the synthesis of adenosine triphosphate (ATP) by clarifying the structural conditions of the enzyme; Nobel Prize, 1997.

Wallace, Alfred Russel (1823–1913), English naturalist. Originated, independently of C. Darwin, theory of natural selection; postulated Wallace's line regarding geographical distribution of animals.

Wallach, Otto (1847–1931), German chemist. Research on essential oils and the terpenes; Nobel Prize, 1910.

Wallis, John (1616–1703), English mathematician. Worked on algebraic curves, interpolation, evaluation of integrals, infinite series, mechanics, and algebra; derived Wallis product and Wallis formulas.

Walton, Ernest Thomas Sinton (1903–1995), British physicist. With J. D. Cockcroft, devised high-voltage apparatus capable of producing fast atomic particles with energies up to 700,000 electronvolts; showed the capability of these particles to disintegrate many light elements; Nobel Prize, 1951.

Wannier, Gregory Hugh (1911–1983), Swiss-born American physicist. Developed harmonization of localized and nonlocalized descriptions of electrons in solids.

Warburg, Otto Heinrich (1883–1970), German physiologist. Worked on chemistry of respiration and on cancer; Nobel Prize, 1931.

Wassermann, August von (1866–1925), German physician. Discovered the Wassermann test for the detection of syphilis.

Watson, James Dewey (1928–), American biochemist. With F. H. C. Crick, determined the double-helix structure of deoxyribonucleic acid; Nobel Prize, 1962.

Watson, John Broadus (1878–1958), American psychologist. Founded the behaviorist school of psychology.

Watt, James (1736–1819), Scottish inventor. Improved the steam engine, making it a commercial success.

Weber, Ernst Heinrich (1795–1878), German anatomist and physiologist. Discovered Weberian apparatus; applied hydrodynamics to study of blood circulation; discovered inhibitory power of vagus nerve; proposed Weber's law of stimuli.

Weber, Heinrich (1842–1913), German mathematician. Introduced Weber differential equation; demonstrated Abel theorem in its most general form; proved that absolute Abelian fields are cyclotomic.

Weber, Wilhelm Eduard (1804–1891), German physicist. Devised instruments for measurement of electrical and magnetic quantities; formulated absolute electrical and magnetic units.

Wegener, Alfred Lothar (1880–1930), German geologist. Presented the idea of continental drift.

Welerstrass, Karl Theodor (1815–1897), German mathematician. Worked on the theory of functions and on the calculus of variations.

Weil, Adolf (1848–1916), German physician. Gave classic description of Weil's disease.

Weil, André (1906–1998), French-born American mathematician. Laid the foundations for abstract algebraic geometry and the modern theory of algebraic varieties, starting a rapid advance in both algebraic geometry and number theory.

Weinberg, Steven (1933–), American physicist. Independently of A. Salam, developed theory uniting two of the basic forces of nature, electromagnetism and the weak nuclear interactions; Nobel Prize, 1979.

Weismann, August (1834–1914), German biologist. Contributed to the theory of heredity, which he attributed to variations in "germ-plasm."

Weiss, Pierre (1865–1940), French physicist. Developed phenomenological theory of ferromagnetism.

Weizsäcker, Carl Friedrich von (1912–), German physicist. Helped develop method for calculating bremsstrahlung in high-energy collisions; developed a theory of origin of solar system.

Weller, Thomas Huckle (1915–), American virologist and parasitologist. Isolated the virus of chickenpox and herpes zoster and proved the common etiology of the two diseases; first to propagate German measles virus; Nobel Prize, 1954.

Wentzel, Gregor (1898–1978), German-born American physicist. Helped develop Wentzel-Kramers-Brillouin method; research on theory of atomic spectra, wave mechanics, quantum electrodynamics, meson field theories, and statistical mechanics of many-body problems, especially superconductivity.

Werner, Alfred (1866–1919), Swiss chemist. Formulated the coordination theory of valency; Nobel Prize, 1913.

Weyl, Hermann (1885–1955), German-born American mathematician and mathematical physicist. Basic research on group representations and Riemann surfaces.

Wheatstone, Charles (1802–1875), English physicist and inventor. Conducted experiments on sound; invented Wheatstone's bridge, an instrument for comparing electrical resistances.

Wheeler, John Archibald (1911–), American physicist. Introduced the concepts of the scattering matrix and resonating group structure into nuclear physics; with N. Bohr, elucidated the mechanism of nuclear fission and predicted the fissibility of plutonium.

Whewell, William (1794–1866), British astronomer. Work on the tides, and on the history and philosophy of science.

Whipple, George Hoyt (1878–1976), American pathologist. Studied anemia and liver treatment; Nobel Prize, 1934.

Whitehead, Alfred North (1861–1947), English mathematician, physicist, and philosopher. With B. Russell, pioneered in mathematical logic and foundations of mathematics.

Whittaker, Edmund Taylor (1873–1956), British mathematician and physicist. Studied special functions of mathematical physics and equations satisfied by them, particularly Whittaker's differential equation; found general integral representation for harmonic functions; made major contributions to analytical dynamics.

Wiedemann, Gustave Heinrich (1826–1899), German physicist and physical chemist. With R. Franz, discovered Wiedemann-Franz law of thermal conductivity of metals; discovered Wiedemann effect.

Wieland, Heinrich (1877–1957), German chemist. Studied bile acids, chlorophyll, and hemoglobin; Nobel Prize, 1927.

Wieman, Carl Edwin (1951–), American physicist. With E. A. Cornell, succeeded in producing Bose-Einstein condensates in a dilute gas of alkali (rubidium) atoms, and carried out fundamental studies of their properties, including studies of collective excitations and vortex formation in condensates; Nobel Prize, 2001.

Wien, Wilhelm (1864–1928), German physicist. Formulated the two Wien laws pertaining to radiation from blackbodies; Nobel Prize, 1911.

Wiener, Norbert (1894–1964), American mathematician. Formulated a mathematical theory of Brownian motion; founded science of cybernetics.

Wieschaus, Eric F. (1947–), American developmental biologist. Using *Drosophila*, he and the German developmental biologist Christiane Nüsslein-Volhard identified and classified a small number of genes that are important in determining the body plan and the formation of body segments; their work, along with that of American development biologist Edward B. Lewis, led to the discovery of important genetic mechanisms which control early embryonic development; Nobel Prize, 1995.

Wiesel, Torsten Nils (1924–), Swedish physiologist. Contributed to the study of the processing of visual information in the brain; Nobel Prize, 1981.

Wigner, Eugene Paul (1902–1995). Hungarian-born American mathematical physicist. With G. Breit, worked out the Breit-Wigner formula for resonant nuclear reactions; proposed the Wigner theorem of conservation of the angular momentum of electron spin; Nobel Prize, 1963.

Wilczek, Frank (1951–), Discovered asymptotic freedom in the strong interactions (in collaboration with D. J. Gross, and independent of H. D. Politzer). Nobel Prize, 2004.

Wiles, Andrew John (1953–), British mathematician. Proved Fermat's last theorem with assistance of R. Taylor.

Wilkins, Maurice Hugh Frederick (1916–2004), English biophysicist born in New Zealand. Made x-ray diffraction studies that contributed to the structural determination of deoxyribonucleic acid; Nobel Prize, 1962.

Wilkinson, Geoffrey (1921–1996), British chemist. Research to determine how metals and organic molecules combine to form unique molecules which have sandwichlike structures; Nobel Prize, 1973.

Williamson, William Crawford (1816–1895), English naturalist. Laid the foundation for paleobotany and showed the importance of plant life forms in coal.

Willstätter, Richard (1872–1942), German chemist. Worked on plant pigments; investigated alkaloids and their derivatives; Nobel Prize, 1915.

Wilson, Charles Thomson Rees (1869–1959), British physicist. Worked on ionization; originated the cloud chamber method of studying ionized particles; Nobel Prize, 1927.

Wilson, Kenneth Geddes (1936–), American physicist. Used renormalization group theory to analyze critical phenomena in the behavior of matter at phase transitions; Nobel Prize, 1982.

Wilson, Robert Woodrow (1936–), American astrophysicist. With A. A. Penzias, discovered cosmic background radiation, confirming the big bang theory of the origin of the universe; Nobel Prize, 1978.

Windaus, Adolf (1876–1959), German chemist. Worked on sterols; discovered that ultraviolet light activates ergosterol and gives vitamin D$_2$; Nobel Prize, 1928.

Witten, Edward (1951–), American mathematical physicist. Applied advanced mathematical tools to theoretical physics, particularly quantum field theory, supersymmetry, and string theory; his physical insights were the basis for major developments in mathematics; Fields Medal, 1990.

Wittig, Georg (1897–1987), German chemist. Work on the linking of carbon and phosphorus (Wittig reaction) made it possible to synthesize new types of compounds, including metal-organic complex compounds; Nobel Prize, 1979.

Wöhler, Friedrich (1800–1882), German chemist. First to synthesize an organic compound, urea.

Wolf, Maximilian Franz Joseph Cornelius (1863–1932), German astronomer. Invented the photographic method of discovering asteroids.

Wollaston, William Hyde (1766–1828), English chemist and physicist. Discovered the lines in the solar spectrum; discovered palladium and rhodium; invented the Wollaston lens.

Woodward, Robert Burns (1917–1979), American chemist. Contributed to the development of total synthesis of complex natural products, and structural determination of several complex natural molecules, later confirmed by total synthesis; Nobei Prize, 1965.

Wright, Almroth Edward (1861–1947), British physician and pathologist. Studied parasitic disease; introduced inoculation against typhoid.

Wright, Wilbur (1867–1912) **and Orville** (1871–1948), American pioneers in aviation. Built the first successful airplane, which each flew at Kitty Hawk, North Carolina, on Dec. 17, 1903.

Wundt, Wilhelm Max (1832–1920), German physiologist and psychologist. Founded the first laboratory for experimental psychology.

Wurtz, Charles Adolphe (1817–1884), French chemist. Discovered methyl and ethyl amines; evolved the Wurtz reaction for synthesis of hydrocarbons.

Wüthrich, Kurt (1938–), Swiss chemist. Developed nuclear magnetic resonance spectroscopy for determining the three-dimensional structure of biological macromolecules in solution; Nobel Prize, 2002.

Yalow, Rosalyn Sussman (1921–), American medical physicist. Developed a radioimmunoassay technique to detect and measure minute levels of substances such as hormones in the body; Nobel Prize, 1977.

Yang, Chen Ning (1922–), Chinese-born American physicist. With T. Lee, disproved the law of conservation of parity for weak interactions; Nobel Prize, 1957.

Yau, Shing-Tung (1949–), Chinese-born American mathematician. Worked in differential geometry and partial differential equations; solved the Calabi conjecture in algebraic geometry and the positive mass conjecture of general relativity theory; Fields Medal, 1982.

Yersin, Alexandre Émile Jean (1863–1943), Swiss bacteriologist. Discovered the bubonic plague bacillus in Hong Kong, working independently of S. Kitasato, and developed a serum for it.

Yoccoz, Jean-Christophe (1957–), French mathematician. Worked on the theory of dynamical systems; Fields Medal, 1994.

Young, Thomas (1773–1829), English physicist and physician. Discovered the effect of the ciliary muscle on the shape of the eye lens (the mechanism of accommodation).

Yukawa, Hideki (1907–1981), Japanese physicist. Postulated the existence of a new fundamental particle, the meson; Nobel Prize, 1949.

Zariski, Oscar (1899–1986), Russian-born American mathematician. Worked in algebraic geometry, in paricular, on local uniformization and reduction of singularities of algebraic varieties.

Zeeman, Pieter (1865–1943), Dutch physicist. Discovered the Zeeman effect in magnetooptics; Nobel Prize, 1902.

Zelmanov, Efim Isaakovich (1955–), Russian mathematician. Contributed to the theory of Jordan algebras and the theory of Lie algebras; solved the restricted Burnside problem, one of the fundamental questions in group theory; Fields Medal, 1994.

Zener, Clarence Melvin (1905–1993), American physicist. Proposed mechanism of Zener breakdown.

Zeno of Elea (ca. 490–425 B.C.), Greek philosopher and mathematician. Formulated a group of paradoxes, important for their stimulation of philosophical and mathematical thought, which appear to deny the possibility of motion.

Zernike, Fritz (1888–1966), Dutch physicist. Developed the phase-contrast microscope, making possible the first microscopic examination of the internal structure of living cells; Nobel Prize, 1953.

Zewail, Ahmed H. (1946–), Egyptian-born American chemist. Studies the transition states of chemical reactions using femtosecond spectroscopy; Nobel Prize, 1999.

Ziegler, Karl (1898–1973), German organic chemist. Developed a low-pressure process for production of polyethylene; Nobel Prize, 1963.

Zinkerngagel, Rolf M. (1944–), Swiss-born American immunologist and physician. Shared in the discovery of the specificity of cell-mediated immune defense with P. C. Doherty; Nobel Prize, 1996.

Zinsser, Hans (1878–1940), American bacteriologist. Developed methods of immunization against typhus.

Zsigmondy, Richard (1865–1929), German chemist. Studied colloidal solutions; introduced the ul-tramicroscope; Nobel Prize, 1925.

Zworykin, Vladimir Kosma (1889–1982), Russian-born American physicist. Pioneer in the development of television and the electron microscope.

Contributor Initials

Each aricle in the Encyclopedia is signed with the contributor's initials; coauthors' initials are separated by semicolons. The section below, Contributor Initials, gives all such initials, alphabetized according to the capital letters in each initials combination (lowercase letters have been added to differentiate contributors with like initials). The contributor's name is provided. The contributor's affiliation can then be found by turning to the next section, Contributor Affiliations.

Contributor Affiliations

The list below comprises an alphabetical sequence, according to surname, of all contributors to the Encyclopedia. A brief affiliation is provided for each author. This list may be used in conjunction with the previous section, Contributor Initials, to fully identify the contributor of each article.

A

Aagaard, Prof. Knut. Department of Oceanography, University of Washington.

Abbott, Dr. Donald P. Professor of Biology, Hopkins Marine Station, Stanford University, Pacific Grove, California.

Able, Dr. Kenneth P. Department of Biological Sciences, State University of New York, Albany.

Abraham, Dr. Bernard M. Solid State Science Division, Argonne National Laboratory, Argonne, Illinois.

Abrahams, David H. Dexter Chemical Corporation, Bronx, New York.

Abrahams, Prof. Elihu. Department of Physics, Rutgers University.

Abrahamson, Prof. Warren G., II. Department of Biology, Bucknell University, Lewisburg, Pennsylvania.

Abramovitch, Dr. Rudolph A. Department of Chemistry and Geology, Clemson University.

Abzug, Dr. Malcolm J. Senior Staff Engineer, Systems Group, TRW, Inc., Redondo Beach, California.

Achey, Prof. Phillip M. Institute of Food and Agricultural Sciences, University of Florida.

Ackerman, Dr. Edward A. Deceased; formerly, Carnegie Institution of Washington.

Adair, Dr. Robert K. Department of Physics, Yale University.

Adams, Dr. Chris. Unilever Research, Merseyside, England.

Adams, Prof. Douglas P. Department of Mechanical Engineering, Massachusetts Institute of Technology.

Adams, Dr. E. Dwight. Department of Physics, University of Florida.

Adams, Dr. Elijah. Professor and Head, Department of Biological Chemistry, School of Medicine, University of Maryland.

Adams, Prof. M. W. Department of Crop and Soil Sciences, Michigan State University.

Adams, Dr. Raymond D. Bullard Professor Emeritus of Neuropathology, Massachusetts General Hospital.

Adamson, Prof. Arthur W. Department of Chemistry, University of Southern California.

Addicott, Prof. Fredrick T. Department of Botany, University of California, Davis.

Addison, Cyril C. Professor of Inorganic Chemistry, University of Nottingham, England.

Adelberg, Dr. Edward A. Department of Microbiology, Yale University.

Adelman, Dr. William J., Jr. National Institutes of Health, Bethesda, Maryland.

Ader, Prof. Robert. Department of Psychiatry, University of Rochester, New York.

Adewumi, Prof. Michael A. Petroleum and Natural Gas Engineering, Pennsylvania State University.

Adkins, George G. Retired; formerly, Chief, Department of River Basins, Bureau of Power, Federal Power Commission.

Adler, Dr. David. Department of Electrical Engineering, Massachusetts Institute of Technology.

Adler, Dr. Ronald J. Lockheed Palo Alto Research Laboratories, Palo Alto, California.

Adrain, Dr. Jonathan. University of Iowa, Department of Geosciences, Iowa City.

Agarwal, Dr. Gyan C. Department of Electrical Engineering, University of Illinois.

Agrios, Dr. George N. Department of Plant Pathology, University of Massachusetts.

Aguiar, Jose L. Farm Advisor, University of California Cooperative Extension, Riverside County, Indio.

Ahearn, Prof. Gregory A. Department of Zoology, University of Hawaii, Manoa.

Ahlstrom, Dr. Elbert H. Deceased; formerly, Fishery Oceanography Center, U.S. Bureau of Commercial Fisheries, La Jolla, California.

Ahmadjian, Dr. Vernon. Department of Biology, Clark University, Worcester, Massachusetts.

Ahuja, Prof. Narendra. Department of Electrical and Computer Engineering, Beckman Institute and Coordinated Science Laboratory, University of Illinois, Urbana.

Ajmone-Marsan, Dr. Cosimo. Chief, Branch of Electroencephalography and Clinical Neurophysiology, National Institute of Neurological Diseases and Stroke, National Institutes of Health, Bethesda, Maryland.

Ajzenberg-Selove, Prof. Fay. Physics Department, University of Pennsylvania.

Akasofu, S.-I. Director, International Arctic Research Center, University of Alaska, Fairbanks.

Akers, Dr. Donald L. School of Medicine, Tulane University.

Akesson, Dr. Norman G. Agricultural Engineering Department, University of California, Davis.

Albert, Dr. Henry J. Manager, Physics and Metallurgy Laboratory, Research and Development Department, Engelhard Industries Division, Engelhard Minerals and Chemicals Corporation, Newark, New Jersey.

Albright, Dr. Louis D. Department of Agricultural and Biological Engineering, Cornell University, Ithaca, New York.

Albright, Dr. Lyle F. Department of Chemical Engineering, Purdue University.

Alcorn, Prof. Stanley M. Department of Plant Pathology, College of Agriculture, University of Arizona.

Aldridge, Dr. R. J. Department of Geology, University of Nottingham, England.

Aldwinckle, Prof. H. S. Department of Plant Pathology, Cornell University.

Alexander, Dr. Gene. Laboratory of Neurosciences, National Institutes of Aging and Health, Bethesda, Maryland.

Alexander, Prof. R. McNeill. Department of Biology, University of Leeds, England.

Alexander, Dr. Vera. Institute of Marine Science, University of Alaska.

Alexeff, Prof. Igor. Department of Electrical and Computer Engineering, University of Tennessee, Knoxville.

Alger, Prof. Philip L. Deceased; formerly, Consulting Professor of Electrical Engineering, Rensselaer Polytechnic Institute.

Algermissen, Dr. S. T. Aurora, Colorado.

Allan, Roger. Executive Editor, “Electronic Design Magazine,” Rochelle Park, New Jersey.

Allan, William. Dean (retired), School of Engineering, City College of the City University of New York.

Alldredge, Alice L. Department of Biological Sciences, University of California, Santa Barbara.

Allen, Dr. John A. U.M.B.S.M., Marine Station, Isle of Cumbrae, Scotland.

Allen, Prof. Lawrence H. Department of Astronomy, University of California, Los Angeles.

Allen, Prof. Leland C. Department of Chemistry, Princeton University.

Allen, Prof. Phillip E. School of Electrical and Computer Engineering, Georgia Institute of Technology, Atlanta.

Allenby, Dr. Braden R. Vice President, AT&T Environment, Health and Safety, Basking Ridge, New Jersey.

Alley, Prof. Charles L. Department of Electrical Engineering, University of Utah.

Allfrey, Dr. Vincent G. Department of Cell Biology, Rockefeller University.

Allport, H. Burnham. Union Carbide Chemical Company, Cleveland, Ohio.

Allred, Dr. Albert L. Department of Chemistry, Northwestern University.

Almgren, Dr. Frederick J., Jr. Department of Mathematics, Princeton University.

Almond, Dr. Peter R. Department of Biophysics, University of Texas, Houston.

Aloia, Dr. John F. Department of Medicine, Winthrop-University Hospital, Mineola, New York.

Alpern, Milton. Manager, Special Projects Division, Shah Associates, P.C., Bellmore, New York.

Altaian, Dr. David. Division Vice President and Technical Director, United Technology Center, Sunnyvale, California.

Altamuro, Vincent M. President, Robotics Research, Division of VMA. Inc., Toms River, New Jersey.

Altrock, Dr. Richard C. National Optical Astronomy Observatories, National Solar Observatory/Sacramento Peak, Sunspot, New Mexico.

Alvim, Dr. Paulo dc T. Centre de Pesquisas Do Cacau (CEPEC), Itabuna. Bahia, Brazil.

Alvord, Dr. Ellsworth C., Jr. Department of Neuropathology, University of Washington.

Ammons, Dr. Nelle. Retired; Department of Biology, West Virginia University.

Amsden, Dr. Thomas W. Geologist, Oklahoma Geological Survey, Norman.

Anagnostakis, Dr. Sandra L. Department of Pathology & Ecology, Connecticut Agriculture Experimental Station, New Haven.

Anders, James E., Sr. President, Hydraulics Associates, Bethlehem, Pennsylvania.

Andersen, Prof. David R. Department of Electrical and Computer Engineering, University of Iowa, Iowa City.

Anderson, Prof. Alan P. Department of Electronic and Electrical Engineering, University of Sheffield, England.

Anderson, Dr. Alfred T., Jr. Department of Geophysical Sciences, University of Chicago.

Anderson, Prof. Dana Z. Joint Institute for Laboratory Astrophysics, University of Colorado.

Anderson, Harry R. H. R. Anderson and Associates, Inc., Consulting Engineers, Eugene, Oregon.

Anderson, Jr., Dr. John D. Jet Propulsion Laboratory, California Institute of Technology.

Anderson, Dr. O. Roger. Lamont-Doherty Geological Observatory, Palisades, New York.

Anderson, Dr. Paul M. Department of Electrical and Computer Engineering, Arizona State University.

Anderson, Prof. Richard G. W. Department of Cell Biology and Neuroscience, University of Texas Southwestern Medical Center, Dallas.

Andors, Dr. Allison V. Department of Ornithology, American Museum of Natural History, New York.

Andreasen, Dr. Christian. Bureau Hydrographique International, Monaco.

Andrew, Dr. Warren. Chairman, Department of Anatomy, School of Medicine, Indiana University.

Andrews, Dr. Lester. Department of Chemistry, University of Virginia.

Andrews, Dr. Peter. Department of Palaeontology, British Museum (Natural History), London.

Andriole, Dr. Stephen J. Department of Information Systems and Systems Engineering, George Mason University, Fairfax, Virginia.

Andrus, Dr. C. F. Agricultural Consultant; formerly, U.S. Department of Agriculture, Charleston, South Carolina.

Angelakos, Dr. Diogenes J. Deceased; formerly, College of Engineering, University of California, Berkeley.

Anglin, Donald L. Consultant, Automotive and Technical Writing, Charlottesville, Virginia.

Angrisano, Rear Admiral Guiseppe. Bureau Hydrographique International, Monaco.

Angus, James W. Staff Engineer, Avionics Division, Kollsman Instrument Corporation, Elmhurst, New York.

Anscombe, Prof. Francis J. Department of Statistics, Yale University.

Anthes, Prof. Richard A. Department of Meteorology, College of Earth and Mineral Sciences, Pennsylvania State University.

Antoni, Dr. Charles M. Department of Civil Engineering, Syracuse University.

Anwyl, Robert D. Retired; formerly, Photographic Consultant, Eastman Kodak Company, Rochester, New York.

Apfel, Prof. Robert E. Department of Engineering and Applied Science, Yale University.

Apker, Dr. L. General Electric Research Laboratory, Schenectady, New York.

Appel, Dr. Max J. G. James A. Baker Institute for Animal Health, Cornell University, Ithaca, New York.

Appenzeller, Dr. Otto. Department of Neurology, University of New Mexico School of Medicine.

Appleby, Dr. Anthony J. Center for Electrochemical Systems and Hydrogen Research, Texas Engineering Experiment Station, Texas A & M University System.

Appleby, Dr. Arnold P. Professor Emeritus of Crop Science, Oregon State University, Corvallis.

Applegate, Charles E. Consulting Engineer, Weston, Maryland.

Applequist, Dr. Thomas. Sloane Laboratory, Department of Physics, Yale University.

Arbuckle, P. Douglas. NASA, Langley Research Center, Hampton, Virginia.

Arbuckle, Earl F., III. Engineering Supervisor, WPIX, Inc., New York, New York.

Arbuckle, Prof. Wendell S. Deceased; formerly, Department of Dairy Science, University of Maryland.

Archer, Mary D. Grantchester, Cambridge, United Kingdom.

Archibald, Dr. J. David. Department of Biology, San Diego State University, San Diego, California.

Ardema, Dr. Mark D. Research Scientist, National Aeronautics and Space Administration, Ames Research Center, Moffett Field, California.

Arey, Prof. Leslie B. Professor Emeritus of Anatomy, Northwestern University.

Armstrong, Dr. Richard L. Institute of Arctic and Alpine Research, University of Colorado.

Arndt, Dr. Kenneth A. Department of Dermatology, Beth Israel Hospital, Boston, Massachusetts.

Arney, Cyril. Engineering & Technology, Marathon Oil Company, Houston, Texas.

Arnold, Dr. Chester A. Professor of Botany and Geology and Curator of Paleobotany, University of Michigan.

Arnstein, Dr. Karl. Vice President in Charge of Engineering (retired), Goodyear Aircraft Corporation, Akron, Ohio.

Aron, Dr. Walter. Consultant, Menlo Park, California.

Arthur, Dr. Michael A. Graduate School of Oceanography, University of Rhode Island.

Ashton, Dr. Mark S. Yale School of Forestry and Environmental Studies, New Haven, Connecticut.

Asik, Dr. Joseph R. Scientific Research Laboratories, Ford Motor Company, Dearborn, Michigan.

Askey, Dr. Richard. Mathematics Research Center, University of Wisconsin.

Aspnes, Dr. David E. Department of Physics, North Carolina State University, Raleigh.

Aston, Dr. James. Deceased; formerly, Consulting Metallurgist, A. M. Beyers Company.

Astrom, Prof. Karl J. Department of Automatic Control, Lund Institute of Technology, Lund, Sweden.

Athenstaedt, Dr. Herbert. Director, Institut für Molekular-Physikalische Physiologie, Hanover, Germany.

Atkins, Dr. Elisha. School of Medicine, Yale University.

Atkins, Dr. P. W. Department of Chemistry, Oxford University, England.

Atlas, Dr. Ronald M. Department of Biology, University of Louisville, Kentucky.

Atoda, Dr. Kenji. Professor of Zoology, Tohoku University, Sendai, Japan.

Atwood, Dr. Ronald L. Foote Mineral Company, Kings Mountain, North Carolina.

Au, Dr. Whitlow W. L. Marine Mammal Research Program, Hawaii Institute of Marine Biology, Kailua.

Audus, Dr. Leslie J. Professor of Botany (retired), Bedford College, University of London, England.

Austrian, Dr. Robert. Department of Research Medicine, School of Medicine, University of Pennsylvania.

Averbach, Prof. Benjamin L. Department of Materials Science and Engineering, Massachusetts Institute of Technology.

Axley, Milton J. Department of Health and Human Services, National Heart, Lung and Blood Institute, Bethesda, Maryland.

Ayers, Arthur R. Assistant Professor, Cellular and Development Biology, Harvard University.

Ayers, Dr. Walter B. Bureau of Economic Geology, University of Texas, Austin.

Azarnoff, Dr. Daniel L. President, Searle Research and Development, G. D. Searle & Co., Skokie, Illinois.

B

Bachinski, Dr. Sharon W. Department of Geology, University of New Brunswick, Fredericton, Canada.

Back, Dr. Thomas G. Department of Chemistry, Faculty of Science, University of Calgary, Alberta, Canada.

Backer, Dr. Donald C. Department of Astronomy, University of California.

Backstrom, Prof. Gunnar. Institute of Physics, University of Umea, Sweden.

Bada, Dr. Jeffrey L. Scripps Institution of Oceanography, University of California, San Diego-La Jolla.

Badgley, Dr. Peter C. Earth Science Division, Office of the Naval Reserve, Arlington, Virginia.

Baer, Prof. Charles J. Department of Mechanical Engineering, University of Kansas.

Baer, Dr. Donald R. Jackson Laboratory, Organic Chemical Department, E. I. du Pont de Nemours and Company, Wilmington, Delaware.

Baer, Dr. Norbert S. Conservation Center of the Institute of Fine Arts, New York University.

Bagley, Dr. Brian G. Bell Laboratories, Murray Hill, New Jersey.

Bagnall, Dr. Kenneth W. Research Chemist, Atomic Energy Research Establishment, Harwell, England.

Bahcall, Dr. John N. Institute for Advanced Studies, Princeton, New Jersey.

Bahr, Dr. Janice M. Professor of Animal Science and Physiology, Department of Animal Sciences, College of Agriculture, University of Illinois, Urbana-Champaign.

Bai, Dr. Er-Wei. Department of Electrical & Computer Engineering, University of Iowa, Iowa City.

Bailar, Prof. John C., Jr. Deceased; formerly, School of Chemical Sciences, University of Illinois, Urbana-Champaign.

Bailey, Prof. A. Earle. Department of Electrical Engineering, University of Southampton, England.

Bailey, Prof. A. G. Department of Electrical Engineering, University of Southampton, England.

Bailey, Prof. Catherine H. Department of Horticulture, Rutgers University.

Bailey, Frederick G. Large Steam Turbine-Generator Department, General Electric Company, Schenectady, New York.

Bailey, Prof. Milton E. Department of Food Science and Nutrition, College of Agriculture, University of Missouri-Columbia.

Bailey, Dr. Reeve M. Deceased; formerly, Curator of Fishes, Museum of Zoology, University of Michigan.

Bailey, Dr. S. W. Department of Geology, University of Wisconsin.

Baker, Edward W. Entomology Research Division, Agricultural Research Service, U.S. Department of Agriculture.

Baker, Dr. Paul A. Department of Geology, Duke University.

Baker, Dr. M. Pauline. National Center for Supercomputing Applications, University of Illinois, Urbana.

Baker, Dr. Victor R. Department of Geosciences, University of Arizona.

Bakken, Prof. George S. Center Director, Center for Biodiversity Studies, Indiana State University, Terre Haute.

Balakrishnan, Dr. V. K. Department of Mathematics, University of Maine.

Balch, Dr. Alan L. Department of Chemistry, University of California, Davis.

Balderes, Dr. T. Engineering Specialist, Grumman Aerospace Corporation, Bethpage, New York.

Baldi, Dr. Bruce G. Plant Hormone Laboratory, U.S. Department of Agriculture, Beltsville, Maryland.

Baldridge, Dr. W. Scott. Earth and Space Science Division, Los Alamos National Laboratory.

Baldwin, Harry L., Jr. Department of Mathematics, San Diego City College, San Diego, California.

Bales, Robert A. Center for Advanced Aviation Development, MITRE Corporation, McLean, Virginia.

Balick, Prof. Bruce. Department of Astronomy, University of Washington, Seattle.

Baliga, Prof. B. Jayant. Department of Electrical and Computer Engineering, North Carolina State University.

Ball, Dr. John E. D. Telecommunications Consultant, Vienna, Virginia.

Ballard, Prof. William W. Department of Biological Sciences, Dartmouth College.

Ballou, Prof. Clinton E. Department of Molecular and Cell Biology, University of California, Berkeley.

Bally, Dr. John. Center of Astrophysics and Space Astronomy, University of Colorado, Boulder.

Baltay, Dr. Charles. Department of Physics, Yale University.

Balzani, Prof. Vincenzo. Departimento de Chimica, Università di Bologna, Italy.

Bambach, Dr. Richard A. Department of Geological Sciences, Virginia Polytechnic Institute.

Bamburg, Prof. James R. Department of Biochemistry, Colorado State University.

Banerjee, Dr. Pat. Associate Professor, Mechanical Engineering, University of Illinois, Chicago.

Banks, Dr. Harlan P. Emeritus Professor of Botany, Division of Biological Sciences, Cornell University.

Banks, Prof. William P. Chairperson, Department of Psychology, Pomona College, Claremont, California.

Banner, Dr. Donald W. Banner, Birch, McKie and Beckett, Washington, D.C.

Bar-Sela, Dr. Shlomo. Department of Medicine, Allergy-Immunology Section, Medical College of Wisconsin.

Barash, Prof. David P. Department of Psychology, University of Washington, Seattle.

Barber, Dr. Richard T. Duke University Marine Laboratory.

Barbosa, Dr. Pedro. Department of Entomology, College of Life Sciences, University of Maryland.

Barbour, Dr. Neil. Charles Stark Draper Laboratory, Inc., Cambridge, Massachusetts.

Barclay, Dr. Harriet G. Professor of Botany, Department of Life Sciences, University of Tulsa.

Bard, Dr. Allen J. Department of Chemistry, College of Natural Sciences, University of Texas, Austin.

Bardsley, Dr. James Norman. Lawrence Livermore National Laboratory, University of California.

Barer, Prof. Robert. Department of Human Biology and Anatomy, University of Sheffield, England.

Bargellini, Dr. Pier L. Retired; formerly, COMSAT Laboratories, Clarksburg, Maryland.

Barger, Prof. Vernon D. Department of Physics, University of Wisconsin, Madison.

Barghoorn, Prof. Elso S. Department of Biology and Botanical Museum, Harvard University.

Barkalow, Dr. David G. Department of Biochemistry, Purdue University.

Barker, Prof. Daniel S. Department of Geological Sciences, University of Texas, Austin.

Barker, Dr. Fred. Geological Survey, U.S. Department of the Interior, Denver, Colorado.

Barker, Dr. Horace A. Department of Biochemistry, University of California, Berkeley.

Barker, Dr. Joseph W. Chairman of the Board (retired), Research Corporation, New York, New York.

Barker, Dr. R. W. J. Department of Electrical and Electronic Engineering, Trent Polytechnic, Peterborough, Ontario, Canada.

Barkley, Prof. T. M. Division of Biology, Kansas State University.

Barksdale, Dr. Lane. Department of Microbiology, School of Medicine, New York University Medical Center.

Barnard, Dr. J. Laurens. Curator of Crustacea, Smithsonian Institution.

Barnes, Dr. Robert K. Research and Development Department, Chemicals and Plastics Operations Division, Union Carbide Corporation, South Charleston, West Virginia.

Barnes, Dr. Ted. Physics Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Barnes, Ivan. Water Resources Division, Geological Survey, U.S. Department of the Interior, Menlo Park, California.

Barnett, Peter D. Forensic Science Associates, Richmond, California.

Barnitz, Edward S. Consultant in Vacuum Engineering, Rochester, New York.

Barr, Dr. David. Department of Entomology, Royal Ontario Museum, Toronto, Ontario, Canada.

Barr, Dr. Donald J. S. Principal Research Scientist, Centre for Land and Biological Resources Research, Ottawa, Ontario, Canada.

Barrett, Dr. A. G. M. Department of Chemistry, Northwestern University.

Barron, Prof. Eric. Director, Earth System Science Center, Pennsylvania State University, University Park.

Barronet, Dr. Alain. Centre de Recherche sur les Méchanismes de la Croissance Cristalline, Marseille, France.

Barry, Brother B. Austin. Civil Engineering Department, Manhattan College.

Barry, Dr. Michelle M. Department of Medical Microbiology and Immunology, University of Alberta, Edmonton, Canada.

Bars, Dr. Itzhak. Department of Physics, Yale University.

Barth, Prof. T. F. W. Deceased; formerly, Geologic Museum, Oslo.

Bartlett, Prof. Robert W. Dean, College of Mines, University of Idaho, Moscow.

Barton, Dr. Jennifer Kehlet. Biomedical Engineering Program, University of Arizona, Tucson.

Barton, Dr. Mark D. Department of Earth and Space Sciences, University of California, Los Angeles.

Barton, Richard L. National Aeronautics and Space Administration, Lyndon B. Johnson Space Center, Houston, Texas.

Bash, Dr. Jack. University–National Oceanographic System Office, University of Rhode Island, Saunderstown.

Basolo, Prof. Fred. Department of Chemistry, Northwestern University.

Bass, Prof. Henry E. National Center for Physical Acoustics, University of Mississippi.

Bass, Prof. Jack. Department of Physics and Astronomy, Michigan State University.

Bassett, Dr. C. Andrew L. Department of Orthopaedic Surgery, Bioelectric Research Center, Columbia University, Riverdale.

Bates, Dr. Robert L. Department of Geology, Ohio State University.

Battles, Byron W. The Battles Group, LLC, Silver Spring, Maryland.

Bauer, Prof. E. Department of Physics, Arizona State University, Tempe.

Bauer, Dr. Simon H. Department of Chemistry, Cornell University.

Baumeister, Prof. Theodore. Deceased; formerly, Consulting Engineer; Stevens Professor of Mechanical Engineering, Emeritus, Columbia University; Editor in Chief, "Standard Handbook for Mechanical Engineers."

Baumgarten, Dr. Alexander. Department of Laboratory Medicine, School of Medicine, Yale University.

Baumiller, Dr. Tomasz. Department of Geological Sciences, University of Michigan, Ann Arbor.

Baver, Prof. Leonard D. Retired; formerly, Agronomy Department, Ohio State University.

Bayfield, Dr. James E. Department of Physics, University of Pittsburgh.

Beall, Christine. Consulting Architect, Columbus, Texas.

Beam, Dr. Charles F. Department of Chemistry, College of Charleston, South Carolina.

Beams, Dr. Jesse. Deceased; formerly, Department of Physics, University of Virginia.

Bean, Howard S. Deceased; formerly, Consultant on Fluid Metering, Liquids and Gases, Sedona, Arizona.

Beard, Dr. Benjamin H. Agronomy and Range Science Extension, University of California, Davis.

Beatty, J. Kelly. Consultant, Chelmsford, Massachusetts.

Beaty, H. Wayne. Consultant, Fairfax, Virginia.

Beaumont, Robert T. Director of Meteorological Operations, E. G. G., Inc., Boulder, Colorado.

Beaumont, Prof. Ross A. Department of Mathematics, University of Washington.

Beaver, Dr. Wallace W. Deceased; formerly, Director of Research and Development, Brush Beryllium Company, Cleveland, Ohio.

Beck, Dr. Charles B. Professor of Botany, University of Michigan.

Beck, Prof. Curt W. Department of Chemistry, Amber Research Laboratory, Vassar College, Poughkeepsie, New York.

Beck, James. Boeing Defense and Space Group, Rocketdyne Division, Boeing North American Inc., Canoga Park, California.

Beck, Karl M. Abbott Laboratories, North Chicago, Illinois.

Becken, Eugene D. Vice President, Operations, RCA Global Communications, Inc., New York.

Becker, Dr. Elery R. Deceased; formerly, Division of Life Sciences, Arizona State University.

Becker, Dr. Henry A. Department of Chemical Engineering, Queen's University, Kingston, Ontario, Canada.

Becker, Dr. Philippe. AT&T Bell Laboratories, Murray Hill, New Jersey.

Bederson, Dr. Benjamin. Department of Physics, New York University.

Beer, Dr. Steven V. Department of Plant Pathology, College of Agriculture and Life Sciences, Cornell University.

Belfit, Dr. Robert W. Manager, Quality Standards, Quality Assurance Department, Dow Chemical Company, Midland, Michigan.

Bell, Morton A. American Air Filter Company, Inc., New York.

Bell, Prof. Norman R. Department of Electrical Engineering, North Carolina State University.

Bell, Robin E. Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York.

Bell, Dr. William E. Department of Pediatrics, University of Iowa.

Belrose, Dr. John S. Communications Research Centre, Department of Communications, Ottawa, Ontario, Canada.

BeMiller, Prof. James N. Director, Whistler Center for Carbohydrate Research, Purdue University.

Bemis, Dr. David A. Director, Clinical Bacteriology and Mycology Services, University of Tennessee, Knoxville.

Bender, Prof. Myron L. Department of Chemistry, Northwestern University.

Bender, Prof. Paul J. Professor of Physical Chemistry, University of Wisconsin.

Benedict, Dr. Manson. Institute Professor Emeritus, Department of Nuclear Engineering, Massachusetts Institute of Technology.

Bengston, Dr. Stefan. Senior Curator (Invertebrate Fossils), Swedish Museum of Natural History, Department of Palaeozoology, Stockholm, Sweden.

Benito, Dr. Jesús. Department of Animal Biology I—Zoology of Invertebrates, University Complutense, Madrid, Spain.

Benner, Dr. Frank C. Assistant Director, Research and Development Department, Norton Company, Worcester, Maine.

Bennett, Prof. Albert F. Department of Ecology and Evolutionary Biology, University of California, Irvine.

Bennett, Dr. H. Stanley. Department of Molecular, Cellular and Developmental Biology, University of Colorado.

Bennett, Prof. Joan W. Department of Cell and Molecular Biology, Tulane University, New Orleans, Louisiana.

Bennett, Dr. M. B. Senior Lecturer, Anatomical Sciences, University of Queensland, Brisbane, Australia.

Bennett, Prof. Michael V. L. Department of Neuroscience, Albert Einstein College of Medicine, New York.

Bennett, Dr. Orus L. Vice President, GRC Panels Unlimited, Leeds, Alabama.

Benninghoff, Dr. William S. Department of Botany, University of Michigan.

Benny, Dr. Gerald L. Department of Plant Pathology, University of Florida, Gainesville.

Benson, Prof. Frank A. Department of Electronic and Electrical Engineering, University of Sheffield, England.

Bent, Prof. Brian E. Department of Chemistry, Columbia University, New York.

Beranek, Dr. Leo L. Chief Scientist (retired), Bolt Beranek and Newman, Inc., Cambridge, Massachusetts.

Beresford, Dr. William A. Department of Anatomy, West Virginia University.

Berg, Dr. Clyde. Clyde Berg and Associates, Long Beach, California.

Berger, Dr. France B. Kearfott Division, The Singer Company, Little Falls, New Jersey.

Berger, Harold. Industrial Quality, Inc., Gaithersburg, Maryland.

Berger, Dr. Richard D. Department of Plant Pathology, University of Florida.

Berger, Prof. Wolfgang H. Geological Research Division, Scripps Institution of Oceanography, La Jolla, California.

Berggren, Dr. W. A. Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.

Bergh, Dr. Berthold O. Department of Plant Sciences, University of California, Riverside.

Berglund, Neil. Manager of Technology Development, Intel Corporation, Aloha, Oregon.

Bergmann, Prof. Peter G. Department of Physics, Syracuse University.

Berkowitz, Dr. Gerald A. Institute for Photobiology of Cells and Organelles, Brandeis University.

Bernard, Dr. E. N. National Oceanic and Atmospheric Administration, Pacific Marine Environmental Laboratory, Seattle, Washington.

Berner, Dr. Elizabeth K. Department of Geology and Geophysics, Yale University.

Berner, Prof. Lewis. Acting Director, Division of Biological Sciences, University of Florida.

Berner, Dr. Robert A. Department of Geology and Geophysics, Yale University.

Bernson, Dr. Laurence. Environmental Management Department, AT&T Bell Laboratories, Murray Hill, New Jersey.

Bernstein, Dr. I. M. Department of Metallurgy and Materials Science, Carnegie-Mellon University.

Bernstein, Dr. Robert I. Professor of Electrical Engineering and Associate Director, Electronics Research Laboratories, Columbia University.

Berry, Dr. Spencer J. Department of Biology, Wesleyan University.

Berry, Dr. William B. N. Museum of Paleontology, University of California, Berkeley.

Bertsch, Dr. George F. Department of Physics, Michigan State University.

Bethe, Prof. Hans A. Floyd R. Newman Laboratory of Nuclear Studies, Cornell University.

Betts, Dr. Russell. Argonne National Laboratory, Argonne, Illinois.

Beutler, Dr. Bruce. Howard Hughes Medical Institute, University of Texas, Dallas.

Bever, Prof. Michael B. Department of Materials Science and Engineering, Massachusetts Institute of Technology.

Bewley, Dr. Loyal V. Dean (retired), College of Engineering, Lehigh University.

Beyer, Dr. Ann L. Department of Microbiology, University of Virginia.

Bichsel, Dr. Hans. Department of Radiology, University of Washington.

Bicknell, Prof. Joseph. Department of Aeronautics and Astronautics, Massachusetts Institute of Technology.

Biederman, Dr. Joseph. Pediatric Psychopharmacological Unit, Massachusetts General Hospital, Boston.

Biegel, Prof. John E. Department of Engineering, University of Central Florida.

Bieler, David B. Department of Geology and Geophysics, Centenary College of Louisiana, Shreveport.

Bienenstock, Dr. Arthur. Professor of Applied Physics, Stanford University; Director, Stanford Synchrotron Radiation Laboratory.

Biermann, Dr. Christopher. Department of Forest Products, Forest Research Laboratory, Oregon State University, Corvallis.

Bigeleisen, Prof. Jacob. Department of Chemistry, University of Rochester.

Bignami, Prof. Giovanni F. Istituto per Ricerche in Fisica Cosmica e Tecnologie Relative, Milan, Italy.

Billet, Prof. Michael. Head, Fluid Dynamics Department, Applied Research Laboratory, Pennsylvania State University, State College.

Billig, Dr. Frederick S. Applied Physics Laboratory, Johns Hopkins University, Laurel, Maryland.

Billingham, Dr. Rupert E. Department of Biology, University of Texas Health and Science Center, Dallas.

Billings, Dr. Bruce H. Special Assistant to the Ambassador of Science and Technology, Embassy of the United States of America, Taipei.

Billington, Dr. Douglas S. Senior Staff Advisor for Materials Science, Metals and Ceramics Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Bing, Prof. R. H. Department of Mathematics, University of Wisconsin.

Bingham, Prof. Carrol. Department of Physics, University of Tennessee, Knoxville.

Bingham, Dr. Richard. Department of Chemistry, Princeton University.

Bird, Dr. Thomas D. University of Washington, School of Medicine, Seattle.

Birkenheuer, Dr. Daniel L. Lakewood, Colorado.

Birkhoff, Prof. Garrett. Department of Mathematics, Harvard University.

Birks, Dr. L. S. Retired; formerly, Radiation Technology Division, Naval Research Laboratory, Washington, D.C.

Biscaye, Dr. Pierre E. Lamont-Doherty Geological Observatory, Palisades, New York.

Bisno, Dr. A. L. Veterans Administration Medical Center, Miami, Florida.

Bisplinghoff, Raymond L. Dean, School of Engineering, Massachusetts Institute of Technology.

Black, Dr. Harold S. Communications Consultant, Summit, New Jersey.

Black, Prof. Paul H. Department of Mechanical Engineering, Ohio University.

Black, Dr. Robert F. Department of Geology, University of Connecticut.

Blackburn, J. Lewis. Consulting Engineer, Bothell, Washington.

Blackwell, Dr. Meredith. Department of Plant Biology, Louisiana State University, Baton Rouge.

Blad, Dr. Blaine L. Agricultural Meteorology Section, University of Nebraska.

Blades, Dr. Brooke. Department of Anthropology, University of Maryland, College Park.

Blain, Dr. Andrew. Institute of Astronomy, Cambridge, United Kingdom.

Blake, Dr. Daniel B. Department of Geology, University of Illinois, Urbana.

Blandford, Prof. Roger D. Department of Theoretical Astrophysics, California Institute of Technology, Pasadena.

Blankenship, Dr. James E. Department of Physiology and Biophysics, Marine Biomedical Institute, University of Texas, Galveston.

Blanton, J. W. General Manager, Advanced Component Technology Department, General Electric Company, Cincinnati, Ohio.

Blaser, Prof. H. Weston. Department of Botany, University of Washington.

Blass, Dr. Elliott M. Department of Psychology, Johns Hopkins University.

Blatt, Prof. Frank J. Department of Physics, Michigan State University.

Blatt, Dr. Harvey. Hebrew University of Jerusalem, Givat Ram, Jerusalem, Israel.

Bleiweis, John J. Consultant, Great Falls, Virginia.

Blencoe, Dr. James G. Chemistry Division, Oak Ridge National Laboratory.

Blitz, Dr. Leo. Laboratory for Millimeter-Wave Astronomy, University of Maryland.

Blobel, Dr. Günter B. Department of Cell Biology, Rockefeller University, New York; Nobelist.

Bloch, Dr. Spencer J. Department of Mathematics, University of Chicago.

Block, Dr. Ira. Department of Textiles-Consumer Economics, University of Maryland.

Bloomfield, Prof. Philip E. Department of Physics, University of Pennsylvania; City College of the City University of New York, Bloomfield.

Blough, Prof. Donald S. Department of Psychology, Brown University.

Blouin, Dr. Edmour F. College of Veterinary Medicine, Oklahoma State University, Stillwater.

Bluestein, Prof. Howard B. Department of Meteorology, University of Oklahoma.

Blumenthal, Prof. Leonard M. Deceased; formerly, Defoe Distinguished Professor of Mathematics, University of Missouri.

Blumenthal, Warren B. Blumenthal-Zirconium, North Tonawanda, New York.

Boast, Dr. Warren B. Anson Marston Distinguished Professor Emeritus of Electrical Engineering, Iowa State University.

Bobart, George F. Manager, Induction Heating and Ultrasonic Cleaning Department, Westinghouse Electric Corporation, Sykesville, Maryland.

Bobbitt, Dr. James M. Department of Chemistry, University of Connecticut.

Bochner, Dr. Salomon. Deceased; formerly, Department of Mathematics, Rice University.

Bock, Dr. Walter J. Professor of Evolutionary Biology, Department of Biological Sciences, Columbia University.

Bocko, Dr. Mark F. Department of Physics and Astronomy, College of Arts and Science, University of Rochester.

Boell, Dr. Edgar J. Department of Biology, Yale University.

Boero, Dr. Ferdinando. Professor of Zoology, Università di Lecce, Dipartmento di Biologia, Stazione di Biologia Marina, Lecce, Italy.

Boggs, Dr. Paul T. Computational Sciences and Mathematics Research Department, Sandia National Laboratories, Livermore, California.

Bogucki, Dr. Peter. Department of Anthropology, Princeton University, Princeton, New Jersey.

Bohach, Dr. Greg. Department of Microbiology, Molecular Biology, and Biochemistry, University of Idaho, Moscow.

Bohme, Prof. M. Department of Chemistry, Friedrich-Wilhelms University, Germany.

Boke, Dr. Norman H. George Lynn Cross Research Professor of Botany, University of Oklahoma.

Boles, Prof. James R. Department of Geological Sciences, University of California, Santa Barbara.

Bolin, Dr. Steven R. Research Leader, Virology Cattle Research, Agricultural Research Service, U.S. Department of Agriculture, Ames, Iowa.

Bolt, Prof. J. A. Department of Mechanical Engineering, University of Michigan.

Bond, Dr. Gerard. Lamont-Doherty Geological Observatory, Palisades, New York.

Bondybey, Dr. Vladimir E. Bell Laboratories, Murray Hill, New Jersey.

Bonner, Dr. Walter D., Jr. Department of Biochemistry and Biophysics, School of Medicine, University of Pennsylvania.

Boothroyd, Dr. Carl W. Department of Plant Pathology, Cornell University.

Bormann, Dr. Bernard T. Department of Forest Sciences, Oregon State University, Corvallis.

Borowiecki, Prof. Barbara Z. Department of Geography, University of Wisconsin, Milwaukee.

Borrello, Sebastian R. Central Research Laboratories, Texas Instruments Inc., Dallas, Texas.

Borst, Henry V. Henry V. Borst & Associates, Wayne, Pennsylvania.

Bortman, Dr. Marci L. Waste Management Institute, Marine Sciences Research Center, State University of New York, Stony Brook.

Bosart, Prof. Lance F. Department of Atmospheric Sciences, State University of New York, Albany.

Boshkov, Prof. Stefan H. Henry Krumb School of Mines, Columbia University.

Boss, Dr. Alan P. Carnegie Institution of Washington, Department of Terrestrial Magnetism, Washington, D.C.

Bothwell, Dr. Mark. Biochemical Sciences Laboratory, Princeton University.

Botset, Holbrook G. Professor Emeritus of Petroleum Engineering, University of Pittsburgh.

Bouchard, Prof. Thomas J. Chairman, Department of Psychology, University of Minnesota.

Bouldin, Dr. Donald W. Electrical and Computer Engineering, University of Tennessee.

Bouwkamp, Dr. John C. Department of Horticulture, College of Agriculture, University of Maryland.

Bowler, Dr. Bruce E. Division of Chemistry and Chemical Engineering, California Institute of Technology.

Bowman, Richard G. Deceased; formerly, Technical Assistant to the President, Republic Aviation Corporation, Far-mingdale, New York.

Bowman, Rush A. Consulting Engineer, Memphis, Tennessee.

Bowman, Dr. Thomas E. Division of Crustacea, Smithsonian Institution.

Bowman, Waldo G. Editor (retired), "Engineering News Record." Boyd, Dr. F. R. Geophysical Laboratory, Washington, D.C.

Box, Dr. Elgene O. Department of Geography, University of Georgia.

Boyd, Dr. Richard H. Department of Chemical Engineering, University of Utah.

Boyden, Prof. Edward A. Department of Biological Structure, School of Medicine, University of Washington.

Boynton, Dr. Robert M. Department of Psychology, University of California, San Diego.

Boynton, Dr. Robert S. National Lime Association, Washington, D.C.

Bozarth, Dr. Robert F. Department of Life Science, Indiana State University, Terre Haute.

Bozorth, Dr. Richard M. Research Physicist (retired), Bell Telephone Laboratories, Murray Hill, New Jersey.

Bracewell, Dr. Ronald N. Professor of Electrical Engineering, Emeritus, Stanford University, Stanford, California.

Bradley, Dr. Robert L., Jr. Department of Food Science, College of Agricultural and Life Sciences, University of Wisconsin.

Bradley, Prof. S. Gaylen. Department of Microbiology and Immunology. Virginia Commonwealth University, Richmond.

Bradley, Prof. William F. Department of Chemical Engineering, University of Texas, Austin.

Bradley, Prof. William W. Department of Civil Engineering and Institute of Colloid and Surface Science, Clarkson College of Technology.

Bradner, Mead. Technical Director, Foxboro Company, Foxboro, Massachusetts.

Bradsher, Prof. Charles K. Department of Chemistry, Duke University.

Bragg, Prof. Michael B. Department of Aeronautical and Astronautical Engineering, University of Illinois at Urbana-Champaign.

Brainard, Dr. George C. Department of Neurology, Thomas Jefferson University, Jefferson Medical College, Philadelphia, Pennsylvania.

Bralla, J. R. Casey. Consultant, Mechanical Engineering, Martinez, Georgia.

Brammer, Dr. Anthony J. Institute for Microstructural Science, National Research Council of Canada, Ottawa, Ontario.

Brand, Dr. Louis. Deceased; formerly, M. D. Anderson Professor of Mathematics, Department of Mathematics, University of Houston.

Brandt, Dr. G. Donald. Professor Emeritus, City University of New York.

Brandt, Prof. John C. Department of Physics and Astronomy, Institute for Astrophysics, University of New Mexico, Albuquerque.

Brandt, Dr. Philip W. Department of Anatomy, College of Physicians and Surgeons, Columbia University.

Brassell, Prof. Simon C. Professor of Geological Sciences, Biogeochemical

Laboratories, Indiana University, Bloomington.

Brasseur, Dr. Guy P. Director, Atmospheric Chemistry Division, National Center for Atmospheric Research, Boulder, Colorado.

Breed, Dr. Michael D. Environmental Population and Organismic Biology, University of Colorado.

Breen, Dr. Patrick J. Department of Horticulture, Oregon State University.

Breger, Dr. Irving A. Deceased; formerly, Office of Energy Resources, U.S. Geological Survey, Reston, Virginia.

Breier, Dr. Alan. Department of Psychiatry, Yale University School of Medicine, and Connecticut Mental Health Center, New Haven.

Breinan, Dr. Edward M. Materials Science Laboratory, United Technologies Research Center, East Hartford, Connecticut.

Breman, Dr. Joel D. Division of Parasitic Diseases, Centers for Disease Control, Department of Health and Human Services, Atlanta, Georgia.

Breslin, Dr. Vincent T. Waste Management Institute, Marine Sciences Research Center, State University of New York, Stony Brook.

Breslow, Dr. David S. David S. Breslow Associates, Wilmington, Delaware.

Bressler, Dr. Peter E. Endocrine & Diabetes Associates of Texas, Dallas.

Brett, Dr. Carlton. Department of Geological Sciences, University of Rochester.

Breuer, Glenn D. Consulting Engineer, Transmission Systems Development and Engineering Department, General Electric Company, Schenectady, New York.

Brewer, Dr. Charles P. Shell Development Corporation, Emeryville, California.

Brewer, S. Theodore. Deceased; formerly, Head, Undersea and Lightwave Engineering Department, Bell Laboratories, Holmdel, New Jersey.

Brian, Dr. M. V. Institute of Terrestrial Ecology, Furzebrook Research Station, Wareham, England.

Brickley, Robert L. Marketing Manager, Westinghouse Electric Corporation, Springfield, Massachusetts.

Bridges, Prof. Patricia S. Deceased; formerly, Department of Anthropology, Queens Collge and CUNY Graduate Center, Flushing, New York.

Bridgman, Prof. Percy W. Deceased; formerly, Harvard University.

Briggs, Dr. Derek E. G. Department of Geology, University of Nottingham, England.

Briggs, Dr. John D. Department of Entomology, Ohio State University.

Briggs, M. Michael. Missile Systems Division, Integrated Systems Inc., Santa Clara, California.

Briggs, Dr. Winslow R. Department of Plant Biology, Carnegie Institution of Washington, Stanford, California.

Brimacombe, Dr. R. Max-Planck Institut für Molekulare Genetik, Berlin, Germany.

Brindley, Dr. George W. Department of Geosciences, Pennsylvania State University.

Brintzinger, Dr. Hans. Fachbereich Biologie-Chemie, Universitat Konstanz, Germany.

Brisbin, Dr. I. Lehr. Savannah River Ecology Laboratory, University of Georgia, Aiken, South Carolina.

Broadus, Dr. Arthur E. Associate Professor of Medicine, Department of Medicine, Yale University.

Brockenbrough, Dr. Roger L. R. L. Brockenbrough Associates, Inc., Pittsburgh, Pennsylvania.

Brockhouse, Dr. Bertram N. Institute for Materials Research, McMaster University.

Brockway, Prof. Lawrence O. Deceased; formerly, Department of Chemistry, University of Michigan.

Brod, Dr. Chris. Glen Canyon Environmental Studies, Bureau of Reclamation, Flagstaff, Arizona.

Brodersen, Prof. Klaus. Professor of Inorganic and Analytical Chemistry, University of Erlangen-Nurnberg, Germany.

Brodsky, Dr. Barbara. Department of Biochemistry, UMDNJ–Robert Wood Johnson Medical School, Piscataway, New Jersey.

Brodsky, Dr. William A. Mount Sinai School of Medicine of the City University of New York; Institute for Medical Research and Studies, New York.

Brofman, Dr. Peter J. Senior Engineering, General Technology Division, IBM Corp., Hopewell Junction, New York.

Bromley, Prof. D. Allan. Science Adviser to the President of the United States.

Bromley, Willard S. Consulting Forester and Association Consultant, New Rochelle, New York.

Bronstein, Dr. Judith. Department of Ecology and Evolutionary Biology, University of Arizona, Tucson.

Brook, Dr. Marx. Department of Physics, New Mexico Institute of Mining and Technology, Socorro.

Brook, Rollins. Bolt Beranek and Newman Inc., Canoga Park, California.

Brooke, Dr. M. M. Deceased; formerly, Deputy Chief, Licensure and Development Branch, Center for Disease Control, U.S. Public Health Service, Atlanta, Georgia.

Brooks, Dr. Frank D. Department of Physics, University of Capetown, Rondebosch, South Africa.

Brooks, Prof. Philip R. Department of Chemistry, Wise School of Natural Sciences, Rice University.

Brotner, Dr. William W. Research Advisor, Eli Lilly and Company, Indianapolis, Indiana.

Brouwer, Prof. Dirk. Deceased; formerly, Director, Observatory, Yale University.

Browder, Dr. James Steve. Department of Physics, Division of Science and Mathematics, Jacksonville University, Jacksonville, Florida.

Brown, Prof. Frederick C. Department of Physics, University of Illinois.

Brown, Dr. Glenn H. Professor of Chemistry and Director of the Liquid Crystal Institute, Kent State University.

Brown, Prof. Herbert C. Department of Chemistry, Purdue University.

Brown, Dr. Jason W. Institute for Research in Behavioral Neuroscience, Department of Neurology, New York University Medical Center.

Brown, Michael D. Department of Biochemistry and Molecular Biology, Colorado State University.

Brown, Dr. Perry. Dean, School of Forestry, Montana Forest and Conservation Experiment Station, University of Montana, Missoula.

Brown, Dr. Robert L. National Radio Astronomy Observatory, Charlottesville, Virginia.

Brown, Dr. Steven S. National Oceanic and Atmospheric Administration Aeronomy Laboratory, Boulder, Colorado, and Cooperative Institute for Research in the Environmental Sciences, University of Colorado, Boulder.

Brown, Dr. William L., Jr. Emeritus Professor of Entomology, Cornell University.

Brownell, Dr. Gordon L. Head, Physics Research Laboratory, Massachusetts General Hospital, Boston.

Browning, Dr. Keith A. Chief, Meteorological Office, Radar Research Laboratory, Royal Signals and Radar Establishment, Worcester, England.

Brownlee, Dr. Donald E., II. Department of Astronomy, University of Washington, Seattle.

Brubaker, Prof. Robert R. Department of Microbiology, Michigan State University, East Lansing.

Bruce, Bill. LID Standards Laboratory, Hewlett-Packard, Loveland, Colorado.

Brummett, Prof. Anna Ruth. Associate Professor of Biology and Associate Dean, Oberlin College.

Brunner, Dr. J. Robert. Department of Food Science and Human Nutrition, Michigan State University.

Bruno, Michael H. Graphics Arts Consultant, Bradenton, Florida.

Brunski, Dr. John B. Department of Biomedical Engineering, Rensselaer Polytechnic Institute.

Brush, Dr. Alan H. Department of Biology, University of Connecticut.

Bruun, Dr. Hans H. Department of Mechanical and Medical Engineering, University of Bradford, United Kingdom.

Bryan, Prof. Leslie A. Director, Institute of Aviation, University of Illinois.

Brylawski, Prof. Thomas. Department of Mathematics, University of North Carolina.

Bryson, Prof. Arthur E., Jr. Chairman, Department of Aeronautics and Astronautics, Stanford University.

Brzozowski, Dr. Victor J. Electronic Systems Group, Baltimore, Maryland.

Brézin, Dr. Edouard. Laboratoire de Physique Theorique, Ecole Normale Supérieur, Paris, France.

Bube, Dr. Richard H. Professor of Electrical Engineering, Department of Material Sciences, Stanford University.

Buchanan, Prof. Bruce. Computer Science Department, University of Pittsburgh, Pennsylvania.

Bucher, Dr. Martin A. Department of Physics, Princeton University.

Buchroeder, Dr. Richard A. Optical Design Service, Tucson, Arizona.

Buck, Dr. Richard P. Department of Chemistry, University of North Carolina.

Buede, Dr. Dennis. Department of Systems Engineering, George Mason University, Fairfax, Virginia.

Buell, Dr. Heinz. Plessey Electronic Systems Corporation, Wayne, New Jersey.

Buermann, Thomas M. President, Gibbs & Cox, Inc., New York, New York.

Bukowski, Richard W. U.S. Department of Commerce, Washington, D.C.

Bunge, Prof. Mario. Foundations and Philosophy of Science Unit, McGill University, Montreal, Canada.

Bunnett, Prof. Joseph F. Department of Chemistry, University of California, Santa Cruz.

Bunshah, Dr. Rointan F. Department of Material Science and Engineering, University of California, Los Angeles.

Burdett, Prof. Jeremy K. Department of Chemistry, University of Chicago.

Bureau of Reclamation. U.S. Department of the Interior, Denver, Colorado.

Burgdorfer, Dr. Willy. Scientist Emeritus, Laboratory of Pathology, Rocky Mountain Laboratories, National Institutes of Health, Department of Health and Human Services, Hamilton, Montana.

Burghard, Ronald A. Gould Semiconductors, Pocatello, Indiana.

Burke, Dr. James D. Jet Propulsion Laboratory, California Institute of Technology.

Burke, Prof. Kevin C. Department of Geosciences, University of Houston.

Burkhalter, Dr. Alan. Department of Pharmacology, School of Medicine, University of California, San Francisco.

Burkhart, Dr. Harold E. Department of Forestry, College of Forestry and Wildlife Resources, Virginia Polytechnic Institute and State University, Blacksburg.

Burnett, Peter G. Petroleum Engineer, Chicago, Illinois.

Burnham, Prof. Charles W. Department of Earth and Planetary Sciences, Harvard University.

Burns, Dr. C. Patrick. Professor and Director, Division of Hematology, Oncology, and Blood and Marrow Transplantation, Department of Medicine and University of Iowa Cancer Center, Iowa City.

Burns, Roger G. Department of Earth Science, Massachusetts Institute of Technology.

Burns, Prof. Stanley G. Department of Electrical Engineering and Computer Engineering, Iowa State University.

Bursey, Prof. Maurice M. Department of Chemistry, University of North Carolina.

Bursky, Dave. "Electronic Design Magazine," Sunnyvale, California.

Burstyn, Dr. Judith N. Department of Chemistry, University of Wisconsin, Madison.

Burton, Prof. Ralph A. Chairman, Department of Mechanical Engineering and Astronautical Sciences, Northwestern University.

Burwell, Dr. Robert L. Department of Chemistry, Northwestern University.

Busch, Prof. Daryle H. Department of Chemistry, Ohio State University.

Bushnell, Dennis M. Langley Research Center, National Aeronautics and Space Administration, Hampton, Virginia.

Busta, Dr. Francis F. Department of Food Science and Human Nutrition, University of Florida.

Butler, Charles. Consultant, Pescadero, California.

Butler, Dr. G. W. Olin Rocket Research Company, Redmond, Washington.

Butler, Dr. Percy M. Egham, Surrey, United Kingdom.

Butler, Dr. R. Paul. Staff Scientist, Carnegie Institute of Washington, Terrestrial Magnetism, Washington, D.C.

Butler, Dr. Robert W. Department of Psychology, Child Development and Rehabilitation Center, Oregon Health Sciences University, Portland.

Butts, Prof. Allison. Professor Emeritus of Metallurgy and Materials Science, Lehigh University.

Byers, Dr. Charles W. Department of Geology, University of Wisconsin.

C

Cable, Prof. Raymond M. Department of Biological Sciences, Purdue University.

Cabrera, Dr. Blas. Department of Physics, Stanford University.

Cady, Dr. Gilbert H. Deceased; formerly, Consulting Coal Geologist, Urbana, Illinois.

Cain, Dr. Joseph C. Department of Geology, Florida State University.

Cain, Dr. William S. John B. Pierce Foundation Laboratories, New Haven, Connecticut.

Caine, Dr. Edsel A. Associate Professor of Marine Sciences, University of South Carolina.

Caine, Nel. Institute of Arctic and Alpine Research, University of Colorado at Boulder.

Calabrese, Dr. Ronald L. Department of Biology, Emory University.

Calderwood, Dr. James H. Department of Electronic Engineering, University College, Galway, Ireland.

Caldwell, Prof. C. Denise. Department of Physics, Yale University.

Callaham, Dr. Michael. Director, Emergency Medical Services, School of Medicine, University of California, San Francisco.

Callaway, Prof. Joseph. Department of Physics and Astronomy, Louisiana State University.

Caller, Dr. Bernard A. Computing Center, University of Michigan.

Calnek, Dr. Bruce W. Chairperson, Department of Avian and Aquatic Animal Medicine, College of Veterinary Medicine, Cornell University.

Cambel, Dr. Ali B. Executive Vice President for Academic Affairs, Wayne State University.

Cameron, Dr. A. G. W. Associate Director for Planetary Sciences, Center for Astrophysics, Harvard College Observatory.

Camin, Dr. Joseph H. Department of Entomology, University of Kansas.

Campana, Dr. Richard J. Department of Botany and Plant Pathology, University of Maine.

Campanella, Dr. Angelo J. Campanella Associates, Hilliard, Ohio.

Campanella, Dr. S. Joseph. Retired; formerly, COMSAT Laboratories, Clarksburg, Maryland.

Campbell, Dr. Andrew C. Department of Zoology and Comparative Physiology, Queen Mary College, University of London, England.

Campbell, Dr. Eleanor. Max-Born-Institut, Berlin, Germany.

Campbell, Harold E. Senior Engineer, Power Distribution Systems Engineering, General Electric Company, Schenectady, New York.

Campbell, Dr. Howard W. National Fisheries and Wildlife Laboratory, Gainesville, Florida.

Campbell, Dr. John S. Department of Biological Sciences, University of Lethbridge, Alberta, Canada.

Campbell, Dr. Laurence J. Low Temperature Physics Group, Los Alamos Scientific Laboratory, Los Alamos, New Mexico.

Campbell, Dr. Wallace H. U.S. Geological Survey, Denver, Colorado.

Campbell, Dr. William B. Professor and Chairman, Department of Pharmacology and Toxicology, Medical College of Wisconsin, Milwaukee.

Cannell, Prof. David S. Department of Physics, University of California, Santa Barbara.

Cannon, Dr. Robert H., Jr. Assistant Secretary of Transportation.

Canter, Prof. Gerald J. Department of Communicative Disorders, Northwestern University.

Capellen, Dr. Jennings. Rare Earth Information Center, Iowa State University.

Capra, Dr. J. Donald. Department of Microbiology, Southwestern Medical School, University of Texas, Dallas.

Carberry, Dr. James J. Department of Chemical Engineering, University of Notre Dame.

Carbone, Dr. Richard E. Director, Atmospheric Technology Division, National Center for Atmospheric Research, Boulder, Colorado.

Cardullo, Dr. Frank. Watson School, Engineering Technology, State University of New York.

Carew, Dr. H. John. Professor of Horticulture, Michigan State University.

Carlson, Dr. Don M. Division of Biological Sciences, University of California, Davis.

Carlson, Dr. Jack H. Rhone Meriux, Inc., Athens, Georgia.

Carlson, Dr. Sandra J. Associate Professor and Research Geologist, Department of Geology/University of California, Davis.

Carlson, William C. Tree Physiologist, Weyerhauser Company, Hot Springs, Arkansas.

Carlsson, Prof. Anders E. Department of Physics, Washington University, St. Louis, Missouri.

Carlsson, Dr. D. J. National Research Council of Canada, Ottawa, Ontario.

Carlton, Dr. Peter L. Department of Psychiatry, University of Medicine and Dentistry of New Jersey, Rutgers Medical School.

Carney, Prof. Bruce W. Department of Physics & Astronomy, University of North Carolina, Chapel Hill.

Carpenter, Dr. C. J. Bath, Avon, England.

Carpenter, Dr. Frank M. Department of Biology, Harvard University.

Carris, Dr. Lori M. Department of Plant Pathology, Washington State University, Pullman.

Carroll, Dr. C. Ronald. Institute of Ecology, University of Georgia, Athens.

Carroll, Dr. John M. Department of Computer Science, University of Western Ontario, Canada.

Carroll, Robert G., Jr. Manager of Technical Development, Mirafi, Inc., Charlotte, North Carolina.

Carroll, Dr. Robert L. Redpath Museum, McGill University, Montreal, Quebec, Canada.

Carruthers, Dr. Marvin H. Department of Chemistry, University of Colorado.

Carson, Dr. John W. President, Jenike & Johanson Inc., North Billerica, Massachusetts.

Carson, Robert W. Formerly, Managing Editor, "Product Engineering," New York.

Carter, Archie N. Buan, Carter & Associates, Inc., Minneapolis, Minnesota.

Carter, Dr. G. R. Professor Emeritus, Department of Patho-biology, Virginia-Maryland Regional College of Veterinary Medicine, Virginia Polytechnic Institute and State University, Blackburg.

Carter, Dr. Joseph G. Department of Geology, University of North Carolina.

Carter, Prof. Herbert E. Vice Chancellor for Academic Affairs, University of Illinois.

Casasent, Prof. David. Department of Electrical and Computer Engineering, Carnegie-Mellon University.

Casey, Dr. H. C., Jr. Department of Electrical Engineering, Duke University.

Cassens, Prof. Linda J. Department of Plant Sciences, College of Agriculture, University of Arizona.

Catania, Prof. A. Charles. Department of Psychology, University of Maryland.

Catchpole, Dr. John. Admiralty Materials Laboratory, Dorset, England.

Caughey, Prof. David A. Sibley School of Mechanical and Aerospace Engineering, Cornell University, Ithaca, New York.

Caughlan, Prof. Georgeanne R. Department of Physics, Montana State University.

Cavanagh, Dr. Dale E. Naples, Florida.

Cave, Dr. M. Donald. Department of Anatomy, University of Arkansas for Medical Sciences.

Cavender, Ted M. Museum of Zoology, University of Michigan.

Cavey, Michael J. Department of Biology, University of Calgary, Alberta, Canada.

Cavin, Dr. Ralph K., III. Director, Design Sciences, Semiconductor Research, Research Triangle Park, North Carolina.

Celander, Dr. Daniel W. Department of Microbiology, University of Illinois, Urbana.

Celler, Dr. George K. AT&T Laboratories, Murray Hill, New Jersey.

Chace, Dr. Fenner A., Jr. Senior Zoologist, Department of Invertebrate Zoology, Smithsonian Institution.

Chakoumakos, Dr. Bryan C. Department of Geology, Northrup Hall, University of New Mexico.

Chambers, Dr. James P. Research Scientist and Research Assistant Professor of Mechanical Engineering, University of Mississippi.

Chambron, Dr. Jean-Claude. Laboratoire de Chimie Organo-Minérale, Institut le Bel, Université Louis Pasteur, Strasbourg, France.

Chameides, Prof. William L. School of Earth and Atmospheric Sciences, Georgia Institute of Technology, Atlanta.

Chan, Dr. Moses H. W. Department of Physics, Pennsylvania State University.

Chang, Dr. Alan J. Chief Curator of Fossil Amphibians, Reptiles and Birds, British Museum, London, England.

Chang, Prof. Howard H. Department of Civil and Environmental Engineering, San Diego State University, San Diego, California.

Chang, Prof. Kang-tsung. Department of Geography, University of Idaho, Moscow.

Chang, Dr. Luke L. Y. Department of Geology, University of Maryland, College Park.

Chang, Dr. M. C. Worcester Foundation for Experimental Biology, Shrewsbury, Massachusetts.

Chang, Prof. S. S. L. Department of Electrical Sciences, State University of New York, Stony Brook.

Chao, Dr. Edward C. T. Geological Survey, U.S. Department of the Interior, Reston, Virginia.

Chapman, Dr. Carleton A. Department of Geology, University of Illinois.

Chapman, Dr. Clark R. Planetary Science Institute, Tucson, Arizona.

Chapman, Dr. Richard A. Central Research Laboratories, Texas Instruments Inc., Dallas, Texas.

Chapman, Dr. Robert D. Section Head, Laboratory for Solar Physics and Astrophysics, NASA Goddard Space Flight Center, Beltsville, Maryland.

Chapman, Prof. Russell L. Chairperson, Department of Botany, Louisiana State University, Baton Rouge.

Chapman, Dr. Sydney. Deceased; formerly, High Altitude Observatory, University of Colorado.

Chappell, Dr. Charles F. University Corporation for Atmospheric Research, COMET, Boulder, Colorado.

Charlton, Dr. Ernest E. Research Engineer (retired), Schenectady, New York.

Charney, Dr. Dennis S. Department of Psychiatry, Yale University School of Medicine, and Connecticut Mental Health Center, New Haven.

Charnock, Dr. Henry Department of Oceanography, University of Southampton, England.

Charrier, Dr. J. M. Department of Chemical Engineering, McGill University, Montreal, Quebec, Canada.

Chaundhari, Dr. Nirupa. University of Miami School of Medicine, Department of Physiology and Biophysics, Rosentiel Medicial Sciences Building, Miami, Florida.

Chaudhari, Praveen. Thomas J. Watson Research Center, IBM, Yorktown Heights, New York.

Cheadle, Prof. Vernon I. Chancellor, University of California, Santa Barbara.

Chellis, Robert D. Deceased; formerly, Structural Engineer, Wellesley Hills, Massachusetts.

Chen, Dr. Albert Fu-Tai. Principal Research Chemist, Applied Research Department, Beckman Instruments, Brea, California.

Chen, Dr. Chong-maw. Department of Life Sciences, Biological Sciences/Biomedical Research Institute, University of Wisconsin, Parkside.

Chen, Dr. H. S. AT&T Bell Laboratories, Murray Hill, New Jersey.

Chen, Prof. Peter P. Director of the Institute of Computer and Information Systems Research, Louisiana State University.

Chen, Dr. Robert T. Medical Epidemiologist, Infant Immunization Section, Centers for Disease Control, Surveillance Investigations and Research Branch, Atlanta, Georgia.

Chen, Dr. Shoei-Sheng. Argonne National Laboratory, Argonne, Illinois.

Chenault, Roy L. Chief Research Engineer (retired), Oilwell Division, U.S. Steel Corporation, Dallas, Texas.

Cheng, Dr. T. C. Department of Electrical Engineering, University of Southern California.

Cherlin, Dr. Gregory L. Mathematical Sciences Research Institute and Rutgers University, Berkeley, California.

Chern, Prof. S. S. Mathematical Sciences Research Institute, University of California, Berkeley.

Chernosky, Prof. J. V. Department of Geological Science, University of Maine.

Chickering, Dr. Arthur M. Museum of Comparative Zoology, Harvard University.

Chien, Dr. Shu. Institute for Biomedical Engineering, University of California, La Jolla, California.

Chin, Dr. Gilbert Y. AT&T Bell Telephone Laboratories, Murray Hill, New Jersey.

Chinitz, Dr. Wallace. Department of Mechanical Engineering, Cooper Union.

Chiodo, Prof. Louis A. Chairperson, Department of Pharmacology, Texas Tech University Health Sciences Center, Lubbock.

Chipkin, Dr. Richard E. Department of Pharmacology, Schering Corporation, Bloomfield, New Jersey.

Chironis, Nicholas P. Senior Editor, “Coal Age,” McGraw-Hill, Inc., New York.

Chisholm, Dr. Malcolm. Department of Chemistry, Indiana University.

Chobor, Karen L. Institute for Research in Behavioral Neuroscience, Department of Neurology, New York University Medical Center.

Chodos, Dr. Alan. Department of Physics, Yale University.

Chokroverty, Prof. Sudhansu. Chief, Neurology Service, VA Medical Center, Lyons, New Jersey.

Choueiri, Dr. Edgar Y. Electric Propulsion Laboratory, Engineering Quadrangle, Princeton University.

Chow, Dr. Wen L. Department of Mechanical Engineering, College of Engineering, Florida Atlantic University, Boca Raton.

Choy, Dr. Patrick C. Department of Biochemistry, University of Manitoba Faculty of Medicine, Winnipeg, Canada.

Christ, Dr. Charles L. Physicist, U.S. Geological Survey.

Christensen, Dr. Bruce M. Assistant Professor, Department of Veterinary Science, University of Wisconsin, Madison.

Christensen, Dr. Martha. Professor Emeritus, Department of Botany, University of Wyoming, Laramie.

Christenson, Dr. Todd R. Photonics and Microfabrication Department, Sandia National Laboratories, Albuquerque, New Mexico.

Christiansen, Dr. Kenneth. Professor Emeritus of Biology, Department of Biology, Grinnell College, Iowa.

Christiansen, Dr. R. L. Petroleum Engineering Department, Colorado School of Mines, Golden.

Christie, Dr. John M. Department of Geology, University of California, Los Angeles.

Christie, Richard W. Hardesty & Hanover, New York.

Christie-Blick, Dr. Nicholas. Professor of Geology, Lamont-Doherty Earth Observatory, Columbia University, Palisades, New York.

Christophorou, Dr. L. G. Head, Atomic, Molecular and High Voltage Physics Group, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Christou, Dr. George. Department of Chemistry, Indiana University.

Christy, Dr. Nicholas. College of Physicians and Surgeons, Columbia University.

Chu, Prof. Benjamin. Department of Chemistry, State University of New York, Stony Brook.

Chu, Dr. Steven. Department of Physics, Stanford University.

Chu, Dr. T. Ming. Roswell Park Memorial Institute, Buffalo, New York.

Ciechanover, Dr. Aaron J. Department of Biochemistry, The Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology.

Ciegler, Dr. Alex. Southern Regional Research Center, USDA Science and Education Administration, New Orleans.

Civardi, Dr. Frank P. Civardi Engineers, Wayne, New Jersey.

Clack, Dr. Jennifer A. University Museum of Zoology, Cambridge, England.

Clapp, Philip F. National Weather Service, National Oceanic and Atmospheric Administration, Washington, D.C.

Claridge, Dr. Elmond L. Retired; formerly, Director of Graduate Program in Petroleum Engineering, Chemical Engineering Department, University of Houston Central Campus, Houston.

Clark, Dr. David A. Department of Medicine, McMaster University, Ontario, Canada.

Clark, Prof. Francis. Department of Microbiology, University of Illinois.

Clark, Prof. George L. Deceased; formerly, Emeritus Research Professor of Analytical Chemistry, University of Illinois.

Clark, Prof. John F. Director, Graduate Studies, and Professor, Space Systems, Spaceport Graduate Center, Florida Institute of Technology, Satellite Beach.

Clark, Dr. Nancy Barnes. Department of Physiology and Neurobiology, University of Connecticut.

Clark, Noel A. Department of Physics, University of Colorado at Boulder.

Clark, Richard F. Division of Physics, National Research Council of Canada, Ottawa, Ontario.

Clark, Prof. Wallis H., Jr. Director, Aquaculture Program, University of California, Davis.

Clarke, Dr. J. Harold. Horticulturist, Clarke Nursery, Long Beach, Washington.

Clarke, Prof. John. Department of Physics, University of California, Berkeley.

Clemence, Dr. Gerald M. Deceased; formerly, Observatory, Yale University.

Clemens, Dr. William A. Museum of Paleontology, University of California, Berkeley.

Clements, Dr. Leo P. Emeritus Professor of Anatomy, School of Medicine, Creighton University.

Cleminshaw, Dr. Clarence H. Deceased; formerly, Director Emeritus, Griffith Observatory, Los Angeles, California.

Cleve, Dr. Hartwig. Institute for Anthropology and Human Genetics, University of Munich, Germany.

Cleveland, Prof. L. F. Department of Electrical Engineering, Northeastern University.

Cleveland, Dr. Robin. Department of Aerospace And Mechanical Engineering, Boston University, Boston, Massachusetts.

Cline, Dr. Douglas. Nuclear Structure Laboratory, University Of Rochester, New York.

Cloud, Dr. Preston E., Jr. Department of Geology, University of California, Santa Barbara.

Clowes, Dr. F. A. L. Botany Department, University of Oxford, England.

Clydesdale, Dr. Fergus M. Department of Food Science and Nutrition, University of Massachusetts.

Coates, Dr. Peter B. Retired; formerly, Division of Electrical Science, National Physical Laboratory. Teddington, United Kingdom.

Cobine, Dr. James D. Deceased; formerly, Professor and Senior Scientist, Atmospheric Sciences Research Center, State University of New York, Albany.

Cochran, Dr. James R. Lamont-Doherty Earth Observatory, Columbia University, Palisades, New York.

Cocks, Dr. George. Los Alamos National Laboratory, Los Alamos, New Mexico.

Cocks, Dr. L. R. M. Department of Palaeontology, Natural History Museum, London, United Kingdom.

Coddington, Dr. Jonathan A. National Museum of Natural History, Smithsonian Institution, Washington, D.C.

Cohen, Dr. Alan S. Director, Thorndike Memorial Laboratory, Boston City Hospital, Boston, Massachusetts.

Cohen, Charles A. Research Associate (retired), Exxon Research and Engineering Company, Florham Park, New Jersey.

Cohen, Dr. David. National Magnetic Laboratory, Massachusetts Institute of Technology.

Cohen, Dr. Donald J. Assistant Professor, Child Study Center, Yale University.

Cohen, Dr. E. Richard. Rockwell International Science Center, Thousand Oaks, California.

Cohen, Dr. Gene. National Institute on Aging, National Institutes of Health, Bethesda, Maryland.

Cohen, Dr. Jay O. Deceased; formerly, Microbiologist, Department of Health and Human Services, Public Health Service, Centers for Disease Control, Atlanta, Georgia.

Cohen, Dr. Jerome. Department of Psychiatry, Medical School, Northwestern University.

Cohen, Dr. Jerry D. Plant Hormone Laboratory, U.S. Department of Agriculture, Beltsville, Maryland.

Cohen, Dr. Lisa M. Department of Dermatology, Beth Israel Hospital, Boston, Massachusetts.

Cohen, Dr. Steven A. Senior Research Scientist, Polymers Business Group, Amoco Corporation, Alpharetta, Georgia.

Colby, Dr. Kenneth Mark. Department of Psychiatry and Behavioral Sciences, School of Medicine, University of California, Los Angeles.

Cole, Dr. Edward H. Department of Immunopathology, Scripps Clinic and Research Foundation, La Jolla, California.

Coleal, Dr. Ernest. Formerly, Assistant for Facilities Development, Flight Research Division, Edwards Air Force Base, California.

Coleman, Dr. David C. Department of Entomology, University of Georgia.

Coleman, Dr. Robert E. Staff Scientist, Sugar Crops Production, National Program Staff, BARC-WEST, Beltsville, Maryland.

Collier, R. J. Bell Telephone Laboratories, Murray Hill, New Jersey.

Collins, Dr. Dean R. Director, CCD Technology Laboratory, Central Research Laboratories, Texas Instruments Inc., Dallas, Texas.

Collins, Dr. Francis. Department of Health and Human Services, National Human Genome Research Institute, Bethesda, Maryland.

Collins, Prof. J. H. Department of Electrical Engineering, University of Texas, Arlington.

Collins, Dr. Steven J. Department of Clinical Neurosciences, St. Vincent's Hospital, Melbourne, and Department of Pathology, University of Melbourne, Australia.

Collinson, Dr. Charles. Department of Geology, University of Illinois.

Colwell, Dr. Rita R. Department of Microbiology, Division of Agricultural and Life Sciences, University of Maryland.

Comeau, Richard. The Foxboro Company, Foxboro, Massachusetts.

Comer, Prof. Jonathan. Deparment of Geography, Oklahoma State University, Stillwater.

Comings, Dr. Edward W. University of Petroleum and Minerals, Dhahran, Saudi Arabia.

Commins, Prof. Eugene D. Department of Physics, University of California, Berkeley.

Compton, Robert D. Electro-Optical Systems Design, Milton S. Kiver Publications, Inc., Chicago, Illinois.

Condie, Dr. Kent C. Department of Earth and Environmental Sciences, New Mexico Institute of Mining and Technolgy, Socorro.

Confer, Prof. Anthony W. Head, Department of Veterinary, Pathology, Oklahoma State University, Stillwater.

Connors, Dr. James F. Propulsion Aerodynamics Division, National Aeronautics and Space Administration.

Conrad, Prof. Albert G. Dean Emeritus and Professor of Electrical Engineering, College of Engineering, University of California, Santa Barbara.

Constabel, Dr. Fred. Plant Biotechnology Institute, National Research Council, Saskatoon, Saskatchewan, Canada.

Converse, Dr. Richard H. Department of Botany, Oregon State University.

Conway Morris, Dr. Simon. Department of Earth Sciences, The Open University, Milton Keynes, England.

Conwell, Dr. Esther M. Xerox Webster Research Center, Rochester, New York.

Cook, Dr. Charles G. Research Geneticist, Agricultural Research Service, U.S. Department of Agriculture, Weslaco, Texas.

Cook, Dr. Frank. Research Assistant Professor, Department of Veterinary Science, Gluck Equine Research Center, University of Kentucky, Lexington.

Cook, Dr. Gerald. Department of Electrical and Computer Engineering, George Mason University, Fairfax, Virginia.

Cook, Philip H. Plastics Department, Texas Division, Dow Chemical U.S.A., Freeport, Texas.

Cook, Dr. Richard K. Formerly, National Bureau of Standards.

Cooley, Dr. William E. Winton Hill Technical Center, Proctor and Gamble Company, Cincinnati, Ohio.

Cooley, Prof. Hollis R. Professor Emeritus of Mathematics, New York University.

Coombs, Dr. Sheryl. Professor of Hearing Sciences, Parmly Hearing Institute, Loyola University, Chicago, Illinois.

Cooper, Dr. Arthur W. Department of Botany, North Carolina State University.

Cooper, Prof. W. Charles. Department of Metallurgical Engineering, Queens University, Kingston, Ontario, Canada.

Copel, Michel. Acoustronics, Inc., Huntington, New York.

Copeland, Prof. Miles A. Faculty of Engineering, Carleton University, Ottawa, Ontario, Canada.

Coppens, Dr. Alan B. Associate Professor of Physics, U.S. Navy Post Graduate School, Pacific Grove, California.

Corben, Dr. Herbert C. Deceased; formerly, Ramo-Wooldridge Corporation, Los Angeles, California.

Corbitt, Robert A. Associate, Metcalf & Eddy, Inc., Atlanta, Georgia.

Core, Prof. Earl L. Professor of Botany, Department of Biology, West Virginia University.

Corliss, Dr. John O. Department of Zoology, University of Maryland.

Costantino, Dr. James. Intelligent Transportation Society of America, Washington, D.C.

Costerton, Dr. J. William F. Department of Biology, University of Calgary, Alberta, Canada.

Cotterill, Carl H. Chief, Division of Statistical and Technical Services, Bureau of Mines, U.S. Department of the Interior.

Couch, Dr. John C. Matson Navigation Company, San Francisco, California.

Couch, Dr. Richard B. Professor of Naval Architecture and Marine Engineering, Ship Hydrodynamics Laboratory, University of Michigan.

Couclelis, Prof. Helen. Department of Geography, University of California, Santa Barbara.

Coulombe, Dr. Mary J. Director, Timber Access and Supply, American Forest and Paper Association, Washington, D.C.

Coulter, Earl E. Manager, Mechanical Technology, Babcock and Wilcox Company, Barberton, Ohio.

Coursen, D. Linn. Dynatec Explosives Consultants, Inc., Española, New Mexico.

Court, Dr. Arnold. Retired; formerly, Department of Climatology, California State University.

Cowan, Dr. Thomas E. General Atomics, Photonics Division, San Diego, California.

Cowles, Prof. Philip B. Professor Emeritus of Microbiology, School of Medicine, Yale University.

Cox, Dr. Charles S. Department of Oceanography, University of California, San Diego.

Coxeter, Prof. H. S. M. Department of Mathematics, University of Toronto, Ontario, Canada.

Coyle, Harold P. Harvard-Smithsonian Center for Astrophysics, Harvard College Observatory, Cambridge, Massachusetts.

Coyle, Dr. Heather. Connecticut State Police Forensic Science Laboratory, Meriden.

Coyne, Dr. Michael J. Senior Veterinarian Technical Services, SmithKline Beecham Animal Health, Exton, Pennsylvania.

Cozzens, Christine S. Biology Laboratory, Harvard University.

Crabill, Dr. Ralph E., Jr. Curator and Supervisor of the Division of Myriapoda and Arachnida, Department of Entomology, Smithsonian Institution, National Museum of Natural History.

Cracraft, Dr. Joel. Department of Ornithology, American Museum of Natural History, New York.

Crafts, Dr. Alden S. Professor Emeritus, Department of Botany, University of California, Davis.

Craig, Prof. Homer V. Department of Mathematics, University of Texas, Austin.

Craine, Dr. Eric R. Western Research Company, Inc., Tucson, Arizona.

Cramer, Dr. Friedrich. Max Planck Institut für Experimentelle Medizin, Gottingen, Germany.

Cramer, Dr. William S. Ship Acoustics Department, Naval Ship Research and Development Center, Washington, D.C.

Crane, Julian C. Professor of Pomology, Agricultural Experimental Station, University of California, Davis.

Cranwell, Dr. Lucy M. Department of Geosciences, University of Arizona.

Crawford, Prof. Michael H. Chief, Division of Cardiology, University of New Mexico School of Medicine, Albuquerque.

Cremer, Prof. Sheldon E. Department of Chemistry, Marquette University.

Creutz, Dr. Carol. Department of Chemistry, Brookhaven National Laboratory, Associated University Inc., Upton, New York.

Crittenden, Dr. Charles V. Geographer, Economic Development Administration, U.S. Department of Commerce.

Crocker, Dr. Burton B. Monsanto Company, St. Louis, Missouri.

Crocker, Prof. Malcolm J. Department of Mechanical Engineering, Purdue University.

Cronin, Dr. Thomas. Department of Biological Sciences, University of Maryland, Baltimore County.

Cronquist, Dr. Arthur. Director of Botany, New York Botanical Gardens, Bronx, New York.

Cross, Dr. Chester E. Agricultural Experiment Station, University of Massachusetts.

Crouse, William H. Consulting Editor, Automotive Books, McGraw-Hill Book Company, New York.

Crow, Dr. James F. Department of Genetics, University of Wisconsin.

Crowe, Prof. Clayton T. Department of Mechanical and Materials Engineering, Washington State University, Pullman.

Crowe, Dr. John H. Department of Zoology, University of California, Davis.

Crowell, Dr. Sears. Department of Zoology, Indiana University.

Crowson, Dr. Roy A. Department of Zoology, University of Glasgow, Scotland.

Cruickshank, Dr. Michael J. Look Laboratory, University of Hawaii.

Crum, Dr. Howard. Herbarium, University of Michigan.

Csanady, Dr. G. T. Department of Physical Oceanography, Old Dominion University, Norfolk, Virginia.

Cuckler, Lee E. Interdivisional Coordinator, Aeronautical and Instrument Division, Robertshaw Controls Company, Anaheim, California.

Cuffey, Dr. Roger J. Department of Geology and Geophysics, Pennsylvania State University.

Culbertson, Dr. Joseph O. Assistant Chief (retired), Oil-seed and Industrial Crops Research Branch, Crops Research Division, U.S. Department of Agriculture, Beltsville, Maryland.

Culotta, Prof. Valeria Cizewski. Associate Professor, Johns Hopkins University School of Public Health, Department of Environmental Health Sciences, Baltimore, Maryland.

Cumberland, Prof. Kenneth B. Professor of Geography, University of Auckland, New Zealand.

Cummings, Dr. Michael R. Department of Biological Sciences, University of Illinois.

Cummins, Dr. Denise Dellarosa. Department of Psychology, University of Arizona.

Cummins, Prof. Harold. Professor Emeritus, School of Medicine, Tulane University.

Cunnane, William P. Assistant Commissioner, Office of Network Services, Information Resources Management, General Services Administration, Washington, D.C.

Cunningham, Prof. Burris B. Deceased; formerly, Radiation Laboratory, University of California, Berkeley.

Curkendall, Dr. David W. NASA Jet Propulsion Laboratory, Pasadena, California.

Curray, Dr. Joseph R. Scripps Institution of Oceanography, University of California, La Jolla.

Curtin, Dr. Charles B. Department of Biology, Creighton University.

Curtis, Prof. Charles F. Department of Chemistry, University of Wisconsin.

Curtiss, Leon F. Formerly, National Bureau of Standards.

Cushman, Dr. Pauline K. College of Integrated Science and Technology, James Madison University, Harrisonburg, Virginia.

Cushman-Roisin, Dr. Benoit. Thayer School of Engineering, Dartmouth College, Hanover, New Hampshire.

Cutler, Prof. Chapin C. Professor of Applied Physics, Stanford University.

Cutler, Dr. Edward B. Department of Biology, Utica College of Syracuse University.

Cutter, Dr. Elizabeth G. Department of Cryptogamic Botany, University of Manchester, England.

Czamanske, Dr. Gerald K. U.S. Geological Survey, Menlo Park, California.

Czarnik, Dr. Anthony W. Senior Director, Chemistry, IRORI Quantum Microchemistry, La Jolla, California.

D

Dabberdt, Dr. Walter F. Atmospheric Technology Division, National Center for Atmospheric Research, Boulder, Colorado.

Dabbs, Dr. David J. Pathologist, Department of Pathology, University of Washington.

Dahl, Dr. Lawrence F. Department of Chemistry, University of Wisconsin.

Dahl, Dr. Leslie R. Consultant, General Electric Company, San Jose, California.

Dahl, Dr. Peter S. Department of Geology, Kent State University, Kent, Ohio.

Daiber, Dr. Franklin C. College of Marine Studies, University of Delaware.

Daigle, Dr. Gilles A. National Research Council, Institute for Microstructural Sciences, Ottawa, Canada.

Dale, Dr. James B. Veteran Affairs Medical Center, Memphis, Tennessee.

Dalitz, Prof. Richard H. Department of Theoretical Physics, Oxford University.

Dalrymple, Dr. David L. Department of Chemistry, University of Delaware.

Dalton, Dr. David R. Department of Chemistry, College of Arts and Sciences, Temple University.

Dalziel, Dr. Ian W. O. Department of Geological Sciences, University of Texas at Austin.

Damberger, Dr. Heinz H. Illinois State Geological Survey, Coal Section, Champaign.

Damian, Dr. Raymond T. Department of Zoology, Franklin College of Arts and Sciences, University of Georgia.

Damman, Prof. Antoni W. H. Department of Biology, University of Connecticut.

Danby, Dr. J. M. A. Department of Mathematics, North Carolina State University.

Daney, Dr. David E. Los Alamos National Laboratory, Los Alamos, New Mexico.

Daniel, James R. Department of Biochemistry, Purdue University.

Daniels, Dr. D. J. ERA Technology, Leatherhead, Surrey, England.

Daniels, Dr. Farrington. Deceased; formerly, Professor Emeritus, Solar Energy Laboratory, University of Wisconsin.

Daniels, Prof. James M. Department of Physics, University of Toronto.

D'Arcangelo, Prof. Amelio M. Department of Naval Architecture, University of Michigan.

Darwin, Dr. C. J. Experimental Psychology, University of Sussex, England.

Date, Prof. Hikaru. Acoustics Department, Kyushu Institute of Design, Fukuoka, Japan.

Daubechies, Dr. Ingrid. AT&T Bell Laboratories, Murray Hill, New Jersey.

Davidson, Dr. Jaime A. Endocrine & Diabetes Associates of Texas, Dallas, Texas.

Davies, David H. DataPlay Inc., Boulder, Colorado.

Davies, Dr. Peter J. Department of Botany, Cornell University.

Davies-Jones, Dr. Robert P. Meteorologist, National Severe Storms Laboratory, U.S. Department of Commerce, Norman, Oklahoma.

Davis, Dr. Andrew M. Enrico Fermi Institute, University of Chicago, Illinois.

Davis, Dr. Bernard D. Deceased; formerly, Bacterial Physiology Unit, Harvard Medical School.

Davis, D. Dwight. Deceased; formerly, Curator of Vertebrate Anatomy, Chicago Museum of Natural History.

Davis, Dr. George H. Department of Geological Sciences, University of Arizona.

Davis, Prof. Gregory A. Department of Geological Sciences, University of Southern California.

Davis, Dr. Jack. Deceased; formerly, Research and Development, Bright Star Industries, Inc., Clifton, New Jersey.

Davis, Dr. John H. Professor Emeritus of Botany, University of Florida.

Davis, Prof. Kenneth P. Deceased; formerly, School of Forestry, Yale University.

Davis, Dr. Richard A., Jr. Department of Geology, University of South Florida.

Davis, Dr. Simon J. M. Ancient Monuments Laboratory, Saville Row, London, England.

Dawood, Dr. M. Yusoff. Department of Obstetrics and Gynecology, University of Illinois College of Medicine, Chicago.

Dawson, Dr. David M. West Roxbury Veterans Affairs Medical Center, West Roxbury, Massachusetts.

Dawson, Prof. Kerry J. Environmental Horticulture, University of California, Davis.

Dawson, Dr. Todd E. Ecology and Systematics, Cornell University, Carson Hall, Ithaca, New York.

Day, Dr. William H. Manager, Advanced Industrial Programs, Pratt & Whitney, East Hartford, Connecticut.

Dayton, Benjamin B. Consulting Physicist, East Flatrock, North Carolina.

Deacon, Margaret. Department of Oceanography, University of Southampton, United Kingdom.

Deacon, T. A. Deceased; formerly, Division of Electrical Science, National Physical Laboratory, Teddington, Middlesex, England.

Deakins, Dr. Ralph R. Director, Computer-Aided Systems, Rockwell International Corporation, El Segundo, California.

Dean, Dr. Thomas S. Architectural Engineer, Lawrence, Kansas.

Dean, Dr. Walter E. U.S. Geological Survey, Denver Federal Center, Denver, Colorado.

de Boor, Dr. Carl. Mathematical Research Center, University of Wisconsin.

DeCarli, Dr. P. S. Poulter Laboratory, Stanford Research Institute.

De Cicco, John. Department of Mathematics, Illinois Institute of Technology.

DeClaris, Dr. Nicholas. Division of Emerging Energy Technologies, National Science Foundation, Washington D.C.

DeFacio, Prof. Brian. Department of Physics and Astronomy, University of Missouri.

de Freitas, Prof. Duarte Mota. Department of Chemistry, Loyola University, Chicago, Illinois.

Dehmelt, Dr. Hans. Department of Physics, University of Washington.

De Jong, Dr. Theodore M. Pomology Department, University of California, Davis.

Dekker, Dr. Adrianus J. Professor of Solid State Physics, University of Groningen, Netherlands.

de la Cruz, Felix. Chief, Mental Retardation and Development Disabilities Branch, National Institute of Child Health and Human Development, Bethesda.

Delahay, Prof. Paul. Department of Chemistry, New York University.

Deland, Dr. Raymond J. Retired; formerly, Department of Meteorology and Oceanography, New York University.

de Levie, Prof. Robert. Department of Chemistry, Georgetown University, Washington, DC.

Dell'Arciprete, Dr. Patricia. Central Nacional Patagónico (CONICET), Chubut, Argentina.

DeLong, Dr. Dwight M. College of Biological Sciences, Ohio State University.

Delson, Dr. Eric. Department of Vertebrate Paleontology, American Museum of Natural History.

DeLuca, Dr. Hector F. Department of Biochemistry, University of Wisconsin, Madison.

Demar, Dr. Robert E. Department of Geology, University of Illinois, Chicago.

Dempsey, Prof. Mary E. Department of Biochemistry, University of Minnesota Medical School, Minneapolis.

de Neufville, Dr. John P. President, Voltaix, Inc., North Branch, New Jersey.

Dengler, Dr. Nancy G. Department of Botany, University of Toronto, Ontario, Canada.

Den Hartog, Prof. J. P. Retired; formerly, Department of Mechanical Engineering, Massachusetts Institute of Technology.

Denison, Dr. Robert H. Deceased; formerly, Curator of Fossil Fishes, Field Museum of Natural History, Chicago, Illinois.

Denniston, Dr. Carter L. Department of Medical Genetics, University of Wisconsin, Madison.

Deno, Dr. Richard A. Professor of Pharmacognosy, University of Michigan.

Dent, Dr. William. Department of Physics and Astronomy, University of Massachusetts.

DePaolo, Dr. Donald J. Department of Geology and Geophysics, University of California, Berkeley.

DePlasco, Mark A. Air Force Flight Standard Agency, Washington, D.C.

Derge, Prof. Gerhard. Department of Metallurgy and Material Science, Carnegie-Mellon University.

Dershowitz, Dr. Nachum. Department of Computer Science, Illinois Institute of Technology, Chicago.

Des S. Thomas, Dr. Donovan. Department of Biology, University of Windsor, Ontario, Canada.

deSatnick, Steve. Vice President, Operations and Engineering, KCET-TV, Los Angeles, California.

Destree, Thomas M. Editor in Chief, Graphic Arts Technical Foundation, Sewickley, Pennsylvania.

DeVaney, Fred D. Consulting Metallurgist, Duluth, Minnesota.

DeVolpi, Dr. A. Argonne National Laboratory, Argonne, Illinois.

DeVore, Dr. George W. Department of Geology, Florida State University.

DeVries, Dr. Arthur L. Department of Physiology and Biophysics, University of Illinois, Urbana-Champaign.

de Week, Dr. A. L. Institut für Klinische Immunologic Inselspital, Universitat Bern, Switzerland.

Dewsbury, Dr. Donald A. Department of Psychology, University of Florida, Gainesville.

Dexter, Dr. Theodore H. Research Supervisor, Inorganic Chemistry, Hooker Chemical Corporation Research Center, Niagara Falls, New York.

Dhir, Prof. Vijay K. Department of Mechanical and Aerospace Engineering, University of California, Los Angeles.

Diamond, Dr. Seymour. Director, Diamond Headache Clinic, Ltd., Chicago, Illinois.

DiBiase, Dr. David. Department of Geography, Pennsylvania State University, University Park.

Dick, Prof. B. Gale. Department of Physics, University of Utah.

Dick, Dr. Henry J. B. Senior Scientist, Department of Geology and Geophysics, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.

Dickinson, Prof. Robert E. Department of Atmospheric Physics, University of Arizona, Tucson.

Dickinson, Dr. W. R. Department of Geosciences, University of Arizona, Tucson.

Dieke, Prof. G. H. Deceased; formerly, Chairman, Department of Physics, Johns Hopkins University.

Diekema, Dr. Daniel James. University of Iowa College of Medicine, Department of Pathology, Division of Medical Microbiology, Iowa City.

Dietrich-Buchecker, Dr. C. O. Laboratoire de Chimie Organo-Minérale, Institut le Bel, Université Louis Pasteur, Strasbourg, France.

Di Fiore, Dr. Anthony. Department of Anthropology, New York University, New York.

Di Giulio, Edmund M. Cinema Products Corporation, Los Angeles, California.

Dill, Dr. Robert F. Ocean Mining Administration, U.S. Department of the Interior.

Dille, Dr. James M. Deceased; formerly, Professor and Chairman, Department of Pharmacology, School of Medicine, University of Washington.

Dillman, Prof. Norman G. Department of Electrical and Computer Engineering, Kansas State University, Manhattan.

Dillon, J. F., Jr. Bell Telephone Laboratories, Murray Hill, New Jersey.

DiMichele, Dr. William A. Department of Paleobotany, Smithsonian Institution, Washington, D.C.

Dimmel, Prof. Donald R. Research Associate, Wood Sciences, Chemical Sciences Division, Institute of Paper Chemistry, Appleton, Wisconsin.

Dine, Dr. Michael. Physics Department, City College of New York.

Dingle, Prof. Hugh. Department of Entomology, College of Agricultural and Environmental Sciences, University of California, Davis.

Dinsmore, Robertson P. International Ice Patrol, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.

DiTallo, Cynthia. United Technologies, Otis Elevator Company, Farmington, Connecticut.

Dix, Dr. Cyril H. Bishop Monkton, North Yorkshire, England.

Doane, Dr. J. William. Liquid Crystal Institute, Kent State University, Kent, Ohio.

Dodds, Robert H. Deceased; formerly, Personnel Manager, Gibbs and Hill, Inc., New York.

Dogramaci, Prof. AH. Department of Industrial and Management Engineering, Columbia University.

Doherty, Dr. Michael F. Head, Department of Chemical Engineering, University of Massachusetts.

Domning, Dr. Daryl P. Department of Anatomy, Howard University, Washington, DC.

Donaldson, Dr. Alex I. Pirbright Laboratory, Pirbright, Surrey, United Kingdom.

Donaldson, Dr. James A. Professor and Chairman, Department of Otolaryn-gology, School of Medicine, University of Washington.

Donovan, Dr. Nowell. Department of Geology, Texas Christian University, Forth Worth.

Doob, Prof. Joseph L. Department of Mathematics, University of Illinois, Urbana-Champaign.

Doolan, Barry L. Department of Geology, Memorial University of Newfoundland, St. John's, Canada.

Dooley, H. D. Marine Laboratory, Department of Agriculture and Fisheries, Aberdeen, Scotland.

Doornbos, Dr. Durk J. Deceased; formerly, Institute for Geophysics, University of Oslo, Norway.

Dorf, Prof. Erling. Department of Geology, Princeton University.

Dorf, Dean Richard C. Division of Extended Learning, University of California, Davis.

Dorfman, Dr. Ralph I. Senior Vice President and Director, Syntex Research Center, Palo Alto, California.

Dorsey, Prof. John G. Department of Chemistry, Florida State University, Tallahassee.

Doscher, Dr. Todd M. Department of Petroleum Engineering, University of Southern California.

Dossel, Dr. William E. Professor and Chairman, Department of Anatomy, School of Medicine, Creighton University.

Dott, Dr. Robert H., Jr. Department of Geology, University of Wisconsin.

Doubiel, Dr. Russell F. Geological Survey, U.S. Department of the Interior, Denver, Colorado.

Doudoroff, Dr. Michael. Deceased; formerly, Department of Bacteriology, University of California, Berkeley.

Douglas, Donald W., Jr. Corporate Vice President—Administration, McDonnell Douglas Corporation, St. Louis, Missouri; Chairperson and President, Douglas Aircraft Company of Canada, Toronto, Ontario.

Douglass, Prof. David H. Department of Physics and Astronomy, College of Art and Science, University of Rochester.

Douglass, Prof. Raymond D. Department of Mathematics, Massachusetts Institute of Technology.

Dover, Dr. Carl B. Department of Physics, Brookhaven National Laboratory, Upton, New York.

Doviak, R. J. National Severe Storms Laboratory, National Oceanic and Atmospheric Administration, Norman, Oklahoma.

Downey, Dr. Joe. Dow Chemical Company, Midland, Michigan.

Downey, Dr. R. K. Agricultural Research Station, Saskatoon, Saskatchewan, Canada.

Doyle, Prof. James A. Department of Biological Sciences, University of California, Davis.

Doyle, Laurence. Senior Scientist, ITT Aerospace/Communications, Clifton, New Jersey.

Doyle, Prof. Michael P. Director, Center for Food Safety and Quality Enhancement, University of Georgia, Griffin.

Drake, A. E. Division of Electrical Science, National Physical Laboratory, United Kingdom.

Drake, Prof. John C. Department of Geology, University of Vermont.

Drake, Dr. Michael V. Department of Ophthalmology, School of Medicine, University of California, San Francisco.

Draper, Dr. Clifton W. Laser Studies Group, Western Electric Company, Princeton, New Jersey.

Dreschel, Dr. Thomas W. Biologist/ Chemist, Bionetics Corporation, Environmental Monitoring and Research Program, Kennedy Space Center, Florida.

Dresden, Prof. Max. Institute for Theoretical Physics, State University of New York, Stony Brook.

Drexter, Dr. Eric. Foresight Institute, Palo Alto, California.

Dropping, Barry. Hewlett-Packard, Santa Clara, California.

Duby, Prof. Paul. Henry Krumb School of Mines, Columbia University.

Duckworth, Dr. Henry E. Department of Physics, University of Manitoba, Canada.

Dugan, Dr. Frank M. American Type Culture Collection, Manassas, Virginia.

Duguay, Dr. Michel A. Laser Development, Sandia Laboratories, Albuquerque, New Mexico.

Duke, Dr. C. B. Manager, Molecular and Organic Materials Area, Xerox Corporation, Rochester, New York.

Duke, Kenneth L. Department of Anatomy, Duke University Medical Center.

Dunbar, Prof. Carl O. Deceased; formerly, Professor Emeritus of Paleontology and Stratigraphy, Yale University.

Duncan, Prof. William G. Department of Agronomy, University of Kentucky.

Duncombe, Dr. Raynor L. Department of Aerospace Engineering, University of Texas, Austin.

Dunlop, Prof. David J. Department of Physics, University of Toronto, Ontario, Canada.

Dunn, Prof. Bruce. Department of Materials Science & Engineering, University of California, Los Angeles.

Dunn, Prof. Floyd. Department of Electrical and Computer Engineering, University of Illinois at Urbana-Champaign.

Dunning, Dr. John B., Jr. Department of Forestry and Natural Resources, Purdue University.

DuPont, Dr. Herbert L. Medical School, University of Texas, Houston.

Duren, Prof. Peter L. Department of Mathematics, University of Michigan.

Durst, Prof. Richard A. Director, Analytical Chemistry Laboratories, New York State Agricultural Experimental Station, Cornell University, Geneva.

Dutro, Dr. J. Thomas, Jr. Museum of Natural History, U.S. Department of the Interior, Washington, D.C.

Duwez, Dr. Pol E. Deceased; formerly, W. M. Keck Laboratory of Engineering Materials, California Institute of Technology.

Dyer, Dr. K. R. Institute of Oceanographic Sciences, Somerset, England.

Dym, Prof. C. L. Department of Civil Engineering, University of Massachusetts.

Dzuiba, Ronald. Senior Member, Electrical Measurements Laboratory, National Institute of Standards and Technology, Gaithersburg, Maryland.

E

Easterbrook, Don J. Department of Geology, Western Washington University, Bellingham.

Eberl, Dr. Dennis D. U.S. Geological Survey, Denver Federal Center, Denver, Colorado.

Eberts, Prof. Ray. Department of Industrial Engineering, Purdue University.

Eckels, Dr. Arthur R. Department of Electrical Engineering, North Carolina State University.

Economou, George A. Formerly, J. W. Pecker Division, American Optical Company, Pittsburgh, Pennsylvania.

Edelman, Robert I. Corporate Communications, Eastman Kodak Company, Rochester, New York.

Edelson, Dr. Marshall. Department of Psychiatry, Yale University.

Edgecombe, Gregory D. American Museum of Natural History, New York.

Edgerton, Dr. Harold E. Institute Professor, Emeritus, Massachusetts Institute of Technology.

Edmonds, Dr. Robert L. College of Forest Resources, University of Washington, Seattle.

Edwards, Alan F. Freeport-McMoran Inc., New Orleans, Louisiana.

Edwards, Prof. John O. Department of Chemistry, Brown University.

Edwards, Dr. Peter A. Department of Biological Chemistry, University of California School of Medicine, Los Angeles.

Edwards, Dr. Russell K. Argonne National Laboratory, Argonne, Illinois.

Edwards, Dr. Steven. Department of Virology, Central Veterinary Laboratory-Weybridge, United Kingdom.

Eesley, Dr. Gary L. GM Research and Development Center, Warren, Michigan.

Egan, Patrick. Department of Physics, Yale University.

Ehernberger, L. J. NASA Dryden Flight Research Facility, Edwards, California.

Ehrlich, Dr. John. Formerly, Laboratory Director in Antibiotic Research, Parke, Davis and Company, Detroit, Michigan.

Ehrlich, Dr. Paul R. Professor of Biological Sciences and Curator of the Entomological Collections, Stanford University.

Ehrlich, Dr. Stanley L. Middletown, Rhode Island.

Ehrmann, Dr. David A. Department of Medicine, Section of Endocrinology, University of Chicago Medical Center.

Eichorn, Dr. Gunther L. Gerontology Research Center, National Institutes of Health, Baltimore, Maryland.

Eidson, Dr. Millicent. Veterinarian, Santa Fe, New Mexico.

Eilers, Carl G. Manager, Electronics Systems Research and Development, Zenith Radio Corporation, Glenview, Illinois.

Einaudi, Prof. Marco T. Department of Applied Earth Science, Stanford University.

Eirich, Dr. F. R. Chemistry/Life Sciences Department, Polytechnic University, New York.

Eisenbud, Dr. Merril. Institute of Environmental Medicine, New York University Medical Center.

Ekdale, Dr. Allan A. Department of Geology and Geophysics, College of Mines and Earth Sciences, University of Utah.

Eldeib, Dr. Hany K. Department of Electrical and Computer Engineering, George Mason University, Fairfax, Virginia.

Elderfield, Prof. Robert C. Deceased; formerly, Department of Chemistry, University of Michigan.

Eldredge, Dr. Niles. American Museum of Natural History, New York.

Elgomayel, Prof. Joseph. School of Industrial Engineering, Purdue University.

Eliel, Prof. Ernest L. Department of Chemistry, University of North Carolina.

Ellen, Dr. C. Wayne. Department of Plant Pathology, Ohio State University.

Ellis, Dr. David E. Research and Development Department, Continental Oil Company, Ponco City, Oklahoma.

Ellis, Dr. Gordon W. Department of Biology, School of Art and Sciences, University of Pennsylvania, Leidy Laboratory of Biology, Philadelphia.

Ellis, Dr. Walther R. Division of Chemistry and Chemical Engineering, California Institute of Technology.

El-Mansy, Youssef. Intel Corporation, Aloha, Oregon.

Elston, Dr. Stuart B. Department of Physics and Astronomy, University of Tennessee, Knoxville.

Eltoweissy, Dr. Mohamed Y. Department of Computer Science, James Madison University, Harrisonburg, Virginia.

Ely, F. G. Retired; Research and Development Division, Babcock and Wilcox Company.

Emanuel, Dr. Kerry Andrew. Department of Earth, Atmospheric and Planetary Sciences, Massachusetts Institute of Technology.

Emerson, Lewis P. Engineer in Charge of Flow Measurement, Foxboro Company, Foxboro, Massachusetts.

Emerson, Dr. Steven. Department of Oceanography, University of Washington.

Encleson, Stephen C. Technical Editor, Corporate Communications, Dow Chemical Company, Midland, Michigan.

Endicott, Prof. John F. Department of Chemistry, Wayne State University.

Engels, Dr. William R. Department of Genetics, University of Wisconsin, Madison.

English, Prof. Van H. Department of Geography, Dartmouth College.

Engstrom, Prof. Arne. Head, Department of Medical Physics, Karolinska Institute, Stockholm, Sweden.

Engstrom, Dr. Ralph W. Electro-Optics and Devices, RCA Laboratories, Lancaster, Pennsylvania.

Enkenfelder, Dr. W. Wesley, Jr. Eckenfelder, Inc., Nashville, Tennessee.

Enlander, Dr. Derek. New York, New York.

Enrich, Fredric F. Aircraft Engine Business Group, General Electric Company, Lynn, Massachusetts.

Enslow, Prof. Philip H., Jr. School of information and Computer Science, Georgia Institute of Technology.

hEocha, Colm. Department of Biochemistry, University College, Galway, Ireland.

Epperly, W. R. Exxon Research and Engineering, Annandale, New Jersey.

Epstein, Dr. W. W. Department of Chemistry, University of Utah.

Erasmus, Dr. Baltus J. Head, Onderstepoort Vaccine Factory, Republic of South Africa.

Erb, Dr. Karl A. Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Erdelyi, Prof. A. Professor of Mathematics, University of Edinburgh, Scotland.

Erdman, Dr. Arthur. Department of Mechanical Engineering, University of Minnesota.

Erickson, Dr. Robert P. Department of Pediatrics, University of Arizona College of Medicine, Tucson.

Eriksson, Dr. Kenneth A. Department of Geology, University of Texas, Richardson.

Ernst, Dr. Ralph A. Extension Poultry Specialist, Avian Sciences, University of California, Davis.

Ernster, Dr. Virginia L. Department of Epidemiology and International Health, School of Medicine, University of California, San Francisco.

Esaki, Leo. Thomas J. Watson Research Center, IBM, Yorktown Heights, New York.

Esau, Prof. Katherine. Department of Botany, University of California, Santa Barbara.

Essene, Prof. Eric J. Department of Geological Sciences, University of Michigan, Ann Arbor.

Ethridge, Dr. Frank G. Department of Earth Resources, Colorado State University.

Ettenberg, Dr. Eugene M. Formerly, Lecturer in Graphic Arts, New York.

Etter, Robert J. David W. Taylor Naval Ship Research and Development Center, Bethesda, Maryland.

Evans, Doris L. Deceased; formerly, Research and Development Division, Corning Glass Works, Corning, New York.

Evans, Dr. Doyle J. Chief, Bacterial Enteropathogens Laboratory, Veterans Affairs Medical Center, Houston, Texas.

Evans, Prof. Francis C. Division of Biological Sciences, University of Michigan.

Evans, Dr. Ginger. Denver, Colorado.

Evans, Prof. Robley D. Retired; Department of Physics, Massachusetts Institute of Technology.

Evenson, Dr. Kenneth M. Time and Frequency Division, National Institute of Standards and Technology, Boulder, Colorado.

Evenson, Dr. Paul. Bartol Research Institute, University of Delaware.

Everetts, Dr. John Jr. Professor of Architectural Engineering, Pennsylvania State University.

Ewing, Dr. Maurice. Deceased; formerly, Lamont-Doherty Geological Observatory, Palisades, New York.

Ewing, Prof. Rodney. Department of Earth and Planetary Sciences, University of New Mexico, Albuquerque.

Eyde, Dr. Richard H. Department of Botany, Smithsonian Institution.

Eyring, Dr. Edward M. Department of Chemistry, University of Utah.

Eyring, Prof. Henry. Deceased; formerly, Institute for the Study of Rate Processes, University of Utah.

Ezzell, Dr. John W. Chief, Special Pathogens Branch, U.S. Army Medical Research Institute, Fort Detrick, Maryland.

F

Failla, Dr. Gioacchino. Deceased; formerly, Argonne National Laboratory, Argonne, Illinois.

Fairbank, Prof. Henry A. Department of Physics, Duke University.

Falchuck, Dr. Kenneth A. Center for Biochemical and Bio-physical Sciences and Medicine, Harvard Medical School.

Faller, Dr. John W. Department of Chemistry, Yale University.

Fan, Prof. Hsu Y. Department of Physics, Purdue University.

Fankhauser, Dr. Gerhard. Deceased; formerly, Department of Biology, Princeton University.

Fano, Prof. U. Deceased; formerly, James Franck Institute, University of Chicago.

Fanta, Prof. Paul E. Department of Chemistry, Illinois Institute of Technology.

Farmer, Dr. David M. Department of the Environment, Pacific Region, Institute of Ocean Sciences, Sidney, British Columbia, Canada.

Farmer, Richard G. Department of Electrical Engineering, Arizona State University, Tempe.

Farrel, Dr. Nicholas. Department of Chemistry, Virginia Commonwealth University, Richmond.

Farrell, R. F. General Manager, Glidden Coatings and Resins, Division of SCM Corporation, Charlotte, North Carolina.

Faure, Dr. Gunter. Department of Geological Sciences, Ohio State University.

Faw, Prof. Richard E. Head, Department of Nuclear Engineering, Kansas State University.

Fawcett, Prof. Eric. Department of Physics, University of Toronto, Ontario, Canada.

Fay, Dr. Richard R. Parmly Hearing Institute and Department of Psychology, Loyola University of Chicago, Illinois.

Fayyad, Dr. Usama. Microsoft Research, Redmond, Washington.

Feduccia, Dr. Alan. Department of Biology, University of North Carolina, Chapel Hill.

Fehr, Prof. Walter R. Department of Agronomy, Iowa State University.

Feigenbaum, Mitchell J. Professor, Department of Physics, Cornell University.

Fein, Dr. Jay S. Division of Atmospheric Sciences, National Science Foundation, Washington, D.C.

Feist, Dr. Blake E. Northwest Fisheries Science Center, Environmental Conservation Division–Watershed Program, Seattle, Washington.

Feldberg, Dr. Steven W. Department of Applied Science, Brookhaven National Laboratory, Upton, New York.

Feldman, Dr. Barry J. Los Alamos Scientific Laboratory, Los Alamos, New Mexico.

Feldman, Leonard. Electronics Laboratories, Great Neck, New York.

Feldman, Dr. Leonard C. AT&T Bell Laboratories, Murray Hill, New Jersey.

Feldmann, Dr. Rodney M. Department of Geology, Kent State University, Kent, Ohio.

Fell, Prof. Howard B. Museum of Comparative Zoology, Harvard University.

Fell, Dr. Jack W. University of Miami, Rosenstiel School of Marine and Atmospheric Science, Marine Biology and Fisheries, Key Biscayne, Florida.

Feller, Prof. William. Deceased; formerly, Department of Mathematics, Princeton University.

Felver, Prof. Richard I. Designer, Carnegie Institute of Technology.

Fendler, Dr. Janos H. Department of Chemistry, Center for Research in Membranes and Colloid Science, Syracuse University.

Ferguson, Prof. J. Homer. Department of Biological Science, University of Idaho.

Ferguson, Dr. Louise. Extension Pomologist, Kearney Agricultural Center, University of California, Parlier.

Fernando, Dr. Quintus. Department of Chemistry, University of Arizona.

Ferrell, Dr. James E., Jr. Department of Molecular Pharmacology, Stanford University, School of Medicine.

Ferrell, Prof. Thomas L. Health and Safety Research Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Ferris, Prof. Gordon F. Deceased; formerly, National History Museum, Stanford University.

Ferry, Dr. James F. Department of Biology, Madison College.

Feshbach, Dr. Herman. Department of Physics, Massachusetts Institute of Technology.

Fetz, Dr. Eberhard E. Department of Physiology and Biophysics, University of Washington School of Medicine.

Few, Prof. Arthur. Department of Space Physics and Astronomy, Rice University.

Fiala, Dr. Alan D. U.S. Naval Observatory, Washington, D.C.

Fidecaro, Dr. Giuseppe. EP Division, CERN, Geneva, Switzerland.

Fiedler, Dr. Peggy L. Piedmont, California.

Fields, Paul R. Senior Chemist, Argonne National Laboratory, Argonne, Illinois.

Fields, Thomas H. Physics Division, Argonne National Laboratory, Argonne, Illinois.

Fincham, Prof. J. R. S. Department of Genetics, University of Leeds, England.

Findlay, Dr. David M. Department of Orthopedics and Trauma, University of Adelaide, Royal Adelaide Hospital, Adelaide, Australia.

Finegold, Dr. Sydney M. Chief, Infectious Disease Section, Veterans Administration Wadsworth Hospital Center, Los Angeles, California.

Fingerman, Dr. Milton. Department of Biology, Tulane University.

Fink, Donald G. Director Emeritus, IEEE; Editor in Chief, "Electronics Engineers' Handbook," McGraw-Hill Book Company, New York.

Fink, Prof. Jordan N. Chief, Allergy-Immunology Section, Department of Medicine, Medical College of Wisconsin.

Finkelstein, Prof. L. Department of Physics, The City University, London, England.

Finkelstein, Dr. Richard. Department of Microbiology, University of Missouri School of Medicine, Columbia.

Finks, Dr. Robert M. Department of Geology, Queens College, City University of New York.

Finotello, Dr. Daniele. Liquid Crystal Institute, Kent State University, Kent, Ohio.

Firebaugh, Millard S. Naval Sea Systems Command, Washington, D.C.

Firk, Prof. Frank W. K. Electron Accelerator Laboratory, Yale University.

Firor, Dr. John W. Director, Advanced Study Program, National Center for Atmospheric Research, Boulder, Colorado.

Fischer, Prof. Alfred G. San Pedro, California.

Fischer, Harold. General Motors Corporation, Flint, Michigan.

Fischer, Henry W. Hardesty & Hanover, New York.

Fischer, Prof. J. E. Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia.

Fisher, Dr. Jack B. Fairchild Tropical Garden and Research Center, Miami, Florida.

Fisher, Dr. Robert A. Los Alamos Scientific Laboratory, Los Alamos, New Mexico.

Fisher, Dr. Robert L. Geological Research Division, Scripps Institution of Oceanography, La Jolla, California.

Fisher, Prof. Russell A. Department of Physics, Northwestern University.

Fisher, Dr. William L. Department of Geological Science, University of Texas, Austin.

Fisk, Prof. Nelson S. Department of Civil Engineering, Columbia University.

Fiske, Capt. Richard P. Retired; formerly, Director of Ocean Engineering/Supervisor of Salvage and Diving, U.S. Navy.

Fitch, Prof. Val. Department of Physics, Princeton University.

Fitzsimons, James T. Physiological Laboratory, University of Cambridge, United Kingdom.

Flathers, George W., II. MITRE Corporation, McLean, Virginia.

Fleischer, Dr. R. L. Physical Science Branch, General Physics Laboratory, General Electric Company, Schenectady, New York.

Fleminger, Dr. Abraham. Research Biologist, Scripps Institution of Oceanography, La Jolla, California.

Flessa, Dr. Karl Walter. Division of Earth Sciences, National Science Foundation, Washington, D.C.

Flint, Dr. Richard F. Department of Geology and Geophysics, Yale University.

Flint, Robert B. VORTAC Consultant, Havana, Illinois.

Floe, Prof. Carl f. Department of Metallurgy, Massachusetts Institute of Technology.

Flye, Prof. M. Wayne. Surgery, Microbiology and Immunology, Washington University School of Medicine, St. Louis, Missouri.

Flynn, Dr. Thomas M. Consultant, Cryogenic Engineering, Boulder, Colorado.

Focht, Prof. Dennis D. Department of Soil and Environmental Sciences, University of California, Riverside.

Fogel, Dr. David B. Natural Selection, Inc., La Jolla, California.

Foon, Dr. Kenneth A. Roswell Park Memorial Institute, Buffalo, New York.

Ford, Prof. Derek C. Department of Geography, McMaster University, Hamilton, Ontario, Canada.

Ford, Prof. E. B. Deceased; formerly, Genetics Laboratory, Department of Zoology, Oxford University, England.

Ford, Dr. Karen Grady. Department of Biology, College of Charleston, South Carolina.

Forey, Dr. Peter. Department of Paleontology, Natural History Museum, London, England.

Forster, Dr. Denis. Monsanto Company, St. Louis, Missouri.

Foster, Prof. Jackson W. Deceased; formerly, Professor of Microbiology, University of Texas.

Foster, Dr. Mark G. Retired; Department of Electrical Engineering, School of Engineering and Applied Science, University of Virginia.

Foster, Prof. Merrill W. Department of Geology, Bradley University.

Foster, Dr. Robert J. Department of Physics, San Jose State University.

Fountain, Dr. David M. Department of Geology and Geophysics, University of Wyoming.

Fourtner, Dr. Charles R. Department of Biological Science, State University of New York, Buffalo.

Fowler, Prof. W. Beall. Department of Physics, Lehigh University.

Fox, Dr. Christopher. Department of Computer Science, James Madison University, Harrisonburg, Virginia.

Fox, Dr. Marye Anne. Department of Chemistry, University of Texas, Austin.

Fox, Dr. Richard. Department of Biological Sciences, University of Alberta, Edmonton, Canada.

Fox, Dr. Robert M. Department of Electrical Engineering, College of Engineering, University of Florida.

Fradkin, Dr. David M. Department of Physics, Wayne State University.

Frailey, Dr. Dennis J. Texas Instruments, Inc., Austin, Texas.

Frakes, Dr. William B. Virginia Tech, Northern Virginia Center, Falls Church.

Frame, Prof. J. Sutherland. Professor Emeritus of Mathematics, Michigan State University.

Franc, Dr. Jean-Marie. Laboratoire d'Histologie et Biologie Tissulaire, Universite Claude Bernard, Villeurbanne, France.

France, Dr. Diane L. Fort Collins, Colorado.

Francis, Dr. Arthur W. Union Carbide Corporation, Tarrytown, New York.

Frank, Prof. Bernard. Deceased; formerly, Professor of Watershed Management, Colorado State University.

Franklin, David. Program Manager, Nuclear Systems and Materials, Electric Power Research Institute, Palo Alto, California.

Franzese, Dr. Kenneth. Research and Development, Bright Star Industries, Inc., Clifton, New Jersey.

Franzini, Dr. Paolo. Dipartimento di Fisica, Universita di Roma I, Italy.

Freeman, Dr. A. E. Department of Animal Science, Iowa State University.

Freedman, Dr. Daniel X. Department of Psychiatry and Behavioral Sciences, University of California School of Medicine.

Freeman, Harry M. Chief, Waste Minimization Branch, Risk Reduction Engineering Laboratory, U.S. Environmental Protection Agency, Cincinnati, Ohio.

Freeman, Prof. Jeremiah P. Department of Chemistry, University of Notre Dame.

Freeman, Prof. Ralph L. Retired; Department of Mechanical Engineering, Iowa State College.

Freedman, Dr. Wendy L. Observatories of the Carnegie Institution of Washington, Pasadena, California.

Freire, Prof. Ernesto. Director, Biocalorimetry Center, Johns Hopkins University, Baltimore, Maryland.

Freiser, Prof. Henry. Department of Chemistry, University of Arizona, Tucson.

Fremed, Raymond F. Burson-Marsteller Associates, New York.

French, Dr. J. Bruce. Department of Physics, University of Rochester.

Fretter, Prof. William B. Department of Physics, University of California, Berkeley.

Freudenstein, Dr. Ferdinand. Department of Mechanical Engineering, Columbia University.

Freundt, Dr. E. A. Institute for Medical Microbiology, Aarhus University, Denmark.

Frey, Dr. Kenneth J. Department of Agronomy, Iowa State University.

Fribourg, Prof. Henry A. Department of Plant and Soil Science, University of Tennessee, Knoxville.

Frick, Dr. Oscar L. Department of Pediatrics, University of California Medical Center.

Fridovich, Dr. Irwin. Department of Biochemistry, Duke University Medical Center.

Fried, Dr. George H. Brooklyn College, City University of New York.

Fried, Dr. Sherman. Chemistry Division, Argonne National Laboratory, Argonne, Illinois.

Fried, Walter R. Deceased; formerly, Navigation Systems Consultant, Hughes Aircraft Company, Santa Ana, California.

Friedlander, Prof. Sheldon K. Department of Chemical Engineering, University of California, Los Angeles.

Friedman, Prof. Harold L. Department of Chemistry, State University of New York, Stony Brook.

Friedman, Lewis. Brookhaven National Laboratory, Upton, New York.

Friedman, Norman. U.S. Naval Institute, Annapolis, Maryland.

Frisancho, Dr. A. Roberto. Center for Human Growth and Development, University of Michigan, Ann Arbor.

Fritsch, J. Michael. Associate Professor, Department of Meteorology, College of Earth and Mineral Sciences, Pennsylvania State University.

Froes, Dr. F. H. Sam. Director, Institute for Materials and Advanced Processes, University of Idaho.

Fromkin, Dr. Victoria A. Dean, Vice Chancellor, Graduate Programs, Department of Linguistics, University of California, Los Angeles.

Frondel, Prof. Clifford. Retired; Department of Geological Sciences, Harvard University.

Frost, Dr. Thomas M. Center for Limnology, University of Wisconsin.

Fruchter, Dr. Benjamin. Department of Educational Psychology, University of Texas, Austin.

Frumhoff, Dr. Peter. Department of Entomology, University of California, Davis.

Fry, Prof. Albert J. Department of Chemistry, Wesleyan University, Middletown, Connecticut.

Fry, Prof. Edward S. Department of Physics, Texas A&M University.

Frye, Gene. Retired; formerly, Technical Staff, Collins Division, Rockwell International, Cedar Rapids, Iowa.

Fryer, Dr. Geoffrey. Freshwater Biological Association, Cumbria, United Kingdom.

Fröhlich, Dr. Claus. Physikalisch-Meteorologisches Observatorium Davos, World Radiation Center, Davos Dorf, Switzerland.

Fuchs, Prof. Ronald. Department of Physics, Iowa State University.

Fudenberg, Dr. H. Hugh. Section of Hematology and Immunology, San Francisco Medical Center, University of California.

Fulford, Prof. George D. Department of Chemical Engineering, University of Waterloo, Ontario, Canada.

Fulks, J. R. Retired; formerly, National Weather Service, Chicago, Illinois.

Fuller, Prof. Dudley D. (Retired) Department of Mechanical Engineering, Columbia University.
Fuller, Dr. Mark Roy. Patuxent Wildlife Reserve Center, Laurel, Maryland.
Fuller, Dr. Thomas C. Retired; formerly, Supervisor, Botany and Seed Laboratories, California Department of Food and Agriculture, Sacramento.
Fulton, Dr. James W. Monsanto Company, St. Louis, Missouri.
Fung, Prof. Y. C. Department of Applied Mechanics, University of California, San Diego.
Furter, Dr. W. F. Dean of Graduate Studies and Research, Royal Military College of Canada.
Fusco, Roberto. Instituto Guido Donegani, EniChem, Polymeric Materials Department, Novara, Italy.
Futral, Prof. J. G. Department of Agricultural Engineering, Georgia Agricultural Experiment Station, Experiment, Georgia.
Futuyma, Dr. Douglas J. Section of Ecology and Systematics, Cornell University.

G

Gaasch, Dr. William H. Director of Cardiovascular Research, Section of Cardiovascular Diseases, Labey Clinic, Burlington, Massachusetts.
Gagliardo, Reginald S. Vice President, Engineering, Burns & Roe Enterprises, Inc., Oradell, New Jersey.
Gagne, Dr. Raymond J. Systematic Entomology Laboratory, U.S. Department of Agriculture.
Gaines, Dr. Alan M. National Science Foundation.
Gaines, Dr. George L. Research and Development Center, General Electric Company, Schenectady, New York.
Galambos, Prof. Theodore V. Emeritus Professor, Department of Civil Engineering, University of Minnesota, Minneapolis.
Gale, Dr. Douglas S. National Science Foundation, Washington, D.C.
Gale, Peter A. Chief Naval Architect, John J. McMullen Associates, Inc., Arlington, Virginia.
Gallant, Dr. Donald M. Department of Psychiatry and Neurology, Tulane University School of Medicine.
Galli, Prof. Stephen J. Department of Pathology, Beth Israel Hospital, Boston, Massachusetts.
Galston, Dr. Arthur W. Department of Biology, Yale University.
Gamble, Dr. Joe D. National Aeronautics and Space Administration, Lyndon B. Johnson Space Center, Houston, Texas.
Gamble, Dr. John. Department of Geology, Victoria University, Wellington, New Zealand.
Gambs, Gerard C. Vice President (retired), Ford, Bacon, & Davis, Inc., New York.
Garbassi, Fabio. Instituto Guido Donegani, EniChem, Polymeric Materials Department, Novara, Italy.
Garcia, Dr. John. Department of Psychology, University of California, Los Angeles.
Gardiner, Dr. Brian. Linnean Society of London, Burlington House, Piccadilly, London, United Kingdom.
Gardiner, Dr. Kathleen. Eleanor Roosevelt Institute for Cancer Research, Denver, Colorado.
Gardner, Prof. Chester S. Department of Electrical Engineering and Computer Science, University of Illinois, Urbana.
Gardner, Dr. Frank E. Horticulturist, Agricultural Research Service, U.S. Department of Agriculture, Orlando, Florida.
Gardner, Dr. Julian W. Director of Nanotechnology Centre, Department of Engineering, University of Warwick, Coventry, United Kingdom.
Gardner, Dr. Walter H. Department of Agronomy and Soils, Washington State University.
Garetz, Dr. Bruce A. Department of Chemistry, Polytechnic University, New York.
Garfield, Dr. Sol L. Department of Psychology, Washington University.
Garland, Dr. John. Professor, Department of Forest Engineering, Oregon State University, Corvallis.
Garrett, Prof. Alfred B. Department of Chemistry, Ohio State University.
Garrett, Dr. Roger E. Department of Agricultural Engineering, University of California, Davis.
Gasaway, Donald C. E.A.R. Division, Cabot Corporation, San Antonio, Texas.
Gass, Dr. Saul I. Potomac, Maryland.
Gastaldo, Dr. Robert A. Department of Geology, Auburn University, Auburn, Alabama.
Gastony, Prof. Gerald J. Department of Plant Sciences, Indiana University.
Gatchell, Charles J. U.S. Department of Agriculture Forest Service, Forestry Sciences Laboratory, Princeton, West Virginia.
Gaudin, Dr. Tim. Department of Biological and Environmental Science, University of Tennessee, Chattanooga.
Gauss, Dr. D. Max-Planck Institut für Experimentelle Medizin, Gottingen, Germany.
Gauss, F. Stephen. Director, Astrometry Department, U.S. Naval Observatory, Washington, D.C.
Gaylord, Prof. Charles N. Deceased; formerly, Chairman, Department of Civil Engineering, University of Virginia.
Gazzaniga, Dr. Michael S. Professor of Psychology and Social Sciences in Medicine, State University of New York, Stony Brook.
Geiger, Prof. Randall L. Department of Electrical Engineering, Texas A&M University.
Geist, Jon. Radiometric Physics Division, National Institute of Standards and Technology, Washington, D.C.
Gelfand, Prof. Erwin W. Chief, Division of Immunology and Rheumatology, Hospital for Sick Children, Toronto, Ontario, Canada.
Gemmell, Dr. Donald S. Physics Division, Argonne National Laboratory, Argonne, Illinois.
Genito, Dennis. Pasture Systems and Watershed Management Research Laboratory, U.S. Department of Agriculture–Agricultural Research Service, University Park, Pennsylvania.
Gensler, Prof. Walter J. Deceased; formerly, Department of Chemistry, Boston University.
George, Dr. Kathleen F. Union Carbide Chemicals and Plastics Company, Inc., South Charleston, West Virginia.
George, Dr. Melvin R. Agronomy and Range Science Extension, University of California, Davis.
Georgorapadakou, Dr. Nafsika H. Department of Infectious Diseases, DuPont Research Laboratories, Wilimington, Delaware.
Gepts, Dr. Paul. Department of Agronomy and Range Science, University of California, Davis.
Gerber, Leah R. National Center for Ecological Analysis and Synthesis, Santa Barbara, California.
Gergely, Dr. John. Department of Muscle Research, Boston Biomedical Research Institute, Boston, Massachusetts.
Gerjuoy, Dr. Edward. Department of Physics, University of Pittsburgh.
Gerlach, Dr. Arch C. Chief Geographer, Geological Survey, U.S. Department of the Interior.
Gerrity, Dr. Joseph P. National Meteorological Center, National Oceanic and Atmospheric Administration, Camp Springs, Maryland.
Gersh, Prof. Isidore. Research Professor, Department of Animal Biology, School of Veterinary Medicine, University of Pennsylvania.
Gershoff, Prof. Stanley N. Department of Nutrition, Harvard School of Public Health, Boston, Massachusetts.
Gertler, Dr. Janos. Department of Electrical and Computer Engineering, George Mason University, Fairfax, Virginia.
Gertsch, Dr. Willis J. American Museum of Natural History, New York.
Gerwartowski, James W. Bell Telephone Laboratories, Murray Hill, New Jersey.
Getman, Dr. Thomas D. Department of Chemistry, Northern Michigan University.
Ghiorso, Dr. Albert. Department of Chemistry, Lawrence Berkeley Laboratory, University of California, Berkeley.

Giallorenzi, Dr. Thomas G. Superintendent, Optical Science Division, Department of the Navy, Naval Research Laboratory, Washington, D.C.

Giannasi, Dr. David E. Department of Botany, University of Georgia.

Gibbons, Dr. Ian. Kewala Laboratory, University of Hawaii.

Gibbs, Dr. Martin. Institute for Photobiology of Cells and Organelles, Brandeis University.

Giblon, Robert P. President, George G. Sharp, Inc., New York.

Gibson, Dr. John E. Dean of Engineering, Oakland University.

Giese, Raymond. Department of Mechanical Engineering, University of Minnesota.

Gigg, Roy H. Chemistry Division, National Institute for Medical Research, London, England.

Giguere, Paul A. Emeritus Professor, St. Petersburg Beach, Florida.

Gilardi, Dr. Gerald L. Microbiology Laboratory, North General Hospital, New York.

Gilbert, Barrie. Analog Devices, Inc., Northwest Laboratories, Beaverton, Oregon.

Gilbert, Dr. Edgar N. Deceased; formerly, AT&T Bell Telephone Laboratories, Murray Hill, New Jersey.

Gill, Dr. D. Michael. Department of Molecular Biology and Microbiology, Tufts University.

Gillespie, Dr. Ronald J. Department of Chemistry, McMaster University, Hamilton, Ontario, Canada.

Gilloteaux, Dr. Jacques. Professor of Cell Biology and Anatomy, Lake Erie College of Osteopathic Medicine, Erie, Pennsylvania.

Gingrich, Prof. Newell S. Department of Physics, University of Missouri.

Ginsburg, Dr. Robert N. Rosenstiel School of Marine and Atmospheric Science, University of Miami.

Girvin, Prof. Steven M. Department of Physics, Indiana University, Bloomington.

Glantz, Dr. Michael. National Center for Atmospheric Research, Boulder, Colorado.

Glasford, Prof. Glenn M. Department of Electrical and Computer Engineering, Syracuse University.

Glass, Dr. Roger I. Chief, Viral Gastroenteritis Unit, Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia.

Glasscock, Dwight L. Deceased; formerly, Harza Engineering Company, Chicago, Illinois.

Gledhill, Dr. S. J. Harpenden Herts, United Kingdom.

Glick, Dr. Benjamin. University of Chicago, Cummings Life Science Center, Chicago, Illinois.

Glowatz, Dr. Michael, Jr. Environmental Health and Safety Department, AT&T Bell Laboratories, Murray Hill, New Jersey.

Gnade, Dr. Bruce E. Defense Advanced Research Projects Agency, Arlington, Virginia.

Goddu, Dr. Robert F. Manager, Fibers and Film Research Division, Hercules, Inc., Wilmington, Delaware.

Goebel, Prof. Charles. Department of Physics, University of Wisconsin.

Goff, Dr. Fraser. Los Alamos National Laboratories, Los Alamos, New Mexico.

Gokel, Prof. George W. Department of Molecular Biology & Pharmacology, Washington University School of Medicine, St. Louis, Missouri.

Goland, Dr. Leonard. Executive Vice President, Dynasciences Corporation, Los Angeles, California.

Gold, Dr. Ronald. Hospital for Sick Children, Toronto, Ontario, Canada.

Goldberg, Prof. David E. Department of General Engineering, University of Illinois, Urbana.

Goldberg, Dr. Ira J. Department of Medicine, Columbia College of Physicians and Surgeons, Division of Metabolism and Nutrition, New York.

Goldenberg, Dr. Victor E. Associate Professor in Pathology, University Hospital, Seattle.

Goldfarb, Dr. Marjorie S. School of Oceanography, University of Washington, Seattle.

Goldhaber, Dr. Gerson. Lawrence Berkeley Laboratory, University of California, Berkeley.

Goldich, Dr. Samuel S. Department of Geology, Colorado School of Mines, Golden.

Goldman, Dr. Marvin. Emeritus Professor, Department of Radiological Sciences, University of California, Davis.

Goldstein, Dr. D. J. Department of Biomedical Science, University of Sheffield, England.

Goldstein, Dr. Irving S. Department of Wood and Paper Science, North Carolina State University, Raleigh.

Golley, Dr. Frank B. Institute of Ecology, Athens, Georgia.

Golub, Dr. Leon. Harvard Smithsonian Center for Astrophysics, Smithsonian Astrophysical Observatory, Cambridge, Massachusetts.

Gomer, Prof. Robert. James Franck Institute, University of Chicago.

Gonser, Dr. Bruce W. Battelle Memorial Institute, Columbus, Ohio.

Good, Dr. Irving J. Department of Statistics and Statistical Laboratory, College of Arts and Sciences, Virginia Polytechnic Institute.

Good, Prof. Roland H., Jr. Department of Physics, Pennsylvania State University.

Goodbody, Dr. Ivan. Department of Zoology, University of the West Indies, Jamaica.

Goodchild, Dr. Chauncey G. Candler Professor of Biology, Emory University.

Goodenough, Prof. John B. Center for Materials Science and Engineering, University of Texas, Austin.

Goodglass, Dr. Harold. Director, Psychology Research, Veterans Administration Hospital, Boston, Massachusetts.

Goodheart, Prof. Clarence F. Department of Electrical Engineering, Union College.

Gooding, Dr. James L. Space Scientist, Planetary Materials Branch, NASA Lyndon B. Johnson Space Center, Houston, Texas.

Goodison, Dr. Barry E. Superintendent, Hydrometeorological Impact and Development Section, Canadian Climate Centre, Atmospheric Environment Service, Downsview, Ontario.

Goodman, Prof. Bernard. Department of Physics, University of Cincinnati.

Goodman, Dr. Joseph W. Stanford Electronics Laboratories, Stanford University.

Goodman, Dr. Matthew S. Bell Communications Research, Inc., Morristown, New Jersey.

Goodman, Dr. Morris. Department of Anatomy, Wayne State University College of Medicine, Detroit, Michigan.

Goodman, Dr. Ralph R. Naval Research Laboratory, Stennis Space Center, Mississippi.

Goodman, Dr. Richard A. Division of Public Health, Emory University.

Goodman, Sidney H. Manager, Materials Products Department, Technology Support Division, Hughes Aircraft Co., Culver City, California; Senior Lecturer, Department of Chemical Engineering, University of Southern California.

Goodman, Dr. Steven R. Chair, Department of Cell Biology and Neuroscience, University of South Alabama College of Medicine, Mobile, Alabama.

Goodstein, David H. Director, Inter/Consult, Cambridge, Massachusetts.

Goosby, Dr. Eric P. AIDS Education and Training Centers Program, U.S. Public Health Service, Rockville, Maryland.

Gordon, Dr. Arnold L. Lamont-Doherty Geological Observatory, Palisades, New York.

Gordon, Dr. Gary D. Program Development, Communication Satellite Corporation, Clarksburg, Maryland.

Gordon, Prof. Louis. Deceased; formerly, Case Institute of Technology.

Gordon, Dr. William E. Associate Professor of Physical Chemistry, Pennsylvania State University, and Consultant.

Gore, Edward W., Jr. Vice President, International Market Requirements, Office Products Division, IBM, Franklin Lakes, New Jersey.

Gosling, Dr. William. Consultant, Radio Communications, Rode, Bath, England.

Gossard, Prof. Arthur C. Materials Department, University of California, Santa Barbara.

Gotelli, Dr. Nick. Department of Biology, University of Vermont, Burlington.

Gots, Dr. Joseph S. Department of Microbiology, School of Medicine, University of Pennsylvania.

Gould, Dr. Richard A. Department of Anthropology, University of Hawaii.
Gould, Dr. Stephen J. Professor of Geology, Museum of Comparative Zoology, Harvard University.
Goulding, Dr. Frederick S. Lawrence Berkeley Laboratory, University of California.
Govindjee, Dr. Department of Botany and Department of Physiology and Biophysics, University of Illinois, Urbana.
Govindjee, Dr. Rajni. Retired; formerly, Department of Botany, University of Illinois, Urbana.
Grabowski, Dr. Martha R. Center for Industrial Innovation, Department of Decision Sciences and Engineering Systems, Rensselaer Polytechnic Institute, Troy, New York.
Grace, Dr. Neville. Biotechnology Division, Department of Scientific and Industrial Research, Palmerston North, New Zealand.
Graham, Dr. Jeffrey B. Scripps Institution of Oceanography, La Jolla, California.
Grande, Dr. Lance. Field Museum of Natural History, Chicago, Illinois.
Granicher, Prof. H. Laboratory of Solid State Physics, Swiss Federal Institute of Technology, Zurich.
Granick, Dr. S. Department of Biochemistry, Rockefeller University.
Grasshoff, Dr. K. Institut für Meereskunde an der Universitat Kiel, Germany.
Grau, Dr. Fred V. Consulting Agronomist, College Park, Maryland.
Graves, Dr. Arthur H. Deceased; formerly, Consultant in Genetics, Connecticut Agricultural Experiment Station.
Graves, Prof. Lawrence M. Professor Emeritus of Mathematics, University of Chicago.
Graves, Walter L. San Diego, California.
Gray, Dr. Ernest. Variety Club Children's Hospital, Department of Pediatrics, University of Minnesota.
Gray, G. Ronald. Director, Syncrude Canada Ltd., Edmonton, Alberta, Canada.
Gray, Dr. Gerald J. Vice President, Forest Policy Center, American Forests, Washington, D.C.
Gray, Dr. Harry B. Division of Chemistry and Chemical Engineering, California Institute of Technology.
Green, Dr. David M. Graduate Research, Department of Psychology, University of Florida.
Green, Dr. Louis C. Department of Astronomy, Haverford College.
Green, Dr. Richard F. National Optical Astronomy Observatory, Tuscon, Arizona.
Green, Prof. Sheldon I. Department of Mechanical Engineering, University of British Columbia, Vancouver, Canada.
Greenberg, Prof. David M. Department of Biochemistry, School of Medicine, University of California, San Francisco.
Greenberger, Prof. Daniel M. Department of Physics, City College of the City University of New York.
Greenfield, Dr. Lazar J. Department of Surgery, University of Michigan Hospitals, Ann Arbor.
Greenler, Dr. Robert. Department of Physics, University of Wisconsin.
Greensfelder, Dr. Bernard S. Deceased; formerly, Director of Oil Research, Shell Development Company, Emeryville, California.
Greenspan, Prof. Ehud. Department of Nuclear Engineering, University of California, Berkeley.
Greenspan, Martin. National Bureau of Standards.
Greenstein, Prof. Jesse L. Hale Observatories, Pasadena, California.
Gregory, Dr. Bob Lee. Sandia National Laboratories, Albuquerque, New Mexico.
Gregory, Dr. Joseph T. Professor of Paleontology and Curator of Lower Vertebrates, Museum of Paleontology, University of California, Berkeley.
Greiling, Dr. Paul T. Hughes Research Laboratories, Malibu, California.
Greiner, Dr. Dale L. Professor of Medicine, University of Massachusetts Medical School, Worcester.
Greiner, Dr. Walter. Institut für Theoretische Physik, Universitat Frankfurt, Germany.
Grest, Dr. Gary S. Exxon Research and Engineering Company, Annandale, New Jersey.
Grey, Jerry. President, Greyrad Corporation, Princeton, New Jersey.
Grierson, Dr. William. Institute of Food and Agricultural Sciences, University of Florida.
Griffen, Prof. Dana T. Department of Geology, Brigham Young University, Provo, Utah.
Griffin, Dr. James. Graduate School of Oceanography, University of Rhode Island, Charleston.
Griffiths, Dr. A. J. F. Department of Botany, University of British Columbia, Vancouver, Canada.
Griffiths, Prof. Peter R. Chairman, College of Letters and Science, Department of Chemistry, University of Idaho.
Grigg, Prof. Neil S. Head, Department of Civil Engineering, Colorado State University, Fort Collins.
Grilo, Dr. Carlos M. Director of Psychology, Yale Psychiatric Institute, New Haven, Connecticut.
Grim, Dr. Ralph E. Department of Geology, University of Illinois, Urbana.
Grimm, Robert A. AC Spark Plug Division, General Motors Corporation, Flint, Michigan.
Grindlay, Dr. Jonathan E. Center for Astrophysics, Harvard University.
Grine, Dr. Frederick E. Department of Anthropology, State University of New York, Stony Brook.
Grissino-Mayer, Dr. Henri D. Department of Physics, Astronomy, and Geosciences, Valdosta State University, Valdosta, Georgia.
Grivell, Dr. Les. A. Afdeling Moleculaire Biologie, Laboratorium voor Biochemie, Universiteit van Amsterdam, Netherlands.
Grodzins, Dr. Lee. Physics Department, Massachusetts Institute of Technology.
Grogan, Dr. R. G. Department of Plant Pathology, University of California, Davis.
Groggins, P. H. Deceased; formerly, Chemical Division, Food Machinery and Chemical Corporation.
Gronstol, Prof. Hallstein. Department of Large Animal Clinical Sciences, Norwegian College of Veterinary Medicine, Oslo, Norway.
Groody, Dr. E. Patrick. Integrated Genetics, Framingham, Massachusetts.
Grosch, Prof. Daniel S. Department of Genetics, North Carolina State University.
Gross, Prof. Jonathan L. Department of Mathematics, Columbia University.
Gross, Marjorie K. Newport, North Carolina.
Gross, William H. Technical Editor, Corporate Communications, Dow Chemical Company, Midland, Michigan.
Grossman, Dr. Lawrence. Department of Geophysical Sciences, University of Chicago.
Grosswald, Prof. Emit. Deceased; formerly, Department of Mathematics, Temple University.
Grotzinger, Dr. John. Department of Earth, Atmosphere, and Space Sciences, Massachusetts Institute of Technology.
Groves, Dr. Gordon W. Institute de Geofisica, Torre de Ciencias, Ciudad Universitaria, Mexico.
Gruen, Dr. Dieter M. Argonne National Laboratory, Argonne, Illinois.
Grunberg, Dr. Emanuel. Director, Department of Chemotherapy, Hoffmann-LaRoche, Inc., Nutley, New Jersey.
Gruver, Prof. William A. School of Engineering Science, Simon Fraser University, Burnaby, British Columbia, Canada.
Grzymala-Busse, Prof. Jerzy W. Department of Computer Science, University of Kansas.
Gschneidner, Prof. Karl A., Jr. Ames Laboratory, Iowa State University.
Guggenheim, Prof. Stephen. Department of Geological Sciences, University of Illinois, Chicago.
Guido, Prof. Louis. Associate Professor, Electrical and Computer Engineering, Virginia Tech, Blacksburg.
Guidry, Dr. Mark R. Fairchild Camera & Instrument Corp., Mountain View, California.
Gunckel, Prof. James E. Department of Botany, Rutgers University.
Gunkler, Dr. Albert A. Chief Process Engineer, Midland Division, Dow Chemical Company, Midland, Michigan.
Gunning, Dr. Brian E. S. Department of Botany, Queen's University, Belfast, Ireland.

Gunning, Dr. Robert C. Department of Mathematics, Princeton University.

Gupta, Dr. Madan M. Intelligent System Research Laboratory, College of Engineering, University of Saskatchewan, Saskatoon.

Gupta, Dr. Y. M. Department of Physics, Shock Dynamics Laboratory, Washington State University.

Gurevich, Michael. Masonary Consultants, Fair Lawn, New Jersey.

Gurney, Dr. Ashley B. Systematic Entomology Laboratory, Entomology Research Division, U.S. Department of Agriculture.

Gustafson, Dr. David A. Department of Computing and Information Science, Kansas State University, Manhattan.

Gutzwiller, Dr. Martin C. T. J. Watson Research Center, IBM Corporation, Yorktown Heights, New York.

Guy, Dr. Arthur W. Bioelectromagnetism Research Laboratory, School for Medicine and College of Engineering, University of Washington, Seattle.

Guzinski, Dr. Gay M. Chief, Section of Benign Gynecology, Department of Obstetrics and Gynecology, School of Medicine, University of Maryland, Baltimore.

Gyakum, Dr. John R. Department of Meteorology, McGill University, Montreal, Quebec, Canada.

Gyftopoulos, Dr. Elias P. Thermo Electron Corporation, Waltham, Massachusetts.

Gönen, Prof. Turan. Department of Electrical & Electronic Engineering, California State University, Sacramento.

Gür, Dr. Turgut M. Senior Research Associate, Department of Materials Science and Engineering, Stanford University.

H

Haber, Bernard. Hardesty & Hanover, New York.

Hackl, Ralph R. Manager, R&D Laboratory, Giant Bay Biotech, Burnaby, British Columbia, Canada.

Hader, Rodney N. Secretary, American Chemical Society, Washington, D.C.

Hadler, Jacques B. Webb Institute of Naval Architecture, Glen Cove, New York.

Hadley, Dr. Elbert H. Assistant Dean (retired), College of Liberal Arts and Sciences, and Professor of Chemistry, Southern Illinois University.

Hadni, A. Laboratoire Infrarouge Lointain, Université de Nancy I, France.

Hagan, Dr. Maura. National Center for Atmospheric Research, Boulder, Colorado.

Hagan, Dr. William J., Jr. Department of Chemistry, College of St. Rose, Albany, New York.

Hagar, Prof. Charles F. Department of Physics and Astronomy, San Francisco State University.

Hagen, Dr. John P. Department of Astronomy, Pennsylvania State University.

Haggerty, Dr. Stephen E. Department of Geology and Geography, University of Massachusetts.

Hagist, Prof. Warren M. Retired; formerly, Department of Mechanical Engineering, University of Rhode Island.

Hagood, Mel A. Irrigated Agriculture Research and Extension Center, Washington State University.

Hague, Wilbur. Oxy Metal Industries Corporation, Warren, Michigan.

Hahn, Dr. John F. Department of Psychology, University of Virginia.

Haile, Dr. William. Swales Aerospace, Inc., Beltsville, Maryland.

Hailpern, Dr. Brent T. IBM Research Laboratory, Yorktown Heights, New York.

Haines, John E. Deceased; formerly, Vice President, Minneapolis-Honeywell Regulator Company.

Haines, Prof. Malcolm G. Blackett Laboratory, Imperial College of Science and Technology, London, England.

Haines, Roger W. Professional Engineer, Laguna Hills, California.

Hainline, Bernard C. Systems Technology, Boeing Commercial Airplane Company, Seattle, Washington.

Halbedel, Dr. Elaine M. Carralitos Observatory, Los Cruces, New Mexico.

Halbouty, Dr. Michael T. Consulting Geologist and Petroleum Engineer, Houston, Texas.

Halde, Dr. Carlyn. Department of Microbiology and Immunology, School of Medicine, University of California, San Francisco.

Hale, Dr. Mason E., Jr. Smithsonian Institution.

Hales, Dr. Milton R. Professor of Pathology, School of Medicine, West Virginia University.

Halkias, Prof. Christos C. Chair of Electronics, National Technical University, Athens, Greece.

Hall, Prof. Dennis G. Director, The Institute of Optics, University of Rochester, New York.

Hall, Dr. Richard P. Deceased; formerly, Professor of Zoology, University of California, Los Angeles.

Hall, Prof. Robert. Director, SE Asia Research Group, Department of Geology, University of London, Egham, Surrey, United Kingdom.

Hallam, Dr. Anthony. Department of Geology, University of Birmingham, England.

Haller, Prof. Gary L. Professor of Engineering and Applied Science, Jonathan Edwards College, Yale University, New Haven, Connecticut.

Hallet, Dr. John. Director, Atmospheric Ice Physics Laboratory, Desert Research Institute, Atmospheric Sciences Center, University of Nevada.

Halliday, Dr. Alex. Department of Geological Sciences, University of Michigan, Ann Arbor.

Halstead, Dr. Thora Waters. American Society of Gravitational and Space Biology, Arlington, Virginia.

Halvorson, Dr. Harlyn O. Department of Biochemistry, University of Minnesota.

Hamad, Dr. Falk. Department of Mechanical and Medical Engineering, University of Bradford, United Kingdom.

Hamer, Dr. Walter J. Institute for Basic Standards, National Bureau of Standards.

Hamilton, Prof. C. Howard. Department of Mechanical and Materials Engineering, Washington State University, Pullman.

Hamilton, Dr. Howard L. (Retired) Department of Biology, University of Virginia.

Hamilton, Dr. John. Gemini Observatory, Hilo, Hawaii.

Hamilton, Dr. Joseph H. Department of Physics-Astronomy, Vanderbilt University.

Hamilton, Dr. Mark F. Department of Mechanical Engineering, University of Texas, Austin.

Hamilton, Dr. R. I. Research Branch, Agriculture Canada, Vancouver, British Columbia, Canada.

Hammar, Dr. Samuel P. The Diagnostic Specialties Laboratory, Washington.

Hammen, Dr. C. S. Department of Zoology, University of Rhode Island.

Hammer, Edward E. Retired; formerly, Fluorescent and High Intensity Systems Department, General Electric Company, Cleveland, Ohio.

Hammond, Prof. Edwin H. Department of Geography. University of Tennessee.

Hand, Dr. Cadet. Bodega Marine Laboratory, University of California, Bodega Bay.

Handsfield, Dr. H. Hunter. Director, Sexually Transmitted Disease Control Program, Seattle-King Country Public Health Department, Harborview Medical Center, Seattle, Washington.

Haney, Dr. Robert L. Department of Meteorology, Naval Postgraduate School, Monterey, California.

Hang, Prof. C. C. Centre for Intelligent Control, Department of Electrical Engineering, National University of Singapore.

Hankley, Prof. William. Department of Computing and Information Science, Kansas State University, Manhattan.

Hanlin, Dr. Richard T. Department of Plant Pathology, University of Georgia, Athens.

Hanna, Dr. Michael. Assistant Professor of Biology, Rensselaer Polytechnic Institute.

Hanna, Dr. Steven R. Sigma Research Corporation, Concord, Massachusetts.

Hanor, Jeffrey S. Department of Geology, Louisiana State University.

Hansch, Dr. Theo W. Department of Physics, Stanford University.

Hansel, Dr. Ardith K. Illinois State Geological Survey, Champaign.

Hansen, Arthur G. President, Georgia Institute of Technology.

Hansen, Dr. John. Department of Neurobiology and Anatomy, University of Rochester Medical Center.

Hansen, Dr. Katherine J. Department of Earth Sciences, Montana State University, Bozeman.

Hanson, Prof. Allen L. Department of Chemistry, Saint Olaf College.

Hanson, Dr. Clarence H. Agricultural Research Service, U.S. Department of Agriculture, Beltsville, Maryland.

Hanson, Dr. Phyllis. Department of Cell Biology and Physiology, Washington University School of Medicine, St. Louis, Missouri.

Happer, Dr. William. Department of Physics, Columbia University.

Haq, Dr. Bilal U. Department of Marine Geology and Geophysics, National Science Foundation, Washington, D.C.

Hardesty, Egbert R. Hardesty & Hanover, New York.

Hardgrove, Ralph M. Sales Engineer, Stock Equipment Company, Cleveland, Ohio.

Hardy, Prof. John. Cyclotron Institute, Texas A & M University, College Station.

Hardy, Dr. John W. Lexington, Massachusetts.

Hare, Dr. Jonathan. School of Chemistry and Molecular Sciences, University of Sussex, United Kingdom.

Hargis, Dr. William J., Jr. Department of Marine Science, University of Virginia.

Harker, Dr. Robert I. Department of Geology, University of Pennsylvania.

Harleman, Dr. Donald R. F. Department of Civil Engineering, Massachusetts Institute of Technology.

Harman, Prof. Jay R. Department of Geography, Michigan State University, East Lansing.

Harper, Dr. Michael J. K. Department of Obstetrics and Gynecology, University of Texas Health Science Center, San Antonio.

Harrigan, Prof. Kevin. TeleLearning Network of Centres of Excellence, Department of Computer Science, University of Waterloo, Ontario, Canada.

Harringon, Roy L. Newport News, Virginia.

Harrington, Clifford. Shaw Pittman, McLean, Virginia.

Harris, Dr. Cyril M. Professor of Electrical Engineering and Architecture, Department of Electrical Engineering, Columbia University.

Harris, Denise B. Senior Mechanical Engineer, Westinghouse Electronic Systems Group, Baltimore, Maryland.

Harris, Dr. Forest K. Electrical Measurements Laboratory, National Institute of Standards and Technology, Gaithersburg, Maryland.

Harris, Dr. J. Postgraduate School of Studies in Chemical Engineering, University of Bradford, England.

Harris, Prof. J. Donald. U.S. Navy Submarine Medical Laboratory, Groton, Connecticut.

Harris, Dr. J. Milton. Department of Chemistry, University of Alabama, Huntsville.

Harris, Lawrence A. Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Harris, Prof. Richard W. Department of Environmental Horticulture, University of California, Davis.

Harrison, David B. Public Relations Department, Goodyear Tire and Rubber, Akron, Ohio.

Harrison, Prof. Edward R. Department of Physics and Astronomy, University of Massachusetts.

Harrison, George R. Deceased; formerly, Dean Emeritus, School of Science, Massachusetts Institute of Technology.

Harrison, Prof. John P. Department of Physics, Queen's University, Ontario, Canada.

Harrison, Dr. Marcia. Department of Biology, Washington University, St. Louis, Missouri.

Harrison, Prof. Terry. Department of Anthropology, New York University, New York.

Harrison, Dr. Walter A. Department of Applied Physics, Stanford University.

Hart, Prof. Gerald W. Chair, Department of Biochemistry and Molecular Genetics, University of Alabama, Birmingham.

Hart, Dr. Harold. Professor Emeritus, Department of Chemistry, Michigan State University.

Hartley, Dr. A. M. Department of Chemistry and Chemical Engineering, University of Illinois, Urbana.

Hartman, Dr. Olga. Deceased; formerly, Allan Hancock Foundation, University of Southern California.

Hartman, Dr. Standish C. Department of Chemistry, Boston University.

Hartman, Dr. Willard D. Associate Professor of Biology and Curator in Invertebrate Zoology, Peabody Museum of Natural History, Yale University.

Hartmann, Dr. Dennis L. Department of Atmospheric Sciences, University of Washington, Seattle.

Hartmann, Prof. Dieter H. Department of Physics and Astronomy, Clemson University, Clemson, South Carolina.

Hartmann, Prof. Hudson T. Pomology Extension, University of California, Davis.

Hartmann, Dr. William M. Michigan State University, Department of Physics, East Lansing.

Hartstein, Dr. Jack. Assistant Professor of Clinical Ophthalmology, Washington University School of Medicine; Chairman of Ophthalmology, Missouri Baptist Hospital, St. Louis.

Hartung, Dr. Walter H. Formerly, Professor of Pharmaceutical Chemistry, Medical College of Virginia.

Hartwig, Dr. William H. Department of Electrical Engineering, University of Texas, Austin.

Harvey, Dr. E. Newton. Deceased, formerly, Henry Fairfield Osborne Professor of Biology, Princeton University.

Harvey, Dr. John A. Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Harvey, Dr. Paul H. Department of Zoology, University of Oxford, United Kingdom.

Harvey, Dr. Philip D. Professor of Psychiatry, Mount Sinai School of Medicine, New York.

Hasey, Dr. Janine K. Cooperative Extension, University of California, Yuba City.

Hasler, Dr. Arthur D. Laboratory of Limnology, University of Wisconsin.

Hassialis, M. D. Krumb School of Mines, Columbia University.

Hassibi, Dr. Babak. Information Systems Laboratory, Stanford University, Stanford, California.

Hassid, Prof. William Z. Deceased; formerly, Department of Biochemistry, University of California, Berkeley.

Hastings, Dr. Alan. Division of Environmental Studies, University of California at Davis.

Hastings, Prof. J. Woodland. Biological Laboratories, Department of Cellular and Development Biology, Harvard University.

Hatsopoulos, Dr. George N. Thermo Electron Corporation, Waltham, Massachusetts.

Haug, John R. Motorola, Schaumburg, Illinois.

Hausner, Henry H. Consulting Engineer, New York.

Haut, Dr. Arthur. Professor of Medicine, Division of Hematology and Oncology, University of Arkansas for Medical Sciences.

Havens, Dr. Donald P. Filter Products, Rockwell International Corporation, Costa Mesa, California.

Hawkins, Dr. W. Lincoln. Bell Laboratories, Murray Hill, New Jersey.

Hawksworth, Dr. Frank G. U.S. Forest Service, Fort Collins, Colorado.

Hawley, Dr. R. Scott. Department of Genetics, Section of Molecular and Cellular Biology, University of California at Davis.

Hawthorne, Dr. Frank C. Department of Geological Sciences, University of Manitoba, Winnipeg, Canada.

Hay, Prof. George W. Department of Chemistry, Queen's University, Ontario, Canada.

Hayes, Dr. Dennis E. Lamont-Doherty Geological Observatory, Columbia University, Palisades, New York.

Hayes, Prof. John P. Department of Electrical Engineering and Computer Science, University of Michigan, Ann Arbor.

Hayes, Dr. Thomas L. Donner Laboratory, University of California, Berkeley.

Hayes, William C. Formerly, Editor in Chief, "Electrical World," McGraw-Hill Publications Company, New York.

Hayes-Roth, Dr. Frederick. Executive Vice President, Technology, Teknowledge Inc., Palo Alto, California.
Hayflick, Prof. Leonard. Center for Gerontological Studies, University of Florida.
Haynes, David O. Deceased; formerly, Consulting Industrial Engineer, Tucson, Arizona.
Hazel, Prof. Jeffrey R. Department of Zoology, Arizona State University.
Hazen, Prof. David C. Department of Aerospace-Mechanical Science, Princeton University.
Hazen, Richard. Hazen and Sawyer, Consulting Engineers, New York.
Hazen, Ronald. Consultant (retired), Indianapolis, Indiana.
Heaney, Dr. Peter J. Department of Geological and Geophysical Sciences, Princeton University.
Hearmon, R. F. S. Formerly, Timber Mechanics Section, Forest Products Research Laboratory, Princes Risborough, Bucks, England.
Hearn, Dr. C. Jack. Research Geneticist, Horticultural Research Laboratory, U.S. Department of Agriculture, Orlando, Florida.
Heath, Michelle. Canadian Energy Research Institute, Calgary, Alberta, Canada.
Heckel, Dr. P. H. Department of Geology, University of Iowa.
Hedger, Dr. Mark. Institute of Reproduction and Development, Monash University, Clayton, Australia.
Hedgpeth, Dr. Joel W. Marine Science Center, Oregon State University.
Heezen, Dr. Bruce C. Deceased; formerly, Lamont-Doherty Geological Observatory, Palisades, New York.
Hein, Dr. James R. U.S. Geological Survey, Branch of Pacific Marine Geology, Menlo Park, California.
Heiney, Prof. Paul A. Department of Physics, University of Pennsylvania, Philadelphia.
Heinrich, Dr. Bernd. Division of Entomology and Parasitology, College of Natural Resources, University of California, Berkeley.
Heinrich, Dr. E. William. Department of Geology and Mineralogy, University of Michigan.
Heinrikson, Dr. Robert L. Department of Biochemistry, University of Chicago.
Heinzel, Dr. Frederick P. Department of Medicine, Division of Infectious Diseases, University of California, School of Medicine, San Francisco.
Held, Dr. Gilbert. Director, 4-Degree Consulting, Macon, Georgia.
Heldman, Dr. Dennis R. Executive Vice President, Scientific Affairs, National Food Processors Association, Washington, D.C.
Helfman, Dr. Gene S. Department of Zoology, University of Georgia.
Hellmers, Dr. Henry. Botany Department, Duke University.
Helman, Marc L. Department of Geological Sciences, University of Durham, England.
Helmers, Dr. Carl J. Vice President, Applied Automation, Inc., Bartlesville, Oklahoma.
Henker, Kevin J. Department of Materials Science and Engineering, Stanford University.
Henriquez, Oscar. California State University of Long Beach, Department of Civil Engineering, Long Beach, California.
Henry, Dr. Alyson E. Department of Psychology, University of Illinois, Chicago.
Henry, Dr. Charles H. Bell Laboratories, Murray Hill, New Jersey.
Herakovitch, Prof. Carl T. Civil Engineering and Applied Mechanics, University of Virginia, Charlottesville.
Herber, Prof. Rolfe H. Department of Chemistry, Rutgers University.
Herberman, Dr. Ronald B. Chief, Biological Development Branch, National Cancer Institute, Frederick Cancer Research Facility, Frederick, Maryland.
Herbst, Dr. Jan F. Physics Department, General Motors Research Laboratories, Warren, Michigan.
Hermach, Dr. F. L. National Institute of Standards and Technology, Gaithersburg, Maryland.
Herman, C. J. Consulting Engineer, Advanced Processes and Products, Insulating Materials Department, General Electric Co., Schenectady, New York.
Herring, Dr. Thomas A. Department of Earth, Atmospheric, and Planetary Sciences, Massachusetts Institute of Technology, Cambridge.
Herron, Dr. Norman. Central Research and Development, DuPont Research, Wilmington, Delaware.
Hersey, Dr. John B. Office of Naval Research, U.S. Department of the Navy.
Hershkowitz, Prof. Noah. Department of Nuclear Engineering, University of Wisconsin, Madison.
Hershleder, William. Consulting Construction Engineer, New York.
Herz, Prof. Carl S. Department of Mathematics, McGill University.
Herzberger, Max J. Deceased; formerly, Consulting Professor, Department of Physics, Louisiana State University.
Herzog, Prof. Gregory F. Department of Chemistry, Rutgers University, Piscataway, New Jersey.
Hess, Garry C. Motorola, Schaumburg, Illinois.
Hess, Dr. Ronald A. Department of Mechanical and Aeronautical Engineering, University of California, Davis.
Hesseltine, Dr. C. W. Fermentation Laboratory, Agricultural Research Service, U.S. Department of Agriculture, Peoria, Illinois.
Hester, Dr. Jeff. Department of Physics and Astronomy, Arizona State University, Tempe.
Hewson, Dr. E. Wendell. Chairman, Department of Atmospheric Sciences, Oregon State University.
Heyn, Dr. A. N. J. Department of Biological Sciences, Louisiana State University.
Heyne, Prof. E. G. Professor of Plant Breeding, Department of Agronomy, Kansas State University.
Heyneman, Dr. Donald. Chair, Health and Medical Sciences Program, University of California, Berkeley.
Hibbard, Robert R. Technical Consultant for Propulsion Chemistry Division, NASA Lewis Research Center, Cleveland, Ohio.
Hickman, Dr. Howard M. Section Manager, Research and Development, Sherex Chemical Company, Dublin, Ohio.
Hicks, Dr. Bruce B. Atmospheric Turbulence and Diffusion Division, National Oceanic and Atmospheric Administration, Oak Ridge, Tennessee.
Hicks, Dr. Glenn R. Associate Director, Plant Biotechnology, Exelixis Pharmaceuticals, South San Francisco, California.
Hicks, Dr. Philip E. President, Hicks & Associates, Consulting Industrial Engineers, Orlando, Florida.
Hicks, Steacy D. Sterling, Virginia.
Hicks, Tyler G. Formerly, Publisher, Professional and Reference Book Division, McGraw-Hill, Inc., New York.
Hieftje, Dr. Gary M. Department of Chemistry, Indiana University.
Higgins, Dr. Robert P. Curator, Department of Invertebrate Zoology, National Museum of Natural History, Smithsonian Institution.
Hildebrand, Dr. Joel H. Deceased; formerly, Department of Chemistry, University of California, Berkeley.
Hill, Dr. Armin J. Dean, College of Physical and Engineering Sciences, Brigham Young University.
Hill, Prof. Dorothy. Research Professor, Department of Geology and Mineralogy, University of Queensland, Brisbane, Australia.
Hill, Prof. Edward L. Deceased; formerly, Professor of Physics and Mathematics, School of Physics, University of Minnesota.
Hill, Dr. Lawrence S. Department of Management, California State University.
Hill, Robert T. Radar Consultant, Bowie, Maryland.
Hill, Dr. Rolla B., Jr. Professor and Chairman, Department of Pathology, Upstate Medical Center, Syracuse.
Hilliard, Dr. Ron. Optomechanics Research, Inc., Vail, Arizona.
Hines, Dr. M. E. Vice President, Microwave Associates, Inc., Burlington, Massachusetts.
Hingorani, Dr. Narian G. Electric Power Research Institute, Palo Alto, California.
Hinrichs, Thomas C. Vice President, Magma Power, San Diego, California.
Hinsch, Dr. Gertrude W. Department of Biology, University of South Florida.
Hintz, Dr. Kenneth J. Department of Electrical and Computer Engineering,

George Mason University, Fairfax, Virginia.

Hipel, Prof. Keith W. Departments of Systems Design Engineering and Statistical Actuarial Science, University of Waterloo, Ontario, Canada.

Hirschberg, Prof. Daniel S. Information and Computer Science, University of California, Irvine.

Hirschfelder, Dr. J. O. Department of Chemistry, University of Wisconsin.

Hitchman, Dr. Matthew H. Department of Meteorology, University of Wisconsin, Madison.

Hodgdon, Dr. James. Naval Health Research Center, San Diego, California.

Hodge, Prof. Paul. Department of Astronomy, University of Washington, Seattle.

Hodge, Prof. Philip. Chair of Polymer Chemistry, Department of Chemistry, University of Manchester, England.

Hodges, Prof. Kip. Department of Earth, Atmospheric, and Planetary Sciences, Massachusetts Institute of Technology, Cambridge.

Hodgin, David M. Senior Member, Institute of Electrical and Electronics Engineers, Cedar Rapids, Iowa.

Hodgson, Brain J. C & P Telephone, Bell Atlantic Company, Washington, D.C.

Hodos, Dr. William. Department of Psychology, University of Maryland, College Park.

Hoering, Dr. Thomas C. Geophysical Laboratory, Carnegie Institution of Washington.

Hoff, Prof. C. Clayton. Department of Biology, University of New Mexico.

Hoffman, Dr. Edward G. Hoffman & Associates, Colorado Springs, Colorado.

Hoffman, Dr. Paul. Department of Earth and Planetary Sciences, Harvard University.

Hoffman, Dr. Paul. Department of Microbiology and Immunology, Faculty of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada.

Hoffman, Dr. Ralph E. Yale Psychiatric Institute, School of Medicine, Yale University.

Hoffman, Richard A. Senior Staff Engineer, Martin Marietta Aerospace, Denver, Colorado.

Hoffman, Prof. Richard L. Department of Biology, Radford College.

Hofstadter, Dr. Robert. Department of Physics, Stanford University.

Hogan, Dr. Brigid. Mill Hill Laboratories, Imperial Cancer Research Fund, London.

Hogan, Dr. Robert. Department of Psychology, Johns Hopkins University.

Hogg, Dr. Helen S. David Dunlap Observatory, University of Toronto.

Hoist, Per A. Foxboro Company, Foxboro, Massachusetts.

Hold, Dr. Robert D. Museum of Natural History, University of Kansas.

Holdaway, Dr. M. J. Department of Geological Sciences, Southern Methodist University.

Holdeman, Dr. Louis B. Communications Satellite Corporation (COMSAT), Clarksburg, Maryland.

Holder, Dr. Nigel. Anatomy and Human Biology Group, Biomedical Sciences Division, Kings College, University of London.

Holland, Dr. Timothy J. B. Department of Mineralogy and Petrology, University of Cambridge, England.

Hollowell, Eugene A. Consultant in Agronomy, Port Republic, Maryland.

Hollweg, Prof. Joseph V. Space Science Center, University of New Hampshire.

Holmes, Dr. Jack K. Holmes Associates, Los Angeles, California.

Holmes, Dr. Robert W. Department of Biological Sciences, University of California, Santa Barbara.

Holt, Dr. Donald L. Monsanto Company, St. Louis, Missouri.

Holt, Dr. Perry C. Department of Biology, Virginia Polytechnic Institute.

Holton, Dr. Gerald. Department of Physics, Harvard University.

Holton, Prof. James R. Department of Atmospheric Sciences, University of Washington.

Holtzman, Dr. Eric. Deceased; formerly, Department of Biological Sciences, Columbia University.

Homann, Prof. Peter H. Institute of Molecular Biophysics, Florida State University.

Hooke, Dr. Roger LeB. Deer Isle, Maine.

Hoover, J. Edgar. Deceased; formerly, Director, Federal Bureau of Investigation, U.S. Department of Justice.

Horan, Dr. Michael. National Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, Maryland.

Horen, Dr. D. J. Nuclear Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Horn, Dr. David J. Department of Entomology, College of Agriculture, Ohio State University.

Horsfall, Dr. James G. Director, Connecticut Agricultural Experiment Station, New Haven.

Horsnail, Dr. R. F. Amax Exploration, Inc., Denver, Colorado.

Horst, Dr. R. K. Department of Plant Pathology, Cornell University.

Horstadins, Prof. Sven. Professor Emeritus of Zoology, University of Uppsala, Sweden.

Horton, Prof. Derek. Department of Chemistry, American University, Washington, D.C.

Horton, G. A. Manager, Engineering Laboratories, Westinghouse Electric Corporation, Cleveland, Ohio.

Horton, Dr. William A. Department of Pediatrics, Medical School, Health Science Center at Houston, University of Texas.

Horwich, Dr. Arthur. Yale University School of Medicine, Howard Hughes Medical Institute, New Haven, Connecticut.

Hosford, Prof. William F. Department of Materials Science and Engineering, College of Engineering, University of Michigan, Ann Arbor.

Hotchkiss, Grosvenor. Coordinating Engineer (retired), Western Union Telegraph Company, New York.

Hotchkiss, Prof. Rollin D. Department of Cellular Physiology, Rockefeller University.

Hough, Dr. L. F. Research Professor in Pomology, Department of Horticulture and Forestry, Rutgers University.

Houghton, Dr. David D. Department of Meteorology, University of Wisconsin, Madison.

Hougie, Dr. Cecil. Professor of Pathology, School of Medicine, University of California, San Diego.

Howe, Prof. Carl E. Deceased; formerly, Professor Emeritus of Physics, Oberlin College.

Howell, Dr. Benjamin F., Jr. Department of Geosciences, Pennsylvania State University.

Howell, William E. NASA Langley Research Center, Hampton, Virginia.

Howells, Dr. T. A Director of Continuing Education (retired), Institute of Paper Chemistry, Appleton, Wisconsin.

Howells, Dr. William W. Peabody Museum of Archeology and Ethnology, Harvard University.

Hoxton, Prof. Llewellyn G. Deceased; formerly, Professor Emeritus of Physics, University of Virginia.

Hrones, Dr. John A. Provost of Science and Technology, Case Western Reserve University.

Hsieh, Dr. Samuel C. Department of Computer Science, Southwestern Oklahoma State University, Weatherfort.

Hu, Dr. A. S. L. Department of Biochemistry, University of Kentucky.

Hubbard, Dr. W. M. Bell Communications Research (Bell-core), Red Bank, New Jersey.

Hubert, Prof. John F. Department of Geosciences, University of Massachusetts, Amherst.

Hudlicky, Dr. Tomas. Department of Chemistry, Illinois Institute of Technology.

Hudson, Dr. Hugh S. Institute of Space and Astronautical Science/Yohkoh, Sagamihara-shi, Kanagawa, Japan.

Hudson, Dr. Ralph P. Retired; formerly, Bureau International des Poids et Mésures, Sevres, France.

Huebler, Dr. Jack. Senior Vice President, Institute of Gas Technology, IIT Center, Chicago, Illinois.

Huelsman, Prof. Lawrence P. Department of Electrical and Computer Engineering, College of Engineering and Mines, University of Arizona.

Huffman, E. O. Consultant, Fertilizer Research and Development, Florence, Alabama.

Hughes, Dr. John M. Associate Dean, College of Arts and Science, Department of Geology, Miami University, Oxford, Ohio.

Huizenga, Dr. John R. Nuclear Structure Research Laboratory, University of Rochester.

Hulbary, Dr. Robert L. Department of Botany, University of Iowa.

Hultsch, Dr. Roland A. Department of Physics, University of Missouri.

Humes, Dr. Arthur G. Department of Biology, Boston University.

Hummon, Dr. William D. Department of Zoological and Biomedical Sciences, Ohio University.

Hundhausen, Dr. Arthur J. High Altitude Observatory, National Center for Atmospheric Research, Boulder, Colorado.

Hungate, Prof. Robert E. Department of Bacteriology, University of California, Davis.

Hunter, Prof. Lloyd P. Department of Electrical Engineering, University of Rochester.

Hunter, Dr. R. H. F. School of Agriculture, University of Edinburgh, Scotland.

Huntington, Prof. H. B. Department of Physics, Rensselaer Polytechnic Institute.

Hurlbut, Prof. Cornelius S., Jr. Professor of Mineralogy, Department of Geological Sciences, Harvard University.

Hurley, Joseph D. Westinghouse Electric Corporation, Orlando, Florida.

Hurll, John. Measurements Standards Laboratory, Marconi Instruments Ltd., Stevenage, Hertfordshire, England.

Hurst, Dr. G. S. Department of Physics, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Hurst, Prof. James K. Department of Biochemistry and Biophysics, Washington State University, Pullman.

Hutcheon, Dr. Ian D. Isotope Sciences Division, Lawrence Livermore National Laboratory, University of California, Livermore.

Hutchinson, Prof. Ian H. Massachusetts Institute of Technology, Plasma Science and Fusion Center, Cambridge, Massachusetts.

Hutchison, Dr. Keith. Department of Biology, Brandeis University.

Hwang, Dr. Patrick. Rockwell International, Cedar Rapids, Iowa.

Hwang, Dr. Richard N. Moh and Associates, Inc., Taipei, Taiwan.

Hyde, Dr. Earl K. Lawrence Berkeley Laboratory, University of California, Berkeley.

Hyde, Dr. Geoffrey. Retired; formerly, COMSAT Laboratories, Clarksburg, Maryland.

Hynek, Dr. J. Allen. Deceased; formerly, Department of Astronomy, Northwestern University.

I

Iachello, Dr. Franco. Department of Physics, Yale University.

Ibrahim, Dr. Aly M. Agricultural Research Service, Western Region, U.S. Department of Agriculture, Salinas, California.

Illis, Alexander. Director, Process Technology, International Nickel Company of Canada, Ltd., Toronto, Ontario.

Imai, Noriyoshi. Toyo Ink Manufacturing Company, Tokyo, Japan.

Imbembo, Prof. Anthony L. Chairperson, Department of Surgery, University of Maryland Hospital, Baltimore.

Ingels, Chuck A. University of California Cooperative Extension, Sacramento.

Ingersoll, Dr. Raymond V. University of California at Los Angeles, Department of Earth and Space Science.

Ingerson, Dr. Earl. Department of Geology, University of Texas, Austin.

Ingram, Dr. B. Lynn. Department of Geology and Geophysics, University of California, Berkeley.

Inman, Dr. Douglas L. Professor of Oceanography, Scripps Institution of Oceanography, La Jolla, California.

Irene, Dr. Eugene A. Department of Chemistry, University of North Carolina.

Ishida, Dr. Nakao. Department of Bacteriology, Tohoku University School of Medicine, Sendai, Japan.

Ishihara, Prof. Teruo. Department of Mechanical and Aerospace Engineering, Rose Polytechnic Institute.

Isley, Dr. Duane. Department of Botany, Iowa State University.

Israel, Dr. Yedy. Department of Pharmacology, University of Toronto, Ontario, Canada.

Issel, Dr. Charles J. College of Agriculture, Veterinary Science, Gluck Equine Research Center, University of Kentucky, Lexington.

Itano, Dr. Wayne M. U.S. Department of Commerce, Time and Frequency Division, National Institute of Standards and Technology, Boulder, Colorado.

Iverson, Dr. Brent L. Department of Chemistry and Biochemistry, University of Texas, Austin.

Ives, Dr. Anthony R. Department of Zoology, University of Wisconsin, Madison.

Izadian, Dr. Jamal S. AntennaEM Communication, LLC, San Jose, California.

J

Jackiw, Prof. Roman. Department of Physics, Massachusetts Institute of Technology.

Jackson, Donald C. Division of Biology and Medicine, Brown University.

Jackson, G. A. Deputy Division Manager, ERA Technology Ltd., Surrey, England.

Jackson, Dr. Kenneth A. AT&T Bell Telephone Laboratories, Murray Hill, New Jersey.

Jackson, Dr. M. P. A. Senior Research Scientist, Bureau of Economic Geology, University of Texas, Austin.

Jackson, Dr. William D. President, HMJ Corporation, Chevy Chase, Maryland.

Jacobs, Prof. Stephen F. Optical Sciences Center, University of Arizona.

Jacobson, Prof. Nathan. Department of Mathematics, Yale University.

Jacobson, Dr. Robert. Chief of the Clinical Branch, Department of Health and Human Services, Gillis W. Long Hansen's Disease Center, Carville, Louisiana.

Jaep, William F. Central Research Department, Experimental Station, E. I. du Pont de Nemours and Company, Wilmington, Delaware.

Jafarey, Prof. S. Behlen Laboratory of Physics, University of Nebraska.

Jaffe, Prof. Robert L. Department of Physics, Massachusetts Institute of Technology, Cambridge.

Jahns, Dr. Richard H. Department of Earth Sciences, Stanford University.

Jain, Dr. P. C. Central Electronics Engineering Research Institute, Pilani, India.

Jain, Dr. Subodh K. Department of Agronomy and Range Science, University of California, Davis.

Jakobi, Prof. Hans. Professor of Animal Physiology, Department of Zoology, University of Parana, Brazil.

James, Prof. Arthur M. Department of Chemistry, Bedford College, London, England.

James, Dr. Gideon T. Department of Earth Sciences, East Texas State University.

James, John W. Vice President, Research, McDonnell and Miller, Inc., Chicago, Illinois.

James, Dr. Mark A. Corriebruach House, Perthshire, United Kingdom.

James, Dr. Richard W. Head, Forecasting Branch, Oceanographic Prediction Division, U.S. Naval Oceanographic Office.

Jamshidi, Dr. Mohamed. Director, CAD Laboratory for Systems and Robotics, Department of Electrical and Computer Engineering, University of New Mexico.

Janick, Prof. Jules. Department of Horticulture, Purdue University.

Janis, Dr. Christine. Department of Ecology and Evolutionary Biology, Brown University, Providence, Rhode Island.

Janna, Prof. William S. Department of Mechanical Engineering, Memphis State University, Tennessee.

Jannasch, Dr. Holger W. Senior Scientist, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.

Japikse, Dr. David. President, Concepts ETI, Inc., Norwich, Vermont.

Japuntich, Daniel A. Occupational Health and Safety Products Division, 3M Company, St. Paul, Minnesota.

Jarvis, J. Gordon. Corporate Communications, Eastman Kodak Company, Rochester, New York.

Jarvis, Dr. John F. Robotics Systems Research Department, Bell Laboratories, Holmdel, New Jersey.

Jeffries, Dr. R. P. S. Department of Paleontology, British Museum of Natural History, London, England.

Jegla, Dr. Dorothy E. Department of Biology, Kenyon College, Gambier, Ohio.
Jen, Dr. C. K. Supervisor, Microwave Physics Group, Applied Physics Laboratory, Johns Hopkins University.
Jenike, Andrew W. Jenike & Johanson, Inc., North Billerica, Massachusetts.
Jenike, Dr. Michael A. Research Psychiatrist, Massachusetts General Hospital, Harvard Medical School.
Jenkins, Prof. Francis A. Deceased; formerly, Department of Physics, University of California, Berkeley.
Jenkins, Dr. Julian L. Director of Research, Bell Helicopter Company, Fort Worth, Texas.
Jennings, Dr. Donald A. Time and Frequency Division, National Institute of Standards and Technology, Boulder, Colorado.
Jennings, Dr. J. B. Department of Pure and Applied Zoology, University of Leeds, England.
Jensen, Prof. Arthur R. School of Education, University of California, Berkeley.
Jensen, Dr. Howard B. Research Supervisor, Laramie Energy Research Center, Energy Research and Development Administration, Wyoming.
Jensen, Richard L. Sirius Satellite Radio, New York.
Jespersen, Dr. Neil D. Department of Chemistry, St. John's University, New York.
Joel, Amos E., Jr. AT&T Bell Telephone Laboratories, Holmdel, New Jersey.
Johansen, Dr. Kjell. Department of Zoophysiology, University of Aarhus, Denmark.
Johnson, Prof. Carl R. Department of Chemistry, Wayne State University.
Johnson, Dr. Donald Lee. Department of Geography, University of Illinois, Urbana.
Johnson, Dr. Edward. Department of Cell Biology, Rockefeller University.
Johnson, Dr. Ellis L. Thomas J. Watson Research Center, IBM Corporation, Yorktown Heights, New York.
Johnson, Dr. Francis S. Acting President, University of Texas, Dallas.
Johnson, Dr. Giles. School of Biological Sciences, University of Manchester, United Kingdom.
Johnson, Dr. James E. Department of Chemistry, Texas Woman's University, Denton.
Johnson, Dr. James G. Department of Geology, Oregon State University.
Johnson, Dr. Jon D. Department of Forestry, University of Florida, Gainesville.
Johnson, K. W. President, Vibra-Grip Corporation, Jamestown, Ohio.
Johnson, Philip C. Research and Development Department, Chemicals and Plastics Operations Division, Union Carbide Corporation, South Charleston, West Virginia.
Johnson, Dr. W. Hilton. Department of Geology, University of Illinois, Urbana-Champaign.
Johnson, Prof. Walter C. Department of Electrical Engineering, Princeton University.
Johnston, Dr. James D. Senior Research Advisor, Pioneering Research, Ethyl Corporation, Baton Rouge, Louisiana.
Johnston, Prof. Keith. Department of Chemical Engineering, University of Texas, Austin.
Joklik, Dr. W. K. Department of Microbiology and Immunology, Duke University Medical Center.
Jones, Prof. B. Frank, Jr. Department of Mathematics, Weiss School of Natural Sciences, Rice University.
Jones, Dr. Clive G. Institute of Ecosystem Studies, New York Botanical Garden, Millbrook, New York.
Jones, Dr. Daniel J. Professor and Chairman, Department of Earth Sciences, California State College, Bakersfield.
Jones, Dr. David R. Department of Zoology, University of British Columbia, Canada.
Jones, Dr. E. Ruffin. Department of Zoology, University of Florida.
Jones, Dr. Edwin C., Jr. Department of Electrical and Computer Engineering, Iowa State University.
Jones, Dr. Hugh D. School of Biological Sciences, University of Manchester, United Kingdom.
Jones, Dr. Jeremy B. Department of Biological Sciences, University of Nevada, Las Vegas.
Jones, Prof. Lawrence W. Harrison M. Randall Laboratory of Physics, University of Michigan.
Jones, Dr. Meredith L. National Museum of Natural History, Smithsonian Institution, Washington, D.C.
Jones, Dr. Morton E. Director, Physical Sciences Research Laboratory, Texas Instruments, Inc., Dallas.
Jones, Dr. Norman S. Senior Lecturer, Marine Biological Station, University of Liverpool, England.
Jones, Dr. Owen C. Superintendent, Division of Electrical Science, National Physical Laboratory, Teddington, England.
Jones, Dr. Patricia M. Department of Mechanical and Industrial Engineering, University of Illinois, Urbana-Champaign.
Jones, Prof. R. Alan. School of Chemical Sciences, University of East Anglia, England.
Jones, Dr. R. Gareth. Division of Electrical Science, National Physical Laboratory, Teddington, England.
Jones, Dr. Richard T. Department of Biochemistry, University of Oregon Medical School.
Joppa, Prof. Robert G. Department of Aeronautics, University of Washington.
Joravsky, Prof. David. Professor of History, Northwestern University.
Jordan, Dr. Elke. Department of Health and Human Services, National Human Genome Research Institute, Bethesda, Maryland.
Jory, Howard R. Varian Associates, Palo Alto, California.
Joseph, Earl C. President, Planning and Development, Anticipatory Sciences Inc., Minneapolis, Minnesota.
Joseph, Leonard M. Lev Zetlin Associates, New York, New York.
Joseph, Dr. Simpson. Department of Chemistry and Biochemistry, University of California, La Jolla.
Juang, Dr. Biing Hwang. Lucent Technologies, Bell Laboratories, Murray Hill, New Jersey.
Judd, Dr. Deane B. Deceased; formerly, Office of Colorimetry, National Bureau of Standards.
Judd, Dr. W. John. Department of Pathology, University of Michigan, Ann Arbor.
Judd, Dr. William R. School of Civil Engineering, Purdue University.
Juranek, Dr. Dennis D. Center for Disease Control, Atlanta, Georgia.
Jurisson, Dr. Silvia S. Department of Chemistry, University of Missouri, Columbia.
Just, Prof. Evan. Department of Mining and Geology, Stanford University.
Juvet, Prof. Richard S., Jr. Department of Chemistry, Arizona State University.

K

Kaesler, Dr. Roger L. Department of Geology, University of Kansas, Lawrence.
Kahn, Dr. Bernd. Environmental Resources Center, Georgia Institute of Technology, Atlanta.
Kailath, Prof. Thomas. Information Systems Laboratory, Stanford University, Stanford, California.
Kaler, Prof. James B. Department of Astronomy, College of Liberal Arts and Sciences, University of Illinois, Urbana-Champaign.
Kalhammer, Dr. Fritz. Electric Power Research Institute, Palo Alto, California.
Kallen, Dr. Bengt. Department of Embryology, University of Lund, Sweden.
Kallio, Dr. R. E. School of Life Sciences, University of Illinois, Urbana.
Kalpakjian, Prof. Serope. Mechanical and Aerospace Engineering Department, Illinois Institute of Technology.
Kaminow, Dr. Ivan P. Bell Telephone Laboratories, Holmdel, New Jersey.
Kamrin, Dr. Michael A. Center for Environmental Toxicology, Department of Pathology, Michigan State University.
Kana, Dr. Todd M. Horn Point Laboratory, Cambridge, Maryland.
Kan-Mitchell, Dr. June. School of Medicine, University of Southern California.
Kanury, Dr. A. Murty. Senior Mechanical Engineer, Stanford Research Center, Menlo Park, California.

Kanzig, Prof. Werner. Department of Physics, Massachusetts Institute of Technology.

Kaplan, Dr. Louis. Senior Chemist, Argonne National Laboratory, Argonne, Illinois.

Kaplan, Robert A. Vice President in Charge of Engineering, Automatic Burner Corporation, Chicago, Illinois.

Kaplan, Prof. Thomas A. Department of Physics and Astronomy, Michigan State University, East Lansing.

Kapner, Robert S. Department of Chemical Engineering, Cooper Union, New York.

Kaprelian, Edward K. Vice President and Technical Director, Keuffel and Esser Company, Morristown, New Jersey.

Kapur, Prof. Kallash C. Director, Industrial Engineering, University of Washington, Seattle.

Karady, Dr. George G. Department of Electrical Engineering, Arizona State University.

Karash, Joseph I. Manufacturing Engineer (retired), Reliance Electric Company, Wickliffe, Ohio.

Kareiva, Prof. Peter. Department of Zoology, University of Washington, Seattle.

Karlson, Dr. Peter. Insitut für Physiologische Chemie, Philipps-Universitat, Marburg, Germany.

Karner, Dr. Garry D. Lamont-Doherty Earth Observatory, Palisades, New York.

Karni, Prof. Shlomo. Department of Electrical and Computer Engineering, University of New Mexico.

Karovska, Dr. Margarita. Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts.

Karp, Dr. Alan H. IBM Scientific Center, Palo Alto, California.

Katz, Dr. Jack L. Department of Psychiatry, Montefiore Hospital and Medical Center, Bronx, New York.

Katz, Dr. Joseph J. Chemistry Division, Argonne National Laboratory, Argonne, Illinois.

Katz, Dr. Leonard A. Health Care Plan Medical Center, Buffalo, New York.

Kaufmann, R. H. Deceased; formerly, Consultant, Schenectady, New York.

Kayan, Prof. Carl F. Deceased; formerly, Department of Mechanical Engineering, School of Engineering, Columbia University.

Kayden, Dr. Herbert J. Department of Medicine, New York University School of Medicine, New York.

Kays, Prof. John M. Animal Industries Department, University of Connecticut.

Keating, Richard E. Time Service Division, U.S. Naval Observatory, Washington, D.C.

Keddy, Prof. Rex J. Schonland Research Center for Nuclear Sciences, University of Witwatersrand, Johannesburg, South Africa.

Keefe, Dr. Richard S. E. Department of Psychiatry, Duke University Medical Center, Durham, North Carolina.

Keeton, Dr. William T. Deceased; formerly, Professor and Chairman, Section of Neurobiology and Behavior, Langmuir Laboratory, Division of Biological Science, Cornell University.

Keffer, Prof. Frederic. Department of Physics, University of Pittsburgh.

Keil, Dr. Stephen L. Chief, Solar Research Branch, National Optical Astronomy Observatories, National Solar Observatory, Air Force Geophysics Laboratory, Sunspot, New Mexico.

Keiser, Bernhard E. President, Keiser Engineering, Inc., Vienna, Virginia.

Keller, George V. Department of Geophysics, Colorado School of Mines.

Keller, Harold W. Associate Professor, Department of Microbiology and Immunology, Wright State University.

Keller, Dr. Joseph M. Department of Physics, Iowa State University.

Keller, Prof. Walter D. Department of Geology, University of Missouri.

Keller, Dr. William E. Los Alamos Scientific Laboratory, Los Alamos, New Mexico.

Kelley, Prof. Michael C. Engineering and Theory Center, Cornell University.

Kellogg, Dr. Douglas S. Center for Disease Control, Atlanta, Georgia.

Kells, Prof. Lyman M. Deceased; formerly, Professor Emeritus, U.S. Naval Academy.

Kelman, Dr. Arthur. Department of Plant Pathology, University of Wisconsin.

Kempers, Dr. Roger D. Department of Obstetrics and Gynecology, Mayo Foundation, Mayo Graduate School of Medicine, Rochester, Minnesota.

Kemppainen, Prof. Robert J. Department of Anatomy, Physiology and Pharmacology, Auburn University of Veterinary Medicine, Auburn, Alabama.

Kendeigh, Dr. S. Charles. Department of Zoology, University of Illinois, Urbana.

Kenning, Dr. David B. B. Department of Engineering Science, Oxford, United Kingdom.

Kensler, Dr. Charles J. Senior Vice President, Life Science Division, Arthur D. Little, Inc., Cambridge, Massachusetts.

Kent, Dr. George C., Jr. Professor Emeritus, Louisiana State University; Authors' Services, Inc., Baton Rouge, Louisiana.

Ker, Dr. Robert F. Department of Pure and Applied Biology, University of Leeds, United Kingdom.

Kerr, Dr. Marilyn S. Department of Biology, Syracuse University.

Kerst, Prof. Donald W. Department of Physics, University of Wisconsin.

Kerstein, Prof. Morris. D. Director, Graduate and Postgraduate Medical Education Programs, Department of Surgery, Hahnemann University, Philadelphia, Pennsylvania.

Kessler, Prof. Edwin. Director, National Severe Storms Laboratory, Norman, Oklahoma.

Kessler, George W. Vice President, Engineering and Technology, Power Generation Division, Babcock and Wilcox Company, Barberton, Ohio.

Kester, Dr. Dale E. Department of Pomology, College of Agriculture, University of California, Davis.

Ketterle, Prof. Wolfgang. Department of Physics, Massachusetts Institute of Technology, Cambridge.

Ketterson, Dr. J. B. Department of Physics, Northwestern University.

Khan, Dr. Tanveer N. Senior Plant Breeder, Division of Plant Industry, Western Australian Department of Agriculture.

Kharasch, Prof. Norman. Department of Biomedicinal Chemistry, University of Southern California.

Kibble, Dr. Bryan P. Division of Electrical Science, National Physical Laboratory, Teddington, Middlesex, England.

Kilbey, Dr. Brian J. Department of Genetics, Institute of Animal Genetics, University of Edinburgh, Scotland.

Kilgore, Dr. Lee A. Retired; formerly, Westinghouse Electric Corporation, East Pittsburgh, Pennsylvania.

Kim, Prof. Chung W. Department of Physics, Johns Hopkins University.

Kimbark, Dr. Edward W. Deceased; formerly, Head, Systems Analysis Group, Bonneville Power Administration, Portland, Oregon.

Kinard, Joseph R. Consultant, Darnestown, Maryland.

Kindstedt, Dr. Paul S. Agricultural Experiment Station, Department of Animal Sciences, University of Vermont, College of Agriculture and Life Sciences, Burlington.

King, Dr. Bryan H. Professor of Psychiatry and Pediatrics, Department of Psychiatry, Dartmouth Hitchcock Medical Center, Lebanon, New Hampshire.

King, Dr. C. Judson. Department of Chemical Engineering, University of California, Berkeley.

King, Dr. Donald W., Jr. Richard T Crane Professor of Pathology, Department of Pathology, University of Chicago.

King, Dr. Elbert A. Department of Geology, University of Houston.

Kinnard, Dr. Isaac F. Deceased; formerly, Manager of Engineering, Instrument Department, General Electric Company, Lynn, Massachusetts.

Kinoshita, Prof. Toichiro. Laboratory of Nuclear Studies, Cornell University.

Kinsler, Prof. Lawrence E. Professor of Physics, U.S. Naval Postgraduates School, Monterey, California.

Kinsman, Prof. Blair. College of Marine Studies, University of Delaware.

Kirby, Dr. H. W. Mound Facility, Monsanto Research Corporation, Miamisburg, Ohio.

Kirby, Robert S. Research Laboratories, NOAA, U.S. Department of Commerce, Boulder, Colorado.

Kirby, Dr. Seth. Dixon Spice Farms, Dixon, California.

Kirk, Prof. Wiley P. Department of Physics, Texas A & M University.

Kirschner, Prof. Stanley. Department of Chemistry, Wayne State University.

Kissel, Dr. David E. Department of Agronomy, Kansas State University.

Kit, Dr. Saul. Novagene Inc., Houston, Texas.

Klein, Dr. Barbara P. Department of Foods and Nutrition, University of Illinois.

Klein, Cornelius. Department of Geology, University of New Mexico.

Klein, Dr. David H. Department of Chemistry, Hope College.

Klein, Dr. Jan. Max Planck Insitut für Biologie, Abteilung Immungenetik, Tubingen, Germany.

Klein, Prof. Richard G. Department of Anthropology, University of Chicago.

Klein, Prof. Richard M. Department of Botany, University of Vermont.

Kleiner, Dr. Mendel. Chalmers University of Technology, Applied Acoustics, Gotheberg, Sweden.

Kleinsmith, Prof. Lewis J. Division of Biological Sciences, University of Michigan.

Klemens, Dr. Paul G. Department of Physics, University of Connecticut.

Klepper, Dr. David Lloyd. Klepper Marshall King Associates, Inc., White Plains, New York.

Kleppner, Prof. Daniel. Department of Physics, Massachusetts Institute of Technology, Cambridge.

Klich, Dr. Maren. Microbiologist, Food and Feed Safety Research, U.S. Department of Agriculture–Agricultural Research Service, New Orleans, Louisiana.

Klick, Dr. Clifford C. Superintendent, Solid Sate Division, U.S. Naval Research Laboratory.

Kliewer, Prof. K. L. Department of Physics, Iowa State University.

Klinger, Dr. Terry. Friday Harbor Laboratories, Friday Harbor, Washington.

Klivans, Dean S. Rockwell International, El Segundo, California.

Klock, Dr. Harold F. Department of Electrical Engineering, Ohio University.

Klutke, Dr. Georgia-Ann. Associate Professor and Director, Institute for Manufacturing Systems, Department of Industrial Engineering, Texas A & M University, College Station.

Knapp, Prof. Anthony W. Department of Mathematics, Cornell University.

Knebelman, Prof. Morris S. Professor of Mathematics, Bucknell University.

Knight, Dr. R. B. D. Retired; formerly, Division of Electrical Science, National Physical Laboratory, Teddington, Middlesex, England.

Knoteck, Dr. M. L. Sandia National Laboratories, Albuquerque, New Mexico.

Knowles, Prof. Paulden F. Department of Agronomy and Range Science, University of California, Davis.

Kobayashi, Dr. George. Washington University School of Medicine, Saint Louis, Missouri.

Kocan, Prof. Katherine M. Department of Veterinary Pathology, Oklahoma State University, Stillwater.

Koch, Prof. Arthur L. Department of Biology, Indiana University.

Koch, Dr. Peter M. Department of Physics, State University of New York at Stony Brook.

Koerker, Frederick W. Technical Expert (retired), Dow Chemical Company, Midland, Michigan.

Kogel, Dr. Jessica Elzea. Thiele Kaolin Company, Sanders–ville, Georgia.

Koglenik, Dr. Herwig. Crawford Hill Laboratory, Bell Laboratories, Holmdel, New Jersey.

Kohl, Arthur L. Project Engineer, Advanced Development, Atomics International Division, North American Rockwell, Woodland Hills, California.

Kohlmeier, Dr. Martin. Department of Nutrition, University of North Carolina at Chapel Hill.

Kohls, Dr. Glen M. Sanitarian Director (retired), U.S. Public Health Service, Rocky Mountain Laboratory, Hamilton, Montana.

Kohnhorst, Lloyd L. Retired; formerly, Senior Research Specialist, Rockwell International, Columbus, Ohio.

Koller, Dr. Noemie. Department of Physics, Rutgers University.

Kolvoord, Dr. Robert A. College of Integrated Science and Technology, James Madison University, Harrisonburg, Virginia.

Komai, Dr. Taku. Professor Emeritus, Kyoto University, Japan.

Kominz, Michelle. Lamont-Doherty Geological Observatory, Palisades, New York.

Koneman, Dr. Elmer W. Department of Pathology, Denver Veterans Affairs Hospital, University of Colorado Medical School, Denver.

Konigsberg, Dr. William H. Department of Molecular Biophysics, Yale University.

Konopka, Dr. Allan E. Department of Biological Sciences, Purdue University.

Konz, Dr. Stephan A. Department of Industrial Engineering, Kansas State University.

Konzo, Prof. Seichi. Department of Mechanical Engineering, University of Illinois.

Koopman, Dr. Karl F. Department of Mammalogy, American Museum of Natural History, New York.

Koral, Dr. Richard L. Visiting Associate Professor, Pratt School of Architecture; Coordinator, Apartment House Institute, New York City Community College.

Korth, Dr. Henry F. Head, Database Principles Research, Murray Hill, New Jersey.

Korth, Dr. William W. Rochester Institute of Vertebrate Paleontology, Penfield, New York.

Korus, Dr. Roger A. Chairperson, Department of Chemical Engineering, College of Engineering, Buchanan Engineering Laboratory, University of Idaho.

Kosikowski, Prof. Frank V. Department of Food Science, Cornell University.

Kosow, Dr. Irving L. Series Editor, Electrical Engineering Technology, John Wiley & Sons, Marietta, Georgia.

Kotter, Dr. F. Ralph. National Bureau of Standards.

Kovar, Dr. Dennis. Hahn-Meitner Institut für Kernsforschung, Berlin, Germany.

Kow, Dr. Yoke Wah. Department of Biochemistry, University of Wisconsin.

Kowal, Dr. Charles T. Department of Astrophysics, California Institute of Technology.

Kraehenbuehl, Prof. John O. Professor Emeritus of Electrical Engineering, University of Illinois, Urbana.

Kramar, Dr. Ernst. Deceased; formerly, Standard Elektrik Lorenz Aktiengesellschaft, Stuttgart, Germany.

Krasan, Dr. Graham P. Lecturer in Pediatrics and Communicable Diseases, University of Michigan Medical School, Ann Arbor.

Krauss, Prof. George. Colorado School of Mines, Golden.

Krauss, Dr. Lawrence M. Center for Theoretical Physics, Yale University.

Kreek, Dr. Mary Jeanne. Rockefeller University.

Krefeld, Prof. William J. Deceased; for merly, Professor of Civil Engineering, Columbia University.

Kreilik, Dr. Robert. Department of Chemistry, University of Rochester.

Kretschmann, Dr. David E. Forest Products Laboratory, U.S. Department of Agriculture Forest Service, Madison, Wisconsin.

Kreutel, Dr. Randall W. Mechanical Engineering Manager, Atlanta Instrumentation Division, Atlanta, Georgia.

Krider, Prof. E. Philip. Director, Institute of Atmospheric Physics, University of Arizona.

Krishnamurti, Dr. T. N. Department of Meteorology, Florida State University.

Kristensen, Dr. Reinhardt Møbjerg. Zoological Museum, University of Copenhagen, Denmark.

Kristofferson, Karl. Public Information Branch, John F. Kennedy Space Center, Cape Canaveral, Florida.

Krol, Dr. Edward. Department of Computer Science, University of Illinois, Urbana.

Krombein, Dr. Karl V. Chairman, Department of Entomology, National Museum of Natural History, Smithsonian Institution.

Kroto, Harold W. School of Chemistry and Molecular Sciences, University of Sussex, United Kingdom.

Kruse, Dr. Paul W. Consultant, Infrared Technology, Edina, Minnesota.

Krusius, Prof. Matti. Low Temperature Laboratory, Helsinki University of Technology, Finland.

Kryter, Dr. Karl D. Director, Sensory Sciences Research Center, Stanford Research Institute, Menlo Park, California.

Krzysztofowicz, Dr. Roman. Department of Systems Engineering, University of Virginia.

Kuchner, Dr. Marc J. Department of Astronomy, California Institute of Technology, Pasadena, California.

Kudo, Prof. Albert M. Department of Earth and Planetary Sciences, University of New Mexico, Albuquerque.

Kuhn, Dr. Wayne E. Professional Engineer, Portland, Oregon.

Kuis, Wietse. Department of Molecular and Experimental Medicine, Research Institute of Scripps Clinic, La Jolla, California.

Kulkarni, Prof. Shrinivas. Department of Astronomy, California Institute of Technology, Pasadena, California.

Kulkarni, Sudhir S. Corporate Research Center, UOP Inc., Des Plaines, Illinois.

Kullerud, Dr. Gunnar. Department of Geosciences, Purdue University.

Kulp, J. Laurence. President, Teledyne Isotopes, Westwood, New Jersey.

Kuntz, Glenn. Regional Director, ETI of North America, Inc., Washington, D.C.

Kunz, Dr. Kaiser S. Research Professor of Physics, New Mexico State University.

Kuo, Dr. Benjamin C. Formerly, Department of Electrical Engineering, University of Illinois, Champaign.

Kuo, Prof. John T. Department of Mining Engineering, Columbia University.

Kupchan, Prof. S. Morris. Deceased; formerly, Department of Chemistry, University of Virginia.

Kupke, Dr. Donald W. Department of Biochemistry, School of Medicine, University of Virginia.

Kupper, Dr. Walter E. Manager, Technical Marketing Services, Mettler Instrument Corporation, Hightstown, New Jersey.

Kusch, Prof. Polykarp. Department of Physics, Columbia Radiation Laboratory, Columbia University.

Kushner, Dr. D. J. Department of Microbiology, University of Toronto, Ontario, Canada.

Kusters, Dr., N. L. Division of Electrical Engineering, National Research Council, Ottawa, Ontario, Canada.

Kutal, Dr. Charles. Department of Chemistry, University of Georgia.

Kutzbach, Prof. John E. Department of Meteorology, University of Wisconsin.

L

Laarhoven, Prof. William H. Department of Organic Chemistry, University of Nijmegen, The Netherlands.

Labandeira, Dr. Conrad C. Department of Paleobiology, National Museum of Natural History, Smithsonian Institution, Washington, DC.

LaBerge, Dr. Stephen. Department of Psychology, Stanford University, Stanford, California.

Labi, Prof. Samuel. Graduate Research Assistant, Purdue University, Civil Engineering, West Lafayette, Indiana.

Labotka, Dr. Theodore C. Department of Geological Sciences, College of Liberal Arts, University of Tennessee.

Lacis, Dr. Andrew A. NASA Goddard Institute for Space Studies, New York.

Lackman, Dr. Leslie. M. Rockwell International, El Segundo, California.

Ladd, Dr. Carll. Connecticut State Police Forensic Science Laboratory, Meriden.

Ladd, Dr. Harry S. (Retired) National Museum, Smithsonian Institution.

LaFrey, Raymond R. Lincoln Laboratory, Massachusetts Institute of Technology, Lexington.

Lagler, Prof. Karl F. School of Natural Resources, University of Michigan.

Lagowski, Dr. J. J. Department of Chemistry, University of Michigan.

Lagunoff, Dr. David. Department of Pathology, School of Medicine, University of Washington.

Laidler, Dr. James J. Director, Chemical Technology Division, Argonne National Laboratory, Argonne, Illinois.

Laitinen, Prof. Herbert A. Department of Chemistry, University of Florida.

Lam, Dr. Stephen W. Center for Excellence for Document Analysis and Recognition, University of Buffalo, Amherst, New York.

Lamb, Prof. Dennis. Department of Meteorology, Pennsylvania State University.

Lamb, Prof. Richard C. Space Radiation Laboratory, California Institute of Technology, Pasadena.

Lambert, Dr. Jack L. Department of Chemistry, Kansas State University.

Lambert, Dr. Samuel. Air Force Research Laboratory, Munition Directorate, Eglin Air Force Base, Florida.

Lambert, Dr. W. David. Louisiana School of Math, Science, and the Arts, Natchitoches.

LaMotte, Dr. Clifford E. Botany Department, Iowa State University.

LaMotte, Dr. Robert. Department of Anesthesiology, School of Medicine, Yale University.

Land, Dr. Cecil E. Sandia Laboratories, Kirtland Air Force Base East, Albuquerque, New Mexico.

Landes, Dr. Hugh S. Department of Electrical Engineering, University of Virginia.

Landsberg, Dr. H. E. Deceased; formerly, Institute for Physical Science and Technology, University of Maryland.

Lane, Dr. John C. Research and Development Department, Research Laboratories, Ethyl Corporation, Ferndale, Michigan.

Lane, Dr. Meredith A. Director, University of Kansas Herbarium, Lawrence.

Lane, Dr. N. Gary. Indiana University.

Lanford, Dr. Pamela. National Institute on Deafness and Other Communication Disorders, Rockville, Maryland.

Lanford, Prof. William A. Department of Physics, State University of New York, Albany.

Lang, Dr. Anton. Department of Botany, MUS-DOE Plant Research Laboratory, Michigan State University.

Lang, Dr. Karl. Director, Department of Invertebrates, Swedish State Museum of Natural History, Stockholm, Sweden.

Langenberg, Prof. D. N. Department of Physics, University of Pennsylvania.

Langenheim, Prof. Jean H. Division of Natural Sciences, University of California, Santa Cruz.

Langford, Prof. George M. Department of Biological Sciences, Dartmouth University.

Lapedes, Daniel N. Deceased; formerly, Editor in Chief, “McGraw-Hill Encyclopedia of Science and Technology,” McGraw-Hill, Inc., New York.

Laport, Edmund A. Director, Communications Engineering, RCA, Princeton, New Jersey.

Lappin-Scott, Hilary. Department of Biology, University of Calgary, Alberta, Canada.

Lapple, Charles E. Consultant (retired), Fluid and Particle Technology, Air Pollution and Chemical Engineering, Los Altos, California.

Larimer, Dr. J. L. Department of Zoology, University of Texas, Austin.

Larive, Dr. Cynthia K. Department of Chemistry, University of Kansas, Lawrence.

Larsen, Dr. David M. Department of Physics and Applied Physics, University of Lowell, Massachusetts.

Larsen, Prof. Edwin M. Department of Chemistry, University of Wisconsin.

Larsen, Dr. R. Paul. Superintendent and Horticulturist, Tree Fruit Research Center, Washington State University.

Larsen, Dr. Robert G. Assistant to the Vice President, Shell Development Company, Emeryville, California.

Larson, Dr. Roy A. Department of Horticulture, North Carolina State University.

Lass, Dr. Harry. Research Specialist, Jet Propulsion Laboratory, California Institute of Technology.

Lassila, Prof. Kenneth E. Department of Physics, Iowa State University.

Last, Prof. John M. Faculty of Health Sciences, School of Medicine/Epidemiology and Community Medicine, University of Ottawa, Ontario, Canada.

Latanision, Prof. R. M. H. H. Ublig Corrosion Laboratory, Department of Materials Science and Engineering, Massachusetts Institute of Technology.

Latham, Dr. David W. Center for Astrophysics, Cambridge, Massachusetts.

Lathl, Prof. B. P. Department of Electrical and Electronic Engineering, California State University, Sacramento.

Lattman, Dr. Laurence H. Dean of Mines, University of Utah.

Laves, Dr. Friz H. Deceased; formerly, Eidg. Technische Hoschschule, Institut fiir Kristallographie und Petrographie, Zurich, Switzerland.

Lavin, Prof. Stephen. Department of Geography, University of Nebraska, Lincoln.

Lavoie, Dr. Ronald L. Chief, Program Requirements and Development Division, U.S. Department of Commerce, National Oceanic and Atmospheric Administration, Silver Spring, Maryland.

Lawley, Dr. Alan. College of Engineering, Drexel University.

Lawrence, Dr. J. Dennis. Lawrence Livermore Laboratory, University of California.

Layton, Dr. J. Preston. Deceased; formerly, RCA Astro-Electronics, Conceptual Design, Princeton, New Jersey.

Layzer, Prof. David. Department of Astronomy, Harvard University.

Lazadder, Prof. Warren J. Department of Engineering Graphics, Purdue University.

Lazarides, Dr. E. Department of Biology, California Institute of Technology.

Leach, Dr. Richard E. Fellow, Reproductive Endocrinology and Fertility, Department of Obstetrics and Gynecology, Mayo Graduate School of Medicine, Rochester, New York.

Leach, Prof. William Marshall, Jr. School of Electrical and Computer Engineering, Georgia Institute of Technology, Atlanta.

Leadbetter, Prof. E. R. Department of Biology, Amherst College.

Leader, Dr. Robert W. Center for Environmental Toxicology, Department of Pathology, Michigan State University.

Lebowitz, Dr. Michael D. Professor of Medicine and Associate Center Director, Respiratory Sciences Center, University of Arizona.

LeBuhn, Dr. Gretchen. Department of Biological Sciences, Florida State University, Tallahassee.

Ledig, Dr. F. Thomas. School of Forestry, Yale University.

Lee, Prof. David M. Department of Physics, Cornell University; Nobelist.

Lee, Dorothy B. Lyndon B. Johnson Space Center, National Aeronautics and Space Administration.

Lee, Dr. Henry C. Director, Connecticut State Police Forensic Laboratory, and Commissioner, Department of Public Safety, Middletown, Connecticut.

Lee, Dr. J. T. Cooperative Institute for Mesoscale Meterological Studies, National Oceanic and Atmospheric Administration, University of Oklahoma.

Lee, Lyndon C. L. C. Lee & Associates, Inc., Seattle, Washington.

Lee, Dr. Roberto. Monsanto Company, St. Louis, Missouri.

Lee, Prof. T. H. Centre for Intelligent Control, Department of Electrical Engineering, National University of Singapore.

Lee, Dr. Tae Young. Department of Chemistry, Seoul National University, Seoul, Korea.

Lee, Dr. Thomas H. Strategic Planning Operation, General Electric Company, Fairfield, Connecticut.

Lee, Dr. W. John. Professor and L. F. Peterson Chair, Department of Petroleum Engineering, Texas A & M University, College Station.

Leete, Prof. Edward. Deceased; formerly, Department of Chemistry, University of Minnesota.

Lefkowitz, Prof. Irving. Systems Engineering Department, Case Western Reserve University.

Legget, Prof. Anthony. Department of Physics, University of Illinois, Urbana.

Lehiste, Prof. Use. Department of Linguistics, Ohio State University.

Lehmann, Prof. Justus F. Department of Rehabilitation Medicine, School of Medicine, University of Washington, Seattle.

Lehn, Prof. Jean-Marie. Collège de France, Paris, and Institut de Science et Ingénierie Supramoléculaires–Université Louis Pasteur, Strasbourg, France; Nobelist.

Lehto, Dr. Mark R. School of Industrial Engineering, Purdue University.

Leibovich, Prof. Sidney. Mechanical & Aerospace Engineering, Cornell University.

Leigh, Dr. Hoyle. Department of Psychiatry, University of California, San Francisco, and Director, Fresno Division, Fresno, California.

Leland, Dr. Henry. Department of Psychology, Ohio State University.

Leland, Dr. Jonathan K. IGEN, Inc., Rockville, Maryland.

Lemont, Prof. Harvey. Chairman, Department of Podiatric Medicine, Pennsylvania College of Podiatric Medicine, Philadelphia.

Lenel, Dr. F. V. Professor Emeritus, Department of Materials Engineering, Rensselaer Polytechnic Institute.

Lennert, Richard. Department of Chemical Engineering, University of Texas, Austin.

Le Noble, Dr. William J. Department of Chemistry, State University of New York, Stony Brook.

Leon, Prof. Roberto T. Roswell, Georgia.

Leonard, Dr. Edward F. Chemical Engineering Department, Columbia University.

Leontis, Dr. Thomas E. Magnesium Research Center, Battelle Columbus Laboratories, Columbus, Ohio.

Leopold, Dr. Luna B. Department of Geology and Geophysics, University of California, Berkeley.

Lepard, Paul E. Mettler Instrument Corporation, Hightstown, New Jersey.

Lerner, Dr. I. Michael. Department of Genetics, University of California, Berkeley.

Lerner-Lam, Dr. Art. Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York.

Lesins, Dr. Glen. Department of Oceanography, Dalhousie University, Halifax, Nova Scotia, Canada.

Lesso, Dr. William G. Department of Mechanical Engineering, University of Texas, Austin.

Levasheff, V. V. American Potash and Chemical Corporation, Whittier, California.

Levi, Prof. Herbert W. Curator in Arachnology, Museum of Comparative Zoology, Agassiz Museum, Harvard University.

Levine, Dr. I. E. Chevron Research Company, Richmond, California.

Levine, Prof. Ira N. Department of Chemistry, Brooklyn College.

Levine, Dr. Norman D. College of Veterinary Medicine, University of Illinois, Urbana.

Levine, Dr. Rachmiel. City of Hope National Medical Center, Duarte, California.

Levitan, Dr. Max. Department of Cell Biology, Mount Sinai School of Medicine, New York.

Lew, Dr. I. Paul. Thornton-Tomasetti, Engineers, New York, New York.

Lewandowski, Dr. Scott M. Department of Computer Science, Brown University, Providence, Rhode Island.

Lewis, Dr. Alcinda C. Institute of Ecosystem Studies, New York Botanical Garden, Millbrook.

Lewis, Prof. Edward B. Department of Biology, California Institute of Technology; Nobelist.

Lewis, Frank D. Consultant, Lexington, Massachusetts.

Lewis, Dr. Frank L. School of Electrical Engineering, Georgia Institute of Technology.

Lewis, Dr. James K. Department of Animal Science, South Dakota State University.

Lewis, Dr. John H. Pratt & Whitney, East Hartford, Connecticut.

Lewis, Prof. M. J. Department of Food Science and Technology, University of California, Davis.

Lewis, Dr. Richard S. Department of Psychology, Pomona College, Claremont, California.

Leventis, Nicholas. Department of Chemistry, University of Missouri, Rolla.

Ley, Dr. Willy. Deceased; formerly, Fairleigh Dickinson University.

Li, Dr. Ching Chun. Graduate School of Public Health, University of Pittsburgh.

Li, Prof. Choh Hao. Deceased; formerly, Hormone Research Laboratory, University of California Medical Center, San Francisco.

Li, Norman N. Director, Separations Research, UOP Inc., World Headquarters, Des Plaines, Illinois.

Lichtenberg, Dr. Don B. Department of Physics, Indiana University.

Liddicoat, Richard T., Jr. Gemological Institute of America, Los Angeles, California.

Liebman, Dr. Joel F. Department of Chemistry and Biochemistry, University of Maryland, Baltimore.

Liedholm, George E. Department Head (retired), Petroleum Processing, Shell Development Company, Emeryville, California.

Lieth, Dr. Helmut. Department of Biochemistry, University of North Carolina.

Liggett, Prof. James A. School of Civil and Environmental Engineering, Cornell University, Ithaca, New York.

Likens, Prof. Gene E. Director, Institute of Ecosystem Studies, The New York Botanical Garden, Millbrook, New York.

Liley, Prof. Peter E. Lafayette, Indiana.

Limpel, Eugene J. Consulting Electrical Engineer, Eagle River, Wisconsin.

Lin, Wen-Hwang. Rocketdyne Propulsion & Power, The Boeing Company, Canoga Park, California.

Linde, Dr. Ronald K. President, Envirodyne, Inc., Los Angeles, California.

Lindenmaier, Dr. Werner A. Hoffmann-LaRoche, Inc., Nutley, New Jersey.

Linderorth, Prof. L. Sigfred, Jr. (Retired) Department of Mechanical Engineering, Duke University.

Lindner, Dr. Hans R. Department of Biodynamics, Weizmann Institute of Science, Rehovoth, Israel.

Lindsey, J. S. Liquid Carbonic Corporation, Chicago, Illinois.

Lindsay, Prof. R. Bruce. Deceased; formerly, Hazard Professor of Physics, Emeritus, Brown University.

Lindzen, Prof. Richard S. Center for Meteorology and Physical Oceanography, Massachusetts Institute of Technology.

Lineback, Dr. David R. Department of Food Science, North Carolina State University.

Lineberger, Dr. W. C. Joint Institute for Laboratory Astrophysics, National Institute for Standards and Technology, University of Colorado.

Lines, Malcom E. Bell Telephone Laboratories, Murray Hill, New Jersey.

Linskey, Dr. Jeffrey. Department of Astrophysics, University of Colorado, Boulder.

Linsley, Prof. Ray K. Department of Civil Engineering, Stanford University.

Linthicum, Jack M. Office of Science and Technology, Federal Communications Commission.

Liou, Dr. J. G. Department of Earth and Planetary Sciences, Tokyo Institute of Technology, Japan.

Liou, Juhn G. Department of Geology, Stanford University.

Liou, Prof. Kuo-Nan. Department Chair, Department of Atmospheric Sciences, University of California, Los Angeles.

Lipin, Bruce R. U.S. Department of the Interior, Reston, Virginia.

Lipkens, Dr. Bart. Assistant Professor, Department of Mechanical Engineering, Virginia Commonwealth University, Richmond, Virginia.

Lipkowitz, Prof. Kenneth B. Department of Chemistry, Indiana-Purdue University, Indianapolis.

Lipner, Prof. Harry J. Department of Biological Science, Florida State University.

Lipshutz, Prof. Bruce H. Department of Chemistry, University of California, Santa Barbara.

Lister, Prof. C. J. A. W. Wright Nuclear Structure Laboratory, Physics Department, Yale University.

Litherland, Prof. Albert E. Director, Isotrace Laboratory, Department of Physics, University of Toronto, Ontario, Canada.

Little, Elbert L., Jr. Dendrologist, Forest Service, U.S. Department of Agriculture.

Little, Dr. James N. Research Division, Waters Associates, Milford, Massachusetts.

Liu, Benjamin Y. H. Department of Mechanical Engineering, University of Minnesota.

Liu, Prof. Clark C. K. Department of Civil Engineering, University of Hawaii at Manoa.

Liu, Dr. Sam H. Department of Physics, Iowa State University.

Liu, Dr. Tanzhuo. Lamont-Doherty Earth Observatory, Columbia University, Palisades, New York.

Livingston, Dr. William C. National Optical Astronomy Observatories, National Solar Observatory, Tucson, Arizona.

Ljung, Dr. Donovan A. Fermi National Accelerator Laboratory, Batavia, Illinois.

Lochhead, Dr. Allan G. Microbiology Research Institute, Canada Department of Agriculture, Ottawa, Ontario.

Lochhead, Dr. John H. London, England.

LoCicero, Prof. Joseph L. Illinois Institute of Technology, Electrical and Computer Engineering Department, Chicago.

Lockhart, Prof. Frank J. Department of Chemical Engineering, University of Southern California.

Loeb, John L. ACLS Corporation, Silver Spring, Maryland.

Loeblich, Dr. Alfred R., Jr. Department of Earth and Space Sciences, University of California, Los Angeles.

Loewenstein, Dr. Werner R. College of Physicians and Surgeons, Columbia University.

Loftus, Dr. Douglas J. Laboratory of Cell Biology, National Cancer Institute, Bethesda, Maryland.

Loftus, Prof. Elizabeth F. Professor of Psychology, Department of Psychology, University of Washington, Seattle.

Logan, Prof. Earl, Jr. Department of Aerospace and Mechanical Engineering, Arizona State University, Tempe.

Loneragan, Prof. J. F. School of Environmental and Life Science, Murdoch University, Perth, Australia.

Long, Prof. Franklin A. Formerly, Department of Chemistry, Cornell University.

Long, Joseph B. Consultant, Columbus, Ohio.

Longacre, Alan. (Retired) Fluor Engineers and Constructors, Irvine, California.

Longmoore, Dr. Kenneth. Department of Chemistry, University of Massachusetts.

Longo, Dr. Dan L. Director, National Cancer Institute, Frederick Cancer Research Facility, Maryland.

Longo, Luca. Instituto Guido Donegani, EniChem, Polymeric Materials Department, Novara, Italy.

Lonngren, Prof. Karl E. Department of Electrical and Computer Engineering, University of Iowa, Iowa City.

Lonsdale, Dr. Carol J. Infrared Processing & Analysis Center, California Institute of Technology, Pasadena.

Lonsdale, Dr. Peter. Scripps Institution of Oceanography, La Jolla, California.

Loope, Dr. David B. Department of Geology, University of Nebraska Medical Center.

Lopiano, Dr. Michael. Chairman, Public Information Committee, American College of Radiology, Reston, Virginia.

Lopresti, Dr. Philip V. Retired; formerly, Engineering Research Center, AT&T Bell Laboratories, Princeton, New Jersey.

Lorand, Dr. L. Department of Biochemistry and Molecular Biology, Northwestern University.

Lord, Prof. Richard C. Department of Chemistry, Massachusetts Institute of Technology.

Lordi, George M. Department of Medicine, College of Medicine and Dentistry, Newark, New Jersey.

Lorenz, Prof. Oscar A. Department of Vegetable Crops, University of California, Davis.

Lotz, Dr. Martin. Department of Molecular and Experimental Medicine, Research Institute of Scripps Clinic, La Jolla, California.

Loughlin, James E. Chemical Process Pilot Plant, Textile Research Center, Texas Tech University.

Love, Dr. Jeffrey J. Institute of Geophysics and Planetary Physics, University of California, San Diego.

Lovell, Dr. Mark A. Director, Diagnostic Molecular Pathology Laboratory, Department of Pathology, University of Virginia Health Sciences Center, Charlottesville.

Lowan, Dr. Arnold N. Deceased; formerly, Chairman, Department of Physics, Yeshiva University.

Lowe, Christopher R. Institute of Biotechnology, Cambridge University, England.

Lowe, Dr. David A. Department of Fermentation Development, Industrial Division, Bristol-Myers Squibb Company, Syracuse, New York.

Lowell, Cadence A. Department of Biology, Central State University, Wiberforce, Ohio.

Lowell, Prof. Wayne R. Department of Geology, Indiana University.

Lowenstein, Prof. Otto E. Department of Zoology, University of Birmingham, England.

Lowenthal, Dr. David. Research Associate, American Geographical Society, New York.

Luanda, Dr. Robert E. Director of Extractive Research and Development, Zinc Smelting Division, St. Joseph Minerals Corporation, Monaca, Pennsylvania.

Luban, Prof. Naomi L. C. Department of Laboratory Medicine, Transfusion Medicine, Children's Hospital, George Washington University Medical Center, Washington, D.C.

Luborsky, Dr. Fred E. Research and Development Center, General Electric Company, Schenectady, New York.

Lucas, Dr. Spencer G. New Mexico Museum of Natural History, Albuquerque, New Mexico.

Luckenbach, Edward C. Exxon Research and Engineering Company, Florham Park, New Jersey.

Ludlam, Prof. Frank H. Deceased; formerly, Department of Meteorology, Imperial College, London, England.

Ludvik, Dr. George F. Insecticide Application Research, Agricultural Research and Development Department, Monsanto Company, St.

Luebbers, Dr. Ralph H. Department of Chemical Engineering, University of Missouri.

Lunte, Dr. Susan M. Associate Director, Center for Bioanalytical Research, University of Kansas, Lawrence.

Luo, Dr. Zhexi. Section of Vertebrate Fossils, Carnegie Museum of Natural History, Pittsburgh, Pennsylvania.

Lusted, Dr. Lee B. Department of Radiology, University of Chicago.

Luth, Dr. William. Department of Earth Sciences, Stanford University.

Luthin, Prof. James N. Department of Civil Engineering, University of California, Davis.

Lutter, Dr. Leonard. Molecular Biology Research Program, Henry Ford Hospital, Detroit, Michigan.

Luttge, Prof. Ulrich. Institut für Botanik, Technische Hochschule Darmstadt, Darmstadt, Germany.

Luu, Dr. Jane. Astronomy Department, University of Leiden, Netherlands.

Lykken, Dr. David T. Department of Psychiatry, University of Minnesota, Minneapolis.

Lyman, Prof. Charles P. Department of Medical Sciences, Harvard University.

Lyman, Dr. John. Department of Oceanography, University of North Carolina.

Lynds, Dr. Beverly T. Center for Astrophysics and Space Astronomy, University of Colorado.

Lyon, Dr. W. S. Analytical Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Lyon, Dr. Waldo. Arctic Submarine Research Laboratory, Naval Undersea Warfare Center, San Diego, California.

Lyons, Prof. Walter. Consultant in Telecommunications, Flushing, New York.

Lyons, Dr. Walter A. Certified Consulting Meteorologist, Forensic Meteorology Associates, Fort Collins, Colorado.

M

Ma, Dr. Yi Hua. Department of Chemical Engineering, Worcester Polytechnic Institute.

MacCarthy, Donnell D. Manager, Voltage Regulator Engineering, Voltage Regulator Product Section, General Electric Company, Pittsfield, Massachusetts.

MacCoull, Neil. Deceased; formerly, Lecturer in Mechanical Engineering, Columbia University.

MacCrone, Prof. Robert K. Department of Physics, Rensselaer Polytechnic Institute.

MacDaniels, Dr. Lawrence H. Professor Emeritus of Floriculture and Ornamental Horticulture, Cornell University.

Macdonald, Dr. Gordon A. Deceased; formerly, Institute of Geophysics, University of Hawaii.

MacDonald, Dr. J. M. Small Animal Clinic, Auburn University, Auburn, Alabama.

MacDonald, Prof. Robert C. Department of Biochemistry, Molecular and Cell Biology, Northwestern University.

MacDonald Ruby I. Department of Biochemistry, Molecular, and Cell Biology, Northwestern University.

Macdoughall, Prof. J. Douglas. Geological Research Division, Scripps Institution of Oceanography, La Jolla, California.

MacDowell, Dr. Samuel W. Department of Physics, Yale University.

Macher, Dr. Abe M. Medical Consultant, AIDS Education and Training Centers Programs, U.S. Public Health Service, Rockville, Maryland.

Machiels, Albert. Nuclear Engineer, Nuclear Radiation Laboratory, University of Illinois, Urbana-Champaign.

Machlin, Dr. Laurence J. Department of Vitamins and Clinical Nutrition, Hoffmann-LaRoche, Inc., Nutley, New Jersey.

Mackay, Dr. Ian R. Center for Molecular Biology and Medicine, Monash University, Clayton, Australia.

MacKenzie, Prof. Innes K. Department of Physics, University of Guelph, Ontario, Canada.

Mackey, Prof. George W. Department of Mathematics, Harvard University.

Mackhann, Prof. Guy Mead. Neurology Department, Johns Hopkins Hospital, Baltimore, Maryland.

Madanshetty, Prof. Sameer I. Department of Aerospace and Mechanical Engineering, Boston University, Boston, Massachusetts.

Maddalon, Dal V. NASA Langley Research Center, Hampton, Virginia.

Maderson, Dr. Paul F. Department of Biology, Brooklyn College.

Madestau, L. Deceased; formerly, Chemicals and Plastics Division, Union Carbide Corp., Bound Brook, New Jersey.

Madin, Dr. Laurence P. Associate Science, Biology Department, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.

Madison, Dr. John H. Environmental Horticulture Department, University of California, Davis.

Madison, Dr. Vincent. Department of Medicinal Chemistry, School of Pharmacy, University of Illinois, Chicago.

Madore, Dr. Barry F. NASA/IPAC Extragalactic Database, Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California.

Magee, Paul T. Department of Microbiology, School of Medicine, Yale University.

Maggenti, Dr. Armand R. Division of Nematology, University of California, Davis.

Mahle, Dr. Christoph E. COMSAT Laboratories, Clarksburg, Maryland.

Mahmoud, Dr. Aly A. School of Engineering, Indiana University-Purdue University of Fort Wayne.

Mahoney, Dr. Lee R. Chemistry Department, Ford Motor Company, Dearborn, Michigan.

Maisey, Dr. John G. Assistant Curator, American Museum of Natural History, New York.

Major, Dr. Jack. Department of Botany, University of California, Davis.

Makulec, Alfred. Product Planning and Application Specialist, Large Lamp Department, General Electric Company, Cleveland, Ohio.

Malacinski, Dr. George M. Department of Biology, Indiana University.

Maldonado-Moll, Dr. Jose F. Special Assistant for Science and Technology, Sistema Universitario de la Fundacion Educative Ana G. Mendez Rio Piedras, Puerto Rico.

Malin, Dr. David F. Anglo-Australian Observatory, Epping, Australia.

Malina, Prof. Robert M. Department of Anthropology, University of Texas.

Mamantov, Dr. Gleb. Chemistry Department, University of Tennessee.

Mamay, Dr. Sergius H. U.S. Geological Survey, National Museum.

Mandel, Dr. Manley. Department of Biology, M.D. Anderson Hospital, Houston, Texas.

Mandler, Dr. George. Department of Psychology, University of California, San Diego.

Mangion, Charles. Technology Laboratory, Science and Technology Division, Systems Group, TRW, Inc., Redondo Beach, California.

Mangum, B. W. Leader, Thermometry Group, Prouss Measurement Division, National Institute of Standards and Technology, Gaithersburg, Maryland.

Mann, Prof. Alfred K. Department of Physics, University of Pennsylvania.

Mann, Dr. Kenneth H. Fisheries Research Board of Canada, Dartmouth, Nova Scotia.

Mann, Prof. Robert W. Department of Mechanical Engineering, Massachusetts Institute of Technology.

Mann, Prof. Stephen. School of Chemistry, University of Bath, United Kingdom.

Mann, William R. Rockwell International Corporation, New Port Beach, California.

Mannheim, Prof. Walter. Med. Zentrum filr Hygiene, Universitat Marburg, Germany.

Manning, Dr. James M. Department of Biochemistry, Rockefeller University.

Manning, Dr. Kenneth V. Professor Emeritus, Pennsylvania State University.

Manning, Dr. Paul D. V. Professor of Chemical Engineering (retired), California Institute of Technology.

Mansfield, Steve. American Radio Relay League, Inc., Newington, Connecticut.

Manson, Dr. John A. Deceased; formerly, Department of Chemistry, Lehigh University.

Mansouri, Freydoon. Department of Physics, Yale University.

Manspeizer, Prof. Warren. Department of Geological Sciences, Faculty of Arts and Sciences, Rutgers University.

Mantell, Dr. Charles L. President, C. L. Mantell and Associates, Manhasset, New York.

Mantler, Dr. Michael. Institut für Angewandte und Technische Physik, Technische Universität Wien, Austria.

Manwell, Dr. Reginald D. Department of Zoology, College of Liberal Arts, Syracuse University.

Maple, M. Brian. Department of Physics, University of California, San Diego.

Maramorosch, Dr. Karl. Department of Entomology, Rutgers University, New Brunswick, New Jersey.

March-Russell, Dr. John. Theory Division, CERN, Geneva, Switzerland.

Marchalonis, Dr. John J. Chairperson, Department of Biochemistry, Medical University of South Carolina.

Marchand, Prof. Alan P. College of Arts and Sciences, Department of Chemistry, University of Texas, Denton.

Marcus, Prof. Ernesto. Deceased; formerly, Department of Zoology, University of Sao Paulo, Brazil.

Marcus, Eveline. Department of Zoology, University of Sao Paulo, Brazil.

Marcus, Prof. Marvin. Department of Computer Science, University of California, Santa Barbara.

Marden, Dr. Albert. School of Mathematics, University of Minnesota.

Marek, Dr. John M. Independent Mining Consultants, Inc., Tucson, Arizona.

Margai, Prof. Florence Lansana. Department of Geography, State University of New York at Binghamton.

Margenau, Prof. Henry. Department of Physics, Yale University.

Margolis, Prof. Simeon. Endocrinology and Metabolism, Johns Hopkins University, Baltimore, Maryland.

Margollash, Dr. E. Department of Biochemistry, Northwestern University.

Margon, Dr. Bruce. Space Sciences Laboratory, University of California, Berkeley.

Margrave, Prof. John L. Dean of Research, Rice University.

Marino, Dr. Paul. Department of Biology, College of Charleston, South Carolina.

Mariño, Prof. Miguel A. Hydrology Program, University of California, Davis.

Maris, Prof. Humphrey J. Department of Physics, Brown University.

Mark, Dr. J. Carson. Member of the Advisory Committee, Reactor Safeguards of U.S. Nuclear Regulatory Commission, Los Alamos, New Mexico.

Markert, Prof. Clement L. Department of Biology, Yale University.

Markovitz, Dr. Hershel. Department of Chemistry, Carnegie-Mellon University.

Markowitz, Dr. William. Oceanographic Center, Nova University; Editor, “Geophysical Surveys.” Marks, Lawrence E. Pierce Foundation, New Haven, Connecticut.

Marks, Dr. Jonathan. Department of Sociology and Anthropology, University of North Carolina at Charlotte.

Marks, Dr. Tobin J. Department of Chemistry, Northwestern University.

Markus, John. Deceased; formerly, Consultant (retired), Sunnyvale, California.

Marsh, Don. Media Services Representative, Portland Cement Association, Skokie, Illinois.

Marsh, Dr. Kenneth N. Thermodynamic Research Center, Texas A & M University.

Marshak, Dr. Harvey. National Bureau of Standards.

Marshall, Dr. H. G. Crops Research Division, Agricultural Research Service and Department of Agronomy, Pennsylvania State University.

Marshall, Dr. Norman B. Retired; formerly, Senior Principal Scientific Officer, British Museum of Natural History, London, England.

Marshall, Peter L. Independent Consultant, Granville, Ohio.

Marshall, Prof. William R., Jr. Associate Dean, College of Engineering, University of Wisconsin.

Marsland, Charles R. Chief Technical Consultant, Handy and Harman, Fairfield, Connecticut.

Martell, Dr. A. E. Department of Chemistry, Texas A&M University.

Martin, Prof. C. Samuel. School of Civil Engineering, Georgia Institute of Technology, Atlanta.

Martin, Dr. Daniel W. Acoustics Consultant, Cincinnati, Ohio.

Martin, Franklin W. Mayaguez Institute of Tropical Agriculture, Mayaguez, Puerto Rico.

Martin, Dr. Peter G. McLennon Physical Laboratories, Canadian Institute for Theoretical Physics, University of Toronto, Canada.

Martin, Prof. R. D. Anthropologisches Institut, Universitat Zurich-Irchel, Zurich, Switzerland.

Martin, R. G. National Institutes of Health, Bethesda, Maryland.

Martin, Prof. Richard J. Division of Neonatology, Rainbow Babies and Childrens Hospital, University Hospitals of Cleveland, Ohio.

Martin, Stanley B. Stanford Research Center, Menlo Park, California.

Martínez-Carrera, Dr. D. College of Postgraduates in Agricultural Sciences, Mushroom Biotechnology, Puebla, Mexico.

Maruyama, Prof. Shige. Department of Earth and Planetary Sciences, Tokyo Institute of Technology, Tokyo, Japan.

Marvier, Dr. Michelle A. Department of Biology, Santa Clara University, Santa Clara, California.

Marx, Dr. Preston A. California Primate Research Center, University of California, Davis.

Marzilli, Dr. Luigi G. Department of Chemistry, Emory University.

Marzilli, Dr. Patricia A. Department of Chemistry, Emory University.

Mascarenhas, Prof. Joseph P. Department of Biological Sciences, State University of New York, Albany.

Mashhoon, Prof. Bahram. Department of Physics and Astronomy, College of Arts and Sciences, University of Missouri—Columbia.

Mason, Dr. Basil J. Program Director, Center for Environmental Technology, Imperial College of Science and Technology, London, England.

Massey, Dr. Vincent. Department of Biological Chemistry, University of Michigan.

Massion, Dr. Jean. Laboratoire de Neurobiologie et Mouvements, Centre de Recherche en Neurosciences Cognitives, Marseille, France.

Mast, Dr. Roy C. Miami Valley Laboratories, Proctor and Gamble Company, Cincinnati, Ohio.

Masters, Dr. Colin L. Head of the National Creutzfeldt-Jakob Disease Registry, Department of Pathology, University of Melbourne, Australia.

Masucci, Dr. Maria G. Microbiology and Tumor Biology Center, Karolinska Institute, Stockholm, Sweden.

Mata-Toledo, Dr. Ramon A. Associate Professor of Computer Science, James Madison University, Harrisonburg, Virginia.

Mattei, Dr. Janet Akyüz. Director, American Association of Variable Star Observers, Cambridge, Massachusetts.

Matyas, Stephen M. IBM Systems Communications Division, Kingston, New York.

Mauchline, Dr. John. Scottish Association for Marine Science, Argyll, Scotland.

Mauk, Dr. Craighton S. Research Associate, Department of Horticultural Science, Mountain Horticultural Crops Research and Extension Center, School of

Agriculture and Life Sciences, North Carolina State University, Fletcher.
Maul, Prof. George A. Director, Division of Marine and Environmental Systems, Florida Institute of Technology, Melbourne.
Maurer, Dr. Brian A. Department of Fisheries and Wildlife, Michigan State University, East Lansing.
Mausner, Dr. Leonard F. Radionuclide/Radiopharmaceutical Research, Brookhaven National Laboratory, Upton, New York.
May, Prof. Bella J. Department of Physical Therapy, Medical College of Georgia, Augusta.
May, F. H. Consultant, Kerr-McGee Corporation, Whittier, California.
May, James E. Lockheed-California Company, Burbank, California.
Mayall, Robert N. Director, Planning and Research Associates, Boston, Massachusetts.
Mayer, Dr. Rudolph L. Deceased; formerly, Leonard Wood Memorial Hospital, Washington, D.C.
Maykuth, Daniel. Tin Research Institute, Inc., Columbus, Ohio.
Maynard, Dr. Harold B. President, Maynard Research Council, Inc., Pittsburgh, Pennsylvania.
Mays, Rolland L. Materials Systems Division, Union Carbide Corporation, Tarrytown, New York.
Mazzo, Anthony. Urban Substructures, Inc., East Elmhurst, New York.
McAlister, Prof. Harold A. Director, Center for High Angular Resolution Astronomy, Georgia State University, Atlanta.
McBride, Dr. Earle F. Department of Geology, University of Texas, Austin.
McCabe, Dr. Allyssa. Eliot-Pearson Department of Child Study, Tufts University.
McCabe, Dr. Warren L. Deceased; formerly, Department of Chemical Engineering, North Carolina State University.
McCann, Dr. Mary B. Nutrition Program, Center for Disease Control, Health Services and Mental Health Administration, U.S. Department of Health, Education and Welfare, Rockville, Maryland.
McCarthy, Dr. Dennis D. Time Service Division, U. S. Naval Observatory, Washington, D.C.
McCarthy, Dr. John. National Center for Atmospheric Research, Boulder, Colorado’.
McCarthy, Prof. Kathryn A. Professor of Physics, and Dean of Graduate School of Arts and Sciences, Tufts University.
McCarty, Dr. John E. Structure Staff Supervisor, Boeing Company, Renton, Washington.
McClain, Prof. Thomas E. Head, Department of Forest Products, Oregon State University, Corvallis.
McClellan, Leslie N. Consulting Engineer, Engineering Consultants, Inc., Denver, Colorado.
McClung, Dr. Leland S. Professor Emeritus, Department of Microbiology, Indiana University.
McClure, Dr. Michelle. Northwest Fisheries Science Center, Seattle, Washington.
McConnaughey, Dr. Bayard H. Department of Biology, University of Oregon.
McCormick, Prof. Barnes W., Jr. Department of Aerospace Engineering, Pennsylvania State University.
McCormick, Dr. Thomas R. Department of Biomedical History, School of Medicine, University of Washington.
McCoy, Prof. Barry M. Division of Engineering and Applied Physics, Harvard University.
McDonald, Prof. Alan T. School of Mechanical Engineering, Purdue University.
McDonald, Prof. John J. Retired; formerly, Head, Textile Engineering Department, University of Lowell.
McDowell, Dr. Robin S. Senior Chief Scientist, Chemical Structure and Dynamics, Molecular Science Research Center, Battelle Pacific Northwest Laboratories, Richland, Washington.
McEvilly, Dr. Thomas V. Department of Geology, University of California, Berkeley.
McEwan, Prof. Robert S. Deceased; formerly, Professor Emeritus, Oberlin College.
McEwen, Dr. Bruce. Harold and Margaret Milliken Hatch Laboratory of Neuroendocrinology, Rockefeller University, New York.
McFarland, Dr. Richard H. Director Emeritus, Avionics Engineering Center, Ohio University, Athens.
McGannon, Harold E. Technical Editor, Research and Technology Division, United States Steel Corporation, Pittsburgh, Pennsylvania.
McGaugh, Dr. James L. Department of Psychobiology, University of California, Irvine.
McGinley, Dr. John A. Chief, Forecast Research Group, National Oceanic and Atmospheric Administration, Environmental Research Laboratory, Boulder, Colorado.
McGinnies, Dr. William G. Professor of Dendrochronology and Arid Land Ecologist, Office of Arid Land Studies, University of Arizona.
McGinnis, Prof. William. Department of Molecular Biophysics and Biochemistry, Yale University.
McGuire, Ann B. Aquaculture Program, University of California, Davis.
McHugh, Dr. J. L. Marine Sciences Research Center, State University of New York, Stony Brook.
McIntire, Prof. Larry V. Chairperson, Institute of Biosciences and Bioengineering, Rice University, Houston, Texas.
McIntosh, Prof. J. Richard. Department of Molecular, Cellular and Developmental Biology, Laboratory for High-Voltage Electron Microscopy, University of Colorado at Boulder.
McIntyre, Dr. Andrew. Lamont-Doherty Geological Observatory, Palisades, New York; Queens College of the City University of New York.
McKenna, Dr. Malcolm C. Frick Curator, American Museum of Natural History, New York.
McKesson, Chris B. John J. McMullen Associates, Bremerton, Washington.
McKinney, Dr. Chester M. Retired; formerly, Applied Research Laboratories, University of Texas, Austin.
McKinney, Prof. Frank K. Department of Geology, Appalachian State University, Boone, North Carolina.
McKnight, Prof. Tom. Department of Geography, University of Caifornia, Los Angeles, California.
McLaughlin, Dr. Patsy. Shannon Point Marine Center, Western Washington University, Anacortes.
McMahon, Dr. John F. Deceased; formerly, New York State Technical Service Program, Alfred, New York.
McNamara, Dr. Ken J. Senior Curator, Invertebrate Paleontology, Western Australian Museum, Perth, Western Australia.
McNamara, Dr. Peter. Department of Medical Microbiology, University of Wisconsin, Madison.
McNaughton, Prof. Samuel J. Department of Biology, Syracuse University.
McNellis, Dr. Donald. Center for Research of Mothers and Children, National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland.
McPartland, Brian J. Electrical Design and Installation, Englewood Cliffs, New Jersey.
McPartland, Joseph F. Electrical Design and Installation, Englewood Cliffs, New Jersey.
McPherson, Prof. George, Jr. Department of Electrical Engineering, School of Engineering, University of Missouri.
McQuillan, James P. AT&T Federal Systems, Washington, D.C.
McVey, Charles I. Fluorescent and High Intensity Systems Department, General Electric Company, Twinsburg, Ohio.
McWilliams, Dr. Michael O. Department of Geophysics, School of Earth Sciences, Stanford University.
Meade, Dr. Thomas J. Division of Chemistry and Chemical Engineering, California Institute of Technology.
Mebus, Dr. Charles A. Laboratory Chief, Foreign Animal Disease Diagnostic Laboratory, U.S. Department of Agriculture, Greenport, New York.
Meeus, Dr. Jean. Consultant, Erps-Kwerps, Belgium.
Meeuse, Dr. Bastiaan J. D. Department of Botany, University of Washington.
Meggers, Dr. William F. Deceased; formerly, National Bureau of Standards.

Mehra, Prof. Raman K. President, Scientific Systems, Inc., Cambridge, Massachusetts.

Meijer, Prof. Paul H. E. Department of Physics, Catholic University of America.

Meijer, Dr. Roelof J. Assistant Director of Research, Philips Research Laboratories, Eindhoven. Netherlands.

Meiklejohn, Dr. Jane. Senior Research Fellow, University College, Salisbury, Rhodesia.

Meinke, Dr. David. Department of Botany and Microbiology, Oklahoma State University.

Meinke, Dr. W. Wayne. Analytical Chemistry Division, National Bureau of Standards.

Meinwald, Dr. J. Department of Chemistry, Cornell University.

Meisel, Dr. David D. Department of Physics and Astronomy, State University of New York, Genesee.

Meisel, Dr. Jerome. Department of Electrical and Computer Engineering, Wayne State University.

Meissner, Dr. Hans W. Department of Physics, Stevens Institute of Technology, Hoboken, New Jersey.

Meixner, Dr. Josef. Director, Institute of Theoretical Physics, Aachen, Germany.

Melander, John. Portland Cement Association, Skokie, Illinois.

Mellichamp, Prof. Duncan. Department of Chemical and Nuclear Engineering, University of California, Santa Barbara.

Melnick, Dr. Joseph L. Department of Virology and Epidemiology, Baylor College of Medicine.

Melosh, Prof. H. J. Lunar and Planetary Laboratory, University of Arizona, Tucson.

Meltzer, Dr. David J. Department of Anthropology, Southern Methodist University, Dallas, Texas.

Menkes, Joshua. Science and Technology Division, Institute for Defense Analyses, Arlington, Virginia.

Menzies, Dr. Robert J. Department of Zoology, Duke University.

Merold, John. M. Rosenblatt and Son, Inc., Arlington, Virginia.

Merritt, Frederick S. Consulting Engineer, West Palm Beach, Florida.

Merwin, Earl J. McCormick and Company, Hunt Valley, Maryland.

Mescher, Prof. Anthony L. Anatomy Section, School of Medicine, Medical Sciences Program, Indiana University.

Messenger, Dr. George C. Vice President and Technical Director, Messenger & Associates, Las Vegas, Nevada.

Messenger, Dr. John B. Department of Zoology, University of Sheffield, United Kingdom.

Messerschmitt, Prof. David. Department of Electrical Engineering and Computer Science, University of California, Berkeley.

Metcalf, William G. Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.

Metzger, Dr. James D. Research Physiologist, U.S. Department of Agriculture, Agricultural Research Service, Biosciences Research Laboratory, Fargo, Indiana.

Meyer, Dr. Bernard S. Department of Botany, Ohio State University.

Meyer, Dr. Carl H. Advisory Engineer, IBM Systems Communications Division, Kingston, New York.

Meyer, Dr. David B. Department of Anatomy, Wayne State University School of Medicine.

Meyer, Prof. Henry O. A. Department of Earth and Atmospheric Sciences, Purdue University.

Meyer, Dr. John F. Department of Electric Engineering and Science, College of Engineering, University of Michigan.

Meyer, Dr. Judy L. Institute of Ecology, University of Georgia.

Meyer, Dr. Karl F. Deceased; formerly, Professor Emeritus of Experimental Pathology, George Williams Hooper Foundation, San Francisco Medical Center, University of California.

Meyers, Dr. Edward. Research Group Leader, Department of Microbiology Squibb Institute, New Brunswick, New Jersey.

Miall, Dr. Andrew D. Department of Geology, University of Toronto, Ontario, Canada.

Michalec, James R. American Electric Power Company, Columbus, Ohio.

Middleton, Dr. Gerard V. Department of Geology, McMaster University, Hamilton, Ontario, Canada.

Mikos, Prof. Antonios G. Director of John W. Cox Laboratory of Biomedical Engineering, Department of Chemical Engineering, Rice University, Houston, Texas.

Miles, Lawrence D. Engineering Consultant, Easton, Maryland.

Miles, Thomas K. Shell Development Company.

Mill, Dr. George S. Research Chemist, Shell Oil Company, New York.

Miller, Barry. Formerly, Senior Editor, “Aviation Week and Space Technology,” McGraw-Hill Publications Company, Los Angeles, California.

Miller, Dr. Clyde A. Falls Church, Virginia.

Miller, Dr. David A. B. AT&T Bell Laboratories, Holmdel, New Jersey.

Miller, Dr. Dorothy A. Wayne State University School of Medicine, Center for Molecular Medicine and Genetics, Detroit, Michigan.

Miller, Prof. Erwin W. Deceased; formerly Department of Physics, Pennsylvania State University.

Miller, Dr. Frederick R. Department of Soil and Crop Sciences, Texas A&M University.

Miller, Dr. Glenn H. Weapons Effects Division, Sandia National Laboratories, Albuquerque, New Mexico.

Miller, Prof. J. Creighton, Jr. Texas Agricultural Experiment Station, Department of Horticultural Science, College of Agriculture, Texas A & M University.

Miller, Dr. Julian C. Department of Horticulture, Louisiana State University.

Miller, Prof. Maynard M. Department of Geology, Michigan State University; Director, Foundation for Glacial and Environmental Research, Seattle, Washington.

Miller, Dr. Milton A. Department of Zoology, University of California, Davis.

Miller, Prof. Orlando J. Wayne State University School of Medicine, Center for Molecular Medicine and Genetics, Detroit, Michigan.

Miller, R. A. Engineering Department, Babcock and Wilcox, Barberton, Ohio.

Miller, Dr. Regis B. Project Leader, Center for Wood Anatomy Research, Forest Products Laboratory, U.S. Department of Agriculture, Forest Service, Madison, Wisconsin.

Miller, Dr. Richard A. Lawrence Berkeley National Laboratory, University of California, Berkeley.

Miller, Dr. Shelby A. Argonne National Laboratory, Argonne, Illinois.

Miller, Prof. Sidney I. Department of Chemistry, Illinois Institute of Technology.

Miller, Terry A. AT&T Bell Laboratories, Murray Hill, New Jersey.

Miller, Thomas E. Department of Biological Sciences, Florida State University, Tallahassee.

Milliard, Dr. Ron. Optomechanics Research Inc., Vail, Arizona.

Milligan, Dr. W. O. Robert A. Welch Foundation, Houston, Texas.

Millman, Dr. Jacob. Department of Electrical Engineering, Columbia University.

Mills, Dr. Dennis. Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois.

Mills, Dr. Harlow B. State Natural History Survey, Urbana, Illinois.

Mills, Prof. Ian M. Department of Chemistry, University of Reading, United Kingdom.

Mills, Thomas B. National Semiconductor Corporation, Santa Clara, California.

Milsom, Dr. William K. Department of Zoology, University of British Columbia, Vancouver, Canada.

Milstein, Prof. Laurence B. Department of Electrical and Computer Engineering, University of California, San Diego.

Milster, Dr. Tom D. Optical Data Storage Center, Optical Sciences Center, University of Arizona, Tucson.

Milus, Dr. E. A. Department of Plant Pathology, University of Arkansas, Fayetteville.

Minifie, Bernard W. Knechtel Laboratories, Bristol, England.

Minkler, Ward W. Vice President, TIMET, Pittsburgh, Pennsylvania.

Minnis, Dr. Wesley. Formerly, Assistant to the Director of Research and Development, Allied Chemical Corporation, New York.

Mitchell, Dr. Charles E. Department of Geology, State University of New York at Buffalo.

Mitchell, Dr. Jeffrey C. Spaceport Graduate Center, Florida Institute of Technology, Satellite Beach.

Mitchell, Dr. Malcolm S. Comprehensive Cancer Center, Kenneth Norris, Jr. Cancer Research Institute, University of Southern California, Los Angeles.

Mitsch, Prof. William J. Graduate Program Environmental Science, School of Natural Resources, Ohio State University, Columbus.

Mitterer, Dr. Richard M. Department of Geosciences, University of Texas, Dallas.

Miyawaki, Dr. Ritsuro. Department of Geology, National Science Museum, Tokyo, Japan.

Mizell, Dr. David W. Project Leader, University of Southern California/ Information Sciences Institute, Marina del Rey.

Moder, Dr. Joseph J. Chairman, Department of Management Science, University of Miami.

Moe, Dr. Richard L. Department of Botany, University of California, Berkeley.

Moffat, Dr. Anthony F. J. Department de Physique, Université

Moffett, Dr. Mark B. Naval Underwater Systems Center, New London Laboratory, New London, Connecticut.

Moh, Dr. Za-Chieh. Moh & Associates, Inc., Oriental Technopolises Tower, Taipei, Taiwan.

Mohanakumar, Dr. T. Department of Surgery, Washington University School of Medicine, St. Louis, Missouri.

Mohr, Prof. David W. Department of Geology, Texas A & M University.

Mohr, Prof. Peter. Department of Physics, Yale University.

Moll, Dr. Gary A. Director, Urban and Community Forestry, American Forestry Association, Washington, D.C.

Møllar, Prof. Aage R. Department of Neurological Surgery, University of Pittsburgh.

Moment, Dr. Gairdner B. Department of Biological Sciences, Goucher College, Towson, Maryland.

Montville, Dr. Thomas J. Department of Food Science, Cook College, Rutgers University.

Mood, Dr. Alexander M. Director, Public Policy Research Organization, University of California, Irvine.

Moody, Capt. Alton B. Navigation Consultant, La Jolla, California.

Mook, Dr. Douglas G. Department of Psychology, University of Virginia.

Moore, Dr. Alice E. Sloan-Kettering Institute of Cancer Research, New York.

Moore, Prof. Charles A. Department of Civil Engineering, Ohio State University.

Moore, Prof. Clyde H., Jr. Director, Applied Carbonate Research Program, Department of Geology, Agricultural and Mechanical College, Louisiana State University.

Moore, Dr. James Alexander. Department of Chemistry, University of Delaware.

Moore, Dr. Jeffrey S. Department of Chemistry, University of Illinois, Urbana-Champaign.

Moore, Dr. Paul B. Department of the Geophysical Sciences, University of Chicago.

Moore, Dr. Raymond C. Deceased; formerly, Department of Geology, University of Kansas.

Moore, Dr. Richard K. Center for Research in Engineering Science, University of Kansas.

Moore, Dr. W. J. M. Division of Electrical Engineering, National Research Council of Canada, Ottawa, Ontario.

Moorer, Daniel F., Jr. Ball Aerospace & Technologies, Boulder, Colorado.

Mordes, Dr. J. P. Department of Medicine, University of Massachusetts Medical School, Worcester.

Moreno, Dr. Giuliana. Institute of Cellular Pathology, Paris, France.

Morgan, Dr. Anne H. Deceased; formerly, Mount Holyoke College.

Morgan, Prof. John W. Department of Mathematics, Columbia University.

Morgan, Dr. Karl Z. Neely Professor, School of Nuclear Engineering, Georgia Institute of Technology.

Moritz, Prof. Helmut. Technische Universität Graz, Abteilung für Physikalische Geodäsie, Graz, Austria.

Morrell, A. M. Manager, Tube Development, Picture Tube Division, RCA Corporation, Lancaster, Pennsylvania.

Morrell, Dr. Jeffrey J. Department of Forest Products, Oregon State University, Corvallis.

Morris, Prof. J. W., Jr. Department of Materials Sciences and Mineral Engineering, University of California, Berkeley.

Morris, Prof. Philip J. Department of Aerospace Engineering, Pennsylvania State University, University Park.

Morris, S. B. Marconi Research Centre Materials Group, Towcester, Northants, England.

Morris, Dr. William F. Department of Zoology, Duke University, Durham, North Carolina.

Morrison, Dr. David C. Associate Director, Basic Research Programs, Department of Microbiology, University of Kansas Medical Center, Kansas City.

Morrison, Dr. George H. Professor of Chemistry and Director, Analytical Facility of Materials Science Center, Cornell University.

Morrison, Dr. Kenneth J. Cooperative Extension Service, Washington State University.

Morse, Dr. Robert W. Associate Director and Dean of Oceanographic Studies, Woods Hole Oceanographic Institute, Woods Hole, Massachusetts.

Morse, Dr. Roger A. Department of Entomology, Cornell University.

Morse, Dr. Roy Earl. Food Science Department, Cook College.

Morse, Dr. Stephen A. Director, Division of Sexually Transmitted Diseases Laboratory Research, Centers for Disease Control and Protection, Atlanta, Georgia.

Mortenson, Leonard E. Department of Biological Sciences, Purdue University.

Morton, Dr. Andrew. Department of Geology and Petroleum Geology, University of Aberdeen, Kings College, Aberdeen, United Kingdom.

Moscowitz, Dr. Albert. Department of Chemistry, University of Minnesota.

Moseley, Dr. Steve L. Department of Microbiology, University of Washington School of Medicine, Seattle.

Moshell, Dr. Alan. Director, Skin Diseases Program, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, Maryland.

Mosher, Dr. William. Deceased; formerly, Chairman, Department of Chemistry, University of Delaware.

Mossman, Prof. Harland W. Emeritus Professor, Department of Anatomy, University of Wisconsin.

Motekaitis, Dr. R. J. Department of Chemistry, Texas A&M University.

Mottershead, Dr. Allen. Physical Science Department, Cypress College, California.

Mottet, Dr. N. Karle. Professor of Pathology and Director of Hospital Pathology, University Hospital, University of Washington.

Moyer, Dr. Kenneth E. Department of Psychology, Carnegie-Mellon University.

Moyer, Dr. William W. Applied Research Laboratory, Pennsylvania State University.

Mrak, Dr. Emil M. Office of Chancellor Emeritus, University of California, Davis.

Mulligan, Dr. Pamela K. Formerly, Department of Biochemistry, University of North Carolina.

Mulliken, Prof. Robert S. Institute of Molecular Biophysics, Florida State University.

Munger, Prof. H. M. Department of Plant Breeding and Biometry, New York State College of Agriculture and Life Sciences, Cornell University.

Munson, Prof. Bruce R. Department of Aerospace Engineering and Mechanics, Iowa State University, Ames.

Murgatroyd, Dr. R. J. Meteorological Office, Bracknell, England.

Murphy, Dr. Frederick A. Centers for Disease Control, Department of Health and Human Services, Tucker, Georgia.

Murphy, Dr. Glenn. Department of Nuclear Engineering, Iowa State University.

Murphy, Dr. Robert L. Division of Infectious Diseases, Northwestern University Medical School, Chicago, Illinois.

Murphy, Dr. Terence M. Department of Anesthesiology, School of Medicine, University of Washington.

Murray, Dr. Haydn H. Executive Vice President, Georgia Kaolin Company, Elizabeth, New Jersey.

Murray, Dr. James W. School of Oceanography, University of Washington, Seattle.

Murray, Prof. M. John. Department of Medicine, University of Minnesota Medical School, Minneapolis.

Murray, Dr. Merritt J. Formerly, A. M. Todd Company, Kalamazoo, Michigan.

Murray, Prof. R. G. E. Department of Microbiology and Immunology, Health Sciences Centre, University of Western Ontario, London, Canada.

Murray, Dr. Royce W. Department of Chemistry, University of North Carolina.

Murray, Stephen S. Center for Astrophysics, Harvard College Observatory, Cambridge, Massachusetts.

Murray, Dr. Thomas P. Applied Research Laboratory, United States Steel Corporation, Monroeville, Pennsylvania.

Murray, Dr. William. Teknowledge Corporation, Palo Alto, California.

Musacchia, Dr. X. J. Department of Physiology and Space Science Research Center, University of Missouri.

Mushlitz, R. D. Ore Department, American Smelting and Refining Company, New York.

Muther, Richard. Executive Director, Richard Muther & Associates, Inc., Kansas City, Missouri.

Mutter, Dr. Carolyn Z. Associate Research Scientist, Lamont-Doherty Earth Observatory, Columbia University, Palisades, New York.

Mutter, Dr. John. Lamont-Doherty Geological Observatory, Columbia University, Multichannel Seismics Group, Palisades, New York.

Muus, Dr. Bent J. Research Biologist, Danish Institute for Fishery and Marine Research, Charlottenund, Denmark.

Myers, Prof. A. L. Department of Chemical Engineering, University of Pennsylvania.

Myklebust, Prof. Arvid. Mechanical Engineering Department, Virginia Polytechnic Institute.

Mynleiff, Dr. Michelle. Department of Biology, Marquette University, Milwaukee, Wisconsin.

N

Nacamulli, Laurette. IGEN, Inc., Rockville, Maryland.

Nace, Dr. Raymond L. Geological Survey, U.S. Department of the Interior, Raleigh, North Carolina.

Nachtrieb, Prof. Norman H. Chairman, Department of Chemistry, University of Chicago.

Nagel, David J. Superintendent, Condensed Matter and Radiation, Sciences Division, Naval Research Laboratory, Department of the Navy, Washington, D.C.

Nagel, Suzanne R. Engineering Research Center, AT&T Bell Laboratories, Princeton, New Jersey.

Nagel, Dr. Walter R. NASA Goddard Space Flight Center, Greenbelt, Maryland.

Naistat, Dr. Samuel S. Department of Chemistry, Stephen F. Austin State College Nacogdoches, Texas.

Namias, Jerome. Climate Research Group, Scripps Institution of Oceanography, La Jolla, California.

Napp-Zinn, Prof. Klaus. Botanical Institute, Cologne, Germany.

Nash, Dr. Irwin. School of Medicine, Yale University.

Natchtsheim, Dr. Philip R. NASA Ames Research Center, Moffett Field, California.

Natland, Prof. James H. Rosentiel School of Marine and Atmospheric Science, University of Miami, Florida.

Naumann, Dr. Robert J. NASA Marshall Space Flight Center, Huntsville, Alabama.

Navrotsky, Dr. Alexandra. Department of Geological and Geophysical Sciences, Princeton University.

Naylor, Dr. Arch. Department of Electrical Engineering, University of Michigan.

Naylor, Dr. Ernest. Reader in Zoology, University College of Swansea, Wales.

Nealson, Dr. Kenneth H. Center for Great Lakes Studies, University of Wisconsin.

Nedelsky, Prof. Leo. Department of Physical Science, University of Chicago.

Nedungadi, Dr. Ashok P. Integrated Electronics Facility, Schlumberger Well Services, Houston, Texas.

Nelms, Dr. W. P. Deputy Chief, Aircraft Technology Division, National Aeronautics and Space Administration, Ames Research Center, Moffett Field, California.

Nelson, Dr. Donna C. Intelligent Transport Society of America, Washington, D.C.

Nelson, Elton G. Collaborator (WOC), Crops Research Division, U.S. Department of Agriculture, Beltsville, Maryland.

Nelson, Dr. George C. Department of Mathematics, University of Iowa, Iowa City.

Nelsen, Dr. Olin E. Department of Biology, University of Pennsylvania.

Nelson, Prof. Raymond J. Professor of Mathematics and Philosophy, Case Institute of Technology.

Nelson, Dr. Richard B. Chief Engineer, Varian Associates, Palo Alto, California.

Nergaard, Dr. Leon S. Director, Microwave Research Laboratory, RCA Laboratories, Princeton, New Jersey.

Nesbitt, Dr. Herbert H. J. Dean, Faculty of Science, Carleton University, Ottawa, Ontario, Canada.

Nestle, Dr. Marion. Chairperson, Department of Home Economics and Nutrition, Division of Education, New York University.

Netravali, Dr. Arun. President, Bell Laboratories, Murray Hill, New Jersey.

Neubecker, T. F. Manager, Engineering, High Intensity and Quartz Lamp Department, General Electric Company, Twinsburg, Ohio.

Neudeck, Prof. Gerald W. Department of Electrical Engineering, Purdue University.

Neuhauser, Robert G. Solid State Division, Electro Optics and Devices, RCA, Lancaster, Pennsylvania.

Nevins, Dr. James L. Charles Stark Draper Laboratory, Cambridge, Massachusetts.

New, Dr. Ronald. NOAA, U.S. Department of Commerce, Rockville, Maryland.

Newcomb, Prof. Robert W. Microsystems Laboratory, Electrical Engineering Department, University of Maryland.

Newell, Dr. Allen. Department of Computer Science, Carnegie-Mellon University.

Newell, Dr. Homer E. National Aeronautics and Space Administration Headquarters, Washington, D.C.

Newhouse, Alan R. Retired; formerly, U.S. Department of Energy.

Newton, Dr. Chester W. National Center for Atmospheric Research, Boulder, Colorado.

Newton, Dr. R. C. Department of the Geophysical Sciences, University of Chicago.

Newton, Prof. Roger G. Department of Physics, Indiana University, Bloomington.

Ng, Dr. Tai P. New Ground Resources Ltd., Alberta, Canada.

Nicodemus, Dr. Fred E. Deceased; formerly, Physicist, Optical Radiation Section, Heat Division, Institute for Basic Standards, National Bureau of Standards.

Niebel, Benjamin W. Professor Emeritus of Industrial Engineering, Pennsylvania State University; Industrial Engineering Consultant, State College, Pennsylvania.

Nier, Prof. Alfred O. School of Physics and Astronomy, University of Minnesota.

Niesz, Dr. Dale E. Director, Center for Ceramics Research, College of Engineering, Rutgers University.

Nigrelli, Dr. Ross F. Osborn Laboratories of Marine Sciences, New York Aquarium, New York.

Nippes, Prof. Ernest F. Department of Materials Engineering, Rensselaer Polytechnic Institute.

Nix, Prof. William D. Associate Chairman, Department of Materials Science and Engineering, Stanford University.

Noback, Dr. Charles R. Department of Anatomy, Columbia University.

Nobel, Prof. Park S. Department of Biology, University of California, Los Angeles,

Noble, Dr. James A. Geological Sciences, California Institute of Technology.

Noble, R. H. Optical Division, Institute National Astrofis, Puebla, Mexico.

Noguchi, Dr. Thomas T. Pasadena, California.

Nolan, Dr. Robert P. Environmental Sciences Laboratory, Brooklyn College, Brooklyn, New York.

Noll, Dr. Kenneth. Department of Microbiology, University of Illinois, Urbana-Champaign.

Norberg, Dr. Ulla M. Department of Zoomorphology, Zoological Institute, University of Goteborg, Sweden.

Norcross, Prof. Neil L. College of Veterinary Medicine, Cornell University, Ithaca, New York.

Nordman, Prof. James E. Department of Electrical and Computer Engineering, University of Wisconsin, Madison.

Norris, Dr. H. Thomas. Chairman, Department of Clinical Pathology and Diagnostic Medicine, East Carolina University School of Medicine.

North, Dr. Gerald R. Director, Climate System Research Program, Department of Meteorology, Texas A&M University.

Northcutt, Dr. R. Glenn. Department of Anatomy, Case Western Reserve University.

Norton, Dr. Jeanette. Department of Plants, Soils and Biometerology, Utah State University, Logan.

Novikoff, Dr. Phyllis. Department of Pathology, Albert Einstein College of Medicine, Bronx, New York.

Novotny, Prof. Donald W. Department of Electrical and Computer Engineering, University of Wisconsin, Madison.

Noy, Dr. Noa. Division of Nutritional Sciences, Cornell University, Ithaca, New York.

Noyes, Richard M. Department of Chemistry, College of Arts and Sciences, University of Oregon.

Noyes, Dr. Robert W. Harvard-Smithsonian Center for Astrophysics, Smithsonian Astrophysical Observatory, Harvard College Observatory, Cambridge, Massachusetts.

Nuccitelli, Prof. Richard. Zoology Department, University of California, Davis.

Nussbaumer, Prof. Harry. Institut für Astronomie, Zürich, Switzerland.

Nygren, Dr. David R. Physics Division, Lawrence Berkeley Laboratory, University of California, Berkeley.

Nygren, Stephen. Bell Telephone Laboratories, Reading, Pennsylvania.

Nyhan, Prof. William L. Department of Pediatrics, University of California, La Jolla.

Nyman, Dr. Matthew W. Senior Research Associate, Department of Earth and Planetary Sciences, University of New Mexico, Albuquerque.

O

Obery, Leonard J. Chief, Plans and Programs Offices, National Aeronautics and Space Administration, Cleveland, Ohio.

O'Brien, Prof. Michael. Department of Agricultural Engineering, University of California, Davis.

O'Connell, Prof. John P. Department of Chemical Engineering, University of Florida.

O'Connor, Dr. Donald J. Department of Civil Engineering, Manhattan College.

O'Donnell, Franklin. Jet Propulsion Laboratory, Pasadena, California.

Odom, Dr. Robert W. Charles Evans Associates, Redwood City, California.

Ogburn, Charles B. Cooperative Extension Service, Auburn University.

Ogle, Dr. Kenneth N. Section of Biophysics, Mayo Clinic, Rochester, Minnesota.

O'Hagan, Dr. David. Department of Chemistry, University of Durham, United Kingdom.

Ohlendorf, Dr. Douglas H. Genex Corporation, Gaithersburg, Maryland.

Ojemann, Dr. Linda M. Regional Epilepsy Center, Harborview Medical Center, University of Washington.

Okandan, Dr. Ender. Department of Petroleum and Natural Gas Engineering, Middle East Technical University, Ankara, Turkey.

Olcott, John W. Editor and Publisher, Business and Commercial Aviation Aerospace and Defense Group, McGraw-Hill, White Plains, New York.

Old, Dr. Bruce S. Senior Vice President, Arthur D. Little, Inc., Cambridge, Massachusetts.

Oldenburger, Prof. Rufus. Director, Automatic Control Center, Purdue University.

O'Leary, Dr. John E. Department of Forest Engineering, Oregon State University.

O'Lenic, Dr. Edward A. Climate Analysis Center, National Weather Service, U.S. Department of Commerce, Washington, D.C.

Oliver, Prof. John E. Department of Geography, Geology, and Anthropology, Indiana State University, Terre Haute, Indiana.

Olmstead, Prof. Richard. Department of Botany, University of Washington, Seattle.

Olness, Dr. John W. Brookhaven National Laboratory, Associated Universities, Inc., Upton, New York.

Olsen, Dr. Edward J. Department of Geology, Field Museum of Natural History, Chicago, Illinois.

Olson, Prof. Edward C. Department of Astronomy, University of Illinois, Urbana.

Olson, Dr. Everett C. Department of Zoology, University of California, Los Angeles.

Olson, Dr. Harry F. Deceased; formerly, Staff Vice President, Acoustical and Electromechanical Research, RCA Laboratories, Princeton, New Jersey.

Olson, Dr. Jerry S. Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Olson, Dr. Norman. Department of Food Science, University of Wisconsin.

Onishi, Steven. Fairchild Imaging, Milpitas, California.

Oosthuizen, Dr. Patrick H. Department of Mechanical Engineering, Queen's University, Kingston, Ontario, Canada.

Oppenheimer, Dr. Ben R. Department of Astronomy, University of California, Berkeley.

Oppenheimer, Dr. Steven B. Department of Biology, California State University, Northridge.

O'Rahilly, Dr. Ronan. Carnegie Embryological Laboratories, University of California, Davis.

Orians, Dr. Gordon. Department of Zoology, University of Washington, Seattle.

Oris, Dr. James T. Department of Zoology, Miami University, Oxford, Ohio.

Orkin, Dr. Frederick K. University of California, San Francisco, The Medical Center at the University of California School of Medicine.

Orrego, Dr. Cristian. Department of Biology, Brandeis University.

Orr-Weaver, Dr. Terry. Whitehead Institute for Biomedical Research, Cambridge, Massachusetts.

Orville, Dr. Harold D. Institute for Atmospheric Science, South Dakota School of Mines, Rapid City, South Dakota.

Orville, Prof. Richard E. Director, Cooperative Institute for Applied Meteorological Studies, Texas A & M University, College Station.

Osberg, Prof. Philip H. Department of Geological Sciences, University of Maine.

Osborn, Dr. Jeffrey M. Division of Science, Northeast Missouri State University, Kirksville.

O'Shaughnessy, Dr. Douglas. INRS-Telecom, Place Bonaventure, Montreal, Canada.

Osofsky, Dr. Michael. Naval Research laboratory Washington, D.C.

Oster, Prof. Gerald. Mount Sinai School of Medicine, City University of New York.

Ostergaard, Dr. H. L. Department of Biology, University of California, Los Angeles.

Ostro, Dr. Steven J. Jet Propulsion Laboratory, California Institute of Technology, Pasadena.

Ostrom, Dr. John H. Division of Vertebrate Paleontology, Peabody Museum of Natural History, Yale University.

Othmer, Prof. Donald F. Deceased; formerly, Department of Chemical Engineering, Polytechnic Institute of Brooklyn.

Otis, Dr. Arthur B. Department of Physiology, College of Medicine, University of Florida.

Otten, Prof. Ernst Wilhelm. Institut für Physik, Johannes Gutenberg-Universität Mainz, Germany.

Otto, Dr. Gilbert F. Zoology Department, University of Maryland.

Otto, Dr. Norman. Ford Motor Research Laboratory, Dearborn, Michigan.

Over, Dr. Jeff. Department of Geological Sciences, State University of New York at Geneseo.

Overhauser, Dr. Albert W. Department of Physics, Purdue University.

Ovshinsky, Stanford R. President, Energy Conversion Devices, Inc., Troy, Michigan.

Owen, Dr. Denis F. Department of Biology, Oxford Polytechnic.

Owen, Prof. Guillermo. Department of Mathematical Sciences, Rice University.

Owen, Dr. Tobias C. Department of Earth and Space Sciences, State University of New York, Stony Brook.

P

Pacella, Gary. AMSTA-AR-CCH-C, United States Army Armament Research Development and Engineering Center, Picatinny Arsenal, New Jersey.

Packer, Dr. Lester. University of California, Department of Molecular and Cell Biology, Berkeley, California.

Padian, Prof. Kevin. Museum of Paleontology, University of California, Berkeley.

Page, Dr. Roy C. Research Center in Oral Biology, School of Medicine, University of Washington.

Pake, Dr. George E. Vice President, Xerox Corporation; General Manager, Xerox Palo Alto Research Center, Palo Alto, California.

Palermo, Dr. David S. Department of Psychology, Pennsylvania State University.

Palevsky, Dr. Gerald. Consulting Professional Engineer, Hastings-on-Hudson, New York.

Palmer, Dr. Allison R. Department of Earth and Space Sciences, State University of New York, Stony Brook.

Palmer, Prof. Darwin L. Chief, Veterans Administration Hospital, Medical Center, Department of Medicine, Infectious Disease Division, University of New Mexico School of Medicine.

Palmer, Prof. Fred. Lighting Research Center, Osram Sylvania, Beverly, Massachusetts.

Palmer, Lawrence M. Federal Communications Commission, Washington, D.C.

Palmerlee, Prof. Albert S. Deceased; formerly, Professor of Engineering Drawing, School of Engineering and Architecture, University of Kansas.

Palzkill, Dr. David A. Department of Plant Sciences, University of Arizona.

Pandolfi, Dr. John M. Department of Paleobiology, National Museum of Natural History, Smithsonian Institution, Washington, D.C.

Pang, Prof. Stella. Department of Electrical Engineering and Computer Science, University of Michigan, Ann Arbor.

Pangbom, Dr. Jon B. Director, Alternative Energy Systems Research, Institute of Gas Technology, Chicago, Illinois.

Panish, Dr. Morton B. Head, Materials Science Research Department, AT&T Bell Laboratories, Murray Hill, New Jersey.

Pantell, Dr. Richard. Electrical Engineering Department, Stanford University.

Papageorgiou, George. Research Associate, Department of Botany, University of Illinois, Urbana.

Papagiannis, Prof. Michael D. President, IAU Commission 51, Department of Astronomy, Boston University.

Papendick, Dr. Robert I. Research Leader, U.S. Department of Agriculture, Agricultural Research Service, Washington State University.

Parente, Michael. MP Technologies, Hendersenville, North Carolina.

Park, Prof. David. Department of Physics, Williams College.

Parker, Dr. Ingrid M. Department of Biology, Earth and Marine Sciences, University of California, Santa Cruz.

Park, Prof. Jae-Woo. Department of Civil Engineering, University of Hawaii at Manoa.

Parker, Sybil P. Formerly, Editor in Chief, "McGraw-Hill Encyclopedia of Science and Technology," McGraw-Hill Book Co., New York.

Parker, Dr. Thomas E. National Institute of Standards and Technology, Time and Frequency Division, Boulder, Colorado.

Parma, Dr. Ana. International Pacific Halibut Commission, Seattle, Washington.

Parmentier, Prof. E. Mark. Department of Geological Sciences, Brown University, Providence, Rhode Island.

Parmesan, Dr. Camille. National Center for Ecological Analysis and Synthesis, Santa Barbara, California.

Parpia, Prof. Jeevak M. Department of Physics, Cornell University.

Parr, Dr. J. F. Biological Waste Management and Organic Resources Laboratory, Beltsville, Maryland.

Parr, Prof. Robert G. Department of Chemistry, University of North Carolina.

Parrish, Dr. Judith Totman. Department of Geosciences, University of Arizona.

Parry, Prof. David A. D. Department of Structural Biology, Rosenstiel Basic Medical Science Research Center, Brandeis University, Waltham, Massachusetts.

Parsons, Dr. Thomas S. Department of Zoology, University of Toronto, Ontario, Canada.

Partridge, Dr. Edward G. Redondo Beach, California.

Parvainen, Dr. Pekka. Polar Image, Turku, Finland.

Pasachoff, Dr. Jay M. Hopkins Observatory, Williams College.

Pascual, Dr. Miguel. Centro Nacional Patagónico (CONICET), Chubut, Argentina.

Pasternak, Dr. Gavril W. Attending Neurologist, Department of Neurology, Memorial Hospital, Sloan-Kettering Institute Cancer Center, New York.

Pasto, Prof. Daniel J. Department of Chemistry, University of Notre Dame.

Patel, Dr. C. K. N. Bell Laboratories, Murray Hill, New Jersey.

Paterson, Eric. Iowa Institute of Hydraulic Research and Department of Mechanical Engineering, University of Iowa, Iowa City.

Patrick, Norman W. RCA Corporation, Lancaster, Pennsylvania.

Patterson, Dr. David J. Department of Zoology, University of Bristol, England.

Patton, Dr. Donald J. Department of Geography, Florida State University.

Patton, Dr. Harry D. Chairman, Department of Physiology-Biophysics, School of Medicine, University of Washington.

Patton, Peter C. Minnesota Supercomputer Institute, University of Minnesota.

Patzkowsky, Dr. Mark E. Department of Geosciences, Pennsylvania State University, University Park.

Paul, Prof. Burton. Department of Mechanical Engineering, University of Pennsylvania.

Paul, Dr. Jacques. Commissariat à l'Energie Atomique, Direction des Sciences de la Matière, Gif-sur-Yvette, France.

Payne, Prof. Joseph N. School of Education, University of Michigan, Ann Arbor.

Payne, Prof. Peter A. Retired; formerly, Vice President for Academic Development, Department of Instrumentation and Analytical Science, University of Manchester, Institute of Science and Technology, Manchester, England.

Peacey, Dr. John G. Centre de Recherche Noranda, Pointe-Claire, Quebec, Canada.

Peacor, Dr. Donald R. Department of Geology, University of Michigan.

Pearce, Prof. R. H. Department of Pathology, Faculty of Medicine, University of British Columbia, Canada.

Peaslee, Dr. Robert L. Vice President, Stainless Steel Division, Wall Colmonoy Corp., Detroit, Michigan.

Pecar, Dr. Joseph A. Joseph A. Pecar & Associates, Inc., Potomac, Maryland.

Pechenik, Dr. Jan. Department of Biology, Tufts University, Medford, Massachusetts.

Peck, Prof. Raymond E. Department of Geology, University of Missouri.

Peck, Dr. Stewart B. Department of Biology, Carleton University, Ottawa, Ontario, Canada.

Pecora, Prof. Robert. Department of Chemistry, Stanford University.

Pecoraro, Dr. Vincent. Department of Chemistry, University of Michigan.

Pedersen, Prof. Niels C. School of Veterinary Medicine, University of California, Davis.

Pegg, Prof. David J. Department of Physics and Astronomy, University of Tennessee, Knoxville.

Pehlke, Dr. Robert D. Department of Materials Science and Engineering, University of Michigan.

Peirce, Dr. G. R. Engineer, Champaign, Illinois.

Pelletier, Dr. S. William. Director, Institute for Natural Product Research, University of Georgia, Athens.

Pelosi, Dr. James J. Colonel, U.S. Army, Retired, Houston, Texas.

Pennak, Dr. Robert W. Department of Biology, University of Colorado.

Penneman, Dr. Robert A. Los Alamos Scientific Laboratory, Los Alamos, New Mexico.

Penner-Hahn, Prof. James E. Department of Chemistry, University of Michigan, Ann Arbor.

Penrose, Prof. Roger. Mathematical Institute, University of Oxford, England.

Pepper, Prof. Darrell W. Department of Mechanical Engineering, University of Nevada, Las Vegas.

Perch, Michael. Koppers Company, Inc., Monroeville, Pennsylvania.

Perl, Prof. Martin L. Stanford Linear Accelerator Center, Stanford, California.

Perlmann, Dr. Gertrude E. Deceased; formerly, Rockefeller University.

Perrin, Arthur M. Deceased; formerly President, National Conveyors Company, Inc., Fairview, New Jersey.

Perry, Astor. Extension Agronomy Specialist, North Carolina State University.

Perry, Stephen F. Exxon Research, Florham Park, New Jersey.

Perryman, Dr. Michael A. C. Space Science Department, European Space Agency, ESTEC (SCI-SA), Noordwijk, Netherlands.

Peskin, Prof. Michael E. Stanford Linear Accelerator Center, Menlo Park, California.

Peters, Prof. Philip C. Department of Physics, University of Washington.

Peters, Dr. William C. Professor Emeritus, Mining and Geological Engineering, University of Arizona.

Petershack, Dr. Victor D. Rexnord, Inc., Milwaukee, Wisconsin.

Peterson, Dr. Benjamin B. Department of Engineering, United States Coast Guard Academy, New London, Connecticut.

Peterson, Dr. Kirk D. Department of Engineering, Calvin College, Grand Rapids, Michigan.

Peterson, Dr. R. L. Department of Botany, University of Guelph, Ontario, Canada.

Petschek, Prof. Albert G. Department of Physics, New Mexico Institute of Mining and Technology, Socorro.

Pfaffmann, Dr. Carl. Department of Psychology, Rockefeller University.

Pfeffer, Dr. Robert A. U.S. Army, Nuclear and Chemical Agency, Springfield, Virginia.

Pfleeger, Dr. Charles P. Trusted Information Systems, Inc., Computer and Communications Security, Networking Telecommunications, Glenwood, Maryland.

Phadke, Prof. Arun G. Director, Center for Power Engineering, Virginia Polytechnic Institute and State University, Blacksburg.

Phaff, Dr. Herman J. Department of Food Science and Technology, College of Agriculture and Environmental Science, University of California, Davis.

Phaneuf, Prof. Ronald A. Chair, Department of Physics, University of Nevada, Reno.

Phelan, Prof. Richard M. Department of Mechanical Systems and Design, Cornell University.

Philander, Prof. S. George. Program in Atmospheric and Oceanic Sciences, Princeton University.

Philip, Dr. Cornelius B. Department of Entomology, California Academy of Sciences, San Francisco.

Philipson, Dr. William R. Department of Botany, University of Canterbury, Christchurch, New Zealand.

Phillips, Dr. James A. CTR-Divison Office, Los Alamos Scientific Laboratory, Los Alamos, New Mexico.

Phillips, Prof. Tom L. Department of Botany, University of Illinois, Urbana.

Phillips, Dr. William D. National Institute of Standards and Technology, Gaithersburg, Maryland; Nobelist.

Phillips, William H. NASA Langley Research Center, Hampton, Virginia.

Pielou, Dr. E. C. Department of Biology, University of Lethbridge, Alberta, Canada.

Pience, Roger D. Watson Technology, Portland, Maine.

Pierce, Prof. Allan D. School of Mechanical Engineering, Georgia Institute of Technology.

Pierce, Prof. E. Lowe. Department of Zoology, University of Florida.

Pierce, Dr. F. J. Department of Crop and Soil Sciences, Michigan State University, East Lansing.

Pierotti, Prof. Robert A. Department of Chemistry, Georgia Institute of Technology.

Pierre, Dr. Donald A. Department of Electrical Engineering, College of Engineering, Montana State University.

Pierscionek, Dr. Barbara K. Department of Biomedical Sciences, University of Bradford, United Kingdom.

Pike, Dr. Andrew C. Neotronics Scientific Ltd., United Kingdom.

Pike-Tay, Dr. Anne. Department of Anthropology, Vassar College, Poughkeepsie, New York.

Pilbrow, Prof. John R. Head, Department of Physics, Monash University, Clayton, Victoria, Australia.

Pimm, Dr. Stuart. Department of Zoology, University of Tennessee, Knoxville.

Pinder, Dr. George F. Department of Civil and Geological Engineering, Princeton University.

Pinedo, Prof. Michael. Statistics and Operations Research Department, Stern School of Business, New York University, New York.

Pinkava, Dr. Donald J. Director, ASU Herbarium, Department of Botany, Arizona State University.

Pinkel, Benjamin. Consulting Engineer, Santa Monica, California.

Pinker, Prof. Rachel T. Department of Meteorology, University of Maryland.

Pionke, Dr. Harry B. Pasture Systems and Watershed Management Research Laboratory, U.S. Department of Agriculture–Agricultural Research Service, University Park, Pennsylvania.

Pipkin, Prof. Francis M. Department of Physics, Harvard University.

Pitchford, Dr. Leanne C. Sandia National Laboratories, Albuquerque, New Mexico.

Pitman, Waker C., III. Lamont-Doherty Geological Observatory, Palisades, New York.

Platt, Donald. Adjunct Professor of Space Systems, Spaceport Graduate Center, Florida Institute of Technology, Satellite Beach.

Plaut, Dr. Gerhard W. E. Professor Emeritus of Biochemistry, Temple University School of Medicine, Philadelphia, Pennsylvania.

Pleasants, Dr. Julian R. International Committee on Laboratory Animals, Lobund Laboratory, University of Notre Dame.

Plecnik, Prof. Joseph M. Department of Civil Engineering, California State University at Long Beach.

Plesset, Dr. Michael. Aerospace Corporation, Los Angeles, California.

Ploem, Dr. Johan S. Laboratorium voor Cytochemie en Cytometrie, Rijksuniversiteit Leiden, Wassenaarseweg, Netherlands.

Plotnick, Dr. Roy E. Department of Geological Sciences, College of Liberal Arts and Sciences, University of Illinois.

Plueddemann, Dr. Edwin P. Organic Laboratories, Dow Corning Corporation, Midland, Michigan.

Pocius, Dr. Alphonsus V. AC&S Division, 3M Company, St. Paul, Minnesota.

Pohl, Dr. D. W. IBM Research Division, Zurich Research Laboratory, Ruschlikon, Switzerland.

Pohl, Prof. Robert O. Laboratory of Atomic and Solid State Physics, Cornell University.

Pohlmann, Prof. Kenneth C. School of Music, University of Miami, Coral Gables, Florida.

Poknivar, Adolph L. Formerly, Manager, Technical Publications, International Lead Zinc Research Organizations, Inc., New York.

Polchinski, Prof. Joseph. Institute for Theoretical Physics, University of California, Santa Barbara.

Policy, Dr. Margaret J. Department of Medicine, Cornell Medical Center, New York.

Polking, Dr. John C. Department of Mathematics, Rice University.

Pollack, Dr. Henry N. Department of Geological Sciences, University of Michigan.

Pollack, Dr. James B. Ames Research Center, Moffett Field, California.

Pollard, Dr. Thomas. Department of Cell Biology and Anatomy, Johns Hopkins

University School of Medicine, Baltimore, Maryland.

Pollard, Dr. William G. Oak Ridge Associated Universities.

Polly, Dr. P. David. Department of Anatomy, Queen Mary and Westfield College, London, United Kingdom.

Pomykalski, Dr. James J. Assistant Professor, Integrated Science and Technology and Computer Science Programs, James Madison University, Harrisonburg, Virginia.

Ponikvar, Ade L. Formerly, Editor, Production and Drilling, "Petroleum Week," New York.

Pont-Lezica, Dr. Rafael. Department of Biology, Washington University, St. Louis, Missouri.

Pontecorvo, Dr. Guido. Imperial Cancer Research Fund Laboratories, London, England.

Poole, Prof. Colin F. Department of Chemistry, Wayne State University, Detroit, Michigan.

Pope, Dr. Joseph. Pope Engineering Company, Newton Centre, Massachusetts.

Pope, Michael. Pope, Evans and Robbins, Consulting Engineers, New York.

Popelka, Dr. Gerald R. Head of Audiology, Research Laboratories, Central Institute for the Deaf, St. Louis, Missouri.

Popper, Dr. Arthur N. Director, Neuroscience and Cognitive Science Program, Department of Biology, University of Maryland, College Park.

Popper, Dr. Daniel M. Department of Astronomy, University of California, Los Angeles.

Porges, Dr. Steven. Department of Human Development, University of Maryland, College Park.

Porter, Dr. Richard D. Chair, Department of Mathematics, Northeastern University, Boston, Massachusetts.

Posada, German. Research Associate, Department of Psychology, State University of New York, Stony Brook.

Postgate, Prof. John R. Department of Microbiology, University of Sussex, England.

Postow, Dr. Elliot. National Institutes of Health, Bethesda, Maryland.

Potter, Dr. Kathleen N. Department of Microbiology, University of Texas Southwestern Medical Center, Dallas.

Potter, Prof. M. David. School of Business, San Francisco State College.

Potter, Prof. Norman N. Department of Food Science, Cornell University.

Potts, Dr. Kevin T. Department of Chemistry, Rensselaer Polytechnic Institute.

Poulson, Dr. Donald F. Department of Biology, Yale University.

Povey, Dr. Sue. Galton Laboratory, University College, London, England.

Povh, Dr. Bogdan. Max Planck Institut filr Kernphysik, Saupfercheckweg, Germany.

Powell, Claud. Consultant, Navigation, Bourton-on-the-Water, Gloucestershire, England.

Powell, Jeffrey R. Department of Biology, Yale University.

Powell, Robert C. Consultant, Physics, Gaithersburg, Maryland.

Powell, Dr. Wayne B. Vice President for Research and Associate Dean of the Graduate College, Oklahoma State University, Stillwater.

Powers, Dr. Kerns H. RCA David Sarnoff Laboratories, Princeton, New Jersey.

Pozar, Prof. David M. Department of Electrical and Computer Engineering, University of Massachusetts, Amherst.

Pozos, Dr. Robert S. Sustained Performance Program Manager, Department of the Navy, Naval Health Research Center, Department of Defense, San Diego, California.

Praston, Dr. Lincoln F. Research Scientist, Institute of Arctic and Alpine Research, Department of Geology, University of Colorado, Boulder.

Prescott, David M. Department of Molecular, Cellular and Developmental Biology, Boulder, Colorado.

Prescott, Dr. Gerald W. Department of Botany, University of Wisconsin.

Presley, Dr. John. McGill University, Department of Anatomy and Cell Biology, Montreal, Canada.

Price, Dr. James F. Department of Physical Oceanography, Woods Hole Oceanographic Institution, Massachusetts.

Price, Dr. P. Buford, Jr. Lawrence Berkeley Laboratory, University of California, Berkeley.

Price, Dr. Peter W. Department of Entomology, Northern Arizona University.

Priester, Gayle B. Consulting Engineer, Baltimore, Maryland.

Primack, Prof. Joel R. Physics Department, University of California, Santa Cruz, California.

Princen, L. H. Associate Center Director, North Regional Research Center, Department of Agriculture, Peoria, Illinois.

Prinn, Prof. Ronald G. Department of Earth, Atmosphere and Planetary Sciences, Massachusetts Institute of Technology, Cambridge.

Prisbrey, Prof. Keith A. Department of Metallurgical and Mining Engineering, College of Mines and Earth Resources, University of Idaho, Moscow.

Pritchard, Prof. David E. Department of Physics, Massachusetts Institute of Technology, Cambridge.

Pritchard, Tram C. Lockheed Missiles and Space Company, Sunnydale, California.

Pritchett, Prof. Wilson S. Senior Project Engineer, Noller Control Systems, Inc., Richmond, California.

Pritsker, Prof. A. Alan B. School of Industrial Engineering, Purdue University.

Proctor, Mary C. Department of Surgery, University of Michigan Hospitals, Ann Arbor.

Prothero, Dr. Donald R. Chair, Department of Geology, Occidental College, Los Angeles, California.

Puchstein, Albert F. Deceased; formerly, Consulting Engineer, Columbus, Ohio.

Puck, Dr. Theodore T. Department of Biophysics, University of Colorado Medical Center, Denver.

Pugel, Andrew. California State University at Long Beach, Department of Civil Engineering, Long Beach, California.

Pullen, Dr. Keats A., Jr. Ballistic Research Laboratories, Aberdeen Proving Ground, Maryland.

Purchon, Dr. Richard D. Department of Zoology, Chelsea College, University of London, England.

Purvis, Dr. Andy. Department of Zoology, University of Oxford, United Kingdom.

Putnam, Prof. Russell C. Professor Emeritus, Case Institute of Technology.

Putterman, Dr. Seth. Department of Physics, University of California, Los Angeles.

Pyeritz, Prof. Reed E. Director, Center for Medical Genetics, Allegheny Health, Education and Research Foundation, Pittsburgh, Pennsylvania.

Pyrke, John K. M. Slocum and Fuller, New York.

Q

Quaife, Carol. Department of Pathology, University of Washington.

Qualset, Dr. Calvin O. Department of Agronomy and Range Science, University of California, Davis.

Quarles, Dr. John M. Department of Medical Microbiology & Immunology, Texas A & M University, College Station.

Que, Prof. Lawrence Jr. Center for Metals in Biocatalysis, University of Minnesota, Minneapolis.

Quigg, Dr. Chris. Lawrence Berkeley Laboratory, University of California, Berkeley.

Quimby, Dr. Edith H. Department of Radiology, College of Physicians and Surgeons, Columbia University.

Quinn, Dr. T. J. Bureau International des Poids et Mésures, Pavillion de Breteuil, Sèvres, France.

Quirin, Edward J. Consulting Engineer, Besier, Gibble & Quirin, Old Saybrook, Connecticut.

Quiroga, Dr. Carlos. Pacific Technical Documentation, Windsor, California.

R

Raab, Dr. Frederick H. President and Owner, Green Mountain Radio Research Company, Winooski, Vermont.

Raad, Prof. Peter E. Mechanical Engineering Department, School of

Engineering and Applied Science, Southern Methodist University, Dallas, Texas.

Rabb, David D. Mining Engineer-Metallurgist, Tucson, Arizona.

Rabinowicz, Prof. Ernest. Department of Mechanical Engineering, Massachusetts Institute of Technology.

Rachubinski, Dr. Richard A. Department of Cell Biology and Anatomy, University of Alberta, Edmonton, Alberta, Canada.

Rademacher, Prof. Hans. Deceased; formerly, Professor Emeritus of Mathematics, University of Pennsylvania.

Radforth, Dr. Norman W. Muskeg Research Institute, University of New Brunswick, Canada.

Radin, Harley W. Chairperson and Chief Executive, Direct Broadcasting Satellite Corporation, Washington, D.C.

Radke, Dr. Rodney O. Agricultural Product Research Laboratory, Monsanto Company, St. Louis, Missouri.

Radok, Dr. Uwe. Environmental Research (CIRES), University of Colorado.

Rae, Dr. Peter M. M. Molecular Diagnostics, Inc., West Haven, Connecticut.

Raffel, Dr. Sidney. Department of Medical Microbiology, School of Medicine, Stanford University.

Rafferty, Vincent F. Siemens Enterprise Networks, Reston, Virginia.

Rahenkamp, Robert A. International Business Machines, Lexington, Kentucky.

Rahn, Frank J. Nuclear Power Division, Electric Power Research Institute, Palo Alto, California.

Raikhel, Dr. Natasha V. Department of Energy, Michigan State University, East Lansing.

Rajagopal, Dr. Krishna. Lyman Laboratory of Physics, Harvard University.

Rajan, Prof. Krishna. Materials Engineering Department, Rensselaer Polytechnic Institute, Troy, New York.

Raju, Prof. G. V. S. Director, Division of Engineering, University of Texas, San Antonio.

Rakovan, Prof. John. Department of Geology, Miami University, Oxford, Ohio.

Ram, Dr. Prahlad T. Department of Pharmacology, Mount Sinai School of Medicine, New York.

Ramberg, Dr. Edward G. RCA Laboratories, Princeton, New Jersey.

Ramdas, Prof. Anant K. Department of Physics, Purdue University, West Lafayette, Indiana.

Ramey, Dr. Robert L. Department of Electrical Engineering, University of Virginia.

Ramsey, Dr. Norman F. Department of Physics, Harvard University.

Randerson, Dr. Peter. Department of Applied Biology, University of Wales Institute of Science and Technology, Cardiff.

Rao, Dr. V. N. M. Dupont Central Research and Development, Wilmington, Delaware.

Raper, Dr. John R. Professor of Botany, Harvard University.

Rapp, Prof. George, Jr. Dean, College of Letters and Science, University of Minnesota.

Raps, Dr. Shirley. Department of Biological Sciences, Hunter College, City University of New York.

Raski, Dr. Dewey J. Department of Nematology, University of California, Davis.

Rasmussen, Dr. D. Tab. Department of Anthropology, Washington University, St. Louis, Missouri.

Rasmussen, Dr. Howard. Department of Biochemistry, School of Medicine, University of Pennsylvania.

Rasmussen, Dr. Norman C. Department of Nuclear Engineering, Massachusetts Institute of Technology.

Rasmusson, Dr. Eugene M. Geophysical Fluid Dynamics Laboratory, Environmental Science Services Administration, Princeton, New Jersey.

Ratay, Dr. Robert T. Consulting Engineer, Manhasset, New York.

Ratliff, Dr. Floyd. Department of Psychology, Rockefeller University.

Ratnoff, Dr. Oscar D. Department of Medicine, Case Western Reserve University.

Rau, Prof. A. R. P. Department of Physics, Louisiana State University, Baton Rouge.

Rauber, Prof. Robert M. Department of Atmospheric Science, University of Illinois at Urbana-Champaign, Urbana.

Rauchfuss, Dr. T. B. School of Chemical Sciences, University of Illinois, Urbana.

Raum, Dr. Donald. Center for Blood Research, Boston, Massachusetts.

Ravishankara, Dr. A. R. National Oceanic and Atmospheric Administration, Aeronomy Laboratory, Boulder, Colorado.

Rayner, Dr. G. H. Consultant, Teddington, Middlesex, England.

Raz, Prof. Tzvi. Faculty of Management, Tel Aviv University, Ramat Aviv, Israel.

Read, Prof. Clark P. Deceased; formerly, Department of Biology, Rice University.

Reay, Dr. Donald T. King County Medical Examiner, Harborview Hospital, Seattle, Washington.

Rebbi, Dr. Claudio. Department of Physics, Brookhaven National Laboratory, Upton, New York.

Rechtin, Dr. Eberhardt. Retired; formerly, Department of Industrial and Systems Engineering, School of Engineering, University of Southern California.

Reddish, Dr. George F. Deceased; formerly, St. Louis College of Pharmacy and Allied Sciences.

Redhead, Dr. Scott A. Mycologist, Biosystematics Research Centre, Agriculture Canada, Research Branch, Central Experimental Farm, Ottawa, Ontario, Canada.

Reed, Oscar, Jr. Consulting Engineer, Telecommunications, Silver Spring, Maryland.

Reed, Dr. Randall. Department of Molecular Biology and Genetics, School of Medicine, Johns Hopkins University.

Reeder, Dr. Richard J. Geosciences Program, Department of Earth and Space Sciences, State University of New York, Stony Brook.

Reed-Hill, Dr. Robert E. Department of Metallurgical Science and Engineering, University of Florida.

Rees, Dr. Bryant E. Professor of Biology, Fresno State College.

Rees, Jack. Corporate Services Staff, Exxon Research and Engineering Company, Florham Park, New Jersey.

Reeve, Dr. Roger M. Western Regional Research Laboratory, U.S. Department of Agriculture, Albany, California.

Regnery, Dr. Russell. Supervisory Research Microbiologist, Viral and Rickettsial Zoonoses Branch, Department of Health and Human Services, Centers for Disease Control and Prevention, Atlanta, Georgia.

Reich, Prof. Herbert J. (Retired), Department of Engineering and Applied Science, Yale University.

Reichman, Lee B. Department of Medicine, College of Medicine and Dentistry, Newark, New Jersey.

Reichmann, Dr. M. E. Department of Microbiology, University of Illinois.

Reid, Dr. David A. Agricultural Research Service, U.S. Department of Agriculture, Tucson, Arizona.

Reid, Prof. Evans B. Professor Emeritus, Department of Chemistry, Colby College.

Reid, Joseph L. Scripps Institution of Oceanography, La Jolla, California.

Reid, Dr. Walter V. World Resources Institute, Washington, D.C.

Reiling, Dr. Gilbert H. Lighting Research and Technical Services Operation, General Electric Company, Cleveland, Ohio.

Reilly, John C., Jr. Naval Historical Center, Navy Department, U.S. Department of Defense.

Reingold, Dr. Edward M. Chairman, Department of Computer Science, Illinois Institute of Technology, Chicago, Illinois.

Reinhardt, Dr. Nicholas. Consultant, Lexington, Massachusetts.

Reintjes, John F. Naval Research Laboratory, Washington, D.C.

Reischmann, Rev. Placidus G., O.S.B., Head, Department of Biology, St. Martin's College, Olympia, Washington.

Reiter, Dr. Elmar R. Department of Atmospheric Science, Colorado State University.

Reitz, Dr. Louis P. (Retired) Corps Research Division, Agricultural Research Service, U.S. Department of Agriculture, Beltsville, Maryland.

Remde, Dr. Harry F. Chief, Basic Physics Research Section, Johns-Manville Research and Engineering Center, Manville, New Jersey.

Remley, Frederick M., Jr. Retired; formerly, Center for Information Technology Integration, University of Michigan.

Retallack, Dr. Gregory J. Department of Geological Sciences, College of Arts and Sciences, University of Oregon.

Rettinger, Michael. Deceased; formerly, Consultant on Acoustics, Encino, California.
Reynolds, Gardner M. Dames & Moore, Los Angeles, California.
Reynolds, Mark F. Graduate Research Assistant, Department of Chemistry, University of Wisconsin, Madison.
Ribbe, Dr. Paul H. Department of Geological Sciences, Virginia Polytechnic Institute.
Rich, Prof. Arthur. Deceased; formerly, Department of Physics, University of Michigan.
Rice, Dr. Mary E. Associate Curator, Division of Worms, Smithsonian Institution.
Rice, Dr. Michael. Department of Fish, Animal and Veterinary Science, University of Rhode Island, Kingston, Rhode Island.
Rich, Dr. Saul. Connecticut Agricultural Experiment Station, New Haven, Connecticut.
Richards, Dr. Frank F. Department of Medicine, Yale University.
Richards, Dr. Oscar W. (Retired) College of Optometry, Pacific University.
Richardson, Dr. Philip. Department of Physical Oceanography, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.
Richter, Reinhard H. Manager, Polyurethane Research, Dow Chemical U.S.A., North Haven Laboratories, North Haven, Connecticut.
Rickert, Richard M. AT&T Consumer Products Laboratories, Indianapolis, Indiana.
Ricksecker, Ralph E. Director of Metallurgy, Chase Brass and Copper Company, Cleveland, Ohio.
Riddle, Dr. Mark. A. Department of Psychiatry and Behavioral Sciences, Johns Hopkins Medical Institutions, Baltimore, Maryland.
Riedel, Dr. Rupert J. Department of Zoology, University of North Carolina.
Ries, Dr. Harold C. Stanford Research Institute, Menlo Park, California.
Rigby, Dr. J. Keith. Department of Geology, Brigham Young University.
Riggs, Dr. Austen F. Department of Zoology, University of Texas, Austin.
Riggs, Dr. Lorrin A. Department of Psychology, Brown University.
Rijnsdorp, Prof. Johannes E. University of Twente, Enschede, Netherlands.
Riley, Frank. Senior Vice-President, Bodine Assembly Systems, Bridgeport, Connecticut.
Riley, Dr. Pete. Science Applications International Corporation, San Diego, California.
Riley, Dr. Ralph. Plant Breeding Institute, Cambridge, England.
Riley, Dr. Reed F. Quantum Electronics Group, General Telephone and Electronics, Bayside, New York.
Rillema, Prof. James A. Professor of Physiology, Department of Physiology, School of Medicine, Wayne State University.
Rindler, Dr. Michael. Associate Professor of Cell Biology, New York University School of Medicine, New York.
Riordan, Prof. James. Center for Biochemical and Biophysical Sciences and Medicine, Harvard Medical School, Boston, Massachusetts.
Risebrough, Dr. Robert W. Research Ecologist, Bodega Marine Laboratory, University of California, Berkeley.
Riser, Dr. Stephen C. School of Oceanography, University of Washington, Seattle.
Risser, Dr. Paul G. Vice President for Research, University of New Mexico.
Ritchey, Dr. H. W. President, Thiokol Chemical Corporation, Ogden, Utah.
Ritchie, Dr. J. C. Department of Biology, Trent University, Peterborough, Ontario, Canada.
Ritchile, Dr. Rufus H. Oak Ridge National Laboratory, Oak Ridge, Tennessee.
Rizack, Dr. Martin A. Department of Medicine, Rockefeller University.
Robb, D. D. D. D. Robb and Associates, Consulting Engineers, Electric Power Systems, Salina, Kansas.
Robbins, Dr. John A. Great Lakes Environmental Research Laboratory, National Oceanic and Atmospheric Administration, Ann Arbor, Michigan.
Robbins, Nathaniel, Jr. Director of Engineering, Residential Division, Honeywell, Inc., Minneapolis, Minnesota.
Roberts, Dr. Andrew. Department of Oceanography, University of Southampton, Southampton Oceanography Centre, United Kingdom.
Roberts, Dr. Arthur. National Accelerator Laboratory, Batavia, Illinois.
Roberts, J. K. (Retired) Research and Development Department, Standard Oil Company, Chicago, Illinois.
Roberts, Prof. Louis D. Department of Physics, University of North Carolina.
Roberts, Dr. Richard J. Cold Spring Harbor Laboratories, Cold Spring Harbor, New York.
Robertson, Dr. J. David. Department of Anatomy, Duke University Medical Center.
Robertson, Dr. James S. Medical Department, Medical Physics Division, Brookhaven National Laboratory, Upton, New York.
Robertson, Lemuel C. Newport News Shipbuilding and Dry Dock Company, Newport News, Virginia.
Robinovitch, Dr. Murray. Department of Oral Biology, University of Washington School of Dentistry, Seattle.
Robinson, Prof. Arthur H. Department of Geography, University of Wisconsin.
Robinson, Prof. Richard W. Department of Seed and Vegetable Sciences, New York State Agricultural Experiment Station, Cornell University.
Robinson, W. V. Processor Technology Research Group, Bell Laboratories, Whippany, New Jersey.
Rochow, Prof. Eugene G. (Retired) Department of Chemistry, Harvard University.
Rock, Dr. Irwin. Department of Psychology, University of California, Berkeley.
Rockett, Frank H. Engineering Consultant, Charlottesville, Virginia.
Rodden, Dr. William P. Consulting Engineer, La Canada-Flintridge, California.
Roddis, Louis H., Jr. President, Consolidated Edison Company of New York, Inc.
Rodier, Dr. Patricia M. Department of Anatomy, School of Medicine, University of Virginia.
Rodman, Dr. James. Program Director for Systematic Biology, National Science Foundation, Arlington, Virginia.
Roe, K. Keith. Chairman and President, Burns & Roe, Inc., Oradell, New Jersey.
Roehl, Dr. Bernie. Department of Electrical and Computer Engineering, University of Waterloo, Ontario, Canada.
Rogallo, Francis M. (Retired) NASA Langley Research Center, Hampton, Virginia.
Rogers, Dr. Harry C. Department of Metallurgical Engineering, Drexel University, Philadelphia, Pennsylvania.
Rogowski, Prof. Augustus R. Department of Mechanical Engineering, Massachusetts Institute of Technology.
Rohde, Dr. Richard A. Department of Plant Pathology, University of Massachusetts.
Rohlf, Dr. James W. Department of Physics, Boston University.
Rohrlich, Prof. F. Department of Physics, Syracuse University.
Roller, Dr. Duane E. Deceased; formerly, Harvey Mudd College, Claremont, California.
Romano, Frank. Consultant, Graphic Arts, Salem, New Hampshire.
Romer, Prof. Alfred S. Deceased; formerly, Museum of Comparative Zoology, Harvard University.
Romick, Dr. Gerald J. Applied Physics Laboratory, Johns Hopkins University, Laurel, Maryland.
Roosen-Runge, Prof. Edward C. Department of Biological Structure, School of Medicine, University of Washington.
Roper, Dr. Stephen D. University of Miami School of Medicine, Department of Physiology and Biophysics, Miami, Florida.
Roper, Paul J. Department of Geology, University of Southwestern Louisiana.
Rosa, Dr. Patricia. National Institutes of Health and Allergies, Rocky Mountain Laboratories, Hamilton, Montana.
Rose, Dr. William Ingersoll, Jr. Department of Geology and Geological Engineering, Michigan Technological University.
Rosen, Prof. Barry. Department of Biological Chemistry, University of Maryland.
Rosen, Dr. Fred S. President, Center for Blood Research, Department of Pediatrics, Harvard Medical School, Children's

Hospital Medical Center, Boston, Massachusetts.

Rosen, Dr. Kenneth H. AT&T Laboratories, Holmdel, New Jersey.

Rosen, Dr. Robert. Department of Physiology and Biophysics, Faculty of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada.

Rosenbaum, Prof. Fred J. Department of Electrical Engineering, Washington University.

Rosenberg, Dr. Eugene. Department of Microbiology, George S. Wise Faculty of Life Sciences, Tel Aviv University, Israel.

Rosenberg, Leon T. Senior Consultant, Generator Design, Generation, Installation, and Service, Allis-Chalmers Manufacturing Company, Milwaukee, Wisconsin.

Roskoski, Dr. Robert, Jr. Department of Biochemistry and Molecular Biology, Louisiana State University, New Orleans.

Ross, Dr. Charles A. Department of Geology, Western Washington State College.

Ross, Dr. Edward S. California Academy of Sciences, San Francisco.

Ross, Dr. Herbert H. Illinois State Natural History Survey, Urbana.

Ross, Dr. J. Central Science Laboratory, Surrey, United Kingdom.

Ross, Dr. Malcolm. Washington, D.C.

Ross, Dr. Robert S. Environmental Structures, Inc., Cleveland, Ohio.

Ross, Prof. Sidney. Department of Chemistry, Rensselaer Polytechnic Institute.

Rossby, Prof. H. Thomas. Graduate School of Oceanography, University of Rhode Island, Kingston.

Rossing, Dr. Thomas D. Department of Physics, Northern Illinois University, DeKalb.

Rossini, Dr. Aldo A. Professor of Medicine, and Director, Division of Diabetes, University of Massachusetts Medical School, Worcester.

Rossmeissl, Dr. Paul G. Senior Research Scientist, American Institute for Research, Washington, D.C.

Rostoker, Dr. William. Department of Materials Engineering, University of Illinois, Chicago.

Roth, Willard. Engineer, Sunbeam Equipment Corporation, Meadville, Pennsylvania.

Rothblum, Richard Stone. David W. Taylor Naval Ship Research and Development Center, Bethesda, Maryland.

Rothschild, Dr. Bruce M. Youngstown, Ohio.

Roundhill, Dr. D. Max. Department of Chemistry, Tulane University.

Rowe, Prof. D. M. NEDO Centre for Thermoelectric Engineering, Division of Electronic Engineering, University of Wales, Cardiff, United Kingdom.

Rowell, Prof. A. J. Department of Geology, University of Kansas.

Rowell, Prof. Roger M. Project Leader, Modified Lignocellulosic Materials, Forest Products Laboratory, University of Wisconsin-Madison.

Rowen, Prof. Alan L. Webb Institute of Naval Architecture, Glen Cove, New York.

Rowley, Dr. W. R. C. Department of Trade and Industry, Division of Mechanical and Optical Metrology, National Physical Laboratory, Teddington, Middlesex, England.

Rownd, Dr. Robert H. Department of Molecular Biology, Northwestern Medical School.

Roy, Natalie, U. Director of Recycling and Legislative Affairs, Glass Packaging Institute, Washington, D.C.

Rozeanu, Prof. L. Department of Material Science, Technion, Israel Institute of Technology.

Rubinstein, Sue R. Marketing Program Services Group, The Aries Group, Rockville, Maryland.

Rubis, Prof. David D. Department of Plant Sciences, College of Agriculture, University of Arizona.

Ruch, Prof. Fritz. Department of General Botany, Swiss Federal Institute of Technology, Zurich.

Ruch, Prof. Theodore C. Director, Regional Primate Research Center; Professor, Department of Physiology and Biophysics, School of Medicine, University of Washington.

Ruddat, Dr. Manfred. Department of Molecular Genetics and Cell Biology, University of Chicago, Barnes Laboratory.

Ruderman, Dr. Audrey J. Department of Psychology, University of Illinois, Chicago.

Rudnick, Dr. Dorothea. Department of Biology, Albertus Magnus College, Yale University.

Ruffing, Jaime. AMSTA-AR-ASP, U.S. Army Armament Research Development and Engineering Center, Picatinny Arsenal, New Jersey.

Rulfs, Dr. Charles L. Department of Chemistry, University of Michigan.

Rumble, Dr. Douglas, III. Petrologist, Geophysical Laboratory, Carnegie Institution, Washington, D.C.

Rumsey, Dr. James W. Department of Agricultural Engineering, University of California, Davis.

Rundman, Prof. Karl. Department of Metallurgical Engineering, Michigan Technological University.

Runham, Dr. Norman. Department of Zoology, University College of North Wales, Bangor.

Runnegar, Dr. Bruce. Department of Earth and Space Sciences, University of California, Los Angeles.

Ruouff, Dr. Kathryn L. Francis Blake Bacteriology Laboratories, Department of Microbiology and Molecular Genetics, Massachusetts General Hospital, Harvard Medical School, Boston, Massachusetts.

Rupp, Arthur F. Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Rusk, Dr. Rogers D. Mount Holyoke College.

Russell, Dr. Allen S. Vice President, Alcoa Laboratories, Aluminum Company of America, Pittsburgh, Pennsylvania.

Russell, Dr. Howard W. Deceased; formerly, Technical Director, Battelle Memorial Institute, Columbus, Ohio.

Russell-Hunter, Prof. W. D. Professor of Zoology, Department of Biology, Syracuse University.

Rust, Dr. Brian R. Department of Geology, University of Ottawa, Ontario, Canada.

Rust, Dr. David M. Applied Physics Laboratory, Johns Hopkins University, Laurel, Maryland.

Rutger, J. N. Department of Agronomy, University of California, Davis.

Ruthroff, Clyde L. Consultant, Holmdel, New Jersey.

Rutkow, Dr. Ira M. Hernia Center, Freehold, New Jersey.

Rutledge, Dr. Steven A. Department of Atmospheric Science, Colorado State University, Fort Collins.

Ryan, Prof. James J. Professor Emeritus of Mechanical Engineering, University of Minnesota.

Ryan, Dr. Kenneth J. Department of Pathology, University of Arizona Medical Center, Tucson.

Ryge, Dr. Peter. Vice President for Engineering, Ancore Corporation, Santa Clara, California.

Ryland, Prof. John S. Head of Biology, School of Natural Resources, University of the South Pacific, Laucala Bay, Suva, Fiji.

S

Saad, Prof. Michael L. Department of Mechanical Engineering, Santa Clara University, Santa Clara, California.

Saaty, Prof. Thomas L. Graduate School of Business, University of Pittsburgh.

Sabo, Dr. John L. National Center for Ecological Analysis and Synthesis, Santa Barbara, California.

Sadoway, Prof. Donald R. Massachusetts Institute of Technology, Department of Materials Science and Engineering, Cambridge.

Sadwick, Dr. Laurence P. Electrical Engineering Department, University of Utah, Salt Lake City.

Saenger, Dr. Peter. Centre for Coastal Management, University of New England, Northern Rivers, Lismore, Australia.

Saenger, Dr. Wolfram. Max Planck-Institut für Experimentelle Medizen, Gottingen, Germany.

Sage, Prof. Andrew P. Founding Dean Emeritus and First American Bank Professor. University Professor, School of Information Technology and Engineering, George Mason University, Fairfax, Virginia.

Saito, Dr. Tsunemasa. Lamont-Doherty Geological Observatory, Palisades, New York.

Šajgalík, Dr. Pavol. Institute of Organic Chemistry, Slovak Academy of Sciences, Bratislava Slovak Republic, Bratislava, Czechoslovakia.

Salam, Prof. Abdus. Deceased; formerly, Director, International Centre for Theoretical Physics, Trieste, Italy.

Salazar, Prof. Deborah A. Department of Geography, Oklahoma State University, Stillwater.

Salisbury, Dr. Alan B. Chairman, Learning Tree International, Reston, Virginia.

Salisbury, Dr. Frank B. Plant Science Department, Utah State University.

Salkin, Dr. Ira F. Wadsworth Center, New York Department of Health, Albany, New York.

Saltzman, Dr. W. Mark. Department of Chemical Engineering, G. W. C. Whiting School of Engineering, Johns Hopkins University, Baltimore, Maryland.

Salutsky, Dr. Murrell L. Vice President, Research, Dearborn Chemical Division, W. R. Grace and Company, Lake Zurich, Illinois.

Samios, Dr. Nicholas P. Brookhaven National Laboratory, Upton, New York.

Samson, Prof. Perry. Department of Atmospheric, Oceanic, and Space Sciences, University of Michigan, Ann Arbor.

Samter, Dr. Max. Institute of Allergy and Clinical Immunology, Grant Hospital of Chicago.

San Martin, Robert L. Deputy Assistant Secretary for Renewable Energy, Department of Energy, Washington, D.C.

Sanchez, Dr. Anthony. Research Officer, Department of Health and Human Services, Centers for Disease Control and Prevention, Atlanta, Georgia.

Sanchez-Sinencio. Dr. Edgar. Department of Electrical Engineering, Texas A & M University.

Sandage, Dr. Allan. Mount Wilson and Palomar Observatories, Pasadena, California.

Sandberg, Dr. Charles. U.S. Geological Survey, Denver, Colorado.

Sandberg, Dr. Philip A. Department of Geology, University of Illinois at Urbana-Champaign.

Sanders, Dr. Frederick. Department of Meteorology, Massachusetts Institute of Technology.

Sanders, Dr. Robert W. Department of Zoology, University of Georgia.

Sanders, Prof. Tom H., Jr. Department of Materials Engineering, Purdue University.

Sandier, Prof. Stanley I. Department of Chemical Engineering, University of Delaware.

Sandretto, Brig. Gen. Peter C. Deceased; formerly, Director, Engineering Management, International Telephone and Telegraph Corporation.

Sankey, Dr. Bruce M. Petroleum Products Division, Imperial Oil, Ltd., Sarnia, Ontario, Canada.

Sankey, E. W. Marion Power Shovel Division, Dresser Industries, Inc., Marion, Ohio.

Sarachik, Prof. Edward S. Department of Atmospheric Sciences, University of Washington, Seattle.

Sargent, Dr. Anneila I. Owens Valley Radio Observatory, California Institute of Technology, Pasadena.

Sasian, Prof. Jose M. Optical Sciences Center, University of Arizona, Tucson.

Sass, Prof. Stephen L. Department of Materials Science and Engineering, Cornell University.

Sathish, Dr. Shamachary. University of Dayton Research Institute, Dayton, Ohio.

Satir, Dr. Peter. Chairman, Department of Anatomy and Structural Biology, Albert Einstein College of Medicine.

Saucer, Prof. Helmut. Department of Biology, Texas A&M University.

Sauer, Fred. Technical Service Department, Pfizer, Inc., Groton, Connecticut.

Saul, Dr. Everett L. Director of Scientific Liaison, Products Division, Bristol-Myers Company.

Saunders, Dr. Gary W. Department of Biology, University of New Brunswick, Fredericton, New Brunswick, Canada.

Saunders, Dr. R. Stephen. Jet Propulsion Laboratory, California Institute of Technology.

Sauvage, Dr. Jean-Pierre. Laboratoire de Chimie Organo-Minérale, Institut le Bel, Université Louis Pasteur, Strasbourg, France.

Savage, Prof. Blair D. Washburn Observatory, Department of Astronomy, University of Wisconsin.

Savage, Dr. Donald E. Department of Paleontology, University of California, Berkeley.

Savage, Dr. George M. Director, Product Research and Development, Upjohn International Inc., Kalamazoo, Michigan.

Savage, Dr. Jay M. Department of Biological Sciences, University of Southern California.

Sawhney, Dr. V. K. Department of Biology, University of Saskatchewan, Saskatoon, Canada.

Sawyer, Dr. Donald. Distinguished Professor, Department of Chemistry, Texas A&M University.

Sayeed, Prof. Ali H. Department of Electrical Engineering, University of California, Los Angeles.

Sayler, Prof. John H. Electrical Engineering and Computer Science Department, University of Michigan, Ann Arbor.

Sayre, Dr. Albert N. Deceased; formerly, Consulting Groundwater Geologist, Behre Dolbear and Company.

Sayre, Prof. Lawrence M. Department of Chemistry, Case Western Reserve University, Cleveland, Ohio.

Scalzi, Dr. John B. Program Director, National Science Foundation, Washington. D.C.

Scanlan, Prof. J. O. Department of Electrical and Electronic Engineering, University College, Dublin, Ireland.

Schachter, Dr. Julius. Department of Laboratory Medicine, University of California, San Francisco.

Schaefer, Dr. Henry P., III. Department of Chemistry, University of California, Berkeley.

Schaeffer, Dr. Bobb. Chairman and Curator, American Museum of Natural History, New York.

Schaumann, Prof. Rolf. Department of Electrical and Computer Engineering, Portland State University, Portland, Oregon.

Schawlow, Prof. Arthur L. Department of Physics, Stanford University.

Scheeline, Dr. Alexander. School of Chemical Sciences, University of Illinois, Urbana-Champaign.

Scheer, Dr. Bradley T. Professor Emeritus, Department of Biology, University of Oregon.

Schelleng, John C. (Retired) Bell Telephone Laboratories.

Scheltema, Amelie H. Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.

Scher, Dr. Robert M. Senior Project Engineer, John J. McMullen Associates, Inc., Arlington, Virginia.

Schetz, Prof. Joseph A. Department of Aerospace and Ocean Engineering, Virginia Polytechnic Institute and State University, Blacksburg.

Schimmel, Dr. Curt. Silicon Graphics, Inc., Mountain View, California.

Schindler, Dr. Anton. Camille Dreyfus Laboratory, Research Triangle Institute, Research Triangle Park, North Carolina.

Schindler, Dr. James E. Department of Biological Sciences, College of Sciences, Clemson University.

Schlecht, Dr. Matthew F. Section Research Chemist, E. I. du Pont de Nemours & Company, Inc., Agricultural Products Department, Newark, Delaware.

Schlitt, Dr. William Joseph. Process Manager/Kvaerner Metals, Davy Nonferrous Division, San Ramon, California.

Schmerling, Dr. Louis. Research Associate, Universal Oil Products Company, Des Plaines, Illinois.

Schmid, Dr. Rudolf. Department of Botany, University of California, Berkeley.

Schmidlin, Dr. Francis. National Aeronautics and Space Administration, Observational Science Branch, Laboratory for Oceans, Goddard Space Flight Center, Wallops Flights Facility, Wallops Island, Virginia.

Schmidt, Dr. Paul W. Department of Physics, University of Missouri.

Schmidt-Nielsen, Dr. Bodil. Department of Zoology, Duke University.

Schmitt, Dr. Raymond. Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.

Schmitt, Dr. Waldo L. Deceased; formerly, Zoologist Emeritus, Department of Zoology, Smithsonian Institution.

Schnabel, Dr. Ronald. Pasture Systems and Watershed Management Research Laboratory, U.S. Department of Agriculture–Agricultural Research Service, University Park, Pennsylvania.

Schneider, Dr. Thomas R. Electric Power Research Institute, Palo Alto, California

Schneidewind, Dr. Norman F. Computer Scientist, Computer Research, Pebble Beach, California.

Schoch, Dr. Robert. Attleboro, Massachusetts.

Schoeffler, Dr. James D. Department of Computer and Information Science, Cleveland State University.

Scholle, Prof. Peter A. Department of Geological Sciences, Southern Methodist University, Dallas, Texas.

Scholz, Christopher H. Lamont-Doherty Geological Observatory, Palisades, New York.

Scholz, Dr. Nathaniel. Northwest Fisheries Science Center, Environmental Conservation Division, Seattle, Washington.

Schooler, Dr. Jonathan. Learning, Research, and Development Center, University of Pittsburgh.

Schoonmaker, G. R. Retired; formerly, Vice President, Production-Exploration, Marathon Oil Company, Findlay, Ohio.

Schowalter, Prof. Timothy D. Department of Entomology, Oregon State University, Corvallis.

Schreiber, Prof. B. Charlotte. Department of Earth and Environmental Sciences, Queens College, New York.

Schreibman, Dr. Martin P. Department of Biology, Brooklyn College, City University of New York.

Schroeder, Dr. Charles A. Department of Botanical Sciences, University of California, Los Angeles.

Schroeder, Dr. Lee S. Lawrence Berkeley Laboratory, Berkeley, California.

Schroeder, Dr. Thomas E. Friday Harbor Laboratories, University of Washington.

Schubert, Dr. Jack. Radiation Health, Graduate School of Public Health, University of Pittsburgh.

Schuchardt, Dr. Lee F. Merck, Sharp, and Dohme, West Point, Pennsylvania.

Schueler, Dr. Donald G. Sandia Laboratories, Albuquerque, New Mexico.

Schugar, Dr. Harvey. Department of Chemistry, Wright and Rieman Laboratories, New Brunswick, Rutgers University.

Schuller, Dr. Ivan K. Physics Department, University of California, La Jolla.

Schulman, Dr. James H. U.S. Naval Research Laboratory.

Schultz, Dr. Cheryl. National Center for Ecological Analysis and Synthesis, University of California, Santa Barbara.

Schultz, Dr. Jack. Gypsy Moth Research Center, Department of Entomology, College of Agriculture, Pesticide Research Laboratory and Graduate Study Center, Pennsylvania State University.

Schultz, Robert M. General Manager, William Langer Jewel Bearing Plant, Bulova Watch Company, Inc., Rolla, North Dakota.

Schultze, Dr. Hanns-Peter. Curator of Vertebrate Paleontology, Museum of Natural History, University of Kansas.

Schur, Dr. Peter H. Robert B. Brigham Hospital, Boston, Massachusetts.

Schuster, Prof. Frederick L. Department of Biology, Brooklyn College.

Schwab, Robert W. Boeing Company, Commercial Airplane Group, Seattle, Washington.

Schwartz, Dr. Karlene V. Department of Biology, University of Massachusetts, Boston.

Schwartz, Mel. Materials Consultant, United Technologies Corporation, Stratford, Connecticut.

Schwartz, Dr. Mel M. Rohr Industries, Inc., Chula Vista, California.

Schwartz, Dr. Morton K. Department of Biochemistry, Memorial Hospital, New York.

Schweizer, Ernest. President, Schweizer Aircraft Corporation, Elmira, New York.

Scotese, Dr. Christopher R. Department of Geology, University of Texas, Arlington.

Scott, Prof. Alwyn. Program in Applied Mathematics, University of Arizona, Tucson.

Scott, Dave. Industrial Engineering Manager, Modular Computer Systems, Inc., Fort Lauderdale, Florida.

Scott, Dr. Edward R. D. Institute of Meteoritics, Department of Geology, University of New Mexico.

Scott, Prof. James F. Department of Physics, University of Colorado.

Scott, Dr. John E., Jr. Department of Aerospace Engineering and Engineering Physics, University of Virginia.

Scott, Dr. John P. Director, Center for Research on Social Behavior, Bowling Green State University.

Scott, Dr. Richard A. U.S. Geological Survey, Department of the Interior, Denver, Colorado.

Scott, Prof. Robert L. Department of Chemistry, University of California, Los Angeles.

Scouten, Dr. Charles W. Stoelting Company, Oakwood Centre, Wood Dale, Illinois.

Scrutton, Dr. Colin T. Department of Geological Sciences, University of Durham, United Kingdom.

Seaborg, Dr. Glenn T. Lawrence Berkeley Laboratory, University of California, Berkeley.

Seagle, Stanley. Vice President, Research and Technical Development, RMI Company, Niles, Ohio.

Searles, Dr. Robert. Rheumatology Division, University of New Mexico School of Medicine.

Searson, Dr. Peter C. H. H. Uhlig Corrosion Laboratory, Department of Materials Science and Engineering, Massachusetts Institute of Technology.

Sebald, Joseph F. Consulting Engineer and President, Heat Power Products Corporation, Bloomfield, New Jersey.

Seed, Prof. John Richard. Department of Epidemiology, School of Public Health, University of North Carolina, Chapel Hill.

Segal, Dr. Bernard L. Professor of Medicine, Cardiovascular Institute, Hahnemann Medical College and Hospital, Philadelphia, Pennsylvania.

Segal, Dr. Nancy L. Department of Psychology, California State University, Fullerton.

Segeler, C. George. Director, Technical Service, Dave Sage, Inc., New York.

Sehgal, Dr. Amita. Howard Hughes Medical Institute, Department of Neuroscience, University of Pennsylvania School of Medicine, Philadelphia.

Seidelmann, Dr. P. K. Director, Nautical Almanac Office, U.S. Naval Observatory, Washington, D.C.

Seitz, Dr. W. Rudolf. Department of Chemistry, College of Engineering and Physical Sciences, University of New Hampshire.

Sekera, Prof. Zdenek. Deceased; formerly, Department of Meteorology, Institute for Geophysics and Planetary Physics, University of California, Los Angeles.

Selamet, Prof. Ahmet. Center for Automotive Research, Ohio State University, Columbus.

Selby, Prof. Michael J. Department of Earth Science, University of Waikato, New Zealand.

Seliskar, Dr. Denise M. Associate Research Scientist, College of Marine Studies, University of Delaware.

Sell, Dr. Heinz G. Metals Development Section, Westinghouse Lamp Divisions, Bloomfield, New Jersey.

Sellars, Dr. John R. Manager, Engineering Mechanics Operations, TRW, Inc., Redondo Beach, California.

Sellin, Dr. Ivan A. Department of Physics, University of Tennessee.

Sellmyer, Prof. David J. Behlen Laboratory of Physics, University of Nebraska.

Selverstone, Dr. Jane. Department of Earth and Planetary Sciences, Hoffman Laboratory, Harvard University.

Sepkoski, Dr. J. John, Jr. Department of Geophysical Sciences, Henry Hinds Laboratory, University of Chicago.

Seshadri, Sridhar. Operations Management Department, Stern School of Business, New York University, New York.

Sessions, Dr. John. Department of Forest Engineering, Oregon State University, Corvallis.

Sessler, Dr. Gerhard M. Institut für Ubertragungstechnik Elektroakustik, Technische Hochschule, Darmstadt, Germany.

Sethares, Dr. William A. Department of Electrical and Computer Engineering, University of Wisconsin, Madison.

Setlow, Dr. Richard B. Brookhaven National Laboratory, Upton, New York.

Shack, Prof. Roland V. Optics Science Center, University of Arizona.

Shaffer, Dr. Albert L. Clinical Professor of Medicine, Brigham and Women's Hospital, Boston, Massachusetts.

Shanmugam, Dr. G. Mobil Research and Development Corporation, Research Department, Dallas Research Laboratory, Dallas, Texas.

Shannon, L. R. "The New York Times," New York.

Shannon, Prof. Robert R. Optical Sciences Center, University of Arizona.

Shapere, Prof. Dudley. Wake Forest University, Winston-Salem, North Carolina.

Shapiro, Hymin. Research and Development Department, Ethyl Corporation, Baton Rouge, Louisiana.

Sharkey, Dr. Thomas D. Department of Botany, University of Wisconsin.

Sharon, Prof. Nathan. Department of Membrane Research and Biophysics, Weizmann Institute of Science, Rehovot, Israel.

Sharpe, Dr. Ralph H. Gainesville, Florida.

Shaw, Brian R. BHP Petroleum (Americas) Inc., Houston, Texas.

Shaw, Dr. Cheng-Mei. Laboratory of Neuropathy, Department of Pathology, University of Washington School of Medicine.

Shaw, Jeffry S. 3M Industrial Tape & Specialties Division, Stopaul, Minnesota.

Shaw, Prof. Peter. Department of Physics, Pennsylvania State University.

Shaw, Dr. Robert A. Department of Chemistry, Birkbeck College, University of London, England.

Shearer, Dr. Charles K. Institute of Meteorites, Department of Earth and Planetary Sciences, University of New Mexico, Albuquerque.

Shedlock, Dr. Kaye M. U.S. Geological Survey, Administrative Officer, Denver, Colorado.

Sheeley, Dr. Neil R., Jr. Naval Research Laboratory, Washington, D.C.

Sheffield, Dr. Harley G. Laboratory of Parasitic Diseases, National Institutes of Health, Bethesda, Maryland.

Sheft, Dr. Irving. Chemistry Division, Argonne National Laboratory, Argonne, Illinois.

Sheingold, Daniel H. Analog Devices, Inc., Norwood, Massachusetts.

Shelton, Dr. Frank H. Chief Scientist, Kaman Sciences Corporation, Colorado Springs, Colorado.

Shenoy, Dr. Gopal. Senior Scientific Director, The Advanced Photon Source, Argonne National Laboratory, Illinois.

Shephard, Dr. Bruce D. Diplomates, American College of Obstetricians and Gynecologists, Tampa Obstetrics and Gynecology Associates, Tampa, Florida.

Shepherd, Dr. Gordon M. Yale University Medical School.

Sheppard, Dr. Edith M. Senior Lecturer in Zoology (retired), University of South Wales and Monmouthshire.

Shergold, Dr. John. H. Chairman, International Subcommission on Cambrian Stratigraphy, Masseret, France.

Sheridan, Prof. Thomas B. Department of Mechanical Engineering, Massachusetts Institute of Technology.

Sheriff, Dr. Robert E. Department of Geology, University of Houston.

Sherwood, Robert S. Deceased; formerly, Manager of Engineering, Steam Turbine Division, Worthington Corporation, Harrison, New York.

Shevell, Prof. Richard S. Department of Aeronautics, Stanford University.

Sheviak, Dr. Charles J. Senior Scientist and Curator of Botany, New York State Museum, Albany.

Shiino, Dr. Sueo M. Faculty of Fisheries, Prefectural University of Mie, Japan.

Shimek, Dr. Ronald L. Reef Safe Enterprises, Inc., Wilsall, Montana.

Shipman, Dr. Harry L. Department of Physics, University of Delaware.

Shires, Dr. G. Tom. Department of Surgery, Texas Technical University, Lubbock.

Shirley, Prof. David A. Deceased; formerly, Department of Chemistry, University of Tennessee.

Shivaram, Dr. Bellave S. Department of Physics, John S. Beams Laboratory, University of Virginia.

Shive, Prof. William. Department of Chemistry and Clayton Foundation Biochemical Institute, University of Texas, Austin.

Shively, R. R. Supervisor, Processor Technology Research Group, Bell Laboratories, Whippany, New Jersey.

Shoemaker, Dr. William C. Martin Luther King, Jr./Charles R. Drew Medical Center, Los Angeles, California.

Shortman, Dr. Ken. Head, Lymphocyte Differentiation Unit, The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia.

Shortreed, Dr. John. Director, Institute for Risk Research, Waterloo, Ontario, Canada.

Shprintzen, Dr. Robert J. Director, Center for Crainofacial Disorders, Montifiore Medical Center, Albert Einstein College of Medicine, New York, New York.

Shreve, Prof. R. Morris. Professor Emeritus of Chemical Engineering, Purdue University.

Shuman, E. C. Regional Professional Engineer, State College, Pennsylvania.

Shuman, Dr. Frederick B. Director, National Meteorological Center, National Oceanic and Atmospheric Administration, Washington, D.C.

Shuster, Dr. Carl N., Jr. Ecologist (retired), Bureau of Water Hygiene, U.S. Public Health Service, Cincinnati, Ohio.

Siebein, Dr. Gary W. Department of Architecture, University of Florida, Gainesville.

Siegbahn, Prof. Kai. Institute of Physics, University of Uppsala, Sweden.

Siegel, Prof. Benjamin M. Department of Applied Physics, Cornell University.

Siegel, Dr. Richard W. Materials Science Division, Argonne National Laboratory, Argonne, Illinois.

Siegman, Dr. A. E. Stanford, California.

Siegmund, C. W. Exxon Research and Engineering Company, Linden, New Jersey.

Siegmund, Dr. Walter P. Director, Research and Development, Schott Fiber Optics, Inc., Southbridge, Massachusetts.

Sieh, Prof. Kerry. Seismological Laboratory, California Institute of Technology, Pasadena.

Siekevitz, Dr. Philip. Department of Cell Biology, Rockefeller University, New York.

Sienko, Dr. Michell J. Deceased; formerly, Department of Chemistry, Cornell University.

Siever, Dr. Raymond. Department of Geological Sciences, Harvard University.

Siggia, Prof. Sidney. Department of Chemistry, University of Massachusetts.

Signorini, Dr. Sergio R. Division of Ocean Sciences, National Science Foundation, Arlington, Virginia.

Silberschatz, Dr. Abraham. Information Sciences Research Center, Murray Hill, New Jersey.

Šiljak, Prof. Dragoslav D. School of Engineering, Santa Clara University, California.

Silk, Dr. Joseph. Department of Astronomy, University of California, Berkeley.

Silman, Robert. Robert Silman Associates, P.C., New York.

Silva, Dr. Paul C. Department of Botany, University of California, Berkeley.

Silverman, Dr. Joseph. Department of Chemical Engineering, University of Maryland.

Simberloff, Prof. Daniel. Department of Biological Science, Florida State University.

Simmons, Dr. James A. Walter S. Hunter Laboratory of Psychology, Brown University.

Simmons, Dr. Nancy. Department of Mammology, American Museum of Natural History, New York.

Simmons, Dr. William H. Department of Biochemistry and Biophysics, Loyola University Medical Center, Maywood, Illinois.

Simon, Dr. Barry. Department of Mathematics, Princeton University.

Simon, Dr. George W. Space Physics Division, Phillips Laboratory (AFSC), National Solar Observatory, New Mexico.

Simon, Dr. Steven. Department of Geophysical Science, University of Chicago, Illinois.

Simonson, Dr. Roy W. Director (retired), Soil Classification and Correlation, U.S.

Department of Agriculture, Hyattsville, Maryland.

Simpson, Dr. Carol. Department of Earth and Planetary Sciences, Johns Hopkins University.

Simpson, Dr. Joanne. Head, Severe Storms Branch, Goddard Space Flight Center, NASA, Greenbelt, Maryland.

Simpson, Prof. Robert H. Retired; formerly, Director, Experimental Meteorology Laboratory, National Weather Service, Miami, Florida.

Simpson, Prof. Stephen G. Department of Chemistry, Massachusetts Institute of Technology.

Sims, Dr. Chester T. Department of Materials Engineering, Rensselaer Polytechnic Institute, New York.

Sims, Dr. G. K. Agricultural Research Service, U.S. Department of Agriculture, Urbana, Illinois.

Sincerbox, Prof. Glenn T. Optical Data Storage Center, Optical Sciences Center, University of Arizona, Tucson.

Sinclair, Dr. Malcom W. Procurement Executive, Ministry of Defense, Royal Signals and Radar Establishment, Great Malvern, Worcestershire, England.

Singer, Dr. S. F. Formerly, Deputy Assistant Secretary, U.S. Department of the Interior.

Singer, Prof. Stanley. Director, ATHENEX Research Associates.

Singleton, John D. Supervisor of Programming, Radio Division, National Broadcasting Company, New York.

Sinha, Prof. Kumares C. Professor and Head, Transportation and Infrastructure Systems Engineering, Purdue University, West Lafayette, Indiana.

Sinha, Prof. P. K. Department of Engineering, University of Reading, Whiteknights, Reading, England.

Sinton, Dr. William M. Department of Astronomy, University of Hawaii.

Sircar, Dr. S. Senior Research Associate, Air Products and Chemicals, Inc., Allentown, Pennsylvania.

Sirignano, Prof. William A. Dean of Engineering, University of California, Irvine.

Sisler, C. W. Corporate Engineering Department Monsanto Company, St. Louis, Missouri.

Sisler, Dr. Harry H. Department of Chemistry, University of Florida.

Sisler, Dr. Hugh D. Department of Botany, Division of Agricultural and Life Sciences, University of Maryland.

Sistare, George, Jr. (Retired) Consultant, Handy and Harman, Fairfield, Connecticut.

Sittig, Marshall. Assistant Director, Office of Research Project Administration, Princeton University.

Sittner, Dr. W. Rex. President, Electro Medical Systems, Inc.

Skalak, Dr. Richard. Deceased; formerly, Founding Director, Institute for Mechanics and Materials, University of California, San Diego.

Skelly, Dr. David. School of Forestry and Environmental Studies, Yale University, New Haven, Connecticut.

Skilling, Prof. Hugh H. Department of Electrical Engineering, Stanford University.

Skinner, A. Douglas. Head of Measurement Standards Laboratory, Marconi Instruments, Ltd., Stevanage, England.

Skinner, Prof. Brian J. Department of Geology and Geophysics, Yale University, New Haven, Connecticut.

Skinner, E. N. Assistant to the Director, Product Research and Development, International Nickel Company, Inc., New York.

Skinner, Dr. Harry B. Department of Orthopedic Surgery, School of Medicine, University of California, San Francisco.

Skotland, Dr. C. B. Irrigated Agriculture Research and Extension Center, Washington State University.

Skrutskie, Dr. Michael F. Department of Physics and Astronomy, University of Massachusetts, Amherst.

Slabaugh, Dr. Wendell H. Deceased; formerly, Department of Chemistry, Oregon State University.

Slichter, Dr. Charles P. Department of Physics, University of Illinois, Urbana.

Slichter, Prof. Louis B. Deceased; formerly, Institute of Geophysics, University of California, Los Angeles.

Slocum, Dr. Donald W. Argonne National Laboratory, Argonne, Illinois.

Slomp, Dr. George. Physical and Analytical Chemistry Division, Upjohn Company, Kalamazoo, Michigan.

Slonecker, Dr. Charles E. Associate Professor of Anatomy, University of British Columbia, Canada.

Sluder, Dr. Greenfield. Senior Scientist, Worcester Foundation for Experimental Biology, Shrewsbury, Massachusetts.

Smartt, Dr. Raymond N. National Solar Observatory, Sunspot, New Mexico.

Smith, Dr. Andrew B. Department of Paleontology, British Museum of Natural History, London, England.

Smith, Prof. David M. Morris K. Jeesup Professor of Silviculture, School of Forestry, Yale University.

Smith, Fred W. Western Union Telegraph Company, Rahway, New Jersey.

Smith, Gaylord, Director, High Nickel Alloys and Precious Metals, Product Development and Research Division, International Nickel Company, New York.

Smith, Dr. Guy D. Deceased; formerly, Soil Conservation Service, U.S. Department of Agriculture.

Smith, Prof. Harlan J. Department of Astronomy, University of Texas, Austin.

Smith, Dr. Jerome A. Marine Physics Laboratory, Scripps Institution of Oceanography, University of California, La Jolla.

Smith, Dr. John Ward. Deceased; formerly, Research Supervisor, Laramie Energy Research Center, Energy Research and Development Administration, Laramie, Wyoming.

Smith, Prof. Julian C. Department of Chemical Engineering, Cornell University.

Smith, Dr. Julius O., III. Center for Computer Research in Music and Acoustics, Department of Music, Stanford University, Stanford, California.

Smith, Prof. Karl U. Director, Behavioral Cybernetics Laboratory, and Professor of Psychology, University of Wisconsin.

Smith, Dr. Kathleen K. Department of Biological Anthropology and Anatomy, Duke University Medical Center, Durham, North Carolina.

Smith, Rear Adm. Levering. Director of Strategic Systems Project Office, U.S. Department of the Navy.

Smith, Dr. Michael S. Leader, Nuclear Astrophysics Research Group, Physics Division, Oak Ridge National Laboratory, Tennessee.

Smith, Prof. Norman D. Department of Geosciences, University of Nebraska, Lincoln.

Smith, Prof. Paul G. Department of Vegetable Crops, College of Agricultural and Environmental Sciences, University of California, Davis.

Smith, Dr. Richard T. Southwest Research Institute, San Antonio, Texas.

Smith, Dr. Robert L. College of Oceanic and Atmospheric Sciences, Oregon State University, Corvallis.

Smith, Dr. Warren E. Science Applications International Corporation, Tucson, Arizona.

Smith, Dr. William F. Department of Mechanical Engineering and Aerospace Sciences, College of Engineering, University of Central Florida, Orlando.

Smithson, Dr. T. R. Head of School, Science Maths and Information Technology, Cambridge Regional College, Kings Hedges Campus, Cambridge, United Kingdom.

Smullyan, Dr. Raymond M. Oscar Ewing Professor of Philosophy Emeritus, Indiana University, Bloomington.

Smythe, Dr. William R. Department of Physics, California Institute of Technology.

Snavely, Dr. Deanne. Center for Photochemical Sciences, Bowling Green State University, Bowling Green, Ohio.

Snelgrove, Prof. Martin. Department of Electronics, Carleton University, Ontario, Canada.

Snell, Dr. Arthur H. Associate Director, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Snell, Dr. Esmond E. Department of Biochemistry, University of California, Berkeley.

Snoke, Dr. David. Los Angeles, California.

Snook, Dr. Theodore. Department of Anatomy, School of Medicine, University of North Dakota.

Snow, William W. Consulting Engineer, William W. Snow Associates, Inc., Woodside, New York.

So, Dr. E. Institute for National Measurement Standards, National Research Council of Canada, Ottawa, Ontario.

Sochacki, Dr. James. Department of Mathematics, James Madison University, Harrisonburg, Virginia.

Soderblom, Dr. David. Space Telescope Science Institute, Baltimore, Maryland.

Sohon, Dr. Harry. Deceased; formerly, Moore School, University of Pennsylvania.

Sokol, Dr. Pamela A. Department of Microbiology and Infectious Diseases, University of Calgary Health Sciences Center, Calgary, Alberta, Canada.

Solberg, Dr. Myron. Department of Food Science, Rutgers University, New Brunswick, New Jersey.

Soldate, Dr. Mark. Department of Physics, Yale University.

Solem, Dr. G. Alan. Curator and Head, Division of Invertebrates, Field Museum of Natural History, Chicago, Illinois.

Solomon, Dr. James C. Associate Curator, Missouri Botanical Garden, St. Louis.

Somlo, Dr. Peter 1. CSIRO Division of Applied Physics, Lindfield, New South Wales, Australia.

Somlyo, Dr. Andrew Paul. Department of Physiology, School of Medicine, University of Virginia.

Sommer, Dr. Alfred. Director, International Center for Epidemiology and Preventive Ophthalmology, Dana Center, Wilmer Institute, Johns Hopkins School of Hygiene and Public Health, Baltimore, Maryland.

Sommer, Dr. Alfred H. Thermo Electron Corporation, Waltham, Massachusetts.

Soost, Dr. R. K. Department of Plant Science, University of California, Riverside.

Sorensen, Dr. Robert M. Coastal Engineering Research Center, Department of the Army, Fort Belvoir, Virginia.

Sorensen, Prof. Robert M. Department of Civil Engineering, Lehigh University, Bethlehem, Pennsylvania.

Sorenson, Prof. S. Department of Physics, University of Tennessee, Knoxville.

Souder, Dr. Paul A. Department of Physics, Yale University.

Souders, Dr. Mott. Deceased; formerly, Director, Oil Development, Shell Oil Company, Emeryville, California.

Soulen, Dr. Robert J., Jr. Naval Research Laboratory, Washington, D.C.

Southwick, Dr. Stephen M. Department of Pomology, University of California, Davis.

Southwick, Dr. Steven. Department of Psychiatry and Connecticut Mental Health Center, School of Medicine, Yale University.

Sovonick-Dunford, Dr. S. Department of Biological Sciences, University of Cincinnati.

Spackman, Dr. William. Department of Geology, Pennsylvania State University.

Spearman, Dr. M. Leroy. NASA Langley Research Center, Hampton, Virginia.

Spector, Dr. David L. Senior Staff Scientist, Cold Spring Harbor Laboratory, Cold Spring Harbor, New York.

Spedding, Prof. Frank H. Deceased; formerly, Ames Laboratory, Energy Research and Development Administration, Iowa State University.

Speer, Dr. J. Alexander. Department of Marine, Earth, and Atmospheric Sciences, School of Physical and Mathematical Sciences, North Carolina State University.

Speight, Dr. James G. Western Research Institute, Laramie, Wyoming.

Spergel, Dr. David N. Department of Astrophysics, Princeton University.

Spiegel, Dr. Allen M. National Institute of Diabetes and Kidney Diseases, National Institutes of Health, Bethesda, Maryland.

Spiegel, Dr. Carol A. Director, Clinical Microbiology, Department of Pathology and Laboratory Medicine, University of Wisconsin Hospital and Clinics, Madison.

Spink, Dr. Wesley W. Regents, Professor of Medicine, School of Medicine, University of Minnesota.

Spinrad, Dr. Bernard I. Department of Nuclear Engineering, Oregon State University.

Splittstoesser, Dr. Don F. New York State Agricultural Experiment Station and Department of Food Science and Technology, Cornell University.

Sposito, Dr. Garrison. Department of Plant and Soil Biology, University of California, Berkeley.

Sprague, Prof. G. F. Department of Agronomy, University of Illinois, Urbana.

Sprague, Dr. Howard B. Agricultural Consultant, Washington, D.C.

Spratt, Dr. Nelson T., Jr. Department of Zoology, University of Minnesota.

Spreadbury, Dr. Peter J. Department of Engineering, University of Cambridge, United Kingdom.

Sprinkle, Dr. James. Department of Geological Sciences, University of Texas, Austin.

Spurgin, Robert A. President, Spurgin & Associates, Irvine, California.

Sreenivasan, Prof. K. R. Engineering and Applied Sciences, Yale University.

Srihari, Dr. Sargur N. Center of Excellence for Document Analysis & Recognition, University of Buffalo, Amherst, New York.

St. Geme, Dr. Joseph W. Associate Professor of Pediatrics and Molecular Microbiology, Department of Pediatrics, Washington University School of Medicine, St. Louis, Missouri.

St. Jean, Dr. Joseph, Jr. Department of Geology, University of North Carolina.

St. Pierre, Prof. George R. Department of Metallurgical Engineering, Ohio State University.

Stadtman, Dr. Theressa C. Department of Health and Human Services, National Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, Maryland.

Stage, Dr. Steven A. Baton Rouge, Louisiana.

Stahnke, Dr. Herbert L. Director, Poisonous Animal Research Laboratory, Arizona State University.

Stall, Prof. Robert E. Plant Pathology Department, Institute of Food and Agricultural Sciences, University of Florida.

Stamm, Dr. Lola. Department of Epidemiology, School of Public Health, University of North Carolina, Chapel Hill.

Standiford, Ferris C., Jr. W. L. Badger Associates, Inc., Consulting Engineers, Ann Arbor, Michigan.

Stanford, Prof. John L. Department of Physics and Astronomy, Iowa State University, Ames.

Stanley, Dr. Bruce A. Department of Cellular and Molecular Physiology, College of Medicine, Pennsylvania State University, Hershey.

Starr, Dr. Eugene C. Bonneville Power Administration, U.S. Department of the Interior, Portland, Oregon.

Stauffer, Dr. Randy C. Halogens Research Laboratory, Dow Chemical Company, Midland, Michigan.

Stebbins, Prof. G. Ledyard. Department of Genetics, College of Agriculture, University of California, Davis.

Steele, Dr. William A. Department of Chemistry, Pennsylvania State University.

Steenrod, Norman E. Department of Mathematics, Princeton University.

Stefanovic, Dr. Victor R. Electrical Engineering Department, University of Missouri.

Stein, Prof. Dale F. Retired; formerly, President Emeritus, Michigan Technological University, Houghton.

Stein, Dr. Gary S. Department of Biochemistry and Molecular Biology, J. Hillis Miller Health Center, College of Medicine, University of Florida.

Stein, Dr. Janet L. Department of Biochemistry and Molecular Biology, J. Hillis Miller Health Center, College of Medicine, University of Florida.

Stein, Dr. Murray B. Anxiety & Traumatic Stress Disorders Research Program, University of California, La Jolla.

Steinberg, Dr. Aephraim M. Department of Physics, University of California, Berkeley.

Steinberg, Dr. Ellis P. Senior Scientist, Argonne National Laboratory, Argonne, Illinois.

Steinert, Emil F. (Retired) Arc Welding Division, Westinghouse Electric Corporation.

Steinschneider, Alfred. President, American Sudden Infant Death Syndrome Institute, Atlanta, Georgia.

Stephenson, Dr. R. J. Department of Physics, Wooster College.

Stepniewski, Wieslaw Z. Aeronautical Consultant, Springfield, Pennsylvania.

Steponkus, Prof. Peter L. Department of Agronomy, Cornell University.

Stern, Prof. Fred. Iowa Institute of Hydraulic Research, University of Iowa, Iowa City.

Stern, Dr. Robert J. Department of Geosciences, University of Texas, Richardson.

Sternberg, Dr. James C. Applied Research Department, Beckman Instruments, Brea, California.

Sternheim, Dr. Charles E. Director of Undergraduate Studies, Department of Psychology, University of Maryland, College Park.

Sterrer, Dr. W. E. Bermuda Biological Station, St. George's West.

Stevens, Dr. C. E. College of Veterinary Medicine, North Carolina State University, Raleigh.

Stevens, Dr. Calvin H. Department of Geology, San Jose State University.

Stevens, Dr. Mary Betty. Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, Maryland.

Stevenson, Dr. Edward C. Deceased; formerly, Department of Electrical Engineering, School of Engineering and Applied Sciences, University of Virginia.

Steward, Dr. John W. Department of Physics, University of Virginia.

Stewart, Dr. David B. Experimental Geochemistry and Mineralogy Branch, U.S. Geological Survey, Department of the Interior.

Stewart, Dewey. Crops Research Division, Agricultural Research Service, U.S. Department of Agriculture, Beltsville, Maryland.

Stewart, Scott R. L. C. Lee & Associates, Inc., Seattle, Washington.

Steyn, Dr. Julian J. Energy Resources International, Inc., Washington, D.C.

Stidd, Prof. Benton M. Department of Biological Science, Western Illinois University, Macomb, Illinois.

Stiles, Dr. Martin. Department of Chemistry, University of Kentucky.

Stillman, Dr. Gregory E. Department of Electrical Engineering, University of Illinois, Urbana.

Stirton, Dr. Robert I. Vice President (retired), Roger Williams Technical and Economic Services, Inc., Berkeley, California.

Stirton, Prof. Ruben A. Director, Museum of Paleontology, University of California, Berkeley.

Stock, Prof. David. School of Mechanical and Materials Engineering, Washington State University, Pullman, Washington.

Stock, Prof. John T. Department of Chemistry, University of Connecticut.

Stocum, Dr. David L. Department of Genetics and Development, University of Illinois.

Stoller, Dr. Marshall L. Department of Urology, University of California, San Francisco.

Stoloff, Dr. Norman S. Department of Materials Engineering, Rensselaer Polytechnic Institute.

Stolper, Dr. Edward M. Division of Geological and Planetary Science, California Institute of Technology.

Stone, Prof. A. Douglas. Department of Applied Physics, Yale University.

Stone, Dr. Anthony J. Department of Chemistry, University of Cambridge, University Chemical Laboratory, Cambridge, England.

Stone, Dr. Jeffrey K. Department of Botany and Plant Pathology, Oregon State University, Corvallis.

Stone, Prof. Kenneth G. Deceased; formerly, Department of Chemistry, Michigan State University.

Storch, Dr. Henry H. Deceased; formerly, Assistant Professor of Chemistry, New York University.

Storer, Dr. Tracy I. Deceased; formerly, Department of Zoology, University of California, Davis.

Storey, Prof. William B. Department of Botany and Plant Sciences, University of California, Riverside.

Stott, Dr. Jeffrey L. Department of Veterinary Microbiology and Immunology, School of Veterinary Medicine, University of California, Davis.

Stout, Gary J. AT&T Submarine Systems, Inc., Morristown, New Jersey.

Strandness, Dr. D. Eugene, Jr. Department of Surgery, University of Washington School of Medicine, Seattle.

Strandtmann, Prof. Russell W. Department of Biological Sciences, Texas Technological College.

Stranks, Prof. Donald R. Department of Physical and Inorganic Chemistry, University of Adelaide, Australia.

Straus, Dr. Reuben. Providence Medical Center, Portland, Oregon.

Strausbaugh, Prof. Carl A. Kimberly Research and Extension Center, University of Idaho, Kimberly.

Streeter, Prof. Victor L. Department of Civil Engineering, College of Engineering, University of Michigan.

Strock, Dr. O. J. Consultant, Sarasota, Florida.

Strohl, Robert, J. Senior Research Scientist, Batelle Laboratories, Columbus, Ohio.

Stroke, Dr. George W. Department of Electrical Sciences and Head, Electro-Optical Sciences Center, State University of New York, Stony Brook.

Strom, Dr. Robert G. Department of Planetary Sciences, Lunar and Planetary Laboratory, University of Arizona.

Stroyan, Dr. Henry L. G. Entomology Department, Ministry of Agriculture, Fisheries and Food, Harpenden, England.

Stuart, Dr. Alastair M. Department of Zoology, University of Massachusetts.

Stuart, Dr. Edward G. Deceased; formerly, West Virginia School of Medicine.

Stuart, William T. Deceased; formerly "Electrical Construction and Maintenance," McGraw-Hill Publications Company, New York.

Stubbings, Dr. H. G. Poole, England.

Stuckas, Kenneth J. Engineering Consultation Services, Jacksonville, Florida.

Stumm, Prof. Erwin Charles. Deceased; formerly, Department of Geology and Mineralogy, Museum of Paleontology, University of Michigan.

Stunkard, Dr. Horace W. Research Associate, American Museum of Natural History, New York.

Sturges, Thomas B., III. Pennsylvania Drilling Company, McKees Rock.

Sturges, Dr. Wilton. Department of Oceanography, Florida State University.

Sturtevant, Prof. Alfred H. Thomas Hunt Morgan Professor of Biology, Emeritus, California Institute of Technology.

Sudarshan, Dr. S. Computer Science and Engineering Department, Indian Institute of Technology–Bombay, Mumbai, India.

Sudds, Dr. Richard. Department of Biological Sciences, State University of New York, Pittsburgh.

Sullivan, Prof. Michael J., Jr. Department of Mathematics, Chicago State University, Chicago, Illinois.

Sumi, Dr. S. Mark. Professor of Neuropathology, School of Medicine, University of Washington.

Summers, Dr. B. A. James A. Baker Institute for Animal Health, Cornell University, Ithaca, New York.

Sumners, Dr. Thomas E. Plant Pathologist, Agricultural Research Service, U.S. Department of Agriculture.

Suppe, John. Department of Geological Sciences, Princeton University.

Surles, Dr. Terry. Limnetics, Inc., Milwaukee, Wisconsin.

Suslick, Dr. Kenneth S. Professor, School of Chemical Sciences, Noyes Laboratory, University of Illinois, Urbana.

Sutherland, J. R. Power Transformer Department, General Electric Company, Pittsfield, Massachusetts.

Sutherland, Dr. S. S. Senior Research Officer, Animal Health Laboratories, Department of Agriculture, Western Australia.

Sutton, Dr. B. C. Head of Taxonomic and Identification Services, Mycological Institute, Ferry Lane, Surrey, United Kingdom.

Sutton, George P. Consulting Engineer, Danville, California.

Suzuki, Dr. Yoichiro. Kamioka Observatory, Institute for Cosmic Ray Research, University of Tokyo, Higashi-Mozumi, Kamioka Gifu, Japan.

Swanson, Dr. Eric. Vice President, Technology, Crystal Semiconductor Corporation, Austin, Texas.

Swanson, Dr. M. L. Department of Physics and Astronomy, University of North Carolina.

Swanson, Dr. R. Lawrence. Director, Waste Management Institute, Marine Sciences Research Center, State University of New York, Stony Brook.

Swearingen, Dr. Will. NASA-Montana State University TechLink, Bozeman, Montana.

Sweat, F. W. Department of Chemistry, University of Utah.

Swets, Dr. John A. Bolt Beranek and Newman, Inc., Cambridge, Massachusetts.

Swider, Dr. William, Jr. Space Physics Division, Air Force Geophysics Laboratory, Hanscom Air Force Base, Bedford, Massachusetts.

Swift, Dr. Gregory W. Condensed Matter and Thermal Physics, Los Alamos National Laboratory, New Mexico.

Switzer, Dr. George. Curator, Department of Mineral Sciences, National Museum of Natural History, Smithsonian Institution.

Sydenham, Dr. Peter H. Systems Engineering and Evaluation Centre, University of South Australia, School of Electrical and Information Engineering, Mawson Lakes, Adelaide.

Symko, Orest G. Department of Physics,University of Utah.

Symons, Dr. Frank. Applied Research Laboratory, Pennsylvania State University, State College.

Symons, Dr. Robert S. Litton Electrical Devices Division, San Carlos, California.

Sytsma, Prof. Kenneth J. Department of Botany, University of Wisconsin at Madison.

Szalay, Dr. Frederick S. Department of Vertebrate Paleontology, American Museum of Natural History, New York.

Szeri, Dr. Andras Z. Professor and Chairperson, Department of Mechanical Engineering, University of Delaware, Newark.

Szody, Dr. Paula. Department of Astronomy, University of Washington, Seattle.

T

Tabor, Paul. Soil Conservation Service, Athens, Georgia.

Tait, Dr. David L. Department of Obstetrics and Gynecology, Vanderbilt University Medical Center, Nashville, Tennesee.

Talbot, Prof. Lawrence. Department of Mechanical Engineering, University of California, Berkeley.

Tan, Prof. K. C. Centre for Intelligent Control, Department of Electrical Engineering, National University of Singapore.

Tang, Prof. K. Y. Deceased; formerly, Department of Electrical Engineering, Ohio State University.

Tanihata, Dr. Isao. Accelerator Facility, Institute of Physical and Chemical Research, Saritama, Japan.

Tannas, Lawrence E., Jr. Aerojet Electro Systems Company, Azusa, California.

Tao, Dr. B. Y. School of Agricultural and Biological Engineering, Purdue University, West Lafayette, Indiana.

Tarling, Dr. D. H. Department of Geophysics and Planetary Physics, University of Newcastle, England.

Taube, Dr. Henry. Department of Chemistry, Stanford University.

Taylor, Prof. Angus E. President's Office, University of California, Berkeley.

Taylor, Dr. Danny L. Chairperson, Department of Mining Engineering, Mackay School of Mines, University of Nevada.

Taylor, Dr. Gordon S. Connecticut Agricultural Experiment Station, Windsor.

Taylor, Prof. J. Herbert. Institute of Molecular Biophysics, Florida State University.

Taylor, Prof. John W. Department of Plant Biology, University of California, Berkeley.

Taylor, Dr. R. E. Associate Professor and Director, Radiocarbon Laboratory, University of California, Riverside.

Taylor, Dr. Robert J. Consultant, Microscopy, Falls Church, Virginia.

Taylor, Dr. Stuart Ros. Department of Geology, Australian National University, Canberra, Australia.

Taylor, Prof. Thomas N. Department of Biology, University of Kansas, Lawrence.

Tchobanoglous, Prof. George. Department of Civil Engineering, University of California, Davis.

Teaguarden, Dr. Dennis E. Professor Emeritus of Forestry, University of California, Berkeley.

Tease, Samuel C. Pennsalt Chemicals Corporation, Philadelphia, Pennsylvania.

Tedesco, Dr. Edward F. Jet Propulsion Laboratory, California Institute of Technology.

Tedford, Dr. Richard H. Department of Vertebrate Paleontology, American Museum of Natural History, New York.

Teichert, Dr. Curt. Department of Geological Sciences, University of Rochester.

Teleki, Dr. Geza. Deceased; formerly, Department of Geology, George Washington University.

Telionis, Prof. Demetri P. Department of Engineering Science and Mechanics, Virginia Polytechnic Institute and State University, Blacksburg.

Teller, Dr. Aaron J. Teller Environmental Systems, Worcester, Massachusetts.

Temin, Dr. Howard M. McArdle Laboratory for Cancer Research, University of Wisconsin Medical Center.

Teng, Lee C. Fermi National Accelerator Laboratory, Batavia, Illinois.

Tenney, Dr. Gerold H. American Society for Nondestructive Testing, Inc., Los Alamos, New Mexico.

Terrell, Dr. James. Los Alamos National Laboratory, Los Alamos, New Mexico.

Terrill, Dr. Clair E. Chief, Sheep and für Animal Research Branch, U.S. Department of Agriculture, Beltsville, Maryland.

Thelemaque, L. E. Product Family Systems Engineering Center, AT&T Information Systems, Lincroft, New Jersey.

Thiess, Helmut E. Washington, D.C.

Thomann, Dr. Gary C. Power Technologies, Inc., Schenectady, New York.

Thomas, Dr. David A. Department of Materials Science and Engineering, Lehigh University, Bethlehem, Pennsylvania.

Thomas, Dr. David Hurst. American Museum of Natural History, New York.

Thomas, Dr. J. Kerry. Department of Chemistry, University of Notre Dame.

Thompson, Prof. Gerald L. Professor of Applied Mathematics and Industrial Administration, Graduate School of Industrial Administration, Carnegie-Mellon University.

Thompson, Dr. Margaret R. Departments of Medical Genetics and Pediatrics, University of Tronoto and the Hospital for Sick Children, Toronto, Ontario, Canada.

Thompson, Dr. Stanley G. Senior Staff Member, Lawrence Berkeley Laboratory, University of California, Berkeley.

Thompson, Dr. T. E. Department of Zoology, University of Bristol, England.

Thompson, Tom. Senior Training Specialist, Metrowerks, Hollis, New Hampshire.

Thompson, William I., III. Senior Systems Engineer, Science Applications International Corporation, Falls Church, Virginia.

Thomson, Dr. Keith S. President, Academy of Natural Sciences, Philadelphia, Pennsylvania.

Thomson, Prof. Robb M. Chairman, Department of Materials Science, State University of New York, Stony Brook.

Thorn, Dr. Robert J. Divisions of Chemistry and Materials Science, Argonne National Laboratory, Argonne, Illinois.

Thorogood, Dr. Robert M. Department of Chemical Engineering,North Carolina State University, Raleigh.

Throp, Prof. H. Holden. Department of Chemistry, University of North Carolina, Chapel Hill.

Tibbitts, Capt. Barry F. Retired, U.S. Navy.

Tichy, Prof. Jiri. Graduate Program in Acoustics, Pennsylvania State University, State College.

Tigner, Dr. Maury. Laboratory of Nuclear Studies, Cornell University.

Tikofsky, Dr. Ronald S. Department of Radiology, Medical College of Wisconsin, Milwaukee.

Timoney, Dr. John F. Department of Veterinary Science, University of Kentucky, Lexington.

Ting, Dr. Irwin P. Department of Botany and Plant Sciences, University of California, Riverside.

Ting, Prof. Samuel C. C. Department of Physics, Massachusetts Institute of Technology.

Tinsley, Dr. Brian A. Center for Space Science, Department of Physics, University of Texas, Dallas.

Tolstoy, Dr. Alexandra I. ATolstoy Sciences, Annandale, Virginia.

Tomasetti, Richard L. Senior Vice President, Lev Zetlin Associates, Inc. New York, New York.

Tonkay, Prof. Gregory L. Department of Industrial Engineering, Lehigh University, Bethlehem, Pennsylvania.

Tonndorf, Prof. Jucrgcn. Deceased; formerly, Department of Otolaryngology, College of Physicians and Surgeons, Columbia University.

Toole, Dr. Floyd. Oak Park, California.

Torres, Dr. Alfonso. Head, Diagnostic Services Section, National Veterinary Services Laboratory, U.S. Department of Agriculture, Greenport, New York.

Toth, Dr. Nicholas. Department of Anthropology, Indiana University.

Townes, Prof. Charles H. Department of Physics, University of California, Berkeley.

Toy, Dr. Pearl. San Francisco General Hospital, San Francisco, California.

Toy, Dr. T. J. Department of Geography, University of Denver, Colorado.

Träbert, Prof. Elmar. Experimentalphysik III, Ruhr-Universität Bochum, Germany.

Tracy, Robert J. Department of Geological Sciences, Harvard University.

Trappe, Dr. James M. Department of Forest Science, Oregon State University, Corvallis.

Trautman, W. Dean. Manager, Laboratory Administration Research and Development, Brush Beryllium Company, Cleveland, Ohio.

Treffers, Dr. Henry P. Professor of Pathology, School of Medicine, Yale University.

Treiman, Prof. Sam B. Deceased; formerly, Department of Physics, Princeton University, Princeton, New Jersey.

Trendall, Dr. Alec. Adjunct Professor, Department of Applied Physics, Curtin University of Technology, Perth, Western Australia.

Treybal, Robert E. Deceased; formerly, Department of Chemical Engineering, New York University.

Triebe, Edward J. Deceased; formerly, Kingsport Press, Inc., Kingsport, Tennessee; Consultant, Franklin Book Programs, Inc.

Trinkaus, Dr. Erik. Department of Anthropology, University of New Mexico.

Trivett, Dr. Mary L. Department of Environmental and Plant Biology, Ohio University, Athens.

Trolinger, Dr. James D. Vice President, Spectron Development Laboratories, Costa Mesa, California.

Trowsdale, Dr. John. Professor of Immunology, Department of Pathology, Cambridge University.

Truant, J. P. Advance Medical & Research Center, Inc., Pontiac, Michigan.

Truax, Dr. Robert C. Truax Engineering Company, Saratoga, California.

Truman, Dr. James W. Department of Zoology, University of Washington, Seattle.

Trump, Benjamin F. Professor and Chairman, Department of Pathology, University of Maryland Medical Center.

Tsaur, Dr. Bor-Yeu. Lincoln Laboratories, Lexington, Massachusetts.

Tsong, Dr. Tien-Tzou. Distinguished Research Fellow, Institute of Physics, Academica Sinica, Taipei, Taiwan.

Tsuchiya, Prof. Henry M. Department of Chemical Engineering, University of Minnesota.

Tucker, Dr. David H. Agriculture Research and Education Center, University of Florida.

Tucker, John T. (Retired) Beltsville Parasitological Laboratory, Agricultural Research Center, Beltsville, Maryland.

Tucker, Dr. Wallace. Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts.

Tukey, Dr. Harold B. Deceased; formerly, Professor Emeritus, Department of Horticulture, Michigan State University.

Tully, Dr. R. Brent. Institute for Astronomy, University of Hawaii at Manoa.

Tur, Dr. Moshe. School of Engineering, Tel Aviv University, Israel.

Turk, Prof. J. L. Department of Pathology, Royal College of Surgeons of England.

Turley, Dr. J. A. Marathon Oil Company, Littleton, Colorado.

Turnbull, Prof. David. Department of Applied Physics, Harvard University.

Turner, Dr. Charles E. Agricultural Research Service, U.S. Department of Agriculture, Albany, California.

Turner, Prof. J. R. G. Department of Genetics, University of Leeds, United Kingdom.

Turner, Prof. John D. Transport Research Laboratory, Crowthorne, Berks, United Kingdom.

Turner, Joyce B. Institute for Advanced Study.

Turner, Dr. Noel H. Chemistry Division, Naval Research Laboratory, Washington, D.C.

Turner, Dr. Ruth D. Museum of Comparative Zoology, Harvard University.

Turner, Dr. Shirley. National Institute of Standards and Technology, U.S. Department of Commerce, Gaithersburg, Maryland.

Turner, Dr. Thomas B. Professor of Microbiology and Dean Emeritus, School of Medicine, Johns Hopkins University.

Turok, Dr. Neil. Department of Physics, Joseph Henry Laboratories, Princeton University.

Turro, Prof. Nicholas J. Department of Chemistry, Columbia University.

Turturro, Dr. Angelo. National Center for Toxicological Research, Department of Health and Human Services, Jefferson, Arkansas.

Tuttle, Alan H. Vocational Division, State University of New York Agricultural and Technical Institute, Wellsville.

Tuttle, Douglas E. Pamarco, Roselle, New Jersey.

Tuttle, Russell H. Professor in Anthropology, Evolutionary Biology and The College, University of Chicago.

Tyler, Prof. Albert. Deceased; formerly, Division of Biology, California Institute of Technology.

Tyrer, Dr. Louise B. Medical Affairs Coordinator, Planned Parenthood Federation of America, New York.

U

Uchida, Dr. Tohru. Professor of Zoology, Hokkaido University.

Uebersax, Dr. Mark A. Department of Food Sciences and Human Nutrition, Michigan State University.

Uhl, Dr. Vincent W. Department of Chemical Engineering, University of Virginia.

Uhler, Dr. Michael D. Department of Biological Chemistry, University of Michigan, Ann Arbor.

Uhrhammer, Dr. Robert A. Seismological Laboratory, University of California, Berkeley.

Ullman, Dr. John E. Department of Marketing-Management, Hofstra University.

Ullrich, Dr. Robert C. Department of Botany, University of Vermont, Burlington.

Underwood, Dr. Erwin E. Alcoa Professor, Georgia Institute of Technology. linger, Walter H. Anaconda Company, Denver, Colorado.

Underwood, Dr. James H. Center for X-Ray Optics, Lawrence Berkeley National Laboratory, University of California, Berkeley.

Unwin, Dr. Stephen C. Owens Valley Radio Observatory, California Institute of Technology, Pasadena.

Upgren, Prof. Arthur R. Van Vleck Observatory, Wesleyan University, Middletown, Connecticut.

Upton, Dr. Arthur C. Institute of Environmental Medicine, New York University Medical Center.

U.S. Army Corps of Engineers. Office of the Secretary of the Army, Washington, D.C.

Uzsoy, Prof. Reha. School of Industrial Engineering, Purdue University, West Lafayette, Indiana.

V

Vaanky, Dr. Kalman. Botanisches Institut, Universitat Tubingen, Germany.

Vaickus, Dr. Louis. Roswell Park Memorial Institute, Buffalo, New York.

Valenti, Dr. Jeff A. Space Telescope Science Institute, Baltimore, Maryland.

Valentine, Dr. J. W. Department of Geology, University of California, Santa Barbara.

Vallee, Dr. Richard. Principal Scientist, Worcester Foundation for Experimental Biology, Shrewsbury, Massachusetts.

Van Allen, Dr. Margot I. Staff Geneticist, Genetics Division, Hospital for Sick Children, Toronto, Ontario, Canada.

Van Andel, Dr. Tjeerd H. Department of Geology, Stanford University.

Van Campenhout, Prof. Ernest L. Deceased; formerly Professor of Anatomy, Histology, and Embryology, School of Medicine, University of Louvain, Belgium.

Vanderkool, Dr. Jane M. Department of Medicine, School of Medicine, University of Pennsylvania.

Van der Pluijm, Prof. Ben. Department of Geological Sciences, University of Michigan, Ann Arbor.

Van der Spiegel, Prof. Jan. Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia.

Vanderzee, Dr. Cecil E. Department of Chemistry, University of Nebraska.

Van Etten, Dr. James P. Navigation Consultant, Nutley, New Jersey.

Van Fleet, Dr. D. S. Department of Botany, University of Georgia.

Van Houten, Prof. Franklyn B. Department of Geology, Princeton University.

Vanick, James S. Consultant, Foundry Castings, Sea Girt, New Jersey.

Van Niel, Dr. Cornelius B. Deceased; formerly, Hopkins Marine Station, Pacific Grove, California.

Van Peteghem, Dr. Peter M. Deceased; formerly, Electrical Engineering Department, Texas A&M University.

Van Schmus, Prof. W. Randall. Department of Geology, University of Kansas.

Van Valkenburg, Dr. Mac E. Department of Electrical Engineering, University of Illinois, Urbana.

Van Vlack, Prof. Lawrence H. Department of Materials Engineering, University of Michigan.

Van Wagtendonk, Dr. Willem J. Veterans Administration Hospital, Miami, Florida.

Van Wazer, Dr. John R. Department of Chemistry, Vanderbilt University.

Van Winkle, Prof. Quentin. Department of Chemistry, Ohio State University.

Vaughan, Prof. Wyman R. Head, Department of Chemistry, University of Connecticut.

Vaya, Dr. Jacob. Migal-Galilee Technological Center, Rosh-Pina, Israel.

Veale, Dr. Chris. A. Zeneca, Inc., Wilmington, Delaware.

Veblen, Dr. David R. Department of Earth and Planetary Sciences, Johns Hopkins University.

Veillon, Dr. Claude. Biophysics Research Laboratory, Peter Bent Brigham Hospital, Harvard Medical School.

Vellozzi, Dr. Joseph. Consulting Engineer, Ardsley, New York.

Venditti, Dr. Ferdinand, Jr. Head, Section of Cardiovascular Diseases, Lahey Clinic, Burlington, Massachusetts.

Venkatesh, Prof. Alladi. Graduate School of Management, University of California, Irvine.

Ventura, Dr. Jose A. Department of Industrial and Management Systems Engineering, Pennsylvania State University, University Park.

Verma, Dr. Pramode K. AT&T Information Systems, Morristown, New Jersey.

Vessey, Dr. Judith A. Department of Physiological Nursing. University of California School of Nursing, San Francisco.

Vestal, Prof. Paul A. A. G. Bush Professor of Science, A. G. Bush Science Center and Department of Biology, Rollins College, Winter Park, Florida.

Veverka, Prof. Joseph. Laboratory for Planetary Studies, Cornell University.

Vickers, Douglas B. Annapolis, Maryland.

Vickers, Dr. Mary Lynne. Department of Veterinary Science, Livestock Disease Diagnostic Center, University of Kentucky, Lexington.

Vidone, Dr. Romeo A. Chairman, Department of Pathology, School of Medicine, Yale University.

Vierstra, Dr. Richard. Horticulture Department, University of Wisconsin.

Villiger, Peter. Research Associate, Department of Molecular and Experimental Medicine, Research Institute of Scripps Clinic, La Jolla, California.

Vinson, Prof. S. B. Department of Entomology, Texas A & M University.

Viro, Dr. Felix. Kind & Knox, Sioux City, Iowa.

Vitek, Dr. Charles. Medical Epidemiologist, HIV Vaccine Section, Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, Georgia.

Voelker, Dr. Richard P. Science and Technology Corporation, Columbia, Maryland.

Vogel, Dr. Friedrich. Institute for Anthropology and Human Genetics, Im Neuenheimer Feld, Germany.

Vogel, Prof. Steven. Department of Zoology, Duke University, Durham, North Carolina.

Vogt, Dr. Peter. Department of the Navy, Naval Research Laboratory, Washington, D.C.

Vogtle, Dr. Fritz. Department of Chemistry, Friedrich-Wilhelms University, Bonn, Germany.

Voit, Dr. Mark. Space Telescope Science Institute, Baltimore, Maryland.

Volk, Dr. Herbert F. Carbon Products Division, Union Carbide Corporation, Parma, Ohio.

Volk, Dr. Wesley A. Department of Microbiology, School of Medicine, University of Virginia.

Volkmar, Dr. Fred R. Child Study Center, Yale University.

Von Doenhoff, Albert E. Deceased; formerly, Staff Scientist, National Aeronautics and Space Administration.

Von Graevenitz, Alexander W. C. Department of Medical Microbiology, University of Zurich, Switzerland.

Von Puttkamer, Jesco. Advanced Programs, Office of Space Transportation Systems, National Aeronautics and Space Administration, Washington, D.C.

Vonder Haar, Prof. Thomas H. Department of Atmospheric Sciences, Colorado State University.

Vonnegut, Dr. Bernard. Retired; formerly, Atmospheric Sciences Research Center, State University of New York, Albany.

Voorhees, Dr. Frank R. Department of Biology, Central Missouri State College.

Vos, Dr. Willem L. Geophysical Laboratory and Center for High Pressure Research, Carnegie Institution, Washington, D.C.

Voss, Prof. Edward W., Jr. Department of Microbiology, University of Illinois, Urbana.

W

Waddington, Prof. Thomas C. Deceased; formerly, Department of Chemistry, University of Durham.

Wade, Dr. Charles Edwin. NASA Ames Research Center, Moffett Field, California.

Waggoner, Dr. Ben. Department of Biology, University of Central Arkansas, Conway.

Wagner, Dr. Frank. Technical Center, Celanese Chemical Company, Corpus Cristi, Texas.

Wagner, Dr. Henry N., Jr. Director, Divisions of Nuclear Medicine and Radiation Health Sciences, Johns Hopkins Medical Institutions.

Wagner, Dr. Richard S. AT&T Telephone Laboratories, Murray Hill, New Jersey.

Wagner, Dr. Robert P. Department of Zoology, University of Texas, Austin.

Wagner, Dr. Warren H., Jr. Department of Botany, University of Michigan.

Wahl, Prof. Floyd M. Professor and Chairman, Department of Geology, University of Florida.

Waidelich, Dr. Donald L. Department of Electrical Engineering, University of Missouri.

Wainwright, Howard W. Coal Research Center, U.S. Bureau of Mines, Morgan-town, West Virginia.

Waisel, Prof. Y. Department of Botany, Tel Aviv University, Israel.

Wakeham, Dr. W. A. Department of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, London, England.

Walbot, Dr. Virginia. Department of Biological Sciences, Stanford University.

Walczak, Mary M. Department of Chemistry, Iowa State University of Science and Technology.

Wald, Prof. Robert M. Department of Physics, University of Chicago, Illinois.

Waldmann, Katherine S. National Institutes of Health, Department of Health and Human Services, Bethesda, Maryland.

Waldmann, Dr. Thomas A. Chief, Metabolism Branch, National Institutes of Health, Department of Health and Human Services, Bethesda, Maryland.

Walker, J. H. Vice President, Portland Cement Association, Skokie, Illinois.

Walker, Michelle Y. Davis, California.

Walker, Dr. R. M. Department of Physics, Washington University.

Walker, Dr. Warren F., Jr. Department of Biology, Oberlin College.

Walkley, Dr. S. U. Department of Neuroscience, Rose F. Kennedy Center for Research in Mental Retardation and Human Development, Albert Einstein College of Medicine, Bronx, New York.

Walkup, Dr. John T. Yale University School of Medicine, New Haven, Connecticut.

Walkup, Dr. Robert D. Department of Chemistry and Biochemistry, Texas Tech University.

Wall, Dr. Joseph S. Northern Regional Research Center, U.S. Department of Agriculture, Peoria, Illinois.

Wallace, Prof. John F. Division of Metallurgy and Material Science, Case Western Reserve University.

Wallace, Dr. John M. Department of Atmospheric Sciences, University of Washington, Seattle.

Walsh, John J. Brookhaven National Laboratories, Upton, New York.

Walsh, Prof. Joseph L. Deceased; formerly, Department of Mathematics, University of Maryland.

Walsh, Dr. Michael A. Department of Biology, Utah State University.

Walsh, Dr. Peter J. Department of Physics, Fairleigh Dickinson University.

Walstedt, Dr. R. E. Bell Laboratories, Murray Hill, New Jersey.

Walt, Prof. Alexander J. Department of Surgery, Harper Hospital, Wayne State University, Detroit, Michigan.

Walt, Dr. Martin. Physical Sciences Laboratory, Lockheed Missiles and Space Company, Palo Alto, California.

Walton, Dr. Peter D. Department of Plant Science, University of Alberta, Edmonton, Canada.

Walworth, Vivian K. Polaroid Corporation, Cambridge, Massachusetts.

Walz, Arthur H., Jr. U.S. Committee on Large Dams, Corps of Engineers, Washington, D.C.

Wamser, Prof. Carl C. Department of Chemistry, California State University.

Wane, Dr. Malcolm T. Krumb School of Mines, Columbia University.

Wang, Prof. C. Y. Departments of Mathematics and Mechanical Engineering, Michigan State University, East Lansing.

Wang, Dr. Changchang. Visiting Scholar, Department of Electrophysics, University of Southern California, Los Angeles.

Wang, Prof. K. K. Sibley School of Mechanical and Aerospace Engineering, Cornell University.

Wang, Prof. William S. Y. Project On Linguistic Analysis, University of California, Berkeley.

Ward, Dr. David. Atomic Energy of Canada Limited, Chalk River Nuclear Laboratories, Ontario, Canada.

Ward, Jeffrey. American Radio, Newington, Connecticut.

Ware, Dr. Bennie R. Department of Chemistry, Syracuse University.

Warf, Dr. James C. Department of Chemistry, University of Southern California.

Warner, Deborah Jean. Curator, History of Astronomy, National Museum of American History, Washington, D.C.

Warner, Dr. Frank L. Royal Signals and Radar Establishment, Great Malvern, Worcestershire, England.

Warner, Dr. Robert M. Department of Horticulture, University of Hawaii at Manoa.

Warren, Prof. Bertram E. Department of Physics, Massachusetts Institute of Technology.

Warren, Dr. John J. K. Resources Pty. Ltd., Mitcham, Australia.

Warren, Dr. Mial E. Sandia National Laboratories, Albuquerque, New Mexico.

Wartik, Prof. Thomas. Department of Chemistry, Pennsylvania State University.

Wasserman, Dr. Zelda R. Department of Central Research and Development, E. I. du Pont de Nemours and Company, Wilmington, Delaware.

Waters, Dr. Everett. Department of Psychology, State University of New York, Stony Brook.

Watkins, Dr. Thomas D. Chabot College, Hayward, California.

Watson, William W. Professor Emeritus of Physics, Yale University.

Wattenberg, Ben J. President, Fairfield Publishers, Inc.

Watterson, Dr. Ray L. Department of Zoology, University of Illinois, Urbana.

Watts, Dr. Anthony B. Department of Earth Sciences, University of Oxford, England.

Watts, Michael. National Aeronautics and Space Administration, Ames Research Center, Moffett Field, California.

Way, George H. Retired; formerly, Vice President of Research and Test Development, Association of American Railroads, Washington, D.C.

Wayne, Dr. Andrew W. Department of Haematology, Kings College Hospital, London, England.

Weaver, Prof. David L. Department of Physics, Tufts University.

Weaver, Dr. E. Eugene. Research Scientist, Product Development Group, Ford Motor Company, Dearborn, Michigan.

Weaver, James L. Lockheed Missiles and Space Company, Palo Alto, California.

Weaver, Prof. Robert J. Department of Viticulture and Enology, College of Agricultural and Environmental Sciences, University of California, Davis.

Weaver, S. E. Northrop Aircraft, Inc.

Webb, Prof. J. E. Professor of Zoology, University College, Ibadan, Nigeria.

Webb, Dr. Jacqueline. Villa Nova, Pennsylvania.

Webb, Dr. Richard A. IBM Research Division, Thomas J. Watson Research Center, IBM Corporation, Yorktown Heights, New York.

Webber, Bonnie. Department of Computer and Information Science, Moore School, University of Pennsylvania.

Weber, Erwin L. Deceased; formerly, Trust Department, National Bank of Commerce, Seattle, Washington.

Weber, Harold C. Chemical Engineer, Boston, Massachusetts.

Webster, Dr. Douglas B. Department of Otorhinolaryngology and Biocommunication, Louisiana State University Medical Center.

Wedell, Dr. Nina. School of Biology, University of Leeds, United Kingdom.

Wedgewood, Prof. Lewis E. Department of Chemical Engineering, University of Washington, Seattle.

Wefer, Dr. Gerold. Department of Geosciences, Universität Bremen, Germany.

Wegner, Dr. Harvey E. Physics Division, Brookhaven National Laboratory, Upton, New York.

Weibell, Dr. Fred J. Biomedical Engineering Society, Culver City, California.

Weichert, Dr. Charles K. Professor of Zoology and Dean, College of Arts and Sciences, University of Cincinnati.

Weigel, Dr, Fritz. Insitut filr Anorganische Chemie, Universitat Munchen, Germany.

Weil, Dr. Andrew T. Division of Social Perspectives in Medicine, University of Arizona Health Science Center, Tucson.

Weil, Jonathan F. Staff Editor, "McGraw-Hill Encyclopedia of Science and Technology," McGraw-Hill, New York.

Weil, Robert T., Jr. Deceased; formerly, Dean, School of Engineering, Manhattan College.

Weil, Rolf. Department of Material and Metallurgical Engineering, Stevens Institute of Technology.

Weiler, Dr. J. Marvin. Professor Emeritus, Department of Geophysical Sciences, University of Chicago.

Weiler, Prof. Robert A. A. W. Wright Nuclear Structure Laboratory, Yale University.

Weinberger, Dr. Peter. Swales Aerospace, Inc., Beltsville, Maryland.

Weiss, Dr. Allison. Department of Molecular Genetics, Biochemistry, and Microbiology, University of Cincinnati, Ohio.

Weiss, Prof. Gerald. Department of Electrical Engineering, Polytechnic Institute of New York.

Weiss, Dr. Marc. National Institute of Standards and Technology, Time and Frequency Division, Boulder, Colorado.

Weiss, Dr. Theodore J. Technical Manager, Food Department, Hunt-Wesson Foods, Inc., Fullerton, California.

Weitz, Dr. Martin. Sektion Physik, Ludwig-Maximilians-Universität, München, Germany.

Weitzenhoffer, Dr. Andre M. Veterans Administration Hospital, Oklahoma City, Oklahoma.

Wejsa, James. AMSTA-AR-FSA-M, United States Army Armament Research Development and Engineering Center, Picatinny Arsenal, New Jersey.

Welch, Dr. Winona H. Department of Botany and Bacteriology, De Pauw University.

Welham, Dr. Chris J. Druck Ltd., United Kingdom.

Welhener, Dr. Herb. Independent Mining Consultants, Inc., Tucson, Arizona.

Weller, Prof. Gunter. Global Change and Arctic Systems, University of Alaska, Fairbanks.

Wellner, Dr. Daniel. Department of Biochemistry, Cornell University Medical College.

Wellstead, Dr. Carl F. Doane College, Crete, Nebraska.

Wendlandt, Prof. Wesley W. Department of Chemistry, University of Houston.

Wendler, Dr. Helen E. Department of Biology, Massachusetts Institute of Technology.

Wenkert, Prof. Ernest. Department of Chemistry, Indiana University.

Wenner, Prof. Adrian M. Department of Biological Sciences, University of California, Santa Barbara.

Wentorf, Robert H., Jr. General Electric Research and Development, Schenectady, New York.

Wenzel, Dr. Elizabeth M. Ames Research Center, National Aeronautics and Space Administration, Moffett Field, California.

West, Dr. William. Eastman Kodak Company, Rochester, New York.

Westfall, Dr. Richard S. Department of History and Philosophy of Science, Indiana University.

Westheimer, Prof. F. H. Chemistry Department, Harvard University, Cambridge, Massachusetts.

Wetzel, Dr. Richard. College of William and Mary, Virginia Institute of Marine Science, School of Marine Science, Gloucester Point, Virginia.

Whaley, Dr. W. Gordon. Cell Research Institute, University of Texas, Austin.

Wheeler, Dr. Harry E. Department of Plant Pathology, University of Kentucky.

Whelan, Dr. Jean K. Senior Research Specialist, Department of Chemistry, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.

Whinnery, Prof. John R. Department of Electrical Engineering and Computer Science, College of Engineering, University of California, Berkeley.

Whistler, Prof. Roy L. Department of Biochemistry, Purdue University.

Whitcomb, Dr. Richard T. NASA Langley Research Center, Langley Field, Virginia.

White, Donald R. J. International Training Centre, Don White Consultants, Inc., Gainesville, Virginia.

White, Dr. Abraham. Consulting Professor of Biochemistry, Stanford University; School of Medicine; Distinguished Scientist, Institute of Biological Sciences, Syntex Research.

White, Prof. Colin. Department of Epidemiology and Public Health, Yale University.

White, Dr. C. Langdon. Professor of Geography, Stanford University.

White, Dr. Lawrence R. Technical Director, "Popular Photography," New York.

White, Dr. K. Preston, Jr. Department of Systems Engineering, University of Virginia.

White, Prof. Robert M. Head, Department of Electrical and Computer Engineering, Carnegie-Mellon University, Pittsburgh, Pennsylvania.

White, Dr. Sidney E. Department of Geology and Mineralogy, Ohio State University.

White, Dr. Stanley A. President, Signal Processing and Controls Engineering, San Clemente, California.

White, Dr. Stephanie. Northrop Grumman, Bethpage, New York.

White, Dr. Tim. School of Forest Resources, University of Florida, Gainesville.

Whitehead, Prof. W. Dexter. Department of Physics, Center for Advanced Studies, University of Virginia.

Whitmore, Dr. T. C. Department of Geography, University of Cambridge, United Kingdom.

Whitney, Eugene C. Consulting Engineer, Pittsburgh, Pennsylvania.

Whittingham, Dr. M. Stanley. Director, Materials Research Center, State University of New York, Binghamton.

Wicks, Dr. Fred J. Department of Mineralogy, Royal Ontario Museum, Ontario, Canada.

Wickstrom, Dr. Conrad. Department of Biological Sciences, Kent State University.

Widder, Prof. David V. Department of Mathematics, Harvard University.

Widom, Dr. Jennifer. IBM Almaden Research Center, San Jose, California.

Wiegand, Dr. Clyde E. Lawrence Berkeley Laboratory, University of California, Berkeley.

Wiens, Prof. Herold J. Deceased; formerly, Department of Geography, Yale University.

Wienski, Robert M. District Manager, ISDN Architecture Planning, Bell Communications Research, Red Bank, New Jersey.

Wiest, Dr. John M. Department of Chemical Engineering, University of Alabama, Tuscaloosa.

Wightman, Prof. Arthur S. Department of Physics, Joseph Henry Laboratories, Princeton University.

Wikle, Prof. Thomas A. Professor and Head, Department of Geography, Oklahoma State University, Stillwater.

Wilbur, Donald A., Sr. Emeritus Professor of Entomology, Kansas State University.

Wilbur, Prof. Paul J. Department of Mechanical Engineering, Colorado State University.

Wilcox, Dr. Hugh. State University College of Forestry, Syracuse University.

Wilcox, Dr. Kimerly J. Dight Laboratories, University of Minnesota.

Wilcox, Prof. William R. Department of Chemical Engineering, Clarkson College of Technology.

Wilczek, Prof. Frank. Institute for Advanced Study, Princeton, New Jersey.

Wilder, Dr. George J. Department of Biological Sciences, University of Illinois, Chicago.

Wildhack, William A. Consultant; formerly, Associate Director, Institute for Basic Standards, National Bureau of Standards.

Wilen, Dr. Samuel H. Department of Chemistry, City University of New York.

Wiles, Dr. D. M. National Research Council of Canada, Ottawa, Ontario.

Wiley, Prof. Edward O., III. Curator, Natural History Museum, University of Kansas, Lawrence.

Wilhelm, Dr. Harley A. Principal Scientist, EMRR Institute and Ames Laboratory of U.S. Department of Energy, Iowa State University.

Wilhoit, Dr. Randolph C. Thermodynamics Research Center, Texas A & M University.

Wilkening, Dr. M. Department of Physics, New Mexico Institute of Mining and Technology.

Wilkinson, Dr. Brian J. Department of Biological Sciences, Illinois State University.

Wilkinson, Prof. Denys H. Department of Nuclear Physics, Oxford University, England.

Wilkinson, Dr. Michael K. Associate Director, Solid State Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

Willett, Prof. Hilda P. Director of Graduate Studies, Department of Microbiology, Duke University Medical Center, Durham, North Carolina.

Willett, Prof. Kurd C. Department of Meteorology, Massachusetts Institute of Technology.

Willey, Dr. Robert B. Department of Biological Sciences, University of Illinois.

Williams, Dr. D. B. Department of Materials Science and Engineering, Lehigh University, Bethlehem, Pennsylvania.

Williams, Prof. Dudley. Department of Physics, Kansas State University.

Williams, Dr. Earl G. Structural Acoustics, Naval Research Laboratory, Washington, D.C.

Williams, Dr. Earle R. Department of Earth, Atmospheric and Planetary Sciences, Massachusetts Institute of Technology, Center for Meteorology and Physical Oceanography.

Williams, Prof. Gary A. Department of Physics, University of California, Los Angeles.

Williams, Dr. Jack M. Chemistry Division, Argonne National Laboratory, Argonne, Illinois.

Williams, Dr. Kathleen M. Extension Pomologist, Tree Fruit Research and

Extension Center, Washington State University, Wenatchee.

Williams, Dr. Peter. Department of Chemistry, Arizona State University.

Williams, Dr. Roger J. Deceased; formerly, Department of Chemistry, University of Texas, Austin.

Williams, S. A. Department of Physics, Iowa State University.

Williams, Prof. Todd D. Department of Chemistry, University of Kansas, Lawrence.

Williamson, Dr. K. D. Los Alamos Scientific Laboratory, Los Alamos, New Mexico.

Willingham, Dr. Mark C. National Institutes of Health, National Cancer Institute, Bethesda, Maryland.

Willis, Dr. William J. European Organization for Nuclear Research (CERN), Geneva, Switzerland.

Wilson, Dr. B. F. Department of Forestry and Wildlife Management, University of Massachusetts.

Wilson, Dr. Curtis B. Department of Immunopathology, Scripps Clinic and Research Foundation, La Jolla, California.

Wilson, Prof. George S. Department of Chemistry, University of Kansas, Lawrence.

Wilson, Grady W. Deputy Director and Chief Test Pilot, Raspet Flight Research Laboratory, Mississippi State University.

Wilson, Dr. Irwin B. Department of Chemistry and Biochemistry, University of Colorado.

Wilson, Dr. James B. Department of Forest Products, Oregon State University, Corvallis.

Wilson, Dr. James L. Department of Geology and Mineralogy, University of Michigan.

Wilson, Dr. Leonard R. George Lynn Cross Research Professor of Geology and Geophysics, School of Geology and Geophysics, University of Oklahoma.

Wilson, Prof. Mason P., Jr. Department of Mechanical Engineering, University of Rhode Island, Kingston.

Wilson, Dr. Therese. Biological Laboratories, Harvard University.

Wilt, Dr. Fred. Department of Zoology, University of California, Berkeley.

Winch, Prof. Ralph P. Department of Physics, Williams College.

Wing, Dr. Robert F. Department of Astronomy, Ohio State University, Columbus.

Winick, Dr. Herman. Deputy Director, Stanford Synchrotron Radiation Laboratory, Stanford, California.

Winn, Kevin. American Sudden Infant Death Syndrome Institute, Atlanta, Georgia.

Winston, Dr. Judith E. Assistant Curator, Department of Invertebrates, American Museum of Natural History, New York.

Winter, Dr. John M., Jr. Department of Materials Science and Engineering, Johns Hopkins University, Baltimore, Maryland.

Winter, Prof. Rolf G. Department of Physics, College of William and Mary.

Winter, Dr. Thomas C. U.S. Geological Survey, Department of the Interior, Denver, Colorado.

Winterer, Dr. Edward L. Geological Research Division, Scripps Institution of Oceanography, La Jolla, California.

Wise, Edmund M. Consultant; formerly, Assistant to Vice President of Research, International Nickel Company, Inc., New York.

Wittmann, H. G. Max-Planck Institut für Molekulare Genetik, Berlin, Germany.

Wittmers, Dr. L. E. School of Medicine, University of Minnesota.

Wnek, Prof. Gary E. Director, Polymer Science and Engineering Program, Department of Chemistry, School of Science, Rensselaer Polytechnic Institute.

Wold, Dr. Marc. Department of Biochemistry, University of Iowa College of Medicine, Iowa City.

Wolf, Dr. Peter. IBM Zurich Research Laboratory, Switzerland.

Wolf, Dr. Werner P. Department of Physics, Yale University.

Wolfe, Dr. Ralph S. Marine Biological Laboratory, Woods Hole, Massachusetts.

Wolfe, Dr. William L. Optical Sciences Center, University of Arizona.

Wolferz, Alfred H. Chief (retired), Tachometer Systems Development, Weston Instruments Division, Daystrom, Inc., Newark, New Jersey.

Wolford, Dr. James C. Mechanical Engineering Department, University of Nebraska.

Wollersheim, Prof. David. Department of Mechanical and Aerospace Engineering, University of Missouri.

Wollnik, Prof. H. Physikalisches Institut, Justus Liebig-Universität, Giessen, Germany.

Wolovich, Dr. William. Department of Engineering, Brown University.

Wonders, Dr. William C. Department of Geography, University of Alberta, Canada.

Wones, Dr. David R. Department of Geological Sciences, Virginia Polytechnic Institute and State University.

Wong, Dr. George S. K. Acoustical Standards, Institute for National Measurement Standards, Ottawa, Ontario, Canada.

Wood, Dr. Albert E. (Retired) Department of Biology, Amherst College.

Wood, Dr. B. J. Department of the Geophysical Sciences, University of Chicago.

Wood, Dr. Chris. Electric Power Research Institute, Palo Alto, California.

Wood, Dr. Earl H. Mayo Foundation, Graduate School of Medicine, University of Minnesota.

Wood, Dr. Frank B. Department of Physics and Astronomy, University of Florida.

Wood, Dr. H. William. Consultant, Aerospace, Roaring Gap, North Carolina.

Woodall, James E. Division Manufacturing Manager, Westinghouse Electric Corporation, Pittsburgh, Pennsylvania.

Woodall, Prof. Jerry M. Yale University, Department of Electrical Engineering, New Haven, Connecticut.

Woodcock, C. L. F. Professor of Zoology, University of Massachussetts.

Woods, Dr. Jon P. Assistant Professor, Department of Medical Microbiology and Immunology, University of Wisconsin Medical School, Madison.

Woodward, Prof. John B., III. Department of Naval Architecture and Marine Engineering, University of Michigan.

Woody, Dr. R. W. Department of Biochemistry, Colorado State University.

Woosley, Prof. Stan E. Lick Observatory, Santa Cruz, California.

Woram, John M. Woram Audio Associates, New York.

Wray, Dr. John L. Marathon Oil Company, Littleton, Colorado.

Wright, Elliott F. Consulting Engineer (retired), Advanced Products Division, Studebaker-Worthington Corporation, Harrison, New Jersey.

Wright, James A. Strategic Marketing Manager, Motorola, Inc., Boynton Beach, Florida.

Wright, Michael E. National Semiconductor Corporation, Santa Clara, California.

Wright, Prof. Raymond. Department of Civil and Environmental Engineering, University of Rhode Island, Kingston.

Wu, Prof. Tai Tsun. Division of Engineering and Applied Physics, Harvard University.

Wuensch, Dr. Bernhardt J. Department of Metallurgy and Materials Science, Massachusetts Institute of Technology.

Wulff, Dr. Verner J. Associate Director of Research, Masonic Medical Research Laboratory, Utica, New York.

Wurtele, Prof. Morgan G. Department of Atmospheric Sciences, University of California, Los Angeles.

Wyant, Prof. James C. Optical Sciences Center, University of Arizona.

Wygodzinsky, Dr. Pedro W. Department of Entomology, American Museum of Natural History, New York.

Wyke, Dr. John A. Wolfson Laboratory for Molecular Pathology, The Beatson Institute for Cancer Research, Glasgow, Scotland.

Wyllie, Dr. Peter J. Chairman, Department of Geophysical Sciences, University of Chicago.

Wyman, Dr. Richard E. Director of Research, Canadian Hunter Exploration, Ltd., Calgary, Alberta.

Wyrtki, Dr. Klaus. Department of Oceanography, University of Hawaii, Manoa.

Wüest, Dr. Alfred Johny. Applied Aquatic Ecology (APEC), Kastanienbaum, Switzerland.

Y

Yagi, Prof. Takehiko. Institute of Solid State Physics, University of Tokyo, Japan.

Yalow, Dr. Rosalyn S. Senior Medical Investigator, Veterans Administration Hospital, New York.

Yamaguchi, Prof. M. Department of Vegetable Crops, University of California, Davis.

Yang, Hongjun. IGEN, Inc., Rockville, Maryland.

Yankee, Prof. Herbert W. Mechanical Engineering Department, Worcester Polytechnic Institute.

Yates, Dr. S. F. Allied Signal Research Center, Inc., Des Plaines, Illinois.

Yeatman, Dr. Harry C. Department of Zoology, University of the South, Sewanee, Tennessee.

Yegulalp, Prof. Tuncel M. Henry Krumb School of Mines, Columbia University, New York.

Yell, Dr. Ralph W. National Physical Laboratory, Teddington, Middlesex, England.

Yelles, Marvin. Formerly, Editor, "McGraw-Hill Encyclopedia of Science and Technology," McGraw-Hill Book Company, New York.

Yellott, John I. Emeritus Professor, College of Architecture, Arizona State University.

Yeomans, Dr. Donald K. Jet Propulsion Laboratory, California Institute of Technology.

Yin, Prof. Frank C.-P. Department of Medicine, Johns Hopkins Schools of Medicine, Baltimore, Maryland.

Yochelson, Dr. Ellis L. Geological Survey, U.S. Department of the Interior, Washington, D.C.

Yokelson, Dr. Howard B. Research and Development Department, Amoco Chemical Company, Naperville, Illinois.

Yost, Prof. Don M. Formerly, California Institute of Technology.

Yost, Dr. William A. Director, Parmly Hearing Institute, Loyola University.

Young, Dr. Anne B. Department of Neurology, University of Michigan.

Young, Dr. David A. Department of Entomology, North Carolina State University.

Young, Edward M. Deceased; formerly, Associate Editor, "Engineering News Record," McGraw-Hill, Inc., New York.

Young, Prof. Grant M. Department of Earth Sciences, University of Western Ontario, London, Ontario, Canada.

Young, Prof. N. J. Department of Mathematics and Statistics, University of Lancaster, England.

Young, Dr. Robert W. Associate Editor, "Journal of the Acoustical Society of America," San Diego, California.

Young, Prof. Thomas F. Deceased; formerly, Department of Chemistry, of Chicago.

Young, Wayne. Director, Environmental Dredging, Maryland Environmental Service, Annapolis.

Younker, Dr. Leland W. Earth Science Department, Lawrence Livermore National Laboratory, University of California.

Yu, Dr. Ching-Sung. Deceased; formerly, Professor Emeritus of Astronomy, Hood College.

Yu, Dr. Robert K. Department of Biochemistry and Molecular Biophysics, Virginia Commonwealth University School of Medicine, Richmond.

Yuen, Prof. Horace P. Department of Electrical Engineering and Computer Science, Northwestern University.

Yungul, Dr. Sulhi H. Chevron Resources Company, San Francisco, California.

Z

Zaitlin, Dr. Milton. Associate Director, Biotechnology Program, Plant Pathology, Cornell University.

Zander, Dr. Andrew T. Varian Associates, Palo Alto, California.

Zangerl, Dr. Rainer. Chief Curator (retired), Department of Geology, Field Museum of Natural History, Chicago, Illinois.

Zanoni, Thomas A. Taxonomist, Jardin Botanico Nacional, Santo Domingo, Dominican Republic; and Honorary Research Associate, New York Botanical Garden.

Zapffe, Dr. Carl A. Consultant, Baltimore, Maryland.

Zbar, Dr. Frederick. Chevy Chase, Maryland.

Zebroski, Dr. Edwin L. Los Altos, California.

Zeitlin, Dr. Andrew D. MITRE Corporation, McLean, Virginia.

Zelitch, Dr. Israel. Department of Biochemistry and Genetics, Connecticut Agricultural Experiment Station, New Haven.

Zelkowitz, Prof. Marvin V. Department of Computer Science, University of Maryland, College Park Maryland.

Zeller, Dr. Andreas. Universität Passau, Lehrstuhl für Software-Systeme, Passau, Germany.

Zeller, Prof. Michael E. Department of Physics, Yale University.

Zelnick, Dr. Ernest. Dispensing Audiologist, New York.

Zhang, Dr. Ruyuan. Department of Geological and Environmental Sciences, Stanford University, Stanford, California.

Zhao, Prof. Wei. Department of Computer Science, Texas A & M University, College Station.

Ziemer, Prof. Rodger, E. Chairperson, Department of Electrical and Computer Engineering, University of Colorado, Colorado Springs.

Zifcak, John H. The Foxboro Company, Foxboro, Massachusetts.

Zimmerman, Dr. John R. Department of Mechanical Engineering, Pennsylvania State University.

Zimmerman, Dr. Leroy H. (Retired) U.S. Department of Agriculture, Tucson, Arizona.

Zinder, Dr. Norton D. Department of Microbial Genetics, Rockefeller University.

Zink, Dr. Frank W. Department of Vegetable Crops, University of California, Davis.

Zinner, Dr. Ernst. McDonnell Center for the Space Sciences, Washington University, St. Louis, Missouri.

Zirin, Dr. Harold. Department of Physics, California Institute of Technology.

Zissis, Dr. George J. Chief Scientist, Environmental Research Institute of Michigan, Ann Arbor.

Zlotnik, Dr. I. Microbiological Research Establishment, Wilts, England.

Zohar, Dr. Joseph. Deputy Director, Beer Sheva Mental Health Center, Beer Sheva, Israel.

Zubay, Dr. Geoffrey. Sherman Fairchild Center for the Life Sciences, Department of Biological Sciences, Columbia University.

Zuk, Dr. William. School of Architecture, University of Virginia.

Zuman, Dr. Petr. Department of Chemistry, Clarkson College of Technology.

Zumberge, Dr. Mark A. Institute of Geophysics and Planetary Physics, Scripps Institution of Oceanography, La Jolla, California.

Zurek, Dr. Wojciech H. Los Alamos National Laboratory, Los Alamos, New Mexico.

Zweifel, Dr. Richard G. Curator, Department of Herpetology, American Museum of Natural History, New York.

Zwerman, Prof. Paul J. Department of Agronomy, Cornell University.
