## CENGAGE

CengageBrain.com is the smart move when it comes to getting the right stuff on time, every time. Whether you rent or buy, we'll save you time, money, and frustration.

## - You've Got Options:

Convenient digital solutions and textbooks the way you want them - to buy or rent.

## - You Get Access:

Anytime, anywhere access of digital products, eBooks, and eChapters, on your desktop, laptop, or phone.

## - You Get Free Stuff:

Free 14-day eBook access, free shipping on orders of $\$ 25$ or more, free study tools like flashcards and quizzes, and a free trial period for most digital products.

Look, we get it. You've got a full schedule - we've got your back(pack). Get what you need to get the grades at CengageBrain.com

## Contents

To the Professor ..... ix
To the Student xiii
Chapter 1 | Chemical Foundations ..... 1
1.1 Chemistry: An Overview ..... 3
1.2 The Scientific Method ..... 5
CHEMIICAL CONNECTIONS A Note-able Achievement ..... 7
1.3 Units of Measurement ..... 8
CHEMIICAL CONNECTIONS Critical Units! ..... 10
1.4 Uncertainty in Measurement ..... 11
1.5 Significant Figures and Calculations ..... 14
1.6 Learning to Solve Problems Systematically ..... 18
1.7 Dimensional Analysis ..... 18
1.8 Temperature ..... २2
1.9 Density ..... 26
1.10 Classification of Matter ..... 27
For Review 31 | Key Terms 31 | Questions and Exercises ..... 33
Chapter $2 \mid$ Atoms, Molecules, and Ions ..... 35
2.1 The Early History of Chemistry ..... 36
2.2 Fundamental Chemical Laws ..... 37
2.3 Dalton's Atomic Theory ..... 40
CHEMIICAL CONNECTIONS Berzelius, Selenium, andSilicon 42
2.4 Early Experiments to Characterize the Atom ..... 42
2.5 The Modern View of Atomic Structure: An Introduction ..... 46
2.6 Molecules and Ions ..... 48
2.7 An Introduction to the Periodic Table ..... 51 CHEMICAL CONNECTIONS Hassium Fits Right In 53
2.8 Naming Simple Compounds ..... 53
For Review $64 \mid$ Key Terms $64 \mid$ Questions and Exercises 66
Chapter 3 | Stoichiometry ..... 68
3.1 Counting by Weighing ..... 69
3.2 Atomic Masses ..... 70
3.3 The Mole ..... 72
3.4 Molar Mass ..... 77
3.5 Learning to Solve Problems ..... 80
3.6 Percent Composition of Compounds ..... 81
3.7 Determining the Formula of a Compound ..... 83
3.8 Chemical Equations ..... 90
3.9 Balancing Chemical Equations ..... 92
3.10 Stoichiometric Calculations: Amounts of Reactantsand Products95
CHEIVICAL CONNECTIONS High Mountains-LowOctane96
3.11 The Concept of Limiting Reactant ..... 100
For Review 111 | Key Terms 111 | Questions and Exercises ..... 115

Chapter 4 | Types of Chemical Reactions and Solution Stoichiometry ..... 116
4.1 Water, the Common Solvent ..... 117
4.2 The Nature of Aqueous Solutions: Strong and Weak Electrolytes ..... 119
CHEMIICAL CONNECTIONS Arrhenius: A Man withSolutions122
4.3 The Composition of Solutions ..... 123
4.4 Types of Chemical Reactions ..... 130
4.5 Precipitation Reactions ..... 131 CHEMICAL CONNECTIONS Tiny Laboratories 135
4.6 Describing Reactions in Solution ..... 136
4.7 Stoichiometry of Precipitation Reactions ..... 138
4.8 Acid-Base Reactions ..... 140
4.9 Oxidation-Reduction Reactions ..... 147
4.10 Balancing Oxidation-Reduction Equations ..... 152
4.11 Simple Oxidation-Reduction Titrations ..... 158
For Review 160 \| Key Terms 160 \| Questions and Exercises 163
Chapter 5 | Gases ..... 164
5.1 Pressure ..... 165
5.2 The Gas Laws of Boyle, Charles, and Avogadro ..... 167
5.3 The Ideal Gas Law ..... 173
5.4 Gas Stoichiometry ..... 179
5.5 Dalton's Law of Partial Pressures ..... 183
CHEMICAL CONNECTIONS Separating Gases ..... 185
CHEMIICAL CONNECTIONS The Chemistry of AirBags 186
5.6 The Kinetic Molecular Theory of Gases ..... 189
5.7 Effusion and Diffusion ..... 196
5.8 Real Gases ..... 198
5.9 Characteristics of Several Real Gases ..... 201
5.10 Chemistry in the Atmosphere ..... 202
For Review 205 | Key Terms 205 | Questions and Exercises 208
Chapter 6 | Thermochemistry ..... 210
6.1 The Nature of Energy ..... 211
6.2 Enthalpy and Calorimetry ..... 218
CHEMIICAL CONNECTIONS Nature Has Hot Plants 221

6.3 Hess's Law ..... 225
6.4 Standard Enthalpies of Formation ..... 229
6.5 Present Sources of Energy ..... 236
6.6 New Energy Sources ..... 240
CHEMIICAL CONNECTIONS Farming the Wind ..... 242
For Review 247 | Key Terms 247 | Questions and Exercises 249
Chapter 7 | Atomic Structure and Periodicity ..... 251
7.1 Electromagnetic Radiation ..... 252
7.2 The Nature of Matter ..... 254
Chemical connections Fireworks ..... 256
7.3 The Atomic Spectrum of Hydrogen ..... 260
7.4 The Bohr Model ..... 262
CHEMIICAL CONNECTIONS 0.035 Femtometer Is a Big Deal 265
7.5 The Quantum Mechanical Model of the Atom ..... 266
7.6 Quantum Numbers ..... 269
7.7 Orbital Shapes and Energies ..... 270
7.8 Electron Spin and the Pauli Principle ..... 273
7.9 Polyelectronic Atoms ..... 274
7.10 The History of the Periodic Table ..... 276
7.11 The Aufbau Principle and the Periodic Table ..... 278
CHEMICAL CONNECTIONS The Chemistry ofCopernicium279
7.12 Periodic Trends in Atomic Properties ..... 284
7.13 The Properties of a Group: The Alkali Metals ..... 291
CHEMICAL CONNECTIONS Potassium-Too Much of aGood Thing Can Kill You 293For Review 295 | Key Terms 295 | Questions and Exercises 298
Chapter 8 | Bonding: General Concepts 300
8.1 Types of Chemical Bonds ..... 301
CHEMICAL CONNECTIONS No Lead Pencils ..... 303
8.2 Electronegativity ..... 305
8.3 Bond Polarity and Dipole Moments ..... 307
8.4 Ions: Electron Configurations and Sizes ..... 310
8.5 Energy Effects in Binary Ionic Compounds ..... 314
8.6 Partial Ionic Character of Covalent Bonds ..... 318
8.7 The Covalent Chemical Bond: A Model ..... 319
8.8 Covalent Bond Energies and Chemical Reactions ..... 322
8.9 The Localized Electron Bonding Model ..... 325
8.10 Lewis Structures ..... 325 CHEMIICAL CONNECTIONS Nitrogen Under Pressure 329
8.11 Exceptions to the Octet Rule ..... 329
8.12 Resonance ..... 333
8.13 Molecular Structure: The VSEPR Model ..... 337
CHEMICAL CONNECTIONS Chemical Structure and Communication: Semiochemicals 346 For Review 350 | Key Terms 350 \| Questions and Exercises 352
Chapter 9 | Covalent Bonding: Orbitals ..... 354
9.1 Hybridization and the Localized Electron Model ..... 355
9.2 The Molecular Orbital Model ..... 366
9.3 Bonding in Homonuclear Diatomic Molecules ..... 369
9.4 Bonding in Heteronuclear Diatomic Molecules ..... 376
9.5 Combining the Localized Electron and Molecular Orbital Models ..... 377
CHEMICAL CONNECTIONS What's Hot? ..... 378
For Review 380 | Key Terms 380 | Questions and Exercises 382
Chapter 10 | Liquids and Solids ..... 383
10.1 Intermolecular Forces ..... 385
10.2 The Liquid State ..... 390
CHEMIICAL CONNECTIONS Smart Fluids ..... 392
10.3 An Introduction to Structures and Types of Solids ..... 393
10.4 Structure and Bonding in Metals 397
CHEMICAL CONNECTIONS Closest Packing of M\&Ms 402

10.5 Carbon and Silicon: Network Atomic Solids ..... 403

Chapter 11 | Properties of Solutions ..... 433
11.1 Solution Composition ..... 434
11.2 The Energies of Solution Formation ..... 437
11.3 Factors Affecting Solubility ..... 441
11.4 The Vapor Pressures of Solutions ..... 445 CHEMICAL C
Tragedy 446
11.5 Boiling-Point Elevation and Freezing-Point Depression ..... 451
11.6 Osmotic Pressure ..... 454
11.7 Colligative Properties of Electrolyte Solutions ..... 459 CHEMICAL CONINECTIONS The Drink of Champions- Water 461
11.8 Colloids ..... 461 ..... 461
CHEMICAL CONNECTIONS Organisms and IceFormation 462For Review 463 | Key Terms 463 | Questions and Exercises 466

## Chapter 12 | Chemical Kinetics 467

12.1 Reaction Rates 468
12.2 Rate Laws: An Introduction 472
12.3 Determining the Form of the Rate Law 474
12.4 The Integrated Rate Law 478
12.5 Reaction Mechanisms 489
12.6 A Model for Chemical Kinetics 494
12.7 Catalysis 500

CHEMICAL CONNECTIONS Enzymes: Nature's Catalysts 504
For Review 506 | Key Terms 506 | Questions and Exercises 509

## Chapter 13 | Chemical Equilibrium 510

13.1 The Equilibrium Condition 511
13.2 The Equilibrium Constant 514
13.3 Equilibrium Expressions Involving Pressures 518
13.4 Heterogeneous Equilibria 520
13.5 Applications of the Equilibrium Constant 522
13.6 Solving Equilibrium Problems 531
13.7 Le Châtelier's Principle 536

For Review 543 | Key Terms 543 | Questions and Exercises 546

## Chapter 14 | Acids and Bases 548

14.1 The Nature of Acids and Bases ..... 549
14.2 Acid Strength ..... 552
14.3 The pH Scale ..... 557
CHEMICAL CONNEETIONS Arnold Beckman, Man ofScience 559
14.4 Calculating the pH of Strong Acid Solutions ..... 560
14.5 Calculating the pH of Weak Acid Solutions ..... 562
14.6 Bases 571
CHEMICAL CONNECTIONS Amines ..... 575
14.7 Polyprotic Acids ..... 576
14.8 Acid-Base Properties of Salts ..... 582
14.9 The Effect of Structure on Acid-Base Properties ..... 587
14.10 Acid-Base Properties of Oxides ..... 589
14.11 The Lewis Acid-Base Model ..... 589
14.12 Strategy for Solving Acid-Base Problems: A Summary ..... 592
For Review $592 \mid$ Key Terms $592 \mid$ Questions and Exercises ..... 597
Chapter 15 | Acid-Base Equilibria ..... 599
15.1 Solutions of Acids or Bases Containing a Common Ion ..... 600
15.2 Buffered Solutions ..... 602
15.3 Buffering Capacity ..... 611
15.4 Titrations and pH Curves ..... 615
15.5 Acid-Base Indicators ..... 629
15.6 Polyprotic Acid Titrations 634 For Review 636 | Key Terms 636 \| Questions and Exercises 638
Chapter 16 | Solubility and Complex Ion Equilibria 640
16.1 Solubility Equilibria and the Solubility Product ..... 641
CHEMICAL CONNECTIONS The Chemistry of Teeth 645
16.2 Precipitation and Qualitative Analysis ..... 649
16.3 Equilibria Involving Complex Ions ..... 656
For Review 661 | Key Terms 661 | Questions and Exercises ..... 663
Chapter 17 | Spontaneity, Entropy, and Free Energy ..... 664
17.1 Spontaneous Processes and Entropy ..... 665
CHEMICAL CONNECTIONS Entropy: An Organizing Force? 671
17.2 Entropy and the Second Law of Thermodynamics ..... 671
17.3 The Effect of Temperature on Spontaneity ..... 672
17.4 Free Energy ..... 675
17.5 Entropy Changes in Aqueous Solutions ..... 678
17.6 Entropy Changes in Chemical Reactions ..... 679
17.7 Free Energy and Chemical Reactions ..... 683
17.8 The Dependence of Free Energy on Pressure ..... 689
17.9 Free Energy and Equilibrium ..... 692
17.10 Free Energy and Work ..... 697
For Review 699 | Key Terms 699 Questions and Exercises ..... 701
Chapter 18 | Electrochemistry ..... 703
18.1 Galvanic Cells ..... 704
18.2 Standard Reduction Potentials ..... 706
18.3 Cell Potential, Electrical Work, and Free Energy ..... 714
18.4 Dependence of Cell Potential on Concentration ..... 717
18.5 Batteries ..... 722Cheivical c

18.6 Corrosion ..... 726
18.7 Electrolysis ..... 728
CHEMICAL CONNECTIONS The Chemistry of SunkenTreasure 732
18.8 Commercial Electrolytic Processes ..... 733
For Review 738 | Key Terms 738 | Questions and Exercises ..... 741
Chapter 19 | The Nucleus: A Chemist's View 743
19.1 Nuclear Stability and Radioactive Decay ..... 744
19.2 The Kinetics of Radioactive Decay ..... 749
19.3 Nuclear Transformations ..... 752
CHEMIICAL CONNECTIONS Tennessine ..... 753
19.4 Detection and Uses of Radioactivity ..... 754
19.5 Thermodynamic Stability of the Nucleus ..... 758
19.6 Nuclear Fission and Nuclear Fusion ..... 762
19.7 Effects of Radiation ..... 766
For Review 768 | Key Terms 768 | Questions and Exercises ..... 770
Chapter 20 | The Representative Elements ..... 772
20.1 A Survey of the Representative Elements ..... 773
20.2 The Group 1A Elements ..... 778
20.3 The Chemistry of Hydrogen ..... 779
20.4 The Group 2A Elements ..... 781
20.5 The Group 3A Elements ..... 783
20.6 The Group 4A Elements ..... 784
CHEMIICAL CONNECTIONS Beethoven: Hair Is theStory 786
20.7 The Group 5A Elements ..... 787
20.8 The Chemistry of Nitrogen ..... 788
CHEMIICAL CONNECTIONS Nitrous Oxide: Laughing GasThat Propels Whipped Cream and Cars 794
20.9 The Chemistry of Phosphorus ..... 795
20.10 The Group 6A Elements ..... 797
20.11 The Chemistry of Oxygen ..... 797
20.12 The Chemistry of Sulfur ..... 799
20.13 The Group 7A Elements ..... 801
20.14 The Group 8A Elements 805For Review 806 | Key Terms 806 | Questions and Exercises 809
Chapter 21 | Transition Metals and Coordination Chemistry 810
21.1 The Transition Metals: A Survey ..... 811
21.2 The First-Row Transition Metals ..... 816 CHEMICAL CONNECTIONS Titanium Dioxide—Miracle Coating 818
21.3 Coordination Compounds ..... 821
21.4 Isomerism ..... 825
CHEMIICAL CONNECTIONS The Importance ofBeing cis 828
21.5 Bonding in Complex Ions: The Localized Electron Model ..... 830
21.6 The Crystal Field Model ..... 832CHEMICAL CONNECTIONS Transition Metal Ions LendColor to Gems 835
21.7 The Biological Importance of Coordination Complexes ..... 838
21.8 Metallurgy and Iron and Steel Production ..... 843 For Review 850 | Key Terms 850 | Questions and Exercises 853
Chapter 22 | Organic and Biological Molecules ..... 854
22.1 Alkanes: Saturated Hydrocarbons ..... 855
22.2 Alkenes and Alkynes ..... 863

## Features of Chemistry, Tenth Edition

Conceptual learning and problem solving are fundamental to the approach of Chemistry. Our philosophy is to help students learn to think like chemists so that they can apply the process of problem solving to all aspects of their lives. We give students the tools to become critical thinkers: to ask questions, to apply rules and models, and to evaluate the outcome. It was also our mission to create a media program that embodies this philosophy so that when instructors and students look online for either study aids or online homework, each resource supports the goals of the textbook-a strong emphasis on models, real-world applications, and visual learning.

## What's New

We have made extensive updates to the Tenth Edition to enhance the learning experience for students. Here's what's new:
> We have added three new Sections to the text:
>4.11: Simple Oxidation-Reduction Titrations
>15.6: Polyprotic Acid Titrations
>17.5: Entropy Changes in Aqueous Ionic Solutions
> We have added several new subsections throughout the text:
> The Process of Heat (in Section 6.1)
>Photoelectron Spectroscopy for Atoms (in Section 7.12)
>Photoelectron Spectroscopy for Molecules (in Section 9.3)
>Distinguishing Between Chemical and Physical Changes at the Molecular Level (in Section 10.1)
) Forces Between Polar and Nonpolar Molecules (in Section 10.1)
> Chromatography (in Section 11.2)
> Mechanisms with Fast Forward and Reverse First Steps (in Section 12.5)
) Acid Catalysis (in Section 12.7)
> Nonspontaneous Reactions (in Section 17.7)
> In Chapter 3 the treatment of stoichiometry has been enhanced by a discussion of "BCA" (Before-Change-After) tables, which allow another method by which students can conceptually understand the role coefficients play in a balanced chemical reaction. Students are shown three methods to select a limiting reactant: comparing the amounts of reactant present, calculating the amounts of products that can be formed by complete consumption of each reactant, and using a BCA table.
> In Chapter 4 we expanded Section 4.10 to include the halfreaction method for balancing complex oxidation-reduction reactions. This change was made to better support typical laboratory programs.
> New end-of-chapter questions and problems have been added throughout the text.
) The art program has been modified and updated as needed, and new macro/micro illustrations have been added.

## Hallmarks of Chemistry

Chemistry contains numerous discussions, illustrations, and exercises aimed at overcoming misconceptions. It has become increasingly clear from our own teaching experience that students often struggle with chemistry because they misunderstand many of the fundamental concepts. In this text, we have gone to great lengths to provide illustrations and explanations aimed at giving students a more accurate picture of the fundamental ideas of chemistry. In particular, we have attempted to represent the microscopic world of chemistry so that students have a picture in their minds of "what the atoms and molecules are doing." The art program along with the animations emphasize this goal. We have also placed a larger emphasis on the qualitative understanding of concepts before quantitative problems are considered. Because using an algorithm to correctly solve a problem often masks misunderstanding-when students assume they understand the material because they got the right "answer"-it is important to probe their understanding in other ways. In this vein, the text includes many Critical Thinking questions throughout the text and a number of Active Learning Questions at the end of each chapter that are intended for group discussion. It is our experience that students often learn the most when they teach each other. Students are forced to recognize their own lack of understanding when they try and fail to explain a concept to another student.
> With a strong problem-solving orientation, this text talks to students about how to approach and solve chemical problems. We emphasize a thoughtful, logical approach rather than simply memorizing procedures. In particular, an innovative method is given for dealing with acid-base equilibria, the material the typical student finds most difficult and frustrating. The key to this approach involves first deciding what species are present in solution, then thinking about the chemical properties of these species. This method provides a general framework for approaching all types of solution equilibria.
> The text contains almost 300 Examples, with more given in the text discussions, to illustrate general problem-solving strategies. When a specific strategy is presented, it is summarized in a Problem-Solving Strategy box, and the Example that follows it reinforces the use of the strategy to solve the problem. In general, we emphasize the use of conceptual understanding to solve problems rather than an algorithmbased approach. This approach is strongly reinforced by the inclusion of many Interactive Examples, which encourage students to thoughtfully consider the example step-by-step.
) We have presented a thorough treatment of reactions that occur in solution, including acid-base reactions. This material appears in Chapter 4, "Types of Chemical Reactions and Solution Stoichiometry," directly after the chapter on chemical stoichiometry, to emphasize the connection between solution reactions and chemical reactions in general. The early presentation of this material provides an opportunity to cover some interesting descriptive chemistry and also supports the lab, which typically involves a great deal of aqueous chemistry. Chapter 4 also includes oxidationreduction reactions and balancing by oxidation state, because a large number of interesting and important chemical reactions involve redox processes. However, coverage of oxidation-reduction is optional at this point and depends on the needs of a specific course.
>Descriptive chemistry and chemical principles are thoroughly integrated in this text. Chemical models may appear sterile and confusing without the observations that stimulated their invention. On the other hand, facts without organizing principles may seem overwhelming. A combination of observation and models can make chemistry both interesting and understandable. In the chapter on the chemistry of the elements, we have used tables and charts to show how properties and models correlate. Descriptive chemistry is presented in a variety of ways-as applications of principles in separate sections, in photographs, in Examples and exercises, in paragraphs, and in Chemical Connections.
> Throughout the book a strong emphasis on models prevails. Coverage includes how they are constructed, how they are tested, and what we learn when they inevitably fail. Models are developed naturally, with pertinent observation always presented first to show why a particular model was invented.
>Chemical Connections boxes present applications of chemistry in various fields and in our daily lives. Margin notes in the Instructor's Annotated Edition also highlight many more Chemical Connections available on the student website.
>We offer end-of-chapter exercises for every type of student and for every kind of homework assignment: questions that promote group learning, exercises that reinforce student understanding, and problems that present the ultimate challenge with increased rigor and by integrating multiple concepts. We have added biochemistry problems to make the connection for students in the course who are not chemistry majors.
> Judging from the favorable comments of instructors and students who have used the ninth edition, the text seems to work very well in a variety of courses. We were especially pleased that readability was cited as a key strength when students were asked to assess the text.

## Supporting Materials

Please visit www.cengage.com /chemistry/zumdahl/chemistry10e for information about student and instructor resources for this text.

## Acknowledgments

This book represents the efforts of many talented and dedicated people. We particularly want to thank Dawn Giovanniello, Product Director, for her vision and oversight of the project, and Lisa Lockwood, Senior Product Manager, whose enthusiasm, powers of organization, and knowledge of the market have contributed immensely to the success of this revision. We also greatly appreciate the work of Teresa Trego, Senior Content Project Manager, who did an outstanding job of managing the production of this complex project.

We are especially grateful to Tom Hummel, University of Illinois, Urbana-Champaign, who managed the revision of the end-of-chapter problems and the solutions manuals. Tom's extensive experience teaching general chemistry and his high standards of accuracy and clarity have resulted in great improvements in the quality of the problems and solutions in this edition. Gretchen Adams supports us in so many ways it is impossible to list all of them. Gretchen constructed all of the online Interactive Examples, created the PowerPoint slides, and worked on many of the other media aspects of the program. We are very grateful to Gretchen for her creativity and incredible work ethic and for being such a wonderful colleague.

Special thanks to Sharon Donahue, who did her usual outstanding job finding just the right photos for this edition. Also we greatly appreciate the advice and support of Janet del Mundo, Senior Marketing Manager.

There are many other people who made important contributions to the success of this edition, including Cassie Carey at Graphic World; Sarah B. Cole, Art Director; Shawn Girsberger, Interior and Cover Designer; Lisa Weber, Senior Content Developer; and Brendan Killion, Content Developer. Special thanks to Margaret O'Neill, Product Assistant, who helped in many different ways.

We are especially thankful to all of the reviewers who participated in different aspects of the development process, from reviewing the illustrations and chapters to providing feedback on the development of new features. We sincerely appreciate all of these suggestions.

## To the Student

As you jump into the study of chemistry, we hope that you will find our text helpful and interesting. Our job is to present the concepts and ideas of chemistry in a way you can understand. We hope to encourage you in your studies and to help you learn to solve problems in ways you can apply in all areas of your professional and personal lives.

Our main goal is to help you learn to become a truly creative problem solver. Our world badly needs people who can "think outside the box." Our focus is to help you learn to think like a chemist. Why would you want to do that? Chemists are great problem solvers. They use logic, trial and error, and intuition-along with lots of patience-to work through complex problems. Chemists make mistakes, as we all do in our lives. The important thing that a chemist does is to learn from the mistakes and to try again. This "can do" attitude is useful in all careers.

In this book we develop the concepts in a natural way: The observations come first and then we develop models to explain the observed behavior. Models help us to understand and explain our world. They are central to scientific thinking. Models are very useful, but they also have limitations, which we will point out. By understanding the basic concepts in chemistry we lay the foundation for solving problems.

Our main goal is to help you learn a thoughtful method of problem solving. True learning is more than memorizing facts. Truly educated people use their factual knowledge as a starting point-a basis for creative problem solving. Our strategy for solving problems is explained first in Section 1.6 and is covered in more details in Section 3.5. To solve a problem we ask ourselves questions, which help us think through the problem. We let the problem guide us to the solution. This process can be applied to all types of problems in all areas of life.

As you study the text, use the Examples and the problemsolving strategies to help you. The strategies are boxed to highlight them for you, and the Examples show how these strategies are applied. It is especially important for you to
do the computer-based Interactive Examples that are found throughout the text. These examples encourage you to think through the examples step-by-step to help you thoroughly understand the concepts involved.

After you have read and studied each chapter of the text, you'll need to practice your problem-solving skills. To do this we have provided plenty of review questions and end-of-chapter exercises. Your instructor may assign these on paper or online; in either case, you'll want to work with your fellow students. One of the most effective ways to learn chemistry is through the exchange of ideas that comes from helping one another. The online homework assignments will give you instant feedback, and in print, we have provided answers to some of the exercises in the back of the text. In all cases, your main goal is not just to get the correct answer but to understand the process for getting the answer. Memorizing solutions for specific problems is not a very good way to prepare for an exam (or to solve problems in the real world!).

To become a great problem solver, you'll need these skills:

1. Look within the problem for the solution. (Let the problem guide you.)
2. Use the concepts you have learned along with a systematic, logical approach to find the solution.
3. Solve the problem by asking questions and learn to trust yourself to think it out.

You will make mistakes, but the important thing is to learn from these errors. The only way to gain confidence is to practice, practice, practice and to use your mistakes to find your weaknesses. Be patient with yourself and work hard to understand rather than simply memorize.

We hope you'll have an interesting and successful year learning to think like a chemist!

Steve and Susan Zumdahl<br>and Don DeCoste

## a gude to Chemistry, тenheanow

Conceptual Understanding Conceptual learning and problem solving are fundamental to the approach of Chemistry. The text gives students the tools to become critical thinkers: to ask questions, to apply rules and models, and to evaluate the outcome.

#### Abstract

"Before students are ready to figure out complex problems, they need to master simpler problems in various contortions. This approach works, and the authors' presentation of it should have the students buying in."

—Jerry Burns, Pellissippi State Technical Community College

The authors' emphasis on modeling (or chemical theories) throughout the text addresses the problem of rote memorization by helping students better understand and appreciate the process of scientific thinking. By stressing the limitations and uses of scientific models, the authors show students how chemists think and work.

E=Al|eAL TEINTKINC Consider the simple reaction
$\mathrm{aA} \rightarrow$ products. You run this reaction and wish to determine its order. What if you made a graph of reaction rate versus time? Could you use this to determine the order? Sketch three plots of rate versus time for the reaction if it is zero, first, or second order. Sketch these plots on the same graph and compare them. Defend your answer.

LET'S REVIEW Summary of the VSEPR Model
The rules for using the VSEPR model to predict molecular structure are as follows: n Determine the Lewis structure(s) for the molecule.
") For molecules with resonance structures, use any of the structures to predict the molecular structure.
" Sum the electron pairs around the central atom.
" In counting pairs, count each multiple bond as a single effective pair.
" The arrangement of the pairs is determined by minimizing electron-pair repulsions. These "The arrangement of the pairs is determ.
" Lone pairs require more space than bonding pairs do. Choose an arrangement that gives the lone pairs as much room as possible. Recognize that the lone pairs may produce a slight distortion of the structure at angles less than 120 degrees.

Let's Review boxes help students organize their thinking about the crucial chemical concepts that they encounter.

The text includes a number of open-ended Critical Thinking questions that emphasize the importance of conceptual learning. These questions are particularly useful for generating group discussion.

xiv

Problem Solving This text talks to the student about how to approach and solve chemical problems, since one of the main goals of general chemistry is to help students become creative problem solvers. The authors emphasize a thoughtful, logical approach rather than simply memorizing procedures.
> "The text gives a meaningful explanation and alternative to memorization. This approach and the explanation [to the student] of the approach will supply the 'secret' of successful problem solving abilities to all students."

-David Boyauian, Palomar College

```
PROBLEM-SOLVING STRATEGY
Determining Molecular Formula from Empirical Formula
" Obtain the empirical formula
" Compute the mass corresponding to the empirical formula.
" Calculate the ratio:
            Molar mass
```

    Molecular formula \(=\) empirical formula \(\times \quad\) molar mass
    Interactive Examples engage students in the problem-solving process by requiring them to think through the example step-by-step rather than simply scanning the written example in the text as many students do.
The integer from the previous step represents the number of empirical formula
units in one molecule. When the empirical formula subscripts are multiplied by
this integer, the molecular formula results. This procedure is summarized by the

The integer from the previous step represents the number of empirical formula
units in one molecule. When the empirical formula subscripts are multiplied by this integer, the molecular formula results. This procedure is summarized by the

In Chapter 3, "Stoichiometry," the authors introduce a new section, Learning to Solve Problems, which emphasizes the importance of problem solving. This new section helps students understand that thinking their way through a problem produces more long-term, meaningful learning than simply memorizing steps, which are soon forgotten.

Chapters 1-6 introduce a series of questions into the in-chapter Examples to engage students in the process of problem solving, such as Where are we going? and How do we get there? This more active approach helps students think their way through the solution to the problem.

Problem-Solving Strategy boxes focus students' attention on the very important process of problem solving.

| INTERACTIVE EXAMPLE 17.2 | Predicting Entropy Changes |
| :---: | :---: |

Predict the sign of the entropy change for each of the following processes. a. Solid sugar is added to water to form a solution.
b. Iodine vapor condenses on a cold surface to form crystals.

SOLUTION
a. The sugar molecules become randomly dispersed in the water when the solution forms and thus have access to a larger volume and a larger number of possible positions. The positional disorder is increased, and there will be an increase in
entropy. $\Delta S$ is positive, since the final state has a larger entropy than the initial state, and $\Delta S=S_{\text {final }}-S_{\text {initial }}$
Gaseous iodine is forming a solid. This process involves a change from a relaively large volume to a much smaller volume, which results in lower positional disorder. For this process $\Delta S$ is negative (the entropy decreases).

Dynamic Art Program Most of the glassware, orbitals, graphs, flowcharts, and molecules have been redrawn to better serve visual learners and enhance the textbook.

The art program emphasizes molecular-level interactions that help students visualize the "micro/macro" connection.

Real-World Applications Interesting applications of modern chemistry show students the relevance of chemistry to their world.

Each chapter begins with an engaging introduction that demonstrates how chemistry is related to everyday life.

Chemical Equilibrium

1
 ximem quantititively converted to products and that the amount of limiting reactant that
remains is negligible. On the other hand, there are many chemical reactions that stop main is negligitle. On the other hand, there are many chemical reactions th $\mathrm{NO}_{2}(g)+\mathrm{NO}_{2}(\mathrm{~g}) \longrightarrow \mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ The reactant, NO , is a dark brown gas, and the product, $\mathrm{N}, \mathrm{O}_{4}$, is a colorless gas. lor decreases in intensity as it is converted to colorersss $\mathrm{N}_{2} \mathrm{O}_{4}$. Howevere, even over
 the 1 Fie. 13.1. This obervion is hort of completion. In tact, the system has reached chemical equilibrium, the state Any chemical reactions carried out in a closed yessel will reach equilibrium. F Ame reactions the equilibrium position so favors the products that he reaction appear shave gone to completion. We say that the equilibrium position for such reactions lies
frro the right (in the direction of the products). For example, when gaseous hydroge Wht the igh (in the direction of the products). For example, when gaseous hydroger teaction proceeds essentially to completion. The amounts of the reactants stat remain
when the system reaches equilibrium are so tiny as to be nefligible. By contrats. som reactions occur only to a slight extent. For example, when solid CaO is placed in dosed vessel at $22^{\circ}$, , the decomposition to solid Ca and gaseous $\mathrm{O}_{\text {i }}$ is virtualy unde
rection of the reactanss).
In hisis chaperer we will discuss how and why a chemical system comes to equilibrium nd the characteristics of equilibrium. In particular, we will discuss how to calculate die
Concentrations of the reactants and products p pesesen for a given system at equilibrium.

The Equilibrium Condition
Since no changes occur in the concentrations of reactants of products in a reaction ystem at equilibrium, it may appear that everything has stopped. However, this is not
he case. On the molecular level, here is frantic activity. Equilibrium is no static but a highly dynamic situation. The concept of chemical equilibrium is anallogous to the
ow of cars across a bridge connecting two island cities. Suppose the traffic flow or

[^0]

Comprehensive End-of-Chapter Practice and Review We offer end-of-chapter exercises for every type of student and for every kind of homework assignment.

Active Learning Questions are designed to promote discussion among groups of students in class.

Each chapter has a For Review section to reinforce key concepts and includes review questions for students to practice independently.

Review Questions
What is meant by the presesce of a common ion? How

Challenge Problems take students one step further and challenge them more rigorously than the Additional Exercises.

The unknown acid $\mathrm{H}_{2} \mathrm{X}$ can be neutralized completely by $\mathrm{OH}^{-}$according to the following (unbalanced) equation
$\mathrm{H}_{2} \mathrm{X}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{X}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(\eta$ The ion formed as a product, $\mathrm{X}^{2-}$, was shown to have 36 total electrons. What is element X ? Propose a name for $\mathrm{H}_{2} \mathrm{X}$. To completely neutralize a sample of $\mathrm{H}_{2} \mathrm{X}, 35.6 \mathrm{~mL}$ of 0.175 M $\mathrm{OH}^{-}$solution was required. What was the mass of the $\mathrm{H}_{2} \mathrm{X}$ sample used?

Marathon Problem

160. Three students were asked to find the identity of the metal in particular sulfate salt. They dissolved a $0.1472-\mathrm{g}$ sample of the salt in water and treated it with excess barium chloride, resulting in the precipitation of barium sulfate. After the precipitate had been filtered and dried, it weighed 0.2327 g .
Each student analyzed the data independently and came to Chris thought it was sodium. Randy reported that it was ga lium. What formula did each student assign to the sulfate salt?

Look for information on the sulfates of galium, sodium, nd titanium in this text and reference books such as the $C R C$ Handbook of Chemistry and Physics. What further tests would you suggest to determine which student is most likel correct?
161. You have two $500.0-\mathrm{mL}$ aqueous solutions. Solution A is solution of a metal nitrate that is $8.246 \%$ nitrogen by is The ionic compound in solution B consist of potsium, chromium, and oxygen; chromium has an oxidation state of +6 and there are 2 potassiums and 1 chromium in the formula. The masses of the solutes in each of the solutions are the same. When the solutions are added together, a blood-red precipital forms. After the reaction has gone to completion, you dry th solid and find that it has a mass of 331.8 g
a. Identify the ionic compounds in solution and solution B.
b. Identify the blood-red precipitate
c. Calculate the concentration (molarity) of all ions in the
original solutions.
d. Calculate the concentration (molarity) of all ions in the

Marathon Problems also combine concepts from multiple chapters; they are the most challenging problems in the end-ofchapter material.
"The end-of-chapter content helps students identify and review the central concepts. There is an impressive range of problems that are well graded by difficulty."

## About the Authors

Steven S. Zumdahl earned a B.S. in Chemistry from Wheaton College (IL) and a Ph.D. from the University of Illinois, Urbana-Champaign. He has been a faculty member at the University of Colorado-Boulder, Parkland College (IL), and the University of Illinois at Urbana-Champaign (UIUC), where he is Professor Emeritus. He has received numerous awards, including the National Catalyst Award for Excellence in Chemical Education, the University of Illinois Teaching Award, the UIUC Liberal Arts and Sciences Award for Excellence in Teaching, UIUC Liberal Arts and Sciences Advising Award, and the School of Chemical Sciences Teaching award (five times). He is the author of several chemistry textbooks. In his leisure time he enjoys traveling and collecting classic cars.

Susan A. Zumdahl earned a B.S. and M.A. in Chemistry at California State University-Fullerton. She has taught science and mathematics at all levels, including middle school, high school, community college, and university. At the University of Illinois at Urbana-Champaign, she developed a program for increasing the retention of minorities and women in science and engineering. This program focused on using active learning and peer teaching to encourage students to excel in the sciences. She has coordinated and led workshops and programs for science teachers from elementary through college levels. These programs encourage and support active learning and creative techniques for teaching science. For several years she was director of an Institute for Chemical Education (ICE) field center in Southern California, and she has authored several chemistry textbooks. Susan spearheaded the development of a sophisticated web-based electronic homework system for teaching chemistry. She enjoys traveling, classic cars, and gardening in her spare time-when she is not playing with her grandchildren.

Donald J. DeCoste is Associate Director of General Chemistry at the University of Illinois, Urbana-Champaign, and has been teaching chemistry at the high school and college levels for over 25 years. He earned a B.S. in Chemistry and a Ph.D. from the University of Illinois, Urbana-Champaign. At Illinois he teaches courses in introductory chemistry and the teaching of chemistry and has developed chemistry courses for non-science majors, preservice secondary teachers, and preservice elementary/middle school teachers. He has received the LAS Award for Excellence in Undergraduate Teaching by Instructional Staff Award, the Provost's Excellence in Undergraduate Teaching Award, and the School of Chemical Sciences Teaching Award (four times). Don has led workshops for secondary teachers and graduate student teaching assistants, discussing the methods and benefits of getting students more actively involved in class. When not involved in teaching and advising, Don enjoys spending time with his wife and three children.

When you start your car, do you think about chemistry? Probably not, but you should. The power to start your car is furnished by a lead storage battery. How does this battery work, and what does it contain? When a battery goes dead, what does that mean? If you use a friend's car to "jump-start" your car, did you know that your battery could explode? How can you avoid such an unpleasant possibility? What is in the gasoline that you put in your tank, and how does it furnish energy to your car so that you can drive it to school? What is the vapor that comes out of the exhaust pipe, and why does it cause air pollution? Your car's air conditioner might have a substance in it that is leading to the destruction of the ozone layer in the upper atmosphere. What are we doing about that? And why is the ozone layer important anyway?

All of these questions can be answered by understanding some chemistry. In fact, we'll consider the answers to all of these questions in this text.

Chemistry is around you all the time. You are able to read and understand this sentence because chemical reactions are occurring in your brain. The food you ate for breakfast or lunch is now furnishing energy through chemical reactions. Trees and grass grow because of chemical changes.

Chemistry also crops up in some unexpected places. When archaeologist Luis Alvarez was studying in college, he probably didn't realize that the chemical elements iridium and niobium would make him very famous when they helped him solve the problem of the disappearing dinosaurs. For decades scientists had wrestled with the mystery of why the dinosaurs, after ruling the earth for millions of years, suddenly became extinct 65 million years ago. In studying core samples of rocks dating back to that period, Alvarez and his coworkers recognized unusual levels of iridium and niobium in these samples-levels much more characteristic of extraterrestrial bodies than of the earth. Based on these observations, Alvarez hypothesized that a large meteor hit the earth 65 million years ago, changing atmospheric conditions so much that the dinosaurs' food couldn't grow, and they died-almost instantly in the geologic time frame.

Chemistry is also important to historians. Did you realize that lead poisoning probably was a significant contributing factor to the decline of the Roman Empire? The Romans had high exposure to lead from lead-glazed pottery, lead water pipes, and a sweetening syrup called sapa that was prepared by boiling down grape juice in leadlined vessels. It turns out that one reason for sapa's sweetness was lead acetate ("sugar of lead"), which formed as the juice was cooked down. Lead poisoning, with its symptoms of lethargy and mental malfunctions, certainly could have contributed to the demise of the Roman society.

Chemistry is also apparently very important in determining a person's behavior. Various studies have shown that many personality disorders can be linked directly to imbalances of trace elements in the body. For example, studies on the inmates at Stateville Prison in Illinois have linked low cobalt levels with violent behavior. Lithium salts have been shown to be very effective in controlling the effects of manic-depressive disease, and you've probably at some time in your life felt a special "chemistry" for another person. Studies suggest there is literally chemistry going on between two people who are attracted to each other. "Falling in love" apparently causes changes in the chemistry of the brain; chemicals are produced that give that "high" associated with a new relationship. Unfortunately, these chemical effects seem to wear off over time, even if the relationship persists and grows.

The importance of chemistry in the interactions of people should not really surprise us. We know that insects communicate by emitting and receiving chemical signals via molecules called pheromones. For example, ants have a very complicated set of chemical signals to signify food sources, danger, and so forth. Also, various female sex
attractants have been isolated and used to lure males into traps to control insect populations. It would not be surprising if humans also emitted chemical signals that we were not aware of on a conscious level. Thus chemistry is pretty interesting and pretty important. The main goal of this text is to help you understand the concepts of chemistry so that you can better appreciate the world around you and can be more effective in whatever career you choose.

### 1.1 Chemistry: An Overview

Since the time of the ancient Greeks, people have wondered about the answer to the question: What is matter made of? For a long time, humans have believed that matter is composed of atoms, and in the previous three centuries, we have collected much indirect evidence to support this belief. Very recently, something exciting has happened-for the first time we can "see" individual atoms. Of course, we cannot see atoms with the naked eye; we must use a special microscope called a scanning tunneling microscope (STM). Although we will not consider the details of its operation here, the STM uses an electron current from a tiny needle to probe the surface of a substance. The STM pictures of several substances are shown in Fig. 1.1. Notice how the atoms are connected to one another by "bridges," which, as we will see, represent the electrons that interconnect atoms.

So, at this point, we are fairly sure that matter consists of individual atoms. The nature of these atoms is quite complex, and the components of atoms don't behave much like the objects we see in the world of our experience. We call this world the macroscopic world-the world of cars, tables, baseballs, rocks, oceans, and so forth. One of the main jobs of a scientist is to delve into the macroscopic world and discover its "parts." For example, when you view a beach from a distance, it looks like a continuous solid substance. As you get closer, you see that the beach is really made up of individual grains of sand. As we examine these grains of sand, we find that they are composed of silicon and oxygen atoms connected to each other to form intricate shapes (Fig. 1.2). One of the main challenges of chemistry is to understand the connection between the macroscopic world that we experience and the microscopic world of atoms and molecules. To truly understand chemistry, you must learn to think on the atomic level. We will spend much time in this text helping you learn to do that.

FIGURE 1.2 Sand on a beach looks uniform from a distance, but up close the irregular sand grains are visible, and each grain is composed of tiny atoms.

 us to "see" atoms. What if you were sent back in time before the invention of the scanning tunneling microscope? What evidence could you give to support the theory that all matter is made of atoms and molecules?

One of the amazing things about our universe is that the tremendous variety of substances we find there results from only about 100 different kinds of atoms. You can think of these approximately 100 atoms as the letters in an alphabet from which all the "words" in the universe are made. It is the way the atoms are organized in a given substance that determines the properties of that substance. For example, water, one of the most common and important substances on the earth, is composed of two types of atoms: hydrogen and oxygen. Two hydrogen atoms and one oxygen atom are bound together to form the water molecule:

water molecule
hydrogen atom
When an electric current passes through it, water is decomposed to hydrogen and oxygen. These chemical elements themselves exist naturally as diatomic (two-atom) molecules:

We can represent the decomposition of water to its component elements, hydrogen and oxygen, as follows:

Notice that it takes two molecules of water to furnish the right number of oxygen and hydrogen atoms to allow for the formation of the two-atom molecules. This reaction explains why the battery in your car can explode if you jump-start it improperly. When you hook up the jumper cables, current flows through the dead battery, which contains water (and other things), and causes hydrogen and oxygen to form by decomposition of some of the water. A spark can cause this accumulated hydrogen and oxygen to explode, forming water again.

This example illustrates two of the fundamental concepts of chemistry: (1) Matter is composed of various types of atoms, and (2) one substance changes to another by reorganizing the way the atoms are attached to each other.

These are core ideas of chemistry, and we will have much more to say about them.

## Science: A Process for Understanding Nature and lts Changes

How do you tackle the problems that confront you in real life? Think about your trip to school. If you live in a city, traffic is undoubtedly a problem you confront daily. How do you decide the best way to drive to school? If you are new in town, you first get a map and look at the possible ways to make the trip. Then you might collect information about the advantages and disadvantages of various routes from people who know the area. Based on this information, you probably try to predict the best route. However, you can find the best route only by trying several of them and comparing the results. After a few experiments with the various possibilities, you probably will be able to select the best way. What you are doing in solving this everyday problem is applying the same process that scientists use to study nature. The first thing you did was collect relevant data. Then you made a prediction, and then you tested it by trying it out. This process contains the fundamental elements of science:

1. Making observations (collecting data)
2. Suggesting a possible explanation (formulating a hypothesis)
3. Doing experiments to test the possible explanation (testing the hypothesis)

Scientists call this process the scientific method. We will discuss it in more detail in the next section. One of life's most important activities is solving problems-not "plug and chug" exercises, but real problems-problems that have new facets to them, that involve things you may have never confronted before. The more creative you are at solving these problems, the more effective you will be in your career and your personal life. Part of the reason for learning chemistry, therefore, is to become a better problem solver. Chemists are usually excellent problem solvers because to master chemistry, you have to master the scientific approach. Chemical problems are frequently very complicated-there is usually no neat and tidy solution. Often it is difficult to know where to begin.

### 1.2 The Scientific Method

Science is a framework for gaining and organizing knowledge. Science is not simply a set of facts but also a plan of action-a procedure for processing and understanding certain types of information. Scientific thinking is useful in all aspects of life, but in this text we will use it to understand how the chemical world operates. As we said in

FIGURE 1.3 The fundamental steps of the scientific method.

FIGURE 1.4 The various parts of the scientific method.
our previous discussion, the process that lies at the center of scientific inquiry is called the scientific method. There are actually many scientific methods, depending on the nature of the specific problem under study and the particular investigator involved. However, it is useful to consider the following general framework for a generic scientific method (Fig. 1.3):

## Steps in the Scientific Method

1. Making observations. Observations may be qualitative (the sky is blue; water is a liquid) or quantitative (water boils at $100^{\circ} \mathrm{C}$; a certain chemistry book weighs 2 kg ). A qualitative observation does not involve a number. A quantitative observation (called a measurement) involves both a number and a unit.
2. Formulating hypotheses. A hypothesis is a possible explanation for an observation.
3. Performing experiments. An experiment is carried out to test a hypothesis. This involves gathering new information that enables a scientist to decide whether the hypothesis is valid-that is, whether it is supported by the new information learned from the experiment. Experiments always produce new observations, and this brings the process back to the beginning again.

To understand a given phenomenon, these steps are repeated many times, gradually accumulating the knowledge necessary to provide a possible explanation of the phenomenon.

## Scientific Models

Once a set of hypotheses that agrees with the various observations is obtained, the hypotheses are assembled into a theory. A theory, which is often called a model, is a set of tested hypotheses that gives an overall explanation of some natural phenomenon.

It is very important to distinguish between observations and theories. An observation is something that is witnessed and can be recorded. A theory is an interpretationa possible explanation of why nature behaves in a particular way. Theories inevitably change as more information becomes available. For example, the motions of the sun and stars have remained virtually the same over the thousands of years during which humans have been observing them, but our explanations-our theories-for these motions have changed greatly since ancient times.

The point is that scientists do not stop asking questions just because a given theory seems to account satisfactorily for some aspect of natural behavior. They continue doing experiments to refine or replace the existing theories. This is generally done by using the currently accepted theory to make a prediction and then performing an experiment (making a new observation) to see whether the results bear out this prediction.

Always remember that theories (models) are human inventions. They represent attempts to explain observed natural behavior in terms of human experiences. A theory is actually an educated guess. We must continue to do experiments and to refine our theories (making them consistent with new knowledge) if we hope to approach a more complete understanding of nature.

As scientists observe nature, they often see that the same observation applies to many different systems. For example, studies of innumerable chemical changes have shown that the total observed mass of the materials involved is the same before and after the change. Such generally observed behavior is formulated into a statement called a natural law. For example, the observation that the total mass of materials is not affected by a chemical change in those materials is called the law of conservation of mass.

Note the difference between a natural law and a theory. A natural law is a summary of observed (measurable) behavior, whereas a theory is an explanation of behavior. A law summarizes what happens; a theory (model) is an attempt to explain why it happens.

## CHEMICAL CONNECTIDNS

## A Note-able Achievement

P
ost-it Notes, a product of the 3 M
Corporation, revolutionized casual written communications and personal reminders. Introduced in the United States in 1980, these sticky-but-not-toosticky notes have now found countless uses in offices, cars, and homes throughout the world.

The invention of sticky notes occurred over a period of about 10 years and involved a great deal of serendipity. The adhesive for Post-it Notes was discovered by Dr. Spencer F. Silver of 3M in 1968. Silver found that when an acrylate polymer material was made in a particular way, it formed cross-linked microspheres. When suspended in a solvent and sprayed on a sheet of paper, this substance formed a "sparse monolayer" of adhesive after the solvent evaporated. Scanning electron microscope images of the adhesive show that it has an irregular surface, a little like the surface of a gravel road. In contrast, the adhesive on cellophane tape looks smooth and uniform, like a superhighway. The bumpy surface of Silver's adhesive caused it to be sticky but not so sticky to produce permanent adhesion, because the number of contact points between the binding surfaces was limited.

When he invented this adhesive, Silver had no specific ideas for its use, so
he spread the word of his discovery to his fellow employees at 3 M to see if anyone had an application for it. In addition, over the next several years development was carried out to improve the adhesive's properties. It was not until 1974 that the idea for Post-it Notes popped up. One Sunday, Art Fry, a chemical engineer for 3 M , was singing in his church choir when he became annoyed that the bookmark in his hymnal kept falling out. He thought to himself that it would be nice if the bookmark were sticky enough to stay in place but not so sticky that it couldn't be moved. Luckily, he remembered Silver's glue-and the Post-it Note was born.

For the next three years, Fry worked to overcome the manufacturing obstacles associated with the product. By 1977 enough Post-it Notes were being produced to supply 3 M 's corporate headquarters, where the employees quickly became addicted to their many uses. Post-it Notes are now available in 62 colors and 25 shapes.

In the years since the introduction of Post-it Notes, 3M has heard some remarkable stories connected to the use of these notes. For example, a Post-it Note was applied to the nose of a

corporate jet, where it was intended to be read by the plane's Las Vegas ground crew. Someone forgot to remove it, however. The note was still on the nose of the plane when it landed in Minneapolis, having survived a takeoff, a landing, and speeds of 500 miles per hour at temperatures as low as $-56^{\circ}$. Stories on the 3 M website describe how a Post-it Note on the front door of a home survived the 140-mile-per-hour winds of Hurricane Hugo and how a foreign official accepted Post-it Notes in lieu of cash when a small bribe was needed to cut through bureaucratic hassles.

Post-it Notes have definitely changed the way we communicate and remember things.

In this section we have described the scientific method as it might ideally be applied (Fig. 1.4). However, it is important to remember that science does not always progress smoothly and efficiently. For one thing, hypotheses and observations are not totally independent of each other, as we have assumed in the description of the idealized scientific method. The coupling of observations and hypotheses occurs because once we begin to proceed down a given theoretical path, our hypotheses are unavoidably couched in the language of that theory. In other words, we tend to see what we expect to see and often fail to notice things that we do not expect. Thus the theory we are testing helps us because it focuses our questions. However, at the same time, this focusing process may limit our ability to see other possible explanations.

It is also important to keep in mind that scientists are human. They have prejudices; they misinterpret data; they become emotionally attached to their theories and thus lose objectivity; and they play politics. Science is affected by profit motives, budgets, fads, wars, and religious beliefs. Galileo, for example, was forced to recant his astronomical

observations in the face of strong religious resistance. Lavoisier, the father of modern chemistry, was beheaded because of his political affiliations. Great progress in the chemistry of nitrogen fertilizers resulted from the desire to produce explosives to fight wars. The try of nitrogen fertilizers resulted from the desire to produce explosives to fight wars. The
progress of science is often affected more by the frailties of humans and their institutions than by the limitations of scientific measuring devices. The scientific methods are only as effective as the humans using them. They do not automatically lead to progress.

#### Abstract

Robert Boyle (1627-1691) was born in Ireland. He became especially interested in experiments involving air and developed an air pump with which he produced evacuated cylinders. He used involving air and developed an air pump with which he produced evacuated cylinders. He used these cylinders to show that a feather and a lump of lead fall at the same rate in the absence of air resistance and that sound cannot be produced in a vacuum. His most famous experiments involved careful measurements of the volume of a gas as a function of pressure. In his book Boyle urged that the ancient view of elements as mystical substances should be abandoned and that an element should instead be defined as anything that cannot be broken down into simpler substances. This concept was an important step in the development of modern chemistry.

 the scientific method to analyze and solve society's problems, and politics were never involved in the solutions? How would this be different from the present situation, and would it be better or worse?

### 1.3 Units of Measurement

Making observations is fundamental to all science. A quantitative observation, or measurement, always consists of two parts: a number and a scale (called a unit). Both parts must be present for the measurement to be meaningful.

In this textbook we will use measurements of mass, length, time, temperature, electric current, and the amount of a substance, among others. Scientists recognized long ago that standard systems of units had to be adopted if measurements were to be useful. If every scientist had a different set of units, complete chaos would result. Unfortunately, different standards were adopted in different parts of the world. The two major systems are the English system used in the United States and the metric system used by most of the rest of the industrialized world. This duality causes a good deal of trouble; for example, parts as simple as bolts are not interchangeable between machines built using the two systems. As a result, the United States has begun to adopt the metric system.

Most scientists in all countries have used the metric system for many years. In 1960, an international agreement set up a system of units called the International System (le Système International in French), or the SI system. This system is based on the metric system and units derived from the metric system. The fundamental SI units are listed in Table 1.1. We will discuss how to manipulate these units later in this chapter.

TABLE 1.1 | Fundamental SI Units

| Physical Quantity | Name of Unit | Abbreviation |
| :--- | :--- | :--- |
| Mass | kilogram | kg |
| Length | meter | m |
| Time | second | s |
| Temperature | kelvin | K |
| Electric current | ampere | A |
| Amount of substance | mole | mol |
| Luminous intensity | candela | cd |

TABLE 1.2 \| Prefixes Used in the SI System (The most commonly encountered are shown in blue.)

| Prefix | Symbol | Meaning | Exponential <br> Notation* |
| :--- | :---: | ---: | :--- |
| exa | E | $1,000,000,000,000,000,000$ | $10^{18}$ |
| peta | P | $1,000,000,000,000,000$ | $10^{15}$ |
| tera | T | $1,000,000,000,000$ | $10^{12}$ |
| giga | G | $1,000,000,000$ | $10^{9}$ |
| mega | M | $1,000,000$ | $10^{6}$ |
| kilo | k | 1,000 | $10^{3}$ |
| hecto | h | 100 | $10^{2}$ |
| deka | da | 10 | $10^{1}$ |

| atto | a | 0.000000000000000001 | $10^{-18}$ |
|  |  |  |  |

*See Appendix 1.1 if you need a review of exponential notation.

TABLE 1.3 | Some Examples of Commonly Used Units

| Length | A dime is 1 mm thick. <br> A quarter is 2.5 cm in <br> diameter. <br> The average height of an <br> adult man is 1.8 m. |
| :--- | :--- |
| Mass | A nickel has a mass of <br> about 5 g. |
|  | A 120-lb person has a <br> mass of about 55 kg. |
| Volume | A 12-oz can of soda has a <br> volume of about 360 mL. |

Because the fundamental units are not always convenient (expressing the mass of a pin in kilograms is awkward), prefixes are used to change the size of the unit. These are listed in Table 1.2. Some common objects and their measurements in SI units are listed in Table 1.3.

One physical quantity that is very important in chemistry is volume, which is not a fundamental SI unit but is derived from length. A cube that measures 1 meter ( m ) on each edge is represented in Fig. 1.5. This cube has a volume of $(1 \mathrm{~m})^{3}=1 \mathrm{~m}^{3}$.

Recognizing that there are 10 decimeters (dm) in a meter, the volume of this cube is $(1 \mathrm{~m})^{3}=(10 \mathrm{dm})^{3}=1000 \mathrm{dm}^{3}$. A cubic decimeter, that is, $(1 \mathrm{dm})^{3}$, is commonly called a liter $(L)$, which is a unit of volume slightly larger than a quart. As shown in Fig. 1.5, 1000 L is contained in a cube with a volume of 1 cubic meter. Similarly, since 1 decimeter equals 10 centimeters ( cm ), the liter can be divided into 1000 cubes, each with a volume of 1 cubic centimeter:

$$
1 \mathrm{~L}=(1 \mathrm{dm})^{3}=(10 \mathrm{~cm})^{3}=1000 \mathrm{~cm}^{3}
$$

Also, since $1 \mathrm{~cm}^{3}=1$ milliliter ( mL ),

$$
1 \mathrm{~L}=1000 \mathrm{~cm}^{3}=1000 \mathrm{~mL}
$$

Thus 1 liter contains 1000 cubic centimeters, or 1000 milliliters.
Chemical laboratory work frequently requires measurement of the volumes of liquids. Several devices for the accurate determination of liquid volume are shown in Fig. 1.6.

An important point concerning measurements is the relationship between mass and weight. Although these terms are sometimes used interchangeably, they are not the same. Mass is a measure of the resistance of an object to a change in its state of motion. Mass is measured by the force necessary to give an object a certain acceleration. On the

## CHEMICAL CDNNECTIDNS

## Critical Units!

How important are conversions from one unit to another? If you ask the National Aeronautics and Space Administration (NASA), very important! In 1999, NASA lost a $\$ 125$ million Mars Climate Orbiter because of a failure to convert from English to metric units.

The problem arose because two teams working on the Mars mission were using different sets of units. NASA's scientists at the Jet Propulsion Laboratory in Pasadena, California, assumed that the thrust data for the rockets on the Orbiter they received from Lockheed Martin Astronautics in Denver, which built the spacecraft, were in metric units. In reality, the units were English. As a result, the Orbiter dipped 100 km lower into the Mars atmosphere than planned, and the friction from the atmosphere caused the craft to burn up.

NASA's mistake refueled the controversy over whether Congress should require the United States to switch to the metric system. About $95 \%$ of the world now uses the metric system, and the United States is slowly switching

Artist's conception of the lost Mars Climate Orbiter.
from English to metric. For example, the automobile industry has adopted metric fasteners, and we buy our soda in 2-L bottles.

Units can be very important. In fact, they can mean the difference between life and death on some occasions. In

1983, for example, a Canadian jetliner almost ran out of fuel when someone pumped $22,300 \mathrm{lb}$ of fuel into the aircraft instead of $22,300 \mathrm{~kg}$. Remember to watch your units!

FIGURE 1.6 Common types of laboratory equipment used to measure liquid volume.

FIGURE 1.7 Measurement of volume using a buret. The volume is read at the bottom of the liquid curve (called the meniscus).

earth we use the force that gravity exerts on an object to measure its mass. We call this force the object's weight. Since weight is the response of mass to gravity, it varies with the strength of the gravitational field. Therefore, your body mass is the same on the earth and on the moon, but your weight would be much less on the moon than on the earth because of the moon's smaller gravitational field.

Because weighing something on a chemical balance involves comparing the mass of that object to a standard mass, the terms weight and mass are sometimes used interchangeably, although this is incorrect.
 for one day? How would this affect your life for that day?

### 1.4 Uncertainty in Measurement

The number associated with a measurement is obtained using some measuring device. For example, consider the measurement of the volume of a liquid using a buret (shown in Fig. 1.7 with the scale greatly magnified). Notice that the meniscus of the liquid occurs at about 20.15 mL . This means that about 20.15 mL of liquid has been delivered from the buret (if the initial position of the liquid meniscus was 0.00 mL ). Note that we must estimate the last number of the volume reading by interpolating between the $0.1-\mathrm{mL}$ marks. Since the last number is estimated, its value may be different if another person makes the same measurement. If five different people read the same volume, the results might be as follows:

| Person | Results of Measurement |
| :---: | :---: |
| 1 | 20.15 mL |
| 2 | 20.14 mL |
| 3 | 20.16 mL |
| 4 | 20.17 mL |
| 5 | 20.16 mL |

A measurement always has some degree of uncertainty.

Uncertainty in measurement is discussed in more detail in Appendix 1.5.

These results show that the first three numbers (20.1) remain the same regardless of who makes the measurement; these are called certain digits. However, the digit to the right of the 1 must be estimated and therefore varies; it is called an uncertain digit. We customarily report a measurement by recording all the certain digits plus the first uncertain digit. In our example it would not make any sense to try to record the volume to thousandths of a milliliter because the value for hundredths of a milliliter must be estimated when using the buret.

It is very important to realize that a measurement always has some degree of uncertainty. The uncertainty of a measurement depends on the precision of the measuring device. For example, using a bathroom scale, you might estimate the mass of a grapefruit to be approximately 1.5 lb . Weighing the same grapefruit on a highly precise balance might produce a result of 1.476 lb . In the first case, the uncertainty occurs in the tenths of a pound place; in the second case, the uncertainty occurs in the thousandths of a pound place. Suppose we weigh two similar grapefruits on the two devices and obtain the following results:

|  | Bathroom Scale | Balance |
| :---: | :---: | :---: |
| Grapefruit 1 | 1.5 lb | 1.476 lb |
| Grapefruit 2 | 1.5 lb | 1.518 lb |

Do the two grapefruits have the same mass? The answer depends on which set of results you consider. Thus a conclusion based on a series of measurements depends on the certainty of those measurements. For this reason, it is important to indicate the uncertainty in any measurement. This is done by always recording the certain digits and the first uncertain digit (the estimated number). These numbers are called the significant figures of a measurement.

The convention of significant figures automatically indicates something about the uncertainty in a measurement. The uncertainty in the last number (the estimated number) is usually assumed to be $\pm 1$ unless otherwise indicated. For example, the measurement 1.86 kg can be taken to mean $1.86 \pm 0.01 \mathrm{~kg}$.

## EXAMPLE 1.1 Uncertainty in Measurement

In analyzing a sample of polluted water, a chemist measured out a $25.00-\mathrm{mL}$ water sample with a pipet (see Fig. 1.6). At another point in the analysis, the chemist used a graduated cylinder (see Fig. 1.6) to measure 25 mL of a solution. What is the difference between the measurements 25.00 mL and 25 mL ?

## SOLUTION

Even though the two volume measurements appear to be equal, they really convey different information. The quantity 25 mL means that the volume is between 24 mL and 26 mL , whereas the quantity 25.00 mL means that the volume is between 24.99 mL and 25.01 mL . The pipet measures volume with much greater precision than does the graduated cylinder.

When making a measurement, it is important to record the results to the appropriate number of significant figures. For example, if a certain buret can be read to $\pm 0.01 \mathrm{~mL}$, you should record a reading of twenty-five milliliters as 25.00 mL , not 25 mL . This way at some later time when you are using your results to do calculations, the uncertainty in the measurement will be known to you.

## Precision and Accuracy

Two terms often used to describe the reliability of measurements are precision and accuracy. Although these words are frequently used interchangeably in everyday life, they have different meanings in the scientific context. Accuracy refers to the agreement of a particular value with the true value. Precision refers to the degree of agreement among several measurements of the same quantity. Precision reflects the reproducibility of a given type of measurement. The difference between these terms is illustrated by the results of three different dart throws shown in Fig. 1.8.

Two different types of errors are illustrated in Fig. 1.8. A random error (also called an indeterminate error) means that a measurement has an equal probability of being high or low. This type of error occurs in estimating the value of the last digit of a measurement. The second type of error is called systematic error (or determinate error). This type of error occurs in the same direction each time; it is either always high or always low. Fig. 1.8(a) indicates large random errors (poor technique). Fig. 1.8(b) indicates small random errors but a large systematic error, and Fig. 1.8(c) indicates small random errors and no systematic error.

In quantitative work, precision is often used as an indication of accuracy; we assume that the average of a series of precise measurements (which should "average out" the random errors because of their equal probability of being high or low) is accurate, or close to the "true" value. However, this assumption is valid only if systematic errors are absent. Suppose we weigh a piece of brass five times on a very precise balance and obtain the following results:

| Weighing | Result |
| :---: | :---: |
| 1 | 2.486 g |
| 2 | 2.487 g |
| 3 | 2.485 g |
| 4 | 2.484 g |
| 5 | 2.488 g |

Normally, we would assume that the true mass of the piece of brass is very close to 2.486 g , which is the average of the five results:

$$
\frac{2.486 \mathrm{~g}+2.487 \mathrm{~g}+2.485 \mathrm{~g}+2.484 \mathrm{~g}+2.488 \mathrm{~g}}{5}=2.486 \mathrm{~g}
$$

However, if the balance has a defect causing it to give a result that is consistently 1.000 g too high (a systematic error of +1.000 g ), then the measured value of 2.486 g would be seriously in error. The point here is that high precision among several measurements is an indication of accuracy only if systematic errors are absent.

FIGURE 1.8 The results of several dart throws show the difference between precise and accurate.

## EXAMPLE 1.2 Precision and Accuracy

To check the accuracy of a graduated cylinder, a student filled the cylinder to the $25-\mathrm{mL}$ mark using water delivered from a buret (see Fig. 1.6) and then read the volume delivered. Following are the results of five trials:

| Trial | Volume Shown by <br> Graduated Cylinder | Volume Shown <br> by the Buret |
| :---: | :---: | :---: |
| 1 | 25 mL | 26.54 mL |
| 2 | 25 mL | 26.51 mL |
| 3 | 25 mL | 26.60 mL |
| 4 | 25 mL | 26.49 mL |
| 5 | 25 mL | 26.57 mL |
| Average | 25 mL | 26.54 mL |

Is the graduated cylinder accurate?

SOLUTION
Precision is an indication of accuracy only if there are no systematic errors.

The results of the trials show very good precision (for a graduated cylinder). The student has good technique. However, note that the average value measured using the buret is significantly different from 25 mL . Thus this graduated cylinder is not very accurate. It produces a systematic error (in this case, the indicated result is low for each measurement).

See Question 1.11

### 1.5 Significant Figures and Calculations

Calculating the final result for an experiment usually involves adding, subtracting, multiplying, or dividing the results of various types of measurements. Since it is very important that the uncertainty in the final result is known correctly, we have developed rules for counting the significant figures in each number and for determining the correct number of significant figures in the final result.

## Rules for Counting Significant Figures

1. Nonzero integers. Nonzero integers always count as significant figures.
2. Zeros. There are three classes of zeros:
a. Leading zeros are zeros that precede all the nonzero digits. These do not count as significant figures. In the number 0.0025 , the three zeros simply indicate the position of the decimal point. This number has only two significant figures.
b. Captive zeros are zeros between nonzero digits. These always count as significant figures. The number 1.008 has four significant figures.
c. Trailing zeros are zeros at the right end of the number. They are significant only if the number contains a decimal point. The number 100 has only one significant figure, whereas the number $1.00 \times 10^{2}$ has three significant figures. The number one hundred written as 100 . also has three significant figures.

Exact numbers never limit the number of significant figures in a calculation.

Exponential notation is reviewed in Appendix 1.1.
3. Exact numbers. Many times calculations involve numbers that were not obtained using measuring devices but were determined by counting: 10 experiments, 3 apples, 8 molecules. Such numbers are called exact numbers. They can be assumed to have an infinite number of significant figures. Other examples of exact numbers are the 2 in $2 \pi r$ (the circumference of a circle) and the 4 and the 3 in $\frac{4}{3} \pi r^{3}$ (the volume of a sphere). Exact numbers also can arise from definitions. For example, 1 inch is defined as exactly 2.54 centimeters. Thus, in the statement $1 \mathrm{in}=2.54 \mathrm{~cm}$, neither the 2.54 nor the 1 limits the number of significant figures when used in a calculation.

Note that the number $1.00 \times 10^{2}$ on the previous page is written in exponential notation. This type of notation has at least two advantages: The number of significant figures can be easily indicated, and fewer zeros are needed to write a very large or very small number. For example, the number 0.000060 is much more conveniently represented as $6.0 \times 10^{-5}$ (the number has two significant figures).

## INTERACTVE EXAMPLE 1.3 Significant Figures

Give the number of significant figures for each of the following results.
a. A student's extraction procedure on tea yields 0.0105 g of caffeine.
b. A chemist records a mass of 0.050080 g in an analysis.
c. In an experiment a span of time is determined to be $8.050 \times 10^{-3} \mathrm{~s}$.

SOLUTION
a. The number contains three significant figures. The zeros to the left of the 1 are leading
zeros and are not significant, but the remaining zero (a captive zero) is significant.
b. The number contains five significant figures. The leading zeros (to the left of the 5) are not significant. The captive zeros between the 5 and the 8 are significant, and the trailing zero to the right of the 8 is significant because the number contains a decimal point.
c. This number has four significant figures. Both zeros are significant.

$$
\text { See Exercises } 1.32 \text { through } 1.34
$$

To this point we have learned to count the significant figures in a given number. Next, we must consider how uncertainty accumulates as calculations are carried out. The detailed analysis of the accumulation of uncertainties depends on the type of calculation involved and can be complex. However, in this textbook we will use the following simple rules that have been developed for determining the appropriate number of significant figures in the result of a calculation.

## Rules for Significant Figures in Mathematical Operations

1. For multiplication or division, the number of significant figures in the result is the same as the number in the least precise measurement used in the calculation. For example, consider the calculation

The product should have only two significant figures, since 1.4 has two significant figures.
(Box continues on following page)

Rule 2 is consistent with the operation of electronic calculators.

Do not round sequentially. The number 6.8347 rounded to three significant figures is 6.83 , not 6.84 .
2. For addition or subtraction, the result has the same number of decimal places as the least precise measurement used in the calculation. For example, consider the sum

The correct result is 31.1 , since 18.0 has only one decimal place.

Note that for multiplication and division, significant figures are counted. For addition and subtraction, the decimal places are counted.

In most calculations you will need to round numbers to obtain the correct number of significant figures. The following rules should be applied when rounding.

## Rules for Rounding

1. In a series of calculations, carry the extra digits through to the final result, then round.
2. If the digit to be removed
a. is less than 5 , the preceding digit stays the same. For example, 1.33 rounds to 1.3 .
b. is equal to or greater than 5 , the preceding digit is increased by 1 . For example, 1.36 rounds to 1.4.

Although rounding is generally straightforward, one point requires special emphasis. As an illustration, suppose that the number 4.348 needs to be rounded to two significant figures. In doing this, we look only at the first number to the right of the 3 :

```
\[
4.348
\]
Look at this number to
round to two significant figures.
```

The number is rounded to 4.3 because 4 is less than 5 . It is incorrect to round sequentially. For example, do not round the 4 to 5 to give 4.35 and then round the 3 to 4 to give 4.4.

When rounding, use only the first number to the right of the last significant figure.
It is important to note that Rule 1 above usually will not be followed in the examples in this text because we want to show the correct number of significant figures in each step of a problem. This same practice is followed for the detailed solutions given in the Solutions Guide. However, when you are doing problems, you should carry extra digits throughout a series of calculations and round to the correct number of significant figures only at the end. This is the practice you should follow. The fact that your rounding procedures are different from those used in this text must be taken into account when you check your answer with the one given at the end of the book or in the Solutions Guide. Your answer (based on rounding only at the end of a calculation) may differ in the last place from that given here as the "correct" answer because we have rounded after each step. To help you understand the difference between these rounding procedures, we will consider them further in Example 1.4.

## INTERACTVE EXAMPLE 1.4 Significant Figures in Mathematical Operations

Carry out the following mathematical operations, and give each result with the correct number of significant figures.
a. $1.05 \times 10^{-3} \div 6.135$
b. $21-13.8$

## A

This number must be rounded to two significant figures.

## SOLUTION

c. As part of a lab assignment to determine the value of the gas constant $(R)$, a student measured the pressure $(P)$, volume $(V)$, and temperature $(T)$ for a sample of gas, where

$$
R=\frac{P V}{T}
$$

The following values were obtained: $P=2.560, T=275.15$, and $V=8.8$. (Gases will be discussed in detail in Chapter 5 ; we will not be concerned at this time about the units for these quantities.) Calculate $R$ to the correct number of significant figures.
a. The result is $1.71 \times 10^{-4}$, which has three significant figures because the term with the least precision $\left(1.05 \times 10^{-3}\right)$ has three significant figures.
b. The result is 7 with no decimal point because the number with the least number of decimal places (21) has none.
c. $R=\frac{P V}{T}=\frac{(2.560)(8.8)}{275.15}$

The correct procedure for obtaining the final result can be represented as follows:

$$
\begin{aligned}
\frac{(2.560)(8.8)}{275.15} & =\frac{22.528}{275.15}=0.0818753 \\
& =0.082=8.2 \times 10^{-2}=R
\end{aligned}
$$

The final result must be rounded to two significant figures because 8.8 (the least precise measurement) has two significant figures. To show the effects of rounding at intermediate steps, we will carry out the calculation as follows:

$$
\frac{(2.560)(8.8)}{275.15}=\frac{22.528}{275.15}=\frac{\begin{array}{c}
\text { Rounded to two } \\
\text { significant figures } \\
\downarrow
\end{array}}{275.15}
$$

Now we proceed with the next calculation:

$$
\frac{23}{275.15}=0.0835908
$$

Rounded to two significant figures, this result is

$$
0.084=8.4 \times 10^{-2}
$$

Note that intermediate rounding gives a significantly different result than that obtained by rounding only at the end. Again, we must reemphasize that in your calculations you should round only at the end. However, because rounding is carried out at intermediate steps in this text (to always show the correct number of significant figures), the final answer given in the text may differ slightly from the one you obtain (rounding only at the end).

## See Exercises 1.39 through 1.42

There is a useful lesson to be learned from Part c of Example 1.4. The student measured the pressure and temperature to greater precision than the volume. A more precise value of $R$ (one with more significant figures) could have been obtained if a more precise measurement of $V$ had been made. As it is, the efforts expended to measure $P$ and $T$ very precisely were wasted. Remember that a series of measurements to obtain some final result should all be done to about the same precision.

### 1.6 Learning to Solve Problems Systematically

One of the main activities in learning chemistry is solving various types of problems. The best way to approach a problem, whether it is a chemistry problem or one from your daily life, is to ask questions such as the following:

1. What is my goal? Or you might phrase it as: Where am I going?
2. Where am I starting? Or you might phrase it as: What do I know?
3. How do I proceed from where I start to where I want to go? Or you might say: How do I get there?

We will use these ideas as we consider unit conversions in this chapter. Then we will have much more to say about problem solving in Chapter 3, where we will start to consider more complex problems.

### 1.7 Dimensional Analysis

It is often necessary to convert a given result from one system of units to another. The best way to do this is by a method called the unit factor method or, more commonly, dimensional analysis. To illustrate the use of this method, we will consider several unit conversions. Some equivalents in the English and metric systems are listed in Table 1.4. A more complete list of conversion factors given to more significant figures appears in Appendix 6.

Consider a pin measuring 2.85 cm in length. What is its length in inches? To accomplish this conversion, we must use the equivalence statement

$$
2.54 \mathrm{~cm}=1 \mathrm{in}
$$

If we divide both sides of this equation by 2.54 cm , we get

$$
1=\frac{1 \mathrm{in}}{2.54 \mathrm{~cm}}
$$

This expression is called a unit factor. Since 1 inch and 2.54 cm are exactly equivalent, multiplying any expression by this unit factor will not change its value.

The pin has a length of 2.85 cm . Multiplying this length by the appropriate unit factor gives

$$
2.85 \mathrm{~cm} \times \frac{1 \mathrm{in}}{2.54 \mathrm{~cm}}=\frac{2.85}{2.54} \mathrm{in}=1.12 \mathrm{in}
$$

Note that the centimeter units cancel to give inches for the result. This is exactly what we wanted to accomplish. Note also that the result has three significant figures, as required by the number 2.85 . Recall that the 1 and 2.54 in the conversion factor are exact numbers by definition.

## INTERACTIVE EXAMPLE 1.5

## SOLUTION

## Unit Conversions I

A pencil is 7.00 in long. What is its length in centimeters?

## Where are we going?

To convert the length of the pencil from inches to centimeters
What do we know?
> The pencil is 7.00 in long.

## How do we get there?

Since we want to convert from inches to centimeters, we need the equivalence statement $2.54 \mathrm{~cm}=1 \mathrm{in}$. The correct unit factor in this case is $\frac{2.54 \mathrm{~cm}}{1 \mathrm{in}}$ :

$$
7.00 \text { iк } \times \frac{2.54 \mathrm{~cm}}{1 \text { íк }}=(7.00)(2.54) \mathrm{cm}=17.8 \mathrm{~cm}
$$

Here the inch units cancel, leaving centimeters, as requested.

## See Exercises 1.43 and 1.44

Note that two unit factors can be derived from each equivalence statement. For example, from the equivalence statement $2.54 \mathrm{~cm}=1 \mathrm{in}$, the two unit factors are

$$
\frac{2.54 \mathrm{~cm}}{1 \mathrm{in}} \text { and } \frac{1 \mathrm{in}}{2.54 \mathrm{~cm}}
$$

How do you choose which one to use in a given situation? Simply look at the direction of the required change. To change from inches to centimeters, the inches must cancel. Thus the factor $2.54 \mathrm{~cm} / 1 \mathrm{in}$ is used. To change from centimeters to inches, centimeters must cancel, and the factor $1 \mathrm{in} / 2.54 \mathrm{~cm}$ is appropriate.

## PROBLEM-SOLVING STRATEGY

## Converting from One Unit to Another

" To convert from one unit to another, use the equivalence statement that relates the two units.
" Derive the appropriate unit factor by looking at the direction of the required change (to cancel the unwanted units).
» Multiply the quantity to be converted by the unit factor to give the quantity with the desired units.

## INTERACTVE EXAMPLE 1.6 Unit Conversions II

You want to order a bicycle with a 25.5 -in frame, but the sizes in the catalog are given only in centimeters. What size should you order?

## SOLUTION Where are we going?

To convert from inches to centimeters

## What do we know?

) The size needed is 25.5 in .

## How do we get there?

Since we want to convert from inches to centimeters, we need the equivalence statement $2.54 \mathrm{~cm}=1 \mathrm{in}$. The correct unit factor in this case is $\frac{2.54 \mathrm{~cm}}{1 \mathrm{in}}$ :

$$
25.5 \text { іп } \times \frac{2.54 \mathrm{~cm}}{1 \text { ік }}=64.8 \mathrm{~cm}
$$

## INTERACTIVE EXAMPLE 1.7

## SOLUTION

In the text we round to the correct number
of significant figures after each step to show the correct significant figures for each calculation. However, since you use a calculator and combine steps on it, you should round only at the end.

To ensure that the conversion procedure is clear, a multistep problem is considered in Example 1.7.

## Unit Conversions III

A student has entered a $10.0-\mathrm{km}$ run. How long is the run in miles?

## Where are we going?

To convert from kilometers to miles

## What do we know?

) The run is 10.00 km long.

## How do we get there?

This conversion can be accomplished in several different ways. Since we have the equivalence statement $1 \mathrm{~m}=1.094 \mathrm{yd}$, we will proceed by a path that uses this fact. Before we start any calculations, let us consider our strategy. We have kilometers, which we want to change to miles. We can do this by the following route:

To proceed in this way, we need the following equivalence statements:

$$
\begin{aligned}
1 \mathrm{k} \mathrm{~m} & =1000 \mathrm{~m} \\
1 \mathrm{~m} & =1.094 \mathrm{yd} \\
1760 \mathrm{y} \mathrm{~d} & =1 \mathrm{mi}
\end{aligned}
$$

To make sure the process is clear, we will proceed step by step:

## Kilometers to Meters

$$
10.0 \mathrm{~km} \times \frac{1000 \mathrm{~m}}{1 \mathrm{kmI}}=1.00 \times 10^{4} \mathrm{~m}
$$

## Meters to Yards

$$
1.00 \times 10^{4} \mathrm{mr} \times \frac{1.094 \mathrm{yd}}{1 \mathrm{mr}}=1.094 \times 10^{4} \mathrm{yd}
$$

Note that we should have only three significant figures in the result. However, since this is an intermediate result, we will carry the extra digit. Remember, round off only the final result.
Yards to Miles

$$
1.094 \times 10^{4} \text { yd } \times \frac{1 \mathrm{mi}}{1760 \mathrm{yd}}=6.216 \mathrm{mi}
$$

Note in this case that 1 mi equals exactly 1760 yd by designation. Thus 1760 is an exact number.

Since the distance was originally given as 10.0 km , the result can have only three significant figures and should be rounded to 6.22 mi . Thus

$$
10.0 \mathrm{~km}=6.22 \mathrm{mi}
$$

Alternatively, we can combine the steps:

$$
10.0 \mathrm{kmI} \times \frac{1000 \mathrm{mI}}{1 \mathrm{kmI}} \times \frac{1.094 \mathrm{yd}}{1 \mathrm{mI}} \times \frac{1 \mathrm{mi}}{1760 \mathrm{yd}}=6.22 \mathrm{mi}
$$

In using dimensional analysis, your verification that everything has been done correctly is that you end up with the correct units. In doing chemistry problems, you should always include the units for the quantities used. Always check to see that the units cancel to give the correct units for the final result. This provides a very valuable check, especially for complicated problems.

Study the procedures for unit conversions in the following examples.

## INTERACTIVE EXAMPLE 1.8 Unit Conversions IV

The speed limit on many highways in the United States is $55 \mathrm{mi} / \mathrm{h}$. What number would be posted in kilometers per hour?

## SOLUTION Where are we going?

To convert the speed limit from 55 miles per hour to kilometers per hour
What do we know?
) The speed limit is $55 \mathrm{mi} / \mathrm{h}$.

## How do we get there?

We use the following unit factors to make the required conversion:

$$
\frac{55 \mathrm{mi}}{\mathrm{~h}} \times \frac{1760 \mathrm{yd}}{1 \mathrm{mi}} \times \frac{1 \mathrm{mI}}{1.094 \text { yd}} \times \frac{1 \mathrm{~km}}{1000 \mathrm{mI}}=88 \mathrm{~km} / \mathrm{h}
$$

Note that all units cancel except the desired kilometers per hour.

## INTERACTIVE EXAMPLE 1.9 Unit Conversions V

A Japanese car is advertised as having a gas mileage of $15 \mathrm{~km} / \mathrm{L}$. Convert this rating to miles per gallon.

## SOLUTION Where are we going?

To convert gas mileage from 15 kilometers per liter to miles per gallon
What do we know?
> The gas mileage is $15 \mathrm{~km} / \mathrm{L}$.
How do we get there?
We use the following unit factors to make the required conversion:

$$
\frac{15 \mathrm{~km}}{\mathrm{~L}} \times \frac{1000 \mathrm{~m}}{1 \mathrm{~km}} \times \frac{1.094 \mathrm{yd}}{1 \mathrm{mI}} \times \frac{1 \mathrm{mi}}{1760 \mathrm{yd}} \times \frac{1 \mathrm{~K}}{1.06 \mathrm{qt}} \times \frac{\underbrace{4 \mathrm{qt}}}{1 \mathrm{gal}}=35 \mathrm{mi} / \mathrm{gal}
$$

## INTERACTIVE EXAMPLE 1.10 Unit Conversions VI

## SOLUTION Where are we going?

The latest model Corvette has an engine with a displacement of 6.20 L . What is the displacement in units of cubic inches?

To convert the engine displacement from liters to cubic inches

## What do we know?

》 The displacement is 6.20 L .

## How do we get there?

We use the following unit factors to make the required conversion:

$$
6.20 \mathrm{~L} \times \frac{1 \mathrm{ft}^{3}}{28.32 \mathrm{~L}} \times \frac{(12 \mathrm{in})^{3}}{(1 \mathrm{ft})^{3}}=378 \mathrm{in}^{3}
$$

Note that the unit factor for conversion of feet to inches must be cubed to accommodate the conversion of $\mathrm{ft}^{3}$ to $\mathrm{in}^{3}$.

### 1.8 Temperature

Three systems for measuring temperature are widely used: the Celsius scale, the Kelvin scale, and the Fahrenheit scale. The first two temperature systems are used in the physical sciences, and the third is used in many of the engineering sciences. Our purpose here is to define the three temperature scales and show how conversions from one scale to another can be performed. Although these conversions can be carried out routinely on most calculators, we will consider the process in some detail here to illustrate methods of problem solving.

The three temperature scales are defined and compared in Fig. 1.9. Note that the size of the temperature unit (the degree) is the same for the Kelvin and Celsius scales. The fundamental difference between these two temperature scales is their zero points. Conversion between these two scales simply requires an adjustment for the different zero points.

$$
\text { Temperature }(\text { Kelvin })=\text { temperature }(\text { Celsius })+273.15
$$

or

$$
\text { Temperature }(\text { Celsius })=\text { temperature }(\text { Kelvin })-273.15
$$

For example, to convert 300.00 K to the Celsius scale, we do the following calculation:

$$
300.00-273.15=26.85^{\circ} \mathrm{C}
$$

Note that in expressing temperature in Celsius units, the designation ${ }^{\circ} \mathrm{C}$ is used. The degree symbol is not used when writing temperature in terms of the Kelvin scale. The unit of temperature on this scale is called a kelvin and is symbolized by the letter K.

Converting between the Fahrenheit and Celsius scales is somewhat more complicated because both the degree sizes and the zero points are different. Thus we need to consider two adjustments: one for degree size and one for the zero point. First, we

FIGURE 1.9 The three major temperature scales.

Understand the process of converting from one temperature scale to another; do not simply memorize the equations.

must account for the difference in degree size. This can be done by reconsidering Fig. 1.9. Notice that since $212^{\circ} \mathrm{F}=100^{\circ} \mathrm{C}$ and $32^{\circ} \mathrm{F}=0^{\circ} \mathrm{C}$,

$$
212-32=180 \text { Fahrenheit degrees }=100-0=100 \text { Celsius degrees }
$$

Thus $180^{\circ}$ on the Fahrenheit scale is equivalent to $100^{\circ}$ on the Celsius scale, and the unit factor is

$$
\frac{180^{\circ} \mathrm{F}}{100^{\circ} \mathrm{C}} \text { or } \frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}}
$$

or the reciprocal, depending on the direction in which we need to go.
Next, we must consider the different zero points. Since $32^{\circ} \mathrm{F}=0^{\circ} \mathrm{C}$, we obtain the corresponding Celsius temperature by first subtracting 32 from the Fahrenheit temperature to account for the different zero points. Then the unit factor is applied to adjust for the difference in the degree size. This process is summarized by the equation

$$
\begin{equation*}
\left(T_{\mathrm{F}}-32^{\circ} \mathrm{F}\right) \frac{5^{\circ} \mathrm{C}}{9^{\circ} \mathrm{F}}=T_{\mathrm{C}} \tag{1.1}
\end{equation*}
$$

where $T_{\mathrm{F}}$ and $T_{\mathrm{C}}$ represent a given temperature on the Fahrenheit and Celsius scales, respectively. In the opposite conversion, we first correct for degree size and then correct for the different zero point. This process can be summarized in the following general equation:

$$
\begin{equation*}
T_{\mathrm{F}}=T_{\mathrm{C}} \times \frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}}+32^{\circ} \mathrm{F} \tag{1.2}
\end{equation*}
$$

Equations (1.1) and (1.2) are really the same equation in different forms. See if you can obtain Equation (1.2) by starting with Equation (1.1) and rearranging.

At this point it is worthwhile to weigh the two alternatives for learning to do temperature conversions: You can simply memorize the equations, or you can take the time to learn the differences between the temperature scales and to understand the processes involved in converting from one scale to another. The latter approach may

## INTERACTIVE EXAMPLE 1.11

## SOLUTION

A nurse taking the temperature of a patient.
take a little more effort, but the understanding you gain will stick with you much longer than the memorized formulas. This choice also will apply to many of the other chemical concepts. Try to think things through!

## Temperature Conversions I

Normal body temperature is $98.6^{\circ} \mathrm{F}$. Convert this temperature to the Celsius and Kelvin scales.

## Where are we going?

To convert the body temperature from degrees Fahrenheit to degrees Celsius and to kelvins.

## What do we know?

> The body temperature is $98.6^{\circ} \mathrm{F}$.

## How do we get there?

Rather than simply using the formulas to solve this problem, we will proceed by thinking it through. The situation is diagramed in Fig. 1.10. First, we want to convert $98.6^{\circ} \mathrm{F}$ to the Celsius scale. The number of Fahrenheit degrees between $32.0^{\circ} \mathrm{F}$ and $98.6^{\circ} \mathrm{F}$ is $66.6^{\circ} \mathrm{F}$. We must convert this difference to Celsius degrees:

$$
66.6^{\circ} \mathrm{F} \times \frac{5^{\circ} \mathrm{C}}{9^{\circ} \mathrm{F}}=37.0^{\circ} \mathrm{C}
$$

Thus $98.6^{\circ} \mathrm{F}$ corresponds to $37.0^{\circ} \mathrm{C}$.
Now we can convert to the Kelvin scale:

$$
T_{\mathrm{K}}=T_{\mathrm{C}}+273.15=37.0+273.15=310.2 \mathrm{~K}
$$

Note that the final answer has only one decimal place (37.0 is limiting).

See Exeraises 1.61, 1.63, and 1.64

FIGURE 1.10 Normal body temperature on the Fahrenheit, Celsius, and Kelvin scales.

## EXAMPLE 1.12 Temperature Conversions II

One interesting feature of the Celsius and Fahrenheit scales is that $-40^{\circ} \mathrm{C}$ and $-40^{\circ} \mathrm{F}$ represent the same temperature, as shown in Fig. 1.9. Verify that this is true.

## SOLUTION Where are we going?

To show that $-40^{\circ} \mathrm{C}=-40^{\circ} \mathrm{F}$
What do we know?
, The relationship between the Celsius and Fahrenheit scales

## How do we get there?

The difference between $32^{\circ} \mathrm{F}$ and $-40^{\circ} \mathrm{F}$ is $72^{\circ} \mathrm{F}$. The difference between $0^{\circ} \mathrm{C}$ and $-40^{\circ} \mathrm{C}$ is $40^{\circ} \mathrm{C}$. The ratio of these is

$$
\frac{72^{\circ} \mathrm{F}}{40^{\circ} \mathrm{C}}=\frac{8 \times 9^{\circ} \mathrm{F}}{8 \times 5^{\circ} \mathrm{C}}=\frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}}
$$

as required. Thus $-40^{\circ} \mathrm{C}$ is equivalent to $-40^{\circ} \mathrm{F}$.

Since, as shown in Example 1.12, $-40^{\circ}$ on both the Fahrenheit and Celsius scales represents the same temperature, this point can be used as a reference point (like $0^{\circ} \mathrm{C}$ and $32^{\circ} \mathrm{F}$ ) for a relationship between the two scales:

$$
\begin{gather*}
\frac{\text { Number of Fahrenheit degrees }}{\text { Number of Celsius degrees }}=\frac{T_{\mathrm{F}}-(-40)}{T_{\mathrm{C}}-(-40)}=\frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}} \\
\frac{T_{\mathrm{F}}+40}{T_{\mathrm{C}}+40}=\frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}} \tag{1.3}
\end{gather*}
$$

where $T_{\mathrm{F}}$ and $T_{\mathrm{C}}$ represent the same temperature (but not the same number). This equation can be used to convert Fahrenheit temperatures to Celsius, and vice versa, and may be easier to remember than Equations (1.1) and (1.2).

## INTERACTIVE EXAMPLE 1.13 Temperature Conversions III

Liquid nitrogen, which is often used as a coolant for low-temperature experiments, has a boiling point of 77 K . What is this temperature on the Fahrenheit scale?

## SOLUTION Where are we going?

To convert 77 K to the Fahrenheit scale

## What do we know?

) The relationship between the Kelvin and Fahrenheit scales

## How do we get there?

-
Liquid nitrogen is so cold that water condenses out of the surrounding air, forming a cloud as the nitrogen is poured.

We will first convert 77 K to the Celsius scale:

$$
T_{\mathrm{C}}=T_{\mathrm{K}}-273.15=77-273.15=-196^{\circ} \mathrm{C}
$$

To convert to the Fahrenheit scale, we will use Equation (1.3):

$$
\begin{aligned}
\frac{T_{\mathrm{F}}+40}{T_{\mathrm{C}}+40} & =\frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}} \\
\frac{T_{\mathrm{F}}+40}{-196^{\circ} \mathrm{C}+40} & =\frac{T_{\mathrm{F}}+40}{-156^{\circ} \mathrm{C}}=\frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}} \\
T_{\mathrm{F}}+40 & =\frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}}\left(-156^{\circ} \mathrm{C}\right)=-281^{\circ} \mathrm{F} \\
T_{\mathrm{F}} & =-281^{\circ} \mathrm{F}-40=-321^{\circ} \mathrm{F}
\end{aligned}
$$

## See Exercises 1.61, 1.63, and 1.64

### 1.9 Density

A property of matter that is often used by chemists as an "identification tag" for a substance is density, the mass of substance per unit volume of the substance:

$$
\text { Density }=\frac{\text { mass }}{\text { volume }}
$$

The density of a liquid can be determined easily by weighing an accurately known volume of liquid. This procedure is illustrated in Example 1.14.

## INTERACTIVE EXAMPLE 1.14 Determining Density

There are two ways of indicating units that occur in the denominator. For example, we can write $\mathrm{g} / \mathrm{cm}^{3}$ or $\mathrm{g} \mathrm{cm}^{-3}$. Although we will use the former system here, the other system is widely used.

A chemist, trying to identify an unknown liquid, finds that $25.00 \mathrm{~cm}^{3}$ of the substance has a mass of 19.625 g at $20^{\circ} \mathrm{C}$. The following are the names and densities of the compounds that might be the liquid:

| Compound | Density in $\mathrm{g} / \mathrm{cm}^{3}$ at $20^{\circ} \mathrm{C}$ |
| :--- | :--- |
| Chloroform | 1.492 |
| Diethyl ether | 0.714 |
| Ethanol | 0.789 |
| Isopropyl alcohol | 0.785 |
| Toluene | 0.867 |

Which of these compounds is the most likely to be the unknown liquid?

## SOLUTION Where are we going?

To calculate the density of the unknown liquid
What do we know?
> The mass of a given volume of the liquid.

## How do we get there?

To identify the unknown substance, we must determine its density. This can be done by using the definition of density:

$$
\text { Density }=\frac{\text { mass }}{\text { volume }}=\frac{19.625 \mathrm{~g}}{25.00 \mathrm{~cm}^{3}}=0.7850 \mathrm{~g} / \mathrm{cm}^{3}
$$

This density corresponds exactly to that of isopropyl alcohol, which therefore most likely is the unknown liquid. However, note that the density of ethanol is also very close. To be sure that the compound is isopropyl alcohol, we should run several more density experiments. (In the modern laboratory, many other types of tests could be done to distinguish between these two liquids.)

See Exercises 1.70 through 1.72

Besides being a tool for the identification of substances, density has many other uses. For example, the liquid in your car's lead storage battery (a solution of sulfuric acid) changes density because the sulfuric acid is consumed as the battery discharges. In a fully charged battery, the density of the solution is about $1.30 \mathrm{~g} / \mathrm{cm}^{3}$. If the density falls below $1.20 \mathrm{~g} / \mathrm{cm}^{3}$, the battery will have to be recharged. Density measurement is also used to determine the amount of antifreeze, and thus the level of protection against freezing, in the cooling system of a car.

The densities of various common substances are given in Table 1.5.
TABLE 1.5 | Densities of Various Common Substances* at $\mathbf{2 0}^{\circ} \mathrm{C}$

| Substance | Physical State | Density $\left(\mathbf{c} / \mathbf{c m}^{3}\right)$ |
| :--- | :--- | :--- |
| Oxygen | Gas | 0.00133 |
| Hydrogen | Gas | 0.000084 |
| Ethanol | Liquid | 0.789 |
| Benzene | Liquid | 0.880 |
| Water | Liquid | 0.9982 |
| Magnesium | Solid | 1.74 |
| Salt (sodium chloride) | Solid | 2.16 |
| Aluminum | Solid | 2.70 |
| Iron | Solid | 7.87 |
| Copper | Solid | 8.96 |
| Silver | Solid | 10.49 |
| Lead | Solid | 11.34 |
| Mercury | Liquid | 13.56 |
| Gold | Solid | 19.32 |

*At 1 atmosphere pressure.

### 1.10 Classification of Matter

Before we can hope to understand the changes we see going on around us-the growth of plants, the rusting of steel, the aging of people, the acidification of rain-we must find out how matter is organized. Matter, best defined as anything occupying space and having mass, is the material of the universe. Matter is complex and has many levels of organization. In this section we will introduce basic ideas about the structure of matter and its behavior.

We will start by considering the definitions of the fundamental properties of matter. Matter exists in three states: solid, liquid, and gas. A solid is rigid; it has a fixed volume and shape. A liquid has a definite volume but no specific shape; it assumes the shape of its container. A gas has no fixed volume or shape; it takes on the shape and volume of its container. In contrast to liquids and solids, which are only slightly compressible, gases are highly compressible; it is relatively easy to decrease the volume of

FIGURE 1.11 The three states of water (where red spheres represent oxygen atoms and blue spheres represent hydrogen atoms).

a gas. Molecular-level pictures of the three states of water are given in Fig. 1.11. The different properties of ice, liquid water, and steam are determined by the different arrangements of the molecules in these substances. Table 1.5 gives the states of some common substances at $20^{\circ} \mathrm{C}$ and 1 atmosphere pressure.

Most of the matter around us consists of mixtures of pure substances. Wood, gasoline, wine, soil, and air all are mixtures. The main characteristic of a mixture is that it has variable composition. For example, wood is a mixture of many substances, the proportions of which vary depending on the type of wood and where it grows. Mixtures can be classified as homogeneous (having visibly indistinguishable parts) or heterogeneous (having visibly distinguishable parts).

A homogeneous mixture is called a solution. Air is a solution consisting of a mixture of gases. Wine is a complex liquid solution. Brass is a solid solution of copper and zinc. Sand in water and iced tea with ice cubes are examples of heterogeneous mixtures. Heterogeneous mixtures usually can be separated into two or more homogeneous mixtures or pure substances (for example, the ice cubes can be separated from the tea).

Mixtures can be separated into pure substances by physical methods. A pure substance is one with constant composition. Water is a good illustration of these ideas. As we will discuss in detail later, pure water is composed solely of $\mathrm{H}_{2} \mathrm{O}$ molecules, but the water found in nature (groundwater or the water in a lake or ocean) is really a mixture. Seawater, for example, contains large amounts of dissolved minerals. Boiling seawater produces steam, which can be condensed to pure water, leaving the minerals behind as solids. The dissolved minerals in seawater also can be separated out by freezing the mixture, since pure water freezes out. The processes of boiling and freezing are physical changes. When water freezes or boils, it changes its state but remains water; it is still composed of $\mathrm{H}_{2} \mathrm{O}$ molecules. A physical change is a change in the form of a substance, not in its chemical composition. A physical change can be used to separate a mixture into pure compounds, but it will not break compounds into elements.

One of the most important methods for separating the components of a mixture is distillation, a process that depends on differences in the volatility (how readily substances become gases) of the components. In simple distillation, a mixture is

FIGURE 1.12 Simple laboratory distillation apparatus. Cool water circulates through the outer portion of the condenser, causing vapors from the distilling flask to condense into a liquid. The nonvolatile component of the mixture remains in the distilling flask.

The term volatile refers to the ease with which a substance can be changed to its vapor.

heated in a device such as that shown in Fig. 1.12. The most volatile component vaporizes at the lowest temperature, and the vapor passes through a cooled tube (a condenser), where it condenses back into its liquid state.

The simple, one-stage distillation apparatus shown in Fig. 1.12 works very well when only one component of the mixture is volatile. For example, a mixture of water and sand is easily separated by boiling off the water. Water containing dissolved minerals behaves in much the same way. As the water is boiled off, the minerals remain behind as nonvolatile solids. Simple distillation of seawater using the sun as the heat source is an excellent way to desalinate (remove the minerals from) seawater.

However, when a mixture contains several volatile components, the one-step distillation does not give a pure substance in the receiving flask, and more elaborate methods are required.

Another method of separation is simple filtration, which is used when a mixture consists of a solid and a liquid. The mixture is poured onto a mesh, such as filter paper, which passes the liquid and leaves the solid behind.

A third method of separation is chromatography. Chromatography is the general name applied to a series of methods that use a system with two phases (states) of matter: a mobile phase and a stationary phase. The stationary phase is a solid, and the mobile phase is either a liquid or a gas. The separation process occurs because the components of the mixture have different affinities for the two phases and thus move through the system at different rates. A component with a high affinity for the mobile phase moves relatively quickly through the chromatographic system, whereas one with a high affinity for the solid phase moves more slowly.

One simple type of chromatography, paper chromatography, uses a strip of porous paper, such as filter paper, for the stationary phase. A drop of the mixture to be separated is placed on the paper, which is then dipped into a liquid (the mobile phase) that travels up the paper as though it were a wick (Fig. 1.13). This method of separating a mixture is often used by biochemists, who study the chemistry of living systems.

It should be noted that when a mixture is separated, the absolute purity of the separated components is an ideal. Because water, for example, inevitably comes into contact with other materials when it is synthesized or separated from a mixture, it is never absolutely pure. With great care, however, substances can be obtained in very nearly pure form.

FIGURE 1.13 Paper chromatography of ink. (a) A dot of the mixture to be separated is placed at one end of a sheet of porous paper. (b) The paper acts as a wick to draw up the liquid.

The element mercury (top left) combines with the element iodine (top right) to form the compound mercuric iodide (bottom). This is an example of a chemical change.

Pure substances are either compounds (combinations of elements) or free elements. A compound is a substance with constant composition that can be broken down into elements by chemical processes. An example of a chemical process is the electrolysis of water, in which an electric current is passed through water to break it down into the free elements hydrogen and oxygen. This process produces a chemical change because the water molecules have been broken down. The water is gone, and in its place we have the free elements hydrogen and oxygen. A chemical change is one in which a given substance becomes a new substance or substances with different properties and different composition. Elements are substances that cannot be decomposed into simpler substances by chemical or physical means.

We have seen that the matter around us has various levels of organization. The most fundamental substances we have discussed so far are elements. As we will see in later chapters, elements also have structure: They are composed of atoms, which in turn are composed of nuclei and electrons. Even the nucleus has structure: It is composed of protons and neutrons. And even these can be broken down further, into elementary particles called quarks. However, we need not concern ourselves with such details at this point. Fig. 1.14 summarizes our discussion of the organization of matter.

FIGURE 1.14 The organization of matter.

，Filtration
＞Chromatography
Compounds can be decomposed to elements only through chemical changes．

## Review Questions Answers to the Review Buestions can be found on the Student website (accessible from wwwur.cengagebrain.com).

1. Define and explain the differences between the following terms.
a. law and theory
b. theory and experiment
c. qualitative and quantitative
d. hypothesis and theory
2. Is the scientific method suitable for solving problems only in the sciences? Explain.
3. Which of the following statements could be tested by quantitative measurement?
a. Ty Cobb was a better hitter than Pete Rose.
b. Ivory soap is $99.44 \%$ pure.
c. Rolaids consumes 47 times its weight in excess stomach acid.
4. For each of the following pieces of glassware, provide a sample measurement and discuss the number of significant figures and uncertainty.

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. a. There are 365 days per year, 24 hours per day, 12 months per year, and 60 minutes per hour. Use these data to determine how many minutes are in a month.
b. Now use the following data to calculate the number of minutes in a month: 24 hours per day, 60 minutes per hour, 7 days per week, and 4 weeks per month.
c. Why are these answers different? Which (if any) is more correct? Why?
2. You go to a convenience store to buy candy and find the owner to be rather odd. He allows you to buy pieces in multiples of four, and to buy four, you need $\$ 0.23$. He only allows you to do this by using 3 pennies and 2 dimes. You have a bunch of pennies and dimes, and instead of counting them, you decide to weigh them. You have 636.3 g of pennies, and each penny
3. A student performed an analysis of a sample for its calcium content and got the following results:

$$
14.92 \% \quad 14.91 \% \quad 14.88 \% \quad 14.91 \%
$$

The actual amount of calcium in the sample is $15.70 \%$. What conclusions can you draw about the accuracy and precision of these results?
6. Compare and contrast the multiplication/division significant figure rule to the significant figure rule applied for addition/subtraction in mathematical operations.
7. Explain how density can be used as a conversion factor to convert the volume of an object to the mass of the object, and vice versa.
8. On which temperature scale $\left({ }^{\circ} \mathrm{F},{ }^{\circ} \mathrm{C}\right.$, or K$)$ does 1 degree represent the smallest change in temperature?
9. Distinguish between physical changes and chemical changes.
10. Why is the separation of mixtures into pure or relatively pure substances so important when performing a chemical analysis?
weighs 3.03 g . Each dime weighs 2.29 g . Each piece of candy weighs 10.23 g .
a. How many pennies do you have?
b. How many dimes do you need to buy as much candy as possible?
c. How much should all these dimes weigh?
d. How many pieces of candy could you buy? (number of dimes from part b)
e. How much would this candy weigh?
f. How many pieces of candy could you buy with twice as many dimes?
3. When a marble is dropped into a beaker of water, it sinks to the bottom. Which of the following is the best explanation?
a. The surface area of the marble is not large enough to be held up by the surface tension of the water.
b. The mass of the marble is greater than that of the water.
c. The marble weighs more than an equivalent volume of the water.
d. The force from dropping the marble breaks the surface tension of the water.
e. The marble has greater mass and volume than the water. Justify your choice, and for choices you did not pick, explain what is wrong about them.
4. You have two beakers, one filled to the $100-\mathrm{mL}$ mark with sugar (the sugar has a mass of 180.0 g ) and the other filled to the $100-\mathrm{mL}$ mark with water (the water has a mass of 100.0 g ). You pour all the sugar and all the water together in a bigger beaker and stir until the sugar is completely dissolved.
a. Which of the following is true about the mass of the solution? Explain.
i. It is much greater than 280.0 g .
ii. It is somewhat greater than 280.0 g .
iii. It is exactly 280.0 g .
iv. It is somewhat less than 280.0 g .
v. It is much less than 280.0 g .
b. Which of the following is true about the volume of the solution? Explain.
i. It is much greater than 200.0 mL .
ii. It is somewhat greater than 200.0 mL .
iii. It is exactly 200.0 mL .
iv. It is somewhat less than 200.0 mL .
v. It is much less than 200.0 mL .
5. You may have noticed that when water boils, you can see bubbles that rise to the surface of the water.
a. What is inside these bubbles?
i. air
ii. hydrogen and oxygen gas
iii. oxygen gas
iv. water vapor
v. carbon dioxide gas
b. Is the boiling of water a chemical or physical change? Explain.
6. If you place a glass rod over a burning candle, the glass appears to turn black. What is happening to each of the following (physical change, chemical change, both, or neither) as the candle burns? Explain each answer.
a. the wax
b. the wick
c. the glass rod
7. Which characteristics of a solid, a liquid, and a gas are exhibited by each of the following substances? How would you classify each substance?
a. a bowl of pudding
b. a bucketful of sand
8. Sketch a magnified view (showing atoms/molecules) of each of the following and explain:
a. a heterogeneous mixture of two different compounds
b. a homogeneous mixture of an element and a compound
9. Paracelsus, a sixteenth-century alchemist and healer, adopted as his slogan: "The patients are your textbook, the sickbed is your study." Is this view consistent with using the scientific method?
10. What is wrong with the following statement?
"The results of the experiment do not agree with the theory. Something must be wrong with the experiment."
11. Why is it incorrect to say that the results of a measurement were accurate but not precise?
12. What data would you need to estimate the money you would spend on gasoline to drive your car from New York to Chicago? Provide estimates of values and a sample calculation.
13. Sketch two pieces of glassware: one that can measure volume to the thousandths place and one that can measure volume only to the ones place.
14. You have a $1.0-\mathrm{cm}^{3}$ sample of lead and a $1.0-\mathrm{cm}^{3}$ sample of glass. You drop each in separate beakers of water. How do the volumes of water displaced by each sample compare? Explain.
15. Consider the addition of 15.4 to 28 . What would a mathematician say the answer is? What would a scientist say? Justify the scientist's answer, not merely citing the rule, but explaining it.
16. Consider multiplying 26.2 by 16.43 . What would a mathematician say the answer is? What would a scientist say? Justify the scientist's answer, not merely citing the rule, but explaining it.
17. True or false? For mathematical operation performed on two measurements, the number of significant figures in the answer is the same as the least number of significant figures in either of the measurements. Explain your answer.
18. Is there a difference between a homogeneous mixture of hydrogen and oxygen in a $2: 1$ ratio and a sample of water vapor? Explain.
A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

19. The difference between a law and a theory is the difference between what and why. Explain.
20. The scientific method is a dynamic process. What does this mean?
21. Explain the fundamental steps of the scientific method.
22. What is the difference between random error and systematic error?
23. A measurement is a quantitative observation involving both a number and a unit. What is a qualitative observation? What are the SI units for mass, length, and volume? What is the assumed uncertainty in a number (unless stated otherwise)? The uncertainty of a measurement depends on the precision of the measuring device. Explain.
24. To determine the volume of a cube, a student measured one of the dimensions of the cube several times. If the true dimension of the cube is 10.62 cm , give an example of four sets of measurements that would illustrate the following.
a. imprecise and inaccurate data
b. precise but inaccurate data
c. precise and accurate data

Give a possible explanation as to why data can be imprecise or inaccurate. What is wrong with saying a set of measurements is imprecise but accurate?
25. What are significant figures? Show how to indicate the number one thousand to 1 significant figure, 2 significant figures, 3 significant figures, and 4 significant figures. Why is the answer, to the correct number of significant figures, not 1.0 for the following calculation?

$$
\frac{1.5-1.0}{0.50}=
$$

26. A cold front moves through and the temperature drops by 20 degrees. In which temperature scale would this 20 degree change represent the largest change in temperature?
27. When the temperature in degrees Fahrenheit $\left(T_{\mathrm{F}}\right)$ is plotted vs. the temperature in degrees Celsius ( $T_{\mathrm{C}}$ ), a straight-line plot results. A straight-line plot also results when $T_{\mathrm{C}}$ is plotted vs. $T_{\mathrm{K}}$ (the temperature in kelvins). Reference Appendix A1.3 and determine the slope and $y$-intercept of each of these two plots.
28. In a multiple-step calculation, is it better to round off the numbers to the correct number of significant figures in each step of the calculation or to round off only the final answer?
29. Is the density of a gaseous substance larger or smaller than the density of a liquid or a solid at the same temperature? Why?
30. Give four examples illustrating each of the following terms.
a. homogeneous mixture
d. element
b. heterogeneous mixture
e. physical change
c. compound
f. chemical change

## Exercises

In this section similar exercises are paired.

## Significant Figures and Unit Conversions

-31 . Which of the following are exact numbers?
a. There are 100 cm in 1 m .
b. One meter equals 1.094 yards.
c. We can use the equation

$$
{ }^{\circ} \mathrm{F}=\frac{9}{5}{ }^{\circ} \mathrm{C}+32
$$

to convert from Celsius to Fahrenheit temperature. Are the numbers $\frac{9}{5}$ and 32 exact or inexact?
d. $\pi=3.1415927$.
32. Indicate the number of significant figures in each of the following:
a. This book contains more than 1000 pages.
b. A mile is about 5300 ft .
c. A liter is equivalent to 1.059 qt.
d. The population of the United States is approaching $3.1 \times 10^{2}$ million.
e. A kilogram is 1000 g .
f. The Boeing 747 cruises at around $600 \mathrm{mi} / \mathrm{h}$.
[33. How many significant figures are there in each of the following values?
a. $6.07 \times 10^{-15}$
b. 0.003840
c. 17.00
d. $8 \times 10^{8}$
e. 463.8052
f. 300
g. 301
h. 300 .
34. How many significant figures are in each of the following?
a. 100
b. $1.0 \times 10^{2}$
c. $1.00 \times 10^{3}$
d. 100 .
e. 0.0048
f. 0.00480
g. $4.80 \times 10^{-3}$
h. $4.800 \times 10^{-3}$
-35. Round off each of the following numbers to the indicated number of significant digits, and write the answer in standard scientific notation.
a. 0.00034159 to three digits
b. $103.351 \times 10^{2}$ to four digits
c. 17.9915 to five digits
d. $3.365 \times 10^{5}$ to three digits
36. Use exponential notation to express the number 385,500 to
a. one significant figure.
b. two significant figures.
c. three significant figures.
d. five significant figures.
-37. You have liquid in each graduated cylinder shown:

You then add both samples to a beaker. How would you write the number describing the total volume? What limits the precision of this number?
38. The beakers shown below have different precisions.

a. Label the amount of water in each of the three beakers to the correct number of significant figures.
b. Is it possible for each of the three beakers to contain the exact same amount of water? If no, why not? If yes, did you report the volumes as the same in part a? Explain.
c. Suppose you pour the water from these three beakers into one container. What should be the volume in the container reported to the correct number of significant figures?
-39. Evaluate each of the following, and write the answer to the appropriate number of significant figures.
a. $212.2+26.7+402.09$
b. $1.0028+0.221+0.10337$
c. $52.331+26.01-0.9981$
d. $2.01 \times 10^{2}+3.014 \times 10^{3}$
e. $7.255-6.8350$
40. Perform the following mathematical operations, and express each result to the correct number of significant figures.
a. $\frac{0.102 \times 0.0821 \times 273}{1.01}$
b. $0.14 \times 6.022 \times 10^{23}$
c. $4.0 \times 10^{4} \times 5.021 \times 10^{-3} \times 7.34993 \times 10^{2}$
d. $\frac{2.00 \times 10^{6}}{3.00 \times 10^{-7}}$
-41. Perform the following mathematical operations, and express the result to the correct number of significant figures.
a. $\frac{2.526}{3.1}+\frac{0.470}{0.623}+\frac{80.705}{0.4326}$
b. $(6.404 \times 2.91) /(18.7-17.1)$
c. $6.071 \times 10^{-5}-8.2 \times 10^{-6}-0.521 \times 10^{-4}$
d. $\left(3.8 \times 10^{-12}+4.0 \times 10^{-13}\right) /\left(4 \times 10^{12}+6.3 \times 10^{13}\right)$
e. $\frac{9.5+4.1+2.8+3.175}{4}$
(Assume that this operation is taking the average of four numbers. Thus 4 in the denominator is exact.)
f. $\frac{8.925-8.905}{8.925} \times 100$
(This type of calculation is done many times in calculating a percentage error. Assume that this example is such a calculation; thus 100 can be considered to be an exact number.)
42. Perform the following mathematical operations, and express the result to the correct number of significant figures.
a. $6.022 \times 10^{23} \times 1.05 \times 10^{2}$
b. $\frac{6.6262 \times 10^{-34} \times 2.998 \times 10^{8}}{2.54 \times 10^{-9}}$
c. $1.285 \times 10^{-2}+1.24 \times 10^{-3}+1.879 \times 10^{-1}$
d. $\frac{(1.00866-1.00728)}{6.02205 \times 10^{23}}$
e. $\frac{9.875 \times 10^{2}-9.795 \times 10^{2}}{9.875 \times 10^{2}} \times 100(100$ is exact)
f. $\frac{9.42 \times 10^{2}+8.234 \times 10^{2}+1.625 \times 10^{3}}{3}(3$ is exact $)$

Perform each of the following conversions.
a. 8.43 cm to millimeters
b. $2.41 \times 10^{2} \mathrm{~cm}$ to meters
c. 294.5 nm to centimeters
d. $1.445 \times 10^{4} \mathrm{~m}$ to kilometers
e. 235.3 m to millimeters
f. 903.3 nm to micrometers
44. a. How many kilograms are in 1 teragram?
b. How many nanometers are in $6.50 \times 10^{2}$ terameters?
c. How many kilograms are in 25 femtograms?
d. How many liters are in 8.0 cubic decimeters?
e. How many microliters are in 1 milliliter?
f. How many picograms are in 1 microgram?
45. Perform the following unit conversions.
a. Congratulations! You and your spouse are the proud parents of a new baby, born while you are studying in a country that uses the metric system. The nurse has informed you that the baby weighs 3.91 kg and measures 51.4 cm . Convert your baby's weight to pounds and ounces and her length to inches (rounded to the nearest quarter inch).
b. The circumference of the earth is $25,000 \mathrm{mi}$ at the equator. What is the circumference in kilometers? in meters?
c. A rectangular solid measures 1.0 m by 5.6 cm by 2.1 dm . Express its volume in cubic meters, liters, cubic inches, and cubic feet.
46. Perform the following unit conversions.
a. 908 oz to kilograms
b. 12.8 L to gallons
c. 125 mL to quarts
d. 2.89 gal to milliliters
e. 4.48 lb to grams
f. 550 mL to quarts
-47. Use the following exact conversion factors to perform the stated calculations:

$$
\begin{aligned}
5 \frac{1}{2} \mathrm{yd} & =1 \text { rod } \\
40 \text { rods } & =1 \text { furlong } \\
8 \text { furlongs } & =1 \text { mile }
\end{aligned}
$$

a. The Kentucky Derby race is 1.25 miles. How long is the race in rods, furlongs, meters, and kilometers?
b. A marathon race is 26 miles, 385 yards. What is this distance in rods, furlongs, meters, and kilometers?
48. Although the preferred SI unit of area is the square meter, land is often measured in the metric system in hectares (ha). One hectare is equal to $10,000 \mathrm{~m}^{2}$. In the English system, land is often measured in acres ( 1 acre $=160 \operatorname{rod}^{2}$ ). Use the exact conversions and those given in Exercise 47 to calculate the following.
a. $1 \mathrm{ha}=$ $\qquad$ $\mathrm{km}^{2}$
b. The area of a 5.5 -acre plot of land in hectares, square meters, and square kilometers
c. A lot with dimensions 120 ft by 75 ft is to be sold for $\$ 6500$. What is the price per acre? What is the price per hectare?
49. Precious metals and gems are measured in troy weights in the English system:

$$
\begin{aligned}
24 \text { grains } & =1 \text { pennyweight (exact) } \\
20 \text { pennyweight } & =1 \text { troy ounce (exact) } \\
12 \text { troy ounces } & =1 \text { troy pound (exact) } \\
1 \text { grain } & =0.0648 \mathrm{~g} \\
1 \text { carat } & =0.200 \mathrm{~g}
\end{aligned}
$$

a. The most common English unit of mass is the pound avoirdupois. What is 1 troy pound in kilograms and in pounds?
b. What is the mass of a troy ounce of gold in grams and in carats?
c. The density of gold is $19.3 \mathrm{~g} / \mathrm{cm}^{3}$. What is the volume of a troy pound of gold?
50. Apothecaries (druggists) use the following set of measures in the English system:

$$
\begin{aligned}
20 \text { grains ap } & =1 \text { scruple (exact) } \\
3 \text { scruples } & =1 \text { dram ap (exact) } \\
8 \text { dram ap } & =1 \mathrm{oz} \text { ap (exact) } \\
1 \text { dram ap } & =3.888 \mathrm{~g}
\end{aligned}
$$

a. Is an apothecary grain the same as a troy grain? (See Exercise 49.)
b. 1 oz ap $=$ $\qquad$ oz troy.
c. An aspirin tablet contains $5.00 \times 10^{2} \mathrm{mg}$ of active ingredient. What mass in grains ap of active ingredient does it contain? What mass in scruples?
d. What is the mass of 1 scruple in grams?
-51. For a pharmacist dispensing pills or capsules, it is often easier to weigh the medication to be dispensed than to count the individual pills. If a single antibiotic capsule weighs 0.65 g , and a pharmacist weighs out 15.6 g of capsules, how many capsules have been dispensed?
52. A children's pain relief elixir contains $80 . \mathrm{mg}$ acetaminophen per 0.50 teaspoon. The dosage recommended for a child who weighs between 24 and 35 lb is 1.5 teaspoons. What is the range of acetaminophen dosages, expressed in mg acetaminophen $/ \mathrm{kg}$ body weight, for children who weigh between 24 and 35 lb ?
53. Science fiction often uses nautical analogies to describe space travel. If the starship U.S.S. Enterprise is traveling at warp factor 1.71 , what is its speed in knots and in miles per hour? (Warp $1.71=5.00$ times the speed of light; speed of light $=$ $3.00 \times 10^{8} \mathrm{~m} / \mathrm{s} ; 1 \mathrm{knot}=2030 \mathrm{yd} / \mathrm{h}$. )
54. The world record for the hundred meter dash is 9.58 s . What is the corresponding average speed in units of $\mathrm{m} / \mathrm{s}, \mathrm{km} / \mathrm{h}, \mathrm{ft} / \mathrm{s}$, and $\mathrm{mi} / \mathrm{h}$ ? At this speed, how long would it take to run $1.00 \times$ $10^{2}$ yards?

You are driving $65 \mathrm{mi} / \mathrm{h}$ and take your eyes off the road for "just a second." What distance (in feet) do you travel in this time?
56. You pass a road sign saying "New York 112 km ." If you drive at a constant speed of $65 \mathrm{mi} / \mathrm{h}$, how long should it take you to reach New York? If your car gets 28 miles to the gallon, how many liters of gasoline are necessary to travel 112 km ?

The dosage for an antibiotic is prescribed at 8.0 mg per kilogram of body weight, taken twice daily for two weeks. What total mass of antibiotic will be taken by a $180-\mathrm{lb}$ person for the two-week period?
58. In recent years, there has been a large push for an increase in the use of renewable resources to produce the energy we need to power our vehicles. One of the newer fuels that has become more widely available is E85, a mixture of $85 \%$ ethanol and $15 \%$ gasoline. Despite being more environmentally friendly, one of the potential drawbacks of E85 fuel is that it produces less energy than conventional gasoline. Assume a car gets $28.0 \mathrm{mi} / \mathrm{gal}$ using gasoline at $\$ 3.50 / \mathrm{gal}$ and $22.5 \mathrm{mi} / \mathrm{gal}$ using E85 at $\$ 2.85 / \mathrm{gal}$. How much will it cost to drive 500 . miles using each fuel?
59. Mercury poisoning is a debilitating disease that is often fatal. In the human body, mercury reacts with essential enzymes leading to irreversible inactivity of these enzymes. If the amount of mercury in a polluted lake is $0.4 \mu \mathrm{~g} \mathrm{Hg} / \mathrm{mL}$, what is the total mass in kilograms of mercury in the lake? (The lake has a surface area of $100 \mathrm{mi}^{2}$ and an average depth of 20 ft .)
60. Carbon monoxide (CO) detectors sound an alarm when peak levels of carbon monoxide reach 100 parts per million (ppm). This level roughly corresponds to a composition of air that contains $400,000 \mu \mathrm{~g}$ carbon monoxide per cubic meter of air $\left(400,000 \mu \mathrm{~g} / \mathrm{m}^{3}\right)$. Assuming the dimensions of a room are $18 \mathrm{ft} \times 12 \mathrm{ft} \times 8 \mathrm{ft}$, estimate the mass of carbon monoxide in the room that would register 100 ppm on a carbon monoxide detector.

## Temperature

-61. Convert the following Fahrenheit temperatures to the Celsius and Kelvin scales.
a. $-459^{\circ} \mathrm{F}$, an extremely low temperature
b. $-40 .{ }^{\circ} \mathrm{F}$, the answer to a trivia question
c. $68^{\circ} \mathrm{F}$, room temperature
d. $7 \times 10^{7}{ }^{\circ} \mathrm{F}$, temperature required to initiate fusion reactions in the sun
62. A thermometer gives a reading of $96.1^{\circ} \mathrm{F} \pm 0.2^{\circ} \mathrm{F}$. What is the temperature in ${ }^{\circ} \mathrm{C}$ ? What is the uncertainty?
63. Convert the following Celsius temperatures to Kelvin and to Fahrenheit degrees.
a. the temperature of someone with a fever, $39.2^{\circ} \mathrm{C}$
b. a cold wintery day, $-25^{\circ} \mathrm{C}$
c. the lowest possible temperature, $-273^{\circ} \mathrm{C}$
d. the melting-point temperature of sodium chloride, $801^{\circ} \mathrm{C}$
64. Convert the following Kelvin temperatures to Celsius and Fahrenheit degrees.
a. the temperature that registers the same value on both the Fahrenheit and Celsius scales, 233 K
b. the boiling point of helium, 4 K
c. the temperature at which many chemical quantities are determined, 298 K
d. the melting point of tungsten, 3680 K

At what temperature is the temperature in degrees Fahrenheit equal to twice the temperature in degrees Celsius?
66. The average daytime temperatures on the earth and Jupiter are $72^{\circ} \mathrm{F}$ and 313 K , respectively. Calculate the difference in temperature, in ${ }^{\circ} \mathrm{C}$, between these two planets.
-67. Use the figure below to answer the following questions.

a. Derive the relationship between ${ }^{\circ} \mathrm{C}$ and ${ }^{\circ} \mathrm{X}$.
b. If the temperature outside is $22.0^{\circ} \mathrm{C}$, what is the temperature in units of ${ }^{\circ} \mathrm{X}$ ?
c. Convert $58.0^{\circ} \mathrm{X}$ to units of ${ }^{\circ} \mathrm{C}, \mathrm{K}$, and ${ }^{\circ} \mathrm{F}$.
68. Ethylene glycol is the main component in automobile antifreeze. To monitor the temperature of an auto cooling system, you intend to use a meter that reads from 0 to 100 . You devise a new temperature scale based on the approximate melting and boiling points of a typical antifreeze solution $\left(-45^{\circ} \mathrm{C}\right.$ and $115^{\circ} \mathrm{C}$ ). You wish these points to correspond to $0^{\circ} \mathrm{A}$ and $100^{\circ} \mathrm{A}$, respectively.
a. Derive an expression for converting between ${ }^{\circ} \mathrm{A}$ and ${ }^{\circ} \mathrm{C}$.
b. Derive an expression for converting between ${ }^{\circ} \mathrm{F}$ and ${ }^{\circ} \mathrm{A}$.
c. At what temperature would your thermometer and a Celsius thermometer give the same numerical reading?
d. Your thermometer reads $86^{\circ} \mathrm{A}$. What is the temperature in ${ }^{\circ} \mathrm{C}$ and in ${ }^{\circ} \mathrm{F}$ ?
e. What is a temperature of $45^{\circ} \mathrm{C}$ in ${ }^{\circ} \mathrm{A}$ ?

## Density

69. A material will float on the surface of a liquid if the material has a density less than that of the liquid. Given that the density of water is approximately $1.0 \mathrm{~g} / \mathrm{mL}$, will a block of material having a volume of $1.2 \times 10^{4} \mathrm{in}^{3}$ and weighing 350 lb float or sink when placed in a reservoir of water?
70. One metal object is a cube with edges of 3.00 cm and a mass of 140.4 g . A second metal object is a sphere with a radius of 1.42 cm and a mass of 61.6 g . Are these objects made of the same or different metals? Assume the calculated densities are accurate to $\pm 1.00 \%$.
-71. A star is estimated to have a mass of $2 \times 10^{36} \mathrm{~kg}$. Assuming it to be a sphere of average radius $7.0 \times 10^{5} \mathrm{~km}$, calculate the average density of the star in units of grams per cubic centimeter.
71. A rectangular block has dimensions $2.9 \mathrm{~cm} \times 3.5 \mathrm{~cm} \times$ 10.0 cm . The mass of the block is 615.0 g . What are the volume and density of the block?
-73. Diamonds are measured in carats, and 1 carat $=0.200 \mathrm{~g}$. The density of diamond is $3.51 \mathrm{~g} / \mathrm{cm}^{3}$.
a. What is the volume of a 5.0 -carat diamond?
b. What is the mass in carats of a diamond measuring 2.8 mL ?
72. At room temperature the element bromine, $\mathrm{Br}_{2}$, is a liquid with a density of $3.12 \mathrm{~g} / \mathrm{cm}^{3}$. Calculate the mass of 125 mL of bromine. What volume does 85.0 g of bromine occupy?
[75. A sample containing 33.42 g of metal pellets is poured into a graduated cylinder initially containing 12.7 mL of water, causing the water level in the cylinder to rise to 21.6 mL . Calculate the density of the metal.
73. The density of pure silver is $10.5 \mathrm{~g} / \mathrm{cm}^{3}$ at $20^{\circ} \mathrm{C}$. If 5.25 g of pure silver pellets is added to a graduated cylinder containing 11.2 mL of water, to what volume level will the water in the cylinder rise?
-77. In each of the following pairs, which has the greater mass? (See Table 1.5.)
a. 1.0 kg of feathers or 1.0 kg of lead
b. 1.0 mL of mercury or 1.0 mL of water
c. 19.3 mL of water or 1.00 mL of gold
d. 75 mL of copper or 1.0 L of benzene
74. a. Calculate the mass of ethanol in 1.50 qt of ethanol. (See Table 1.5.)
b. Calculate the mass of mercury in $3.5 \mathrm{in}^{3}$ of mercury. (See Table 1.5.)
-79. In each of the following pairs, which has the greater volume?
a. 1.0 kg of feathers or 1.0 kg of lead
b. 100 g of gold or 100 g of water
c. 1.0 L of copper or 1.0 L of mercury
75. Using Table 1.5, calculate the volume of 25.0 g of each of the following substances at 1 atm .
a. hydrogen gas
b. water
c. iron

Chapter 5 discusses the properties of gases. One property unique to gases is that they contain mostly empty space. Explain using the results of your calculations.
-81. The density of osmium (the densest metal) is $22.57 \mathrm{~g} / \mathrm{cm}^{3}$. If a $1.00-\mathrm{kg}$ rectangular block of osmium has two dimensions of $4.00 \mathrm{~cm} \times 4.00 \mathrm{~cm}$, calculate the third dimension of the block.
82. A copper wire (density $=8.96 \mathrm{~g} / \mathrm{cm}^{3}$ ) has a diameter of 0.25 mm . If a sample of this copper wire has a mass of 22 g , how long is the wire?

## Classification and Separation of Matter

83. Match each description below with the following microscopic pictures. More than one picture may fit each description. A picture may be used more than once or not used at all.

iv

v

vi
a. a gaseous compound
b. a mixture of two gaseous elements
c. a solid element
d. a mixture of a gaseous element and a gaseous compound
84. Define the following terms: solid, liquid, gas, pure substance, element, compound, homogeneous mixture, heterogeneous mixture, solution, chemical change, physical change.
85. What is the difference between homogeneous and heterogeneous matter? Classify each of the following as homogeneous or heterogeneous.
a. a door
d. the water you drink
b. the air you breathe
e. salsa
c. a cup of coffee (black)
f. your lab partner
86. Classify the following mixtures as homogeneous or heterogeneous.
a. potting soil
d. window glass
b. white wine
e. granite
c. your sock drawer
87. Classify each of the following as a mixture or a pure substance.
a. water
f. uranium
b. blood
g. wine
c. the oceans
h. leather
d. iron
i. table salt
e. brass

Of the pure substances, which are elements and which are compounds?
88. Suppose a teaspoon of magnesium filings and a teaspoon of powdered sulfur are placed together in a metal beaker. Would this constitute a mixture or a pure substance? Suppose the magnesium filings and sulfur are heated so that they react with each other, forming magnesium sulfide. Would this still be a "mixture"? Why or why not?
89. If a piece of hard, white blackboard chalk is heated strongly in a flame, the mass of the piece of chalk will decrease, and eventually the chalk will crumble into a fine white dust. Does this change suggest that the chalk is composed of an element or a compound?
90. During a very cold winter, the temperature may remain below freezing for extended periods. However, fallen snow can still disappear, even though it cannot melt. This is possible because a solid can vaporize directly, without passing through the liquid state. Is this process (sublimation) a physical or a chemical change?
-91. Classify the following as physical or chemical changes.
a. Moth balls gradually vaporize in a closet.
b. Hydrofluoric acid attacks glass and is used to etch calibration marks on glass laboratory utensils.
c. A French chef making a sauce with brandy is able to boil off the alcohol from the brandy, leaving just the brandy flavoring.
d. Chemistry majors sometimes get holes in the cotton jeans they wear to lab because of acid spills.
92. The properties of a mixture are typically averages of the properties of its components. The properties of a compound may differ dramatically from the properties of the elements that combine to produce the compound. For each process described below, state whether the material being discussed is most likely a mixture or a compound, and state whether the process is a chemical change or a physical change.
a. An orange liquid is distilled, resulting in the collection of a yellow liquid and a red solid.
b. A colorless, crystalline solid is decomposed, yielding a pale yellow-green gas and a soft, shiny metal.
c. A cup of tea becomes sweeter as sugar is added to it.

## Additional Exercises

93. Two spherical objects have the same mass. One floats on water; the other sinks. Which object has the greater diameter? Explain.
94. A 194-g sample of caffeine $\left(\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}\right)$ contains $6.02 \times 10^{23}$ molecules of caffeine. If a typical 10 -hour energy drink contains 422 mg of caffeine, how many molecules of caffeine are present in the drink?
95. Lipitor, a pharmaceutical drug that has been shown to lower "bad" cholesterol levels while raising "good" cholesterol levels in patients taking the drug, had over $\$ 3$ billion in sales in 2015. Assuming one $2.5-\mathrm{g}$ pill contains $4.0 \%$ of the active ingredient by mass, what mass in kg of active ingredient is present in one bottle of 100 pills?
96. In Shakespeare's Richard III, the First Murderer says:
"Take that, and that! [Stabs Clarence]
If that is not enough, I'll drown you in a malmsey butt within!"
Given that 1 butt $=126$ gal, in how many liters of malmsey (a foul brew similar to mead) was the unfortunate Clarence about to be drowned?
97. The contents of one $40 . \mathrm{lb}$ bag of topsoil will cover 10 . square feet of ground to a depth of 1.0 inch. What number of bags is needed to cover a plot that measures 200. by 300 . m to a depth of 4.0 cm ?
98. In the opening scenes of the movie Raiders of the Lost Ark, Indiana Jones tries to remove a gold idol from a booby-trapped pedestal. He replaces the idol with a bag of sand of approximately equal volume. (Density of gold $=19.32 \mathrm{~g} / \mathrm{cm}^{3}$; density of sand $\approx 2 \mathrm{~g} / \mathrm{cm}^{3}$.)
a. Did he have a reasonable chance of not activating the mass-sensitive booby trap?
b. In a later scene, he and an unscrupulous guide play catch with the idol. Assume that the volume of the idol is about 1.0 L. If it were solid gold, what mass would the idol have? Is playing catch with it plausible?
99. A parsec is an astronomical unit of distance where 1 parsec $=$ 3.26 light years (1 light year equals the distance traveled by light in one year). If the speed of light is $186,000 \mathrm{mi} / \mathrm{s}$, calculate the distance in meters of an object that travels 9.6 parsecs.
100. The active ingredient of aspirin tablets is acetylsalicylic acid, which has a density of $1.4 \mathrm{~g} / \mathrm{cm}^{3}$. In a lab class, a student used paper chromatography to isolate another common ingredient of headache remedies. The isolated sample had a mass of 0.384 g and a volume of $0.32 \mathrm{~cm}^{3}$. Given the data in the following table, what was the other ingredient in the headache remedy?

## Density Values for Potential Headache Remedies

| Compound | Density $\left(\mathrm{g} / \mathrm{cm}^{3}\right)$ |
| :--- | :---: |
| White table sugar | 0.70 |
| Caffeine | 1.2 |
| Acetylsalicylic acid | 1.4 |
| Sodium chloride | 2.2 |

101. This year, like many past years, you begin to feel very sleepy after eating a large helping of Thanksgiving turkey. Some people attribute this sleepiness to the presence of the amino acid tryptophan in turkey. Tryptophan can be used by the body to produce serotonin, which can calm the brain's activity and help to bring on sleep.
a. What mass in grams of tryptophan is in a $0.25-\mathrm{lb}$ serving of turkey? (Assume tryptophan accounts for $1.0 \%$ of the turkey mass.)
b. What mass in grams of tryptophan is in 0.25 quart of milk? (Assume tryptophan accounts for $2.0 \%$ of milk by mass and that the density of milk is $1.04 \mathrm{~kg} / \mathrm{L}$.)
102. Which of the following are chemical changes? Which are physical changes?
a. the cutting of food
b. interaction of food with saliva and digestive enzymes
c. proteins being broken down into amino acids
d. complex sugars being broken down into simple sugars
e. making maple syrup by heating maple sap to remove water through evaporation
f. DNA unwinding
103. A person with high cholesterol has 250 mg of cholesterol per 100.0 mL of blood. If the total blood volume of the person is 5.4 L , what is the total mass (in grams) of cholesterol present in the person's blood?
104. Assume the following numbers are known to $\pm 1$ in the last digit. Perform the following divisions and estimate the maximum uncertainty in each result, that is, determine the largest and smallest number that could occur for each case (see Appendix 1.5).
a. $103 \div 101$
b. $101 \div 99$
c. $99 \div 101$

Considering your calculated error limits, to how many significant figures should each result be expressed? Do any of these constitute an exception to the rule for division listed in Section 1.5? Rationalize any discrepancies.
105. A column of liquid is found to expand linearly on heating. Assume the column rises 5.25 cm for a $10.0^{\circ} \mathrm{F}$ rise in temperature. If the initial temperature of the liquid is $98.6^{\circ} \mathrm{F}$, what will the final temperature be in ${ }^{\circ} \mathrm{C}$ if the liquid has expanded by 18.5 cm ?
106. A $25.00-\mathrm{g}$ sample of a solid is placed in a graduated cylinder, and then the cylinder is filled to the $50.0-\mathrm{mL}$ mark with benzene. The mass of benzene and solid together is 58.80 g . Assuming that the solid is insoluble in benzene and that the density of benzene is $0.880 \mathrm{~g} / \mathrm{cm}^{3}$, calculate the density of the solid.
107. For each of the following, decide which block is more dense: the orange block, the blue block, or it cannot be determined. Explain your answers.

108. According to the Official Rules of Baseball, a baseball must have a circumference not more than 9.25 in or less than 9.00 in and a mass not more than 5.25 oz or less than 5.00 oz . What range of densities can a baseball be expected to have? Express this range as a single number with an accompanying uncertainty limit.
109. The density of an irregularly shaped object was determined as follows. The mass of the object was found to be $28.90 \mathrm{~g} \pm$ 0.03 g . A graduated cylinder was partially filled with water. The reading of the level of the water was $6.4 \mathrm{~cm}^{3} \pm 0.1 \mathrm{~cm}^{3}$. The object was dropped in the cylinder, and the level of the water rose to $9.8 \mathrm{~cm}^{3} \pm 0.1 \mathrm{~cm}^{3}$. What is the density of the object with appropriate error limits? (See Appendix 1.5.)
110. The chemist in Example 1.14 did some further experiments. She found that the pipet used to measure the volume of the liquid is accurate to $\pm 0.03 \mathrm{~cm}^{3}$. The mass measurement is accurate to $\pm 0.002 \mathrm{~g}$. Are these measurements sufficiently precise for the chemist to distinguish between isopropyl alcohol and ethanol?

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
111. The longest river in the world is the Nile River with a length of 4145 mi . How long is the Nile in cable lengths, meters, and nautical miles?
Use these exact conversions to help solve the problem:

$$
\begin{aligned}
6 \mathrm{ft} & =1 \text { fathom } \\
100 \text { fathoms } & =1 \text { cable length } \\
10 \text { cable lengths } & =1 \text { nautical mile } \\
3 \text { nautical miles } & =1 \text { league }
\end{aligned}
$$

112. Secretariat is known as the horse with the fastest run in the Kentucky Derby. If Secretariat's record $1.25-\mathrm{mi}$ run lasted 1 minute 59.2 seconds, what was his average speed in $\mathrm{m} / \mathrm{s}$ ?
113. The hottest temperature recorded in the United States is $134^{\circ} \mathrm{F}$ in Greenland Ranch, CA. The melting point of phosphorus is $44^{\circ} \mathrm{C}$. At this temperature, would phosphorus be a liquid or a solid?
114. The radius of a neon atom is 69 pm , and its mass is $3.35 \times$ $10^{-23} \mathrm{~g}$. What is the density of the atom in grams per cubic centimeter $\left(\mathrm{g} / \mathrm{cm}^{3}\right)$ ? Assume the nucleus is a sphere with volume $=\frac{4}{3} \pi r^{3}$.
115. Which of the following statements is(are) true?
a. A spoonful of sugar is a mixture.
b. Only elements are pure substances.
c. Air is a mixture of gases.
d. Gasoline is a pure substance.
e. Compounds can be broken down only by chemical means.
116. Which of the following describes a chemical property?
a. The density of iron is $7.87 \mathrm{~g} / \mathrm{cm}^{3}$.
b. A platinum wire glows red when heated.
c. An iron bar rusts.
d. Aluminum is a silver-colored metal.

## Challenge Problems

117. A rule of thumb in designing experiments is to avoid using a result that is the small difference between two large measured quantities. In terms of uncertainties in measurement, why is this good advice?
118. Draw a picture showing the markings (graduations) on glassware that would allow you to make each of the following volume measurements of water, and explain your answers (the numbers given are as precise as possible).
a. 128.7 mL
b. 18 mL
c. 23.45 mL

If you made these measurements for three samples of water and then poured all of the water together in one container, what total volume of water should you report? Support your answer.
119. Many times errors are expressed in terms of percentage. The percent error is the absolute value of the difference of the true value and the experimental value, divided by the true value, and multiplied by 100 .

$$
\text { Percent error }=\frac{\mid \text { true value }- \text { experimental value } \mid}{\text { true value }} \times 100
$$

Calculate the percent error for the following measurements.
a. The density of an aluminum block determined in an experiment was $2.64 \mathrm{~g} / \mathrm{cm}^{3}$. (True value $2.70 \mathrm{~g} / \mathrm{cm}^{3}$.)
b. The experimental determination of iron in iron ore was $16.48 \%$. (True value $16.12 \%$.)
c. A balance measured the mass of a $1.000-\mathrm{g}$ standard as 0.9981 g.
120. A person weighed 15 pennies on a balance and recorded the following masses:

| 3.112 g | 3.109 g | 3.059 g |
| :--- | :--- | :--- |
| 2.467 g | 3.079 g | 2.518 g |
| 3.129 g | 2.545 g | 3.050 g |
| 3.053 g | 3.054 g | 3.072 g |
| 3.081 g | 3.131 g | 3.064 g |

Curious about the results, he looked at the dates on each penny. Two of the light pennies were minted in 1983 and one in 1982. The dates on the 12 heavier pennies ranged from 1970 to 1982. Two of the 12 heavier pennies were minted in 1982.
a. Do you think the Bureau of the Mint changed the way it made pennies? Explain.
b. The person calculated the average mass of the 12 heavy pennies. He expressed this average as $3.0828 \mathrm{~g} \pm 0.0482 \mathrm{~g}$. What is wrong with the numbers in this result, and how should the value be expressed?
121. On October 21, 1982, the Bureau of the Mint changed the composition of pennies (see Exercise 120). Instead of an alloy of $95 \% \mathrm{Cu}$ and $5 \% \mathrm{Zn}$ by mass, a core of $99.2 \% \mathrm{Zn}$ and $0.8 \% \mathrm{Cu}$ with a thin shell of copper was adopted. The overall composition of the new penny was $97.6 \% \mathrm{Zn}$ and $2.4 \% \mathrm{Cu}$ by mass. Does this account for the difference in mass among the pennies in Exercise 120? Assume the volume of the individual metals that make up each penny can be added together to give the overall volume of the penny, and assume each penny is the same size. (Density of $\mathrm{Cu}=8.96 \mathrm{~g} / \mathrm{cm}^{3}$; density of $\mathrm{Zn}=7.14 \mathrm{~g} / \mathrm{cm}^{3}$.)
122. As part of a science project, you study traffic patterns in your city at an intersection in the middle of downtown. You set up a device that counts the cars passing through this intersection for a $24-\mathrm{hr}$ period during a weekday. The graph of hourly traffic looks like this.

a. At what time(s) does the highest number of cars pass through the intersection?
b. At what time(s) does the lowest number of cars pass through the intersection?
c. Briefly describe the trend in numbers of cars over the course of the day.
d. Provide a hypothesis explaining the trend in numbers of cars over the course of the day.
e. Provide a possible experiment that could test your hypothesis.
123. Sterling silver is a solid solution of silver and copper. If a piece of a sterling silver necklace has a mass of 105.0 g and a volume of 10.12 mL , calculate the mass percent of copper in the piece of necklace. Assume that the volume of silver present plus the volume of copper present equals the total volume. Refer to Table 1.5.

$$
\text { Mass percent of copper }=\frac{\text { mass of copper }}{\text { total mass }} \times 100
$$

124. Make molecular-level (microscopic) drawings for each of the following.
a. Show the differences between a gaseous mixture that is a homogeneous mixture of two different compounds, and a gaseous mixture that is a homogeneous mixture of a compound and an element.
b. Show the differences among a gaseous element, a liquid element, and a solid element.
*From Yoder, Suydam, and Snavely, Chemistry (New York: Harcourt Brace Jovanovich, 1975), pp. 9-11.
125. Confronted with the box shown in the diagram, you wish to discover something about its internal workings. You have no tools and cannot open the box. You pull on rope B, and it moves rather freely. When you pull on rope A , rope C appears to be pulled slightly into the box. When you pull on rope C, rope A almost disappears into the box.*

a. Based on these observations, construct a model for the interior mechanism of the box.
b. What further experiments could you do to refine your model?
126. An experiment was performed in which an empty $100-\mathrm{mL}$ graduated cylinder was weighed. It was weighed once again after it had been filled to the $10.0-\mathrm{mL}$ mark with dry sand. A $10-\mathrm{mL}$ pipet was used to transfer 10.00 mL of methanol to the cylinder. The sand-methanol mixture was stirred until bubbles no longer emerged from the mixture and the sand looked uniformly wet. The cylinder was then weighed again. Use the data obtained from this experiment (and displayed at the end of this problem) to find the density of the dry sand, the density of methanol, and the density of sand particles. Does the bubbling that occurs when the methanol is added to the dry sand indicate that the sand and methanol are reacting?

| Mass of cylinder plus wet sand | 45.2613 g |
| :--- | :--- |
| Mass of cylinder plus dry sand | 37.3488 g |
| Mass of empty cylinder | 22.8317 g |
| Volume of dry sand | 10.0 mL |
| Volume of sand plus methanol | 17.6 mL |
| Volume of methanol | 10.00 mL |

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
127. The U.S. trade deficit at the beginning of 2005 was $\$ 475,000,000$. If the wealthiest $1.00 \%$ of the U.S. population ( $297,000,000$ ) contributed an equal amount of money to bring the trade deficit to $\$ 0$, how many dollars would each person contribute? If one of these people were to pay his or her share in nickels only, how many nickels are needed? Another person living abroad at the time decides to pay in pounds sterling (£). How many pounds sterling does this person contribute (assume a conversion rate of $1 £=\$ 1.869$ )?
128. The density of osmium is reported by one source to be $22,610 \mathrm{~kg} / \mathrm{m}^{3}$. What is this density in $\mathrm{g} / \mathrm{cm}^{3}$ ? What is the mass of a block of osmium measuring $10.0 \mathrm{~cm} \times 8.0 \mathrm{~cm} \times 9.0 \mathrm{~cm}$ ?
129. At the Amundsen-Scott South Pole base station in Antarctica, when the temperature is $-100.0^{\circ} \mathrm{F}$, researchers who live there can join the " 300 Club" by stepping into a sauna heated to $200.0^{\circ} \mathrm{F}$ then quickly running outside and around the pole that marks the South Pole. What are these temperatures in ${ }^{\circ} \mathrm{C}$ ? What are these temperatures in K? If you measured the temperatures only in ${ }^{\circ} \mathrm{C}$ and K , can you become a member of the " 300 Club" (that is, is there a 300.-degree difference between the temperature extremes when measured in ${ }^{\circ} \mathrm{C}$ and K )?

Polarized light micrograph of crystals of vitamin C. (Marek Mis/Science Source)

where does one start in learning chemistry? Clearly we must consider some essential vocabulary and something about the origins of the science before we can proceed very far. Thus, while Chapter 1 provided background on the fundamental ideas and procedures of science in general, Chapter 2 covers the specific chemical background necessary for understanding the material in the next few chapters. The coverage of these topics is necessarily brief at this point. We will develop these ideas more fully as it becomes appropriate to do so. A major goal of this chapter is to present the systems for naming chemical compounds to provide you with the vocabulary necessary to understand this book and to pursue your laboratory studies.

Because chemistry is concerned first and foremost with chemical changes, we will proceed as quickly as possible to a study of chemical reactions (Chapters 3 and 4). However, before we can discuss reactions, we must consider some fundamental ideas about atoms and how they combine.

### 2.1 The Early History of Chemistry

Chemistry has been important since ancient times. The processing of natural ores to produce metals for ornaments and weapons and the use of embalming fluids are just two applications of chemical phenomena that were utilized prior to 1000 b.c.

The Greeks were the first to try to explain why chemical changes occur. By about 400 b.c. they had proposed that all matter was composed of four fundamental substances: fire, earth, water, and air. The Greeks also considered the question of whether matter is continuous, and thus infinitely divisible into smaller pieces, or composed of small, indivisible particles. Supporters of the latter position were Demokritos* of Abdera (c. 460-c. 370 в.c.) and Leucippos, who used the term atomos (which later became atoms) to describe these ultimate particles. However, because the Greeks had no experiments to test their ideas, no definitive conclusion could be reached about the divisibility of matter.

The next 2000 years of chemical history were dominated by a pseudoscience called alchemy. Some alchemists were mystics and fakes who were obsessed with the idea of turning cheap metals into gold. However, many alchemists were serious scientists, and this period saw important advances: The alchemists discovered several elements and learned to prepare the mineral acids.

The foundations of modern chemistry were laid in the sixteenth century with the development of systematic metallurgy (extraction of metals from ores) by a German, Georg Bauer (1494-1555), and the medicinal application of minerals by a Swiss alchemist/physician known as Paracelsus (full name: Philippus Theophrastus Bombastus von Hohenheim [1493-1541]).

The first "chemist" to perform truly quantitative experiments was Robert Boyle (1627-1691), who carefully measured the relationship between the pressure and volume of air. When Boyle published his book The Skeptical Chymist in 1661, the quantitative sciences of physics and chemistry were born. In addition to his results on the quantitative behavior of gases, Boyle's other major contribution to chemistry consisted of his ideas about the chemical elements. Boyle held no preconceived notion about the number of elements. In his view, a substance was an element unless it could be broken down into two or more simpler substances. As Boyle's experimental definition of an element became generally accepted, the list of known elements began to grow, and the Greek system of four elements finally died. Although Boyle was an excellent scientist, he was not always right. For example, he clung to the alchemists' views that metals were not true elements and that a way would eventually be found to change one metal into another.

[^2]

FIGURE 2.1 The Priestley Medal is the highest honor given by the American Chemical Society. It is named for Joseph Priestley, who was born in England on March 13, 1733. He performed many important scientific experiments, among them the discovery that a gas later identified as carbon dioxide could be dissolved in water to produce seltzer. Also, as a result of meeting Benjamin Franklin in London in 1766, Priestley became interested in electricity and was the first to observe that graphite was an electrical conductor. However, his greatest discovery occurred in 1774 when he isolated oxygen by heating mercuric oxide.

Because of his nonconformist political views, Priestley was forced to leave England. He died in the United States in 1804.

The phenomenon of combustion evoked intense interest in the seventeenth and eighteenth centuries. The German chemist Georg Stahl (1660-1734) suggested that a substance he called "phlogiston" flowed out of the burning material. Stahl postulated that a substance burning in a closed container eventually stopped burning because the air in the container became saturated with phlogiston. Oxygen gas, discovered by Joseph Priestley (1733-1804),* an English clergyman and scientist (Fig. 2.1), was found to support vigorous combustion and was thus supposed to be low in phlogiston. In fact, oxygen was originally called "dephlogisticated air."

### 2.2 Fundamental Chemical Laws

By the late eighteenth century, combustion had been studied extensively; the gases carbon dioxide, nitrogen, hydrogen, and oxygen had been discovered; and the list of elements continued to grow. However, it was Antoine Lavoisier (1743-1794), a French chemist (Fig. 2.2), who finally explained the true nature of combustion, thus clearing the way for the tremendous progress that was made near the end of the eighteenth century. Lavoisier, like Boyle, regarded measurement as the essential operation of chemistry. His experiments, in which he carefully weighed the reactants and products of various reactions, suggested that mass is neither created nor destroyed. Lavoisier's
*Oxygen gas was actually first observed by the Swedish chemist Karl W. Scheele (1742-1786), but because his results were published after Priestley's, the latter is commonly credited with the discovery of oxygen.

FIGURE 2.2 Antoine Lavoisier was born in Paris on August 26, 1743. Although Lavoisier's father wanted his son to follow him into the legal profession, young Lavoisier was fascinated by science. From the beginning of his scientific career, Lavoisier recognized the importance of accurate measurements. His careful weighings showed that mass is conserved in chemical reactions and that combustion involves reaction with oxygen. Also, he wrote the first modern chemistry textbook. It is not surprising that Lavoisier is often called the father of modern chemistry.

To help support his scientific work, Lavoisier invested in a private taxcollecting firm and married the daughter of one of the company executives. His connection to the tax collectors proved fatal, for radical French revolutionaries demanded his execution, which occurred on the guillotine on May 8, 1794.

Oxygen is from the French oxygène, meaning "generator of acid," because it was initially considered to be an integral part of all acids.

verification of this law of conservation of mass was the basis for the developments in chemistry in the nineteenth century. Mass is neither created nor destroyed in a chemical reaction.

Lavoisier's quantitative experiments showed that combustion involved oxygen (which Lavoisier named), not phlogiston. He also discovered that life was supported by a process that also involved oxygen and was similar in many ways to combustion. In 1789 Lavoisier published the first modern chemistry textbook, Elementary Treatise on Chemistry, in which he presented a unified picture of the chemical knowledge assembled up to that time. Unfortunately, in the same year the text was published, the French Revolution broke out. Lavoisier, who had been associated with collecting taxes for the government, was executed on the guillotine as an enemy of the people in 1794.

After 1800, chemistry was dominated by scientists who, following Lavoisier's lead, performed careful weighing experiments to study the course of chemical reactions and to determine the composition of various chemical compounds. One of these chemists, a Frenchman, Joseph Proust (1754-1826), showed that a given compound always contains exactly the same proportion of elements by mass. For example, Proust found that the substance copper carbonate is always 5.3 parts copper to 4 parts oxygen to 1 part carbon (by mass). The principle of the constant composition of compounds, originally called "Proust's law," is now known as the law of definite proportion. A given compound always contains exactly the same proportion of elements by mass.

Proust's discovery stimulated John Dalton (1766-1844), an English schoolteacher (Fig. 2.3), to think about atoms as the particles that might compose elements. Dalton reasoned that if elements were composed of tiny individual particles, a given compound should always contain the same combination of these atoms. This concept explained why the same relative masses of elements were always found in a given compound.

But Dalton discovered another principle that convinced him even more of the existence of atoms. He noted, for example, that carbon and oxygen form two different compounds that contain different relative amounts of carbon and oxygen, as shown by the following data:

|  | Mass of Oxygen That <br> Combines with 1 g of Carbon |
| :--- | :---: |
| Compound I | 1.33 g |
| Compound II | 2.66 g |

Dalton noted that compound II contains twice as much oxygen per gram of carbon as compound I, a fact that could easily be explained in terms of atoms. Compound I might be CO , and compound II might be $\mathrm{CO}_{2}$.* This principle, which was found to apply to compounds of other elements as well, became known as the law of multiple proportions: When two elements form a series of compounds, the ratios of the masses of the second element that combine with 1 g of the first element can always be reduced to small whole numbers.
*Subscripts are used to show the numbers of atoms present. The number 1 is understood (not written). The symbols for the elements and the writing of chemical formulas will be illustrated further in Sections 2.6 and 2.7.

To make sure the significance of this observation is clear, in Example 2.1 we will consider data for a series of compounds consisting of nitrogen and oxygen.

## EXAMPLE 2.1 Illustrating the Law of Multiple Proportions

The following data were collected for several compounds of nitrogen and oxygen:

|  | Mass of Nitrogen That <br> Combines with 1 g of Oxygen |
| :--- | :---: |
| Compound A | 1.750 g |
| Compound B | 0.8750 g |
| Compound C | 0.4375 g |

Show how these data illustrate the law of multiple proportions.
SOLUTION For the law of multiple proportions to hold, the ratios of the masses of nitrogen combining with 1 g of oxygen in each pair of compounds should be small whole numbers. We therefore compute the ratios as follows:

$$
\begin{aligned}
& \frac{\mathrm{A}}{\mathrm{~B}}=\frac{1.750}{0.8750}=\frac{2}{1} \\
& \frac{\mathrm{~B}}{\mathrm{C}}=\frac{0.8750}{0.4375}=\frac{2}{1} \\
& \frac{\mathrm{~A}}{\mathrm{C}}=\frac{1.750}{0.4375}=\frac{4}{1}
\end{aligned}
$$

These results support the law of multiple proportions.

## See Exercises 2.41 and 2.42

The significance of the data in Example 2.1 is that compound A contains twice as much nitrogen $(\mathrm{N})$ per gram of oxygen $(\mathrm{O})$ as does compound B and that compound B contains twice as much nitrogen per gram of oxygen as does compound C .

These data can be explained readily if the substances are composed of molecules made up of nitrogen atoms and oxygen atoms. For example, one set of possibilities for compounds $\mathrm{A}, \mathrm{B}$, and C is
A:

B:

C:

Now we can see that compound A contains two atoms of N for every atom of O , whereas compound B contains one atom of N per atom of O . That is, compound A contains twice as much nitrogen per given amount of oxygen as does compound B. Similarly, since compound B contains one N per O and compound C contains one N per two Os, the nitrogen content of compound $C$ per given amount of oxygen is half that of compound $B$.

Another set of compounds that fits the data in Example 2.1 is
A:

$\frac{\mathrm{N}}{\mathrm{O}}=\frac{1}{1}$
B:

$\frac{\mathrm{N}}{\mathrm{O}}=\frac{1}{2}$
C:

Verify for yourself that these compounds satisfy the requirements.

Still another set that works is
A:

$\frac{\mathrm{N}}{\mathrm{O}}=\frac{4}{2}$
B:

$\frac{\mathrm{N}}{\mathrm{O}}=\frac{2}{2}$
C:

$\frac{\mathrm{N}}{\mathrm{O}}=\frac{2}{4}$

See if you can come up with still another set of compounds that satisfies the data in Example 2.1. How many more possibilities are there?

In fact, an infinite number of other possibilities exists. Dalton could not deduce absolute formulas from the available data on relative masses. However, the data on the composition of compounds in terms of the relative masses of the elements supported his hypothesis that each element consisted of a certain type of atom and that compounds were formed from specific combinations of atoms.

### 2.3 Dalton's Atomic Theory

These statements are a modern paraphrase of Dalton's ideas.

In 1808 Dalton published A New System of Chemical Philosophy, in which he presented his theory of atoms:

## Dalton's Atomic Theory

1. Each element is made up of tiny particles called atoms.
2. The atoms of a given element are identical; the atoms of different elements are different in some fundamental way or ways.
3. Chemical compounds are formed when atoms of different elements combine with each other. A given compound always has the same relative numbers and types of atoms.
4. Chemical reactions involve reorganization of the atoms-changes in the way they are bound together. The atoms themselves are not changed in a chemical reaction.

It is instructive to consider Dalton's reasoning on the relative masses of the atoms of the various elements. In Dalton's time water was known to be composed of the elements hydrogen and oxygen, with 8 g of oxygen present for every 1 g of hydrogen. If the formula for water were OH , an oxygen atom would have to have 8 times the mass of a hydrogen atom. However, if the formula for water were $\mathrm{H}_{2} \mathrm{O}$ (two atoms of hydrogen for every oxygen atom), this would mean that each atom of oxygen is 16 times as massive as each atom of hydrogen (since the ratio of the mass of one oxygen to that of two hydrogens is 8 to 1 ). Because the formula for water was not then known, Dalton could not specify the relative masses of oxygen and hydrogen unambiguously. To solve the problem, Dalton made a fundamental assumption: He decided that nature would be as simple as possible. This assumption led him to conclude that the formula for water should be OH . He thus assigned hydrogen a mass of 1 and oxygen a mass of 8 .

Using similar reasoning for other compounds, Dalton prepared the first table of atomic masses (sometimes called atomic weights by chemists, since mass is often determined by comparison to a standard mass-a process called weighing). Many of the masses were later proved to be wrong because of Dalton's incorrect assumptions about the formulas of certain compounds, but the construction of a table of masses was an important step forward.

Although not recognized as such for many years, the keys to determining absolute formulas for compounds were provided in the experimental work of the French chemist Joseph Gay-Lussac (1778-1850) and by the hypothesis of an Italian chemist named

There are seven elements that occur as diatomic molecules:

$$
\mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{O}_{2}, \mathrm{~F}_{2}, \mathrm{Cl}_{2}, \mathrm{Br}_{2}, \mathrm{I}_{2}
$$

Joseph Louis Gay-Lussac, a French physicist and chemist, was remarkably versatile. Although he is now known primarily for his studies on the combining of volumes of gases, Gay-Lussac was instrumental in the studies of many of the other properties of gases. Some of Gay-Lussac's motivation to learn about gases arose from his passion for ballooning. In fact, he made ascents to heights of over 4 miles to collect air samples, setting altitude records that stood for about 50 years. Gay-Lussac also was the codiscoverer of boron and the developer of a process for manufacturing sulfuric acid. As chief assayer of the French mint, Gay-Lussac developed many techniques for chemical analysis and invented many types of glassware now used routinely in labs. Gay-Lussac spent his last 20 years as a lawmaker in the French government.

Amadeo Avogadro (1776-1856). In 1809 Gay-Lussac performed experiments in which he measured (under the same conditions of temperature and pressure) the volume of gases that reacted with each other. For example, Gay-Lussac found that 2 volumes of hydrogen react with 1 volume of oxygen to form 2 volumes of gaseous water and that 1 volume of hydrogen reacts with 1 volume of chlorine to form 2 volumes of hydrogen chloride. These results are represented schematically in Fig. 2.4.

In 1811 Avogadro interpreted these results by proposing that at the same temperature and pressure, equal volumes of different gases contain the same number of particles. This assumption (called Avogadro's hypothesis) makes sense if the distances between the particles in a gas are very great compared with the sizes of the particles. Under these conditions, the volume of a gas is determined by the number of molecules present, not by the size of the individual particles.

If Avogadro's hypothesis is correct, Gay-Lussac's result,
2 volumes of hydrogen react with 1 volume of oxygen $\longrightarrow 2$ volumes of water vapor can be expressed as follows:

2 molecules* of hydrogen react with 1 molecule of oxygen $\longrightarrow 2$ molecules of water
These observations can best be explained by assuming that gaseous hydrogen, oxygen, and chlorine are all composed of diatomic (two-atom) molecules: $\mathrm{H}_{2}, \mathrm{O}_{2}$, and $\mathrm{Cl}_{2}$, respectively. Gay-Lussac's results can then be represented as shown in Fig. 2.5. (Note that this reasoning suggests that the formula for water is $\mathrm{H}_{2} \mathrm{O}$, not OH as Dalton believed.)

Unfortunately, Avogadro's interpretations were not accepted by most chemists, and a half-century of confusion followed, in which many different assumptions were made about formulas and atomic masses.

During the nineteenth century, painstaking measurements were made of the masses of various elements that combined to form compounds. From these experiments a list of relative atomic masses could be determined. One of the chemists involved in contributing to this list was a Swede named Jöns Jakob Berzelius (1779-1848), who
*A molecule is a collection of atoms (see Section 2.6).

2 volumes hydrogen
combines with 1 volume oxygen
to form
2 volumes gaseous water

1 volume hydrogen

FIGURE 2.4 A representation of some of Gay-Lussac's experimental results on combining gas volumes.

## Berzelius, Selenium, and Silicon

Jox
öns Jakob Berzelius was probably the best experimental chemist of his generation and, given the crudeness of his laboratory equipment, maybe the best of all time. Unlike Lavoisier, who could afford to buy the best laboratory equipment available, Berzelius worked with minimal equipment in very plain surroundings. One of Berzelius's students described the Swedish chemist's workplace:"The laboratory consisted of two ordinary rooms with the very simplest arrangements; there were neither furnaces nor hoods, neither water system nor gas. Against the walls stood some closets with the chemicals, in the middle the mercury trough and the blast lamp table. Beside this was the sink consisting of a stone water holder with a stopcock and a pot standing under it. [Next door in the kitchen] stood a small heating furnace."

In these simple facilities, Berzelius performed more than 2000 experiments over a 10-year period to determine accurate atomic masses for the 50 elements then known. His success can be seen from the data in the table at right. These remarkably accurate values attest to his experimental skills and patience.

Besides his table of atomic masses, Berzelius made many other major contributions to chemistry. The most important of these was the invention of a simple set of symbols for the elements along with a system for writing the formulas of compounds to replace the awkward symbolic representations of the alchemists. Although some chemists, including Dalton, objected to the new system, it was gradually adopted and forms the basis of the system we use today.

In addition to these accomplishments, Berzelius discovered the elements cerium, thorium, selenium, and silicon. Of these elements, selenium

Comparison of Several of Berzelius's Atomic Masses with the Modern Values

|  | Atomic Mass |  |
| :--- | ---: | ---: |
| Element | Berzelius's <br> Value | Current <br> Value |
| Chlorine | 35.41 | 35.45 |
| Copper | 63.00 | 63.55 |
| Hydrogen | 1.00 | 1.01 |
| Lead | 207.12 | 207.2 |
| Nitrogen | 14.05 | 14.01 |
| Oxygen | 16.00 | 16.00 |
| Potassium | 39.19 | 39.10 |
| Silver | 108.12 | 107.87 |
| Sulfur | 32.18 | 32.07 |

FIGURE 2.5 A representation of combining gases at the molecular level. The spheres represent atoms in the molecules.

discovered the elements cerium, selenium, silicon, and thorium and developed the modern symbols for the elements used in writing the formulas of compounds.

### 2.4 Early Experiments to Characterize the Atom

On the basis of the work of Dalton, Gay-Lussac, Avogadro, and others, chemistry was beginning to make sense. The concept of atoms was clearly a good idea. Inevitably, scientists began to wonder about the nature of the atom. What is an atom made of, and how do the atoms of the various elements differ?

## The Alchemists' Symbols for Some Common Elements and Compounds

| Substance | Alchemists' <br> Symbol |
| :--- | :---: |
| Silver | $D$ |
| Lead | 5 |
| Tin | DC |
| Platinum | $+\bigoplus$ |
| Sulfuric acid | $\boxed{5}$ |
| Alcohol | $\ddots$ |
| Sea salt |  |

and silicon are particularly important in today's world. Berzelius discovered selenium in 1817 in connection with his studies of sulfuric acid. For years selenium's toxicity has been known, but only recently have we become aware that it may have a positive effect on human health. Studies have shown that trace amounts of selenium in the diet may protect people from heart disease and cancer. One study based

on data from 27 countries showed an inverse relationship between the cancer death rate and the selenium content of soil in a particular region (low cancer death rate in areas with high selenium content). Another research paper reported an inverse relationship between the selenium content of the blood and the incidence of breast cancer in women. A study reported in 1998 used the toenail clippings of 33,737 men to show that selenium seems to protect against prostate cancer. Selenium is also found in the heart muscle and may play an important role in proper heart function. Because of these and other studies, selenium's reputation has improved, and many scientists are now studying its function in the human body.

Silicon is the second most abundant element in the earth's crust, exceeded only by oxygen. As we will see in Chapter 10, compounds involving silicon bonded to oxygen make up most of the earth's sand, rock, and soil. Berzelius prepared silicon in its
pure form in 1824 by heating silicon tetrafluoride $\left(\mathrm{SiF}_{4}\right)$ with potassium metal. Today, silicon forms the basis for the modern microelectronics industry centered near San Francisco in a place that has come to be known as "Silicon Valley." The technology of the silicon chip (see figure) with its printed circuits has transformed computers from room-sized monsters with thousands of unreliable vacuum tubes to desktop and notebook-sized units with trouble-free "solid-state" circuitry.

A chip capable of transmitting 4,000,000 simultaneous phone conversations.

## The Electron

The first important experiments that led to an understanding of the composition of the atom were done by the English physicist J. J. Thomson (Fig. 2.6), who studied electrical discharges in partially evacuated tubes called cathode-ray tubes (Fig. 2.7) during the period from 1898 to 1903 . Thomson found that when high voltage was applied to the tube, a "ray" he called a cathode ray (because it emanated from the negative electrode, or cathode) was produced. Because this ray was produced at the negative electrode and was repelled by the negative pole of an applied electric field (Fig. 2.8), Thomson postulated that the ray was a stream of negatively charged particles, now called electrons. From experiments in which he measured the deflection of the beam of electrons in a magnetic field, Thomson determined the charge-to-mass ratio of an electron:

$$
\frac{e}{m}=-1.76 \times 10^{8} \mathrm{C} / \mathrm{g}
$$

where $e$ represents the charge on the electron in coulombs (C) and $m$ represents the electron mass in grams.

FIGURE 2.6 J. J. Thomson (1856-1940) was an English physicist at Cambridge University. He received the Nobel Prize in physics in 1906.

FIGURE 2.7 A cathode-ray tube. The fast-moving electrons excite the gas in the tube, causing a glow between the electrodes. The green color in the photo is due to the response of the screen (coated with zinc sulfide) to the electron beam.

## A

A classic English plum pudding in which the raisins represent the distribution of electrons in the atom.

One of Thomson's primary goals in his cathode-ray tube experiments was to gain an understanding of the structure of the atom. He reasoned that since electrons could be produced from electrodes made of various types of metals, all atoms must contain electrons. Since atoms were known to be electrically neutral, Thomson further assumed that atoms also must contain some positive charge. Thomson postulated that an atom consisted of a diffuse cloud of positive charge with the negative electrons embedded randomly in it. This model, shown in Fig. 2.9, is often called the plum pudding model because the electrons are like raisins dispersed in a pudding (the positive charge cloud), as in plum pudding, a favorite English dessert.

In 1909 Robert Millikan (1868-1953), working at the University of Chicago, performed very clever experiments involving charged oil drops. These experiments allowed him to determine the magnitude of the electron charge (Fig. 2.10). With this value and the charge-to-mass ratio determined by Thomson, Millikan was able to calculate the mass of the electron as $9.11 \times 10^{-31} \mathrm{~kg}$.

## Radioactivity

In the late nineteenth century, scientists discovered that certain elements produce highenergy radiation. For example, in 1896 the French scientist Henri Becquerel found accidentally that a piece of a mineral containing uranium could produce its image on a photographic plate in the absence of light. He attributed this phenomenon to a spontaneous emission of radiation by the uranium, which he called radioactivity. Studies in the early twentieth century demonstrated three types of radioactive emission: gamma ( $\gamma$ ) rays, beta $(\beta)$ particles, and alpha $(\alpha)$ particles. A $\gamma$ ray is high-energy "light"; a $\beta$ particle is a high-speed electron; and an $\alpha$ particle has a $2+$ charge, that is, a charge twice that of the electron and with the opposite sign. The mass of an $\alpha$ particle

FIGURE 2.8 Deflection of cathode rays by an applied electric field.
is 7300 times that of the electron. More modes of radioactivity are now known, and we will discuss them in Chapter 19. Here we will consider only $\alpha$ particles because they were used in some crucial early experiments.

## The Nuclear Atom

In 1911 Ernest Rutherford (Fig. 2.11), who performed many of the pioneering experiments to explore radioactivity, carried out an experiment to test Thomson's plum pudding model. The experiment involved directing $\alpha$ particles at a thin sheet of metal foil, as illustrated in Fig. 2.12. Rutherford reasoned that if Thomson's model were accurate, the massive $\alpha$ particles should crash through the thin foil like cannonballs through gauze, as shown in Fig. 2.13(a). He expected the $\alpha$ particles to travel through the foil with, at the most, very minor deflections in their paths. The results of the experiment

FIGURE 2. 11 Ernest Rutherford (1871-1937) was born on a farm in New Zealand. In 1895 he placed second in a scholarship competition to attend Cambridge University but was awarded the scholarship when the winner decided to stay home and get married. As a scientist in England, Rutherford did much of the early work on characterizing radioactivity. He named the $\alpha$ and $\beta$ particles and the $\gamma$ ray and coined the term half-life to describe an important attribute of radioactive elements. His experiments on the behavior of $\alpha$ particles striking thin metal foils led him to postulate the nuclear atom. He also invented the name proton for the nucleus of the hydrogen atom. He received the Nobel Prize in chemistry in 1908.

FIGURE 2.12 Rutherford's experiment on $\alpha$-particle bombardment of metal foil.

FIGURE 2.10 (a) A schematic representation of the apparatus Millikan used to determine the charge on the electron. The fall of charged oil droplets due to gravity can be halted by adjusting the voltage across the two plates. This voltage and the mass of the oil drop can then be used to calculate the charge on the oil drop. Millikan's experiments showed that the charge on an oil drop is always a whole-number multiple of the electron charge. (b) A photograph of Millikan's apparatus.

FIGURE 2.13 Rutherford's experiment.

-a
The expected results of the metal foil experiment if Thomson's model were correct.

-b
Actual results.
were very different from those Rutherford anticipated. Although most of the $\alpha$ particles passed straight through, many of the particles were deflected at large angles, as shown in Fig. 2.13(b), and some were reflected, never hitting the detector. This outcome was a great surprise to Rutherford. (He wrote that this result was comparable with shooting a howitzer at a piece of paper and having the shell reflected back.)

Rutherford knew from these results that the plum pudding model for the atom could not be correct. The large deflections of the $\alpha$ particles could be caused only by a center of concentrated positive charge that contains most of the atom's mass, as illustrated in Fig. 2.13(b). Most of the $\alpha$ particles pass directly through the foil because the atom is mostly open space. The deflected $\alpha$ particles are those that had a "close encounter" with the massive positive center of the atom, and the few reflected $\alpha$ particles are those that made a "direct hit" on the much more massive positive center.

In Rutherford's mind these results could be explained only in terms of a nuclear atom-an atom with a dense center of positive charge (the nucleus) with electrons moving around the nucleus at a distance that is large relative to the nuclear radius.
 models of the atom: Dalton's model, Thomson's model, and Rutherford's model. What if Dalton was correct? What would Rutherford have expected from his experiments with gold foil? What if Thomson was correct? What would Rutherford have expected from his experiments with gold foil?

### 2.5 The Modern View of Atomic Structure: An Introduction

In the years since Thomson and Rutherford, a great deal has been learned about atomic structure. Because much of this material will be covered in detail in later chapters, only an introduction will be given here. The simplest view of the atom is that it consists of a tiny nucleus (with a diameter of about $10^{-13} \mathrm{~cm}$ ) and electrons that move about the nucleus at an average distance of about $10^{-8} \mathrm{~cm}$ from it (Fig. 2.14).

As we will see later, the chemistry of an atom mainly results from its electrons. For this reason, chemists can be satisfied with a relatively crude nuclear model. The nucleus is assumed to contain protons, which have a positive charge equal in magnitude to the electron's negative charge, and neutrons, which have virtually the same mass as a proton

FIGURE 2.14 A nuclear atom viewed in cross section. Note that this drawing is not to scale.

A
If the atomic nucleus were the size of this ball bearing, a typical atom would be the size of this stadium.

The chemistry of an atom arises from its electrons.

TABLE 2.1 | The Mass and Charge of the Electron, Proton, and Neutron

| Particle | Mass | Charge* |
| :--- | :--- | :--- |
| Electron | $9.109 \times 10^{-31} \mathrm{~kg}$ | $1-$ |
| Proton | $1.673 \times 10^{-27} \mathrm{~kg}$ | $1+$ |
| Neutron | $1.675 \times 10^{-27} \mathrm{~kg}$ | None |

*The magnitude of the charge of the electron and the proton is $1.60 \times 10^{-19} \mathrm{C}$.
but no charge. The masses and charges of the electron, proton, and neutron are shown in Table 2.1.

Two striking things about the nucleus are its small size compared with the overall size of the atom and its extremely high density. The tiny nucleus accounts for almost all the atom's mass. Its great density is dramatically demonstrated by the fact that a piece of nuclear material about the size of a pea would have a mass of 250 million tons!

An important question to consider at this point is, "If all atoms are composed of these same components, why do different atoms have different chemical properties?" The answer to this question lies in the number and the arrangement of the electrons. The electrons constitute most of the atomic volume and thus are the parts that "intermingle" when atoms combine to form molecules. Therefore, the number of electrons possessed by a given atom greatly affects its ability to interact with other atoms. As a result, the atoms of different elements, which have different numbers of protons and electrons, show different chemical behavior.

A sodium atom has 11 protons in its nucleus. Since atoms have no net charge, the number of electrons must equal the number of protons. Therefore, a sodium atom has 11 electrons moving around its nucleus. It is always true that a sodium atom has 11 protons and 11 electrons. However, each sodium atom also has neutrons in its nucleus, and different types of sodium atoms exist that have different numbers of neutrons. For example, consider the sodium atoms represented in Fig. 2.15. These two atoms are isotopes, or atoms with the same number of protons but different numbers of neutrons. Note that the symbol for one particular type of sodium atom is written

where the atomic number $Z$ (number of protons) is written as a subscript, and the mass number $A$ (the total number of protons and neutrons) is written as a superscript. (The particular atom represented here is called "sodium twenty-three." It has 11 electrons, 11 protons, and 12 neutrons.) Because the chemistry of an atom is due to its electrons,

FIGURE 2.15 Two isotopes of sodium. Both have 11 protons and 11 electrons, but they differ in the number of neutrons in their nuclei.

isotopes show almost identical chemical properties. In nature most elements contain mixtures of isotopes.
 $2 \times 10^{-10} \mathrm{~m}$. What if the average diameter of an atom were 1 cm ? How tall would you be?

## INTERACTVE EXAMPLE 2.2 Writing the Symbols for Atoms

Write the symbol for the atom that has an atomic number of 9 and a mass number of 19 . How many electrons and how many neutrons does this atom have?

## SOLUTION

The atomic number 9 means the atom has 9 protons. This element is called fluorine, symbolized by F. The atom is represented as

$$
{ }_{9}^{19} \mathrm{~F}
$$

and is called fluorine nineteen. Since the atom has 9 protons, it also must have 9 electrons to achieve electrical neutrality. The mass number gives the total number of protons and neutrons, which means that this atom has 10 neutrons.

### 2.6 Molecules and lons

From a chemist's viewpoint, the most interesting characteristic of an atom is its ability to combine with other atoms to form compounds. It was John Dalton who first recognized that chemical compounds are collections of atoms, but he could not determine the structure of atoms or their means for binding to each other. During the twentieth century, we learned that atoms have electrons and that these electrons participate in bonding one atom to another. We will discuss bonding thoroughly in Chapters 8 and 9 ; here, we will introduce some simple bonding ideas that will be useful in the next few chapters.

The forces that hold atoms together in compounds are called chemical bonds. One way that atoms can form bonds is by sharing electrons. These bonds are called covalent bonds, and the resulting collection of atoms is called a molecule. Molecules can be represented in several different ways. The simplest method is the chemical formula, in which the symbols for the elements are used to indicate the types of atoms present and subscripts are used to indicate the relative numbers of atoms. For example, the formula for carbon dioxide is $\mathrm{CO}_{2}$, meaning that each molecule contains 1 atom of carbon and 2 atoms of oxygen.

Examples of molecules that contain covalent bonds are hydrogen $\left(\mathrm{H}_{2}\right)$, water $\left(\mathrm{H}_{2} \mathrm{O}\right)$, oxygen $\left(\mathrm{O}_{2}\right)$, ammonia $\left(\mathrm{NH}_{3}\right)$, and methane $\left(\mathrm{CH}_{4}\right)$. More information about a molecule is given by its structural formula, in which the individual bonds are shown (indicated by lines). Structural formulas may or may not indicate the actual shape of the molecule. For example, water might be represented as

$$
\mathrm{H}-\mathrm{O}-\mathrm{H} \text { or }{ }_{\mathrm{H}}^{\mathrm{H}}
$$

The structure on the right shows the actual shape of the water molecule. Scientists know from experimental evidence that the molecule looks like this. (We will study the shapes of molecules further in Chapter 8.)

Ammonia

FIGURE 2.16 (a) The structural formula for methane. (b) Space-filling model of methane. This type of model shows both the relative sizes of the atoms in the molecule and their spatial relationships. (c) Ball-and-stick model of methane.

The structural formula for ammonia is shown in the margin at left. Note that atoms connected to the central atom by dashed lines are behind the plane of the paper, and atoms connected to the central atom by wedges are in front of the plane of the paper.

In a compound composed of molecules, the individual molecules move around as independent units. For example, a molecule of methane gas can be represented in several ways. The structural formula for methane $\left(\mathrm{CH}_{4}\right)$ is shown in Fig. 2.16(a). The space-filling model of methane, which shows the relative sizes of the atoms as well as their relative orientation in the molecule, is given in Fig. 2.16(b). Ball-and-stick models are also used to represent molecules. The ball-and-stick structure of methane is shown in Fig. 2.16(c).

A second type of chemical bond results from attractions among ions. An ion is an atom or group of atoms that has a net positive or negative charge. The best-known ionic compound is common table salt, or sodium chloride, which forms when neutral chlorine and sodium react.

To see how the ions are formed, consider what happens when an electron is transferred from a sodium atom to a chlorine atom (the neutrons in the nuclei will be ignored):

$\mathrm{Na}^{+}$is usually called the sodium ion rather than the sodium cation. Also $\mathrm{Cl}^{-}$is called the chloride ion rather than the chloride anion. In general, when a specific ion is referred to, the word ion rather than cation or anion is used.

With one electron stripped off, the sodium, with its 11 protons and only 10 electrons, now has a net $1+$ charge-it has become a positive ion. A positive ion is called a cation. The sodium ion is written as $\mathrm{Na}^{+}$, and the process can be represented in shorthand form as

$$
\mathrm{Na} \longrightarrow \mathrm{Na}^{+}+\mathrm{e}^{-}
$$

If an electron is added to chlorine,

> Chloride ion
> $\left(\mathrm{Cl}^{-}\right)$

the 18 electrons produce a net 1 - charge; the chlorine has become an ion with a negative charge-an anion. The chloride ion is written as $\mathrm{Cl}^{-}$, and the process is represented as

$$
\mathrm{Cl}+\mathrm{e}^{-} \longrightarrow \mathrm{Cl}^{-}
$$

Because anions and cations have opposite charges, they attract each other. This force of attraction between oppositely charged ions is called ionic bonding. As illustrated in Fig. 2.17, sodium metal and chlorine gas (a green gas composed of

FIGURE 2.17 Sodium metal (which is so soft it can be cut with a knife and which consists of individual sodium atoms) reacts with chlorine gas (which contains $\mathrm{Cl}_{2}$ molecules) to form solid sodium chloride (which contains $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions packed together).

FIGURE 2.18 Ball-and-stick models of the ammonium ion $\left(\mathrm{NH}_{4}{ }^{+}\right)$and the nitrate ion $\left(\mathrm{NO}_{3}^{-}\right)$. These ions are each held together by covalent bonds.

### 2.7 An Introduction to the Periodic Table

In a room where chemistry is taught or practiced, a chart called the periodic table is almost certain to be found hanging on the wall. This chart shows all the known elements and gives a good deal of information about each. As our study of chemistry progresses, the usefulness of the periodic table will become more obvious. This section will simply introduce it to you.

A simplified version of the periodic table is shown in Fig. 2.19. The letters in the boxes are the symbols for the elements; these abbreviations are based on the current

*Lanthanides
${ }^{\dagger}$ Actinides

FIGURE 2.19 The periodic table.

Metals tend to form positive ions; nonmetals tend to form negative ions.

Samples of chlorine gas, liquid bromine, and solid iodine.

TABLE 2.2 | The Symbols for the Elements That Are Based on the Original Names

| Current Name | Original Name | Symbol |
| :--- | :--- | :---: |
| Antimony | Stibium | Sb |
| Copper | Cuprum | Cu |
| Iron | Ferrum | Fe |
| Lead | Plumbum | Pb |
| Mercury | Hydrargyrum | Hg |
| Potassium | Kalium | K |
| Silver | Argentum | Ag |
| Sodium | Natrium | Na |
| Tin | Stannum | Sn |
| Tungsten | Wolfram | W |

element names or the original names (Table 2.2). The number shown above each symbol is the atomic number (number of protons) for that element. For example, carbon $(\mathrm{C})$ has atomic number 6 , and lead $(\mathrm{Pb})$ has atomic number 82 . Most of the elements are metals. Metals have characteristic physical properties such as efficient conduction of heat and electricity, malleability (they can be hammered into thin sheets), ductility (they can be pulled into wires), and (often) a lustrous appearance. Chemically, metals tend to lose electrons to form positive ions. For example, copper is a typical metal. It is lustrous (although it tarnishes readily); it is an excellent conductor of electricity (it is widely used in electrical wires); and it is readily formed into various shapes, such as pipes for water systems. Copper is also found in many salts, such as the beautiful blue copper sulfate, in which copper is present as $\mathrm{Cu}^{2+}$ ions. Copper is a member of the transition metals-the metals shown in the center of the periodic table.

The relatively few nonmetals appear in the upper-right corner of the table (to the right of the heavy line in Fig. 2.19), except hydrogen, a nonmetal that resides in the upper-left corner. The nonmetals lack the physical properties that characterize the metals. Chemically, they tend to gain electrons in reactions with metals to form negative ions. Nonmetals often bond to each other by forming covalent bonds. For example, chlorine is a typical nonmetal. Under normal conditions it exists as $\mathrm{Cl}_{2}$ molecules; it reacts with metals to form salts containing $\mathrm{Cl}^{-}$ions ( NaCl , for example); and it forms covalent bonds with nonmetals (for example, hydrogen chloride gas, HCl ).

The periodic table is arranged so that elements in the same vertical columns (called groups or families) have similar chemical properties. For example, all of the alkali metals, members of Group 1A—lithium (Li), sodium ( Na ), potassium (K), rubidium ( Rb ), cesium (Cs), and francium (Fr)—are very active elements that readily form ions with a $1+$ charge when they react with nonmetals. The members of Group 2Aberyllium (Be), magnesium ( Mg ), calcium ( Ca ), strontium $(\mathrm{Sr})$, barium $(\mathrm{Ba})$, and radium ( Ra )—are called the alkaline earth metals. They all form ions with a $2+$ charge when they react with nonmetals. The halogens, the members of Group 7Afluorine (F), chlorine ( Cl ), bromine ( Br ), iodine (I), and astatine (At)—all form diatomic molecules. Fluorine, chlorine, bromine, and iodine all react with metals to form salts containing ions with a $1-$ charge $\left(\mathrm{F}^{-}, \mathrm{Cl}^{-}, \mathrm{Br}^{-}\right.$, and $\mathrm{I}^{-}$). The members of Group 8A—helium (He), neon (Ne), argon (Ar), krypton ( Kr ), xenon (Xe), and radon ( Rn ) —are known as the noble gases. They all exist under normal conditions as monatomic (single-atom) gases and have little chemical reactivity.

## CHEMICAL

## Hassium Fits Right In

Haassium, element 108, does not exist in nature but must be made in a particle accelerator. It was first created in 1984 and can be made by shooting magnesium- $26\left({ }_{12}^{26} \mathrm{Mg}\right)$ atoms at curium-248 ( ${ }_{96}^{248} \mathrm{Cm}$ ) atoms. The collisions between these atoms produce some hassium- $265\left({ }_{108}^{265} \mathrm{Hs}\right)$ atoms. The position of hassium in the periodic table (see Fig. 2.19) in the vertical column containing iron, ruthenium, and osmium suggests that hassium should have chemical properties similar to these metals. However, it is not easy to
test this prediction-only a few atoms of hassium can be made at a given time and they last for only about 9 seconds. Imagine having to get your next lab experiment done in 9 seconds!

Amazingly, a team of chemists from the Lawrence Berkeley National Laboratory in California, the Paul Scherrer Institute and the University of Bern in Switzerland, and the Institute of Nuclear Chemistry in Germany have done experiments to characterize the chemical behavior of hassium.

For example, they have observed that hassium atoms react with oxygen to form a hassium oxide compound of the type expected from its position on the periodic table. The team has also measured other properties of hassium, including the energy released as it undergoes nuclear decay to another atom.

This work would have surely pleased Dmitri Mendeleev (see Fig. 7.24), who originally developed the periodic table and showed its power to predict chemical properties.

Another format of the periodic table will be discussed in Section 7.11.

Note from Fig. 2.19 that alternate sets of symbols are used to denote the groups. The symbols 1 A through 8 A are the traditional designations, whereas the numbers 1 to 18 have been suggested recently. In this text the 1 A to 8 A designations will be used.

The horizontal rows of elements in the periodic table are called periods. Horizontal row 1 is called the first period (it contains H and He ); row 2 is called the second period (elements Li through Ne ); and so on.

We will learn much more about the periodic table as we continue with our study of chemistry. Meanwhile, when an element is introduced in this text, you should always note its position on the periodic table.

### 2.8 Naming Simple Compounds

When chemistry was an infant science, there was no system for naming compounds. Names such as sugar of lead, blue vitrol, quicklime, Epsom salts, milk of magnesia, gypsum, and laughing gas were coined by early chemists. Such names are called common names. As chemistry grew, it became clear that using common names for compounds would lead to unacceptable chaos. Nearly 5 million chemical compounds are currently known. Memorizing common names for these compounds would be an impossible task.

The solution, of course, is to adopt a system for naming compounds in which the name tells something about the composition of the compound. After learning the system, a chemist given a formula should be able to name the compound or, given a name, should be able to construct the compound's formula. In this section we will specify the most important rules for naming compounds other than organic compounds (those based on chains of carbon atoms).

We will begin with the systems for naming inorganic binary compoundscompounds composed of two elements-which we classify into various types for easier recognition. We will consider both ionic and covalent compounds.

A monatomic cation has the same name as its parent element.

In formulas of ionic compounds, simple ions are represented by the element symbol: Cl means $\mathrm{Cl}^{-}$, Na means $\mathrm{Na}^{+}$, and so on.

## Binary Ionic Compounds (Type I]

Binary ionic compounds contain a positive ion (cation) always written first in the formula and a negative ion (anion). In naming these compounds, the following rules apply:

## Naming Type I Binary Compounds

1. The cation is always named first and the anion second.
2. A monatomic (meaning "one-atom") cation takes its name from the name of the element. For example, $\mathrm{Na}^{+}$is called sodium in the names of compounds containing this ion.
3. A monatomic anion is named by taking the root of the element name and adding -ide. Thus the $\mathrm{Cl}^{-}$ion is called chloride.

Some common monatomic cations and anions and their names are given in Table 2.3.
The rules for naming binary ionic compounds are illustrated by the following examples:

| Compound | Ions Present |
| :--- | :---: |
| NaCl | $\mathrm{Na}^{+}, \mathrm{Cl}^{-}$ |
| KI | $\mathrm{K}^{+}, \mathrm{I}^{-}$ |
| CaS | $\mathrm{Ca}^{2+}, \mathrm{S}^{2-}$ |
| $\mathrm{Li}_{3} \mathrm{~N}$ | $\mathrm{Li}^{+}, \mathrm{N}^{3-}$ |
| CsBr | $\mathrm{Cs}^{+}, \mathrm{Br}^{-}$ |
| MgO | $\mathrm{Mg}^{2+}, \mathrm{O}^{2-}$ |

## Ions Present

$\mathrm{Na}^{+}, \mathrm{Cl}^{-}$
$\mathrm{K}^{+}, \mathrm{I}^{-}$
$\mathrm{Ca}^{2+}, \mathrm{S}^{2-}$
$\mathrm{Cs}^{+}, \mathrm{Br}^{-}$
$\mathrm{Mg}^{2+}, \mathrm{O}^{2-}$

## Name

Sodium chloride
Potassium iodide
Calcium sulfide
Lithium nitride
Cesium bromide
Magnesium oxide

## INTERACTIVE EXAMPLE 2.3 Naming Type I Binary Compounds

Name each binary compound.
a. CsF
b. $\mathrm{AlCl}_{3}$
c. LiH

## SOLUTION

a. CsF is cesium fluoride.
b. $\mathrm{AlCl}_{3}$ is aluminum chloride.
c. LiH is lithium hydride.

Notice that, in each case, the cation is named first and then the anion is named.

TABLE 2.3 | Common Monatomic Cations and Anions

| Cation | Name | Anion | Name |
| :--- | :--- | :--- | :--- |
| $\mathrm{H}^{+}$ | Hydrogen | $\mathrm{H}^{-}$ | Hydride |
| $\mathrm{Li}^{+}$ | Lithium | $\mathrm{F}^{-}$ | Fluoride |
| $\mathrm{Na}^{+}$ | Sodium | $\mathrm{Cl}^{-}$ | Chloride |
| $\mathrm{K}^{+}$ | Potassium | $\mathrm{Br}^{-}$ | Bromide |
| $\mathrm{Cs}^{+}$ | Cesium | $\mathrm{I}^{-}$ | Iodide |
| $\mathrm{Be}^{2+}$ | Beryllium | $\mathrm{O}^{2-}$ | Oxide |
| $\mathrm{Mg}^{2+}$ | Magnesium | $\mathrm{S}^{2-}$ | Sulfide |
| $\mathrm{Ca}^{2+}$ | Calcium | $\mathrm{N}^{3-}$ | Nitride |
| $\mathrm{Ba}^{2+}$ | Barium | $\mathrm{P}^{3-}$ | Phosphide |
| $\mathrm{Al}^{3+}$ | Aluminum |  |  |

| TABLE 2.4 | Common Type II <br> Cations |
| :--- | :--- |
| Ion | Systematic Name |$|$| $\mathrm{Fe}^{3+}$ | Iron(III) |
| :--- | :--- |
| $\mathrm{Fe}^{2+}$ | Copper(II) |
| $\mathrm{Cu}^{2+}$ | Copper(I) |
| $\mathrm{Cu}^{+}$ | Cobalt(III) |
| $\mathrm{Co}^{3+}$ | Tin(IV) |
| $\mathrm{Co}^{2+}$ | Tin(II) |
| $\mathrm{Sn}^{4+}$ | Lead(IV) |
| $\mathrm{Sn}^{2+}$ | Lead(II) |
| $\mathrm{Pb}^{4+}$ | Mercury(II) |
| $\mathrm{Pb}^{2+}$ | Mercury(I) |
| $\mathrm{Hg}^{2+}$ | Silver ${ }^{+}$ |
| $\mathrm{Hg}_{2}{ }^{2+*}$ | Zinc ${ }^{\dagger}$ |
| $\mathrm{Ag}^{+}$ | Cadmium ${ }^{+}$ |
| $\mathrm{Zn}^{2+}$ |  |
| $\mathrm{Cd}^{2+}$ |  |

## TABLE 2.4 | Common Type II Cations

*Note that mercury(I) ions always occur bound together to form $\mathrm{Hg}_{2}{ }^{2+}$ ions. Although these are transition metals, they numeral is not used.

## Formulas from Names

So far we have started with the chemical formula of a compound and decided on its systematic name. The reverse process is also important. For example, given the name calcium chloride, we can write the formula as $\mathrm{CaCl}_{2}$ because we know that calcium forms only $\mathrm{Ca}^{2+}$ ions and that, since chloride is $\mathrm{Cl}^{-}$, two of these anions will be required to give a neutral compound.

## Binary Ionic Compounds (Type II)

In the binary ionic compounds considered earlier (Type I), the metal present forms only a single type of cation. That is, sodium forms only $\mathrm{Na}^{+}$, calcium forms only $\mathrm{Ca}^{2+}$, and so on. However, as we will see in more detail later in the text, there are many metals that form more than one type of positive ion and thus form more than one type of ionic compound with a given anion. For example, the compound $\mathrm{FeCl}_{2}$ contains $\mathrm{Fe}^{2+}$ ions, and the compound $\mathrm{FeCl}_{3}$ contains $\mathrm{Fe}^{3+}$ ions. In a case such as this, the charge on the metal ion must be specified. The systematic names for these two iron compounds are iron(II) chloride and iron(III) chloride, respectively, where the Roman numeral indicates the charge of the cation.

Another system for naming these ionic compounds that is seen in the older literature was used for metals that form only two ions. The ion with the higher charge has a name ending in -ic, and the one with the lower charge has a name ending in -ous. In this system, for example, $\mathrm{Fe}^{3+}$ is called the ferric ion, and $\mathrm{Fe}^{2+}$ is called the ferrous ion. The names for $\mathrm{FeCl}_{3}$ and $\mathrm{FeCl}_{2}$ are then ferric chloride and ferrous chloride, respectively. In this text we will use the system that employs Roman numerals. Table 2.4 lists the systematic names for many common type II cations.

## INTERACTIVE EXAMPLE 2.4

SOLUTION

## Formulas from Names for Type I Binary Compounds

Given the following systematic names, write the formula for each compound:
a. potassium iodide
b. calcium oxide
c. gallium bromide

## SOLUTION

Type II binary ionic compounds contain a metal that can form more than one type of cation.

A compound must be electrically neutral.

A compound containing a transition metal usually requires a Roman numeral in its name.

All of these compounds include a metal that can form more than one type of cation. Thus we must first determine the charge on each cation. This can be done by recognizing that a compound must be electrically neutral; that is, the positive and negative charges must exactly balance.

| 1. Formula | Name |
| :---: | :---: |
| a. CuCl | Copper(I) <br> chloride |
| b. HgO | Mercury(II) <br> oxide |
| c. $\mathrm{Fe}_{2} \mathrm{O}_{3}$ | Iron(III) <br> oxide |

## 2. Name

| a.Manganese(IV) <br> oxide | $\mathrm{MnO}_{2}$ |
| :--- | :--- |
| b.Lead(II) <br> chloride | $\mathrm{PbCl}_{2}$ |

## Comments

Because the anion is $\mathrm{Cl}^{-}$, the cation must be $\mathrm{Cu}^{+}$(for charge balance), which requires a Roman numeral I.
Because the anion is $\mathrm{O}^{2-}$, the cation must be $\mathrm{Hg}^{2+}$ [mercury(II)].
The three $\mathrm{O}^{2-}$ ions carry a total charge of $6-$, so two $\mathrm{Fe}^{3+}$ ions [iron(III)] are needed to give a $6+$ charge.

## Comments

Two $\mathrm{O}^{2-}$ ions (total charge 4-) are required by the $\mathrm{Mn}^{4+}$ ion [manganese(IV)].
Two $\mathrm{Cl}^{-}$ions are required by the $\mathrm{Pb}^{2+}$ ion [lead(II)] for charge balance.

## See Exercise 2.76

Note that the use of a Roman numeral in a systematic name is required only in cases where more than one ionic compound forms between a given pair of elements. This case most commonly occurs for compounds containing transition metals, which often form more than one cation. Elements that form only one cation do not need to be identified by a Roman numeral. Common metals that do not require Roman numerals are the Group 1A elements, which form only $1+$ ions; the Group 2A elements, which form only $2+$ ions; and aluminum, which forms only $\mathrm{Al}^{3+}$. The element silver deserves special mention at this point. In virtually all its compounds, silver is found as the $\mathrm{Ag}^{+}$ion. Therefore, although silver is a transition metal (and can potentially form ions other than $\mathrm{Ag}^{+}$), silver compounds are usually named without a Roman numeral. Thus AgCl is typically called silver chloride rather than silver(I) chloride, although the latter name is technically correct. Also, a Roman numeral is not used for zinc compounds, since zinc forms only the $\mathrm{Zn}^{2+}$ ion.

As shown in Example 2.5, when a metal ion is present that forms more than one type of cation, the charge on the metal ion must be determined by balancing the positive and negative charges of the compound. To do this you must be able to recognize the common cations and anions and know their charges (see Tables 2.3 and 2.5). The procedure for naming binary ionic compounds is summarized in Fig. 2.20.

[^3]FIGURE 2.20 Flowchart for naming binary ionic compounds.

## INTERACTIVE EXAMPLE 2.6

SOLUTION

## -

Various chromium compounds dissolved in water. From left to right: $\mathrm{CrCl}_{2}$, $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}, \mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}, \mathrm{CrCl}_{3}, \mathrm{~K}_{2} \mathrm{CrO}_{4}$.

[^4]
## Naming Binary Compounds

1. Give the systematic name for each of the following compounds:
a. $\mathrm{CoBr}_{2}$
b. $\mathrm{CaCl}_{2}$
c. $\mathrm{Al}_{2} \mathrm{O}_{3}$
2. Given the following systematic names, write the formula for each compound:
a. Chromium(III) chloride
b. Gallium iodide
3. Formula
a. $\mathrm{CoBr}_{2} \quad$ Cobalt(II) bromide
b. $\mathrm{CaCl}_{2}$
c. $\mathrm{Al}_{2} \mathrm{O}_{3}$
4. Name
$\begin{array}{ll}\text { a. } \begin{array}{l}\text { Chromium(III) } \\ \text { chloride }\end{array} & \mathrm{CrCl}_{3} \\ \text { b. Gallium iodide } & \mathrm{GaI}_{3}\end{array}$

Aluminum oxide

## Formula

## Comments

 charge balance.
## Comments

Cobalt is a transition metal; the compound name must have a Roman numeral. The two $\mathrm{Br}^{-}$ions must be balanced by a $\mathrm{Co}^{2+}$ ion.
Calcium, an alkaline earth metal, forms only the $\mathrm{Ca}^{2+}$ ion. A Roman numeral is not necessary.
Aluminum forms only the $\mathrm{Al}^{3+}$ ion. A Roman numeral is not necessary.

Chromium(III) indicates that $\mathrm{Cr}^{3+}$ is present, so $3 \mathrm{Cl}^{-}$ions are needed for

Gallium always forms $3+$ ions, so $3 \mathrm{I}^{-}$ ions are required for charge balance.

See Exercises 2.77 and 2.78

The common Type I and Type II ions are summarized in Fig. 2.21. Also shown in Fig. 2.21 are the common monatomic ions.

## Ionic Compounds with Polyatomic Ions

We have not yet considered ionic compounds that contain polyatomic ions. For example, the compound ammonium nitrate, $\mathrm{NH}_{4} \mathrm{NO}_{3}$, contains the polyatomic ions $\mathrm{NH}_{4}{ }^{+}$ and $\mathrm{NO}_{3}{ }^{-}$. Polyatomic ions are assigned special names that must be memorized to name the compounds containing them. The most important polyatomic ions and their names are listed in Table 2.5.

FIGURE 2.21 The common cations and anions.

Note in Table 2.5 that several series of anions contain an atom of a given element and different numbers of oxygen atoms. These anions are called oxyanions. When there are two members in such a series, the name of the one with the smaller number of oxygen atoms ends in -ite and the name of the one with the larger number ends in -ate-for example, sulfite $\left(\mathrm{SO}_{3}{ }^{2-}\right)$ and sulfate $\left(\mathrm{SO}_{4}{ }^{2-}\right)$. When more than two oxyanions make up a series, hypo- (less than) and per-(more than) are used as prefixes to name the members of the series with the fewest and the most oxygen atoms, respectively. The best example involves the oxyanions containing chlorine, as shown in Table 2.5.

TABLE 2.5 \| Common Polyatomic lons

| Ion | Name | Ion | Name |
| :---: | :---: | :---: | :---: |
| $\mathrm{Hg}_{2}{ }^{2+}$ | Mercury(l) | $\mathrm{CO}_{3}{ }^{2-}$ | Carbonate |
| $\mathrm{NH}_{4}^{+}$ | Ammonium | $\mathrm{HCO}_{3}{ }^{-}$ | Hydrogen carbonate (bicarbonate is a widely used common name) |
| $\mathrm{NO}_{2}{ }^{-}$ | Nitrite |  |  |
| $\mathrm{NO}_{3}{ }^{-}$ | Nitrate |  |  |
| $\mathrm{SO}_{3}{ }^{2-}$ | Sulfite | $\mathrm{ClO}^{-}$or OCl ${ }^{-}$ | Hypochlorite |
| $\mathrm{SO}_{4}{ }^{2-}$ | Sulfate | $\mathrm{ClO}_{2}{ }^{-}$ | Chlorite |
| $\mathrm{HSO}_{4}{ }^{-}$ | Hydrogen sulfate (bisulfate is a widely used common name) | $\mathrm{ClO}_{3}{ }^{-}$ | Chlorate |
|  |  | $\mathrm{ClO}_{4}{ }^{-}$ | Perchlorate |
|  |  | $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}$ | Acetate |
| $\mathrm{OH}^{-}$ | Hydroxide | $\mathrm{MnO}_{4}{ }^{-}$ | Permanganate |
| $\mathrm{CN}^{-}$ | Cyanide | $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ | Dichromate |
| $\mathrm{PO}_{4}{ }^{3-}$ | Phosphate | $\mathrm{CrO}_{4}{ }^{2-}$ | Chromate |
| $\mathrm{HPO}_{4}{ }^{2-}$ | Hydrogen phosphate | $\mathrm{O}_{2}{ }^{2-}$ | Peroxide |
| $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$ | Dihydrogen phosphate | $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}$ | Oxalate |
| $\mathrm{NCS}^{-}$or $\mathrm{SCN}^{-}$ | Thiocyanate | $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$ | Thiosulfate |

## INTERACTIVE EXAMPLE 2.7 Naming Compounds Containing Polyatomic lons

1. Give the systematic name for each of the following compounds:
a. $\mathrm{Na}_{2} \mathrm{SO}_{4}$
b. $\mathrm{KH}_{2} \mathrm{PO}_{4}$
c. $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$
d. $\mathrm{Mn}(\mathrm{OH})_{2}$
e. $\mathrm{Na}_{2} \mathrm{SO}_{3}$
f. $\mathrm{Na}_{2} \mathrm{CO}_{3}$

SOLUTION

1. Formula
a. $\mathrm{Na}_{2} \mathrm{SO}_{4}$
b. $\mathrm{KH}_{2} \mathrm{PO}_{4}$
c. $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$

Name
Sodium sulfate
Potassium dihydrogen phosphate
a. Sodium hydrogen carbonate
d. Sodium selenate
b. Cesium perchlorate
c. Sodium hypochlorite

Iron(III) nitrate
d. $\mathrm{Mn}(\mathrm{OH})_{2}$

Manganese(II) hydroxide
e. $\mathrm{Na}_{2} \mathrm{SO}_{3}$
f. $\mathrm{Na}_{2} \mathrm{CO}_{3}$
2. Name
a. Sodium hydrogen carbonate
b. Cesium perchlorate
c. Sodium hypochlorite
d. Sodium selenate
$\mathrm{Na}_{2} \mathrm{SeO}_{4}$
e. Potassium bromate

## Formula Comments

$\mathrm{NaHCO}_{3} \quad$ Often called sodium bicarbonate.

## Comments

Transition metal—name must contain a Roman numeral. The $\mathrm{Fe}^{3+}$ ion balances three $\mathrm{NO}_{3}{ }^{-}$ions.
Transition metal-name must contain a Roman numeral. The $\mathrm{Mn}^{2+}$ ion balances three $\mathrm{OH}^{-}$ions.

TABLE 2.6 | Prefixes Used to Indicate Number in Chemical Names

| Prefix | Number Indicated |
| :--- | :--- |
| mono- | 1 |
| di- | 2 |
| tri- | 3 |
| tetra- | 4 |
| penta- | 5 |
| hexa- | 6 |
| hepta- | 7 |
| octa- | 8 |
| nona- | 9 |
| deca- | 10 |

To see how these rules apply, we will now consider the names of the several covalent compounds formed by nitrogen and oxygen:

| Compound | Systematic Name | Common Name |
| :---: | :--- | :--- |
| $\mathrm{N}_{2} \mathrm{O}$ | Dinitrogen monoxide | Nitrous oxide |
| NO | Nitrogen monoxide | Nitric oxide |
| $\mathrm{NO}_{2}$ | Nitrogen dioxide |  |
| $\mathrm{N}_{2} \mathrm{O}_{3}$ | Dinitrogen trioxide |  |
| $\mathrm{N}_{2} \mathrm{O}_{4}$ | Dinitrogen tetroxide |  |
| $\mathrm{N}_{2} \mathrm{O}_{5}$ | Dinitrogen pentoxide |  |

Notice from the preceding examples that to avoid awkward pronunciations, we often drop the final $o$ or $a$ of the prefix when the element begins with a vowel. For example, $\mathrm{N}_{2} \mathrm{O}_{4}$ is called dinitrogen tetroxide, not dinitrogen tetraoxide, and CO is called carbon monoxide, not carbon monooxide.

Some compounds are always referred to by their common names. Three examples are water, ammonia, and hydrogen peroxide. The systematic names for $\mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}$, and $\mathrm{H}_{2} \mathrm{O}_{2}$ are never used.

## INTERACTIVE EXAMPLE 2.8 Naming Type III Binary Compounds

1. Name each of the following compounds:
a. $\mathrm{PCl}_{5}$
b. $\mathrm{PCl}_{3}$
c. $\mathrm{SO}_{2}$
2. From the following systematic names, write the formula for each compound:
a. Sulfur hexafluoride
b. Sulfur trioxide
c. Carbon dioxide
3. Formula
a. $\mathrm{PCl}_{5}$
b. $\mathrm{PCl}_{3}$
c. $\mathrm{SO}_{2}$
4. Name
a. Sulfur hexafluoride
b. Sulfur trioxide
c. Carbon dioxide

## Name

Phosphorus pentachloride
Phosphorus trichloride
Sulfur dioxide

## Formula

$\mathrm{SF}_{6}$
$\mathrm{SO}_{3}$
$\mathrm{CO}_{2}$

The rules for naming binary compounds are summarized in Fig. 2.22. Prefixes to indicate the number of atoms are used only in Type III binary compounds (those containing two nonmetals). An overall strategy for naming compounds is given in Fig. 2.23.

FIGURE 2.22 A flowchart for naming binary compounds.

FIGURE 2.23 Overall strategy for naming chemical compounds.

## INTERACTIVE EXAMPLE 2.9 Naming Various Types of Compounds

1. Give the systematic name for each of the following compounds:
a. $\mathrm{P}_{4} \mathrm{O}_{10}$
b. $\mathrm{Nb}_{2} \mathrm{O}_{5}$
c. $\mathrm{Li}_{2} \mathrm{O}_{2}$
d. $\mathrm{Ti}\left(\mathrm{NO}_{3}\right)_{4}$
2. Given the following systematic names, write the formula for each compound:
a. Vanadium(V) fluoride
b. Dioxygen difluoride
c. Rubidium peroxide
d. Gallium oxide

## SOLUTION

Acids can be recognized by the hydrogen that appears first in the formula.

## 1. Compound

a. $\mathrm{P}_{4} \mathrm{O}_{10}$
b. $\mathrm{Nb}_{2} \mathrm{O}_{5}$
c. $\mathrm{Li}_{2} \mathrm{O}_{2}$
d. $\mathrm{Ti}\left(\mathrm{NO}_{3}\right)_{4}$

## Name

## Tetraphosphorus decaoxide

Niobium(V) oxide

Lithium peroxide Titanium(IV) nitrate

## Comments

Binary covalent compound (Type III), so prefixes are used. The $a$ in decais sometimes dropped.
Type II binary compound containing $\mathrm{Nb}^{5+}$ and $\mathrm{O}^{2-}$ ions. Niobium is a transition metal and requires a Roman numeral.
Type I binary compound containing the $\mathrm{Li}^{+}$and $\mathrm{O}_{2}{ }^{2-}$ (peroxide) ions.
Not a binary compound. Contains the $\mathrm{Ti}^{4+}$ and $\mathrm{NO}_{3}{ }^{-}$ions. Titanium is a transition metal and requires a Roman numeral.

## Chemical

## 2. Name

 Formulaa. Vanadium(V)
$\mathrm{VF}_{5}$ fluoride
b. Dioxygen
$\mathrm{O}_{2} \mathrm{~F}_{2}$ difluoride
c. Rubidium
$\mathrm{Rb}_{2} \mathrm{O}_{2}$ peroxide
d. Gallium oxide

## Comments

The compound contains $\mathrm{V}^{5+}$ ions and requires five $\mathrm{F}^{-}$ions for charge balance.

The prefix $d i$ - indicates two of each atom.
Because rubidium is in Group 1A, it forms only $1+$ ions. Thus two $\mathrm{Rb}^{+}$ions are needed to balance the $2-$ charge on the peroxide ion $\left(\mathrm{O}_{2}{ }^{2-}\right)$.
Because gallium is in Group 3A, like aluminum, it forms only $3+$ ions. Two $\mathrm{Ga}^{3+}$ ions are required to balance the charge on three $\mathrm{O}^{2-}$ ions.

## Acids

When dissolved in water, certain molecules produce a solution containing free $\mathrm{H}^{+}$ions (protons). These substances, acids, will be discussed in detail in Chapters 4, 14, and 15 . Here we will simply present the rules for naming acids.

An acid is a molecule in which one or more $\mathrm{H}^{+}$ions are attached to an anion. The rules for naming acids depend on whether the anion contains oxygen. If the name of the anion ends in -ide, the acid is named with the prefix hydro- and the suffix -ic. For example, when gaseous HCl is dissolved in water, it forms hydrochloric acid. Similarly, HCN and $\mathrm{H}_{2} \mathrm{~S}$ dissolved in water are called hydrocyanic and hydrosulfuric acids, respectively.

When the anion contains oxygen, the acidic name is formed from the root name of the anion with a suffix of -ic or -ous, depending on the name of the anion.

1. If the anion name ends in -ate, the suffix -ic is added to the root name. For example, $\mathrm{H}_{2} \mathrm{SO}_{4}$ contains the sulfate anion $\left(\mathrm{SO}_{4}{ }^{2-}\right)$ and is called sulfuric acid; $\mathrm{H}_{3} \mathrm{PO}_{4}$ contains the phosphate anion $\left(\mathrm{PO}_{4}{ }^{3-}\right)$ and is called phosphoric acid; and $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ contains the acetate ion $\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right)$and is called acetic acid.

## TABLE 2.7 | Names of Acids* That Do Not Contain Oxygen

| Acid | Name |
| :--- | :--- |
| HF | Hydrofluoric acid |
| HCl | Hydrochloric acid |
| HBr | Hydrobromic acid |
| HI | Hydroiodic acid |
| HCN | Hydrocyanic acid |
| $\mathrm{H}_{2} \mathrm{~S}$ | Hydrosulfuric acid |

*Note that these acids are aqueous solutions containing these substances.

## TABLE 2.8 | Names of Some <br> TABLE 2.8 $\begin{aligned} & \text { Names of Some } \\ & \text { Oxygen-Containing } \\ & \text { Acids }\end{aligned}$ Acids

| Acid | Name |
| :--- | :--- |
| $\mathrm{HNO}_{3}$ | Nitric acid |
| $\mathrm{HNO}_{2}$ | Nitrous acid |
| $\mathrm{H}_{2} \mathrm{SO}_{4}$ | Sulfuric acid |
| $\mathrm{H}_{2} \mathrm{SO}_{3}$ | Sulfurous acid |
| $\mathrm{H}_{3} \mathrm{PO}_{4}$ | Phosphoric acid |
| $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ | Acetic acid |

2. If the anion has an -ite ending, the -ite is replaced by -ous. For example, $\mathrm{H}_{2} \mathrm{SO}_{3}$, which contains sulfite $\left(\mathrm{SO}_{3}{ }^{2-}\right)$, is named sulfurous acid; and $\mathrm{HNO}_{2}$, which contains nitrite $\left(\mathrm{NO}_{2}{ }^{-}\right)$, is named nitrous acid.

The application of these rules can be seen in the names of the acids of the oxyanions of chlorine:

| Acid | Anion | Name |
| :--- | :--- | :--- |
| $\mathrm{HClO}_{4}$ | Perchlorate | Perchloric acid |
| $\mathrm{HClO}_{3}$ | Chlorate | Chloric acid |
| $\mathrm{HClO}_{2}$ | Chlorite | Chlorous acid |
| HClO | Hypochlorite | Hypochlorous acid |

The names of the most important acids are given in Tables 2.7 and 2.8. An overall strategy for naming acids is shown in Fig. 2.24.
 systematic way to name chemical compounds. What if all compounds had only common names? What problems would this cause?

FIGURE 2.24 A flowchart for naming acids. An acid is best considered as one or more $\mathrm{H}^{+}$ions attached to an anion.

## Review Questions Answers to the Review Questions can be found on the Student website (accessible from www.cengagebrain.com).

1. Use Dalton's atomic theory to account for each of the following.
a. the law of conservation of mass
b. the law of definite proportion
c. the law of multiple proportions
2. What evidence led to the conclusion that cathode rays had a negative charge?
3. What discoveries were made by J. J. Thomson, Henri Becquerel, and Lord Rutherford? How did Dalton's model of the atom have to be modified to account for these discoveries?
4. Consider Ernest Rutherford's $\alpha$-particle bombardment experiment illustrated in Fig. 2.12. How did the results of this experiment lead Rutherford away from the plum pudding model of the atom to propose the nuclear model of the atom?
5. Do the proton and the neutron have exactly the same mass? How do the masses of the proton and neutron compare to the mass of the electron? Which particles make the greatest contribution to the mass of an atom?

Which particles make the greatest contribution to the chemical properties of an atom?
6. What is the distinction between atomic number and mass number? Between mass number and atomic mass?
7. Distinguish between the terms family and period in connection with the periodic table. For which of these terms is the term group also used?
8. The compounds $\mathrm{AlCl}_{3}, \mathrm{CrCl}_{3}$, and $\mathrm{ICl}_{3}$ have similar formulas, yet each follows a different set of rules to name it. Name these compounds, and then compare and contrast the nomenclature rules used in each case.
9. When metals react with nonmetals, an ionic compound generally results. What is the predicted general formula for the compound formed between an alkali metal and sulfur? Between an alkaline earth metal and nitrogen? Between aluminum and a halogen?
10. How would you name $\mathrm{HBrO}_{4}, \mathrm{KIO}_{3}, \mathrm{NaBrO}_{2}$, and HIO? Refer to Table 2.5 and the acid nomenclature discussion in the text.

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. Which of the following is true about an individual atom? Explain.
a. An individual atom should be considered to be a solid.
b. An individual atom should be considered to be a liquid.
c. An individual atom should be considered to be a gas.
d. The state of the atom depends on which element it is.
e. An individual atom cannot be considered to be a solid, liquid, or gas.
Justify your choice, and for choices you did not pick, explain what is wrong with them.
2. How would you go about finding the number of "chalk molecules" it takes to write your name on the board? Provide an explanation of all you would need to do and a sample calculation.
3. These questions concern the work of J. J. Thomson.
a. From Thomson's work, which particles do you think he would feel are most important for the formation of compounds (chemical changes) and why?
b. Of the remaining two subatomic particles, which do you place second in importance for forming compounds and why?
c. Propose three models that explain Thomson's findings and evaluate them. To be complete you should include Thomson's findings.
4. Heat is applied to an ice cube in a closed container until only steam is present. Draw a representation of this process, assuming you can see it at an extremely high level of magnification. What happens to the size of the molecules? What happens to the total mass of the sample?
5. You have a chemical in a sealed glass container filled with air. The setup is sitting on a balance as shown below. The chemical is ignited by means of a magnifying glass focusing sunlight on the reactant. After the chemical has completely burned, which of the following is true? Explain your answer.

a. The balance will read less than 250.0 g .
b. The balance will read 250.0 g .
c. The balance will read greater than 250.0 g .
d. Cannot be determined without knowing the identity of the chemical.
6. The formula of water is $\mathrm{H}_{2} \mathrm{O}$. Which of the following is indicated by this formula? Explain your answer.
a. The mass of hydrogen is twice that of oxygen in each molecule.
b. There are two hydrogen atoms and one oxygen atom per water molecule.
c. The mass of oxygen is twice that of hydrogen in each molecule.
d. There are two oxygen atoms and one hydrogen atom per water molecule.
7. You may have noticed that when water boils, you can see bubbles that rise to the surface of the water. Which of the following is inside these bubbles? Explain.
a. air
b. hydrogen and oxygen gas
c. oxygen gas
d. water vapor
e. carbon dioxide gas
8. One of the best indications of a useful theory is that it raises more questions for further experimentation than it originally answered. Does this apply to Dalton's atomic theory? Give examples.
9. Dalton assumed that all atoms of the same element were identical in all their properties. Explain why this assumption is not valid.
10. Label each of the following as an atomic element, a molecular element, or a compound.

11. Why is the term "sodium chloride molecule" incorrect whereas the term "carbon dioxide molecule" is correct?
12. Evaluate each of the following as an acceptable name for water:
a. dihydrogen oxide
b. hydroxide hydride
c. hydrogen hydroxide
d. oxygen dihydride
13. Why do we call $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$ barium nitrate, but we call $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{2}$ iron(II) nitrate?
14. Why is calcium dichloride not the correct systematic name for $\mathrm{CaCl}_{2}$ ?
15. The common name for $\mathrm{NH}_{3}$ is ammonia. What would be the systematic name for $\mathrm{NH}_{3}$ ? Support your answer.
16. Which (if any) of the following can be determined by knowing the number of protons in a neutral element? Explain your answer.
a. the number of neutrons in the neutral element
b. the number of electrons in the neutral element
c. the name of the element
17. Which of the following explain how an ion is formed? Explain your answer.
a. adding or subtracting protons to/from an atom
b. adding or subtracting neutrons to/from an atom
c. adding or subtracting electrons to/from an atom

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

18. What refinements had to be made in Dalton's atomic theory to account for Gay-Lussac's results on the combining volumes of gases?
19. When hydrogen is burned in oxygen to form water, the composition of water formed does not depend on the amount of oxygen reacted. Interpret this in terms of the law of definite proportion.
20. The two most reactive families of elements are the halogens and the alkali metals. How do they differ in their reactivities?
21. Explain the law of conservation of mass, the law of definite proportion, and the law of multiple proportions.
22. Section 2.3 describes the postulates of Dalton's atomic theory. With some modifications, these postulates hold up very well regarding how we view elements, compounds, and chemical reactions today. Answer the following questions concerning Dalton's atomic theory and the modifications made today.
a. The atom can be broken down into smaller parts. What are the smaller parts?
b. How are atoms of hydrogen identical to each other, and how can they be different from each other?
c. How are atoms of hydrogen different from atoms of helium? How can H atoms be similar to He atoms?
d. How is water different from hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$ even though both compounds are composed of only hydrogen and oxygen?
e. What happens in a chemical reaction, and why is mass conserved in a chemical reaction?
23. The contributions of J. J. Thomson and Ernest Rutherford led the way to today's understanding of the structure of the atom. What were their contributions?
24. What is the modern view of the structure of the atom?
25. The number of protons in an atom determines the identity of the atom. What does the number and arrangement of the electrons in an atom determine? What does the number of neutrons in an atom determine?
26. If the volume of a proton were similar to the volume of an electron, how will the densities of these two particles compare to each other?
27. For lighter, stable isotopes, the ratio of the mass number to the atomic number is close to a certain value. What is the value? What happens to the value of the mass number to atomic number ratio as stable isotopes become heavier?
28. List some characteristic properties that distinguish the metallic elements from the nonmetallic elements.
29. Consider the elements of Group 4A (the "carbon family"): $\mathrm{C}, \mathrm{Si}, \mathrm{Ge}, \mathrm{Sn}$, and Pb . What is the trend in metallic character as one goes down this group? What is the trend in metallic character going from left to right across a period in the periodic table?
30. Chlorine has two natural isotopes: ${ }_{17}^{37} \mathrm{Cl}$ and ${ }_{17}^{35} \mathrm{Cl}$. Hydrogen reacts with chlorine to form the compound HCl . Would a given amount of hydrogen react with different masses of the two chlorine isotopes? Does this conflict with the law of definite proportion? Why or why not?
31. Before an electrocardiogram (ECG) is recorded for a cardiac patient, the ECG leads are usually coated with a moist paste containing sodium chloride. Why is sodium chloride applied to the leads?
32. Distinguish between the following terms.
a. molecule versus ion
b. covalent bonding versus ionic bonding
c. molecule versus compound
d. anion versus cation
33. Label the type of bonding for each of the following.

b.

34. The vitamin niacin (nicotinic acid, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2}$ ) can be isolated from a variety of natural sources such as liver, yeast, milk, and whole grain. It also can be synthesized from commercially available materials. From a nutritional point of view, which source of nicotinic acid is best for use in a multivitamin tablet? Why?
35. Which of the following statements is(are) true? For the false statements, correct them.
a. Most of the known elements are metals.
b. Element 118 should be a nonmetal.
c. Hydrogen has mostly metallic properties.
d. A family of elements is also known as a period of elements.
e. When an alkaline earth metal, A, reacts with a halogen, X , the formula of the covalent compound formed should be $\mathrm{A}_{2} \mathrm{X}$.
36. Each of the following compounds has three possible names listed for it. For each compound, what is the correct name and why aren't the other names used?
a. $\mathrm{N}_{2} \mathrm{O}$ : nitrogen oxide, nitrogen(I) oxide, dinitrogen monoxide
b. $\mathrm{Cu}_{2} \mathrm{O}$ : copper oxide, copper(I) oxide, dicopper monoxide
c. $\mathrm{Li}_{2} \mathrm{O}$ : lithium oxide, lithium(I) oxide, dilithium monoxide

## Exercises

In this section similar exercises are paired.

## Development of the Atomic Theory

-37. When mixtures of gaseous $\mathrm{H}_{2}$ and gaseous $\mathrm{Cl}_{2}$ react, a product forms that has the same properties regardless of the relative amounts of $\mathrm{H}_{2}$ and $\mathrm{Cl}_{2}$ used.
a. How is this result interpreted in terms of the law of definite proportion?
b. When a volume of $\mathrm{H}_{2}$ reacts with an equal volume of $\mathrm{Cl}_{2}$ at the same temperature and pressure, what volume of product having the formula HCl is formed?
38. Observations of the reaction between nitrogen gas and hydrogen gas show us that 1 volume of nitrogen reacts with 3 volumes of hydrogen to make 2 volumes of gaseous product, as shown below:

Determine the formula of the product and justify your answer.
-39. A sample of chloroform is found to contain 12.0 g of carbon, 106.4 g of chlorine, and 1.01 g of hydrogen. If a second sample of chloroform is found to contain 30.0 g of carbon, what is the total mass of chloroform in the second sample?
-40. A sample of $\mathrm{H}_{2} \mathrm{SO}_{4}$ contains 2.02 g of hydrogen, 32.07 g of sulfur, and 64.00 g of oxygen. How many grams of sulfur and grams of oxygen are present in a second sample of $\mathrm{H}_{2} \mathrm{SO}_{4}$ containing 7.27 g of hydrogen?
41. Consider $80.0-\mathrm{g}$ samples of two different compounds consisting of only carbon and oxygen. One of the compounds consists of 21.8 g of carbon, and the other has 34.3 g of carbon. Determine the ratio in whole numbers of the masses of carbon that combine with 1.00 g of oxygen between the two compounds.
42. Several compounds containing sulfur and fluorine are known. Three of them have the following compositions:
i. $\quad 1.188 \mathrm{~g}$ of F for every 1.000 g of S
ii. $\quad 2.375 \mathrm{~g}$ of F for every 1.000 g of S
iii. 3.563 g of F for every 1.000 g of S

How do these data illustrate the law of multiple proportions?
-43. The three most stable oxides of carbon are carbon monoxide $(\mathrm{CO})$, carbon dioxide $\left(\mathrm{CO}_{2}\right)$, and carbon suboxide $\left(\mathrm{C}_{3} \mathrm{O}_{2}\right)$. The molecules can be represented as

Explain how these molecules illustrate the law of multiple proportions.
44. Two elements, R and Q , combine to form two binary compounds. In the first compound, 14.0 g of R combines with 3.00 g of Q . In the second compound, 7.00 g of R combines with 4.50 g of Q . Show that these data are in accord with the law of multiple proportions. If the formula of the second compound is RQ , what is the formula of the first compound?
-45. In Section 1.1 of the text, the concept of a chemical reaction was introduced with the example of the decomposition of water, represented as follows:

Use ideas from Dalton's atomic theory to explain how the above representation illustrates the law of conservation of mass.
46. In a combustion reaction, 46.0 g of ethanol reacts with 96.0 g of oxygen to produce water and carbon dioxide. If 54.0 g of water is produced, what mass of carbon dioxide is produced?
-47. Early tables of atomic weights (masses) were generated by measuring the mass of a substance that reacts with 1.00 g of oxygen. Given the following data and taking the atomic mass of hydrogen as 1.00 , generate a table of relative atomic masses for oxygen, sodium, and magnesium.

| Element | Mass That Combines <br> with 1.00 g Oxygen | Assumed <br> Formula |
| :---: | :---: | :---: |
| Hydrogen | 0.126 g | HO |
| Sodium | 2.875 g | NaO |
| Magnesium | 1.500 g | MgO |

How do your values compare with those in the periodic table? How do you account for any differences?
48. Indium oxide contains 4.784 g of indium for every 1.000 g of oxygen. In 1869, when Mendeleev first presented his version of the periodic table, he proposed the formula $\mathrm{In}_{2} \mathrm{O}_{3}$ for indium oxide. Before that time it was thought that the formula was InO. What values for the atomic mass of indium are obtained using these two formulas? Assume that oxygen has an atomic mass of 16.00 .

## The Nature of the Atom

49. From the information in this chapter on the mass of the proton, the mass of the electron, and the sizes of the nucleus and the atom, calculate the densities of a hydrogen nucleus and a hydrogen atom.
50. If you wanted to make an accurate scale model of the hydrogen atom and decided that the nucleus would have a diameter of 1 mm , what would be the diameter of the entire model?
-51. In an experiment it was found that the total charge on an oil drop was $5.93 \times 10^{-18} \mathrm{C}$. How many negative charges does the drop contain?
51. A chemist in a galaxy far, far away performed the Millikan oil drop experiment and got the following results for the charges on various drops. Use these data to calculate the charge of the electron in zirkombs.

$$
\begin{array}{ll}
2.56 \times 10^{-12} \text { zirkombs } & 7.68 \times 10^{-12} \text { zirkombs } \\
3.84 \times 10^{-12} \text { zirkombs } & 6.40 \times 10^{-13} \text { zirkombs }
\end{array}
$$

53. Give the names of the metals that correspond to the following symbols: $\mathrm{Sn}, \mathrm{Pt}, \mathrm{Hg}, \mathrm{Mg}, \mathrm{K}, \mathrm{Ag}$.
54. What are the symbols of the following nonmetals: fluorine, chlorine, bromine, sulfur, oxygen, phosphorus?
55. In the periodic table, how many elements are found in each of the following?
a. Group 2A
b. the oxygen family
c. the nickel group
d. Group 8A
56. In the periodic table, how many elements are found in each of the following?
a. the halogen family
b. the alkali family
c. the lanthanide series
d. transition metals
a. Classify the following elements as metals or nonmetals:

| Mg | Si | Rn |
| :--- | :--- | :--- |
| Ti | Ge | Eu |
| Au | B | Am |
| Bi | At | Br |

b. The distinction between metals and nonmetals is really not a clear one. Some elements, called metalloids, are intermediate in their properties. Which of these elements would you reclassify as metalloids? What other elements in the periodic table would you expect to be metalloids?
58. a. List the noble gas elements. Which of the noble gases has only radioactive isotopes? (This situation is indicated on most periodic tables by parentheses around the mass of the element. See inside front cover.)
b. Which lanthanide element has only radioactive isotopes?
59. For each of the following sets of elements, label each as either noble gases, halogens, alkali metals, alkaline earth metals, or transition metals.
a. $\mathrm{Ti}, \mathrm{Fe}, \mathrm{Ag}$
b. $\mathrm{Mg}, \mathrm{Sr}, \mathrm{Ba}$
c. $\mathrm{Li}, \mathrm{K}, \mathrm{Rb}$
d. $\mathrm{Ne}, \mathrm{Kr}, \mathrm{Xe}$
e. $\mathrm{F}, \mathrm{Br}, \mathrm{I}$
60. Identify the elements that correspond to the following atomic numbers. Label each as either a noble gas, a halogen, an alkali metal, an alkaline earth metal, a transition metal, a lanthanide metal, or an actinide metal.
a. 17
b. 4
c. 63
d. 72
e. 2
f. 92
g. 55
[61. Write the atomic symbol ( $\left.{ }_{Z}^{A} X\right)$ for each of the following isotopes.
a. $Z=8$, number of neutrons $=9$
b. the isotope of chlorine in which $A=37$
c. $Z=27, A=60$
d. number of protons $=26$, number of neutrons $=31$
e. the isotope of $I$ with a mass number of 131
f. $Z=3$, number of neutrons $=4$
62. Write the atomic symbol $\left({ }_{Z}^{A} \mathrm{X}\right)$ for each of the isotopes described below.
a. number of protons $=27$, number of neutrons $=31$
b. the isotope of boron with mass number 10
c. $Z=12, A=23$
d. atomic number 53 , number of neutrons $=79$
e. $Z=20$, number of neutrons $=27$
f. number of protons $=29$, mass number 65

64. For carbon-14 and carbon-12, how many protons and neutrons are in each nucleus? Assuming neutral atoms, how many electrons are present in an atom of carbon-14 and in an atom of carbon-12?
-65. How many protons and neutrons are in the nucleus of each of the following atoms? In a neutral atom of each element, how many electrons are present?
a. ${ }^{79} \mathrm{Br}$
b. ${ }^{81} \mathrm{Br}$
c. ${ }^{239} \mathrm{Pu}$
d. ${ }^{133} \mathrm{Cs}$
e. ${ }^{3} \mathrm{H}$
f. ${ }^{56} \mathrm{Fe}$
66. What number of protons and neutrons are contained in the nucleus of each of the following atoms? Assuming each atom is uncharged, what number of electrons are present?
a. ${ }_{92}^{235} \mathrm{U}$
b. ${ }_{13}^{27} \mathrm{Al}$
c. ${ }_{26}^{57} \mathrm{Fe}$
d. ${ }_{82}^{208} \mathrm{~Pb}$
e. ${ }_{37}^{86} \mathrm{Rb}$
f. ${ }_{20}^{41} \mathrm{Ca}$
-67. For each of the following ions, indicate the number of protons and electrons the ion contains.
a. $\mathrm{Ba}^{2+}$
b. $\mathrm{Zn}^{2+}$
c. $\mathrm{N}^{3-}$
d. $\mathrm{Rb}^{+}$
e. $\mathrm{Co}^{3+}$
f. $\mathrm{Te}^{2-}$
g. $\mathrm{Br}^{-}$
68. How many protons, neutrons, and electrons are in each of the following atoms or ions?
a. ${ }_{12}^{24} \mathrm{Mg}$
b. ${ }_{12}^{24} \mathrm{Mg}^{2+}$
c. ${ }_{27}^{59} \mathrm{Co}^{2+}$
d. ${ }_{27}^{59} \mathrm{Co}^{3+}$
e. ${ }_{27}^{59} \mathrm{Co}$
f. ${ }_{34}^{79} \mathrm{Se}$
g. ${ }_{34}^{7} \mathrm{Se}^{2-}$
h. ${ }_{28}^{63} \mathrm{Ni}$
i. ${ }_{28}^{59} \mathrm{Ni}^{2+}$
-69. What is the symbol for an ion with 63 protons, 60 electrons, and 88 neutrons? If an ion contains 50 protons, 68 neutrons, and 48 electrons, what is its symbol?
70. What is the symbol of an ion with 16 protons, 18 neutrons, and 18 electrons? What is the symbol for an ion that has 16 protons, 16 neutrons, and 18 electrons?
-71. Complete the following table:

| Number <br> of Protons <br> in Nucleus | Number of <br> Neutrons <br> in Nucleus | Number of <br> ${ }_{92} \mathrm{U}$ |  |
| :---: | :---: | :---: | :---: |
| Electrons |  |  |  |$\quad$| Net |
| :---: |
| Charge |

72. Complete the following table:
$\left.\begin{array}{|cccc|}\hline & \begin{array}{c}\text { Number } \\ \text { of Protons } \\ \text { Symbol }\end{array} & \begin{array}{c}\text { Number of } \\ \text { Neutrons } \\ \text { in Nucleus }\end{array} & \begin{array}{c}\text { Number of } \\ \text { Electrons }\end{array}\end{array} \begin{array}{c}\text { Net } \\ \text { Charge }\end{array}\right]$
73. Would you expect each of the following atoms to gain or lose electrons when forming ions? What ion is the most likely in each case?
a. Ra
c. P
e. Br
b. In
d. Te
f. Rb
74. For each of the following atomic numbers, use the periodic table to write the formula (including the charge) for the simple ion that the element is most likely to form in ionic compounds.
a. 13
b. 34
c. 56
d. 7
e. 87
f. 35

## Nomenclature

-75. Name the compounds in parts a-d and write the formulas for the compounds in parts e-h.
a. NaBr
e. strontium fluoride
b. $\mathrm{Rb}_{2} \mathrm{O}$
f. aluminum selenide
c. CaS
g. potassium nitride
d. $\mathrm{AlI}_{3}$
h. magnesium phosphide
76. Name the compounds in parts a-d and write the formulas for the compounds in parts e-h.
a. $\mathrm{Hg}_{2} \mathrm{O}$
e. $\operatorname{tin}(\mathrm{II})$ nitride
b. $\mathrm{FeBr}_{3}$
f. cobalt(III) iodide
c. CoS
g. mercury(II) oxide
d. $\mathrm{TiCl}_{4}$
h. chromium(VI) sulfide
77. Name each of the following compounds:
a. CsF
b. $\mathrm{Li}_{3} \mathrm{~N}$
c. $\mathrm{Ag}_{2} \mathrm{~S}$
d. $\mathrm{MnO}_{2}$
e. $\mathrm{TiO}_{2}$
f. $\mathrm{Sr}_{3} \mathrm{P}_{2}$
78. Write the formula for each of the following compounds:
a. zinc chloride
d. aluminum sulfide
b. tin(IV) fluoride
e. mercury(I) selenide
c. calcium nitride
f. silver iodide
79. Name each of the following compounds:
a. $\mathrm{BaSO}_{3}$
b. $\mathrm{NaNO}_{2}$
c. $\mathrm{KMnO}_{4}$
d. $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$
80. Write the formula for each of the following compounds:
a. chromium(III) hydroxide
c. lead(IV) carbonate
b. magnesium cyanide
d. ammonium acetate
81. Name each of the following compounds:

b.

c. $\mathrm{SO}_{2}$
d. $\mathrm{P}_{2} \mathrm{~S}_{5}$
82. Write the formula for each of the following compounds:
a. diboron trioxide
b. arsenic pentafluoride
c. dinitrogen monoxide
d. sulfur hexachloride
83. Name each of the following compounds:
a. CuI
b. $\mathrm{CuI}_{2}$
c. $\mathrm{CoI}_{2}$
d. $\mathrm{Na}_{2} \mathrm{CO}_{3}$
e. $\mathrm{NaHCO}_{3}$
f. $\mathrm{S}_{4} \mathrm{~N}_{4}$
g. $\mathrm{SeCl}_{4}$
h. NaOCl
i. $\mathrm{BaCrO}_{4}$
j. $\mathrm{NH}_{4} \mathrm{NO}_{3}$
84. Name each of the following compounds. Assume the acids are dissolved in water.
a. $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
b. $\mathrm{NH}_{4} \mathrm{NO}_{2}$
c. $\mathrm{Co}_{2} \mathrm{~S}_{3}$
d. ICl
e. $\mathrm{Pb}_{3}\left(\mathrm{PO}_{4}\right)_{2}$
f. $\mathrm{KClO}_{3}$
g. $\mathrm{H}_{2} \mathrm{SO}_{4}$
h. $\mathrm{Sr}_{3} \mathrm{~N}_{2}$
i. $\mathrm{Al}_{2}\left(\mathrm{SO}_{3}\right)_{3}$
j. $\mathrm{SnO}_{2}$
k. $\mathrm{Na}_{2} \mathrm{CrO}_{4}$
l. HClO
85. Elements in the same family often form oxyanions of the same general formula. The anions are named in a similar fashion. What are the names of the oxyanions of selenium and tellurium: $\mathrm{SeO}_{4}{ }^{2-}, \mathrm{SeO}_{3}{ }^{2-}$, $\mathrm{TeO}_{4}{ }^{2-}, \mathrm{TeO}_{3}{ }^{2-}$ ?
86. Knowing the names of similar chlorine oxyanions and acids, deduce the names of the following: $\mathrm{IO}^{-}, \mathrm{IO}_{2}^{-}, \mathrm{IO}_{3}^{-}, \mathrm{IO}_{4}^{-}$, $\mathrm{HIO}, \mathrm{HIO}_{2}, \mathrm{HIO}_{3}, \mathrm{HIO}_{4}$.
87. Write the formula for each of the following compounds:
a. sulfur difluoride
b. sulfur hexafluoride
c. sodium dihydrogen phosphate
d. lithium nitride
e. chromium(III) carbonate
f. $\operatorname{tin}(\mathrm{II})$ fluoride
g. ammonium acetate
h. ammonium hydrogen sulfate
i. cobalt(III) nitrate
j. mercury(I) chloride
k. potassium chlorate
l. sodium hydride
88. Write the formula for each of the following compounds:
a. chromium(VI) oxide
b. disulfur dichloride
c. nickel(II) fluoride
d. potassium hydrogen phosphate
e. aluminum nitride
f. ammonia
g. manganese(IV) sulfide
h. sodium dichromate
i. ammonium sulfite
j. carbon tetraiodide
89. Write the formula for each of the following compounds:
a. sodium oxide
b. sodium peroxide
c. potassium cyanide
d. copper(II) nitrate
e. selenium tetrabromide
f. iodous acid
g. lead(IV) sulfide
h. copper(I) chloride
i. gallium arsenide
j. cadmium selenide
k. zinc sulfide
l. nitrous acid
m. diphosphorus pentoxide
90. Write the formula for each of the following compounds:
a. ammonium hydrogen phosphate
b. mercury(I) sulfide
c. silicon dioxide
d. sodium sulfite
e. aluminum hydrogen sulfate
f. nitrogen trichloride
g. hydrobromic acid
h. bromous acid
i. perbromic acid
j. potassium hydrogen sulfide
k. calcium iodide
l. cesium perchlorate
-91. Name the acids illustrated below.

a.

d.

b.

c.

e.

99. The isotope of an unknown element, X , has a mass number of 79. The most stable ion of the isotope has 36 electrons and forms a binary compound with sodium, having a formula of $\mathrm{Na}_{2} \mathrm{X}$. Which of the following statements is(are) true? For the false statements, correct them.
a. The binary compound formed between X and fluorine will be a covalent compound.
b. The isotope of X contains 38 protons.
c. The isotope of X contains 41 neutrons.
d. The identity of X is strontium, Sr .
100. For each of the following ions, indicate the total number of protons and electrons in the ion. For the positive ions in the list, predict the formula of the simplest compound formed between each positive ion and the oxide ion. Name the compounds. For the negative ions in the list, predict the formula of the simplest compound formed between each negative ion and the aluminum ion. Name the compounds.
a. $\mathrm{Fe}^{2+}$
b. $\mathrm{Fe}^{3+}$
c. $\mathrm{Ba}^{2+}$
d. $\mathrm{Cs}^{+}$
e. $\mathrm{S}^{2-}$
f. $\mathrm{P}^{3-}$
g. $\mathrm{Br}^{-}$
h. $\mathrm{N}^{3-}$
101. The formulas and common names for several substances are given below. Give the systematic names for these substances.
a. sugar of lead
$\mathrm{Pb}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}$
b. blue vitrol
$\mathrm{CuSO}_{4}$
c. quicklime
CaO
d. Epsom salts $\mathrm{MgSO}_{4}$
e. milk of magnesia $\mathrm{Mg}(\mathrm{OH})_{2}$
f. gypsum $\mathrm{CaSO}_{4}$
g. laughing gas
$\mathrm{N}_{2} \mathrm{O}$
102. Identify each of the following elements:
a. a member of the same family as oxygen whose most stable ion contains 54 electrons
b. a member of the alkali metal family whose most stable ion contains 36 electrons
c. a noble gas with 18 protons in the nucleus
d. a halogen with 85 protons and 85 electrons
103. An element's most stable ion forms an ionic compound with bromine, having the formula $\mathrm{XBr}_{2}$. If the ion of element X has a mass number of 230 and has 86 electrons, what is the identity of the element, and how many neutrons does it have?
104. A certain element has only two naturally occurring isotopes: one with 18 neutrons and the other with 20 neutrons. The element forms 1 - charged ions when in ionic compounds. Predict the identity of the element. What number of electrons does the 1 - charged ion have?
105. The designations 1A through 8A used for certain families of the periodic table are helpful for predicting the charges on ions in binary ionic compounds. In these compounds, the metals generally take on a positive charge equal to the family number, while the nonmetals take on a negative charge equal to the family number minus eight. Thus the compound between sodium and chlorine contains $\mathrm{Na}^{+}$ions and $\mathrm{Cl}^{-}$ions and has the formula NaCl . Predict the formula and the name of the binary compound formed from the following pairs of elements.
a. Ca and N
d. Mg and S
g. Cs and P
b. K and O
e. Ba and I
h. In and Br
106. By analogy with phosphorus compounds, name the following: $\mathrm{Na}_{3} \mathrm{AsO}_{4}, \mathrm{H}_{3} \mathrm{AsO}_{4}, \mathrm{Mg}_{3}\left(\mathrm{SbO}_{4}\right)_{2}$.
107. Identify each of the following elements. Give the number of protons and neutrons in each nucleus.
a. ${ }_{15}^{31} \mathrm{X}$
b. ${ }_{53}^{127} \mathrm{X}$
c. ${ }_{19}^{39} \mathrm{X}$
d. ${ }_{70}^{173} \mathrm{X}$
108. In a reaction, 34.0 g of chromium(III) oxide reacts with 12.1 g of aluminum to produce chromium and aluminum oxide. If 23.3 g of chromium is produced, what mass of aluminum oxide is produced?
109. Consider $100.0-\mathrm{g}$ samples of two different compounds consisting only of carbon and oxygen. One compound contains 27.2 g of carbon, and the other has 42.9 g of carbon. How can these data support the law of multiple proportions if 42.9 is not a multiple of 27.2? Show that these data support the law of multiple proportions.
110. Give the systematic name for the following compounds that are found in everyday life:
a. $\mathrm{H}_{2} \mathrm{~S}$ (rotten egg smell)
b. $\mathrm{SO}_{2}$ (smell of burnt matches)
c. $\mathrm{SF}_{6}$ (aerosol can propellant)
d. $\mathrm{Na}_{2} \mathrm{SO}_{3}$ (dried fruit preservative)

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
111. Complete the following table, including the mass number and the atomic number, with the symbol for the isotope.

| Number of Protons | Number of Neutrons |
| :---: | :---: |
| 9 | 10 |
| 13 | 14 |
| 53 | 74 |
| 34 | 45 |
| 16 | 16 |

112. Complete the following table.

| Symbol $\quad$ Number of Protons |  |
| :--- | :--- |
| ${ }_{2}^{4} \mathrm{He}$ |  |
| ${ }_{10}^{20} \mathrm{Ne}$ |  |
| ${ }_{22}^{48} \mathrm{Ti}$ |  |
| ${ }^{19} 9$ |  |
| ${ }_{76}^{50} \mathrm{Os}$ |  |
| 27 Co |  |

113. Complete the following table.

| Atom/lon Protons $\quad$ Neutrons Electrons |  |
| :--- | :--- | :--- |
| ${ }_{50}^{120} \mathrm{Sn}$ |  |
| ${ }_{12}^{25} \mathrm{Mg}^{2+}$ |  |
| ${ }_{26}^{56} \mathrm{Fe}^{2+}$ |  |
| 79 |  |
| ${ }_{34} \mathrm{Se}$ |  |
| ${ }^{35} \mathrm{Cl}$ |  |
| ${ }_{29}^{63} \mathrm{Cu}$ |  |

114. Which of the following is(are) correct?
a. ${ }^{40} \mathrm{Ca}^{2+}$ contains 20 protons and 18 electrons.
b. Rutherford created the cathode-ray tube and was the founder of the charge-to-mass ratio of an electron.
c. An electron is heavier than a proton.
d. The nucleus contains protons, neutrons, and electrons.
115. What are the formulas of the compounds that correspond to the names given in the following table?

| Compound Name |
| :--- |
| Carbon tetrabromide |
| Cobalt(II) phosphate |
| Magnesium chloride |
| Nickel(II) acetate |
| Calcium nitrate |

116. What are the names of the compounds that correspond to the formulas given in the following table?

| Formula | Compound Name |
| :--- | :--- |
| $\mathrm{Co}\left(\mathrm{NO}_{2}\right)_{2}$ |  |
| $\mathrm{AsF}_{5}$ |  |
| LiCN |  |
| $\mathrm{K}_{2} \mathrm{SO}_{3}$ |  |
| $\mathrm{Li}_{3} \mathrm{~N}$ |  |
| $\mathrm{PbCrO}_{4}$ |  |

117. Complete the following table to predict whether the given atom will gain or lose electrons in forming the ion most likely to form when in ionic compounds.

| Atom | Gain (G) or Lose (L) <br> Electrons |
| :--- | :--- |
| K |  |
| Cs |  |
| Br |  |
| S |  |
| Se |  |

118. Which of the following statements is(are) correct?
a. The symbols for the elements magnesium, aluminum, and xenon are $\mathrm{Mn}, \mathrm{Al}$, and Xe , respectively.
b. The elements P, As, and Bi are in the same family on the periodic table.
c. All of the following elements are expected to gain electrons to form ions in ionic compounds: $\mathrm{Ga}, \mathrm{Se}$, and Br .
d. The elements $\mathrm{Co}, \mathrm{Ni}$, and Hg are all transition elements.
e. The correct name for $\mathrm{TiO}_{2}$ is titanium dioxide.

## Challenge Problems

119. The elements in one of the groups in the periodic table are often called the coinage metals. Identify the elements in this group based on your own experience.
120. Reaction of 2.0 L of hydrogen gas with 1.0 L of oxygen gas yields 2.0 L of water vapor. All gases are at the same temperature and pressure. Show how these data support the idea that oxygen gas is a diatomic molecule. Must we consider hydrogen to be a diatomic molecule to explain these results?
121. A combustion reaction involves the reaction of a substance with oxygen gas. The complete combustion of any hydrocarbon (binary compound of carbon and hydrogen) produces carbon dioxide and water as the only products. Octane is a hydrocarbon that is found in gasoline. Complete combustion of octane produces 8 L of carbon dioxide for every 9 L of water vapor (both measured at the same temperature and pressure). What is the ratio of carbon atoms to hydrogen atoms in a molecule of octane?
122. A chemistry instructor makes the following claim: "Consider that if the nucleus were the size of a grape, the electrons would be about 1 mile away on average." Is this claim reasonably accurate? Provide mathematical support.
123. The early alchemists used to do an experiment in which water was boiled for several days in a sealed glass container. Eventually, some solid residue would appear in the bottom of the flask, which was interpreted to mean that some of the water in the flask had been converted into "earth." When Lavoisier repeated this experiment, he found that the water weighed the same before and after heating, and the mass of the flask plus the solid residue equaled the original mass of the flask. Were the alchemists correct? Explain what really happened. (This experiment is described in the article by A. F. Scott in Scientific American, January 1984.)
124. Consider the chemical reaction as depicted below. Label as much as you can using the terms atom, molecule, element, compound, ionic, gas, and solid.

125. Each of the following statements is true, but Dalton might have had trouble explaining some of them with his atomic theory. Give explanations for the following statements.
a. The space-filling models for ethyl alcohol and dimethyl ether are shown below.

These two compounds have the same composition by mass ( $52 \%$ carbon, $13 \%$ hydrogen, and $35 \%$ oxygen), yet the two have different melting points, boiling points, and solubilities in water.
b. Burning wood leaves an ash that is only a small fraction of the mass of the original wood.
c. Atoms can be broken down into smaller particles.
d. One sample of lithium hydride is $87.4 \%$ lithium by mass, while another sample of lithium hydride is $74.9 \%$ lithium by mass. However, the two samples have the same chemical properties.
126. You have two distinct gaseous compounds made from element X and element Y . The mass percents are as follows:
Compound I: $30.43 \% \mathrm{X}, 69.57 \% \mathrm{Y}$
Compound II: $63.64 \%$ X, $36.36 \%$ Y
In their natural standard states, element $X$ and element $Y$ exist as gases. (Monatomic? Diatomic? Triatomic? That is for you to determine.) When you react "gas X" with "gas Y" to make the products, you get the following data (all at the same pressure and temperature):
1 volume "gas X " +2 volumes "gas Y " $\longrightarrow$
2 volumes compound I
2 volumes "gas X " +1 volume "gas Y " $\longrightarrow$
2 volumes compound II
Assume the simplest possible formulas for reactants and products in the chemical equations above. Then, determine the relative atomic masses of element X and element Y .
127. A single molecule has a mass of $7.31 \times 10^{-23} \mathrm{~g}$. Provide an example of a real molecule that can have this mass. Assume the elements that make up the molecule are made of light isotopes where the number of protons equals the number of neutrons in the nucleus of each element.
128. You take three compounds, each consisting of two elements ( $\mathrm{X}, \mathrm{Y}$, and/or Z ), and decompose them to their respective elements. To determine the relative masses of $\mathrm{X}, \mathrm{Y}$, and Z , you collect and weigh the elements, obtaining the following data:

| Elements in Compound | Masses of Elements |
| :--- | :--- |
| 1. $X$ and $Y$ | $X=0.4 \mathrm{~g}, \mathrm{Y}=4.2 \mathrm{~g}$ |
| 2. Y and Z | $\mathrm{Y}=1.4 \mathrm{~g}, \mathrm{Z}=1.0 \mathrm{~g}$ |
| 3. X and Y | $\mathrm{X}=2.0 \mathrm{~g}, \mathrm{Y}=7.0 \mathrm{~g}$ |

a. What are the assumptions needed to solve this problem?
b. What are the relative masses of $\mathrm{X}, \mathrm{Y}$, and Z ?
c. What are the chemical formulas of the three compounds?
d. If you decompose 21 g of compound XY, how much of each element is present?

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
129. What is the systematic name of $\mathrm{Ta}_{2} \mathrm{O}_{5}$ ? If the charge on the metal remained constant and then sulfur was substituted for oxygen, how would the formula change? What is the difference in the total number of protons between $\mathrm{Ta}_{2} \mathrm{O}_{5}$ and its sulfur analog?
130. A binary ionic compound is known to contain a cation with 51 protons and 48 electrons. The anion contains one-third the number of protons as the cation. The number of electrons in the anion is equal to the number of protons plus 1 . What is the formula of this compound? What is the name of this compound?
131. Using the information in Table 2.1, answer the following questions. In an ion with an unknown charge, the total mass of all the electrons was determined to be $2.55 \times 10^{-26} \mathrm{~g}$, while the total mass of its protons was $5.34 \times 10^{-23} \mathrm{~g}$. What is the identity and charge of this ion? What is the symbol and mass number of a neutral atom whose total mass of its electrons is $3.92 \times 10^{-26} \mathrm{~g}$, while its neutrons have a mass of $9.35 \times 10^{-23} \mathrm{~g}$ ?

## Marathon Problem

This problem is designed to incorporate several concepts and techniques into one situation.
132. You have gone back in time and are working with Dalton on a table of relative masses. Following are his data.
0.602 g gas A reacts with 0.295 g gas B
0.172 g gas B reacts with 0.401 g gas C
0.320 g gas A reacts with 0.374 g gas C
a. Assuming simplest formulas $(\mathrm{AB}, \mathrm{BC}$, and AC$)$, construct a table of relative masses for Dalton.
b. Knowing some history of chemistry, you tell Dalton that if he determines the volumes of the gases reacted at constant temperature and pressure, he need not assume simplest formulas. You collect the following data:
6 volumes gas $A+1$ volume gas $B \rightarrow$
4 volumes product
1 volume gas $B+4$ volumes gas $C \rightarrow$ 4 volumes product
3 volumes gas $\mathrm{A}+2$ volumes gas $\mathrm{C} \rightarrow$
6 volumes product
Write the simplest balanced equations, and find the actual relative masses of the elements. Explain your reasoning.

Fireworks provide a spectacular example of chemical reactions. (jamesbenet/istockphoto.com)

Amounts of Reactants and Products
3.11 The Concept of Limiting Reactant Determination of Limiting Reactant Using Reactant Quantities
Determination of Limiting Reactant Using Quantities of Products Formed

Chemical reactions have a profound effect on our lives. There are many examples: Food is converted to energy in the human body; nitrogen and hydrogen are combined to form ammonia, which is used as a fertilizer; fuels and plastics are produced from petroleum; the starch in plants is synthesized from carbon dioxide and water using energy from sunlight; human insulin is produced in laboratories by bacteria; cancer is induced in humans by substances from our environment; and so on, in a seemingly endless list. The central activity of chemistry is to understand chemical changes such as these, and the study of reactions occupies a central place in this book. We will examine why reactions occur, how fast they occur, and the specific pathways they follow.

In this chapter we will consider the quantities of materials consumed and produced in chemical reactions. This area of study is called chemical stoichiometry (pronounced stoy $\left.\cdot \mathrm{ke} \cdot \mathrm{om}^{\prime} \cdot \mathrm{uh} \cdot \mathrm{trē}\right)$. To understand chemical stoichiometry, you must first understand the concept of relative atomic masses.

### 3.1 Counting by Weighing

Suppose you work in a candy store that sells gourmet jelly beans by the bean. People come in and ask for 50 beans, 100 beans, 1000 beans, and so on, and you have to count them out-a tedious process at best. As a good problem solver, you try to come up with a better system. It occurs to you that it might be far more efficient to buy a scale and count the jelly beans by weighing them. How can you count jelly beans by weighing them? What information about the individual beans do you need to know?

Assume that all of the jelly beans are identical and that each has a mass of 5 g . If a customer asks for 1000 jelly beans, what mass of jelly beans would be required? Each bean has a mass of 5 g , so you would need 1000 beans $\times 5 \mathrm{~g} /$ bean, or $5000 \mathrm{~g}(5 \mathrm{~kg})$. It takes just a few seconds to weigh out 5 kg of jelly beans. It would take much longer to count out 1000 of them.

In reality, jelly beans are not identical. For example, let's assume that you weigh 10 beans individually and get the following results:

| Bean | Mass | Bean |
| :---: | :---: | :---: |
| 1 | 5.1 g | 6 |
| 2 | 5.0 g |  |
| 3 | 5.0 g | 7 |
| 4 | 4.8 g | 9 |
| 5 | 4.9 g | 10 |
|  |  | 5.9 g |
|  |  |  |

Can we count these nonidentical beans by weighing? Yes. The key piece of information we need is the average mass of the jelly beans. Let's compute the average mass for our 10-bean sample.

$$
\begin{aligned}
& \text { Average mass }=\frac{\text { total mass of beans }}{\text { number of beans }} \\
& =\frac{5.1 \mathrm{~g}+5.2 \mathrm{~g}+5.0 \mathrm{~g}+4.8 \mathrm{~g}+4.9 \mathrm{~g}+5.0 \mathrm{~g}+5.0 \mathrm{~g}+5.1 \mathrm{~g}+4.9 \mathrm{~g}+5.0 \mathrm{~g}}{10} \\
& =\frac{50.0}{10}=5.0 \mathrm{~g}
\end{aligned}
$$

The average mass of a jelly bean is 5.0 g . Thus, to count out 1000 beans, we need to weigh out 5000 g of beans. This sample of beans, in which the beans have an average mass of 5.0 g , can be treated exactly like a sample where all of the beans
are identical. Objects do not need to have identical masses to be counted by weighing. We simply need to know the average mass of the objects. For purposes of counting, the objects behave as though they were all identical, as though they each actually had the average mass.

We count atoms in exactly the same way. Because atoms are so small, we deal with samples of matter that contain huge numbers of atoms. Even if we could see the atoms, it would not be possible to count them directly. Thus we determine the number of atoms in a given sample by finding its mass. However, just as with jelly beans, to relate the mass to a number of atoms, we must know the average mass of the atoms.

### 3.2 Atomic Masses

As we saw in Chapter 2, the first quantitative information about atomic masses came from the work of Dalton, Gay-Lussac, Lavoisier, Avogadro, and Berzelius. By observing the proportions in which elements combine to form various compounds, nineteenthcentury chemists calculated relative atomic masses. The modern system of atomic masses, instituted in 1961, is based on ${ }^{12} \mathrm{C}$ ("carbon twelve") as the standard. In this system, ${ }^{12} \mathrm{C}$ is assigned a mass of exactly 12 atomic mass units $(\mathrm{u})$, and the masses of all other atoms are given relative to this standard.

The most accurate method currently available for comparing the masses of atoms involves the use of the mass spectrometer. In this instrument, diagramed in Fig. 3.1, atoms or molecules are passed into a beam of high-speed electrons, which knock electrons off the atoms or molecules being analyzed and change them into positive ions. An applied electric field then accelerates these ions into a magnetic field. Because an accelerating ion produces its own magnetic field, an interaction with the applied magnetic field occurs, which tends to change the path of the ion. The amount of path deflection for each ion depends on its mass-the most massive ions are deflected the smallest amount-which causes the ions to separate, as shown in Fig. 3.1. A comparison of the positions where the ions hit the detector plate gives very accurate values of their relative masses. For example, when ${ }^{12} \mathrm{C}$ and ${ }^{13} \mathrm{C}$ are analyzed in a mass spectrometer, the ratio of their masses is found to be

$$
\frac{\text { Mass }{ }^{13} \mathrm{C}}{\text { Mass }{ }^{12} \mathrm{C}}=1.0836129
$$

FIGURE 3.1 (left) A scientist using a mass spectrometer. (right) Schematic diagram of a mass spectrometer.

Heating device to vaporize sample

Electron beam

The International Union of Pure and Applied Chemistry (IUPAC) has declared that what we refer to as the "average atomic mass" should be called the "atomic weight" of an element, which is dimensionless by custom. However, we will retain the term "average atomic mass" because this name accurately describes what the term represents.

Most elements occur in nature as mixtures of isotopes; thus atomic masses are usually average values.

$\Delta$
It is much easier to weigh out 600 hex nuts than to count them one by one.

Since the atomic mass unit is defined such that the mass of ${ }^{12} \mathrm{C}$ is exactly 12 atomic mass units, then on this same scale,

$$
\text { Mass of }{ }^{13} \mathrm{C}=(1.0836129)(12 \mathrm{u})=13.003355 \mathrm{u}
$$

The masses of other atoms can be determined in a similar fashion.
The mass for each element is given in the table inside the front cover of this text. This value, even though it is actually a mass, is sometimes called the atomic weight for each element.

Look at the value of the atomic mass of carbon given in this table. You might expect to see 12 , since we said the system of atomic masses is based on ${ }^{12} \mathrm{C}$. However, the number given for carbon is not 12 but 12.01. Why? The reason for this apparent discrepancy is that the carbon found on earth (natural carbon) is a mixture of the isotopes ${ }^{12} \mathrm{C},{ }^{13} \mathrm{C}$, and ${ }^{14} \mathrm{C}$. All three isotopes have six protons, but they have six, seven, and eight neutrons, respectively. Because natural carbon is a mixture of isotopes, the atomic mass we use for carbon is an average value reflecting the average of the isotopes composing it.

The average atomic mass for carbon is computed as follows: It is known that natural carbon is composed of $98.89 \%{ }^{12} \mathrm{C}$ atoms and $1.11 \%{ }^{13} \mathrm{C}$ atoms. The amount of ${ }^{14} \mathrm{C}$ is negligibly small at this level of precision. Using the masses of ${ }^{12} \mathrm{C}$ (exactly 12 u ) and ${ }^{13} \mathrm{C}(13.003355 \mathrm{u})$, we can calculate the average atomic mass for natural carbon as follows:
$98.89 \%$ of $12 \mathrm{u}+1.11 \%$ of $13.0034 \mathrm{u}=$

$$
(0.9889)(12 \mathrm{u})+(0.0111)(13.0034 \mathrm{u})=12.01 \mathrm{u}
$$

In this text we will call the average mass for an element the average atomic mass or, simply, the atomic mass for that element.

Even though natural carbon does not contain a single atom with mass 12.01, for stoichiometric purposes, we can consider carbon to be composed of only one type of atom with a mass of 12.01 . This enables us to count atoms of natural carbon by weighing a sample of carbon.

Recall from Section 3.1 that counting by weighing works if you know the average mass of the units being counted. Counting by weighing works just the same for atoms as for jelly beans. For natural carbon with an average mass of 12.01 atomic mass units,

FIGURE 3.2 (a) Neon guitars on Beale Street in Memphis. The relative intensities of the signals recorded when natural neon is injected into a mass spectrometer, represented in terms of (b) "peaks" and (c) a bar graph. The relative areas of the peaks are $0.9092\left({ }^{20} \mathrm{Ne}\right), 0.00257\left({ }^{21} \mathrm{Ne}\right)$, and $0.0882\left({ }^{22} \mathrm{Ne}\right)$; natural neon is therefore $90.92 \%{ }^{20} \mathrm{Ne}$, $0.257 \%{ }^{21} \mathrm{Ne}$, and $8.82 \%{ }^{22} \mathrm{Ne}$.
to obtain 1000 atoms would require weighing out 12,010 atomic mass units of natural carbon (a mixture of ${ }^{12} \mathrm{C}$ and ${ }^{13} \mathrm{C}$ ).

As in the case of carbon, the mass for each element listed in the table inside the front cover of the text is an average value based on the isotopic composition of the naturally occurring element. For instance, the mass listed for hydrogen (1.008) is the average mass for natural hydrogen, which is a mixture of ${ }^{1} \mathrm{H}$ and ${ }^{2} \mathrm{H}$ (deuterium). No atom of hydrogen actually has the mass 1.008.

In addition to being useful for determining accurate mass values for individual atoms, the mass spectrometer is used to determine the isotopic composition of a natural element. For example, when a sample of natural neon is injected into a mass spectrometer, the mass spectrum shown in Fig. 3.2 is obtained. The areas of the "peaks" or the heights of the bars indicate the relative abundances of ${ }_{10}^{20} \mathrm{Ne},{ }_{10}^{21} \mathrm{Ne}$, and ${ }_{10}^{22} \mathrm{Ne}$ atoms.

## EXAMPLE 3.1 The Average Mass of an Element

When a sample of natural copper is vaporized and injected into a mass spectrometer, the results shown in Fig. 3.3 are obtained. Use these data to compute the average mass of natural copper. (The mass values for ${ }^{63} \mathrm{Cu}$ and ${ }^{65} \mathrm{Cu}$ are 62.93 u and 64.93 u , respectively.)

## SOLUTION Where are we going?

To calculate the average mass of natural copper
What do we know?

$$
\begin{aligned}
& >{ }^{63} \mathrm{Cu} \text { mass }=62.93 \mathrm{u} \\
& >{ }^{65} \mathrm{Cu} \text { mass }=64.93 \mathrm{u}
\end{aligned}
$$

## How do we get there?

As shown by the graph, of every 100 atoms of natural copper, 69.09 are ${ }^{63} \mathrm{Cu}$ and 30.91 are ${ }^{65} \mathrm{Cu}$. Thus the mass of 100 atoms of natural copper is

$$
(69.09 \text { atoms })\left(62.93 \frac{\mathrm{u}}{\text { atom }}\right)+(30.91 \text { atoms })\left(64.93 \frac{\mathrm{u}}{\text { atom }}\right)=6355 \mathrm{u}
$$

The average mass of a copper atom is

$$
\frac{6355 \mathrm{u}}{100 \text { atoms }}=63.55 \mathrm{u} / \text { atom }
$$

This mass value is used in doing calculations involving the reactions of copper and is the value given in the table inside the front cover of this book.

Reality Check When you finish a calculation, you should always check whether your answer makes sense. In this case our answer of 63.55 u is between the masses of the atoms that make up natural copper. This makes sense. The answer could not be smaller than 62.93 u or larger than 64.93 u .

$$
\text { See Exercises } 3.39 \text { and } 3.46
$$

### 3.3 The Mole

Because samples of matter typically contain so many atoms, a unit of measure called the mole has been established for use in counting atoms. For our purposes, it is most convenient to define the mole (abbreviated mol ) as the number equal to the number of

FIGURE 3.4 One-mole samples of several elements.

The SI definition of the mole is the amount of a substance that contains as many entities as there are in exactly 12 g of carbon-12.

Avogadro's number is $6.022 \times 10^{23}$. One mole of anything is $6.022 \times 10^{23}$ units of that substance.

The mass of 1 mole of an element is equal to its atomic mass in grams.

carbon atoms in exactly 12 g of pure ${ }^{12} \mathrm{C}$. Techniques such as mass spectrometry, which count atoms very precisely, have been used to determine this number as $6.02214 \times 10^{23}$ ( $6.022 \times 10^{23}$ will be sufficient for our purposes). This number is called Avogadro's number to honor his contributions to chemistry. One mole of something consists of $6.022 \times 10^{23}$ units of that substance. Just as a dozen eggs is 12 eggs, a mole of eggs is $6.022 \times 10^{23}$ eggs.

The magnitude of the number $6.022 \times 10^{23}$ is very difficult to imagine. To give you some idea, 1 mole of seconds represents a span of time 4 million times as long as the earth has already existed, and 1 mole of marbles is enough to cover the entire earth to a depth of 50 miles! However, since atoms are so tiny, a mole of atoms or molecules is a perfectly manageable quantity to use in a reaction (Fig. 3.4).

##  from 1 to $6 \times 10^{23}$ at a rate of one number each second? <br> Determine your hourly wage. Would you do it? Could you do it?

How do we use the mole in chemical calculations? Recall that Avogadro's number is defined as the number of atoms in exactly 12 g of ${ }^{12} \mathrm{C}$. This means that 12 g of ${ }^{12} \mathrm{C}$ contains $6.022 \times 10^{23}$ atoms. It also means that a $12.01-\mathrm{g}$ sample of natural carbon contains $6.022 \times 10^{23}$ atoms (a mixture of ${ }^{12} \mathrm{C},{ }^{13} \mathrm{C}$, and ${ }^{14} \mathrm{C}$ atoms, with an average atomic mass of 12.01 ). Since the ratio of the masses of the samples ( $12 \mathrm{~g} / 12.01 \mathrm{~g}$ ) is the same as the ratio of the masses of the individual components ( $12 \mathrm{u} / 12.01 \mathrm{u}$ ), the two samples contain the same number of atoms ( $6.022 \times 10^{23}$ ) .

To be sure this point is clear, think of oranges with an average mass of 0.5 lb each and grapefruit with an average mass of 1.0 lb each. Any two sacks for which the sack of grapefruit weighs twice as much as the sack of oranges will contain the same number of pieces of fruit. The same idea extends to atoms. Compare natural carbon (average mass of 12.01) and natural helium (average mass of 4.003). A sample of 12.01 g of natural carbon contains the same number of atoms as 4.003 g of natural helium. Both samples contain 1 mole of atoms ( $6.022 \times 10^{23}$ ). Table 3.1 gives more examples that illustrate this basic idea.

Thus the mole is defined such that a sample of a natural element with a mass equal to the element's atomic mass expressed in grams contains 1 mole of atoms. This

TABLE 3.1 \| Comparison of 1-Mole Samples of Various Elements

| Element | Number of Atoms Present | Mass of Sample (g) |
| :--- | :---: | :---: |
| Aluminum | $6.022 \times 10^{23}$ | 26.98 |
| Copper | $6.022 \times 10^{23}$ | 63.55 |
| Iron | $6.022 \times 10^{23}$ | 55.85 |
| Sulfur | $6.022 \times 10^{23}$ | 32.07 |
| lodine | $6.022 \times 10^{23}$ | 126.9 |
| Mercury | $6.022 \times 10^{23}$ | 200.6 |

definition also fixes the relationship between the atomic mass unit and the gram. Since $6.022 \times 10^{23}$ atoms of carbon (each with a mass of 12 u ) have a mass of 12 g , then

$$
\left(6.022 \times 10^{23} \text { atoms }\right)\left(\frac{12 \mathrm{u}}{\text { atom }}\right)=12 \mathrm{~g}
$$

and

$$
6.022 \times 10^{23} \mathrm{u}=\underset{\substack{\uparrow \\ \text { Exact } \\ \text { number }}}{1 \mathrm{~g}}
$$

This relationship can be used to derive the unit factor needed to convert between atomic mass units and grams.
 was not $6.02 \times 10^{23}$ but $3.01 \times 10^{23}$ ? Would this affect the relative masses given on the periodic table? If so, how? If not, why not?

## INTERACTIVE EXAMPLE 3.2 Determining the Mass of a Sample of Atoms

Americium is an element that does not occur naturally. It can be made in very small amounts in a device known as a particle accelerator. Compute the mass in grams of a sample of americium containing six atoms.

## SOLUTION Where are we going?

To calculate the mass of six americium atoms

## What do we know?

> Mass of 1 atom of $\mathrm{Am}=243 \mathrm{u}$ (from the periodic table inside the front cover)

## How do we get there?

The mass of six atoms is

$$
6 \text { atoms } \times 243 \frac{\mathrm{u}}{\text { atom }}=1.46 \times 10^{3} \mathrm{u}
$$

Using the relationship

$$
6.022 \times 10^{23} \mathrm{u}=1 \mathrm{~g}
$$

we write the conversion factor for converting atomic mass units to grams:

$$
\frac{1 \mathrm{~g}}{6.022 \times 10^{23} \mathrm{u}}
$$

The mass of six americium atoms in grams is

$$
1.46 \times 10^{3} k \times \frac{1 \mathrm{~g}}{6.022 \times 10^{23} k}=2.42 \times 10^{-21} \mathrm{~g}
$$

Reality Check Since this sample contains only six atoms, the mass should be very small as the amount $2.42 \times 10^{-21} \mathrm{~g}$ indicates.

## See Exercise 3.47

To do chemical calculations, you must understand what the mole means and how to determine the number of moles in a given mass of a substance. These procedures are illustrated in Examples 3.3 and 3.4.

## INTERACTVE EXAMPLE 3.3 Determining Moles of Atoms

Aluminum ( Al ) is a metal with a high strength-to-mass ratio and a high resistance to corrosion; thus it is often used for structural purposes. Compute both the number of moles of atoms and the number of atoms in a $10.0-\mathrm{g}$ sample of aluminum.
(left) Pure aluminum. (right) Aluminum alloys are used for many products used in our kitchens.

## SOLUTION

## Where are we going?

To calculate the moles and number of atoms in a sample of Al
What do we know?
> Sample contains 10.0 g of Al
> Mass of 1 mole ( $6.022 \times 10^{23}$ atoms $)$ of $\mathrm{Al}=26.93 \mathrm{~g}$

## How do we get there?

We can calculate the number of moles of Al in a $10.0-\mathrm{g}$ sample as follows:

$$
10.0 \mathrm{~g} \mathrm{AI} \times \frac{1 \mathrm{~mol} \mathrm{Al}}{26.98 \mathrm{~g} \mathrm{AI}}=0.371 \mathrm{~mol} \mathrm{Al} \text { atoms }
$$

The number of atoms in 10.0 g ( 0.371 mole ) of aluminum is

$$
0.371 \mathrm{~mol} \mathrm{At} \times \frac{6.022 \times 10^{23} \text { atoms }}{1 \mathrm{~mol} \text { At }}=2.23 \times 10^{23} \text { atoms }
$$

Reality Check One mole of Al has a mass of 26.98 g and contains $6.022 \times 10^{23}$ atoms. Our sample is 10.0 g , which is roughly $1 / 3$ of 26.98 . Thus the calculated amount should be on the order of $1 / 3$ of $6 \times 10^{23}$, which it is.

## INTERACTIVE EXAMPLE 3.4 Calculating Numbers of Atoms

## SOLUTION

Paying careful attention to units and making sure the answer is reasonable can help you detect an inverted conversion factor or a number that was incorrectly entered in your calculator.

Always check to see if your answer is sensible.

A silicon chip used in an integrated circuit of a microcomputer has a mass of 5.68 mg . How many silicon $(\mathrm{Si})$ atoms are present in the chip?

## Where are we going?

To calculate the atoms of Si in the chip

## What do we know?

) The chip has 5.68 mg of Si
) Mass of 1 mole ( $6.022 \times 10^{23}$ atoms $)$ of $\mathrm{Si}=28.09 \mathrm{~g}$

## How do we get there?

The strategy for doing this problem is to convert from milligrams of silicon to grams of silicon, then to moles of silicon, and finally to atoms of silicon:

$$
\begin{array}{r}
5.68 \mathrm{mgSi} \times \frac{1 \mathrm{~g} \mathrm{Si}}{1000 \mathrm{mg} \mathrm{Si}}=5.68 \times 10^{-3} \mathrm{~g} \mathrm{Si} \\
5.68 \times 10^{-3} \mathrm{~g} \mathrm{Si} \times \frac{1 \mathrm{~mol} \mathrm{Si}}{28.09 \mathrm{gSi}}=2.02 \times 10^{-4} \mathrm{~mol} \mathrm{Si} \\
2.02 \times 10^{-4} \operatorname{motSi} \times \frac{6.022 \times 10^{23} \mathrm{atoms}}{1 \mathrm{~mol} \mathrm{Si}}=1.22 \times 10^{20} \text { atoms }
\end{array}
$$

Reality Check Note that 5.68 mg of silicon is clearly much less than 1 mole of silicon (which has a mass of 28.09 g ), so the final answer of $1.22 \times 10^{20}$ atoms (compared with $6.022 \times 10^{23}$ atoms) is in the right direction.

## See Exercise 3.49

## INTERACTIVE EXAMPLE 3.5 Calculating the Number of Moles and Mass

Cobalt (Co) is a metal that is added to steel to improve its resistance to corrosion. Calculate both the number of moles in a sample of cobalt containing $5.00 \times 10^{20}$ atoms and the mass of the sample.

## SOLUTION Where are we going?

$\Delta$
Fragments of cobalt metal.

To calculate the number of moles and the mass of a sample of Co
What do we know?
> Sample contains $5.00 \times 10^{20}$ atoms of Co

## How do we get there?

Note that the sample of $5.00 \times 10^{20}$ atoms of cobalt is less than 1 mole $\left(6.022 \times 10^{23}\right.$ atoms ) of cobalt. What fraction of a mole it represents can be determined as follows:

$$
5.00 \times 10^{20} \text { atoms Co } \times \frac{1 \mathrm{~mol} \mathrm{Co}}{6.022 \times 10^{23} \text { atoms Co }}=8.30 \times 10^{-4} \mathrm{~mol} \mathrm{Co}
$$

Since the mass of 1 mole of cobalt atoms is 58.93 g , the mass of $5.00 \times 10^{20}$ atoms can be determined as follows:

$$
8.30 \times 10^{-4} \mathrm{motCo} \times \frac{58.93 \mathrm{~g} \mathrm{Co}}{1 \mathrm{motCo}}=4.89 \times 10^{-2} \mathrm{~g} \mathrm{Co}
$$

Reality Check In this case the sample contains $5 \times 10^{20}$ atoms, which is approximately $1 / 1000$ of a mole. Thus the sample should have a mass of about $(1 / 1000)$ $(58.93) \cong 0.06$. Our answer of $\sim 0.05$ makes sense.

See Exercise 3.50

### 3.4 Molar Mass

A chemical compound is, ultimately, a collection of atoms. For example, methane (the major component of natural gas) consists of molecules that each contain one carbon and four hydrogen atoms $\left(\mathrm{CH}_{4}\right)$. How can we calculate the mass of 1 mole of methane; that is, what is the mass of $6.022 \times 10^{23} \mathrm{CH}_{4}$ molecules? Since each $\mathrm{CH}_{4}$ molecule contains one carbon atom and four hydrogen atoms, 1 mole of $\mathrm{CH}_{4}$ molecules contains 1 mole of carbon atoms and 4 moles of hydrogen atoms. The mass of 1 mole of methane can be found by summing the masses of carbon and hydrogen present:

$$
\begin{aligned}
\text { Mass of } 1 \mathrm{~mol} \mathrm{C} & =12.01 \mathrm{~g} \\
\text { Mass of } 4 \mathrm{~mol} \mathrm{H} & =\underline{4 \times 1.008 \mathrm{~g}} \\
\text { Mass of } 1 \mathrm{~mol} \mathrm{CH}_{4} & =16.04 \mathrm{~g}
\end{aligned}
$$

Because 16.04 g represents the mass of 1 mole of methane molecules, it makes sense to call it the molar mass for methane. Thus the molar mass of a substance is the mass in grams of 1 mole of the compound. Traditionally, the term molecular weight has been used for this quantity. However, we will use molar mass exclusively in this text. The molar mass of a known substance is obtained by summing the masses of the component atoms as we did for methane.

Methane is a molecular compound-its components are molecules. Many substances are ionic-they contain simple ions or polyatomic ions. Examples are NaCl (contains $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$) and $\mathrm{CaCO}_{3}$ (contains $\mathrm{Ca}^{2+}$ and $\mathrm{CO}_{3}{ }^{2-}$ ). Because ionic compounds do not contain molecules, we need a special name for the fundamental unit of these materials. Instead of molecule, we use the term formula unit. Thus $\mathrm{CaCO}_{3}$ is the formula unit for calcium carbonate, and NaCl is the formula unit for sodium chloride.

## INTERACTIVE EXAMPLE 3.6 Calculating Molar Mass I

Juglone, a dye known for centuries, is produced from the husks of black walnuts. It is also a natural herbicide (weed killer) that kills off competitive plants around the black walnut tree but does not affect grass and other noncompetitive plants. The formula for juglone is $\mathrm{C}_{10} \mathrm{H}_{6} \mathrm{O}_{3}$.
a. Calculate the molar mass of juglone.
b. A sample of $1.56 \times 10^{-2} \mathrm{~g}$ of pure juglone was extracted from black walnut husks. How many moles of juglone does this sample represent?

## SOLUTION

Juglone
a. The molar mass is obtained by summing the masses of the component atoms. In 1 mole of juglone, there are 10 moles of carbon atoms, 6 moles of hydrogen atoms, and 3 moles of oxygen atoms:

$$
\begin{array}{rl}
10 \mathrm{C}: & 10 \times 12.01 \mathrm{~g}=120.1 \mathrm{~g} \\
6 \mathrm{H}: & 6 \times 1.008 \mathrm{~g}=6.048 \mathrm{~g} \\
3 \mathrm{O}: & 3 \times 16.00 \mathrm{~g}=\frac{48.00 \mathrm{~g}}{174.1 \mathrm{~g}} \\
\text { Mass of } 1 & \mathrm{~mol} \mathrm{C}_{10} \mathrm{H}_{6} \mathrm{O}_{3}=
\end{array}
$$

The mass of 1 mole of juglone is 174.1 g , which is the molar mass.
b. The mass of 1 mole of this compound is 174.1 g ; thus $1.56 \times 10^{-2} \mathrm{~g}$ is much less than a mole. The exact fraction of a mole can be determined as follows:

$$
1.56 \times 10^{-2} \text { g jugłone } \times \frac{1 \mathrm{~mol} \text { juglone }}{174.1 \text { g jugłone }}=8.96 \times 10^{-5} \mathrm{~mol} \text { juglone }
$$

See Exercises 3.51 through 3.56

## INTERACTIVE EXAMPLE $3.7 \quad$ Calculating Molar Mass II

Calcium carbonate $\left(\mathrm{CaCO}_{3}\right)$, also called calcite, is the principal mineral found in limestone, marble, chalk, pearls, and the shells of marine animals such as clams.
a. Calculate the molar mass of calcium carbonate.
b. A certain sample of calcium carbonate contains 4.86 moles. What is the mass in grams of this sample? What is the mass of the $\mathrm{CO}_{3}{ }^{2-}$ ions present?

## SOLUTION

A
A calcite $\left(\mathrm{CaCO}_{3}\right)$ crystal.
b. The mass of 1 mole of $\mathrm{CaCO}_{3}$ is 100.09 g . The sample contains nearly 5 moles, or close to 500 g . The exact amount is determined as follows:

$$
4.86 \mathrm{~mol} \mathrm{CaCO}_{3} \times \frac{100.09 \mathrm{~g} \mathrm{CaCO}_{3}}{1 \mathrm{~mol} \mathrm{CaCO}_{3}}=486 \mathrm{~g} \mathrm{CaCO}_{3}
$$

To find the mass of carbonate ions $\left(\mathrm{CO}_{3}{ }^{2-}\right)$ present in this sample, we must realize that 4.86 moles of $\mathrm{CaCO}_{3}$ contains 4.86 moles of $\mathrm{Ca}^{2+}$ ions and 4.86 moles of $\mathrm{CO}_{3}{ }^{2-}$ ions. The mass of 1 mole of $\mathrm{CO}_{3}{ }^{2-}$ ions is

$$
\begin{aligned}
1 \mathrm{C}: \quad 1 \times 12.01 & =12.01 \mathrm{~g} \\
3 \mathrm{O}: \quad 3 \times 16.00 & =\underline{48.00 \mathrm{~g}} \\
\text { Mass of } 1 \mathrm{~mol} \mathrm{CO}_{3}{ }^{2-} & =60.01 \mathrm{~g}
\end{aligned}
$$

Thus the mass of 4.86 moles of $\mathrm{CO}_{3}{ }^{2-}$ ions is

$$
4.86 \mathrm{~mol} \mathrm{CO}_{3}^{2-} \times \frac{60.01 \mathrm{~g} \mathrm{CO}_{3}^{2-}}{1 \mathrm{molCO}_{3}^{2-}}=292 \mathrm{~g} \mathrm{CO}_{3}^{2-}
$$

## INTERACTIVE EXAMPLE $3.8 \quad$ Molar Mass and Numbers of Molecules

Isopentyl acetate $\left(\mathrm{C}_{7} \mathrm{H}_{14} \mathrm{O}_{2}\right)$ is the compound responsible for the scent of bananas. A molecular model of isopentyl acetate is shown in the margin below. Interestingly, bees release about $1 \mu \mathrm{~g}\left(1 \times 10^{-6} \mathrm{~g}\right)$ of this compound when they sting. The resulting scent attracts other bees to join the attack. How many molecules of isopentyl acetate are released in a typical bee sting? How many atoms of carbon are present?

## SOLUTION

A
Isopentyl acetate is released when a bee stings.

Oydrogen

To show the correct number of significant figures in each calculation, we round after each step. In your calculations, always carry extra significant figures through to the end, then round.

## Where are we going?

To calculate the number of molecules of isopentyl acetate and the number of carbon atoms in a bee sting

What do we know?
) Mass of isopentyl acetate in a typical bee sting is 1 microgram $=1 \times 10^{-6} \mathrm{~g}$
How do we get there?
Since we are given a mass of isopentyl acetate and want to find the number of molecules, we must first compute the molar mass of $\mathrm{C}_{7} \mathrm{H}_{14} \mathrm{O}_{2}$ :

$$
\begin{aligned}
7 \operatorname{mot~} \mathrm{C} \times 12.01 \frac{\mathrm{~g}}{\mathrm{mot}} & =84.07 \mathrm{~g} \mathrm{C} \\
14 \operatorname{mot~H} \times 1.008 \frac{\mathrm{~g}}{\operatorname{mot}} & =14.11 \mathrm{~g} \mathrm{H} \\
2 \operatorname{mot~O} \times 16.00 \frac{\mathrm{~g}}{\operatorname{mot}} & =\frac{32.00 \mathrm{~g} \mathrm{O}}{130.18 \mathrm{~g}}
\end{aligned}
$$

This means that 1 mole of isopentyl acetate ( $6.022 \times 10^{23}$ molecules) has a mass of 130.18 g .

To find the number of molecules released in a sting, we must first determine the number of moles of isopentyl acetate in $1 \times 10^{-6} \mathrm{~g}$ :

$$
1 \times 10^{-6} \mathrm{~g} \mathrm{C}_{7} \mathrm{H}_{14} \mathrm{O}_{2} \times \frac{1 \mathrm{~mol} \mathrm{C}_{7} \mathrm{H}_{14} \mathrm{O}_{2}}{130.18 \mathrm{gC}_{7} \mathrm{H}_{14} \mathrm{O}_{2}}=8 \times 10^{-9} \mathrm{~mol} \mathrm{C}_{7} \mathrm{H}_{14} \mathrm{O}_{2}
$$

Since 1 mole is $6.022 \times 10^{23}$ units, we can determine the number of molecules:

$$
8 \times 10^{-9} \mathrm{molC}_{7} \mathrm{H}_{14} \mathrm{O}_{2} \times \frac{6.022 \times 10^{23} \text { molecules }}{1 \mathrm{~mol} \mathrm{C}_{7} \mathrm{H}_{14} \mathrm{O}_{2}}=5 \times 10^{15} \text { molecules }
$$

To determine the number of carbon atoms present, we must multiply the number of molecules by 7 , since each molecule of isopentyl acetate contains seven carbon atoms:

$$
5 \times 10^{15} \text { moleeutes } \times \frac{7 \text { carbon atoms }}{\text { molecute }}=4 \times 10^{16} \text { carbon atoms }
$$

Note: In keeping with our practice of always showing the correct number of significant figures, we have rounded after each step. However, if extra digits are carried throughout this problem, the final answer rounds to $3 \times 10^{16}$.

One of the great rewards of studying chemistry is to become a good problem solver. Being able to solve complex problems is a talent that will serve you well in all walks of life. It is our purpose in this text to help you learn to solve problems in a flexible, creative way based on understanding the fundamental ideas of chemistry. We call this approach conceptual problem solving.

The ultimate goal is to be able to solve new problems (that is, problems you have not seen before) on your own. In this text we will provide problems and offer solutions by explaining how to think about the problems. While the answers to these problems are important, it is perhaps even more important to understand the process-the thinking necessary to get the answer. Although at first we will be solving the problem for you, do not take a passive role. While studying the solution, it is crucial that you interactively think through the problem with us. Do not skip the discussion and jump to the answer. Usually, the solution will involve asking a series of questions. Make sure that you understand each step in the process. This active approach should apply to problems outside of chemistry as well. For example, imagine riding with someone in a car to an unfamiliar destination. If your goal is simply to have the other person get you to that destination, you will probably not pay much attention to how to get there (passive), and if you have to find this same place in the future on your own, you probably will not be able to do it. If, however, your goal is to learn how to get there, you would pay attention to distances, signs, and turns (active). This is how you should read the solutions in the text (and the text in general).

While actively studying our solutions to problems is helpful, at some point you will need to know how to think through these problems on your own. If we help you too much as you solve a problem, you won't really learn effectively. If we always "drive," you won't interact as meaningfully with the material. Eventually you need to learn to drive yourself. We will provide more help at the beginning of the text and less as we proceed to later chapters.

There are two fundamentally different ways you might use to approach a problem. One way emphasizes memorization. We might call this the "pigeonholing method." In this approach, the first step is to label the problem-to decide in which pigeonhole it fits. The pigeonholing method requires that we provide you with a set of steps that you memorize and store in the appropriate slot for each different problem you encounter. The difficulty with this method is that it requires a new pigeonhole each time a problem is changed by even a small amount.

Consider the driving analogy again. Suppose you have memorized how to drive from your house to the grocery store. Do you know how to drive back from the grocery store to your house? Not necessarily. If you have only memorized the directions and do not understand fundamental principles such as "I traveled north to get to the store, so my house is south of the store," you may find yourself stranded. In a more complicated example, suppose you know how to get from your house to the store (and back) and from your house to the library (and back). Can you get from the library to the store without having to go back home? Probably not if you have only memorized directions and you do not have a "big picture" of where your house, the store, and the library are relative to one another.

The second approach is conceptual problem solving, in which we help you get the "big picture"-a real understanding of the situation. This approach to problem solving looks within the problem for a solution. In this method we assume that the problem is a new one, and we let the problem guide us as we solve it. In this approach we ask a series of questions as we proceed and use our knowledge of fundamental principles to answer these questions. Learning this approach requires some patience, but the reward for learning to solve problems this way is that we become an effective solver of any new problem that confronts us in daily life or in our work in any field. In summary, instead of looking outside the problem for a memorized solution, we will look inside the problem and let the problem help us as we proceed to a solution.

As we have seen in problems we have already considered, there are several organizing principles to help you become a creative problem solver. Although we have been using these ideas in earlier problems, let's review and expand on them. Because as we progress in our study of chemistry the problems become more complicated, we will need to rely on this approach even more.

1. We need to read the problem and decide on the final goal. Then we sort through the facts given, focusing on the key words and often drawing a diagram of the problem. In this part of the analysis we need to state the problem as simply and as visually as possible. We could summarize this entire process as "Where are we going?"
2. In order to reach our final goal, we need to decide where to start. For example, in a stoichiometry problem we always start with the chemical reaction. Then we ask a series of questions as we proceed, such as, "What are the reactants and products?" "What is the balanced equation?" "What are the amounts of the reactants?" and so on. Our understanding of the fundamental principles of chemistry will enable us to answer each of these simple questions and eventually will lead us to the final solution. We might summarize this process as "How do we get there?"
3. Once we get the solution of the problem, then we ask ourselvves, "Does it make sense?" That is, does our answer seem reasonable? We call this the Reality Check. It always pays to check your answer.

Using a conceptual approach to problem solving will enable you to develop real confidence as a problem solver. You will no longer panic when you see a problem that is different in some ways from those you have solved in the past. Although you might be frustrated at times as you learn this method, we guarantee that it will pay dividends later and should make your experience with chemistry a positive one that will prepare you for any career you choose.

To summarize, one of our major goals in this text is to help you become a creative problem solver. We will do this by, at first, giving you lots of guidance in how to solve problems. We will "drive," but we hope you will be paying attention instead of just "riding along." As we move forward, we will gradually shift more of the responsibility to you. As you gain confidence in letting the problem guide you, you will be amazed at how effective you can be at solving some really complex problems-just like the ones you will confront in "real life."

### 3.6 Percent Composition of Compounds

There are two common ways of describing the composition of a compound: in terms of the numbers of its constituent atoms and in terms of the percentages (by mass) of its elements. We can obtain the mass percents of the elements from the formula of the compound by comparing the mass of each element present in 1 mole of the compound to the total mass of 1 mole of the compound.

For example, for ethanol, which has the formula $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$, the mass of each element present and the molar mass are obtained as follows:

$$
\begin{aligned}
& \text { Mass of } \mathrm{C}=2 \mathrm{mot} \times 12.01 \frac{\mathrm{~g}}{\mathrm{mot}}=24.02 \mathrm{~g} \\
& \text { Mass of } \mathrm{H}=6 \mathrm{mot} \times 1.008 \frac{\mathrm{~g}}{\mathrm{mot}}=6.048 \mathrm{~g} \\
& \text { Mass of } \mathrm{O}=1 \mathrm{mot} \times 16.00 \frac{\mathrm{~g}}{\mathrm{mot}}=\underline{16.00 \mathrm{~g}} \\
& \text { Mass of } 1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}=46.07 \mathrm{~g}
\end{aligned}
$$

The mass percent (often called the weight percent) of carbon in ethanol can be computed by comparing the mass of carbon in 1 mole of ethanol to the total mass of 1 mole of ethanol and multiplying the result by 100 :

$$
\begin{aligned}
\text { Mass percent of } \mathrm{C} & =\frac{\text { mass of } \mathrm{C} \text { in } 1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}{\text { mass of } 1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}} \times 100 \% \\
& =\frac{24.02 \mathrm{~g}}{46.07 \mathrm{~g}} \times 100 \%=52.14 \%
\end{aligned}
$$

The mass percents of hydrogen and oxygen in ethanol are obtained in a similar manner:

$$
\begin{aligned}
\text { Mass percent of } \mathrm{H} & =\frac{\text { mass of } \mathrm{H} \text { in } 1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}{\text { mass of } 1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}} \times 100 \% \\
& =\frac{6.048 \mathrm{~g}}{46.07 \mathrm{~g}} \times 100 \%=13.13 \% \\
\text { Mass percent of } \mathrm{O} & =\frac{\text { mass of O in } 1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}{\text { mass of } 1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}} \times 100 \% \\
& =\frac{16.00 \mathrm{~g}}{46.07 \mathrm{~g}} \times 100 \%=34.73 \%
\end{aligned}
$$

Reality Check Notice that the percentages add up to $100.00 \%$; this provides a check that the calculations are correct.

## INTERACTIVE EXAMPLE $3.9 \quad$ Calculating Mass Percent

Carvone is a substance that occurs in two forms having different arrangements of the atoms but the same molecular formula $\left(\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}\right)$ and mass. One type of carvone gives caraway seeds their characteristic smell, and the other type is responsible for the smell of spearmint oil. Compute the mass percent of each element in carvone.

## SOLUTION Where are we going?

To find the mass percent of each element in carvone
What do we know?
> Molecular formula is $\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}$
What information do we need to find the mass percent?
> Mass of each element (we'll use 1 mole of carvone)
) Molar mass of carvone

## How do we get there?

What is the mass of each element in 1 mole of $\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}$ ?

$$
\begin{aligned}
& \text { Mass of } \mathrm{C} \text { in } 1 \mathrm{~mol}=10 \mathrm{mot} \times 12.01 \frac{\mathrm{~g}}{\mathrm{mot}}=120.1 \mathrm{~g} \\
& \text { Mass of } \mathrm{H} \text { in } 1 \mathrm{~mol}=14 \mathrm{mot} \times 1.008 \frac{\mathrm{~g}}{\mathrm{mot}}=14.11 \mathrm{~g} \\
& \text { Mass of O in } 1 \mathrm{~mol}=1 \mathrm{mot} \times 16.00 \frac{\mathrm{~g}}{\mathrm{mot}}=16.00 \mathrm{~g}
\end{aligned}
$$

What is the molar mass of $\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}$ ?

$$
\begin{aligned}
120.1 \mathrm{~g}+14.11 \mathrm{~g}+16.00 \mathrm{~g} & =150.2 \mathrm{~g} \\
\mathrm{C}_{10}+\mathrm{H}_{14}+\mathrm{O} & =\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}
\end{aligned}
$$

What is the mass percent of each element?
We find the fraction of the total mass contributed by each element and convert it to a percentage:

$$
\begin{aligned}
& \text { Mass percent of } \mathrm{C}=\frac{120.1 \mathrm{~g} \mathrm{C}}{150.2 \mathrm{~g} \mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}} \times 100 \%=79.96 \% \\
& \text { Mass percent of } \mathrm{H}=\frac{14.11 \mathrm{~g} \mathrm{H}^{150.2 \mathrm{~g} \mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}} \times 100 \%=9.394 \%}{150.2 \mathrm{~g} \mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}} \times 100 \%=10.65 \% \\
& \text { Mass percent of } \mathrm{O}=\frac{16.00 \mathrm{~g} \mathrm{O}_{1}}{150}
\end{aligned}
$$

Reality Check Sum the individual mass percent values-they should total to $100 \%$ within round-off errors. In this case, the percentages add up to $100.00 \%$.

## See Exercises 3.75 and 3.76

### 3.1 Determining the Formula of a Compound

When a new compound is prepared, one of the first items of interest is the formula of the compound. This is most often determined by taking a weighed sample of the compound and either decomposing it into its component elements or reacting it with oxygen to produce substances such as $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$, which are then collected and weighed. A device for doing this type of analysis is shown in Fig. 3.5. The results of such analyses provide the mass of each type of element in the compound, which can be used to determine the mass percent of each element.

We will see how information of this type can be used to compute the formula of a compound. Suppose a substance has been prepared that is composed of carbon, hydrogen, and nitrogen. When 0.1156 g of this compound is reacted with oxygen, 0.1638 g of carbon dioxide $\left(\mathrm{CO}_{2}\right)$ and 0.1676 g of water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ are collected. Assuming that all

FIGURE 3.5 A schematic diagram of the combustion device used to analyze substances for carbon and hydrogen. The sample is burned in the presence of excess oxygen, which converts all its carbon to carbon dioxide and all its hydrogen to water. These products are collected by absorption using appropriate materials, and their amounts are determined by measuring the increase in masses of the absorbents.

$\mathrm{CO}_{2}$

$\mathrm{H}_{2} \mathrm{O}$
the carbon in the compound is converted to $\mathrm{CO}_{2}$, we can determine the mass of carbon originally present in the $0.1156-\mathrm{g}$ sample. To do this, we must use the fraction (by mass) of carbon in $\mathrm{CO}_{2}$. The molar mass of $\mathrm{CO}_{2}$ is

$$
\begin{aligned}
& \mathrm{C}: \quad 1 \operatorname{mot} \times 12.01 \frac{\mathrm{~g}}{\operatorname{mot}}=12.01 \mathrm{~g} \\
& \text { O: } \quad 2 \operatorname{mot} \times 16.00 \frac{\mathrm{~g}}{\operatorname{mot}}=\underline{32.00 \mathrm{~g}} \\
& \\
& \\
& \text { Molar mass of } \mathrm{CO}_{2}=44.01 \mathrm{~g} / \mathrm{mol}
\end{aligned}
$$

The fraction of carbon present by mass is

$$
\frac{\text { Mass of } \mathrm{C}}{\text { Total mass of } \mathrm{CO}_{2}}=\frac{12.01 \mathrm{~g} \mathrm{C}}{44.01 \mathrm{~g} \mathrm{CO}_{2}}
$$

This factor can now be used to determine the mass of carbon in 0.1638 g of $\mathrm{CO}_{2}$ :

$$
0.1638 \mathrm{~g} \mathrm{CO}_{2} \times \frac{12.01 \mathrm{~g} \mathrm{C}}{44.01 \mathrm{gCO}_{2}}=0.04470 \mathrm{~g} \mathrm{C}
$$

Remember that this carbon originally came from the $0.1156-\mathrm{g}$ sample of unknown compound. Thus the mass percent of carbon in this compound is

$$
\frac{0.04470 \mathrm{~g} \mathrm{C}}{0.1156 \mathrm{~g} \text { compound }} \times 100 \%=38.67 \% \mathrm{C}
$$

The same procedure can be used to find the mass percent of hydrogen in the unknown compound. We assume that all the hydrogen present in the original 0.1156 g of compound was converted to $\mathrm{H}_{2} \mathrm{O}$. The molar mass of $\mathrm{H}_{2} \mathrm{O}$ is 18.02 g , and the fraction of hydrogen by mass in $\mathrm{H}_{2} \mathrm{O}$ is

$$
\frac{\text { Mass of } \mathrm{H}}{\text { Mass of } \mathrm{H}_{2} \mathrm{O}}=\frac{2.016 \mathrm{~g} \mathrm{H}}{18.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}
$$

Therefore, the mass of hydrogen in 0.1676 g of $\mathrm{H}_{2} \mathrm{O}$ is

$$
0.1676 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \times \frac{2.016 \mathrm{~g} \mathrm{H}}{18.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}=0.01875 \mathrm{~g} \mathrm{H}
$$

The mass percent of hydrogen in the compound is

$$
\frac{0.01875 \mathrm{~g} \mathrm{H}}{0.1156 \mathrm{~g} \text { compound }} \times 100 \%=16.22 \% \mathrm{H}
$$

The unknown compound contains only carbon, hydrogen, and nitrogen. So far we have determined that it is $38.67 \%$ carbon and $16.22 \%$ hydrogen. The remainder must be nitrogen:

$$
100.00 \%-(38.67 \%+\underset{\uparrow}{16.22 \%})=45.11 \% \mathrm{~N}
$$

We have determined that the compound contains $38.67 \%$ carbon, $16.22 \%$ hydrogen, and $45.11 \%$ nitrogen. Next we use these data to obtain the formula.

Since the formula of a compound indicates the numbers of atoms in the compound, we must convert the masses of the elements to numbers of atoms. The easiest way to do this is to work with 100.00 g of the compound. In the present case, $38.67 \%$ carbon by mass means 38.67 g of carbon per 100.00 g of compound; $16.22 \%$ hydrogen means 16.22 g of hydrogen per 100.00 g of compound; and so on. To determine the formula, we must calculate the number of carbon atoms in 38.67 g of carbon, the number of

Molecular formula $=(\text { empirical formula })_{n}$ where $n$ is an integer.

FIGURE 3.6 Examples of substances whose empirical and molecular formulas differ. Notice that molecular formula $=$ (empirical formula) ${ }_{n}$, where $n$ is an integer.
hydrogen atoms in 16.22 g of hydrogen, and the number of nitrogen atoms in 45.11 g of nitrogen. We can do this as follows:

$$
\begin{aligned}
& 38.67 \mathrm{ge} \times \frac{1 \mathrm{~mol} \mathrm{C}}{12.01 \mathrm{gC}}=3.220 \mathrm{~mol} \mathrm{C} \\
& 16.22 \mathrm{gH} \times \frac{1 \mathrm{~mol} \mathrm{H}}{1.008 \mathrm{gH}}=16.09 \mathrm{~mol} \mathrm{H} \\
& 45.11 \mathrm{~g} \times \frac{1 \mathrm{~mol} \mathrm{~N}}{14.01 \mathrm{gN}}=3.220 \mathrm{~mol} \mathrm{~N}
\end{aligned}
$$

Thus 100.00 g of this compound contains 3.220 moles of carbon atoms, 16.09 moles of hydrogen atoms, and 3.220 moles of nitrogen atoms.

We can find the smallest whole-number ratio of atoms in this compound by dividing each of the mole values above by the smallest of the three:

$$
\begin{aligned}
& \mathrm{C}: \quad \frac{3.220}{3.220}=1.000=1 \\
& \mathrm{H}: \quad \frac{16.09}{3.220}=4.997=5 \\
& \mathrm{~N}: \quad \frac{3.220}{3.220}=1.000=1
\end{aligned}
$$

Thus the formula might well be $\mathrm{CH}_{5} \mathrm{~N}$. However, it also could be $\mathrm{C}_{2} \mathrm{H}_{10} \mathrm{~N}_{2}$ or $\mathrm{C}_{3} \mathrm{H}_{15} \mathrm{~N}_{3}$, and so on-that is, some multiple of the smallest whole-number ratio. Each of these alternatives also has the correct relative numbers of atoms. That is, any molecule that can be represented as $\left(\mathrm{CH}_{5} \mathrm{~N}\right)_{n}$, where $n$ is an integer, has the empirical formula $\mathrm{CH}_{5} \mathrm{~N}$. To be able to specify the exact formula of the molecule involved, the molecular formula, we must know the molar mass.

Suppose we know that this compound with empirical formula $\mathrm{CH}_{5} \mathrm{~N}$ has a molar mass of $31.06 \mathrm{~g} / \mathrm{mol}$. How do we determine which of the possible choices represents the molecular formula? Since the molecular formula is always a whole-number multiple of the empirical formula, we must first find the empirical formula mass for $\mathrm{CH}_{5} \mathrm{~N}$ :

$$
\begin{aligned}
1 \mathrm{C}: \quad 1 \times 12.01 \mathrm{~g} & =12.01 \mathrm{~g} \\
5 \mathrm{H}: \quad 5 \times 1.008 \mathrm{~g} & =5.040 \mathrm{~g} \\
1 \mathrm{~N}: \quad 1 \times 14.01 \mathrm{~g} & =\underline{14.01 \mathrm{~g}} \\
\text { Formula mass of } \mathrm{CH}_{5} \mathrm{~N} & =31.06 \mathrm{~g} / \mathrm{mol}
\end{aligned}
$$

This is the same as the known molar mass of the compound. Thus in this case the empirical formula and the molecular formula are the same; this substance consists of molecules with the formula $\mathrm{CH}_{5} \mathrm{~N}$. It is quite common for the empirical and molecular formulas to be different; some examples where this is the case are shown in Fig. 3.6.

Numbers very close to whole numbers, such as 9.92 and 1.08 , should be rounded to whole numbers. Numbers such as 2.25 , 4.33 , and 2.72 should not be rounded to whole numbers.

## PROBLEM-SOLVING STRATEGY

## Empirical Formula Determination

" Since mass percentage gives the number of grams of a particular element per 100 g of compound, base the calculation on 100 g of compound. Each percent will then represent the mass in grams of that element.
» Determine the number of moles of each element present in 100 g of compound using the atomic masses of the elements present.
\# Divide each value of the number of moles by the smallest of the values. If each resulting number is a whole number (after appropriate rounding), these numbers represent the subscripts of the elements in the empirical formula.
" If the numbers obtained in the previous step are not whole numbers, multiply each number by an integer so that the results are all whole numbers.

One part of the problem-solving strategy
for empirical formula determination is to base the calculation on 100 g of compound. What if you chose a mass other than 100 g ? Would this work? What if you chose to base the calculation on 100 moles of compound? Would this work?

## PROBLEM-SOLVING STRATEGY

Determining Molecular Formula from Empirical Formula
" Obtain the empirical formula.
» Compute the mass corresponding to the empirical formula.
" Calculate the ratio:

$$
\frac{\text { Molar mass }}{\text { Empirical formula mass }}
$$

» The integer from the previous step represents the number of empirical formula units in one molecule. When the empirical formula subscripts are multiplied by this integer, the molecular formula results. This procedure is summarized by the equation:

$$
\text { Molecular formula }=\text { empirical formula } \times \frac{\text { molar mass }}{\text { empirical formula mass }}
$$

Determine the empirical and molecular formulas for a compound that gives the following percentages on analysis (in mass percents):

$$
71.65 \% \mathrm{Cl} \quad 24.27 \% \mathrm{C} \quad 4.07 \% \mathrm{H}
$$

The molar mass is known to be $98.96 \mathrm{~g} / \mathrm{mol}$.

## SOLUTION Where are we going?

To find the empirical and molecular formulas for the given compound

## What do we know?

> Percent of each element
> Molar mass of the compound is $98.96 \mathrm{~g} / \mathrm{mol}$

FIGURE 3.7 The two forms of dichloroethane.

What information do we need to find the empirical formula?
> Mass of each element in 100.00 g of compound
> Moles of each element

## How do we get there?

What is the mass of each element in 100.00 g of compound?

$$
\begin{array}{llllll}
\mathrm{Cl} & 71.65 \mathrm{~g} & \mathrm{C} & 24.27 \mathrm{~g} & \mathrm{H} & 4.07 \mathrm{~g}
\end{array}
$$

What are the moles of each element in 100.00 g of compound?

$$
\begin{gathered}
71.65 \mathrm{gCt} \times \frac{1 \mathrm{~mol} \mathrm{Cl}}{35.45 \mathrm{gCt}}=2.021 \mathrm{~mol} \mathrm{Cl} \\
24.27 \mathrm{gC} \times \frac{1 \mathrm{~mol} \mathrm{C}}{12.01 \mathrm{gC}}=2.021 \mathrm{~mol} \mathrm{C} \\
4.07 \mathrm{gH} \times \frac{1 \mathrm{~mol} \mathrm{H}}{1.008 \mathrm{~g} \mathrm{H}}=4.04 \mathrm{~mol} \mathrm{H}
\end{gathered}
$$

What is the empirical formula for the compound?
Dividing each mole value by 2.021 (the smallest number of moles present), we find the empirical formula $\mathrm{ClCH}_{2}$.

What is the molecular formula for the compound?
Compare the empirical formula mass to the molar mass.
Empirical formula mass $=49.48 \mathrm{~g} / \mathrm{mol}($ Confirm this! $)$
Molar mass is given $=98.96 \mathrm{~g} / \mathrm{mol}$

$$
\begin{aligned}
\frac{\text { Molar mass }}{\text { Empirical formula mass }} & =\frac{98.96 \mathrm{~g} / \mathrm{mol}}{49.48 \mathrm{~g} / \mathrm{mol}}=2 \\
\text { Molecularf ormula } & =\left(\mathrm{ClCH}_{2}\right)_{2}=\mathrm{Cl}_{2} \mathrm{C}_{2} \mathrm{H}_{4}
\end{aligned}
$$

This substance is composed of molecules with the formula $\mathrm{Cl}_{2} \mathrm{C}_{2} \mathrm{H}_{4}$.
Note: The method we use here allows us to determine the molecular formula of a compound but not its structural formula. The compound $\mathrm{Cl}_{2} \mathrm{C}_{2} \mathrm{H}_{4}$ is called dichloroethane. There are two forms of this compound, shown in Fig. 3.7. The form at the bottom was formerly used as an additive in leaded gasoline.

## INTERACTVE EXAMPLE 3.11 Determining Empirical and Molecular Formulas II

A white powder is analyzed and found to contain $43.64 \%$ phosphorus and $56.36 \%$ oxygen by mass. The compound has a molar mass of $283.88 \mathrm{~g} / \mathrm{mol}$. What are the compound's empirical and molecular formulas?

## SOLUTION Where are we going?

To find the empirical and molecular formulas for the given compound
What do we know?
) Percent of each element
> Molar mass of the compound is $283.88 \mathrm{~g} / \mathrm{mol}$

FIGURE 3.8 The structure of $\mathrm{P}_{4} \mathrm{O}_{10}$. Note that some of the oxygen atoms act as "bridges" between the phosphorus atoms. This compound has a great affinity for water and is often used as a desiccant, or drying agent.

What information do we need to find the empirical formula?
> Mass of each element in 100.00 g of compound
> Moles of each element

## How do we get there?

What is the mass of each element in 100.00 g of compound?

$$
\begin{array}{llll}
\mathrm{P} & 43.64 \mathrm{~g} & \mathrm{O} & 56.36 \mathrm{~g}
\end{array}
$$

What are the moles of each element in 100.00 g of compound?

$$
\begin{aligned}
& 43.64 \mathrm{gP} \times \frac{1 \mathrm{~mol} \mathrm{P}}{30.97 \mathrm{gP}}=1.409 \mathrm{~mol} \mathrm{P} \\
& 56.36 \mathrm{~g} \theta \times \frac{1 \mathrm{~mol} \mathrm{O}}{16.00 \mathrm{~g} \theta}=3.523 \mathrm{~mol} \mathrm{O}
\end{aligned}
$$

What is the empirical formula for the compound?
Dividing each mole value by the smaller one gives

$$
\frac{1.409}{1.409}=1 \mathrm{P} \quad \text { and } \quad \frac{3.523}{1.409}=2.5 \mathrm{O}
$$

This yields the formula $\mathrm{PO}_{2.5}$. Since compounds must contain whole numbers of atoms, the empirical formula should contain only whole numbers. To obtain the simplest set of whole numbers, we multiply both numbers by 2 to give the empirical formula $\mathrm{P}_{2} \mathrm{O}_{5}$.

What is the molecular formula for the compound?
Compare the empirical formula mass to the molar mass.
Empirical formula mass $=141.94 \mathrm{~g} / \mathrm{mol}$ (Confirm this!)
Molar mass is given $=283.88 \mathrm{~g} / \mathrm{mol}$

$$
\frac{\text { Molar mass }}{\text { Empirical formula mass }}=\frac{283.88}{141.94}=2
$$

■ The molecular formula is $\left(\mathrm{P}_{2} \mathrm{O}_{5}\right)_{2}$, or $\mathrm{P}_{4} \mathrm{O}_{10}$.
Note: The structural formula for this interesting compound is given in Fig. 3.8.

## See Exercise 3.91

In Examples 3.10 and 3.11 we found the molecular formula by comparing the empirical formula mass with the molar mass. There is an alternate way to obtain the molecular formula. For example, in Example 3.10 we know the molar mass of the compound is $98.96 \mathrm{~g} / \mathrm{mol}$. This means that 1 mole of the compound weighs 98.96 g . Since we also know the mass percentages of each element, we can compute the mass of each element present in 1 mole of compound:

$$
\begin{aligned}
\text { Chlorine: } & \frac{71.65 \mathrm{~g} \mathrm{Cl}}{100.0 \mathrm{~g} \text { compound }} \times \frac{98.96 \mathrm{~g}}{\mathrm{~mol}}=\frac{70.90 \mathrm{~g} \mathrm{Cl}}{\mathrm{~mol} \mathrm{compound}} \\
\text { Carbon: } & \frac{24.27 \mathrm{~g} \mathrm{C}}{100.0 \mathrm{~g} \text { compound }} \times \frac{98.96 \mathrm{~g}}{\mathrm{~mol}}=\frac{24.02 \mathrm{~g} \mathrm{C}}{\mathrm{~mol} \mathrm{compound}} \\
\text { Hydrogen: } & \frac{4.07 \mathrm{~g} \mathrm{H}}{100.0 \mathrm{~g} \mathrm{compound}} \times \frac{98.96 \mathrm{~g}}{\mathrm{~mol}}=\frac{4.03 \mathrm{~g} \mathrm{H}}{\mathrm{~mol} \mathrm{compound}}
\end{aligned}
$$

Now we can compute moles of atoms present per mole of compound:

$$
\begin{aligned}
\text { Chlorine: } & \frac{70.90 \mathrm{gCt}}{\text { mol compound }} \times \frac{1 \mathrm{~mol} \mathrm{Cl}}{35.45 \mathrm{gCl}}=\frac{2.000 \mathrm{~mol} \mathrm{Cl}}{\mathrm{~mol} \mathrm{compound}} \\
\text { Carbon: } & \frac{24.02 \mathrm{gC}}{\text { mol compound }} \times \frac{1 \mathrm{~mol} \mathrm{C}}{12.01 \mathrm{gC}}=\frac{2.000 \mathrm{~mol} \mathrm{C}}{\mathrm{~mol} \mathrm{compound}} \\
\text { Hydrogen: } & \frac{4.03 \mathrm{gH}}{\text { mol compound }} \times \frac{1 \mathrm{~mol} \mathrm{H}}{1.008 \mathrm{gH}}=\frac{4.00 \mathrm{~mol} \mathrm{H}}{\mathrm{~mol} \mathrm{compound}}
\end{aligned}
$$

Thus 1 mole of the compound contains 2 moles of Cl atoms, 2 moles of C atoms, and 4 moles of H atoms, and the molecular formula is $\mathrm{Cl}_{2} \mathrm{C}_{2} \mathrm{H}_{4}$, as obtained in Example 3.10.

## PROBLEM-SOLVING STRATEGY

## Determining Molecular Formula from Mass Percent and Molar Mass

" Using the mass percentages and the molar mass, determine the mass of each element present in 1 mole of compound.
» Determine the number of moles of each element present in 1 mole of compound.
» The integers from the previous step represent the subscripts in the molecular formula.

## INTERACTIVE EXAMPLE 3.12 Determining a Molecular Formula

Caffeine, a stimulant found in coffee, tea, and chocolate, contains $49.48 \%$ carbon, $5.15 \%$ hydrogen, $28.87 \%$ nitrogen, and $16.49 \%$ oxygen by mass and has a molar mass of $194.2 \mathrm{~g} / \mathrm{mol}$. Determine the molecular formula of caffeine.

## SOLUTION Where are we going?

A
Computer-generated molecule of caffeine.

To find the molecular formula for caffeine
What do we know?
> Percent of each element

| $>49.48 \% \mathrm{C}$ | $>28.87 \% \mathrm{~N}$ |
| :--- | :--- |
| $>5.15 \% \mathrm{H}$ | $>16.49 \% \mathrm{O}$ |

> Molar mass of caffeine is $194.2 \mathrm{~g} / \mathrm{mol}$
What information do we need to find the molecular formula?
》 Mass of each element (in 1 mole of caffeine)
> Mole of each element (in 1 mole of caffeine)

## How do we get there?

What is the mass of each element in 1 mole $(194.2 \mathrm{~g})$ of caffeine?

$$
\begin{aligned}
& \frac{49.48 \mathrm{~g} \mathrm{C}}{100.0 \mathrm{~g} \text { caffeine }} \times \frac{194.2 \mathrm{~g}}{\mathrm{~mol}}=\frac{96.09 \mathrm{~g} \mathrm{C}}{\text { mol caffeine }} \\
& \frac{5.15 \mathrm{~g} \mathrm{H}}{100.0 \mathrm{~g} \text { caffeine }} \times \frac{194.2 \mathrm{~g}}{\mathrm{~mol}}=\frac{10.0 \mathrm{~g} \mathrm{H}}{\text { mol caffeine }} \\
& \frac{28.87 \mathrm{~g} \mathrm{~N}}{100.0 \mathrm{~g} \mathrm{caffeine}} \times \frac{194.2 \mathrm{~g}}{\mathrm{~mol}}=\frac{56.07 \mathrm{~g} \mathrm{~N}}{\text { mol caffeine }} \\
& \frac{16.49 \mathrm{~g} \mathrm{O}}{100.0 \mathrm{~g} \text { caffeine }} \times \frac{194.2 \mathrm{~g}}{\mathrm{~mol}}=\frac{32.02 \mathrm{~g} \mathrm{O}}{\text { mol caffeine }}
\end{aligned}
$$

What are the moles of each element in 1 mole of caffeine?

$$
\begin{aligned}
\text { Carbon: } & \frac{96.09 \mathrm{ge}}{\text { mol caffeine }} \times \frac{1 \mathrm{~mol} \mathrm{C}}{12.01 \mathrm{gC}}=\frac{8.001 \mathrm{~mol} \mathrm{C}}{\text { mol caffeine }} \\
\text { Hydrogen: } & \frac{10.0 \mathrm{gH}}{\text { mol caffeine }} \times \frac{1 \mathrm{~mol} \mathrm{H}}{1.008 \mathrm{gH}}=\frac{9.92 \mathrm{~mol} \mathrm{H}}{\text { mol caffeine }} \\
\text { Nitrogen: } & \frac{56.07 \mathrm{gN}}{\text { mol caffeine }} \times \frac{1 \mathrm{~mol} \mathrm{~N}}{14.01 \mathrm{gN}}=\frac{4.002 \mathrm{~mol} \mathrm{~N}}{\mathrm{~mol} \mathrm{caffeine}} \\
\text { Oxygen: } & \frac{32.02 \mathrm{~g} \theta}{\text { mol caffeine }} \times \frac{1 \mathrm{~mol} \mathrm{O}}{16.00 \mathrm{~g} \theta}=\frac{2.001 \mathrm{~mol} \mathrm{O}}{\text { mol caffeine }}
\end{aligned}
$$

Rounding the numbers to integers gives the molecular formula for caffeine: $\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}$.

### 3.8 Chemical Equations

## Chemical Reactions

A chemical change involves a reorganization of the atoms in one or more substances. For example, when the methane $\left(\mathrm{CH}_{4}\right)$ in natural gas combines with oxygen $\left(\mathrm{O}_{2}\right)$ in the air and burns, carbon dioxide $\left(\mathrm{CO}_{2}\right)$ and water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ are formed. This process is represented by a chemical equation with the reactants (here methane and oxygen) on the left side of an arrow and the products (carbon dioxide and water) on the right side:

$$
\underset{\text { Reactants }}{\mathrm{CH}_{4}}+\mathrm{O}_{2} \longrightarrow \underset{\text { Products }}{\mathrm{CO}_{2}}+\underset{\mathrm{H}_{2} \mathrm{O}}{\mathrm{H}^{2}}
$$

Notice that the atoms have been reorganized. Bonds have been broken, and new ones have been formed. It is important to recognize that in a chemical reaction, atoms are neither created nor destroyed. All atoms present in the reactants must be accounted for among the products. In other words, there must be the same number of each type of atom on the products side and on the reactants side of the arrow. Making sure that this rule is obeyed is called balancing a chemical equation for a reaction.

The equation (shown above) for the reaction between $\mathrm{CH}_{4}$ and $\mathrm{O}_{2}$ is not balanced. We can see this from the following representation of the reaction:

Notice that the number of oxygen atoms (in $\mathrm{O}_{2}$ ) on the left of the arrow is two, while on the right there are three O atoms (in $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ ). Also, there are four hydrogen atoms (in $\mathrm{CH}_{4}$ ) on the left and only two (in $\mathrm{H}_{2} \mathrm{O}$ ) on the right. Remember that a chemical reaction is simply a rearrangement of the atoms (a change in the way they are organized). Atoms are neither created nor destroyed in a chemical reaction. Thus the reactants and products must occur in numbers that give the same number of each type of atom among both the reactants and products. Simple trial and error will allow us to figure this out for the reaction of methane with oxygen. The needed numbers of molecules are

Notice that now we have the same number of each type of atom represented among the reactants and the products.

We can represent the preceding situation in a shorthand manner by the following chemical equation:

$$
\mathrm{CH}_{4}+2 \mathrm{O}_{2} \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}
$$

We can check that the equation is balanced by comparing the number of each type of atom on both sides:

To summarize, we have

| Reactants | Products |
| :---: | :---: |
| 1 C | 1 C |
| 4 H | 4 H |
| 4 O | 4 O |

## The Meaning of a Chemical Equation

The chemical equation for a reaction gives two important types of information: the nature of the reactants and products and the relative numbers of each.

The reactants and products in a specific reaction must be identified by experiment. Besides specifying the compounds involved in the reaction, the equation often gives the physical states of the reactants and products:

| State | Symbol |
| :--- | :---: |
| Solid | $(s)$ |
| Liquid | $(l)$ |
| Gas | $(g)$ |
| Dissolved in water <br> (in aqueous solution) | $(a q)$ |

For example, when hydrochloric acid in aqueous solution is added to solid sodium hydrogen carbonate, the products carbon dioxide gas, liquid water, and sodium chloride (which dissolves in the water) are formed:

$$
\mathrm{HCl}(a q)+\mathrm{NaHCO}_{3}(s) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{NaCl}(a q)
$$

The relative numbers of reactants and products in a reaction are indicated by the coefficients in the balanced equation. (The coefficients can be determined because we know that the same number of each type of atom must occur on both sides of the equation.) For example, the balanced equation

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

can be interpreted in several equivalent ways, as shown in Table 3.2. Note that the total mass is 80 g for both reactants and products. We expect the mass to remain constant, since chemical reactions involve only a rearrangement of atoms. Atoms, and therefore mass, are conserved in a chemical reaction.

From this discussion you can see that a balanced chemical equation gives you a great deal of information.

TABLE 3.2 \| Information Conveyed by the Balanced Equation for the Combustion of Methane

| Reactants |  | Products |
| :---: | :---: | :---: |
| $\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g})$ | $\longrightarrow$ | $\mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ |
| 1 molecule +2 molecules | $\longrightarrow$ | 1 molecule +2 molecules |
| 1 mole +2 moles | $\longrightarrow$ | 1 mole +2 moles |
| $6.022 \times 10^{23}$ molecules $+2\left(6.022 \times 10^{23}\right.$ molecules $)$ | $\longrightarrow$ | $6.022 \times 10^{23}$ molecules $+2\left(6.022 \times 10^{23}\right.$ molecules $)$ |
| $16 \mathrm{~g}+2(32 \mathrm{~g})$ |  | $44 \mathrm{~g}+2(18 \mathrm{~g})$ |
| 80 g reactants | $\longrightarrow$ | 80 g products |

### 3.9 Balancing Chemical Equations

An unbalanced chemical equation is of limited use. Whenever you see an equation, you should ask yourself whether it is balanced. The principle that lies at the heart of the balancing process is that atoms are conserved in a chemical reaction. The same number of each type of atom must be found among the reactants and products. It is also important to recognize that the identities of the reactants and products of a reaction are determined by experimental observation. For example, when liquid ethanol is burned in the presence of sufficient oxygen gas, the products are always carbon dioxide and water. When the equation for this reaction is balanced, the identities of the reactants and products must not be changed. The formulas of the compounds must never be changed in balancing a chemical equation. That is, the subscripts in a formula cannot be changed, nor can atoms be added or subtracted from a formula.

> equations by changing the values of the subscripts instead of using the coefficients? How would you explain to your friend that this was the wrong thing to do?

Most chemical equations can be balanced by inspection, that is, by trial and error. It is always best to start with the most complicated molecules (those containing the greatest number of atoms). For example, consider the reaction of ethanol with oxygen, given by the unbalanced equation

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

which can be represented by the following molecular models:

Notice that the carbon and hydrogen atoms are not balanced. There are two carbon atoms on the left and one on the right, and there are six hydrogens on the left and two on the right. We need to find the correct numbers of reactants and products so that we have the same number of all types of atoms among the reactants and products. We will balance the equation "by inspection" (a systematic trial-and-error procedure).

The most complicated molecule here is $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$. We will begin by balancing the products that contain the atoms in $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$. Since $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ contains two carbon atoms, we place the coefficient 2 before the $\mathrm{CO}_{2}$ to balance the carbon atoms:

$$
\underset{2 \mathrm{C} \text { atoms }}{\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)}+\mathrm{O}_{2}(g) \longrightarrow \underset{2 \mathrm{C} \text { atoms }}{2 \mathrm{CO}_{2}(g)}+\mathrm{H}_{2} \mathrm{O}(g)
$$

Since $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ contains six hydrogen atoms, the hydrogen atoms can be balanced by placing a 3 before the $\mathrm{H}_{2} \mathrm{O}$ :

$$
\underset{(5+1) \mathrm{H}}{\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)}+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+\underset{(3 \times 2) \mathrm{H}}{3 \mathrm{H}_{2} \mathrm{O}(g)}
$$

Last, we balance the oxygen atoms. Note that the right side of the preceding equation contains seven oxygen atoms, whereas the left side has only three. We can correct this by putting a 3 before the $\mathrm{O}_{2}$ to produce the balanced equation:

Now we check:

$$
\begin{array}{cc}
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+3 \mathrm{O}_{2}(g) \longrightarrow \\
2 \mathrm{C} \text { atoms } \\
6 \mathrm{H} \text { atoms } \\
7 \mathrm{O} \text { atoms } & 2 \mathrm{CO}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(g) \\
2 \mathrm{C} \text { atoms } \\
6 \mathrm{H} \text { atoms } \\
7 \mathrm{O} \text { atoms }
\end{array}
$$

The equation is balanced.
The balanced equation can be represented as follows:

You can see that all the elements balance.

## PROBLEM-SOLVING STRATEGY

Writing and Balancing the Equation for a Chemical Reaction

1. Determine what reaction is occurring. What are the reactants, the products, and the physical states involved?
2. Write the unbalanced equation that summarizes the reaction described in Step 1.
3. Balance the equation by inspection, starting with the most complicated molecule(s). Determine what coefficients are necessary so that the same number of each type of atom appears on both reactant and product sides. Do not change the identities (formulas) of any of the reactants or products.

## INTERACTIVE EXAMPLE 3.13 Balancing a Chemical Equation I

Chromium compounds exhibit a variety of bright colors. When solid ammonium dichromate, $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$, a vivid orange compound, is ignited, a spectacular reaction occurs, as shown in the two photographs. Although the reaction is actually somewhat more complex, let's assume here that the products are solid chromium(III) oxide,

Chromate and dichromate compounds are carcinogens (cancer-inducing agents) and should be handled very carefully.

## SOLUTION

nitrogen gas (consisting of $\mathrm{N}_{2}$ molecules), and water vapor. Balance the equation for this reaction.

1. From the description given, the reactant is solid ammonium dichromate, $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}(s)$, and the products are nitrogen gas, $\mathrm{N}_{2}(g)$, water vapor, $\mathrm{H}_{2} \mathrm{O}(g)$, and solid chromium(III) oxide, $\mathrm{Cr}_{2} \mathrm{O}_{3}(s)$. The formula for chromium(III) oxide can be determined by recognizing that the Roman numeral III means that $\mathrm{Cr}^{3+}$ ions are present. For a neutral compound, the formula must then be $\mathrm{Cr}_{2} \mathrm{O}_{3}$, since each oxide ion is $\mathrm{O}^{2-}$.
2. The unbalanced equation is

$$
\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}(s) \rightarrow \mathrm{Cr}_{2} \mathrm{O}_{3}(s)+\mathrm{N}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

3. Note that nitrogen and chromium are balanced (two nitrogen atoms and two chromium atoms on each side), but hydrogen and oxygen are not. A coefficient of 4 for $\mathrm{H}_{2} \mathrm{O}$ balances the hydrogen atoms:

Note that in balancing the hydrogen we also have balanced the oxygen, since there are seven oxygen atoms in the reactants and in the products.

Reality Check

$$
\begin{aligned}
& 2 \mathrm{~N}, 8 \mathrm{H}, 2 \mathrm{Cr}, 7 \mathrm{O} \rightarrow 2 \mathrm{~N}, 8 \mathrm{H}, 2 \mathrm{Cr}, 7 \mathrm{O} \\
& \text { Reactant Product } \\
& \text { atoms atoms }
\end{aligned}
$$

The equation is balanced.

A
Decomposition of ammonium dichromate.

## INTERACTIVE EXAMPLE 3.14

## Balancing a Chemical Equation II

At $1000^{\circ} \mathrm{C}$, ammonia gas, $\mathrm{NH}_{3}(g)$, reacts with oxygen gas to form gaseous nitric oxide, $\mathrm{NO}(g)$, and water vapor. This reaction is the first step in the commercial production of nitric acid by the Ostwald process. Balance the equation for this reaction.

1, 2. The unbalanced equation for the reaction is

$$
\mathrm{NH}_{3}(g)+\mathrm{O}_{2}(g) \rightarrow \mathrm{NO}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

3. Because all the molecules in this equation are of about equal complexity, where we start in balancing it is rather arbitrary. Let's begin by balancing the hydrogen. A coefficient of 2 for $\mathrm{NH}_{3}$ and a coefficient of 3 for $\mathrm{H}_{2} \mathrm{O}$ give six atoms of hydrogen on both sides:

$$
2 \mathrm{NH}_{3}(g)+\mathrm{O}_{2}(g) \rightarrow \mathrm{NO}(g)+3 \mathrm{H}_{2} \mathrm{O}(g)
$$

The nitrogen can be balanced with a coefficient of 2 for NO:

$$
2 \mathrm{NH}_{3}(g)+\mathrm{O}_{2}(g) \rightarrow 2 \mathrm{NO}(g)+3 \mathrm{H}_{2} \mathrm{O}(g)
$$

Finally, note that there are two atoms of oxygen on the left and five on the right. The oxygen can be balanced with a coefficient of $\frac{5}{2}$ for $\mathrm{O}_{2}$ :

$$
2 \mathrm{NH}_{3}(g)+\frac{5}{2} \mathrm{O}_{2}(g) \rightarrow 2 \mathrm{NO}(g)+3 \mathrm{H}_{2} \mathrm{O}(g)
$$

However, the usual custom is to have whole-number coefficients. We simply multiply the entire equation by 2 .

$$
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \rightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
$$

Reality Check There are $4 \mathrm{~N}, 12 \mathrm{H}$, and 10 O on both sides, so the equation is balanced.

We can represent this balanced equation visually as

### 3.10 Stoichiometric Calculations: Amounts of Reactants and Products

As we have seen in previous sections of this chapter, the coefficients in chemical equations represent numbers of molecules, not masses of molecules. However, when a reaction is to be run in a laboratory or chemical plant, the amounts of substances needed cannot be determined by counting molecules directly. Counting is always done by weighing. In this section we will see how chemical equations can be used to determine the masses of reacting chemicals.

To develop the principles for dealing with the stoichiometry of reactions, we will consider the reaction of propane with oxygen to produce carbon dioxide and water. We

Before doing any calculations involving a chemical reaction, be sure the equation for the reaction is balanced.
will consider the question: "What mass of oxygen will react with 96.1 g of propane?"

## CHEMICAL CONNECTIONS

## High Mountains-Low Octane

The next time you visit a gas station, take a moment to note the octane rating that accompanies the grade of gasoline that you are purchasing. The gasoline is priced according to its octane rating-a measure of the fuel's antiknock properties. In a conventional internal combustion engine, gasoline vapors and air are drawn into the combustion cylinder on the downward stroke of the piston. This air-fuel mixture is compressed on the upward piston stroke (compression stroke), and a spark from the sparkplug ignites the mix. The rhythmic combustion of the air-fuel mix occurring sequentially in several cylinders furnishes the power to propel the vehicle down the road. Excessive heat and pressure (or poorquality fuel) within the cylinder may
cause the premature combustion of the mixture-commonly known as engine "knock" or "ping." Over time, this engine knock can damage the engine, resulting in inefficient performance and costly repairs.

A consumer typically is faced with three choices of gasoline, with octane ratings of 87 (regular), 89 (midgrade), and 93 (premium). But if you happen to travel or live in the higher elevations of the Rocky Mountain states, you might be surprised to find different octane ratings at the gasoline pumps. The reason for this provides a lesson in stoichiometry. At higher elevations the air is less dense-the volume of oxygen per unit volume of air is smaller. Most engines are designed to achieve a 14:1 oxygen-to-fuel ratio in the cylinder prior
to combustion. If less oxygen is available, then less fuel is required to achieve this optimal ratio. In turn, the lower volumes of oxygen and fuel result in a lower pressure in the cylinder. Because high pressure tends to promote knocking, the lower pressure within engine cylinders at higher elevations promotes a more controlled combustion of the air-fuel mixture, and therefore octane requirements are lower. While consumers in the Rocky Mountain states can purchase three grades of gasoline, the octane ratings of these fuel blends are different from those in the rest of the United States. In Denver, Colorado, regular gasoline is 85 octane, midgrade is 87 octane, and premium is 91 octane-2 points lower than gasoline sold in most of the rest of the country.

In doing stoichiometry, the first thing we must do is write the balanced chemical equation for the reaction. In this case the balanced equation is

$$
\mathrm{C}_{3} \mathrm{H}_{8}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 3 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(g)
$$

which can be visualized as

This equation means that 1 mole of $\mathrm{C}_{3} \mathrm{H}_{8}$ reacts with 5 moles of $\mathrm{O}_{2}$ to produce 3 moles of $\mathrm{CO}_{2}$ and 4 moles of $\mathrm{H}_{2} \mathrm{O}$. To use this equation to find the masses of reactants and products, we must be able to convert between masses and moles of substances. Thus we must first ask: "How many moles of propane are present in 96.1 g of propane?" The molar mass of propane to three significant figures is 44.1 (that is, $3 \times 12.01+8 \times 1.008$ ). The moles of propane can be calculated as follows:

$$
96.1 \mathrm{gCC}_{3} \mathrm{H}_{8} \times \frac{1 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}}{44.1 \mathrm{gC}_{3} \mathrm{H}_{8}}=2.18 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}
$$

Next we must take into account the fact that each mole of propane reacts with 5 moles of oxygen. The best way to do this is to use the balanced equation to construct a mole ratio. In this case we want to convert from moles of propane to moles of oxygen. From the balanced equation, we see that 5 moles of $\mathrm{O}_{2}$ are required for each mole of $\mathrm{C}_{3} \mathrm{H}_{8}$, so the appropriate ratio is

$$
\frac{5 \mathrm{~mol} \mathrm{O}_{2}}{1 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}}
$$

Multiplying the number of moles of $\mathrm{C}_{3} \mathrm{H}_{8}$ by this factor gives the number of moles of $\mathrm{O}_{2}$ required:

$$
2.18 \mathrm{molC}_{3} \mathrm{H}_{8} \times \frac{5 \mathrm{~mol} \mathrm{O}_{2}}{1 \mathrm{molC}_{3} \mathrm{H}_{8}}=10.9 \mathrm{~mol} \mathrm{O}
$$

Notice that the mole ratio is set up so that the moles of $\mathrm{C}_{3} \mathrm{H}_{8}$ cancel out, and the units that result are moles of $\mathrm{O}_{2}$.

Since the original question asked for the mass of oxygen needed to react with 96.1 g of propane, the 10.9 moles of $\mathrm{O}_{2}$ must be converted to grams. Since the molar mass of $\mathrm{O}_{2}$ is $32.0 \mathrm{~g} / \mathrm{mol}$,

$$
10.9 \mathrm{mot}_{2} \times \frac{32.0 \mathrm{~g} \mathrm{O}_{2}}{1 \mathrm{mot}_{2}}=349 \mathrm{~g} \mathrm{O}_{2}
$$

Therefore, 349 g of oxygen are required to burn 96.1 g of propane.
This example can be extended by asking: "What mass of carbon dioxide is produced when 96.1 g of propane are combusted with oxygen?" In this case we must convert between moles of propane and moles of carbon dioxide. This can be accomplished by looking at the balanced equation, which shows that 3 moles of $\mathrm{CO}_{2}$ are produced for each mole of $\mathrm{C}_{3} \mathrm{H}_{8}$ reacted. The mole ratio needed to convert from moles of propane to moles of carbon dioxide is

$$
\frac{3 \mathrm{~mol} \mathrm{CO}_{2}}{1 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}}
$$

The conversion is

$$
2.18 \mathrm{molC}_{3} \mathrm{H}_{8} \times \frac{3 \mathrm{~mol} \mathrm{CO}_{2}}{1 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}}=6.54 \mathrm{~mol} \mathrm{CO} 2
$$

Then, using the molar mass of $\mathrm{CO}_{2}(44.0 \mathrm{~g} / \mathrm{mol})$, we calculate the mass of $\mathrm{CO}_{2}$ produced:

$$
6.54 \mathrm{mot} \mathrm{CO}_{2} \times \frac{44.0 \mathrm{~g} \mathrm{CO}_{2}}{1 \mathrm{molCO}_{2}}=288 \mathrm{~g} \mathrm{CO}_{2}
$$

We will now summarize the sequence of steps needed to carry out stoichiometric calculations.

$$
\begin{gathered}
96.1 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{8} \frac{1 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}}{44.1 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{8}} \quad 2.18 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8} \frac{3 \mathrm{~mol} \mathrm{CO}_{2}}{1 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}} \quad 6.54 \mathrm{~mol} \mathrm{CO}_{2} \\
\frac{44.0 \mathrm{~g} \mathrm{CO}_{2}}{1 \mathrm{~mol} \mathrm{CO}_{2}} \quad 288 \mathrm{~g} \mathrm{CO}_{2}
\end{gathered}
$$

 that you always take the mass of chemicals in lab, but then you use mole ratios to balance the equation. "Why not use the masses in the equation?" your partner asks. What if your lab partner decided to balance equations by using masses as coefficients? Is this even possible? Why or why not?

## PROBLEM-SOLVING STRATEGY

## Calculating Masses of Reactants and Products in Chemical Reactions

1. Balance the equation for the reaction.
2. Convert the known mass of the reactant or product to moles of that substance.
3. Use the balanced equation to set up the appropriate mole ratios.
4. Use the appropriate mole ratios to calculate the number of moles of the desired reactant or product.
5. Convert from moles back to grams if required by the problem.

## INTERACTIVE EXAMPLE 3.15 Chemical Stoichiometry I

Solid lithium hydroxide is used in space vehicles to remove exhaled carbon dioxide from the living environment by forming solid lithium carbonate and liquid water. What mass of gaseous carbon dioxide can be absorbed by 1.00 kg of lithium hydroxide?

## SOLUTION Where are we going?

To find the mass of $\mathrm{CO}_{2}$ absorbed by 1.00 kg LiOH
What do we know?
> Chemical reaction

$$
\mathrm{LiOH}(s)+\mathrm{CO}_{2}(g) \longrightarrow \mathrm{Li}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l)
$$

> 1.00 kg LiOH
What information do we need to find the mass of $\mathrm{CO}_{2}$ ?
> Balanced equation for the reaction

## How do we get there?

1. What is the balanced equation?

$$
2 \mathrm{LiOH}(s)+\mathrm{CO}_{2}(g) \rightarrow \mathrm{Li}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l)
$$

2. What are the moles of LiOH ?

To find the moles of LiOH , we need to know the molar mass.
What is the molar mass for LiOH ?

$$
6.941+16.00+1.008=23.95 \mathrm{~g} / \mathrm{mol}
$$

Now we use the molar mass to find the moles of LiOH :

$$
1.00 \mathrm{~kg} \mathrm{LiOH} \times \frac{1000 \mathrm{~g} \text { LiOH }}{1 \mathrm{~kg} \text { LiOH }} \times \frac{1 \mathrm{~mol} \mathrm{LiOH}}{23.95 \mathrm{gLiOH}}=41.8 \mathrm{~mol} \mathrm{LiOH}
$$

3. What is the mole ratio between $\mathrm{CO}_{2}$ and LiOH in the balanced equation?

$$
\frac{1 \mathrm{~mol} \mathrm{CO}_{2}}{2 \mathrm{~mol} \mathrm{LiOH}}
$$

4. What are the moles of $\mathrm{CO}_{2}$ ?

$$
41.8 \mathrm{molLiOH} \times \frac{1 \mathrm{~mol} \mathrm{CO}_{2}}{2 \mathrm{molLi} H}=20.9 \mathrm{~mol} \mathrm{CO}_{2}
$$

5. What is the mass of $\mathrm{CO}_{2}$ formed from 1.00 kg LiOH ?

$$
20.9 \mathrm{motCO}_{2} \times \frac{44.0 \mathrm{~g} \mathrm{CO}_{2}}{1 \mathrm{motCO}_{2}}=9.20 \times 10^{2} \mathrm{~g} \mathrm{CO}_{2}
$$

Thus 920. g of $\mathrm{CO}_{2}(\mathrm{~g})$ will be absorbed by 1.00 kg of $\mathrm{LiOH}(s)$.

## See Exercises 3.109 and 3.110

## INTERACTVE EXAMPLE 3.16 Chemical Stoichiometry II

Baking soda $\left(\mathrm{NaHCO}_{3}\right)$ is often used as an antacid. It neutralizes excess hydrochloric acid secreted by the stomach:

$$
\mathrm{NaHCO}_{3}(s)+\mathrm{HCl}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(a q)
$$

Milk of magnesia, which is an aqueous suspension of magnesium hydroxide, is also used as an antacid:

$$
\operatorname{Mg}(\mathrm{OH})_{2}(s)+2 \mathrm{HCl}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\operatorname{MgCl}_{2}(a q)
$$

Which is the more effective antacid per gram, $\mathrm{NaHCO}_{3}$ or $\mathrm{Mg}(\mathrm{OH})_{2}$ ?

## SOLUTION

## Where are we going?

To compare the acid neutralizing power of $\mathrm{NaHCO}_{3}$ and $\mathrm{Mg}(\mathrm{OH})_{2}$ per gram
What do we know?
> Balanced equations for the reactions
> $1.00 \mathrm{~g} \mathrm{NaHCO}_{3}$
> $1.00 \mathrm{~g} \mathrm{Mg}(\mathrm{OH})_{2}$
How do we get there?
For $\mathrm{NaHCO}_{3}$

1. What is the balanced equation?

$$
\mathrm{NaHCO}_{3}(s)+\mathrm{HCl}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(a q)
$$

2. What are the moles of $\mathrm{NaHCO}_{3}$ in 1.00 g ?

To find the moles of $\mathrm{NaHCO}_{3}$, we need to know the molar mass ( $84.01 \mathrm{~g} / \mathrm{mol}$ ).

$$
1.00 \mathrm{~g} \mathrm{NaHCO}_{3} \times \frac{1 \mathrm{~mol} \mathrm{NaHCO}_{3}}{84.01 \mathrm{~g} \mathrm{NaHCO}_{3}}=1.19 \times 10^{-2} \mathrm{~mol} \mathrm{NaHCO}_{3}
$$

-
Milk of magnesia contains a suspension of $\mathrm{Mg}(\mathrm{OH})_{2}(\mathrm{~s})$.
3. What is the mole ratio between HCl and $\mathrm{NaHCO}_{3}$ in the balanced equation?

$$
\frac{1 \mathrm{~mol} \mathrm{HCl}^{1 \mathrm{~mol} \mathrm{NaHCO}_{3}}}{\text { an }}
$$

4. What are the moles of HCl ?

$$
1.19 \times 10^{-2} \mathrm{~mol} \mathrm{NaHCO}_{3} \times \frac{1 \mathrm{~mol} \mathrm{HCl}}{1 \mathrm{~mol} \mathrm{NaHCO}_{3}}=1.19 \times 10^{-2} \mathrm{~mol} \mathrm{HCl}
$$

Thus 1.00 g of $\mathrm{NaHCO}_{3}$ will neutralize $1.19 \times 10^{-2}$ mole of HCl .

## For $\mathbf{M g}(\mathbf{O H})_{2}$

1. What is the balanced equation?

$$
\operatorname{Mg}(\mathrm{OH})_{2}(s)+2 \mathrm{HCl}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\operatorname{MgCl}_{2}(a q)
$$

2. What are the moles of $\mathrm{Mg}(\mathrm{OH})_{2}$ in 1.00 g ?

To find the moles of $\mathrm{Mg}(\mathrm{OH})_{2}$, we need to know the molar mass $(58.32 \mathrm{~g} / \mathrm{mol})$.

$$
1.00 \mathrm{~g} \mathrm{Mg}(\mathrm{OH})_{2} \times \frac{1 \mathrm{~mol} \mathrm{Mg}(\mathrm{OH})_{2}}{58.32 \mathrm{~g} \mathrm{Mg}(\mathrm{OH})_{2}}=1.71 \times 10^{-2} \mathrm{~mol} \mathrm{Mg}(\mathrm{OH})_{2}
$$

3. What is the mole ratio between HCl and $\mathrm{Mg}(\mathrm{OH})_{2}$ in the balanced equation?

$$
\frac{2 \mathrm{~mol} \mathrm{HCl}}{1 \mathrm{~mol} \mathrm{Mg}(\mathrm{OH})_{2}}
$$

4. What are the moles of HCl ?

$$
1.71 \times 10^{-2} \mathrm{~mol} \mathrm{Mg}(\mathrm{OH})_{2} \times \frac{2 \mathrm{~mol} \mathrm{HCl}}{1 \mathrm{~mol} \mathrm{Mg}(\mathrm{OH})_{2}}=3.42 \times 10^{-2} \mathrm{~mol} \mathrm{HCl}
$$

Thus 1.00 g of $\mathrm{Mg}(\mathrm{OH})_{2}$ will neutralize $3.42 \times 10^{-2}$ mole of HCl .
Since $1.00 \mathrm{~g} \mathrm{NaHCO}_{3}$ neutralizes $1.19 \times 10^{-2}$ mole of HCl and $1.00 \mathrm{~g} \mathrm{Mg}(\mathrm{OH})_{2}$ neutralizes $3.42 \times 10^{-2}$ mole of $\mathrm{HCl}, \mathrm{Mg}(\mathrm{OH})_{2}$ is the more effective antacid.

See Exercises 3.111 through 3.113

### 3.11 The Concept of Limiting Reactant

Suppose you have a part-time job in a sandwich shop. One very popular sandwich is always made as follows:

$$
2 \text { slices bread }+3 \text { slices meat }+1 \text { slice cheese } \longrightarrow \text { sandwich }
$$

Assume that you come to work one day and find the following quantities of ingredients:
8 slices bread 9 slices meat 5 slices cheese
How many sandwiches can you make? What will be left over?
To solve this problem, let's see how many sandwiches we can make with each component:

Bread: $\quad 8$ slices bread $\times \frac{1 \text { sandwich }}{2 \text { slices bread }}=4$ sandwiches
Meat: $\quad 9$ slices meat $\times \frac{1 \text { sandwich }}{3 \text { slices meat }}=3$ sandwiches
Cheese: $\quad 5$ slices cheese $\times \frac{1 \text { sandwich }}{1 \text { slice cheese }}=5$ sandwiches

FIGURE $\mathbf{3 . 9}$ Making sandwiches.

How many sandwiches can you make? The answer is three. When you run out of meat, you must stop making sandwiches. The meat is the limiting ingredient (Fig. 3.9).

What do you have left over? Making three sandwiches requires six pieces of bread. You started with eight slices, so you have two slices of bread left. You also used three pieces of cheese for the three sandwiches, so you have two pieces of cheese left.

In this example, the ingredient present in the largest number (the meat) was actually the component that limited the number of sandwiches you could make. This situation arose because each sandwich required three slices of meat-more than the quantity required of any other ingredient.

When molecules react with each other to form products, considerations very similar to those involved in making sandwiches arise. We can illustrate these ideas with the reaction of $\mathrm{N}_{2}(g)$ and $\mathrm{H}_{2}(g)$ to form $\mathrm{NH}_{3}(g)$ :

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
$$

Consider the following container of $\mathrm{N}_{2}(g)$ and $\mathrm{H}_{2}(g)$ :

What will this container look like if the reaction between $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ proceeds to completion? To answer this question, you need to remember that each $\mathrm{N}_{2}$ requires $3 \mathrm{H}_{2}$ molecules to form $2 \mathrm{NH}_{3}$. To make things clear, we will circle groups of reactants:

In this case, the mixture of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ contained just the number of molecules needed to form $\mathrm{NH}_{3}$ with nothing left over. That is, the ratio of the number of $\mathrm{H}_{2}$ molecules to $\mathrm{N}_{2}$ molecules was

$$
\frac{15 \mathrm{H}_{2}}{5 \mathrm{~N}_{2}}=\frac{3 \mathrm{H}_{2}}{1 \mathrm{~N}_{2}}
$$

This ratio exactly matches the numbers in the balanced equation

$$
3 \mathrm{H}_{2}(g)+\mathrm{N}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
$$

This type of mixture is called a stoichiometric mixture-one that contains the relative amounts of reactants that match the numbers in the balanced equation. In this case all reactants will be consumed to form products.

Now consider another container of $\mathrm{N}_{2}(\mathrm{~g})$ and $\mathrm{H}_{2}(\mathrm{~g})$ :

What will the container look like if the reaction between $\mathrm{N}_{2}(g)$ and $\mathrm{H}_{2}(g)$ proceeds to completion? Remember that each $\mathrm{N}_{2}$ requires $3 \mathrm{H}_{2}$. Circling groups of reactants, we have

In this case, the hydrogen $\left(\mathrm{H}_{2}\right)$ is limiting. That is, the $\mathrm{H}_{2}$ molecules are used up before all the $\mathrm{N}_{2}$ molecules are consumed. In this situation the amount of hydrogen limits the amount of product (ammonia) that can form-hydrogen is the limiting reactant. Some $\mathrm{N}_{2}$ molecules are left over in this case because the reaction runs out of $\mathrm{H}_{2}$ molecules first.

Although this pictorial representation is a good visual to show us what is happening in the course of the reaction, we can also present this information in a table. To do so we must use the balanced chemical equation. Remember that the balanced equation tells us the relative numbers of molecules that react. The relative numbers of molecules mixed together are usually different from the coefficients in the balanced equation. In this case we are starting with 5 molecules of $\mathrm{N}_{2}$ and 9 molecules of $\mathrm{H}_{2}$. These are numbers we use when trying to determine which reactant is limiting and how much product we form. We can organize our data as shown below:

| Balanced equation | $\mathrm{N}_{2}$ | + | $3 \mathrm{H}_{2}$ | $\rightarrow$ |
| :--- | ---: | :---: | :---: | :---: |
| Before | 5 |  | 9 |  |
| Change | $-?$ |  | $-?$ |  |
| After | $?$ | $?$ | $+?$ |  |

Note that the 5 molecules of $\mathrm{N}_{2}$ and 9 molecules of $\mathrm{H}_{2}$ (and no $\mathrm{NH}_{3}$ initially) are presented in the Before row. The Change row represents how much of each substance reacts or is produced. The After row represents how much of each substance remains in the final reaction mixture. We can tell from the pictorial representation which numbers belong in this table, but it is not always practical to do this, so let's look at a general way to determine these numbers.

Because we are assuming that the reaction goes to completion, we know that at least one of the values for $\mathrm{N}_{2}$ or $\mathrm{H}_{2}$ must be zero (0) in the After row. That is, we run out of at least one of the reactants. Thus, the two possibilities are:
Possibility I: $\mathrm{H}_{2}$ runs out first

|  | $\mathrm{N}_{2}$ | + | $3 \mathrm{H}_{2}$ | $\rightarrow$ |
| :--- | ---: | ---: | ---: | :---: |
| Before | 5 |  | 9 |  |
| Change | $-?$ |  | -9 |  |
| After | $?$ |  | 0 |  |

Possibility II: $\mathrm{N}_{2}$ runs out first

|  | $\mathrm{N}_{2}$ | + | $3 \mathrm{H}_{2}$ | $\rightarrow$ |
| :--- | ---: | ---: | ---: | :---: |
| Before | 5 |  | 9 |  |
| Change | -5 |  | $-?$ |  |
| After | 0 |  | $?$ |  |

For Possibility I we are assuming that we run out of $\mathrm{H}_{2}$, and for Possibility II we are assuming we run out of $\mathrm{N}_{2}$. How do we decide which of the possibilities is correct? We decide from our understanding of what a balanced chemical equation represents-the relative numbers of molecules that react. Recall that this is what the Change row represents as well. This brings us to a crucial idea: the ratio of the numbers in the Change row has to be the same as the ratio of the coefficients in the balanced equation. Let's reconsider, then, the two possibilities with this in mind:

Possibility I: $\mathrm{H}_{2}$ runs out first so the change for $\mathrm{H}_{2}$ must be -9 :

|  | $\mathrm{N}_{2}$ | + | $3 \mathrm{H}_{2}$ | $\rightarrow$ |
| :--- | ---: | ---: | ---: | :---: |
| Before | 5 |  | 9 |  |
| Change | -3 |  | -9 |  |
| After | 2 |  | 0 |  |

How did we come up with these numbers? We know the numbers in blue because the numbers in the Before row reflect the original mixture. Because we are assuming that the $\mathrm{H}_{2}$ runs out first we have -9 in the Change row. We determine the other two numbers in the Change row by using the ratio of the coefficients in the balanced equation. Because the ratio of the coefficients of $\mathrm{N}_{2}$ to $\mathrm{H}_{2}$ is $1: 3$, we can determine that the change for $\mathrm{H}_{2}$ must be -3 . That is, one-third as much $\mathrm{N}_{2}$ is used as $\mathrm{H}_{2}$. The reactants are consumed, so the sign is negative. The ratio of the coefficients of $\mathrm{N}_{2}$ to $\mathrm{NH}_{3}$ is $1: 2$, so we can determine the change for $\mathrm{NH}_{3}$ must be +6 . That is, twice as much $\mathrm{NH}_{3}$ is produced as $\mathrm{N}_{2}$ consumed.

We can use similar reasoning to complete the table for Possibility II:
Possibility II: $\mathrm{N}_{2}$ runs out first so the change for $\mathrm{N}_{2}$ is -5 :

|  | $\mathrm{N}_{2}$ | + | $3 \mathrm{H}_{2}$ | $\rightarrow$ |
| :--- | ---: | ---: | ---: | :---: |
| Before | 5 |  | 9 |  |
| Change | -5 |  | -15 |  |
| After | 0 |  | -6 |  |

Now we can determine that the change for $\mathrm{H}_{2}$ must be -15 since three times as much $\mathrm{H}_{2}$ is consumed as $\mathrm{N}_{2}$. Also, the change for $\mathrm{NH}_{3}$ must be +10 (twice as much $\mathrm{NH}_{3}$ is formed as $\mathrm{N}_{2}$ consumed).

We can see why $\mathrm{N}_{2}$ is not limiting by looking at Possibility II. For all of the $\mathrm{N}_{2}$ to react, we need 6 more molecules of $\mathrm{H}_{2}$ than we have. Because we cannot have a negative amount of a substance, Possibility II must not represent the reaction correctly.

Notice also that Possibility I conveys all of the information we initially saw in the picture of the reaction container. We begin with 5 molecules of $\mathrm{N}_{2}$ and 9 molecules of $\mathrm{H}_{2}$, and after the reaction is complete we are left with 2 molecules of $\mathrm{N}_{2}$ and 6 molecules of $\mathrm{NH}_{3}$.

Using a table such as this is convenient in that all of the information is conveyed: we now know which reactant runs out first, how much of the excess reactant is left over, and how much product is formed. It also emphasizes an understanding of what a balanced equation means because we have to use the ratio for the balanced equation in the Change row.

To determine how much product can be formed from a given mixture of reactants, we have to look for the reactant that is limiting-the one that runs out first and thus limits the amount of product that can form. In some cases, the mixture of reactants might be stoichiometric-that is, all reactants run out at the same time. In general, however, you cannot assume that a given mixture of reactants is a stoichiometric mixture, so you must determine whether one of the reactants is limiting. The reactant that runs out first and thus limits the amounts of products that can form is called the limiting reactant.

To this point we have considered examples where the numbers of reactant molecules could be counted. In "real life" you can't count the molecules directly-you can't see them, and even if you could, there would be far too many to count. Instead, you must count by weighing. We must therefore explore how to find the limiting reactant, given the masses of the reactants.

## Determination of Limiting Reactant Using Reactant Quantities

There are two ways to determine the limiting reactant in a chemical reaction. One involves comparing the moles of reactants to see which runs out first. We will consider this approach here.

In the laboratory or chemical plant, we work with much larger quantities than the few molecules of the preceding example. Therefore, we must learn to deal with limiting reactants using moles. The ideas are exactly the same, except that we are using moles of molecules instead of individual molecules. For example, suppose 25.0 kg of nitrogen and 5.00 kg of hydrogen are mixed and reacted to form ammonia. How do we calculate the mass of ammonia produced when this reaction is run to completion (until one of the reactants is completely consumed)?

As in the preceding example, we must use the balanced equation

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
$$

to determine whether nitrogen or hydrogen is the limiting reactant and then to determine the amount of ammonia that is formed. We first calculate the moles of reactants present:

$$
\begin{aligned}
& 25.0 \mathrm{~kg} \mathrm{~N}_{2} \times \frac{1000 \mathrm{~g} \mathrm{~N}_{2}}{1 \mathrm{~kg} \mathrm{~N}_{2}} \times \frac{1 \mathrm{~mol} \mathrm{~N}_{2}}{28.0 \mathrm{gN}_{2}}=8.93 \times 10^{2} \mathrm{~mol} \mathrm{~N}_{2} \\
& 5.00 \mathrm{~kg} \mathrm{H}_{2} \times \frac{1000 \mathrm{~g} \mathrm{H}_{2}}{1 \mathrm{~kg} \mathrm{H}_{2}} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2}}{2.016 \mathrm{gH}_{2}}=2.48 \times 10^{3} \mathrm{~mol} \mathrm{H}_{2}
\end{aligned}
$$

Since 1 mole of $\mathrm{N}_{2}$ reacts with 3 moles of $\mathrm{H}_{2}$, the number of moles of $\mathrm{H}_{2}$ that will react exactly with $8.93 \times 10^{2}$ moles of $\mathrm{N}_{2}$ is

$$
8.93 \times 10^{2} \mathrm{molN}_{2} \times \frac{3 \mathrm{~mol} \mathrm{H}_{2}}{1 \mathrm{~mol} \mathrm{~N}_{2}}=2.68 \times 10^{3} \mathrm{~mol} \mathrm{H}_{2}
$$

To determine which reactant is limiting, we can place our data in a table as before, in this case looking at the Before and Change rows:

Possibility I: $\mathrm{N}_{2}$ runs out first

|  | $\mathrm{N}_{2}$ | + | $3 \mathrm{H}_{2}$ | $\rightarrow$ |
| :---: | :---: | :---: | :---: | :---: |
| Before | $8.93 \times 10^{3}$ |  | $2.48 \times 10^{3}$ |  |
| Change | $-8.93 \times 10^{3}$ |  | $-2.68 \times 10^{3}$ |  |

Thus $8.93 \times 10^{2}$ moles of $\mathrm{N}_{2}$ require $2.68 \times 10^{3}$ moles of $\mathrm{H}_{2}$ to react completely. However, in this case, only $2.48 \times 10^{3}$ moles of $\mathrm{H}_{2}$ are present. This means that the hydrogen will be consumed before the nitrogen. But what if we had chosen the case where the $\mathrm{H}_{2}$ runs out first? Assuming that $2.48 \times 10^{3}$ moles of $\mathrm{H}_{2}$ are used, we can

Always determine which reactant is limiting.
calculate the moles of $\mathrm{N}_{2}$ that would be required.

$$
2.48 \times 10^{3} \mathrm{molH}_{2} \times \frac{1 \mathrm{~mol} \mathrm{~N}_{2}}{3 \mathrm{~mol} \mathrm{H}_{2}}=8.27 \times 10^{2} \mathrm{~mol} \mathrm{~N}_{2}
$$

Let's represent these data in table form, once again focusing on the Before and Change rows:

Possibility II: $\mathrm{H}_{2}$ runs out first

|  | $\mathrm{N}_{2}$ | + | $3 \mathrm{H}_{2}$ | $\rightarrow$ |
| :---: | :---: | :---: | :---: | :---: |
| Before | $8.93 \times 10^{3}$ |  | $2.48 \times 10^{3}$ |  |
| Change | $-8.27 \times 10^{3}$ |  | $-2.48 \times 10^{3}$ |  |

Thus $2.48 \times 10^{3}$ moles of $\mathrm{H}_{2}$ require $8.27 \times 10^{2}$ moles of $\mathrm{N}_{2}$. Because $8.93 \times 10^{2}$ moles of $\mathrm{N}_{2}$ are actually present, the nitrogen is in excess. Thus hydrogen is the limiting reactant in this particular situation, and we must use the amount of hydrogen to compute the quantity of ammonia formed:

$$
2.48 \times 10^{3} \mathrm{molH}_{2} \times \frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{3 \mathrm{molH}_{2}}=1.65 \times 10^{3} \mathrm{~mol} \mathrm{NH}_{3}
$$

Converting moles to kilograms gives

$$
1.65 \times 10^{3} \mathrm{~mol} \mathrm{NH}_{3} \times \frac{17.0 \mathrm{~g} \mathrm{NH}_{3}}{1 \mathrm{~mol} \mathrm{NH}_{3}}=2.80 \times 10^{4} \mathrm{~g} \mathrm{NH}_{3}=28.0 \mathrm{~kg} \mathrm{NH}_{3}
$$

## Determination of Limiting Reactant Using Quantities of Products Formed

A second method for determining which reactant in a chemical reaction is limiting is to consider the amounts of products that can be formed by completely consuming each reactant. We can see this by considering our results when we reacted 5 molecules of $\mathrm{N}_{2}$ with 9 molecules of $\mathrm{H}_{2}$ to form $\mathrm{NH}_{3}$ :

Possibility I: $\mathrm{H}_{2}$ runs out first

|  | $\mathrm{N}_{2}$ | + | $3 \mathrm{H}_{2}$ | $\rightarrow$ |
| :--- | ---: | ---: | ---: | :---: |
| 9 |  | $2 \mathrm{NH}_{3}$ |  |  |
| Before | 5 |  | 0 |  |
| Change | -3 |  | -9 |  |
| After | 2 |  | 0 |  |

Possibility II: $\mathrm{N}_{2}$ runs out first

|  | $\mathrm{N}_{2}$ | + | $3 \mathrm{H}_{2}$ | $\rightarrow$ | $2 \mathrm{NH}_{3}$ |
| :--- | ---: | ---: | ---: | ---: | :---: |
| Before | 5 |  | 9 |  | 0 |
| Change | -5 |  | -15 |  | +10 |
| After | 0 |  | -6 |  | 10 |

Possibility I shows the amount of $\mathrm{NH}_{3}$ formed if $\mathrm{H}_{2}$ is limiting, and Possibility II shows us the amount of $\mathrm{NH}_{3}$ formed if $\mathrm{N}_{2}$ is limiting. Possibility I is correct because we cannot end up with a negative number of $\mathrm{H}_{2}$ molecules. Notice that the amount of $\mathrm{NH}_{3}$ produced in Possibility I is less than that in Possibility II. This leads us to the general idea that the reactant that produces the smallest amount of product must run out first and thus be limiting. As another example, consider again the reaction of $25.0 \mathrm{~kg}\left(8.93 \times 10^{2}\right.$ moles $)$ of nitrogen with $5.00 \mathrm{~kg}\left(2.48 \times 10^{3} \mathrm{moles}\right)$ of hydrogen.

We will now use these amounts of reactants to determine how much $\mathrm{NH}_{3}$ would form. Since 1 mole of $\mathrm{N}_{2}$ forms 2 moles of $\mathrm{NH}_{3}$, the amount of $\mathrm{NH}_{3}$ that would be formed if all of the $\mathrm{N}_{2}$ was used up is calculated as follows:

$$
8.93 \times 10^{2} \mathrm{~mol} \mathrm{~N}_{2} \times \frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{1 \mathrm{~mol} \mathrm{~N}_{2}}=1.79 \times 10^{3} \mathrm{~mol} \mathrm{NH}_{3}
$$

Next we will calculate how much $\mathrm{NH}_{3}$ would be formed if the $\mathrm{H}_{2}$ was completely used up:

$$
2.48 \times 10^{3} \mathrm{~mol} \mathrm{H}_{2} \times \frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{3 \mathrm{~mol} \mathrm{H}_{2}}=1.65 \times 10^{3} \mathrm{~mol} \mathrm{NH}_{3}
$$

Because a smaller amount of $\mathrm{NH}_{3}$ is produced from the $\mathrm{H}_{2}$ than from the $\mathrm{N}_{2}$, the amount of $\mathrm{H}_{2}$ must be limiting.

Thus because the $\mathrm{H}_{2}$ is the limiting reactant, the amount of $\mathrm{NH}_{3}$ that can form is $1.65 \times 10^{3}$ moles. Converting moles to kilograms gives:

$$
1.65 \times 10^{3} \mathrm{~mol} \mathrm{NH}_{3} \times \frac{17 \mathrm{~g} \mathrm{NH}_{3}}{1 \mathrm{~mol} \mathrm{NH}_{3}}=2.80 \times 10^{4} \mathrm{~g} \mathrm{NH}_{3}=28.0 \mathrm{~kg} \mathrm{NH} 3
$$

## INTERACTIVE EXAMPLE 3.17 Stoichiometry: Limiting Reactant

Nitrogen gas can be prepared by passing gaseous ammonia over solid copper(II) oxide at high temperatures. The other products of the reaction are solid copper and water vapor. If a sample containing 18.1 g of $\mathrm{NH}_{3}$ is reacted with 90.4 g of CuO , which is the limiting reactant? How many grams of $\mathrm{N}_{2}$ will be formed?

## SOLUTION Where are we going?

To find the limiting reactant
To find the mass of $\mathrm{N}_{2}$ produced
What do we know?
) The chemical reaction

$$
\mathrm{NH}_{3}(g)+\mathrm{CuO}(s) \longrightarrow \mathrm{N}_{2}(g)+\mathrm{Cu}(s)+\mathrm{H}_{2} \mathrm{O}(g)
$$

> $18.1 \mathrm{~g} \mathrm{NH}_{3}$
> 90.4 g CuO
What information do we need?
> Balanced equation for the reaction
> Moles of $\mathrm{NH}_{3}$
) Moles of CuO

## How do we get there?

To find the limiting reactant
What is the balanced equation?

$$
2 \mathrm{NH}_{3}(g)+3 \mathrm{CuO}(s) \longrightarrow \mathrm{N}_{2}(g)+3 \mathrm{Cu}(s)+3 \mathrm{H}_{2} \mathrm{O}(g)
$$

What are the moles of $\mathrm{NH}_{3}$ and CuO ?
To find the moles, we need to know the molar masses.

$$
\begin{gathered}
\mathrm{NH}_{3} \quad 17.03 \mathrm{~g} / \mathrm{mol} \\
\mathrm{CuO} \quad 79.55 \mathrm{~g} / \mathrm{mol} \\
18.1 \mathrm{~g} \mathrm{NH}_{3} \times \frac{1 \mathrm{~mol} \mathrm{NH}_{3}}{17.03 \mathrm{gAH}_{3}}=1.06 \mathrm{~mol} \mathrm{NH}_{3} \\
90.4 \mathrm{~g} \mathrm{CuO} \times \frac{1 \mathrm{~mol} \mathrm{CuO}}{79.55 \mathrm{~g} \mathrm{CuO}}=1.14 \mathrm{~mol} \mathrm{CuO}
\end{gathered}
$$

A. First we will determine the limiting reactant by comparing the moles of reactants to see which one is consumed first.

What is the mole ratio between $\mathrm{NH}_{3}$ and CuO in the balanced equation?

$$
\frac{3 \mathrm{~mol} \mathrm{CuO}}{2 \mathrm{~mol} \mathrm{NH}_{3}}
$$

How many moles of CuO are required to react with 1.06 moles of $\mathrm{NH}_{3}$ ?

$$
1.06 \mathrm{~mol} \mathrm{NH}_{3} \times \frac{3 \mathrm{~mol} \mathrm{CuO}}{2 \mathrm{~mol} \mathrm{NH}_{3}}=1.59 \mathrm{~mol} \mathrm{CuO}
$$

Thus 1.59 moles of CuO are required to react with 1.06 moles of $\mathrm{NH}_{3}$. Since only 1.14 moles of CuO are actually present, the amount of CuO is limiting; CuO will run out before $\mathrm{NH}_{3}$ does. We can see this by placing the data in a table:

|  | $2 \mathrm{NH}_{3}$ | + | 3 CuO | $\rightarrow$ |
| :--- | ---: | ---: | ---: | :--- |
| Before | 1.06 |  | 1.14 |  |
| Change | -1.06 |  | -1.59 |  |

- As we can see, there is not enough CuO to react with all of the $\mathrm{NH}_{3}$, so CuO is the limiting reactant.
B. Alternatively we can determine the limiting reactant by computing the moles of $\mathrm{N}_{2}$ that would be formed by complete consumption of $\mathrm{NH}_{3}$ and CuO :

$$
\begin{aligned}
& 1.06 \mathrm{~mol} \mathrm{HH}_{3} \times \frac{1 \mathrm{~mol} \mathrm{~N}_{2}}{2 \mathrm{~mol} \mathrm{NH}_{3}}=0.530 \mathrm{~mol} \mathrm{~N}_{2} \\
& 1.14 \mathrm{~mol} \mathrm{CuO} \times \frac{1 \mathrm{~mol} \mathrm{~N}_{2}}{3 \mathrm{molCuO}}=0.380 \mathrm{~mol} \mathrm{~N}_{2}
\end{aligned}
$$

As before, we see that the CuO is limiting since it produces the smaller amount of $\mathrm{N}_{2}$.

To find the mass of $\mathrm{N}_{2}$ produced

## What are the moles of $N_{2}$ formed?

Because CuO is the limiting reactant, we must use the amount of CuO to calculate the amount of $\mathrm{N}_{2}$ formed.

What is the mole ratio between $N_{2}$ and CuO in the balanced equation?

$$
\frac{1 \mathrm{~mol} \mathrm{~N}_{2}}{3 \mathrm{~mol} \mathrm{CuO}}
$$

What are the moles of $\mathrm{N}_{2}$ ?

$$
1.14 \mathrm{molCuO} \times \frac{1 \mathrm{~mol} \mathrm{~N}_{2}}{3 \mathrm{molCuO}}=0.380 \mathrm{~mol} \mathrm{~N}_{2}
$$

What mass of $N_{2}$ is produced?
Using the molar mass of $\mathrm{N}_{2}(28.02 \mathrm{~g} / \mathrm{mol})$, we can calculate the mass of $\mathrm{N}_{2}$ produced:
$0.380 \mathrm{~mol} \mathrm{~N}_{2} \times \frac{28.02 \mathrm{~g} \mathrm{~N}_{2}}{1 \mathrm{~mol} \mathrm{~N}_{2}}=10.6 \mathrm{~g} \mathrm{~N}_{2}$

## See Exercises 3.123 through 3.128

The amount of a product formed when the limiting reactant is completely consumed is called the theoretical yield of that product. In Example $3.17,10.6 \mathrm{~g}$ of nitrogen represent the theoretical yield. This is the maximum amount of nitrogen that can

Percent yield is important as an indicator of the efficiency of a particular laboratory or industrial reaction.
be produced from the quantities of reactants used. Actually, the amount of product predicted by the theoretical yield is seldom obtained because of side reactions (other reactions that involve one or more of the reactants or products) and other complications. The actual yield of product is often given as a percentage of the theoretical yield. This is called the percent yield:

$$
\frac{\text { Actual yield }}{\text { Theoretical yield }} \times 100 \%=\text { percent yield }
$$

For example, if the reaction considered in Example 3.17 actually gave 6.63 g of nitrogen instead of the predicted 10.6 g , the percent yield of nitrogen would be

$$
\frac{6.63 \mathrm{gA}_{2}}{10.6 \mathrm{gN}_{2}} \times 100 \%=62.5 \%
$$

## INTERACTIVE EXAMPLE 3.18 Calculating Percent Yield

Methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$, also called methyl alcohol, is the simplest alcohol. It is used as a fuel in race cars and is a potential replacement for gasoline. Methanol can be manufactured by combining gaseous carbon monoxide and hydrogen. Suppose $68.5 \mathrm{~kg} \mathrm{CO}(g)$ is reacted with $8.60 \mathrm{~kg} \mathrm{H}_{2}(g)$. Calculate the theoretical yield of methanol. If $3.57 \times 10^{4} \mathrm{~g} \mathrm{CH}_{3} \mathrm{OH}$ is actually produced, what is the percent yield of methanol?

## SOLUTION

## Where are we going?

To calculate the theoretical yield of methanol
To calculate the percent yield of methanol

## What do we know?

》 The chemical reaction

$$
\mathrm{H}_{2}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(l)
$$

> $68.5 \mathrm{~kg} \mathrm{CO}(\mathrm{g})$
> $8.60 \mathrm{~kg} \mathrm{H}_{2}(g)$
> $3.57 \times 10^{4} \mathrm{~g} \mathrm{CH}_{3} \mathrm{OH}$ is produced
What information do we need?
> Balanced equation for the reaction
> Moles of $\mathrm{H}_{2}$
) Moles of CO
) Which reactant is limiting
》 Amount of $\mathrm{CH}_{3} \mathrm{OH}$ produced

## How do we get there?

To find the limiting reactant

What is the balanced equation?

$$
2 \mathrm{H}_{2}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(l)
$$

What are the moles of $\mathrm{H}_{2}$ and CO ?
To find the moles, we need to know the molar masses.

$$
\begin{gathered}
\mathrm{H}_{2} \quad 2.016 \mathrm{~g} / \mathrm{mol} \\
\mathrm{CO} \\
28.02 \mathrm{~g} / \mathrm{mol} \\
68.5 \mathrm{kgCO} \times \frac{1000 \mathrm{gCO}}{1 \mathrm{kgCO}} \times \frac{1 \mathrm{~mol} \mathrm{CO}}{28.02 \mathrm{gCO}}=2.44 \times 10^{3} \mathrm{~mol} \mathrm{CO} \\
8.60 \mathrm{~kg} \mathrm{H}_{2} \times \frac{1000 \mathrm{gH}_{2}}{1 \mathrm{~kg} \mathrm{H}_{2}} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2}}{2.016 \mathrm{gH}_{2}}=4.27 \times 10^{3} \mathrm{~mol} \mathrm{H}_{2}
\end{gathered}
$$

We can determine the limiting reactant by calculating the amounts of $\mathrm{CH}_{3} \mathrm{OH}$ formed by complete consumption of $\mathrm{CO}(g)$ and $\mathrm{H}_{2}(g)$ :

$$
\begin{aligned}
& 2.44 \times 10^{3} \mathrm{molCO} \times \frac{1 \mathrm{~mol} \mathrm{CH}_{3} \mathrm{OH}}{1 \mathrm{~mol} \mathrm{CO}_{2}}=2.44 \times 10^{3} \mathrm{~mol} \mathrm{CH}_{3} \mathrm{OH} \\
& 4.27 \times 10^{3} \mathrm{~mol} \mathrm{H}_{2} \times \frac{1 \mathrm{~mol} \mathrm{CH}_{3} \mathrm{OH}}{2 \mathrm{~mol} \mathrm{H}_{2}}=2.14 \times 10^{3} \mathrm{~mol} \mathrm{CH}_{3} \mathrm{OH}
\end{aligned}
$$

Since complete consumption of the $\mathrm{H}_{2}$ produces the smaller amount of $\mathrm{CH}_{3} \mathrm{OH}$, the $\mathrm{H}_{2}$ is the limiting reactant as we determined above.

To calculate the theoretical yield of methanol
What are the moles of $\mathrm{CH}_{3} \mathrm{OH}$ formed?
We must use the amount of $\mathrm{H}_{2}$ and the mole ratio between $\mathrm{H}_{2}$ and $\mathrm{CH}_{3} \mathrm{OH}$ to determine the maximum amount of methanol that can be produced:

$$
4.27 \times 10^{3} \mathrm{molH}_{2} \times \frac{1 \mathrm{~mol} \mathrm{CH}_{3} \mathrm{OH}}{2 \mathrm{molH}_{2}}=2.14 \times 10^{3} \mathrm{~mol} \mathrm{CH}_{3} \mathrm{OH}
$$

What is the theoretical yield of $\mathrm{CH}_{3} \mathrm{OH}$ in grams?

$$
2.14 \times 10^{3} \mathrm{molCH}_{3} \mathrm{OH} \times \frac{32.04 \mathrm{~g} \mathrm{CH}_{3} \mathrm{OH}}{1 \mathrm{molCH}_{3} \mathrm{OH}}=6.86 \times 10^{4} \mathrm{~g} \mathrm{CH}_{3} \mathrm{OH}
$$

- Thus, from the amount of reactants given, the maximum amount of $\mathrm{CH}_{3} \mathrm{OH}$ that can be formed is $6.86 \times 10^{4} \mathrm{~g}$. This is the theoretical yield.

What is the percent yield of $\mathrm{CH}_{3} \mathrm{OH}$ ?
$\square \frac{\text { Actual yield (grams) }}{\text { Theoretical yield (grams) }} \times 100=\frac{3.57 \times 10^{4} \mathrm{gCH}_{3} \mathrm{OH}}{6.86 \times 10^{4} \mathrm{~g} \mathrm{gH}_{3} \mathrm{OH}} \times 100 \%=52.0 \%$

## PROBLEM-SOLVING STRATEGY

## Solving a Stoichiometry Problem Involving Masses of Reactants and Products

1. Write and balance the equation for the reaction.
2. Convert the known masses of substances to moles.
3. Determine which reactant is limiting.
4. Using the amount of the limiting reactant and the appropriate mole ratios, compute the number of moles of the desired product.
5. Convert from moles to grams, using the molar mass.

This process is summarized in the diagram below:

## Empirical formula

) The simplest whole-number ratio of the various types of atoms in a compound
> Can be obtained from the mass percent of elements in a compound

## Molecular formula

> For molecular substances:
> The formula of the constituent molecules
) Always an integer multiple of the empirical formula
> For ionic substances:
) The same as the empirical formula

## Chemical reactions

> Reactants are turned into products.
) Atoms are neither created nor destroyed.
) All of the atoms present in the reactants must also be present in the products.

## Characteristics of a chemical equation

> Represents a chemical reaction
) Reactants on the left side of the arrow, products on the right side
) When balanced, gives the relative numbers of reactant and product molecules or ions

## Stoichiometry calculations

> Amounts of reactants consumed and products formed can be determined from the balanced chemical equation.
> The limiting reactant is the one consumed first, thus limiting the amount of product that can form.

## Yield

> The theoretical yield is the maximum amount that can be produced from a given amount of the limiting reactant.
> The actual yield, the amount of product actually obtained, is always less than the theoretical yield.
> Percent yield $=\frac{\text { actual yield }(\mathrm{g})}{\text { theoretical yield }(\mathrm{g})} \times 100 \%$

Review Questions Answers to the Review Questions can be found on the Student website (accessible from www.cengagebrain.com).

1. Explain the concept of "counting by weighing" using marbles as your example.
2. Atomic masses are relative masses. What does this mean?
3. The atomic mass of boron $(\mathrm{B})$ is given in the periodic table as 10.81 , yet no single atom of boron has a mass of 10.81 u . Explain.
4. What three conversion factors and in what order would you use them to convert the mass of a compound into atoms of a particular element in that compound-for example, from 1.00 g aspirin $\left(\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}\right)$ to number of hydrogen atoms in the $1.00-\mathrm{g}$ sample?
5. Fig. 3.5 illustrates a schematic diagram of a combustion device used to analyze organic compounds. Given that a certain amount of a compound containing carbon, hydrogen, and oxygen is combusted in this device, explain how the data relating to the mass of $\mathrm{CO}_{2}$ produced and the mass of $\mathrm{H}_{2} \mathrm{O}$ produced can be manipulated to determine the empirical formula.
6. What is the difference between the empirical and molecular formulas of a compound? Can they ever be the same? Explain.
7. Consider the hypothetical reaction between $A_{2}$ and $A B$ pictured below.

What is the balanced equation? If 2.50 moles of $\mathrm{A}_{2}$ are reacted with excess AB , what amount (moles) of product will form? If the mass of $A B$ is 30.0 u and the mass of $\mathrm{A}_{2}$ are 40.0 u , what is the mass of the product? If 15.0 g of $A B$ is reacted, what mass of $A_{2}$ is required to react with all of the AB , and what mass of product is formed?
8. What is a limiting reactant problem? Explain the method you are going to use to solve limiting reactant problems.

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. The following are actual student responses to the question: Why is it necessary to balance chemical equations?
a. The chemicals will not react until you have added the correct mole ratios.
b. The correct products will not be formed unless the right amount of reactants have been added.
c. A certain number of products cannot be formed without a certain number of reactants.
d. The balanced equation tells you how much reactant you need and allows you to predict how much product you'll make.
e. A mole-to-mole ratio must be established for the reaction to occur as written.
Justify the best choice, and for choices you did not pick, explain what is wrong with them.
2. What information do we get from a chemical formula? From a chemical equation?
3. True or false? The atom with the largest subscript in a formula is the atom with the largest percent by mass in the compound. If true, explain why with an example. If false, explain why with an example. In either case, provide mathematical support.
4. You have a $20.0-\mathrm{g}$ sample of silver metal. You are given 10.0 g of another metal and told that this sample contains twice the number of atoms as the sample of silver metal. Is this possible?
5. You are making cookies and are missing a key ingredienteggs. You have most of the other ingredients needed to make the cookies, except you have only 1.33 cups of butter and no eggs. You note that the recipe calls for two cups of
6. Consider the following mixture of $\mathrm{SO}_{2}(g)$ and $\mathrm{O}_{2}(g)$.

If $\mathrm{SO}_{2}(g)$ and $\mathrm{O}_{2}(g)$ react to form $\mathrm{SO}_{3}(g)$, draw a representation of the product mixture assuming the reaction goes to completion. What is the limiting reactant in the reaction? If 96.0 g of $\mathrm{SO}_{2}$ react with $32.0 \mathrm{~g} \mathrm{O}_{2}$, what mass of product will form?
10. Why is the actual yield of a reaction often less than the theoretical yield?
butter and three eggs (plus the other ingredients) to make six dozen cookies. You call a friend and have him bring you some eggs.
a. What number of eggs do you need?
b. If you use all the butter (and get enough eggs), what number of cookies will you make?
Unfortunately, your friend hangs up before you tell him how many eggs you need. When he arrives, he has a surprise for you-to save time, he has broken them all in a bowl for you. You ask him how many he brought, and he replies, "I can't remember." You weigh the eggs and find that they weigh 62.1 g . Assuming that an average egg weighs 34.21 g ,
a. What quantity of butter is needed to react with all the eggs?
b. What number of cookies can you make?
c. Which will you have left over, eggs or butter?
d. What quantity is left over?
6. Nitrogen gas $\left(\mathrm{N}_{2}\right)$ and hydrogen gas $\left(\mathrm{H}_{2}\right)$ react to form ammonia gas $\left(\mathrm{NH}_{3}\right)$.
Consider the mixture of $\mathrm{N}_{2}(\bigcirc)$ and $\mathrm{H}_{2}(\bigcirc)$ in a closed container as illustrated below:

Assuming the reaction goes to completion, draw a representation of the product mixture. Explain how you arrived at this representation.
7. For the preceding question, which of the following equations best represents the reaction?
a. $6 \mathrm{~N}_{2}+6 \mathrm{H}_{2} \longrightarrow 4 \mathrm{NH}_{3}+4 \mathrm{~N}_{2}$
b. $\mathrm{N}_{2}+\mathrm{H}_{2} \longrightarrow \mathrm{NH}_{3}$
c. $\mathrm{N}+3 \mathrm{H} \longrightarrow \mathrm{NH}_{3}$
d. $\mathrm{N}_{2}+3 \mathrm{H}_{2} \longrightarrow 2 \mathrm{NH}_{3}$
e. $2 \mathrm{~N}_{2}+6 \mathrm{H}_{2} \longrightarrow 4 \mathrm{NH}_{3}$

Justify your choice, and for choices you did not pick, explain what is wrong with them.
8. You know that chemical $A$ reacts with chemical $B$. You react $10.0 \mathrm{~g} A$ with $10.0 \mathrm{~g} B$. What information do you need to determine the amount of product that will be produced? Explain.
9. A new grill has a mass of 30.0 kg . You put 3.0 kg of charcoal in the grill. You burn all the charcoal and the grill has a mass of 30.0 kg . What is the mass of the gases given off? Explain.
10. Consider an iron bar on a balance as shown.

As the iron bar rusts, which of the following is true? Explain your answer.
a. The balance will read less than 75.0 g .
b. The balance will read 75.0 g .
c. The balance will read greater than 75.0 g .
d. The balance will read greater than 75.0 g , but if the bar is removed, the rust is scraped off, and the bar replaced, the balance will read 75.0 g .
11. You may have noticed that water sometimes drips from the exhaust of a car as it is running. Is this evidence that there is at least a small amount of water originally present in the gasoline? Explain.

Questions 12 and 13 deal with the following situation: You react chemical $A$ with chemical $B$ to make one product. It takes 100 g of $A$ to react completely with 20 g of $B$.
12. What is the mass of the product?
a. less than 10 g
b. between 20 and 100 g
c. between 100 and 120 g
d. exactly 120 g
e. more than 120 g
13. What is true about the chemical properties of the product?
a. The properties are more like chemical $A$.
b. The properties are more like chemical $B$.
c. The properties are an average of those of chemical $A$ and chemical $B$.
d. The properties are not necessarily like either chemical $A$ or chemical $B$.
e. The properties are more like chemical $A$ or more like chemical $B$, but more information is needed.
Justify your choice, and for choices you did not pick, explain what is wrong with them.
14. Is there a difference between a homogeneous mixture of hydrogen and oxygen in a 2:1 mole ratio and a sample of water vapor? Explain.
15. Chlorine exists mainly as two isotopes, ${ }^{37} \mathrm{Cl}$ and ${ }^{35} \mathrm{Cl}$. Which is more abundant? How do you know?
16. The average mass of a carbon atom is 12.011 . Assuming you could pick up one carbon atom, estimate the chance that you would randomly get one with a mass of 12.011. Support your answer.
17. Can the subscripts in a chemical formula be fractions? Explain. Can the coefficients in a balanced chemical equation be fractions? Explain. Changing the subscripts of chemicals can balance the equations mathematically. Why is this unacceptable?
18. Consider the equation $2 A+B \longrightarrow A_{2} B$. If you mix 1.0 mole of $A$ with 1.0 mole of $B$, what amount (moles) of $A_{2} B$ can be produced?
19. According to the law of conservation of mass, mass cannot be gained or destroyed in a chemical reaction. Why can't you simply add the masses of two reactants to determine the total mass of product?
20. Which of the following pairs of compounds have the same empirical formula?
a. acetylene, $\mathrm{C}_{2} \mathrm{H}_{2}$, and benzene, $\mathrm{C}_{6} \mathrm{H}_{6}$
b. ethane, $\mathrm{C}_{2} \mathrm{H}_{6}$, and butane, $\mathrm{C}_{4} \mathrm{H}_{10}$
c. nitrogen dioxide, $\mathrm{NO}_{2}$, and dinitrogen tetroxide, $\mathrm{N}_{2} \mathrm{O}_{4}$
d. diphenyl ether, $\mathrm{C}_{12} \mathrm{H}_{10} \mathrm{O}$, and phenol, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}$
21. Atoms of three different elements are represented by $\mathrm{O}, \square$, and $\Delta$. Which compound is left over when three molecules of $\mathrm{O} \Delta$ and three molecules of $\square \square \Delta$ react to form $\mathrm{O} \square \Delta$ and $\mathrm{O} \Delta \Delta$ ?
22. In chemistry, what is meant by the term "mole"? What is the importance of the mole concept?
23. Which (if any) of the following is(are) true regarding the limiting reactant in a chemical reaction?
a. The limiting reactant has the lowest coefficient in a balanced equation.
b. The limiting reactant is the reactant for which you have the fewest number of moles.
c. The limiting reactant has the lowest ratio of moles available/coefficient in the balanced equation.
d. The limiting reactant has the lowest ratio of coefficient in the balanced equation/moles available.
Justify your choice. For those you did not choose, explain why they are incorrect.
24. Consider the equation $3 \mathrm{~A}+\mathrm{B} \rightarrow \mathrm{C}+\mathrm{D}$. You react 4 moles of A with 2 moles of B . Which of the following is true?
a. The limiting reactant is the one with the higher molar mass.
b. A is the limiting reactant because you need 6 moles of A and have 4 moles.
c. B is the limiting reactant because you have fewer moles of B than A.
d. $B$ is the limiting reactant because three A molecules react with each B molecule.
e. Neither reactant is limiting.

Justify your choice. For those you did not choose, explain why they are incorrect.

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of the book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

25. The atomic masses in the periodic table are relative masses and average masses. Explain.
26. Avogadro's number, molar mass, and the chemical formula of a compound are three useful conversion factors. What unit conversions can be accomplished using these conversion factors?
27. If you had a mole of U.S. dollar bills and equally distributed the money to all of the people of the world, how rich would every person be? Assume a world population of 7 billion.
28. Describe 1 mole of $\mathrm{CO}_{2}$ in as many ways as you can.
29. Which of the following compounds have the same empirical formulas?

a.

c.

d.
30. What is the difference between the molar mass and the empirical formula mass of a compound? When are these masses the same, and when are they different? When different, how is the molar mass related to the empirical formula mass?
31. How is the mass percent of elements in a compound different for a $1.0-\mathrm{g}$ sample versus a $100 . \mathrm{g}$ sample versus a 1 -mole sample of the compound?
32. A balanced chemical equation contains a large amount of information. What information is given in a balanced equation?
33. The reaction of an element X with element Y is represented in the following diagram. Which of the equations best describes this reaction?

a. $3 \mathrm{X}+8 \mathrm{Y} \rightarrow \mathrm{X}_{3} \mathrm{Y}_{8}$
b. $3 \mathrm{X}+6 \mathrm{Y} \rightarrow \mathrm{X}_{3} \mathrm{Y}_{6}$
c. $\mathrm{X}+2 \mathrm{Y} \rightarrow \mathrm{XY}_{2}$
d. $3 \mathrm{X}+8 \mathrm{Y} \rightarrow 3 \mathrm{XY}_{2}+2 \mathrm{Y}$
34. Hydrogen gas and oxygen gas react to form water, and this reaction can be depicted as follows:

Explain why this equation is not balanced, and draw a picture of the balanced equation.
35. What is the theoretical yield for a reaction, and how does this quantity depend on the limiting reactant?
36. What does it mean to say a reactant is present "in excess" in a process? Can the limiting reactant be present in excess? Does the presence of an excess of a reactant affect the mass of products expected for a reaction?
37. Consider the following generic reaction:

$$
\mathrm{A}_{2} \mathrm{~B}_{2}+2 \mathrm{C} \longrightarrow 2 \mathrm{CB}+2 \mathrm{~A}
$$

What steps and information are necessary to perform the following determinations assuming that $1.00 \times 10^{4}$ molecules of $\mathrm{A}_{2} \mathrm{~B}_{2}$ are reacted with excess C ?
a. mass of CB produced
b. atoms of A produced
c. moles of C reacted
d. percent yield of CB
38. Consider the following generic reaction:

$$
\mathrm{Y}_{2}+2 \mathrm{XY} \longrightarrow 2 \mathrm{XY}_{2}
$$

In a limiting reactant problem, a certain quantity of each reactant is given and you are usually asked to calculate the mass of product formed. If 10.0 g of $\mathrm{Y}_{2}$ is reacted with 10.0 g of XY , outline two methods you could use to determine which reactant is limiting (runs out first) and thus determines the mass of product formed.

## Exercises

In this section similar exercises are paired.

## Atomic Masses and the Mass Spectrometer

-39. An element consists of $1.40 \%$ of an isotope with mass 203.973 u, $24.10 \%$ of an isotope with mass 205.9745 u, $22.10 \%$ of an isotope with mass 206.9759 u , and $52.40 \%$ of an isotope with mass 207.9766 u . Calculate the average atomic mass, and identify the element.
40. An element " $X$ " has five major isotopes, which are listed below along with their abundances. What is the element?

| Isotope | Percent Natural <br> Abundance | Mass (u) |
| :---: | :---: | :---: |
| ${ }^{46} \mathrm{X}$ | $8.00 \%$ | 45.95232 |
| ${ }^{47} \mathrm{X}$ | $7.30 \%$ | 46.951764 |
| ${ }^{48} \mathrm{X}$ | $73.80 \%$ | 47.947947 |
| ${ }^{49} \mathrm{X}$ | $5.50 \%$ | 48.947841 |
| ${ }^{50} \mathrm{X}$ | $5.40 \%$ | 49.944792 |

41. The element rhenium (Re) has two naturally occurring isotopes, ${ }^{185} \mathrm{Re}$ and ${ }^{187} \mathrm{Re}$, with an average atomic mass of 186.207 u . Rhenium is $62.60 \%{ }^{187} \mathrm{Re}$, and the atomic mass of ${ }^{187} \mathrm{Re}$ is 186.956 u . Calculate the mass of ${ }^{185} \mathrm{Re}$.
42. Assume silicon has three major isotopes in nature as shown in the table below. Fill in the missing information.

| Isotope | Mass (u) | Abundance |
| :---: | :---: | :---: |
| ${ }^{28} \mathrm{Si}$ | 27.98 | - |
| ${ }^{29} \mathrm{Si}$ | - | $4.70 \%$ |
| ${ }^{30} \mathrm{Si}$ | 29.97 | $3.09 \%$ |

43. The element europium exists in nature as two isotopes: ${ }^{151} \mathrm{Eu}$ has a mass of 150.9196 u and ${ }^{153} \mathrm{Eu}$ has a mass of 152.9209 u . The average atomic mass of europium is 151.96 u . Calculate the relative abundance of the two europium isotopes.
44. The element silver (Ag) has two naturally occurring isotopes: ${ }^{109} \mathrm{Ag}$ and ${ }^{107} \mathrm{Ag}$ with a mass of 106.905 u . Silver consists of $51.82 \%{ }^{107} \mathrm{Ag}$ and has an average atomic mass of 107.868 u . Calculate the mass of ${ }^{109} \mathrm{Ag}$.
-45. The mass spectrum of bromine $\left(\mathrm{Br}_{2}\right)$ consists of three peaks with the following characteristics:

| Mass (u) | Relative Size |
| :---: | :---: |
| 157.84 | 0.2534 |
| 159.84 | 0.5000 |
| 161.84 | 0.2466 |

How do you interpret these data?
46. The stable isotopes of iron are ${ }^{54} \mathrm{Fe},{ }^{56} \mathrm{Fe},{ }^{57} \mathrm{Fe}$, and ${ }^{58} \mathrm{Fe}$. The mass spectrum of iron looks like the following:

Use the data on the mass spectrum to estimate the average atomic mass of iron, and compare it to the value given in the table inside the front cover of this book.

## Moles and Molar Masses

47. Calculate the mass of 500. atoms of iron (Fe).
48. What number of Fe atoms and what amount (moles) of Fe atoms are in 500.0 g of iron?
49. Diamond is a natural form of pure carbon. What number of atoms of carbon are in a 1.00 -carat diamond ( 1.00 carat $=$ $0.200 \mathrm{~g})$ ?
50. Chromium ( Cr ) is a metal that is added to steel to improve its resistance to corrosion. Calculate the number of moles in a sample of chromium containing $5.00 \times 10^{20}$ atoms and the mass of the sample.
-51. Selective serotonin reuptake inhibitors (SSRIs) are a common prescribed antidepressant. SSRIs block the reabsorption of the neurotransmitter serotonin in the brain. Changing the balance of serotonin helps brain cells send and receive chemical messages, which in turn boosts mood. Two SSRI medications are Prozac (fluoxetine, $\mathrm{C}_{17} \mathrm{H}_{18} \mathrm{~F}_{3} \mathrm{NO}$ ) and Zoloft (sertraline, $\mathrm{C}_{17} \mathrm{H}_{17} \mathrm{Cl}_{2} \mathrm{~N}$ ). Determine the molar masses of Prozac and Zoloft.
-52. The Freons are a class of compounds containing carbon, chlorine, and fluorine. While they have many valuable uses, they have been shown to be responsible for depletion of the ozone in the upper atmosphere. In 1991, two replacement compounds for Freons went into production: HFC-134a $\left(\mathrm{CH}_{2} \mathrm{FCF}_{3}\right)$ and HCFC-124 ( $\mathrm{CHClFCF}_{3}$ ). Calculate the molar masses of these two compounds.
-53. Calculate the molar mass of the following substances.
a. $\bigcirc \stackrel{\mathrm{H}}{\mathrm{N}}$
b.

c. $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$
51. Calculate the molar mass of the following substances.
a.

b. $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$
c. $\mathrm{Na}_{2} \mathrm{HPO}_{4}$
-55. What amount (moles) of compound is present in 1.00 g of each of the compounds in Exercise 53?
52. What amount (moles) of compound is present in 1.00 g of each of the compounds in Exercise 54?

What mass of compound is present in 5.00 moles of each of the compounds in Exercise 53?
58. What mass of compound is present in 5.00 moles of each of the compounds in Exercise 54?
59. What mass of nitrogen is present in 5.00 moles of each of the compounds in Exercise 53?
60. What mass of phosphorus is present in 5.00 moles of each of the compounds in Exercise 54?
61. What number of molecules (or formula units) are present in 1.00 g of each of the compounds in Exercise 53?
62. What number of molecules (or formula units) are present in 1.00 g of each of the compounds in Exercise 54?
63. What number of atoms of nitrogen are present in 1.00 g of each of the compounds in Exercise 53?
64. What number of atoms of phosphorus are present in 1.00 g of each of the compounds in Exercise 54?
65. Freon-12 $\left(\mathrm{CCl}_{2} \mathrm{~F}_{2}\right)$ is used as a refrigerant in air conditioners and as a propellant in aerosol cans. Calculate the number of molecules of Freon- 12 in 5.56 mg of Freon-12. What is the mass of chlorine in 5.56 mg of Freon-12?
66. Prevacid is used to treat gastroesophageal reflux disease (GERD). The chemical formula of Prevacid is $\mathrm{C}_{16} \mathrm{H}_{14} \mathrm{~F}_{3} \mathrm{~N}_{3} \mathrm{O}_{2} \mathrm{~S}$.
a. What is the molar mass of Prevacid?
b. What mass of fluorine is in 0.75 mol of Prevacid?
c. What number of carbon atoms is in 0.75 mol of Prevacid?
d. What is the mass of $4.25 \times 10^{21}$ molecules of Prevacid?
67. What amount (moles) is represented by each of these samples?
a. $150.0 \mathrm{~g} \mathrm{Fe}_{2} \mathrm{O}_{3}$
b. $10.0 \mathrm{mg} \mathrm{NO}_{2}$
c. $1.5 \times 10^{16}$ molecules of $\mathrm{BF}_{3}$
68. Consider the following space-filling models for dry ice, ethanol, and caffeine:

Dry ice

Ethanol

Caffeine

What amount (moles) is represented by each of the following samples?
a. 1.50 g of dry ice
b. $2.72 \times 10^{21}$ molecules of ethanol
c. 20.0 mg of caffeine
-69. What number of atoms of nitrogen are present in 5.00 g of each of the following?
a. glycine, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{O}_{2} \mathrm{~N}$
c. calcium nitrate
b. magnesium nitride
d. dinitrogen tetroxide
70. Complete the following table.

| Mass of Sample | Moles of Sample | Molecules in Sample | Total Atoms in Sample |
| :---: | :---: | :---: | :---: |
| $4.24 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{6}$ | - | -__ | -__ |
| - | $0.224 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}$ | - | - |
| - | - | $2.71 \times 10^{22}$ | - |
|  |  | molecules $\mathrm{CO}_{2}$ |  |
|  |  | - | $3.35 \times 10^{22}$ |
|  |  |  | total atoms |
|  |  |  | $\text { in } \mathrm{CH}_{3} \mathrm{OH}$ |

-71. Ascorbic acid, or vitamin $\mathrm{C}\left(\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{6}\right)$, is an essential vitamin. It cannot be stored by the body and must be present in the diet. What is the molar mass of ascorbic acid? Vitamin C tablets are taken as a dietary supplement. If a typical tablet contains 500.0 mg of vitamin C, what amount (moles) of vitamin C is contained in 10 tablets? What number of vitamin C molecules is in eight tablets?
72. The molecular formula of acetylsalicylic acid (aspirin), one of the most commonly used pain relievers, is $\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}$.
a. Calculate the molar mass of aspirin.
b. A typical aspirin tablet contains $500 . \mathrm{mg} \mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}$. What amount (moles) of $\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}$ molecules and what number of molecules of acetylsalicylic acid are in a 500.-mg tablet?
-73. Chloral hydrate $\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{Cl}_{3} \mathrm{O}_{2}\right)$ is a drug formerly used as a sedative and hypnotic. It is the compound used to make "Mickey Finns" in detective stories.
a. Calculate the molar mass of chloral hydrate.
b. What amount (moles) of $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{Cl}_{3} \mathrm{O}_{2}$ molecules are in 500.0 g chloral hydrate?
c. What is the mass in grams of $2.0 \times 10^{-2}$ mole of chloral hydrate?
d. What number of chlorine atoms are in 5.0 g chloral hydrate?
e. What mass of chloral hydrate would contain 1.0 g Cl ?
f. What is the mass of exactly 500 molecules of chloral hydrate?
74. Dimethylnitrosamine, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~N}_{2} \mathrm{O}$, is a carcinogenic (cancercausing) substance that may be formed in foods, beverages, or gastric juices from the reaction of nitrite ion (used as a food preservative) with other substances.
a. What is the molar mass of dimethylnitrosamine?
b. How many moles of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~N}_{2} \mathrm{O}$ molecules are present in 250 mg dimethylnitrosamine?
c. What is the mass of 0.050 mole of dimethylnitrosamine?
d. How many atoms of hydrogen are in 1.0 mole of dimethylnitrosamine?
e. What is the mass of $1.0 \times 10^{6}$ molecules of dimethylnitrosamine?
f. What is the mass in grams of one molecule of dimethylnitrosamine?

## Percent Composition

-75. Calculate the percent composition by mass of the following compounds that are important starting materials for synthetic polymers:
a. $\mathrm{C}_{3} \mathrm{H}_{4} \mathrm{O}_{2}$ (acrylic acid, from which acrylic plastics are made)
b. $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{2}$ (methyl acrylate, from which Plexiglas is made)
c. $\mathrm{C}_{3} \mathrm{H}_{3} \mathrm{~N}$ (acrylonitrile, from which Orlon is made)
76. In 1987 the first substance to act as a superconductor at a temperature above that of liquid nitrogen ( 77 K ) was discovered. The approximate formula of this substance is $\mathrm{YBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7}$. Calculate the percent composition by mass of this material.
-77. The percent by mass of nitrogen for a compound is found to be $46.7 \%$. Which of the following could be this species?

78. Arrange the following substances in order of increasing mass percent of carbon.
a. caffeine, $\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}$
b. sucrose, $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$
c. ethanol, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$
-79. Fungal laccase, a blue protein found in wood-rotting fungi, is $0.390 \% \mathrm{Cu}$ by mass. If a fungal laccase molecule contains four copper atoms, what is the molar mass of fungal laccase?
80. Hemoglobin is the protein that transports oxygen in mammals. Hemoglobin is $0.347 \%$ Fe by mass, and each hemoglobin molecule contains four iron atoms. Calculate the molar mass of hemoglobin.

## Empirical and Molecular Formulas

-81. Express the composition of each of the following compounds as the mass percents of its elements.
a. formaldehyde, $\mathrm{CH}_{2} \mathrm{O}$
b. glucose, $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$
c. acetic acid, $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
82. Considering your answer to Exercise 81, which type of formula, empirical or molecular, can be obtained from elemental analysis that gives percent composition?
83. Give the empirical formula for each of the compounds represented below.

a.

b.

c.

d.
84. Determine the molecular formulas to which the following empirical formulas and molar masses pertain.
a. $\mathrm{SNH}(188.35 \mathrm{~g} / \mathrm{mol})$
b. $\mathrm{NPCl}_{2}(347.64 \mathrm{~g} / \mathrm{mol})$
c. $\mathrm{CoC}_{4} \mathrm{O}_{4}(341.94 \mathrm{~g} / \mathrm{mol})$
d. $\mathrm{SN}(184.32 \mathrm{~g} / \mathrm{mol})$
85. A compound that contains only carbon, hydrogen, and oxygen is $48.64 \% \mathrm{C}$ and $8.16 \% \mathrm{H}$ by mass. What is the empirical formula of this substance?
86. The most common form of nylon (nylon-6) is $63.68 \%$ carbon, $12.38 \%$ nitrogen, $9.80 \%$ hydrogen, and $14.14 \%$ oxygen. Calculate the empirical formula for nylon-6.
87. There are two binary compounds of mercury and oxygen. Heating either of them results in the decomposition of the compound, with oxygen gas escaping into the atmosphere while leaving a residue of pure mercury. Heating 0.6498 g of one of the compounds leaves a residue of 0.6018 g . Heating 0.4172 g of the other compound results in a mass loss of 0.016 g . Determine the empirical formula of each compound.
88. A sample of urea contains $1.121 \mathrm{~g} \mathrm{~N}, 0.161 \mathrm{~g} \mathrm{H}, 0.480 \mathrm{~g} \mathrm{C}$, and 0.640 g O . What is the empirical formula of urea?
89. A compound containing only sulfur and nitrogen is $69.6 \% \mathrm{~S}$ by mass; the molar mass is $184 \mathrm{~g} / \mathrm{mol}$. What are the empirical and molecular formulas of the compound?
90. Determine the molecular formula of a compound that contains $26.7 \% \mathrm{P}, 12.1 \% \mathrm{~N}$, and $61.2 \% \mathrm{Cl}$, and has a molar mass of $580 \mathrm{~g} / \mathrm{mol}$.
-91. A compound contains $47.08 \%$ carbon, $6.59 \%$ hydrogen, and $46.33 \%$ chlorine by mass; the molar mass of the compound is $153 \mathrm{~g} / \mathrm{mol}$. What are the empirical and molecular formulas of the compound?
92. Maleic acid is an organic compound composed of $41.39 \%$ C, $3.47 \% \mathrm{H}$, and the rest oxygen. If 0.129 mole of maleic acid has a mass of 15.0 g , what are the empirical and molecular formulas of maleic acid?
-93. One of the components that make up common table sugar is fructose, a compound that contains only carbon, hydrogen, and oxygen. Complete combustion of 1.50 g of fructose produced 2.20 g of carbon dioxide and 0.900 g of water. What is the empirical formula of fructose?
94. A compound contains only $\mathrm{C}, \mathrm{H}$, and N . Combustion of 35.0 mg of the compound produces $33.5 \mathrm{mg} \mathrm{CO}_{2}$ and 41.1 mg $\mathrm{H}_{2} \mathrm{O}$. What is the empirical formula of the compound?
-95. Cumene is a compound containing only carbon and hydrogen that is used in the production of acetone and phenol in the chemical industry. Combustion of 47.6 mg cumene produces some $\mathrm{CO}_{2}$ and 42.8 mg water. The molar mass of cumene is between 115 and $125 \mathrm{~g} / \mathrm{mol}$. Determine the empirical and molecular formulas.
96. A compound contains only carbon, hydrogen, and oxygen. Combustion of 10.68 mg of the compound yields 16.01 mg $\mathrm{CO}_{2}$ and $4.37 \mathrm{mg} \mathrm{H}_{2} \mathrm{O}$. The molar mass of the compound is $176.1 \mathrm{~g} / \mathrm{mol}$. What are the empirical and molecular formulas of the compound?

## Balancing Chemical Equations

-97. Give the balanced equation for each of the following chemical reactions:
a. Glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ reacts with oxygen gas to produce gaseous carbon dioxide and water vapor.
b. Solid iron(III) sulfide reacts with gaseous hydrogen chloride to form solid iron(III) chloride and hydrogen sulfide gas.
c. Carbon disulfide liquid reacts with ammonia gas to produce hydrogen sulfide gas and solid ammonium thiocyanate $\left(\mathrm{NH}_{4} \mathrm{SCN}\right)$.
98. Give the balanced equation for each of the following.
a. The combustion of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ forms carbon dioxide and water vapor. A combustion reaction refers to a reaction of a substance with oxygen gas.
b. Aqueous solutions of lead(II) nitrate and sodium phosphate are mixed, resulting in the precipitate formation of lead(II) phosphate with aqueous sodium nitrate as the other product.
c. Solid zinc reacts with aqueous HCl to form aqueous zinc chloride and hydrogen gas.
d. Aqueous strontium hydroxide reacts with aqueous hydrobromic acid to produce water and aqueous strontium bromide.
99. A common demonstration in chemistry courses involves adding a tiny speck of manganese(IV) oxide to a concentrated hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$ solution. Hydrogen peroxide decomposes quite spectacularly under these conditions to produce oxygen gas and steam (water vapor). Manganese(IV) oxide is a catalyst for the decomposition of hydrogen peroxide and is not consumed in the reaction. Write the balanced equation for the decomposition reaction of hydrogen peroxide.
100. Iron oxide ores, commonly a mixture of FeO and $\mathrm{Fe}_{2} \mathrm{O}_{3}$, are given the general formula $\mathrm{Fe}_{3} \mathrm{O}_{4}$. They yield elemental iron when heated to a very high temperature with either carbon monoxide or elemental hydrogen. Balance the following equations for these processes:

$$
\begin{gathered}
\mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{H}_{2}(g) \longrightarrow \mathrm{Fe}(s)+\mathrm{H}_{2} \mathrm{O}(g) \\
\mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{CO}(g) \longrightarrow \mathrm{Fe}(s)+\mathrm{CO}_{2}(g)
\end{gathered}
$$

-101. Balance the following equations:
a. $\mathrm{Ca}(\mathrm{OH})_{2}(a q)+\mathrm{H}_{3} \mathrm{PO}_{4}(a q) \rightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)$
b. $\mathrm{Al}(\mathrm{OH})_{3}(s)+\mathrm{HCl}(a q) \rightarrow \mathrm{AlCl}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
c. $\mathrm{AgNO}_{3}(a q)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \rightarrow \mathrm{Ag}_{2} \mathrm{SO}_{4}(s)+\mathrm{HNO}_{3}(a q)$
102. Balance each of the following chemical equations.
a. $\mathrm{KO}_{2}(s)+\mathrm{H}_{2} \mathrm{O}(l) \rightarrow \mathrm{KOH}(a q)+\mathrm{O}_{2}(g)+\mathrm{H}_{2} \mathrm{O}_{2}(a q)$
b. $\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+\mathrm{HNO}_{3}(\mathrm{aq}) \rightarrow \mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(l)$
c. $\mathrm{NH}_{3}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{NO}(\mathrm{g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$
d. $\mathrm{PCl}_{5}(l)+\mathrm{H}_{2} \mathrm{O}(l) \rightarrow \mathrm{H}_{3} \mathrm{PO}_{4}(a q)+\mathrm{HCl}(g)$
e. $\mathrm{CaO}(s)+\mathrm{C}(s) \rightarrow \mathrm{CaC}_{2}(s)+\mathrm{CO}_{2}(g)$
f. $\mathrm{MoS}_{2}(s)+\mathrm{O}_{2}(g) \rightarrow \mathrm{MoO}_{3}(s)+\mathrm{SO}_{2}(g)$
g. $\mathrm{FeCO}_{3}(s)+\mathrm{H}_{2} \mathrm{CO}_{3}(a q) \rightarrow \mathrm{Fe}\left(\mathrm{HCO}_{3}\right)_{2}(a q)$
-103. Balance the following equations representing combustion reactions:
a.

b.

c. $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(s)+\mathrm{O}_{2}(g) \rightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)$
d. $\mathrm{Fe}(s)+\mathrm{O}_{2}(g) \rightarrow \mathrm{Fe}_{2} \mathrm{O}_{3}(s)$
e. $\mathrm{FeO}(s)+\mathrm{O}_{2}(g) \rightarrow \mathrm{Fe}_{2} \mathrm{O}_{3}(s)$
104. Balance the following equations:
a. $\mathrm{Cr}(s)+\mathrm{S}_{8}(s) \rightarrow \mathrm{Cr}_{2} \mathrm{~S}_{3}(s)$
b. $\mathrm{NaHCO}_{3}(s) \xrightarrow{\text { Heat }} \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(g)$
c. $\mathrm{KClO}_{3}(s) \xrightarrow{\text { Heat }} \mathrm{KCl}(s)+\mathrm{O}_{2}(g)$
d. $\mathrm{Eu}(s)+\mathrm{HF}(g) \rightarrow \mathrm{EuF}_{3}(s)+\mathrm{H}_{2}(g)$
-105 . Silicon is produced for the chemical and electronics industries by the following reactions. Give the balanced equation for each reaction.
a. $\mathrm{SiO}_{2}(s)+\mathrm{C}(s) \xrightarrow[\text { arc furnace }]{\text { Electic }} \mathrm{Si}(s)+\mathrm{CO}(g)$
b. Liquid silicon tetrachloride is reacted with very pure solid magnesium, producing solid silicon and solid magnesium chloride.
c. $\mathrm{Na}_{2} \mathrm{SiF}_{6}(s)+\mathrm{Na}(s) \rightarrow \mathrm{Si}(s)+\mathrm{NaF}(s)$
106. Glass is a mixture of several compounds, but a major constituent of most glass is calcium silicate, $\mathrm{CaSiO}_{3}$. Glass can be etched by treatment with hydrofluoric acid; HF attacks the calcium silicate of the glass, producing gaseous and water-soluble products (which can be removed by washing the glass). For example, the volumetric glassware in chemistry laboratories is often graduated by using this process. Balance the following equation for the reaction of hydrofluoric acid with calcium silicate.

$$
\mathrm{CaSiO}_{3}(s)+\mathrm{HF}(a q) \longrightarrow \mathrm{CaF}_{2}(a q)+\mathrm{SiF}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

-107. Phosphorus occurs naturally in the form of fluorapatite, $\mathrm{CaF}_{2} \cdot 3 \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$. The dot indicates 1 part $\mathrm{CaF}_{2}$ to 3 parts $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$. This mineral is reacted with an aqueous solution of $\mathrm{H}_{2} \mathrm{SO}_{4}$ in the preparation of a fertilizer. The products are phosphoric acid, hydrogen fluoride, and gypsum, $\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$. Write the balanced equation describing this process.
108. The sugar sucrose, which is present in many fruits and vegetables, reacts in the presence of certain yeast enzymes to produce ethanol and carbon dioxide gas. Balance the following equation for this reaction of sucrose.

$$
\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightarrow \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(a q)+\mathrm{CO}_{2}(g)
$$

## Reaction Stoichiometry

-109. Over the years, the thermite reaction has been used for welding railroad rails, in incendiary bombs, and to ignite solid-fuel rocket motors. The reaction is

$$
\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+2 \mathrm{Al}(s) \longrightarrow 2 \mathrm{Fe}(l)+\mathrm{Al}_{2} \mathrm{O}_{3}(s)
$$

What masses of iron(III) oxide and aluminum must be used to produce 15.0 g iron? What is the maximum mass of aluminum oxide that could be produced?
110. The reaction between potassium chlorate and red phosphorus takes place when you strike a match on a matchbox. If you were to react 52.9 g of potassium chlorate $\left(\mathrm{KClO}_{3}\right)$ with excess red phosphorus, what mass of tetraphosphorus decaoxide $\left(\mathrm{P}_{4} \mathrm{O}_{10}\right)$ could be produced?

$$
\mathrm{KClO}_{3}(s)+\mathrm{P}_{4}(s) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{10}(s)+\mathrm{KCl}(s) \quad \text { (unbalanced) }
$$

The reusable booster rockets of the U.S. space shuttle employ a mixture of aluminum and ammonium perchlorate for fuel. A possible equation for this reaction is

$$
\begin{aligned}
& 3 \mathrm{Al}(s)+3 \mathrm{NH}_{4} \mathrm{ClO}_{4}(s) \longrightarrow \\
& \mathrm{Al}_{2} \mathrm{O}_{3}(s)+\mathrm{AlCl}_{3}(s)+3 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
\end{aligned}
$$

What mass of $\mathrm{NH}_{4} \mathrm{ClO}_{4}$ should be used in the fuel mixture for every kilogram of Al ?
112. One of relatively few reactions that takes place directly between two solids at room temperature is

$$
\mathrm{Ba}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}(s)+\underset{\mathrm{Ba}(\mathrm{SCN})_{2}(s)}{\mathrm{NH}_{4} \mathrm{SCN}(s)}+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{NH}_{3}(g)
$$

In this equation, the $\cdot 8 \mathrm{H}_{2} \mathrm{O}$ in $\mathrm{Ba}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ indicates the presence of eight water molecules. This compound is called barium hydroxide octahydrate.
a. Balance the equation.
b. What mass of ammonium thiocyanate $\left(\mathrm{NH}_{4} \mathrm{SCN}\right)$ must be used if it is to react completely with 6.5 g barium hydroxide octahydrate?
-113. The compound cisplatin, $\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}$, has been studied as an antitumor agent. Cisplatin is synthesized as follows:

$$
\mathrm{K}_{2} \mathrm{PtCl}_{4}(a q)+2 \mathrm{NH}_{3}(a q) \rightarrow \mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}(s)+2 \mathrm{KCl}(a q)
$$

What mass of cisplatin can be produced from 100. g of $\mathrm{K}_{2} \mathrm{PtCl}_{4}$ and sufficient $\mathrm{NH}_{3}$ ?
114. a. Write the balanced equation for the combustion of isooctane $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$ to produce water vapor and carbon dioxide gas.
b. Assuming gasoline is $100 . \%$ isooctane, with a density of $0.692 \mathrm{~g} / \mathrm{mL}$, what is the theoretical yield of carbon dioxide produced by the combustion of $1.2 \times 10^{10} \mathrm{gal}$ of gasoline (the approximate annual consumption of gasoline in the United States)?
-115. Elixirs such as Alka-Seltzer use the reaction of sodium bicarbonate with citric acid in aqueous solution to produce a fizz:

$$
\begin{aligned}
& 3 \mathrm{NaHCO}_{3}(a q)+\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7}(a q) \\
& 3 \mathrm{CO}_{2}(g) \longrightarrow 3 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Na}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}(a q)
\end{aligned}
$$

a. What mass of $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7}$ should be used for every $1.0 \times 10^{2} \mathrm{mg} \mathrm{NaHCO} 3$ ?
b. What mass of $\mathrm{CO}_{2}(g)$ could be produced from such a mixture?
116. Aspirin $\left(\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}\right)$ is synthesized by reacting salicylic acid $\left(\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{3}\right)$ with acetic anhydride $\left(\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{3}\right)$. The balanced equation is

$$
\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{3}+\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{3} \longrightarrow \mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}+\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}
$$

a. What mass of acetic anhydride is needed to completely consume $1.00 \times 10^{2} \mathrm{~g}$ salicylic acid?
b. What is the maximum mass of aspirin (the theoretical yield) that could be produced in this reaction?
117. Bacterial digestion is an economical method of sewage treatment. The reaction

$$
\begin{aligned}
& 5 \mathrm{CO}_{2}(g)+55 \mathrm{NH}_{4}^{+}(a q)+76 \mathrm{O}_{2}(g) \xrightarrow{\text { bacteria }} \\
& \quad \begin{array}{l}
\mathrm{C}_{5} \mathrm{H}_{7} \mathrm{O}_{2} \mathrm{~N}(s)+54 \mathrm{NO}_{2}^{-}(a q)+52 \mathrm{H}_{2} \mathrm{O}(l) \\
\text { bacterial tissue }
\end{array} \\
& \hline
\end{aligned} 109 \mathrm{H}^{+}(a q)
$$

is an intermediate step in the conversion of the nitrogen in organic compounds into nitrate ions. What mass of bacterial tissue is produced in a treatment plant for every $1.0 \times 10^{4} \mathrm{~kg}$ of wastewater containing $3.0 \% \mathrm{NH}_{4}{ }^{+}$ions by mass? Assume that $95 \%$ of the ammonium ions are consumed by the bacteria.
118. Phosphorus can be prepared from calcium phosphate by the following reaction:

$$
2 \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)+6 \mathrm{SiO}_{2}(s)+\underset{6 \mathrm{CaSiO}_{3}(s)+\mathrm{P}_{4}(s)+10 \mathrm{CO}(g)}{10 \mathrm{C}(s)} \longrightarrow
$$

Phosphorite is a mineral that contains $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ plus other non-phosphorus-containing compounds. What is the maximum amount of $\mathrm{P}_{4}$ that can be produced from 1.0 kg of phosphorite if the phorphorite sample is $75 \% \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ by mass? Assume an excess of the other reactants.
119. Coke is an impure form of carbon that is often used in the industrial production of metals from their oxides. If a sample of coke is $95 \%$ carbon by mass, determine the mass of coke needed to react completely with 1.0 ton of copper(II) oxide.

$$
2 \mathrm{CuO}(s)+\mathrm{C}(s) \longrightarrow 2 \mathrm{Cu}(s)+\mathrm{CO}_{2}(g)
$$

120. The space shuttle environmental control system handled excess $\mathrm{CO}_{2}$ (which the astronauts breathe out; it is $4.0 \%$ by mass of exhaled air) by reacting it with lithium hydroxide, LiOH , pellets to form lithium carbonate, $\mathrm{Li}_{2} \mathrm{CO}_{3}$, and water. If there were seven astronauts on board the shuttle, and each exhales 20. L of air per minute, how long could clean air be generated if there were $25,000 \mathrm{~g}$ of LiOH pellets available for each shuttle mission? Assume the density of air is $0.0010 \mathrm{~g} / \mathrm{mL}$.

## Limiting Reactants and Percent Yield

-121. Consider the reaction between $\mathrm{NO}(g)$ and $\mathrm{O}_{2}(g)$ represented below.

What is the balanced equation for this reaction, and what is the limiting reactant?
122. Consider the following reaction:

$$
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

If a container were to have 10 molecules of $\mathrm{O}_{2}$ and 10 molecules of $\mathrm{NH}_{3}$ initially, how many total molecules (reactants plus products) would be present in the container after this reaction goes to completion?
-123. Ammonia is produced from the reaction of nitrogen and hydrogen according to the following balanced equation:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
$$

a. What is the maximum mass of ammonia that can be produced from a mixture of $1.00 \times 10^{3} \mathrm{~g} \mathrm{~N}_{2}$ and $5.00 \times 10^{2} \mathrm{~g} \mathrm{H}_{2}$ ?
b. What mass of which starting material would remain unreacted?
124. Consider the following unbalanced equation:

$$
\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \longrightarrow \mathrm{CaSO}_{4}(s)+\mathrm{H}_{3} \mathrm{PO}_{4}(a q)
$$

What masses of calcium sulfate and phosphoric acid can be produced from the reaction of 1.0 kg calcium phosphate with 1.0 kg concentrated sulfuric acid $\left(98 \% \mathrm{H}_{2} \mathrm{SO}_{4}\right.$ by mass)?
125. Hydrogen peroxide is used as a cleansing agent in the treatment of cuts and abrasions for several reasons. It is an oxidizing agent that can directly kill many microorganisms; it decomposes on contact with blood, releasing elemental oxygen gas (which inhibits the growth of anaerobic microorganisms); and it foams on contact with blood, which provides a cleansing action. In the laboratory, small quantities of hydrogen peroxide can be prepared by the action of an acid on an alkaline earth metal peroxide, such as barium peroxide:

$$
\mathrm{BaO}_{2}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}_{2}(a q)+\mathrm{BaCl}_{2}(a q)
$$

What mass of hydrogen peroxide should result when 1.50 g barium peroxide is treated with 88.0 mL hydrochloric acid solution containing 0.0272 g HCl per mL ? What mass of which reagent is left unreacted?
126. Silver sulfadiazine burn-treating cream creates a barrier against bacterial invasion and releases antimicrobial agents directly into the wound. If $25.0 \mathrm{~g} \mathrm{Ag}_{2} \mathrm{O}$ is reacted with $50.0 \mathrm{~g} \mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{SO}_{2}$, what mass of silver sulfadiazine, $\mathrm{AgC}_{10} \mathrm{H}_{9} \mathrm{~N}_{4} \mathrm{SO}_{2}$, can be produced, assuming $100 \%$ yield?

$$
\mathrm{Ag}_{2} \mathrm{O}(s)+2 \mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{SO}_{2}(s) \longrightarrow 2 \mathrm{AgC}_{10} \mathrm{H}_{9} \mathrm{~N}_{4} \mathrm{SO}_{2}(s)+\mathrm{H}_{2} \mathrm{O}(l)
$$

127. Hydrogen cyanide is produced industrially from the reaction of gaseous ammonia, oxygen, and methane:

$$
2 \mathrm{NH}_{3}(g)+3 \mathrm{O}_{2}(g)+2 \mathrm{CH}_{4}(g) \longrightarrow 2 \mathrm{HCN}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
$$

If $5.00 \times 10^{3} \mathrm{~kg}$ each of $\mathrm{NH}_{3}, \mathrm{O}_{2}$, and $\mathrm{CH}_{4}$ are reacted, what mass of HCN and of $\mathrm{H}_{2} \mathrm{O}$ will be produced, assuming $100 \%$ yield?
128. Acrylonitrile $\left(\mathrm{C}_{3} \mathrm{H}_{3} \mathrm{~N}\right)$ is the starting material for many synthetic carpets and fabrics. It is produced by the following reaction.
$2 \mathrm{C}_{3} \mathrm{H}_{6}(\mathrm{~g})+2 \mathrm{NH}_{3}(\mathrm{~g})+3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{C}_{3} \mathrm{H}_{3} \mathrm{~N}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$
If $15.0 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{6}, 10.0 \mathrm{~g} \mathrm{O}_{2}$, and $5.00 \mathrm{~g} \mathrm{NH}_{3}$ are reacted, what mass of acrylonitrile can be produced, assuming $100 \%$ yield?
-129. Aluminum reacts with bromine, producing aluminum bromide:

$$
2 \mathrm{Al}(s)+3 \mathrm{Br}_{2}(l) \rightarrow 2 \mathrm{AlBr}_{3}(s)
$$

In a certain experiment, 20.0 mL of bromine (density $=$ $3.10 \mathrm{~g} / \mathrm{mL}$ ) was reacted with excess aluminum to yield 50.3 g of aluminum bromide. What is the percent yield for this experiment?
130. Hexamethylenediamine $\left(\mathrm{C}_{6} \mathrm{H}_{16} \mathrm{~N}_{2}\right)$ is one of the starting materials for the production of nylon. It can be prepared from adipic acid $\left(\mathrm{C}_{6} \mathrm{H}_{10} \mathrm{O}_{4}\right)$ by the following overall equation:

$$
\mathrm{C}_{6} \mathrm{H}_{10} \mathrm{O}_{4}(l)+2 \mathrm{NH}_{3}(g)+4 \mathrm{H}_{2}(g) \rightarrow \mathrm{C}_{6} \mathrm{H}_{16} \mathrm{~N}_{2}(l)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

What is the percent yield for the reaction if 765 g of hexamethylenediamine is made from $1.00 \times 10^{3} \mathrm{~g}$ of adipic acid?
-131. The reaction of ethane gas $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ with chlorine gas produces $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}$ as its main product (along with HCl ). In addition, the reaction invariably produces a variety of other minor products, including $\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}, \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{Cl}_{3}$, and others. Naturally, the production of these minor products reduces the yield of the main product. Calculate the percent yield of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}$ if the reaction of $300 . \mathrm{g}$ of ethane with $650 . \mathrm{g}$ of chlorine produced $490 . \mathrm{g}$ of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}$.
132. DDT, an insecticide harmful to fish, birds, and humans, is produced by the following reaction:

$$
\underset{\text { chlorobenzene }}{2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}}+\underset{\text { chloral }}{\mathrm{C}_{2} \mathrm{HOCl}_{3}} \longrightarrow \underset{\text { DDT }}{\mathrm{C}_{14} \mathrm{H}_{9} \mathrm{Cl}_{5}}+\mathrm{H}_{2} \mathrm{O}
$$

In a government lab, 1142 g of chlorobenzene is reacted with 485 g of chloral.
a. What mass of DDT is formed, assuming $100 \%$ yield?
b. Which reactant is limiting? Which is in excess?
c. What mass of the excess reactant is left over?
d. If the actual yield of DDT is 200.0 g , what is the percent yield?
-133 . Bornite $\left(\mathrm{Cu}_{3} \mathrm{FeS}_{3}\right)$ is a copper ore used in the production of copper. When heated, the following reaction occurs:

$$
2 \mathrm{Cu}_{3} \mathrm{FeS}_{3}(s)+7 \mathrm{O}_{2}(g) \longrightarrow 6 \mathrm{Cu}(s)+2 \mathrm{FeO}(s)+6 \mathrm{SO}_{2}(g)
$$

If 2.50 metric tons of bornite is reacted with excess $\mathrm{O}_{2}$ and the process has an $86.3 \%$ yield of copper, what mass of copper is produced?
134. Consider the following unbalanced reaction:

$$
\mathrm{P}_{4}(s)+\mathrm{F}_{2}(\mathrm{~g}) \longrightarrow \mathrm{PF}_{3}(\mathrm{~g})
$$

What mass of $\mathrm{F}_{2}$ is needed to produce 120. g of $\mathrm{PF}_{3}$ if the reaction has a $78.1 \%$ yield?

## Additional Exercises

135. In using a mass spectrometer, a chemist sees a peak at a mass of 30.0106 . Of the choices ${ }^{12} \mathrm{C}_{2}{ }^{1} \mathrm{H}_{6},{ }^{12} \mathrm{C}^{1} \mathrm{H}_{2}{ }^{16} \mathrm{O}$, and ${ }^{14} \mathrm{~N}^{16} \mathrm{O}$, which is responsible for this peak? Pertinent masses are ${ }^{1} \mathrm{H}$, $1.007825 ;{ }^{16} \mathrm{O}, 15.994915$; and ${ }^{14} \mathrm{~N}, 14.003074$.
136. Boron consists of two isotopes, ${ }^{10} \mathrm{~B}$ and ${ }^{11} \mathrm{~B}$. Chlorine also has two isotopes, ${ }^{35} \mathrm{Cl}$ and ${ }^{37} \mathrm{Cl}$. Consider the mass spectrum of $\mathrm{BCl}_{3}$. How many peaks would be present, and what approximate mass would each peak correspond to in the $\mathrm{BCl}_{3}$ mass spectrum?
137. A given sample of a xenon fluoride compound contains molecules of the type $\mathrm{XeF}_{n}$, where $n$ is some whole number. Given that $9.03 \times 10^{20}$ molecules of $\mathrm{XeF}_{n}$ weigh 0.368 g , determine the value for $n$ in the formula.
138. Aspartame is an artificial sweetener that is 160 times sweeter than sucrose (table sugar) when dissolved in water. It is marketed as NutraSweet. The molecular formula of aspartame is $\mathrm{C}_{14} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{O}_{5}$.
a. Calculate the molar mass of aspartame.
b. What amount (moles) of molecules are present in 10.0 g aspartame?
c. Calculate the mass in grams of 1.56 mole of aspartame.
d. What number of molecules are in 5.0 mg aspartame?
e. What number of atoms of nitrogen are in 1.2 g aspartame?
f. What is the mass in grams of $1.0 \times 10^{9}$ molecules of aspartame?
g. What is the mass in grams of one molecule of aspartame?
139. Anabolic steroids are performance enhancement drugs whose use has been banned from most major sporting activities. One anabolic steroid is fluoxymesterone $\left(\mathrm{C}_{20} \mathrm{H}_{29} \mathrm{FO}_{3}\right)$. Calculate the percent composition by mass of fluoxymesterone.
140. In the spring of 1984, concern arose over the presence of ethylene dibromide, or EDB, in grains and cereals. EDB has the molecular formula $\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Br}_{2}$ and until 1984 was commonly used as a plant fumigant. The federal limit for EDB in finished cereal products is 30.0 parts per billion ( ppb ), where $1.0 \mathrm{ppb}=$ $1.0 \times 10^{-9} \mathrm{~g}$ of EDB for every 1.0 g of sample. How many molecules of EDB are in 1.0 lb of flour if 30.0 ppb of EDB is present?
141. You find a compound composed only of element $X$ and chlorine, and you know that the compound is $13.10 \% \mathrm{X}$ by mass. Each molecule of the compound contains six times as many chlorine atoms as X atoms. What is element X ?
142. What mass of sodium hydroxide has the same number of oxygen atoms as 100.0 g of ammonium carbonate?
143. The compound adrenaline contains $56.79 \% \mathrm{C}, 6.56 \% \mathrm{H}$, $28.37 \% \mathrm{O}$, and $8.28 \% \mathrm{~N}$ by mass. What is the empirical formula for adrenaline?
144. Adipic acid is an organic compound composed of $49.31 \% \mathrm{C}$, $43.79 \% \mathrm{O}$, and the rest hydrogen. If the molar mass of adipic acid is $146.1 \mathrm{~g} / \mathrm{mol}$, what are the empirical and molecular formulas for adipic acid?
145. Vitamin $B_{12}$, cyanocobalamin, is essential for human nutrition. It is concentrated in animal tissue but not in higher plants. Although nutritional requirements for the vitamin are quite low, people who abstain completely from animal products may develop a deficiency anemia. Cyanocobalamin is the form used in vitamin supplements. It contains $4.34 \%$ cobalt by mass. Calculate the molar mass of cyanocobalamin, assuming that there is one atom of cobalt in every molecule of cyanocobalamin.
146. Some bismuth tablets, a medication used to treat upset stomachs, contain 262 mg of bismuth subsalicylate, $\mathrm{C}_{7} \mathrm{H}_{5} \mathrm{BiO}_{4}$, per tablet. Assuming two tablets are digested, calculate the mass of bismuth consumed.
147. The empirical formula of styrene is CH ; the molar mass of styrene is $104.14 \mathrm{~g} / \mathrm{mol}$. What number of H atoms are present in a $2.00-\mathrm{g}$ sample of styrene?
148. Terephthalic acid is an important chemical used in the manufacture of polyesters and plasticizers. It contains only C, H, and O . Combustion of 19.81 mg terephthalic acid produces $41.98 \mathrm{mg} \mathrm{CO}_{2}$ and $6.45 \mathrm{mg} \mathrm{H}_{2} \mathrm{O}$. If 0.250 mole of terephthalic acid has a mass of 41.5 g , determine the molecular formula for terephthalic acid.
149. A sample of a hydrocarbon (a compound consisting of only carbon and hydrogen) contains $2.59 \times 10^{23}$ atoms of hydrogen and is $17.3 \%$ hydrogen by mass. If the molar mass of the hydrocarbon is between 55 and $65 \mathrm{~g} / \mathrm{mol}$, what amount (moles) of compound is present, and what is the mass of the sample?
150. A binary compound between an unknown element $E$ and hydrogen contains $91.27 \% \mathrm{E}$ and $8.73 \% \mathrm{H}$ by mass. If the formula of the compound is $\mathrm{E}_{3} \mathrm{H}_{8}$, calculate the atomic mass of $E$.
151. A $0.755-\mathrm{g}$ sample of hydrated copper(II) sulfate

$$
\mathrm{CuSO}_{4} \cdot x \mathrm{H}_{2} \mathrm{O}
$$

was heated carefully until it had changed completely to anhydrous copper(II) sulfate $\left(\mathrm{CuSO}_{4}\right)$ with a mass of 0.483 g . Determine the value of $x$. [This number is called the number of waters of hydration of copper(II) sulfate. It specifies the number of water molecules per formula unit of $\mathrm{CuSO}_{4}$ in the hydrated crystal.]
152. ABS plastic is a tough, hard plastic used in applications requiring shock resistance. The polymer consists of three monomer units: acrylonitrile $\left(\mathrm{C}_{3} \mathrm{H}_{3} \mathrm{~N}\right)$, butadiene $\left(\mathrm{C}_{4} \mathrm{H}_{6}\right)$, and styrene $\left(\mathrm{C}_{8} \mathrm{H}_{8}\right)$.
a. A sample of ABS plastic contains $8.80 \% \mathrm{~N}$ by mass. It took 0.605 g of $\mathrm{Br}_{2}$ to react completely with a $1.20-\mathrm{g}$ sample of ABS plastic. Bromine reacts 1:1 (by moles) with the butadiene molecules in the polymer and nothing else. What is the percent by mass of acrylonitrile and butadiene in this polymer?
b. What are the relative numbers of each of the monomer units in this polymer?
153. A sample of LSD (D-lysergic acid diethylamide, $\mathrm{C}_{24} \mathrm{H}_{30} \mathrm{~N}_{3} \mathrm{O}$ ) is added to some table salt (sodium chloride) to form a mixture. Given that a $1.00-\mathrm{g}$ sample of the mixture undergoes combustion to produce 1.20 g of $\mathrm{CO}_{2}$, what is the mass percent of LSD in the mixture?
154. Methane $\left(\mathrm{CH}_{4}\right)$ is the main component of marsh gas. Heating methane in the presence of sulfur produces carbon disulfide and hydrogen sulfide as the only products.
a. Write the balanced chemical equation for the reaction of methane and sulfur.
b. Calculate the theoretical yield of carbon disulfide when 120. g of methane is reacted with an equal mass of sulfur.
155. A potential fuel for rockets is a combination of $\mathrm{B}_{5} \mathrm{H}_{9}$ and $\mathrm{O}_{2}$. The two react according to the following balanced equation:

$$
2 \mathrm{~B}_{5} \mathrm{H}_{9}(l)+12 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 5 \mathrm{~B}_{2} \mathrm{O}_{3}(\mathrm{~s})+9 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

If one tank in a rocket holds $126 \mathrm{~g} \mathrm{~B}_{5} \mathrm{H}_{9}$ and another tank holds $192 \mathrm{~g} \mathrm{O}_{2}$, what mass of water can be produced when the entire contents of each tank react together?
156. A $0.4230-\mathrm{g}$ sample of impure sodium nitrate was heated, converting all the sodium nitrate to 0.2864 g of sodium nitrite and oxygen gas. Determine the percent of sodium nitrate in the original sample.
157. An iron ore sample contains $\mathrm{Fe}_{2} \mathrm{O}_{3}$ plus other impurities. A $752-\mathrm{g}$ sample of impure iron ore is heated with excess carbon, producing 453 g of pure iron by the following reaction:

$$
\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+3 \mathrm{C}(s) \longrightarrow 2 \mathrm{Fe}(s)+3 \mathrm{CO}(g)
$$

What is the mass percent of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ in the impure iron ore sample? Assume that $\mathrm{Fe}_{2} \mathrm{O}_{3}$ is the only source of iron and that the reaction is $100 \%$ efficient.
158. Commercial brass, an alloy of Zn and Cu , reacts with hydrochloric acid as follows:

$$
\mathrm{Zn}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{ZnCl}_{2}(a q)+\mathrm{H}_{2}(g)
$$

$(\mathrm{Cu}$ does not react with HCl .) When 0.5065 g of a certain brass alloy is reacted with excess $\mathrm{HCl}, 0.0985 \mathrm{~g} \mathrm{ZnCl}_{2}$ is eventually isolated.
a. What is the composition of the brass by mass?
b. How could this result be checked without changing the above procedure?
159. Vitamin A has a molar mass of $286.4 \mathrm{~g} / \mathrm{mol}$ and a general molecular formula of $\mathrm{C}_{x} \mathrm{H}_{y} \mathrm{E}$, where E is an unknown element. If vitamin A is $83.86 \% \mathrm{C}$ and $10.56 \% \mathrm{H}$ by mass, what is the molecular formula of vitamin A?
160. You have seven closed containers, each with equal masses of chlorine gas $\left(\mathrm{Cl}_{2}\right)$. You add 10.0 g of sodium to the first sample, 20.0 g of sodium to the second sample, and so on (adding 70.0 g of sodium to the seventh sample). Sodium and chlorine react to form sodium chloride according to the equation

$$
2 \mathrm{Na}(s)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NaCl}(s)
$$

After each reaction is complete, you collect and measure the amount of sodium chloride formed. A graph of your results is shown below.

Answer the following questions:
a. Explain the shape of the graph.
b. Calculate the mass of NaCl formed when 20.0 g of sodium is used.
c. Calculate the mass of $\mathrm{Cl}_{2}$ in each container.
d. Calculate the mass of NaCl formed when 50.0 g of sodium is used.
e. Identify the leftover reactant, and determine its mass for parts $b$ and d above.
161. A substance $X_{2} Z$ has the composition (by mass) of $40.0 \% ~ X$ and $60.0 \% \mathrm{Z}$. What is the composition (by mass) of the compound $\mathrm{XZ}_{2}$ ?

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
162. Consider samples of phosphine $\left(\mathrm{PH}_{3}\right)$, water $\left(\mathrm{H}_{2} \mathrm{O}\right)$, hydrogen sulfide ( $\mathrm{H}_{2} \mathrm{~S}$ ), and hydrogen fluoride (HF), each with a mass of 119 g . Rank the compounds from the least to the greatest number of hydrogen atoms contained in the samples.
163. Calculate the number of moles for each compound in the following table.

| Compound | Mass | Moles |
| :--- | :---: | :--- |
| Magnesium phosphate | 326.4 g | - |
| Calcium nitrate | 303.0 g | - |
| Potassium chromate | 141.6 g | - |
| Dinitrogen pentoxide | 406.3 g | - |

164. Arrange the following substances in order of increasing mass percent of nitrogen.
a. NO
c. $\mathrm{NH}_{3}$
b. $\mathrm{N}_{2} \mathrm{O}$
d. SNH
165. Para-cresol, a substance used as a disinfectant and in the manufacture of several herbicides, is a molecule that contains the elements carbon, hydrogen, and oxygen. Complete combustion of a $0.345-\mathrm{g}$ sample of $p$-cresol produced 0.983 g carbon dioxide and 0.230 g water. Determine the empirical formula for $p$-cresol.
166. A compound with molar mass $180.1 \mathrm{~g} / \mathrm{mol}$ has the following composition by mass:

| C | $40.0 \%$ |
| :---: | :---: |
| $H$ | $6.70 \%$ |
| O | $53.3 \%$ |

Determine the empirical and molecular formulas of the compound.
167. Which of the following statements about chemical equations is(are) true?
a. When balancing a chemical equation, you can never change the coefficient in front of any chemical formula.
b. The coefficients in a balanced chemical equation refer to the number of grams of reactants and products.
c. In a chemical equation, the reactants are on the right and the products are on the left.
d. When balancing a chemical equation, you can never change the subscripts of any chemical formula.
e. In chemical reactions, matter is neither created nor destroyed so a chemical equation must have the same number of atoms on both sides of the equation.
168. Consider the following unbalanced chemical equation for the combustion of pentane $\left(\mathrm{C}_{5} \mathrm{H}_{12}\right)$ :

$$
\mathrm{C}_{5} \mathrm{H}_{12}(l)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

If 20.4 g of pentane are burned in excess oxygen, what mass of water can be produced, assuming $100 \%$ yield?
169. Sulfur dioxide gas reacts with sodium hydroxide to form sodium sulfite and water. The unbalanced chemical equation for this reaction is given below:

$$
\mathrm{SO}_{2}(g)+\mathrm{NaOH}(s) \longrightarrow \mathrm{Na}_{2} \mathrm{SO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Assuming you react 38.3 g sulfur dioxide with 32.8 g sodium hydroxide and assuming that the reaction goes to completion, calculate the mass of each product formed.

## Challenge Problems

170. Gallium arsenide, GaAs, has gained widespread use in semiconductor devices that convert light and electrical signals in fiber-optic communications systems. Gallium consists of $60 . \%{ }^{69} \mathrm{Ga}$ and $40 . \%{ }^{71} \mathrm{Ga}$. Arsenic has only one naturally occurring isotope, ${ }^{75} \mathrm{As}$. Gallium arsenide is a polymeric material, but its mass spectrum shows fragments with the formulas GaAs and $\mathrm{Ga}_{2} \mathrm{As}_{2}$. What would the distribution of peaks look like for these two fragments?
171. Consider the following data for three binary compounds of hydrogen and nitrogen:

|  | \% H (by Mass) | \% N (by Mass) |
| :---: | :---: | :---: |
| I | 17.75 | 82.25 |
| II | 12.58 | 87.42 |
| III | 2.34 | 97.66 |

When 1.00 L of each gaseous compound is decomposed to its elements, the following volumes of $\mathrm{H}_{2}(g)$ and $\mathrm{N}_{2}(g)$ are obtained:

|  | $\mathrm{H}_{2}(\mathrm{~L})$ | $\mathrm{N}_{2}(\mathrm{~L})$ |
| :--- | :---: | :---: |
| I | 1.50 | 0.50 |
| III | 2.00 | 1.00 |
| III | 0.50 | 1.50 |

Use these data to determine the molecular formulas of compounds I, II, and III and to determine the relative values for the atomic masses of hydrogen and nitrogen.
172. Natural rubidium has the average mass of 85.4678 u and is composed of isotopes ${ }^{85} \mathrm{Rb}$ (mass $=84.9117 \mathrm{u}$ ) and ${ }^{87} \mathrm{Rb}$. The ratio of atoms ${ }^{85} \mathrm{Rb} /{ }^{77} \mathrm{Rb}$ in natural rubidium is 2.591 . Calculate the mass of ${ }^{87} \mathrm{Rb}$.
173. A compound contains only carbon, hydrogen, nitrogen, and oxygen. Combustion of 0.157 g of the compound produced $0.213 \mathrm{~g} \mathrm{CO}_{2}$ and $0.0310 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$. In another experiment, it is found that 0.103 g of the compound produces $0.0230 \mathrm{~g} \mathrm{NH}_{3}$. What is the empirical formula of the compound? Hint: Combustion involves reacting with excess $\mathrm{O}_{2}$. Assume that all the carbon ends up in $\mathrm{CO}_{2}$ and all the hydrogen ends up in $\mathrm{H}_{2} \mathrm{O}$. Also assume that all the nitrogen ends up in the $\mathrm{NH}_{3}$ in the second experiment.
174. Nitric acid is produced commercially by the Ostwald process, represented by the following equations:

$$
\begin{aligned}
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) & \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g) \\
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) & \longrightarrow 2 \mathrm{NO}_{2}(g) \\
3 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{HNO}_{3}(a q)+\mathrm{NO}(g)
\end{aligned}
$$

What mass of $\mathrm{NH}_{3}$ must be used to produce $1.0 \times 10^{6} \mathrm{~kg}$ $\mathrm{HNO}_{3}$ by the Ostwald process? Assume $100 \%$ yield in each reaction, and assume that the NO produced in the third step is not recycled.
175. When the supply of oxygen is limited, iron metal reacts with oxygen to produce a mixture of FeO and $\mathrm{Fe}_{2} \mathrm{O}_{3}$. In a certain experiment, 20.00 g iron metal was reacted with 11.20 g oxygen gas. After the experiment, the iron was totally consumed, and 3.24 g oxygen gas remained. Calculate the amounts of FeO and $\mathrm{Fe}_{2} \mathrm{O}_{3}$ formed in this experiment.
176. A $9.780-\mathrm{g}$ gaseous mixture contains ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ and propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$. Complete combustion to form carbon dioxide and water requires 1.120 mole of oxygen gas. Calculate the mass percent of ethane in the original mixture.
177. Zinc and magnesium metal each reacts with hydrochloric acid to make chloride salts of the respective metals, and hydrogen gas. A $10.00-\mathrm{g}$ mixture of zinc and magnesium produces 0.5171 g of hydrogen gas upon being mixed with an excess of hydrochloric acid. Determine the percent magnesium by mass in the original mixture.
178. A gas contains a mixture of $\mathrm{NH}_{3}(g)$ and $\mathrm{N}_{2} \mathrm{H}_{4}(g)$, both of which react with $\mathrm{O}_{2}(g)$ to form $\mathrm{NO}_{2}(g)$ and $\mathrm{H}_{2} \mathrm{O}(g)$. The gaseous mixture (with an initial mass of 61.00 g ) is reacted with 10.00 moles $\mathrm{O}_{2}$, and after the reaction is complete, 4.062 moles of $\mathrm{O}_{2}$ remains. Calculate the mass percent of $\mathrm{N}_{2} \mathrm{H}_{4}(\mathrm{~g})$ in the original gaseous mixture.
179. Consider a gaseous binary compound with a molar mass of $62.09 \mathrm{~g} / \mathrm{mol}$. When 1.39 g of this compound is completely burned in excess oxygen, 1.21 g of water is formed. Determine the formula of the compound. Assume water is the only product that contains hydrogen.
180. A $2.25-\mathrm{g}$ sample of scandium metal is reacted with excess hydrochloric acid to produce 0.1502 g hydrogen gas. What is the formula of the scandium chloride produced in the reaction?
181. In the production of printed circuit boards for the electronics industry, a $0.60-\mathrm{mm}$ layer of copper is laminated onto an insulating plastic board. Next, a circuit pattern made of a chemically resistant polymer is printed on the board. The unwanted copper is removed by chemical etching, and the protective polymer is finally removed by solvents. One etching reaction is

$$
\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}(a q)+4 \mathrm{NH}_{3}(a q)+\mathrm{Cu}(s) \underset{2 \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}(a q)}{\longrightarrow}
$$

A plant needs to manufacture 10,000 printed circuit boards, each $8.0 \times 16.0 \mathrm{~cm}$ in area. An average of $80 . \%$ of the copper is removed from each board (density of copper $=8.96 \mathrm{~g} / \mathrm{cm}^{3}$ ). What masses of $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}$ and $\mathrm{NH}_{3}$ are needed to do this? Assume 100\% yield.
182. The aspirin substitute, acetaminophen $\left(\mathrm{C}_{8} \mathrm{H}_{9} \mathrm{O}_{2} \mathrm{~N}\right)$, is produced by the following three-step synthesis:

$$
\text { I. } \quad \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{3} \mathrm{~N}(s)+3 \mathrm{H}_{2}(g)+\underset{\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{ONCl}(s)}{\mathrm{HCl}(a q)} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

II. $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{ONCl}(s)+\mathrm{NaOH}(a q) \longrightarrow$

$$
\mathrm{C}_{6} \mathrm{H}_{7} \mathrm{ON}(s)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{NaCl}(a q)
$$

III. $\mathrm{C}_{6} \mathrm{H}_{7} \mathrm{ON}(s)+\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{3}(l) \longrightarrow$

$$
\mathrm{C}_{8} \mathrm{H}_{9} \mathrm{O}_{2} \mathrm{~N}(s)+\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(l)
$$

The first two reactions have percent yields of $87 \%$ and $98 \%$ by mass, respectively. The overall reaction yields 3 moles of acetaminophen product for every 4 moles of $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{3} \mathrm{~N}$ reacted.
a. What is the percent yield by mass for the overall process?
b. What is the percent yield by mass of Step III?
183. An element X forms both a dichloride $\left(\mathrm{XCl}_{2}\right)$ and a tetrachloride $\left(\mathrm{XCl}_{4}\right)$. Treatment of $10.00 \mathrm{~g} \mathrm{XCl}_{2}$ with excess chlorine forms $12.55 \mathrm{~g} \mathrm{XCl}_{4}$. Calculate the atomic mass of X , and identify X .
184. When $\mathrm{M}_{2} \mathrm{~S}_{3}(s)$ is heated in air, it is converted to $\mathrm{MO}_{2}(s)$. A $4.000-\mathrm{g}$ sample of $\mathrm{M}_{2} \mathrm{~S}_{3}(s)$ shows a decrease in mass of 0.277 g when it is heated in air. What is the average atomic mass of M ?
185. When aluminum metal is heated with an element from Group 6 A of the periodic table, an ionic compound forms. When the experiment is performed with an unknown Group 6A element, the product is $18.56 \% \mathrm{Al}$ by mass. What is the formula of the compound?
186. Consider a mixture of potassium chloride and potassium nitrate that is $43.2 \%$ potassium by mass. What is the percent KCl by mass of the original mixture?
187. Lanthanum was reacted with hydrogen in a given experiment to produce the nonstoichiometric compound $\mathrm{LaH}_{2.90}$. Assuming that the compound contains $\mathrm{H}^{-}, \mathrm{La}^{2+}$, and $\mathrm{La}^{3+}$, calculate the fractions of $\mathrm{La}^{2+}$ and $\mathrm{La}^{3+}$ present.
188. A $1.500-\mathrm{g}$ sample of a mixture containing only $\mathrm{Cu}_{2} \mathrm{O}$ and CuO was treated with hydrogen to produce 1.252 g of pure cupper metal. Calculate the mass percent of $\mathrm{Cu}_{2} \mathrm{O}$ in the original mixture.
189. Ammonia reacts with $\mathrm{O}_{2}$ to form either $\mathrm{NO}(g)$ or $\mathrm{NO}_{2}(g)$ according to these unbalanced equations:

$$
\begin{aligned}
& \mathrm{NH}_{3}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \\
& \mathrm{NH}_{3}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)
\end{aligned}
$$

In a certain experiment 2.00 moles of $\mathrm{NH}_{3}(g)$ and 10.00 moles of $\mathrm{O}_{2}(\mathrm{~g})$ are contained in a closed flask. After the reaction is complete, 6.75 moles of $\mathrm{O}_{2}(\mathrm{~g})$ remains. Calculate the number of moles of $\mathrm{NO}(\mathrm{g})$ in the product mixture: (Hint: You cannot do this problem by adding the balanced equations because you cannot assume that the two reactions will occur with equal probability.)
190. You take 1.00 g of an aspirin tablet (a compound consisting solely of carbon, hydrogen, and oxygen), burn it in air, and collect $2.20 \mathrm{~g} \mathrm{CO}_{2}$ and $0.400 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$. You know that the molar mass of aspirin is between 170 and $190 \mathrm{~g} / \mathrm{mol}$. Reacting 1 mole of salicylic acid with 1 mole of acetic anhydride $\left(\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{3}\right)$ gives you 1 mole of aspirin and 1 mole of acetic acid $\left(\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O}_{2}\right)$. Use this information to determine the molecular formula of salicylic acid.

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
191. With the advent of techniques such as scanning tunneling microscopy, it is now possible to "write" with individual atoms by manipulating and arranging atoms on an atomic surface.
a. If an image is prepared by manipulating iron atoms and their total mass is $1.05 \times 10^{-20} \mathrm{~g}$, what number of iron atoms were used?
b. If the image is prepared on a platinum surface that is exactly 20 platinum atoms high and 14 platinum atoms wide, what is the mass (grams) of the atomic surface?
c. If the atomic surface were changed to ruthenium atoms and the same surface mass as determined in part $b$ is used, what number of ruthenium atoms is needed to construct the surface?
192. Tetrodotoxin is a toxic chemical found in fugu pufferfish, a popular but rare delicacy in Japan. This compound has an $\mathrm{LD}_{50}$ (the amount of substance that is lethal to $50 . \%$ of a population sample) of $10 . \mu \mathrm{g}$ per kg of body mass. Tetrodotoxin is $41.38 \%$ carbon by mass, $13.16 \%$ nitrogen by mass, and $5.37 \%$ hydrogen by mass, with the remaining amount consisting of oxygen. What is the empirical formula of tetrodotoxin? If three molecules of tetrodotoxin have a mass of $1.59 \times 10^{-21} \mathrm{~g}$, what is the molecular formula of tetrodotoxin? What number of molecules of tetrodotoxin would be the $\mathrm{LD}_{50}$ dosage for a person weighing 165 lb ?
193. An ionic compound $\mathrm{MX}_{3}$ is prepared according to the following unbalanced chemical equation.

$$
\mathrm{M}+\mathrm{X}_{2} \longrightarrow \mathrm{MX}_{3}
$$

A $0.105-\mathrm{g}$ sample of $\mathrm{X}_{2}$ contains $8.92 \times 10^{20}$ molecules. The compound $\mathrm{MX}_{3}$ consists of $54.47 \% \mathrm{X}$ by mass. What are the identities of M and X , and what is the correct name for $\mathrm{MX}_{3}$ ? Starting with 1.00 g each of M and $\mathrm{X}_{2}$, what mass of $\mathrm{MX}_{3}$ can be prepared?
194. The compound $\mathrm{As}_{2} \mathrm{I}_{4}$ is synthesized by reaction of arsenic metal with arsenic triiodide. If a solid cubic block of arsenic ( $d=5.72 \mathrm{~g} / \mathrm{cm}^{3}$ ) that is 3.00 cm on edge is allowed to react with $1.01 \times 10^{24}$ molecules of arsenic triiodide, what mass of $\mathrm{As}_{2} \mathrm{I}_{4}$ can be prepared? If the percent yield of $\mathrm{As}_{2} \mathrm{I}_{4}$ was $75.6 \%$, what mass of $\mathrm{As}_{2} \mathrm{I}_{4}$ was actually isolated?

## Marathon Problems

These problems are designed to incorporate several concepts and techniques into one situation.
195. A $2.077-\mathrm{g}$ sample of an element, which has an atomic mass between 40 and 55 , reacts with oxygen to form 3.708 g of an oxide. Determine the formula of the oxide (and identify the element).
196. Consider the following balanced chemical equation:

$$
A+5 B \longrightarrow 3 C+4 D
$$

a. Equal masses of A and B are reacted. Complete each of the following with either " A is the limiting reactant because $\qquad$ "; "B is the limiting reactant because tant because $\qquad$ ."
i. If the molar mass of A is greater than the molar mass of B, then
ii. If the molar mass of $B$ is greater than the molar mass of A, then
b. The products of the reaction are carbon dioxide (C) and water (D). Compound A has a similar molar mass to carbon dioxide. Compound B is a diatomic molecule. Identify compound B, and support your answer.
c. Compound A is a hydrocarbon that is $81.71 \%$ carbon by mass. Determine its empirical and molecular formulas.

[^5] solved in water. For example, virtually all the chemistry that makes life possible occurs in an aqueous environment. Also, various medical tests involve aqueous reactions, depending heavily on analyses of blood and other body fluids. In addition to the common tests for sugar, cholesterol, and iron, analyses for specific chemical markers allow detection of many diseases before obvious symptoms occur.

Aqueous chemistry is also important in our environment. In recent years, contamination of the groundwater by substances such as chloroform and nitrates has been widely publicized. Water is essential for life, and the maintenance of an ample supply of clean water is crucial to all civilization.

To understand the chemistry that occurs in such diverse places as the human body, the atmosphere, the groundwater, the oceans, the local water treatment plant, your hair as you shampoo it, and so on, we must understand how substances dissolved in water react with each other.

However, before we can understand solution reactions, we need to discuss the nature of solutions in which water is the dissolving medium, or solvent. These solutions are called aqueous solutions. In this chapter we will study the nature of materials after they are dissolved in water and various types of reactions that occur among these substances. You will see that the procedures developed in Chapter 3 to deal with chemical reactions work very well for reactions that take place in aqueous solutions. To understand the types of reactions that occur in aqueous solutions, we must first explore the types of species present. This requires an understanding of the nature of water.

### 4.1 Water, the Common Solvent

FIGURE 4.1 (top) The water molecule is polar. (bottom) A space-filling model of the water molecule.

Water is one of the most important substances on the earth. It is essential for sustaining the reactions that keep us alive, but it also affects our lives in many indirect ways. Water helps moderate the earth's temperature; it cools automobile engines, nuclear power plants, and many industrial processes; it provides a means of transportation on the earth's surface and a medium for the growth of a myriad of creatures we use as food; and much more.

One of the most valuable properties of water is its ability to dissolve many different substances. For example, salt "disappears" when you sprinkle it into the water used to cook vegetables, as does sugar when you add it to your iced tea. In each case the "disappearing" substance is obviously still present-you can taste it. What happens when a solid dissolves? To understand this process, we need to consider the nature of water. Liquid water consists of a collection of $\mathrm{H}_{2} \mathrm{O}$ molecules. An individual $\mathrm{H}_{2} \mathrm{O}$ molecule is "bent" or V-shaped, with an $\mathrm{H}-\mathrm{O}-\mathrm{H}$ angle of approximately 105 degrees:

$$
\mathrm{H}_{\mathrm{O}}^{105^{\circ}} \mathrm{H}
$$

The $\mathrm{O}-\mathrm{H}$ bonds in the water molecule are covalent bonds formed by electron sharing between the oxygen and hydrogen atoms. However, the electrons of the bond are not shared equally between these atoms. For reasons we will discuss in later chapters, oxygen has a greater attraction for electrons than does hydrogen. If the electrons were shared equally between the two atoms, both would be electrically neutral because, on average, the number of electrons around each would equal the number of protons in that nucleus. However, because the oxygen atom has a greater attraction for electrons, the shared electrons tend to spend more time close to the oxygen than to either of the hydrogens. Thus the oxygen atom gains a slight excess of negative charge, and the hydrogen atoms become slightly positive. This is shown in Fig. 4.1, where $\delta$ (delta) indicates a partial charge (less than one unit of charge). Because of this unequal charge distribution, water is said to be a polar molecule. It is this polarity that gives water its great ability to dissolve compounds.

A schematic of an ionic solid dissolving in water is shown in Fig. 4.2. Note that the "positive ends" of the water molecules are attracted to the negatively charged anions and that the "negative ends" are attracted to the positively charged cations. This process is called hydration. The hydration of its ions tends to cause a salt to "fall apart" in the water, or to dissolve. The strong forces present among the positive and negative ions of the solid are replaced by strong water-ion interactions.

It is very important to recognize that when ionic substances (salts) dissolve in water, they break up into the individual cations and anions. For instance, when ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$ dissolves in water, the resulting solution contains $\mathrm{NH}_{4}{ }^{+}$and $\mathrm{NO}_{3}{ }^{-}$ ions moving around independently. This process can be represented as

$$
\mathrm{NH}_{4} \mathrm{NO}_{3}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}(t)} \mathrm{NH}_{4}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q)
$$

where $(a q)$ designates that the ions are hydrated by unspecified numbers of water molecules.

The solubility of ionic substances in water varies greatly. For example, sodium chloride is quite soluble in water, whereas silver chloride (contains $\mathrm{Ag}^{+}$and $\mathrm{Cl}^{-}$ions) is only very slightly soluble. The differences in the solubilities of ionic compounds in water typically depend on the relative attractions of the ions for each other (these forces hold the solid together) and the attractions of the ions for water molecules (which cause the solid to disperse [dissolve] in water). Solubility is a complex topic that we will explore in much more detail in Chapter 11. However, the most important thing to remember at this point is that when an ionic solid does dissolve in water, the ions become hydrated and are dispersed (move around independently).

Water also dissolves many nonionic substances. Ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$, for example, is very soluble in water. Wine, beer, and mixed drinks are aqueous solutions of ethanol and other substances. Why is ethanol so soluble in water? The answer lies in the structure of the alcohol molecules, which is shown in Fig. 4.3(a). The molecule contains a polar $\mathrm{O}-\mathrm{H}$ bond like those in water, which makes it very compatible with water. The interaction of water with ethanol is represented in Fig. 4.3(b).

Many substances do not dissolve in water. Pure water will not, for example, dissolve animal fat, because fat molecules are nonpolar and do not interact effectively

FIGURE 4.2 Polar water molecules interact with the positive and negative ions of a salt, assisting in the dissolving process.

FIGURE 4.3 (a) The ethanol molecule contains a polar $\mathrm{O}-\mathrm{H}$ bond similar to those in the water molecule. (b) The polar water molecule interacts strongly with the polar $\mathrm{O}-\mathrm{H}$ bond in ethanol. This is a case of "like dissolving like."

with polar water molecules. In general, polar and ionic substances are expected to be more soluble in water than nonpolar substances. "Like dissolves like" is a useful rule for predicting solubility. We will explore the basis for this generalization when we discuss the details of solution formation in Chapter 11.

## 

 water? How would this affect the way reactions occur in aqueous solutions?
### 4.2 The Nature of Aqueous Solutions: Strong and Weak Electrolytes

As we discussed in Chapter 1, a solution is a homogeneous mixture. It is the same throughout (the first sip of a cup of coffee is the same as the last), but its composition can be varied by changing the amount of dissolved substances (you can make weak or strong coffee). In this section we will consider what happens when a substance, the solute, is dissolved in liquid water, the solvent.

One useful property for characterizing a solution is its electrical conductivity, its ability to conduct an electric current. This characteristic can be checked conveniently by using an apparatus like the ones shown in Fig. 4.4. If the solution in the container conducts electricity, the bulb lights. Pure water is not an electrical conductor. However, some aqueous solutions conduct current very efficiently, and the bulb shines very brightly; these solutions contain strong electrolytes. Other solutions conduct only a small current, and the bulb glows dimly; these solutions contain weak electrolytes. Some solutions permit no current to flow, and the bulb remains unlit; these solutions contain nonelectrolytes.

The basis for the conductivity properties of solutions was first correctly identified by Svante Arrhenius (1859-1927), then a Swedish graduate student in physics, who carried out research on the nature of solutions at the University of Uppsala in the early 1880s. Arrhenius came to believe that the conductivity of solutions arose from the presence of ions, an idea that was at first scorned by the majority of the scientific establishment. However, in the late 1890s when atoms were found to contain charged particles, the ionic theory suddenly made sense and became widely accepted.

As Arrhenius postulated, the extent to which a solution can conduct an electric current depends directly on the number of ions present. Some materials, such as sodium chloride, readily produce ions in aqueous solution and thus are strong electrolytes. Other substances, such as acetic acid, produce relatively few ions when dissolved in water and are weak electrolytes. A third class of materials, such as sugar, form virtually no ions when dissolved in water and are nonelectrolytes.

FIGURE 4.4 Electrical conductivity of aqueous solutions. The circuit will be completed and will allow current to flow only when there are charge carriers (ions) in the solution. Note: Water molecules are present but not shown in these pictures. (a) A hydrochloric acid solution, which is a strong electrolyte, contains ions that readily conduct the current and give a brightly lit bulb. (b) An acetic acid solution, which is a weak electrolyte, contains only a few ions and does not conduct as much current as a strong electrolyte. The bulb is only dimly lit. (c) A sucrose solution, which is a nonelectrolyte, contains no ions and does not conduct a current. The bulb remains unlit.

FIGURE 4.5 When solid NaCl dissolves, the $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions are randomly dispersed in the water.

## Strong Electrolytes

Strong electrolytes are substances that are completely ionized when they are dissolved in water, as represented in Fig. 4.4(a). We will consider several classes of strong electrolytes: (1) soluble salts, (2) strong acids, and (3) strong bases.

As shown in Fig. 4.2, a salt consists of an array of cations and anions that separate and become hydrated when the salt dissolves. For example, when NaCl dissolves in water, it produces hydrated $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions in the solution (Fig. 4.5). Virtually no NaCl units are present. Thus NaCl is a strong electrolyte. It is important to recognize that these aqueous solutions contain millions of water molecules that we will not include in our molecular-level drawings.

One of Arrhenius's most important discoveries concerned the nature of acids. Acidity was first associated with the sour taste of citrus fruits. In fact, the word acid comes

FIGURE 4.6 HCI(aq) is completely ionized.

The Arrhenius definition of an acid is a substance that produces $\mathrm{H}^{+}$ions in solution.

Strong electrolytes dissociate (ionize) completely in aqueous solution.

Perchloric acid, $\mathrm{HClO}_{4}(a q)$, is another strong acid.

FIGURE 4.7 An aqueous solution of sodium hydroxide.

Weak electrolytes dissociate (ionize) only to a small extent in aqueous solution.
directly from the Latin word acidus, meaning "sour." The mineral acids sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$ and nitric acid $\left(\mathrm{HNO}_{3}\right)$, so named because they were originally obtained by the treatment of minerals, were discovered around 1300.

Although acids were known for hundreds of years before the time of Arrhenius, no one had recognized their essential nature. In his studies of solutions, Arrhenius found that when the substances $\mathrm{HCl}, \mathrm{HNO}_{3}$, and $\mathrm{H}_{2} \mathrm{SO}_{4}$ were dissolved in water, they behaved as strong electrolytes. He postulated that this was the result of ionization reactions in water, for example:

$$
\begin{gathered}
\mathrm{HCl} \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q) \\
\mathrm{HNO}_{3} \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{H}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q) \\
\mathrm{H}_{2} \mathrm{SO}_{4} \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{H}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q)
\end{gathered}
$$

Thus Arrhenius proposed that an acid is a substance that produces $H^{+}$ions (protons) when it is dissolved in water.

We now understand that the polar nature of water plays a very important role in causing acids to produce $\mathrm{H}^{+}$in solution. In fact, it is most appropriate to represent the "ionization" of an acid as follows:

$$
\mathrm{HA}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{A}^{-}(a q)
$$

which emphasizes the important role of water in this process. We will have much more to say about this process in Chapter 14.

Studies of conductivity show that when $\mathrm{HCl}, \mathrm{HNO}_{3}$, and $\mathrm{H}_{2} \mathrm{SO}_{4}$ are placed in water, virtually every molecule ionizes. These substances are strong electrolytes and are thus called strong acids. All three are very important chemicals, and much more will be said about them as we proceed. However, at this point the following facts are important:

Sulfuric acid, nitric acid, and hydrochloric acid are aqueous solutions and should be written in chemical equations as $\mathrm{H}_{2} \mathrm{SO}_{4}(a q), \mathrm{HNO}_{3}(a q)$, and $\mathrm{HCl}(a q)$, respectively, although they often appear without the (aq) symbol.

A strong acid is one that completely dissociates into its ions. Thus, if 100 mol ecules of HCl are dissolved in water, $100 \mathrm{H}^{+}$ions and $100 \mathrm{Cl}^{-}$ions are produced. Virtually no HCl molecules exist in aqueous solutions (Fig. 4.6).

Sulfuric acid is a special case. The formula $\mathrm{H}_{2} \mathrm{SO}_{4}$ indicates that this acid can produce two $\mathrm{H}^{+}$ions per molecule when dissolved in water. However, only the first $\mathrm{H}^{+}$ion is completely dissociated. The second $\mathrm{H}^{+}$ion can be pulled off under certain conditions, which we will discuss later. Thus an aqueous solution of $\mathrm{H}_{2} \mathrm{SO}_{4}$ contains mostly $\mathrm{H}^{+}$ions and $\mathrm{HSO}_{4}^{-}$ions.
Another important class of strong electrolytes consists of the strong bases, soluble ionic compounds containing the hydroxide ion $\left(\mathrm{OH}^{-}\right)$. When these compounds are dissolved in water, the cations and $\mathrm{OH}^{-}$ions separate and move independently. Solutions containing bases have a bitter taste and a slippery feel. The most common basic solutions are those produced when solid sodium hydroxide $(\mathrm{NaOH})$ or potassium hydroxide $(\mathrm{KOH})$ is dissolved in water to produce ions, as follows (Fig. 4.7):

$$
\begin{aligned}
& \mathrm{NaOH}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q) \\
& \mathrm{KOH}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \\
& \mathrm{~K}^{+}(a q)+\mathrm{OH}^{-}(a q)
\end{aligned}
$$

## Weak Electrolytes

Weak electrolytes are substances that exhibit a small degree of ionization in water. That is, they produce relatively few ions when dissolved in water, as shown in Fig. 4.4(b). The most common weak electrolytes are weak acids and weak bases.

The main acidic component of vinegar is acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$. The formula is written to indicate that acetic acid has two chemically distinct types of hydrogen

## CHEMICAL CONNECTIONS

## Arrhenius: A Man with Solutions

$S$
cience is a human endeavor, subject to human frailties and governed by personalities, politics, and prejudices. One of the best illustrations of the often bumpy path of the advancement of scientific knowledge is the story of Swedish chemist Svante Arrhenius. When Arrhenius began studies toward his doctorate at the University of Uppsala around 1880, he chose to investigate the passage of electricity through solutions, a mystery that had baffled scientists for a century. The first experiments had been done in the 1770 s by Cavendish, who compared the conductivity of salt solution with that of rain water using his own physiologic reaction to the electric shocks he received! Arrhenius had an array of instruments to measure electric current, but the process of carefully weighing, measuring, and recording data from a multitude of experiments was a tedious one.

After his long series of experiments was performed, Arrhenius quit his laboratory bench and returned to his country home to try to formulate a model that could account for his data. He wrote, "I got the idea in the night of the 17th of May in the year 1883, and I could not sleep that night until I had worked through the whole problem." His idea was that ions were responsible for conducting electricity through a solution.

Back at Uppsala, Arrhenius took his doctoral dissertation containing the
new theory to his advisor, Professor Cleve, an eminent chemist and the discoverer of the elements holmium and thulium. Cleve's uninterested response was what Arrhenius had expected. It was in keeping with Cleve's resistance to new ideas-he had not even accepted Mendeleev's periodic table, introduced 10 years earlier.

It is a long-standing custom that before a doctoral degree is granted, the dissertation must be defended before a panel of professors. Although this procedure is still followed at most universities today, the problems are usually worked out in private with the evaluating professors before the actual defense. However, when Arrhenius did it, the dissertation defense was an open debate, which could be rancorous and humiliating. Knowing that it would be unwise to antagonize his professors, Arrhenius downplayed his convictions about his new theory as he defended his dissertation. His diplomacy paid off: He was awarded his degree, albeit reluctantly, because the professors still did not believe his model and considered him to be a marginal scientist, at best.

Such a setback could have ended his scientific career, but Arrhenius was a crusader; he was determined to see his theory triumph. He promptly embarked on a political campaign, enlisting the aid of several prominent scientists, to get his theory accepted.

Svante August Arrhenius.

Ultimately, the ionic theory triumphed. Arrhenius's fame spread, and honors were heaped on him, culminating in the Nobel Prize in chemistry in 1903. Not one to rest on his laurels, Arrhenius turned to new fields, including astronomy; he formulated a new theory that the solar system may have come into being through the collision of stars. His exceptional versatility led him to study the use of serums to fight disease, energy resources and conservation, and the origin of life.

Additional insight on Arrhenius and his scientific career can be obtained from his address on receiving the Willard Gibbs Award. See Journal of the American Chemical Society 36 (1912): 353.
atoms. Formulas for acids are often written with the acidic hydrogen atom or atoms (any that will produce $\mathrm{H}^{+}$ions in solution) listed first. If any nonacidic hydrogens are present, they are written later in the formula. Thus the formula $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ indicates one acidic and three nonacidic hydrogen atoms. The dissociation reaction for acetic acid in water can be written as follows:

$$
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)
$$

Acetic acid is very different from the strong acids because only about $1 \%$ of its molecules dissociate in aqueous solutions at typical concentrations. For example, in a

FIGURE 4.8 Acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$ exists in water mostly as undissociated molecules. Only a small percentage of the molecules are ionized.

FIGURE 4.9 The reaction of $\mathrm{NH}_{3}$ in water.
solution containing 0.1 mole of $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ per liter, for every 100 molecules of $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ originally dissolved in water, approximately 99 molecules of $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ remain intact (Fig. 4.8). That is, only one molecule out of every 100 dissociates (to produce one $\mathrm{H}^{+}$ ion and one $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}$ion). The double arrow indicates the reaction can occur in either direction.

Because acetic acid is a weak electrolyte, it is called a weak acid. Any acid, such as acetic acid, that dissociates (ionizes) only to a slight extent in aqueous solutions is called a weak acid. We will explore the subject of weak acids in detail in Chapter 14.

The most common weak base is ammonia $\left(\mathrm{NH}_{3}\right)$. When ammonia is dissolved in water, it reacts as follows:

$$
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

The solution is basic because $\mathrm{OH}^{-}$ions are produced. Ammonia is called a weak base because the resulting solution is a weak electrolyte; that is, very few ions are formed. In fact, in a solution containing 0.1 mole of $\mathrm{NH}_{3}$ per liter, for every 100 molecules of $\mathrm{NH}_{3}$ originally dissolved, only one $\mathrm{NH}_{4}{ }^{+}$ion and one $\mathrm{OH}^{-}$ion are produced; 99 molecules of $\mathrm{NH}_{3}$ remain unreacted (Fig. 4.9). The double arrow indicates the reaction can occur in either direction.

## Nonelectrolytes

Nonelectrolytes are substances that dissolve in water but do not produce any ions, as shown in Fig. 4.4(c). An example of a nonelectrolyte is ethanol (see Fig. 4.3 for the structural formula). When ethanol dissolves, entire $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ molecules are dispersed in the water. Since the molecules do not break up into ions, the resulting solution does not conduct an electric current. Another common nonelectrolyte is table sugar (sucrose, $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$ ), which is very soluble in water but which produces no ions when it dissolves. The sucrose molecules remain intact.

### 4.3 The Composition of Solutions

Chemical reactions often take place when two solutions are mixed. To perform stoichiometric calculations in such cases, we must know two things: (1) the nature of the reaction, which depends on the exact forms the chemicals take when dissolved, and (2) the amounts of chemicals present in the solutions, usually expressed as concentrations.

The concentration of a solution can be described in many different ways, as we will see in Chapter 11. At this point we will consider only the most commonly used expression of concentration, molarity $(M)$, which is defined as moles of solute per volume of solution in liters:

$$
M=\text { molarity }=\frac{\text { moles of solute }}{\text { liters of solution }}
$$

A solution that is 1.0 molar (written as 1.0 M ) contains 1.0 mole of solute per liter of solution.

## INTERACTVE EXAMPLE 4.1 Calculation of Molarity I

Calculate the molarity of a solution prepared by dissolving 11.5 g of solid NaOH in enough water to make 1.50 L of solution.

## SOLUTION

## Where are we going?

To find the molarity of NaOH solution

What do we know?
> 11.5 g NaOH
> 1.50 L solution
What information do we need to find molarity?
> Moles solute
) Molarity $=\frac{\text { mol solute }}{\mathrm{L} \text { solution }}$
How do we get there?
What are the moles of $\mathrm{NaOH}(40.00 \mathrm{~g} / \mathrm{mol})$ ?

$$
11.5 \mathrm{~g} \mathrm{NaOH} \times \frac{1 \mathrm{~mol} \mathrm{NaOH}}{40.00 \mathrm{~g} \mathrm{NaOH}}=0.288 \mathrm{~mol} \mathrm{NaOH}
$$

What is the molarity of the solution?

$$
\text { Molarity }=\frac{\text { mol solute }}{\mathrm{L} \text { solution }}=\frac{0.288 \mathrm{~mol} \mathrm{NaOH}}{1.50 \mathrm{~L} \text { solution }}=0.192 \mathrm{M} \mathrm{NaOH}
$$

Reality Check The units are correct for molarity.

## INTERACTIVE EXAMPLE 4.2 Calculation of Molarity II

Calculate the molarity of a solution prepared by dissolving 1.56 g of gaseous HCl in enough water to make 26.8 mL of solution.

## SOLUTION Where are we going?

To find the molarity of HCl solution
What do we know?
> 1.56 g HCl
> 26.8 mL solution
What information do we need to find molarity?
> Moles solute
) Molarity $=\frac{\text { mol solute }}{\mathrm{L} \text { solution }}$
How do we get there?
What are the moles of $\mathrm{HCl}(36.46 \mathrm{~g} / \mathrm{mol})$ ?

$$
1.56 \mathrm{~g} \mathrm{HCt} \times \frac{1 \mathrm{~mol} \mathrm{HCl}}{36.46 \mathrm{gHCt}}=4.28 \times 10^{-2} \mathrm{~mol} \mathrm{HCl}
$$

What is the volume of solution (in liters)?

$$
26.8 \mathrm{mt} \times \frac{1 \mathrm{~L}}{1000 \mathrm{mt}}=2.68 \times 10^{-2} \mathrm{~L}
$$

What is the molarity of the solution?

$$
\text { Molarity }=\frac{4.28 \times 10^{-2} \mathrm{~mol} \mathrm{HCl}}{2.68 \times 10^{-2} \mathrm{~L} \text { solution }}=1.60 \mathrm{M} \mathrm{HCl}
$$

Reality Check The units are correct for molarity.

## INTERACTIVE EXAMPLE 4.3 Concentration of lons I

Give the concentration of each type of ion in the following solutions:
a. $0.50 \mathrm{M} \mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}$
b. $1 M \mathrm{Fe}\left(\mathrm{ClO}_{4}\right)_{3}$

## SOLUTION Where are we going?

To find the molarity of each ion in the solution
What do we know?

$$
\begin{array}{ll}
> & 0.50 M \mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2} \\
> & 1 M \mathrm{Fe}\left(\mathrm{ClO}_{4}\right)_{3}
\end{array}
$$

What information do we need to find the molarity of each ion?
> Moles of each ion

## How do we get there?

For $\mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}$
What is the balanced equation for dissolving the ions?

$$
\mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Co}^{2+}(a q)+2 \mathrm{NO}_{3}^{-}(a q)
$$

What is the molarity for each ion?

$$
\begin{array}{ll}
\mathrm{Co}^{2+} & 1 \times 0.50 \mathrm{M}=0.50 \mathrm{M} \mathrm{Co}^{2+} \\
\mathrm{NO}_{3}^{-} & 2 \times 0.50 \mathrm{M}=1.0 \mathrm{M} \mathrm{NO}_{3}^{-}
\end{array}
$$

For $\mathrm{Fe}\left(\mathrm{ClO}_{4}\right)_{3}$
What is the balanced equation for dissolving the ions?

$$
\mathrm{Fe}\left(\mathrm{ClO}_{4}\right)_{3}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Fe}^{3+}(a q)+3 \mathrm{ClO}_{4}^{-}(a q)
$$

What is the molarity for each ion?

$$
\begin{array}{ll}
\mathrm{Fe}^{3+} & 1 \times 1 M=1 M \mathrm{Fe}^{3+} \\
\mathrm{ClO}_{4}^{-} & 3 \times 1 M=3 M \mathrm{ClO}_{4}^{-}
\end{array}
$$

## See Exercises 4.38 and 4.34

Often chemists need to determine the number of moles of solute present in a given volume of a solution of known molarity. The procedure for doing this is easily derived from the definition of molarity. If we multiply the molarity of a solution by the volume
moles of solute
liters of solution
(in liters) of a particular sample of the solution, we get the moles of solute present in that sample:

Liters of solution $\times$ molarity $=$ liters of solution $\times \frac{\text { moles of solute }}{\text { liters of solution }}=$ moles of solute
This procedure is demonstrated in Examples 4.4 and 4.5.

## INTERACTIVE EXAMPLE 4.4

SOLUTION Where are we going?
To find the moles of $\mathrm{Cl}^{-}$ion in the solution
What do we know?
> $1.0 \times 10^{-3} \mathrm{M} \mathrm{ZnCl}_{2}$
$>1.75 \mathrm{~L}$
What information do we need to find moles of $\mathrm{Cl}^{-}$?
> Balanced equation for dissolving $\mathrm{ZnCl}_{2}$

## How do we get there?

What is the balanced equation for dissolving the ions?

$$
\mathrm{ZnCl}_{2}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Zn}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q)
$$

What is the molarity of $\mathrm{Cl}^{-}$ion in the solution?

$$
2 \times\left(1.0 \times 10^{-3} M\right)=2.0 \times 10^{-3} \mathrm{M} \mathrm{Cl}^{-}
$$

How many moles of $\mathrm{Cl}^{-}$?
■ 1.75 L solution $\times 2.0 \times 10^{-3} \mathrm{M} \mathrm{Cl}^{-}=1.75 \mathrm{~L}$ solution $\times \frac{2.0 \times 10^{-3} \mathrm{~mol} \mathrm{Cl}^{-}}{\mathrm{L} \text { solution }}$

$$
=3.5 \times 10^{-3} \mathrm{~mol} \mathrm{Cl}^{-}
$$

See Exercise 4.35

## INTERACTIVE EXAMPLE 4.5 Concentration and Volume

Typical blood serum is about 0.14 M NaCl . What volume of blood contains 1.0 mg of NaCl ?

## SOLUTION Where are we going?

To find the volume of blood containing 1.0 mg of NaCl
What do we know?
> 0.14 M NaCl
> 1.0 mg NaCl
What information do we need to find volume of blood containing 1.0 mg of NaCl ?
> Moles of NaCl (in 1.0 mg )

## How do we get there?

What are the moles of $\mathrm{NaCl}(58.44 \mathrm{~g} / \mathrm{mol})$ ?

$$
1.0 \mathrm{mg} \mathrm{NaCt} \times \frac{1 \mathrm{~g} \mathrm{NaCt}}{1000 \mathrm{mg} \mathrm{NaCl}} \times \frac{1 \mathrm{~mol} \mathrm{NaCl}}{58.44 \mathrm{~g} \mathrm{NaCt}}=1.7 \times 10^{-5} \mathrm{~mol} \mathrm{NaCl}
$$

What volume of 0.14 M NaCl contains $1.0 \mathrm{mg}\left(1.7 \times 10^{-5}\right.$ mole) of NaCl ?
There is some volume, call it $V$, that when multiplied by the molarity of this solution will yield $1.7 \times 10^{-5}$ mole of NaCl . That is,

$$
V \times \frac{0.14 \mathrm{~mol} \mathrm{NaCl}}{\mathrm{~L} \text { solution }}=1.7 \times 10^{-5} \mathrm{~mol} \mathrm{NaCl}
$$

We want to solve for the volume:

$$
V=\frac{1.7 \times 10^{-5} \mathrm{~mol} \mathrm{NaCt}}{\frac{0.14 \mathrm{~mol} \mathrm{NaCl}}{\mathrm{~L} \text { solution }}}=1.2 \times 10^{-4} \mathrm{~L} \text { solution }
$$

- Thus 0.12 mL of blood contains $1.7 \times 10^{-5}$ mole of NaCl or 1.0 mg of NaCl .

## See Exercises 4.37 and 4.38

A standard solution is a solution whose concentration is accurately known. Standard solutions, often used in chemical analysis, can be prepared as shown in Fig. 4.10 and in Example 4.6.

## INTERACTIVE EXAMPLE 4.6

## SOLUTION

FIGURE 4.10 Steps involved in the preparation of a standard aqueous solution. (a) Put a weighed amount of a substance (the solute) into the volumetric flask, and add a small quantity of water. (b) Dissolve the solid in the water by gently swirling the flask (with the stopper in place). (c) Add more water (with gentle swirling) until the level of the solution just reaches the mark etched on the neck of the flask. Then mix the solution thoroughly by inverting the flask several times.

## Where are we going?

To find the mass of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ required for the solution

## What do we know?

> 1.00 L of $0.200 M \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ is required

## Solutions of Known Concentration

To analyze the alcohol content of a certain wine, a chemist needs 1.00 L of an aqueous $0.200-M \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ (potassium dichromate) solution. How much solid $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ must be weighed out to make this solution?

## What information do we need to find the mass of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ ?

) Moles of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ in the required solution

## How do we get there?

What are the moles of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ required?

$$
\begin{aligned}
& M \times V=\mathrm{mol} \\
& 1.00 \mathrm{~L} \text { solution } \times \frac{0.200 \mathrm{~mol} \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}}{\mathrm{~L} \text { solution }}=0.200 \mathrm{~mol} \mathrm{~K}
\end{aligned} \mathrm{Cr}_{2} \mathrm{O}_{7}
$$

What mass of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ is required for the solution?

$$
0.200 \mathrm{~mol} \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7} \times \frac{294.20 \mathrm{~g} \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}}{\mathrm{~mol} \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}}=58.8 \mathrm{~g} \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}
$$

■ To make 1.00 L of $0.200 M \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$, the chemist must weigh out $58.8 \mathrm{~g} \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$, transfer it to a $1.00-\mathrm{L}$ volumetric flask, and add distilled water to the mark on the flask.

## See Exercises 4.41a,c and 4.42c,e

Dilution with water does not alter the numbers of moles of solute present.

## Dilution

To save time and space in the laboratory, routinely used solutions are often purchased or prepared in concentrated form (called stock solutions). Water is then added to achieve the molarity desired for a particular solution. This process is called dilution. For example, the common acids are purchased as concentrated solutions and diluted as needed. A typical dilution calculation involves determining how much water must be added to an amount of stock solution to achieve a solution of the desired concentration. The key to doing these calculations is to remember that

Moles of solute after dilution $=$ moles of solute before dilution
because only water (no solute) is added to accomplish the dilution.
For example, suppose we need to prepare $500 . \mathrm{mL}$ of 1.00 M acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$ from a $17.4-M$ stock solution of acetic acid. What volume of the stock solution is required? The first step is to determine the number of moles of acetic acid in the final solution by multiplying the volume by the molarity (remembering that the volume must be changed to liters):
500. mL solution $\times \frac{1 \mathrm{~L} \text { solution }}{1000 \mathrm{~mL} \text { solution }} \times \frac{1.00 \mathrm{~mol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}}{\mathrm{~L} \text { solution }}=0.500 \mathrm{~mol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$

Thus we need to use a volume of 17.4 M acetic acid that contains 0.500 mole of $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$. That is,

$$
V \times \frac{17.4 \mathrm{~mol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}}{\text { L solution }}=0.500 \mathrm{~mol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}
$$

Solving for $V$ gives

$$
V=\frac{0.500 \mathrm{~mol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}}{\frac{17.4 \mathrm{~mol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}}{\mathrm{~L} \text { solution }}}=0.0287 \mathrm{~L} \text { or } 28.7 \mathrm{~mL} \text { solution }
$$

Thus to make 500 mL of a $1.00-M$ acetic acid solution, we can take 28.7 mL of 17.4 $M$ acetic acid and dilute it to a total volume of 500 mL with distilled water.

FIGURE 4.11 (a) A measuring pipet is graduated and can be used to measure various volumes of liquid accurately. (b) A volumetric (transfer) pipet is designed to measure one volume accurately. When filled to the mark, it delivers the volume indicated on the pipet.

FIGURE 4.12 (a) A measuring pipet is used to transfer 28.7 mL of 17.4 M acetic acid solution to a volumetric flask. (b) Water is added to the flask to the calibration mark. (c) The resulting solution is 1.00 M acetic acid.

A dilution procedure typically involves two types of glassware: a pipet and a volumetric flask. A pipet is a device for accurately measuring and transferring a given volume of solution. There are two common types of pipets: volumetric (or transfer) pipets and measuring pipets (Fig. 4.11). Volumetric pipets come in specific sizes, such as $5 \mathrm{~mL}, 10 \mathrm{~mL}, 25 \mathrm{~mL}$, and so on. Measuring pipets are used to measure volumes for which a volumetric pipet is not available. For example, we would use a measuring pipet as shown in Fig. 4.12 above to deliver 28.7 mL of 17.4 M acetic acid into a $500-\mathrm{mL}$ volumetric flask and then add water to the mark to perform the dilution described previously.

## INTERACTIVE EXAMPLE 4.1 Concentration and Volume

What volume of $16 M$ sulfuric acid must be used to prepare 1.5 L of a $0.10-M \mathrm{H}_{2} \mathrm{SO}_{4}$ solution?

## SOLUTION Where are we going?

To find the volume of $\mathrm{H}_{2} \mathrm{SO}_{4}$ required to prepare the solution
What do we know?
> 1.5 L of $0.10 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ is required
) We have $16 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$
What information do we need to find the volume of $\mathrm{H}_{2} \mathrm{SO}_{4}$ ?
> Moles of $\mathrm{H}_{2} \mathrm{SO}_{4}$ in the required solution

When diluting an acid, "Do what you oughta, always add acid to water."

How do we get there?
What are the moles of $\mathrm{H}_{2} \mathrm{SO}_{4}$ required?

$$
M \times V=\mathrm{mol}
$$

$$
1.5 \mathrm{~L}_{\text {solution }} \times \frac{0.10 \mathrm{~mol} \mathrm{H}_{2} \mathrm{SO}_{4}}{\text { Lsolution }}=0.15 \mathrm{~mol} \mathrm{H}_{2} \mathrm{SO}_{4}
$$

What volume of $16 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ contains 0.15 mole of $\mathrm{H}_{2} \mathrm{SO}_{4}$ ?

$$
V \times \frac{16 \mathrm{~mol} \mathrm{H}_{2} \mathrm{SO}_{4}}{\mathrm{~L} \text { solution }}=0.15 \mathrm{~mol} \mathrm{H}_{2} \mathrm{SO}_{4}
$$

Solving for $V$ gives

$$
V=\frac{0.15 \mathrm{~mol} \mathrm{H}_{2} \mathrm{SO}_{4}^{-}}{\frac{16 \mathrm{~mol} \mathrm{H}_{2} \mathrm{SO}_{4}}{1 \mathrm{~L} \text { solution }}}=9.4 \times 10^{-3} \mathrm{~L} \text { or } 9.4 \mathrm{~mL} \text { solution }
$$

To make 1.5 L of $0.10 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ using $16 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$, we must take 9.4 mL of the concentrated acid and dilute it with water to 1.5 L . The correct way to do this is to add the 9.4 mL of acid to about 1 L of distilled water and then dilute to 1.5 L by adding more water.

## See Exercises 4.41b,d, and 4.42a,b,d

As noted earlier, the central idea in performing the calculations associated with dilutions is to recognize that the moles of solute are not changed by the dilution. Another way to express this condition is by the following equation:

$$
M_{1} V_{1}=M_{2} V_{2}
$$

where $M_{1}$ and $V_{1}$ represent the molarity and volume of the original solution (before dilution) and $M_{2}$ and $V_{2}$ represent the molarity and volume of the diluted solution. This equation makes sense because

$$
\begin{aligned}
M_{1} \times V_{1} & =\text { mol solute before dilution } \\
& =\text { mol solute after dilution }=M_{2} \times V_{2}
\end{aligned}
$$

Repeat Example 4.7 using the equation $M_{1} V_{1}=M_{2} V_{2}$. Note that in doing so,

$$
M_{1}=16 M \quad M_{2}=0.10 M \quad V_{2}=1.5 \mathrm{~L}
$$

and $V_{1}$ is the unknown quantity sought. The equation $M_{1} V_{1}=M_{2} V_{2}$ always holds for a dilution. This equation will be easy for you to remember if you understand where it comes from.

### 4.4 Types of Chemical Reactions

Although we have considered many reactions so far in this text, we have examined only a tiny fraction of the millions of possible chemical reactions. To make sense of all these reactions, we need some system for grouping reactions into classes. Although there are many different ways to do this, we will use the system most commonly used by practicing chemists:

## Types of Solution Reactions

» Precipitation reactions
" Acid-base reactions
") Oxidation-reduction reactions

Virtually all reactions can be put into one of these classes. We will define and illustrate each type in the following sections.

### 4.5 Precipitation Reactions

A precipitation reaction also can be called a double displacement reaction.

The quantitative aspects of precipitation reactions are covered in Chapter 15.

When ionic compounds dissolve in water, the resulting solution contains the separated ions.

When two solutions are mixed, an insoluble substance sometimes forms; that is, a solid forms and separates from the solution. Such a reaction is called a precipitation reaction, and the solid that forms is called a precipitate. For example, a precipitation reaction occurs when an aqueous solution of potassium chromate, $\mathrm{K}_{2} \mathrm{CrO}_{4}(\mathrm{aq})$, which is yellow, is added to a colorless aqueous solution containing barium nitrate, $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q)$. As shown in Fig. 4.13, when these solutions are mixed, a yellow solid forms. What is the equation that describes this chemical change? To write the equation, we must know the identities of the reactants and products. The reactants have already been described: $\mathrm{K}_{2} \mathrm{CrO}_{4}(a q)$ and $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q)$. Is there some way we can predict the identities of the products? In particular, what is the yellow solid?

The best way to predict the identity of this solid is to think carefully about what products are possible. To do this, we need to know what species are present in the solution after the two reactant solutions are mixed. First, let's think about the nature of each reactant solution. The designation $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})$ means that barium nitrate (a white solid) has been dissolved in water. Notice that barium nitrate contains the $\mathrm{Ba}^{2+}$ and $\mathrm{NO}_{3}{ }^{-}$ions. Remember: In virtually every case, when a solid containing ions dissolves in water, the ions separate and move around independently. That is, $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q)$ does not contain $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$ units; it contains separated $\mathrm{Ba}^{2+}$ and $\mathrm{NO}_{3}{ }^{-}$ ions [Fig. 4.14(a)].

Similarly, since solid potassium chromate contains the $\mathrm{K}^{+}$and $\mathrm{CrO}_{4}{ }^{2-}$ ions, an aqueous solution of potassium chromate (which is prepared by dissolving solid $\mathrm{K}_{2} \mathrm{CrO}_{4}$ in water) contains these separated ions [Fig. 4.14(b)].

We can represent the mixing of $\mathrm{K}_{2} \mathrm{CrO}_{4}(a q)$ and $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q)$ in two ways. First, we can write

$$
\mathrm{K}_{2} \mathrm{CrO}_{4}(a q)+\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q) \longrightarrow \text { products }
$$

FIGURE 4.13 When yellow aqueous potassium chromate is added to a colorless barium nitrate solution, yellow barium chromate precipitates.

However, a much more accurate representation is

$$
\underbrace{2 \mathrm{~K}^{+}(a q)+\mathrm{CrO}_{4}{ }^{2-}(a q)}_{\substack{\text { The ions in } \\
\mathrm{K}_{2} \mathrm{CrO}_{4}(a q)}}+\underbrace{\mathrm{Ba}^{2+}(a q)+2 \mathrm{NO}_{3}{ }^{-}(a q)}_{\begin{array}{c}
\text { The ions in } \\
\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q)
\end{array}} \longrightarrow \text { products }
$$

Thus the mixed solution contains the ions:

$$
\mathrm{K}^{+} \quad \mathrm{CrO}_{4}^{2-} \quad \mathrm{Ba}^{2+} \quad \mathrm{NO}_{3}^{-}
$$

as illustrated in Fig. 4.15(a).
How can some or all of these ions combine to form a yellow solid? This is not an easy question to answer. In fact, predicting the products of a chemical reaction is one of the hardest things a beginning chemistry student is asked to do. Even an experienced chemist, when confronted with a new reaction, is often not sure what will happen. The chemist tries to think of the various possibilities, considers the likelihood of each possibility, and then makes a prediction (an educated guess). Only after identifying each product experimentally is the chemist sure what reaction has taken place. However, an educated guess is very useful because it provides a place to start. It tells us what kinds of products we are most likely to find. We already know some things that will help us predict the products of the above reaction.

1. When ions form a solid compound, the compound must have a zero net charge. Thus the products of this reaction must contain both anions and cations. For example, $\mathrm{K}^{+}$and $\mathrm{Ba}^{2+}$ could not combine to form the solid, nor could $\mathrm{CrO}_{4}{ }^{2-}$ and $\mathrm{NO}_{3}{ }^{-}$.
2. Most ionic materials contain only two types of ions: one type of cation and one type of anion (for example, $\mathrm{NaCl}, \mathrm{KOH}, \mathrm{Na}_{2} \mathrm{SO}_{4}, \mathrm{~K}_{2} \mathrm{CrO}_{4}, \mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}, \mathrm{NH}_{4} \mathrm{Cl}$, $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ).

The possible combinations of a given cation and a given anion from the list of ions $\mathrm{K}^{+}, \mathrm{CrO}_{4}{ }^{2-}, \mathrm{Ba}^{2+}$, and $\mathrm{NO}_{3}{ }^{-}$are

$$
\mathrm{K}_{2} \mathrm{CrO}_{4} \quad \mathrm{KNO}_{3} \quad \mathrm{BaCrO}_{4} \quad \mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}
$$

Which of these possibilities is most likely to represent the yellow solid? We know it's not $\mathrm{K}_{2} \mathrm{CrO}_{4}$ or $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$. They are the reactants. They were present (dissolved) in the separate solutions that were mixed. The only real possibilities for the solid that formed are

$$
\mathrm{KNO}_{3} \text { and } \mathrm{BaCrO}_{4}
$$

To decide which of these most likely represents the yellow solid, we need more facts. An experienced chemist knows that the $\mathrm{K}^{+}$ion and the $\mathrm{NO}_{3}{ }^{-}$ion are both colorless. Thus, if the solid is $\mathrm{KNO}_{3}$, it should be white, not yellow. On the other hand, the $\mathrm{CrO}_{4}{ }^{2-}$ ion is yellow (note in Fig. 4.14 that $\mathrm{K}_{2} \mathrm{CrO}_{4}(a q)$ is yellow). Thus the yellow solid is almost certainly $\mathrm{BaCrO}_{4}$. Further tests show that this is the case.

FIGURE 4.15 The reaction of $\mathrm{K}_{2} \mathrm{CrO}_{4}(\mathrm{aq})$ and $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})$. (a) The molecular-level "picture" of the mixed solution before any reaction has occurred. (b) The molecular-level "picture" of the solution after the reaction has occurred to form $\mathrm{BaCrO}_{4}(\mathrm{~s})$. Note: $\mathrm{BaCrO}_{4}(\mathrm{~s})$ is not molecular. It actually contains $\mathrm{Ba}^{2+}$ and $\mathrm{CrO}_{4}{ }^{2-}$ ions packed together in a lattice. (c) A photo of the solution after the reaction has occurred, showing the solid $\mathrm{BaCrO}_{4}$ on the bottom.

FIGURE 4.16 Precipitation of silver chloride by mixing solutions of silver nitrate and potassium chloride. The $\mathrm{K}^{+}$and $\mathrm{NO}_{3}{ }^{-}$ions remain in solution.

So far we have determined that one product of the reaction between $\mathrm{K}_{2} \mathrm{CrO}_{4}(a q)$ and $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q)$ is $\mathrm{BaCrO}_{4}(s)$, but what happened to the $\mathrm{K}^{+}$and $\mathrm{NO}_{3}{ }^{-}$ions? The answer is that these ions are left dissolved in the solution; $\mathrm{KNO}_{3}$ does not form a solid when the $\mathrm{K}^{+}$and $\mathrm{NO}_{3}{ }^{-}$ions are present in this much water. In other words, if we took solid $\mathrm{KNO}_{3}$ and put it in the same quantity of water as is present in the mixed solution, it would dissolve. Thus, when we mix $\mathrm{K}_{2} \mathrm{CrO}_{4}(a q)$ and $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q), \mathrm{BaCrO}_{4}(s)$ forms, but $\mathrm{KNO}_{3}$ is left behind in solution (we write it as $\mathrm{KNO}_{3}(\mathrm{aq})$ ). Thus the overall equation for this precipitation reaction using the formulas of the reactants and products is

$$
\mathrm{K}_{2} \mathrm{CrO}_{4}(a q)+\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q) \longrightarrow \mathrm{BaCrO}_{4}(s)+2 \mathrm{KNO}_{3}(a q)
$$

As long as water is present, the $\mathrm{KNO}_{3}$ remains dissolved as separated ions. (See Fig. 4.15 to help visualize what is happening in this reaction. Note the solid $\mathrm{BaCrO}_{4}$ on the bottom of the container, while the $\mathrm{K}^{+}$and $\mathrm{NO}_{3}{ }^{-}$ions remain dispersed in the solution.) If we removed the solid $\mathrm{BaCrO}_{4}$ and then evaporated the water, white solid $\mathrm{KNO}_{3}$ would be obtained; the $\mathrm{K}^{+}$and $\mathrm{NO}_{3}{ }^{-}$ions would assemble themselves into solid $\mathrm{KNO}_{3}$ when the water is removed.

Now let's consider another example. When an aqueous solution of silver nitrate is added to an aqueous solution of potassium chloride, a white precipitate forms (Fig. 4.16). We can represent what we know so far as

$$
\mathrm{AgNO}_{3}(a q)+\mathrm{KCl}(a q) \longrightarrow \text { unknown white solid }
$$

Remembering that when ionic substances dissolve in water, the ions separate, we can write

Since we know the white solid must contain both positive and negative ions, the possible compounds that can be assembled from this collection of ions are

$$
\mathrm{AgNO}_{3} \quad \mathrm{KCl} \quad \mathrm{AgCl} \quad \mathrm{KNO}_{3}
$$

Since $\mathrm{AgNO}_{3}$ and KCl are the substances dissolved in the two reactant solutions, we know that they do not represent the white solid product. Therefore, the only real possibilities are

$$
\mathrm{AgCl} \text { and } \mathrm{KNO}_{3}
$$

From the first example considered, we know that $\mathrm{KNO}_{3}$ is quite soluble in water. Thus solid $\mathrm{KNO}_{3}$ will not form when the reactant solids are mixed. The product must be $\mathrm{AgCl}(s)$ (which can be proved by experiment to be true). The overall equation for the reaction now can be written

$$
\mathrm{AgNO}_{3}(a q)+\mathrm{KCl}(a q) \longrightarrow \mathrm{AgCl}(s)+\mathrm{KNO}_{3}(a q)
$$

Figure 4.17 shows the result of mixing aqueous solutions of $\mathrm{AgNO}_{3}$ and KCl , including a microscopic visualization of the reaction.

Notice that in these two examples we had to apply both concepts (solids must have a zero net charge) and facts ( $\mathrm{KNO}_{3}$ is very soluble in water, $\mathrm{CrO}_{4}{ }^{2-}$ is yellow, and so on). Doing chemistry requires both understanding ideas and remembering key information. Predicting the identity of the solid product in a precipitation reaction requires knowledge of the solubilities of common ionic substances. As an aid in predicting the products of precipitation reactions, some simple solubility rules are given in Table 4.1. You should memorize these rules.

The phrase slightly soluble used in the solubility rules in Table 4.1 means that the tiny amount of solid that dissolves is not noticeable. The solid appears to be insoluble to the naked eye. Thus the terms insoluble and slightly soluble are often used interchangeably.

FIGURE 4.17 Photos and accompanying molecular-level representations illustrating the reaction of $\mathrm{KCI}(a q)$ with $\mathrm{AgNO}_{3}(\mathrm{aq})$ to form $\mathrm{AgCl}(\mathrm{s})$. Note that it is not possible to have a photo of the mixed solution before the reaction occurs, because it is an imaginary step that we use to help visualize the reaction. Actually, the reaction occurs immediately when the two solutions are mixed.

Note that the information in Table 4.1 allows us to predict that AgCl is the white solid formed when solutions of $\mathrm{AgNO}_{3}$ and KCl are mixed. Rules 1 and 2 indicate that $\mathrm{KNO}_{3}$ is soluble, and Rule 3 states that AgCl is insoluble.

When solutions containing ionic substances are mixed, it will be helpful in determining the products if you think in terms of ion interchange. For example, in the preceding discussion we considered the results of mixing $\mathrm{AgNO}_{3}(a q)$ and $\mathrm{KCl}(a q)$. In determining the products, we took the cation from one reactant and combined it with the anion of the other reactant:

## TABLE 4.1 | Simple Rules for the Solubility of Salts in Water

1. Most nitrate $\left(\mathrm{NO}_{3}^{-}\right)$salts are soluble.
2. Most salts containing the alkali metal ions ( $\left.\mathrm{Li}^{+}, \mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{Cs}^{+}, \mathrm{Rb}^{+}\right)$and the ammonium ion $\left(\mathrm{NH}_{4}{ }^{+}\right)$are soluble.
3. Most chloride, bromide, and iodide salts are soluble. Notable exceptions are salts containing the ions $\mathrm{Ag}^{+}, \mathrm{Pb}^{2+}$, and $\mathrm{Hg}_{2}{ }^{2+}$.
4. Most sulfate salts are soluble. Notable exceptions are $\mathrm{BaSO}_{4}, \mathrm{PbSO}_{4}, \mathrm{Hg}_{2} \mathrm{SO}_{4}$, and $\mathrm{CaSO}_{4}$.
5. Most hydroxides are only slightly soluble. The important soluble hydroxides are NaOH and KOH . The compounds $\mathrm{Ba}(\mathrm{OH})_{2}, \mathrm{Sr}(\mathrm{OH})_{2}$, and $\mathrm{Ca}(\mathrm{OH})_{2}$ are marginally soluble.
6. Most sulfide $\left(\mathrm{S}^{2-}\right)$, carbonate $\left(\mathrm{CO}_{3}{ }^{2-}\right)$, chromate $\left(\mathrm{CrO}_{4}{ }^{2-}\right)$, and phosphate $\left(\mathrm{PO}_{4}{ }^{3-}\right)$ salts are only slightly soluble, except for those containing the cations in Rule 2.

## CHEMICAL CDNNECTIDNS

## Tiny Laboratories

One of the major impacts of modern technology is to make things smaller. The best example is the computer. Calculations that years ago required a machine the size of a large room now can be carried out on a hand-held calculator. This tendency toward miniaturization is also having a major impact on the science of chemical analysis. Using the techniques of computer chip makers, researchers are now constructing minuscule laboratories on the surface of a tiny chip made of silicon, glass, or plastic (see photo). Instead of electrons, $10^{-6}$ to $10^{-9} \mathrm{~L}$ of liquids moves between reaction chambers on the chip through tiny capillaries. The chips typically contain no moving parts. Instead of conventional pumps, the chip-based laboratories use
voltage differences to move liquids that contain ions from one reaction chamber to another.

Microchip laboratories have many advantages. They require only tiny amounts of sample. This is especially advantageous for expensive, difficult-to-prepare materials or in cases such as criminal investigations, where only small amounts of evidence may exist. The chip laboratories also minimize contamination because they represent a "closed system" once the material has been introduced to the chip. In addition, the chips can be made to be disposable to prevent crosscontamination of different samples.

The chip laboratories present some difficulties not found in macroscopic laboratories. The main problem concerns the large surface area of the

A microfluidic lab on a chip. Stainless steel needles inserted into the device serve as access points for fluids.
capillaries and reaction chambers relative to the sample volume. Molecules or biological cells in the sample solution encounter so much "wall" that they may undergo unwanted reactions with the wall materials. Glass seems to present the least of these problems, and the walls of silicon chip laboratories can be protected by formation of relatively inert silicon dioxide. Because plastic is inexpensive, it seems a good choice for disposable chips, but plastic also is the most reactive with the samples and the least durable of the available materials.

PerkinElmer, Inc. is working toward creating a miniature chemistry laboratory about the size of a toaster that can be used with "plug-in" chip-based laboratories. Various chips would be furnished with the unit that would be appropriate for different types of analyses. The entire unit would be connected to a computer to collect and analyze the data. There is even the possibility that these "laboratories" could be used in the home to perform analyses such as blood sugar and blood cholesterol and to check for the presence of bacteria such as $E$. coli and many others. This would revolutionize the healthcare industry.

Adapted from "The Incredible Shrinking Laboratory," by Corinna Wu, as appeared in Science News, Vol. 154, August 15, 1998, p. 104.

[^6]The solubility rules in Table 4.1 allow us to predict whether either product forms as a solid.

The key to dealing with the chemistry of an aqueous solution is first to focus on the actual components of the solution before any reaction occurs and then to figure out how these components will react with each other. Example 4.8 illustrates this process for three different reactions.

## INTERACTIVE EXAMPLE 4.8 Predicting Reaction Products

## SOLUTION

$\Delta$
Solid $\mathrm{Fe}(\mathrm{OH})_{3}$ forms when aqueous KOH and $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$ are mixed.

Using the solubility rules in Table 4.1, predict what will happen when the following pairs of solutions are mixed.
a. $\mathrm{KNO}_{3}(a q)$ and $\mathrm{BaCl}_{2}(a q)$
b. $\mathrm{Na}_{2} \mathrm{SO}_{4}(\mathrm{aq})$ and $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})$
c. $\mathrm{KOH}(a q)$ and $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}(a q)$
a. The formula $\mathrm{KNO}_{3}(a q)$ represents an aqueous solution obtained by dissolving solid $\mathrm{KNO}_{3}$ in water to form a solution containing the hydrated ions $\mathrm{K}^{+}(a q)$ and $\mathrm{NO}_{3}{ }^{-}(a q)$. Likewise, $\mathrm{BaCl}_{2}(a q)$ represents a solution formed by dissolving solid $\mathrm{BaCl}_{2}$ in water to produce $\mathrm{Ba}^{2+}(a q)$ and $\mathrm{Cl}^{-}(a q)$. When these two solutions are mixed, the resulting solution contains the ions $\mathrm{K}^{+}, \mathrm{NO}_{3}^{-}, \mathrm{Ba}^{2+}$, and $\mathrm{Cl}^{-}$. All ions are hydrated, but the $(a q)$ is omitted for simplicity. To look for possible solid products, combine the cation from one reactant with the anion from the other:

Note from Table 4.1 that the rules predict that both KCl and $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$ are soluble in water. Thus no precipitate forms when $\mathrm{KNO}_{3}(a q)$ and $\mathrm{BaCl}_{2}(a q)$ are mixed. All the ions remain dissolved in solution. No chemical reaction occurs.
b. Using the same procedures as in part a , we find that the ions present in the combined solution before any reaction occurs are $\mathrm{Na}^{+}, \mathrm{SO}_{4}{ }^{2-}, \mathrm{Pb}^{2+}$, and $\mathrm{NO}_{3}{ }^{-}$. The possible salts that could form precipitates are

$$
\mathrm{Na}^{+}+\mathrm{SO}_{4}^{2-}+\mathrm{Pb}^{2+}+\mathrm{NO}_{3}^{-} \longrightarrow
$$

The compound $\mathrm{NaNO}_{3}$ is soluble, but $\mathrm{PbSO}_{4}$ is insoluble (see Rule 4 in Table 4.1). When these solutions are mixed, $\mathrm{PbSO}_{4}$ will precipitate from the solution. The balanced equation is

$$
\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}(a q) \longrightarrow \mathrm{PbSO}_{4}(s)+2 \mathrm{NaNO}_{3}(a q)
$$

c. The combined solution (before any reaction occurs) contains the ions $\mathrm{K}^{+}, \mathrm{OH}^{-}$, $\mathrm{Fe}^{3+}$, and $\mathrm{NO}_{3}{ }^{-}$. The salts that might precipitate are $\mathrm{KNO}_{3}$ and $\mathrm{Fe}(\mathrm{OH})_{3}$. The solubility rules in Table 4.1 indicate that both $\mathrm{K}^{+}$and $\mathrm{NO}_{3}{ }^{-}$salts are soluble. However, $\mathrm{Fe}(\mathrm{OH})_{3}$ is only slightly soluble (Rule 5) and hence will precipitate. The balanced equation is

$$
3 \mathrm{KOH}(a q)+\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}(a q) \longrightarrow \mathrm{Fe}(\mathrm{OH})_{3}(s)+3 \mathrm{KNO}_{3}(a q)
$$

### 4.6 Describing Reactions in Solution

In this section we will consider the types of equations used to represent reactions in solution. For example, when we mix aqueous potassium chromate with aqueous barium nitrate, a reaction occurs to form a precipitate $\left(\mathrm{BaCrO}_{4}\right)$ and dissolved potassium nitrate. So far we have written the overall or formula equation for this reaction:

$$
\mathrm{K}_{2} \mathrm{CrO}_{4}(a q)+\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q) \longrightarrow \mathrm{BaCrO}_{4}(s)+2 \mathrm{KNO}_{3}(a q)
$$

A strong electrolyte is a substance that completely breaks apart into ions when dissolved in water.

Net ionic equations include only those components that undergo changes in the reaction.

## INTERACTIVE EXAMPLE 4.9 Writing Equations for Reactions

## SOLUTION

For each of the following reactions, write the formula equation, the complete ionic equation, and the net ionic equation.
a. Aqueous potassium chloride is added to aqueous silver nitrate to form a silver chloride precipitate plus aqueous potassium nitrate.
b. Aqueous potassium hydroxide is mixed with aqueous iron(III) nitrate to form a precipitate of iron(III) hydroxide and aqueous potassium nitrate.
a. Formula Equation

$$
\mathrm{KCl}(a q)+\mathrm{AgNO}_{3}(a q) \longrightarrow \mathrm{AgCl}(s)+\mathrm{KNO}_{3}(a q)
$$

## Complete Ionic Equation

(Remember: Any ionic compound dissolved in water will be present as the separated ions.)

Canceling the spectator ions

$$
\mathrm{K}^{ \pm}(a q)+\mathrm{Cl}^{-}(a q)+\mathrm{Ag}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q) \longrightarrow \mathrm{AgCl}(s)+\mathrm{K}^{ \pm}(a q)+\mathrm{NO}_{3}^{-}(a q)
$$

gives the following net ionic equation.
Net Ionic Equation

$$
\mathrm{Cl}^{-}(a q)+\mathrm{Ag}^{+}(a q) \longrightarrow \mathrm{AgCl}(s)
$$

b. Formula Equation

$$
3 \mathrm{KOH}(a q)+\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}(a q) \longrightarrow \mathrm{Fe}(\mathrm{OH})_{3}(s)+3 \mathrm{KNO}_{3}(a q)
$$

## Complete Ionic Equation

$$
\left.\begin{array}{rl}
3 \mathrm{~K}^{+}(a q) & 3 \mathrm{OH}^{-}(a q)+\mathrm{Fe}^{3+}(a q) \\
& 3 \mathrm{NO}_{3}^{-}(a q) \\
\mathrm{Fe}(\mathrm{OH})_{3}(s)+3 \mathrm{~K}^{+}(a q)
\end{array}\right) 3 \mathrm{NO}_{3}^{-}(a q)
$$

Net Ionic Equation

$$
3 \mathrm{OH}^{-}(a q)+\mathrm{Fe}^{3+}(a q) \longrightarrow \mathrm{Fe}(\mathrm{OH})_{3}(s)
$$

See Exercises 4.53 through 4.58

### 4.7 Stoichiometry of Precipitation Reactions

In Chapter 3 we covered the principles of chemical stoichiometry: the procedures for calculating quantities of reactants and products involved in a chemical reaction. Recall that in performing these calculations we first convert all quantities to moles and then use the coefficients of the balanced equation to assemble the appropriate mole ratios. In cases where reactants are mixed, we must determine which reactant is limiting, since the reactant that is consumed first will limit the amounts of products formed. These same principles apply to reactions that take place in solutions. However, two points about solution reactions need special emphasis. The first is that it is sometimes difficult to tell immediately what reaction will occur when two solutions are mixed. Usually we must do some thinking about the various possibilities and then decide what probably will happen. The first step in this process always should be to write down the species that are actually present in the solution, as we did in Section 4.5. The second special point about solution reactions is that to obtain the moles of reactants we must use the volume of the solution and its molarity. This procedure was covered in Section 4.3.

We will introduce stoichiometric calculations for reactions in solution in Example 4.10.
 How would this affect stoichiometry calculations for reactions in aqueous solution?

## INTERACTIVE EXAMPLE 4.10 Determining the Mass of Product Formed I

Calculate the mass of solid NaCl that must be added to 1.50 L of a $0.100-M \mathrm{AgNO}_{3}$ solution to precipitate all the $\mathrm{Ag}^{+}$ions in the form of AgCl .

## SOLUTION Where are we going?

To find the mass of solid NaCl required to precipitate the $\mathrm{Ag}^{+}$
What do we know?
> 1.50 L of $0.100 \mathrm{M} \mathrm{AgNO}_{3}$

What information do we need to find the mass of NaCl ?
> Moles of $\mathrm{Ag}^{+}$in the solution

## How do we get there?

What are the ions present in the combined solution?

$$
\begin{array}{llll}
\mathrm{Ag}^{+} & \mathrm{NO}_{3}^{-} & \mathrm{Na}^{+} & \mathrm{Cl}^{-}
\end{array}
$$

What is the balanced net ionic equation for the reaction?
Note from Table 4.1 that $\mathrm{NaNO}_{3}$ is soluble and that AgCl is insoluble. Therefore, solid AgCl forms according to the following net ionic equation:

$$
\mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{AgCl}(s)
$$

What are the moles of $\mathrm{Ag}^{+}$ions present in the solution?

$$
1.50 \mathrm{~K} \times \frac{0.100 \mathrm{~mol} \mathrm{Ag}^{+}}{L}=0.150 \mathrm{~mol} \mathrm{Ag}^{+}
$$

How many moles of $\mathrm{Cl}^{-}$are required to react with all the $\mathrm{Ag}^{+}$?
Because $\mathrm{Ag}^{+}$and $\mathrm{Cl}^{-}$react in a $1: 1$ ratio, 0.150 mole of $\mathrm{Cl}^{-}$and thus 0.150 mole of NaCl are required.

## What mass of NaCl is required?

$0.150 \mathrm{~mol} \mathrm{NaCl} \times \frac{58.44 \mathrm{~g} \mathrm{NaCl}}{\mathrm{mol} \mathrm{NaCl}}=8.77 \mathrm{~g} \mathrm{NaCl}$

See Exercise 4.61

Notice from Example 4.10 that the procedures for doing stoichiometric calculations for solution reactions are very similar to those for other types of reactions. It is useful to think in terms of the following steps for reactions in solution.

## PROBLEM-SOLVING STRATEGY

## Solving Stoichiometry Problems for Reactions in Solution

1. Identify the species present in the combined solution, and determine what reaction occurs.
2. Write the balanced net ionic equation for the reaction.
3. Calculate the moles of reactants.
4. Determine which reactant is limiting.
5. Calculate the moles of product or products, as required.
6. Convert to grams or other units, as required.

## INTERACTIVE EXAMPLE 4.11

## Determining the Mass of Product Formed II

When aqueous solutions of $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$ are mixed, $\mathrm{PbSO}_{4}$ precipitates. Calculate the mass of $\mathrm{PbSO}_{4}$ formed when 1.25 L of $0.0500 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$ and 2.00 L of $0.0250 M \mathrm{Na}_{2} \mathrm{SO}_{4}$ are mixed.

## SOLUTION Where are we going?

To find the mass of solid $\mathrm{PbSO}_{4}$ formed

What do we know?
> 1.25 L of $0.0500 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$
> 2.00 L of $0.0250 \mathrm{M} \mathrm{Na}_{2} \mathrm{SO}_{4}$
> Chemical reaction

$$
\mathrm{Pb}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q) \longrightarrow \mathrm{PbSO}_{4}(s)
$$

What information do we need?
> The limiting reactant

## How do we get there?

1. What are the ions present in the combined solution?

$$
\mathrm{Na}^{+} \quad \mathrm{SO}_{4}^{2-} \quad \mathrm{Pb}^{2+} \quad \mathrm{NO}_{3}^{-}
$$

What is the reaction?
Since $\mathrm{NaNO}_{3}$ is soluble and $\mathrm{PbSO}_{4}$ is insoluble, solid $\mathrm{PbSO}_{4}$ will form.
2. What is the balanced net ionic equation for the reaction?

$$
\mathrm{Pb}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q) \longrightarrow \mathrm{PbSO}_{4}(s)
$$

3. What are the moles of reactants present in the solution?

$$
\begin{aligned}
1.25 \mathrm{~K} \times \frac{0.0500 \mathrm{~mol} \mathrm{~Pb}^{2+}}{L} & =0.0625 \mathrm{~mol} \mathrm{~Pb}^{2+} \\
2.00 \mathrm{~K} \times \frac{0.0250 \mathrm{~mol} \mathrm{SO}_{4}^{2-}}{L} & =0.0500 \mathrm{~mol} \mathrm{SO}_{4}^{2-}
\end{aligned}
$$

4. Which reactant is limiting?

Because $\mathrm{Pb}^{2+}$ and $\mathrm{SO}_{4}{ }^{2-}$ react in a $1: 1$ ratio, the amount of $\mathrm{SO}_{4}{ }^{2-}$ will be limiting ( $0.0500 \mathrm{~mol} \mathrm{SO}_{4}{ }^{2-}$ is less than 0.0625 mole of $\mathrm{Pb}^{2+}$ ).
5. What number of moles of $\mathrm{PbSO}_{4}$ will be formed?

Since $\mathrm{SO}_{4}{ }^{2-}$ is limiting, only 0.0500 mole of solid $\mathrm{PbSO}_{4}$ will be formed.
6. What mass of $\mathrm{PbSO}_{4}$ will be formed?
$\square 0.0500 \mathrm{~mol} \mathrm{PbSO}_{4} \times \frac{303.3 \mathrm{~g} \mathrm{PbSO}_{4}}{1 \mathrm{~mol} \mathrm{PbSO}_{4}}=15.2 \mathrm{~g} \mathrm{PbSO}_{4}$

## See Exercises 4.63 and 4.64

### 4.8 Acid-Base Reactions

The Brønsted-Lowry concept of acids and bases will be discussed in detail in Chapter 14.

Earlier in this chapter we considered Arrhenius's concept of acids and bases: An acid is a substance that produces $\mathrm{H}^{+}$ions when dissolved in water, and a base is a substance that produces $\mathrm{OH}^{-}$ions. Although these ideas are fundamentally correct, it is convenient to have a more general definition of a base, which includes substances that do not contain $\mathrm{OH}^{-}$ions. Such a definition was provided by Johannes N. Brønsted (1879-1947) and Thomas M. Lowry (1874-1936), who defined acids and bases as follows:

An acid is a proton donor.
A base is a proton acceptor.
How do we know when to expect an acid-base reaction? One of the most difficult tasks for someone inexperienced in chemistry is to predict what reaction might occur when two solutions are mixed. With precipitation reactions, we found that the best way
to deal with this problem is to focus on the species actually present in the mixed solution. This idea also applies to acid-base reactions. For example, when an aqueous solution of hydrogen chloride $(\mathrm{HCl})$ is mixed with an aqueous solution of sodium hydroxide $(\mathrm{NaOH})$, the combined solution contains the ions $\mathrm{H}^{+}, \mathrm{Cl}^{-}, \mathrm{Na}^{+}$, and $\mathrm{OH}^{-}$. The separated ions are present because HCl is a strong acid and NaOH is a strong base. How can we predict what reaction occurs, if any? First, will NaCl precipitate? From Table 4.1 we can see that NaCl is soluble in water and thus will not precipitate. Therefore, the $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions are spectator ions. On the other hand, because water is a nonelectrolyte, large quantities of $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ions cannot coexist in solution. They react to form $\mathrm{H}_{2} \mathrm{O}$ molecules:

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

This is the net ionic equation for the reaction that occurs when aqueous solutions of HCl and NaOH are mixed.

Next, consider mixing an aqueous solution of acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$ with an aqueous solution of potassium hydroxide ( KOH ). In our earlier discussion of conductivity we said that an aqueous solution of acetic acid is a weak electrolyte. This tells us that acetic acid does not dissociate into ions to any great extent. In fact, in $0.1 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ approximately $99 \%$ of the $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ molecules remain undissociated. However, when solid KOH is dissolved in water, it dissociates completely to produce $\mathrm{K}^{+}$and $\mathrm{OH}^{-}$ions. Therefore, in the solution formed by mixing aqueous solutions of $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and KOH , before any reaction occurs, the principal species are $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \mathrm{~K}^{+}$, and $\mathrm{OH}^{-}$. What reaction will occur? A possible precipitation reaction could occur between $\mathrm{K}^{+}$and $\mathrm{OH}^{-}$. However, we know that KOH is soluble, so precipitation does not occur. Another possibility is a reaction involving the hydroxide ion (a proton acceptor) and some proton donor. Is there a source of protons in the solution? The answer is yes-the $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ molecules. The $\mathrm{OH}^{-}$ion has such a strong affinity for protons that it can strip them from the $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ molecules. The net ionic equation for this reaction is

$$
\mathrm{OH}^{-}(a q)+\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)
$$

This reaction illustrates a very important general principle: The hydroxide ion is such a strong base that for purposes of stoichiometric calculations it can be assumed to react completely with any weak acid that we will encounter. Of course, $\mathrm{OH}^{-}$ions also react completely with the $\mathrm{H}^{+}$ions in solutions of strong acids.

We will now deal with the stoichiometry of acid-base reactions in aqueous solutions. The procedure is fundamentally the same as that used previously for precipitation reactions.

## PROBLEM-SOLVING STRATEGY

## Performing Calculations for Acid-Base Reactions

1. List the species present in the combined solution before any reaction occurs, and decide what reaction will occur.
2. Write the balanced net ionic equation for this reaction.
3. Calculate the moles of reactants. For reactions in solution, use the volumes of the original solutions and their molarities.
4. Determine the limiting reactant where appropriate.
5. Calculate the moles of the required reactant or product.
6. Convert to grams or volume (of solution), as required.

An acid-base reaction is often called a neutralization reaction. When just enough base is added to react exactly with the acid in a solution, we say the acid has been neutralized.

## INTERACTIVE EXAMPLE 4.12 Neutralization Reactions I

## SOLUTION

What volume of a $0.100-M \mathrm{HCl}$ solution is needed to neutralize 25.0 mL of 0.350 M NaOH ?

## Where are we going?

To find the volume of 0.100 M HCl required for neutralization

## What do we know?

> 25 mL of 0.350 M NaOH
> 0.100 M HCl
> The chemical reaction

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

How do we get there?
Use the Problem-Solving Strategy for Performing Calculations for Acid-Base Reactions.

1. What are the ions present in the combined solution?

$$
\mathrm{H}^{+} \quad \mathrm{Cl}^{-} \quad \mathrm{Na}^{+} \quad \mathrm{OH}^{-}
$$

What is the reaction?
The two possibilities are

$$
\begin{aligned}
& \mathrm{Na}^{+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{NaCl}(s) \\
& \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

Since we know that NaCl is soluble, the first reaction does not take place $\left(\mathrm{Na}^{+}\right.$and $\mathrm{Cl}^{-}$
are spectator ions). However, as we have seen before, the reaction of the $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ ions to form $\mathrm{H}_{2} \mathrm{O}$ does occur.
2. What is the balanced net ionic equation for the reaction?

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

3. What are the moles of reactant present in the solution?

$$
25.0 \mathrm{mLNaOH} \times \frac{1 \mathrm{~K}}{1000 \mathrm{mt}} \times \frac{0.350 \mathrm{~mol} \mathrm{OH}^{-}}{\mathrm{LNaOH}}=8.75 \times 10^{-3} \mathrm{~mol} \mathrm{OH}^{-}
$$

4. Which reactant is limiting?

This problem requires the addition of just enough $\mathrm{H}^{+}$to react exactly with the $\mathrm{OH}^{-}$ions present. We do not need to be concerned with limiting reactant here.
5. What moles of $\mathrm{H}^{+}$are needed?

Since $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ions react in a $1: 1$ ratio, $8.75 \times 10^{-3}$ mole of $\mathrm{H}^{+}$is required to neutralize the $\mathrm{OH}^{-}$ions present.
6. What volume of HCl is required?

$$
V \times \frac{0.100 \mathrm{~mol} \mathrm{H}^{+}}{\mathrm{L}}=8.75 \times 10^{-3} \mathrm{~mol} \mathrm{H}^{+}
$$

Solving for $V$ gives

$$
V=\frac{8.75 \times 10^{-3} \mathrm{moH}^{+}}{\frac{0.100 \mathrm{molH}^{+}}{\mathrm{L}}}=8.75 \times 10^{-2} \mathrm{~L}
$$

## INTERACTIVE EXAMPLE 4.13 Neutralization Reactions II

## SOLUTION Where are we going?

To find the concentration of $\mathrm{H}^{+}$or $\mathrm{OH}^{-}$in excess after the reaction is complete

## What do we know?

> 28.0 mL of $0.250 \mathrm{M} \mathrm{HNO}_{3}$
> 53.0 mL of 0.320 M KOH
> The chemical reaction

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

## How do we get there?

Use the Problem-Solving Strategy for Performing Calculations for Acid-Base Reactions.

1. What are the ions present in the combined solution?

$$
\mathrm{H}^{+} \quad \mathrm{NO}_{3}^{-} \quad \mathrm{K}^{+} \quad \mathrm{OH}^{-}
$$

2. What is the balanced net ionic equation for the reaction?

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

3. What are the moles of reactant present in the solution?

$$
\begin{aligned}
& 28.0 \mathrm{mLHNO}_{3} \times \frac{1 \mathrm{~L}}{1000 \mathrm{mt}} \times \frac{0.250 \mathrm{~mol} \mathrm{H}^{+}}{\mathrm{LHNO}_{3}}=7.00 \times 10^{-3} \mathrm{~mol} \mathrm{H}^{+} \\
& 53.0 \mathrm{~mL} \mathrm{KOH} \times \frac{1 \mathrm{~K}}{1000 \mathrm{mt}} \times \frac{0.320 \mathrm{~mol} \mathrm{OH}^{-}}{\mathrm{LKOH}}=1.70 \times 10^{-2} \mathrm{~mol} \mathrm{OH}^{-}
\end{aligned}
$$

4. Which reactant is limiting?

Since $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ions react in a $1: 1$ ratio, the limiting reactant is $\mathrm{H}^{+}$.
5. What amount of $\mathrm{OH}^{-}$will react?
$7.00 \times 10^{-3}$ mole of $\mathrm{OH}^{-}$is required to neutralize the $\mathrm{H}^{+}$ions present.
What amount of $\mathrm{OH}^{-}$ions are in excess?
The amount of $\mathrm{OH}^{-}$ions in excess is obtained from the following difference:

$$
\text { Original amount }- \text { amount consumed }=\text { amount in excess }
$$

$1.70 \times 10^{-2} \mathrm{~mol} \mathrm{OH}^{-}-7.00 \times 10^{-3} \mathrm{~mol} \mathrm{OH}^{-}=1.00 \times 10^{-2} \mathrm{~mol} \mathrm{OH}^{-}$
What is the volume of the combined solution?
The volume of the combined solution is the sum of the individual volumes:
Original volume of $\mathrm{HNO}_{3}+$ original volume of $\mathrm{KOH}=$ total volume

$$
28.0 \mathrm{~mL}+53.0 \mathrm{~mL}=81.0 \mathrm{~mL}=8.10 \times 10^{-2} \mathrm{~L}
$$

6. What is the molarity of the $\mathrm{OH}^{-}$ions in excess?

$$
\frac{\mathrm{mol} \mathrm{OH}^{-}}{\mathrm{L} \text { solution }}=\frac{1.00 \times 10^{-2} \mathrm{~mol} \mathrm{OH}^{-}}{8.10 \times 10^{-2} \mathrm{~L}}=0.123 \mathrm{M} \mathrm{OH}^{-}
$$

Reality Check This calculated molarity is less than the initial molarity, as it should be.

Ideally, the endpoint and stoichiometric point should coincide.

## Acid-Base Titrations

Volumetric analysis is a technique for determining the amount of a certain substance by doing a titration. A titration involves delivery (from a buret) of a measured volume of a solution of known concentration (the titrant) into a solution containing the substance being analyzed (the analyte). The titrant contains a substance that reacts in a known manner with the analyte. The point in the titration where enough titrant has been added to react exactly with the analyte is called the equivalence point or the stoichiometric point. This point is often marked by an indicator, a substance added at the beginning of the titration that changes color at (or very near) the equivalence point. The point where the indicator actually changes color is called the endpoint of the titration. The goal is to choose an indicator such that the endpoint (where the indicator changes color) occurs exactly at the equivalence point (where just enough titrant has been added to react with all the analyte).

## Requirements for a Successful Titration

\# The exact reaction between titrant and analyte must be known (and rapid).
" The stoichiometric (equivalence) point must be marked accurately.
\# The volume of titrant required to reach the stoichiometric point must be known accurately.

When the analyte is a base or an acid, the required titrant is a strong acid or strong base, respectively. This procedure is called an acid-base titration. An indicator very commonly used for acid-base titrations is phenolphthalein, which is colorless in an acidic solution and pink in a basic solution. Thus, when an acid is titrated with a base, the phenolphthalein remains colorless until after the acid is consumed and the first drop of excess base is added. In this case, the endpoint (the solution changes from colorless to pink) occurs approximately one drop of base beyond the stoichiometric point. This type of titration is illustrated in Fig. 4.18.

We will deal with the acid-base titrations only briefly here but will return to the topic of titrations and indicators in more detail in Chapter 15. The titration of an acid with a standard solution containing hydroxide ions is described in Example 4.15. In Example 4.14 we show how to determine accurately the concentration of a sodium hydroxide solution. This procedure is called standardizing the solution.

## INTERACTIVE EXAMPLE 4.14 Neutralization Titration

A student carries out an experiment to standardize (determine the exact concentration of) a sodium hydroxide solution. To do this, the student weighs out a $1.3009-\mathrm{g}$ sample of potassium hydrogen phthalate $\left(\mathrm{KHC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}\right.$, often abbreviated KHP). KHP (molar mass $204.22 \mathrm{~g} / \mathrm{mol}$ ) has one acidic hydrogen. The student dissolves the KHP in distilled water, adds phenolphthalein as an indicator, and titrates the resulting solution with the sodium hydroxide solution to the phenolphthalein endpoint. The difference between the final and initial buret readings indicates that 41.20 mL of the sodium hydroxide solution is required to react exactly with the 1.3009 g KHP. Calculate the concentration of the sodium hydroxide solution.

## SOLUTION Where are we going?

To find the concentration of NaOH solution

## What do we know?

> $1.3009 \mathrm{~g} \mathrm{KHC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}$ (KHP), molar mass ( $204.22 \mathrm{~g} / \mathrm{mol}$ )
> 41.20 mL NaOH solution to neutralize KHP

FIGURE 4. 18 The titration of an acid with a base. (a) The titrant (the base) is in the buret, and the flask contains the acid solution along with a small amount of indicator. (b) As base is added drop by drop to the acid solution in the flask during the titration, the indicator changes color, but the color disappears on mixing. (c) The stoichiometric (equivalence) point is marked by a permanent indicator color change. The volume of base added is the difference between the final and initial buret readings.
) The chemical reaction

$$
\mathrm{HC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}^{-}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{C}_{8} \mathrm{H}_{4} \mathrm{O}_{4}{ }^{2-}(a q)
$$

How do we get there?
Use the Problem-Solving Strategy for Performing Calculations for Acid-Base Reactions.

1. What are the ions present in the combined solution?

$$
\mathrm{K}^{+} \quad \mathrm{HC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}^{-} \quad \mathrm{Na}^{+} \quad \mathrm{OH}^{-}
$$

2. What is the balanced net ionic equation for the reaction?

$$
\mathrm{HC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}^{-}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{C}_{8} \mathrm{H}_{4} \mathrm{O}_{4}^{2-}(a q)
$$

3. What are the moles of KHP?

$$
1.3009 \mathrm{~g} \mathrm{KHC}_{8} \mathrm{H}_{4} \mathrm{O}_{4} \times \frac{1 \mathrm{~mol} \mathrm{KHC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}}{204.22 \mathrm{~g} \mathrm{KHC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}}=6.3701 \times 10^{-3} \mathrm{~mol} \mathrm{KHC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}
$$

4. Which reactant is limiting?

This problem requires the addition of just enough $\mathrm{OH}^{-}$ions to react exactly with the KHP present. We do not need to be concerned with limiting reactant here.

## 5. What moles of $\mathrm{OH}^{-}$are required?

$6.3701 \times 10^{-3} \mathrm{~mole}^{2}$ of $\mathrm{OH}^{-}$is required to neutralize the KHP present.
6. What is the molarity of the NaOH solution?

$$
\text { - Molarity of } \begin{aligned}
\mathrm{NaOH} & =\frac{\mathrm{mol} \mathrm{NaOH}}{\mathrm{~L} \text { solution }}=\frac{6.3701 \times 10^{-3} \mathrm{~mol} \mathrm{NaOH}}{4.120 \times 10^{-2} \mathrm{~L}} \\
& =0.1546 \mathrm{M}
\end{aligned}
$$

This standard sodium hydroxide solution can now be used in other experiments (see Example 4.15).

## See Exercises 4.79 and 4.84

## INTERACTIVE EXAMPLE 4.15

## Neutralization Analysis

An environmental chemist analyzed the effluent (the released waste material) from an industrial process known to produce the compounds carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$ and benzoic acid $\left(\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}\right)$, a weak acid that has one acidic hydrogen atom per molecule. A sample of this effluent weighing 0.3518 g was shaken with water, and the resulting aqueous solution required 10.59 mL of 0.1546 M NaOH for neutralization. Calculate the mass percent of $\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}$ in the original sample.

## SOLUTION

## Where are we going?

To find the mass percent of $\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}$ in the original sample

## What do we know?

> 0.3518 g effluent (original sample)
> 10.59 mL 0.1546 M NaOH for neutralization of $\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}$
) The chemical reaction

$$
\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{C}_{7} \mathrm{H}_{5} \mathrm{O}_{2}^{-}(a q)
$$

How do we get there?
Use the Problem-Solving Strategy for Performing Calculations for Acid-Base Reactions.

1. What are the species present in the combined solution?

$$
\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2} \quad \mathrm{Na}^{+} \quad \mathrm{OH}^{-}
$$

2. What is the balanced net ionic equation for the reaction?

$$
\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{C}_{7} \mathrm{H}_{5} \mathrm{O}_{2}^{-}(a q)
$$

3. What are the moles of $\mathrm{OH}^{-}$required?

$$
10.59 \mathrm{~mL} \mathrm{NaOH} \times \frac{1 屯}{1000 \mathrm{mt}} \times \frac{0.1546 \mathrm{~mol} \mathrm{OH}^{-}}{\mathrm{LNaOH}}=1.637 \times 10^{-3} \mathrm{~mol} \mathrm{OH}^{-}
$$

4. Which reactant is limiting?

This problem requires the addition of just enough $\mathrm{OH}^{-}$ions to react exactly with the $\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}$ present. We do not need to be concerned with limiting reactant here.
5. What mass of $\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}$ is present?

$$
1.637 \times 10^{-3} \mathrm{~mol} \mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2} \times \frac{122.12 \mathrm{~g} \mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}}{1 \mathrm{~mol} \mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}}=0.1999 \mathrm{~g} \mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}
$$

6. What is the mass percent of the $\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}$ in the effluent?

$$
\frac{0.1999 \mathrm{~g}}{0.3518 \mathrm{~g}} \times 100 \%=56.82 \%
$$

Reality Check The calculated percent of $\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}$ is less than $100 \%$, as it should be.

## See Exercise 4.83

The first step in the analysis of a complex solution is to write down the components and focus on the chemistry of each one. When a strong electrolyte is present, write it as separated ions.

In doing problems involving titrations, you must first decide what reaction is occurring. Sometimes this seems difficult because the titration solution contains several components. The key to success in doing solution reactions is to first write down all the components in the solution and focus on the chemistry of each one. We have been emphasizing this approach in dealing with the reactions between ions in solution. Make it a habit to write down the components of solutions before trying to decide what reaction(s) might take place as you attempt the end-of-chapter problems involving titrations.

### 4.9 Oxidation-Reduction Reactions

We have seen that many important substances are ionic. Sodium chloride, for example, can be formed by the reaction of elemental sodium and chlorine:

$$
2 \mathrm{Na}(s)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NaCl}(s)
$$

In this reaction, solid sodium, which contains neutral sodium atoms, reacts with chlorine gas, which contains diatomic $\mathrm{Cl}_{2}$ molecules, to form the ionic solid NaCl , which contains $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions. This process is represented in Fig. 4.19. Reactions like this one, in which one or more electrons are transferred, are called oxidation-reduction reactions or redox reactions.

Many important chemical reactions involve oxidation and reduction. Photosynthesis, which stores energy from the sun in plants by converting carbon dioxide and water to sugar, is a very important oxidation-reduction reaction. In fact, most reactions used for energy production are redox reactions. In humans, the oxidation of sugars, fats, and proteins provides the energy necessary for life. Combustion reactions, which provide most of the energy to power our civilization, also involve oxidation and reduction. An example is the reaction of methane with oxygen:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)+\text { energy }
$$

Even though none of the reactants or products in this reaction is ionic, the reaction is still assumed to involve a transfer of electrons from carbon to oxygen. To explain this, we must introduce the concept of oxidation states.

## Oxidation States

The concept of oxidation states (also called oxidation numbers) provides a way to keep track of electrons in oxidation-reduction reactions, particularly redox reactions involving covalent substances. Recall that electrons are shared by atoms in covalent bonds. The oxidation states of atoms in covalent compounds are obtained by arbitrarily assigning the

FIGURE 4.19 The reaction of solid sodium and gaseous chlorine to form solid sodium chloride.
electrons (which are actually shared) to particular atoms. We do this as follows: For a covalent bond between two identical atoms, the electrons are split equally between the two. In cases where two different atoms are involved (and the electrons are thus shared unequally), the shared electrons are assigned completely to the atom that has the stronger attraction for electrons. For example, recall from the discussion of the water molecule in Section 4.1 that oxygen has a greater attraction for electrons than does hydrogen. Therefore, in assigning the oxidation state of oxygen and hydrogen in $\mathrm{H}_{2} \mathrm{O}$, we assume that the oxygen atom actually possesses all the electrons. Recall that a hydrogen atom has one electron. Thus, in water, oxygen has formally "taken" the electrons from two hydrogen atoms. This gives the oxygen an excess of two electrons (its oxidation state is -2 ) and leaves each hydrogen with no electrons (the oxidation state of each hydrogen is thus +1 ).

We define the oxidation states (or oxidation numbers) of the atoms in a covalent compound as the imaginary charges the atoms would have if the shared electrons were divided equally between identical atoms bonded to each other or, for different atoms, were all assigned to the atom in each bond that has the greater attraction for electrons. Of course, for ionic compounds containing monatomic ions, the oxidation states of the ions are equal to the ion charges.

These considerations lead to a series of rules for assigning oxidation states that are summarized in Table 4.2. Application of these simple rules allows the assignment of oxidation states in most compounds. To apply these rules, recognize that the sum of the oxidation states must be zero for an electrically neutral compound. For an ion, the sum of the oxidation states must equal the charge of the ion. The principles are illustrated by Example 4.16.

It is worthwhile to note at this point that the convention is to write actual charges on ions as $n+$ or $n-$, the number being written before the plus or minus sign. On the other hand, oxidation states (not actual charges) are written $+n$ or $-n$, the number being written after the plus or minus sign.

## TABLE 4.2 \| Rules for Assigning Oxidation States

| The Oxidation State of ... | Summary | Examples |
| :---: | :---: | :---: |
| - An atom in an element is zero | Element: 0 | $\mathrm{Na}(\mathrm{s}), \mathrm{O}_{2}(\mathrm{~g}), \mathrm{O}_{3}(\mathrm{~g}), \mathrm{Hg}(\mathrm{l})$ |
| - A monatomic ion is the same as its charge | Monatomic ion: charge of ion | $\mathrm{Na}^{+}, \mathrm{Cl}^{-}$ |
| - Fluorine is -1 in its compounds | Fluorine: - 1 | HF, $\mathrm{PF}_{3}$ |
| - Oxygen is usually -2 in its compounds Exception: peroxides (containing $\mathrm{O}_{2}{ }^{2-}$ ), in which oxygen is -1 | Oxygen: - 2 | $\mathrm{H}_{2} \mathrm{O}, \mathrm{CO}_{2}$ |
| - Hydrogen is +1 in its covalent compounds | Hydrogen: +1 | $\mathrm{H}_{2} \mathrm{O}, \mathrm{HCl}, \mathrm{NH}_{3}$ |

## INTERACTIVE EXAMPLE 4.16 Assigning Oxidation States

Assign oxidation states to all atoms in the following.
a. $\mathrm{CO}_{2}$
b. $\mathrm{SF}_{6}$
c. $\mathrm{NO}_{3}{ }^{-}$

## SOLUTION

a. Since we have a specific rule for the oxidation state of oxygen, we will assign its value first. The oxidation state of oxygen is -2 . The oxidation state of the carbon atom can be determined by recognizing that since $\mathrm{CO}_{2}$ has no charge, the sum of the oxidation states for oxygen and carbon must be zero. Since each oxygen is -2 and there are two oxygen atoms, the carbon atom must be assigned an oxidation state of +4 :

Reality Check We can check the assigned oxidation states by noting that when the number of atoms is taken into account, the sum is zero as required:

b. Since we have no rule for sulfur, we first assign the oxidation state of each fluorine as -1 . The sulfur must then be assigned an oxidation state of +6 to balance the total of -6 from the fluorine atoms:

Reality Check $+6+6(-1)=0$
c. Oxygen has an oxidation state of -2 . Because the sum of the oxidation states of the three oxygens is -6 and the net charge on the $\mathrm{NO}_{3}{ }^{-}$ion is $1-$, the nitrogen must have an oxidation state of +5 :

$$
\begin{gathered}
{ }_{7} \mathrm{NO}_{3}^{-} \\
+5 \\
+5
\end{gathered}
$$

A
Magnetite is a magnetic ore containing $\mathrm{Fe}_{3} \mathrm{O}_{4}$. Note that the compass needle points toward the ore.

A helpful mnemonic device is OIL RIG (Oxidation Involves Loss; Reduction Involves Gain). Another common mnemonic is LEO says GER. (Loss of Electrons, Oxidation; Gain of Electrons, Reduction).

Reality Check $+5+3(-2)=-1$
Note that in this case the sum must be -1 (the overall charge on the ion).

## See Exercises 4.85 through 4.88

We need to make one more point about oxidation states, and this can be illustrated by the compound $\mathrm{Fe}_{3} \mathrm{O}_{4}$, which is the main component in magnetite, an iron ore that accounts for the reddish color of many types of rocks and soils. To determine the oxidation states in $\mathrm{Fe}_{3} \mathrm{O}_{4}$, we first assign each oxygen atom its usual oxidation state of -2 . The three iron atoms must yield a total of +8 to balance the total of -8 from the four oxygens. This means that each iron atom has an oxidation state of $+\frac{8}{3}$. A noninteger value for the oxidation state may seem strange because charge is expressed in whole numbers. However, although they are rare, noninteger oxidation states do occur because of the rather arbitrary way that electrons are divided up by the rules in Table 4.2. $\mathrm{For}_{\mathrm{Fe}}^{3} \mathrm{O}_{4}$, for example, the rules assume that all the iron atoms are equal, when in fact this compound can best be viewed as containing four $\mathrm{O}^{2-}$ ions, two $\mathrm{Fe}^{3+}$ ions, and one $\mathrm{Fe}^{2+}$ ion per formula unit. (Note that the "average" charge on iron works out to be $\frac{8}{3}+$, which is equal to the oxidation state we determined above.) Noninteger oxidation states should not intimidate you. They are used in the same way as integer oxidation states-for keeping track of electrons.

## The Characteristics of Oxidation-Reduction Reactions

Oxidation-reduction reactions are characterized by a transfer of electrons. In some cases, the transfer occurs in a literal sense to form ions, such as in the reaction

$$
2 \mathrm{Na}(s)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NaCl}(s)
$$

However, sometimes the transfer is less obvious. For example, consider the combustion of methane (the oxidation state for each atom is given):

Note that the oxidation state for oxygen in $\mathrm{O}_{2}$ is 0 because it is in elemental form. In this reaction there are no ionic compounds, but we can still describe the process in terms of a transfer of electrons. Note that carbon undergoes a change in oxidation state from -4 in $\mathrm{CH}_{4}$ to +4 in $\mathrm{CO}_{2}$. Such a change can be accounted for by a loss of eight electrons (the symbol $\mathrm{e}^{-}$stands for an electron):

On the other hand, each oxygen changes from an oxidation state of 0 in $\mathrm{O}_{2}$ to -2 in $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$, signifying a gain of two electrons per atom. Since four oxygen atoms are involved, this is a gain of eight electrons:

No change occurs in the oxidation state of hydrogen, and it is not formally involved in the electron-transfer process.

With this background, we can now define some important terms. Oxidation is an increase in oxidation state (a loss of electrons). Reduction is a decrease in oxidation state (a gain of electrons). Thus in the reaction

FIGURE 4.20 A summary of an oxidation-reduction process, in which M is oxidized and X is reduced.
sodium is oxidized and chlorine is reduced. In addition, $\mathrm{Cl}_{2}$ is called the oxidizing agent (electron acceptor), and Na is called the reducing agent (electron donor). These terms are summarized in Fig. 4.20.

Concerning the reaction
we can say the following:
Methane is oxidized because there has been an increase in carbon's oxidation state (the carbon atom has formally lost electrons).

Oxygen is reduced because there has been a decrease in its oxidation state (oxygen has formally gained electrons).
$\mathrm{CH}_{4}$ is the reducing agent.
$\mathrm{O}_{2}$ is the oxidizing agent.
Note that when the oxidizing or reducing agent is named, the whole compound is specified, not just the element that undergoes the change in oxidation state.

## INTERACTIVE EXAMPLE 4.17

Oxidation is an increase in oxidation state. Reduction is a decrease in oxidation state.

An oxidizing agent is reduced and a reducing agent is oxidized in a redox reaction.

## Oxidation-Reduction Reactions

Metallurgy, the process of producing a metal from its ore, always involves oxidationreduction reactions. In the metallurgy of galena $(\mathrm{PbS})$, the principal lead-containing ore, the first step is the conversion of lead sulfide to its oxide (a process called roasting):

$$
2 \mathrm{PbS}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{PbO}(s)+2 \mathrm{SO}_{2}(g)
$$

The oxide is then treated with carbon monoxide to produce the free metal:

$$
\mathrm{PbO}(s)+\mathrm{CO}(g) \longrightarrow \mathrm{Pb}(s)+\mathrm{CO}_{2}(g)
$$

For each reaction, identify the atoms that are oxidized and reduced, and specify the oxidizing and reducing agents.

For the first reaction, we can assign the following oxidation states:

The oxidation state for the sulfur atom increases from -2 to +4 . Thus sulfur is oxidized. The oxidation state for each oxygen atom decreases from 0 to -2 . Oxygen is reduced. The oxidizing agent (that accepts the electrons) is $\mathrm{O}_{2}$, and the reducing agent (that donates electrons) is PbS .

For the second reaction we have

Lead is reduced (its oxidation state decreases from +2 to 0 ), and carbon is oxidized (its oxidation state increases from +2 to +4 ). PbO is the oxidizing agent, and CO is the reducing agent.

### 4.10 Balancing Oxidation-Reduction Equations

Oxidation-reduction reactions in aqueous solutions are often complicated, which means that it can be difficult to balance their equations by simple inspection. In this section we will discuss a special technique for balancing the equations of redox reactions that occur in aqueous solutions. It is called the half-reaction method.

## The Half-Reaction Method for Balancing Oxidation-Reduction Reactions in Aqueous Solutions

For oxidation-reduction reactions that occur in aqueous solution, it is useful to separate the reaction into two half-reactions: one involving oxidation and the other involving reduction. For example, consider the unbalanced equation for the oxidationreduction reaction between cerium(IV) ion and $\operatorname{tin}(\mathrm{II})$ ion:

$$
\mathrm{Ce}^{4+}(a q)+\mathrm{Sn}^{2+}(a q) \longrightarrow \mathrm{Ce}^{3+}(a q)+\mathrm{Sn}^{4+}(a q)
$$

This reaction can be separated into a half-reaction involving the substance being reduced,

$$
\mathrm{Ce}^{4+}(a q) \longrightarrow \mathrm{Ce}^{3+}(a q)
$$

and one involving the substance being oxidized,

$$
\mathrm{Sn}^{2+}(a q) \longrightarrow \mathrm{Sn}^{4+}(a q)
$$

The general procedure is to balance the equations for the half-reactions separately and then to add them to obtain the overall balanced equation. The half-reaction method for balancing oxidation-reduction equations differs slightly depending on whether the reaction takes place in acidic or basic solution.

## PROBLEM-SOLVING STRATEGY

The Half-Reaction Method for Balancing Equations for Oxidation-Reduction Reactions Occurring in Acidic Solution

1. Write separate equations for the oxidation and reduction half-reactions.
2. For each half-reaction,
a. balance all the elements except hydrogen and oxygen.
b. balance oxygen using $\mathrm{H}_{2} \mathrm{O}$.
c. balance hydrogen using $\mathrm{H}^{+}$.
d. balance the charge using electrons.
(Box continues on following page)
3. If necessary, multiply one or both balanced half-reactions by an integer to equalize the number of electrons transferred in the two half-reactions.
4. Add the half-reactions, and cancel identical species.
5. Check that the elements and charges are balanced.

We will illustrate this method by balancing the equation for the reaction between permanganate and iron(II) ions in acidic solution:

$$
\mathrm{MnO}_{4}^{-}(a q)+\mathrm{Fe}^{2+}(a q) \xrightarrow{\text { Acid }} \mathrm{Fe}^{3+}(a q)+\mathrm{Mn}^{2+}(a q)
$$

This reaction can be used to analyze iron ore for its iron content.

1. Identify and write equations for the half-reactions. The oxidation states for the half-reaction involving the permanganate ion show that manganese is reduced:

This is the reduction half-reaction. The other half-reaction involves the oxidation of iron(II) to iron(III) ion and is the oxidation half-reaction:

2. Balance each half-reaction. For the reduction reaction, we have

$$
\mathrm{MnO}_{4}^{-}(a q) \longrightarrow \mathrm{Mn}^{2+}(a q)
$$

a. The manganese is balanced.
b. We balance oxygen by adding $4 \mathrm{H}_{2} \mathrm{O}$ to the right side of the equation:

$$
\mathrm{MnO}_{4}^{-}(a q) \longrightarrow \mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

c. Next, we balance hydrogen by adding $8 \mathrm{H}^{+}$to the left side:

$$
8 \mathrm{H}^{+}(a q)+\mathrm{MnO}_{4}^{-}(a q) \longrightarrow \mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

The number of electrons gained in the reduction half-reaction must equal the number of electrons lost in the oxidation half-reaction.
d. All the elements have been balanced, but we need to balance the charge using electrons. At this point we have the following overall charges for reactants and products in the reduction half-reaction:

We can equalize the charges by adding five electrons to the left side:

$$
\underbrace{5 \mathrm{e}^{-}+8 \mathrm{H}^{+}(a q)+\mathrm{MnO}_{4}^{-}(a q)}_{2+} \longrightarrow \underbrace{\mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)}_{2+}
$$

Both the elements and the charges are now balanced, so this represents the balanced reduction half-reaction. The fact that five electrons appear on the reactant side of the equation makes sense, since five electrons are required to reduce $\mathrm{MnO}_{4}^{-}(\mathrm{Mn}$ has an oxidation state of +7$)$ to $\mathrm{Mn}^{2+}(\mathrm{Mn}$ has an oxidation state of +2 ).

For the oxidation reaction

$$
\mathrm{Fe}^{2+}(a q) \longrightarrow \mathrm{Fe}^{3+}(a q)
$$

the elements are balanced, and we must simply balance the charge:

$$
\underbrace{\mathrm{Fe}^{2+}(a q)}_{2+} \longrightarrow \underbrace{\mathrm{Fe}^{3+}(a q)}_{3+}
$$

One electron is needed on the right side to give a net $2+$ charge on both sides:

$$
\underbrace{\mathrm{Fe}^{2+}(a q)}_{2+} \longrightarrow \underbrace{\mathrm{Fe}^{3+}(a q)+\mathrm{e}^{-}}_{2+}
$$

3. Equalize the electron transfer in the two half-reactions. Since the reduction halfreaction involves a transfer of five electrons and the oxidation half-reaction involves a transfer of only one electron, the oxidation half-reaction must be multiplied by 5 :

$$
5 \mathrm{Fe}^{2+}(a q) \longrightarrow 5 \mathrm{Fe}^{3+}(a q)+5 \mathrm{e}^{-}
$$

4. Add the half-reactions. The half-reactions are added to give

$$
\begin{aligned}
5 \mathrm{e}^{-}+5 \mathrm{Fe}^{2+}(a q)+\mathrm{MnO}_{4}^{-}(a q)+ & 8 \mathrm{H}^{+}(a q) \longrightarrow \\
& 5 \mathrm{Fe}^{3+}(a q)+\mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)+5 \mathrm{e}^{-}
\end{aligned}
$$

Note that the electrons cancel (as they must) to give the final balanced equation:

$$
5 \mathrm{Fe}^{2+}(a q)+\mathrm{MnO}_{4}^{-}(a q)+8 \mathrm{H}^{+}(a q) \longrightarrow 5 \mathrm{Fe}^{3+}(a q)+\mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

5. Check that elements and charges are balanced.

Elements balance: $\quad 5 \mathrm{Fe}, 1 \mathrm{Mn}, 4 \mathrm{O}, 8 \mathrm{H} \longrightarrow 5 \mathrm{Fe}, 1 \mathrm{Mn}, 4 \mathrm{O}, 8 \mathrm{H}$
Charges balance: $\quad 5(2+)+(1-)+8(1+)=17+\longrightarrow(2+)+0=17+$
The equation is balanced.

## INTERACTIVE EXAMPLE 4.18 <br> Balancing Oxidation-Reduction Reactions (Acidic)

Potassium dichromate $\left(\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}\right)$ is a bright orange compound that can be reduced to a blue-violet solution of $\mathrm{Cr}^{3+}$ ions. Under certain conditions, $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ reacts with ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ as follows:

$$
\mathrm{H}^{+}(a q)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l) \longrightarrow \mathrm{Cr}^{3+}(a q)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Balance this equation using the half-reaction method.

## A

When potassium dichromate reacts with ethanol, a blue-violet solution containing $\mathrm{Cr}^{3+}$ is formed.

1. The reduction half-reaction is

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \longrightarrow \mathrm{Cr}^{3+}(a q)
$$

Chromium is reduced from an oxidation state of +6 in $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ to one of +3 in $\mathrm{Cr}^{3+}$.

The oxidation half-reaction is

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\mathrm{l}) \longrightarrow \mathrm{CO}_{2}(g)
$$

Carbon is oxidized from an oxidation state of -2 in $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ to +4 in $\mathrm{CO}_{2}$.
2. Balancing all elements except hydrogen and oxygen in the first half-reaction, we have

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \longrightarrow 2 \mathrm{Cr}^{3+}(a q)
$$

Balancing oxygen using $\mathrm{H}_{2} \mathrm{O}$, we have

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l)
$$

Balancing hydrogen using $\mathrm{H}^{+}$, we have

$$
14 \mathrm{H}^{+}(a q)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l)
$$

Balancing the charge using electrons, we have

$$
6 \mathrm{e}^{-}+14 \mathrm{H}^{+}(a q)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l)
$$

Next, we turn to the oxidation half-reaction

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l) \longrightarrow \mathrm{CO}_{2}(g)
$$

Balancing carbon, we have

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l) \longrightarrow 2 \mathrm{CO}_{2}(g)
$$

Balancing oxygen using $\mathrm{H}_{2} \mathrm{O}$, we have

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{CO}_{2}(g)
$$

Balancing hydrogen using $\mathrm{H}^{+}$, we have

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{CO}_{2}(g)+12 \mathrm{H}^{+}(a q)
$$

We then balance the charge by adding $12 \mathrm{e}^{-}$to the right side:

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{CO}_{2}(g)+12 \mathrm{H}^{+}(a q)+12 \mathrm{e}^{-}
$$

3. In the reduction half-reaction, there are 6 electrons on the left-hand side, and there are 12 electrons on the right-hand side of the oxidation half-reaction. Thus we multiply the reduction half-reaction by 2 to give

$$
12 \mathrm{e}^{-}+28 \mathrm{H}^{+}(a q)+2 \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \longrightarrow 4 \mathrm{Cr}^{3+}(a q)+14 \mathrm{H}_{2} \mathrm{O}(l)
$$

## Reduction Half-Reaction: <br> Oxidation Half-Reaction: <br> Complete Reaction:

4. Adding the half-reactions and canceling identical species, we have

$$
\begin{aligned}
12 \mathrm{e}^{-}+28 \mathrm{H}^{+}(a q)+2 \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) & \longrightarrow 4 \mathrm{Cr}^{3+}(a q)+14 \mathrm{H}_{2} \mathrm{O}(l) \\
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+3 \mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{CO}_{2}(g)+12 \mathrm{H}^{+}(a q)+12 \mathrm{e}^{-} \\
\hline 16 \mathrm{H}^{+}(a q)+2 \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l) & \longrightarrow 4 \mathrm{Cr}^{3+}+11 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{CO}_{2}(g)
\end{aligned}
$$

5. Check that elements and charges are balanced.

Elements balance: $22 \mathrm{H}, 4 \mathrm{Cr}, 15 \mathrm{O}, 2 \mathrm{C} \longrightarrow 22 \mathrm{H}, 4 \mathrm{Cr}, 15 \mathrm{O}, 2 \mathrm{C}$
Charges balance: $+16+2(-2)+0=+12 \longrightarrow 4(+3)+0+0=+12$

## See Exercises 4.91 and 4.92

Oxidation-reduction reactions can occur in basic solutions (the reactions involve $\mathrm{OH}^{-}$ions) as well as in acidic solutions (the reactions involve $\mathrm{H}^{+}$ions). The halfreaction method for balancing equations is slightly different for the two cases.

## PROBLEM-SOLVING STRATEGY

The Half-Reaction Method for Balancing Equations for OxidationReduction Reactions Occurring in Basic Solution

1. Use the half-reaction method as specified for acidic solutions to obtain the final balanced equation as if $\mathrm{H}^{+}$ions were present.
2. To both sides of the equation obtained above, add a number of $\mathrm{OH}^{-}$ions that is equal to the number of $\mathrm{H}^{+}$ions. (We want to eliminate $\mathrm{H}^{+}$by forming $\mathrm{H}_{2} \mathrm{O}$.)
3. Form $\mathrm{H}_{2} \mathrm{O}$ on the side containing both $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ions, and eliminate the number of $\mathrm{H}_{2} \mathrm{O}$ molecules that appear on both sides of the equation.
4. Check that elements and charges are balanced.

When balancing redox reactions occurring in basic solutions, the text instructs you to first use the half-reaction method as specified for acidic solutions. What if you started by adding $\mathrm{OH}^{-}$first instead of $\mathrm{H}^{+}$? What potential problem could there be with this approach?

## INTERACTIVE EXAMPLE 4.19 Balancing Oxidation-Reduction Reactions (Basic)

## SOLUTION

## Oxidation Half-Reaction:

Reduction Half-Reaction:
Complete Reaction:

Silver is sometimes found in nature as large nuggets; more often it is found mixed with other metals and their ores. An aqueous solution containing cyanide ion is often used to extract the silver using the following reaction that occurs in basic solution:

$$
\mathrm{Ag}(s)+\mathrm{CN}^{-}(a q)+\mathrm{O}_{2}(g) \xrightarrow{\text { Base }} \mathrm{Ag}(\mathrm{CN})_{2}^{-}(a q)
$$

Balance this equation using the half-reaction method.

1. Balance the equation as if $\mathrm{H}^{+}$ions were present. Balance the oxidation half-reaction:

$$
\mathrm{CN}^{-}(a q)+\mathrm{Ag}(s) \longrightarrow \mathrm{Ag}(\mathrm{CN})_{2}^{-}-(a q)
$$

Balance carbon and nitrogen:

$$
2 \mathrm{CN}^{-}(a q)+\mathrm{Ag}(s) \longrightarrow \mathrm{Ag}(\mathrm{CN})_{2}^{-}(a q)
$$

Balance the charge:

$$
2 \mathrm{CN}^{-}(a q)+\mathrm{Ag}(s) \longrightarrow \mathrm{Ag}(\mathrm{CN})_{2}^{-}(a q)+\mathrm{e}^{-}
$$

Balance the reduction half-reaction:

$$
\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow
$$

Balance oxygen:

$$
\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Balance hydrogen:

$$
\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Balance the charge:

$$
4 \mathrm{e}^{-}+\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Multiply the balanced oxidation half-reaction by 4 :

$$
8 \mathrm{CN}^{-}(a q)+4 \mathrm{Ag}(s) \longrightarrow 4 \mathrm{Ag}(\mathrm{CN})_{2}^{-}(a q)+4 \mathrm{e}^{-}
$$

Add the half-reactions, and cancel identical species:

$$
\begin{aligned}
8 \mathrm{CN}^{-}(a q)+4 \mathrm{Ag}(s) & \longrightarrow 4 \mathrm{Ag}(\mathrm{CN})_{2}^{-}(a q)+4 \mathrm{e}^{-} \\
4 \mathrm{e}^{-}+\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q) & \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) \\
\hline 8 \mathrm{CN}^{-}(a q)+4 \mathrm{Ag}(s)+\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q) & \longrightarrow 4 \mathrm{Ag}(\mathrm{CN})_{2}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

2. Add $\mathrm{OH}^{-}$ions to both sides of the balanced equation to eliminate the $\mathrm{H}^{+}$ions. We need to add $4 \mathrm{OH}^{-}$to each side:

$$
\begin{aligned}
8 \mathrm{CN}^{-}(a q)+4 \mathrm{Ag}(s)+\mathrm{O}_{2}(g)+\underbrace{4 \mathrm{H}^{+}(a q)+4 \mathrm{OH}^{-}(a q)}_{4 \mathrm{H}_{2} \mathrm{O}(l)} \longrightarrow
\end{aligned}
$$

3. Eliminate as many $\mathrm{H}_{2} \mathrm{O}$ molecules as possible:

$$
8 \mathrm{CN}^{-}(a q)+4 \mathrm{Ag}(s)+\mathrm{O}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{Ag}(\mathrm{CN})_{2}^{-}(a q)+4 \mathrm{OH}^{-}(a q)
$$

4. Check that elements and charges are balanced.

$$
\begin{aligned}
& \text { Elements balance: } \quad 8 \mathrm{C}, 8 \mathrm{~N}, 4 \mathrm{Ag}, 4 \mathrm{O}, 4 \mathrm{H} \longrightarrow 8 \mathrm{C}, 8 \mathrm{~N}, 4 \mathrm{Ag}, 4 \mathrm{O}, 4 \mathrm{H} \\
& \text { Charges balance: } 8(1-)+0+0+0=8-\longrightarrow 4(1-)+4(1-)=8-
\end{aligned}
$$

### 4.11 Simple Oxidation-Reduction Titrations

In Section 4.8 we discussed volumetric analysis, specifically acid-base titrations. Oxidation-reduction reactions (discussed in Sections 4.9 and 4.10) can also be used for volumetric analytical procedures. For example, a reducing substance can be titrated with a solution of a strong oxidizing agent or vice versa. Three of the most frequently used oxidizing agents are aqueous solutions of potassium permanganate $\left(\mathrm{KMnO}_{4}\right)$, potassium dichromate $\left(\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}\right)$, and cerium hydrogen sulfate $\left[\mathrm{Ce}\left(\mathrm{HSO}_{4}\right)_{4}\right]$.

The strong oxidizing agent, the permanganate ion $\left(\mathrm{MnO}_{4}^{-}\right)$, can undergo several different reactions. The reaction that occurs in acidic solution is the one most commonly used:

$$
\mathrm{MnO}_{4}^{-}(a q)+8 \mathrm{H}^{+}(a q)+5 \mathrm{e}^{-} \rightarrow \mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

Permanganate has the advantage of being its own indicator-the $\mathrm{MnO}_{4}^{-}$ion is intensely purple, and the $\mathrm{Mn}^{2+}$ ion is almost colorless. As long as some reducing agent remains in the solution being titrated, the solution remains colorless (assuming all other species present are colorless), because the purple $\mathrm{MnO}_{4}^{-}$ion being added is converted to the essentially colorless $\mathrm{Mn}^{2+}$ ion. However, when all the reducing agent has been consumed, the next drop of permanganate titrant will turn the solution being titrated light purple (pink). Thus, the endpoint (where the color change indicates the titration should stop) occurs approximately one drop beyond the stoichiometric point (the actual point at which all the reducing agent has been consumed).

The example problem below describes a typical volumetric analysis using permanganate.

Iron ores often involve a mixture of oxides and contain both $\mathrm{Fe}^{2+}$ and $\mathrm{Fe}^{3+}$ ions. Such an ore can be analyzed for its iron content by dissolving it in acidic solution, reducing all the iron to $\mathrm{Fe}^{2+}$ ions, and then titrating with a standard solution of potassium permanganate. In the resulting solution, $\mathrm{MnO}_{4}^{-}$is reduced to $\mathrm{Mn}^{2+}$, and $\mathrm{Fe}^{2+}$ is oxidized to $\mathrm{Fe}^{3+}$. A sample of iron ore weighing 0.3500 g was dissolved in acidic solution, and all the iron was reduced to $\mathrm{Fe}^{2+}$. Then the solution was titrated with a $1.621 \times 10^{-2} M \mathrm{KMnO}_{4}$ solution. The titration required 41.56 mL of the permanganate solution to reach the light purple (pink) endpoint. Determine the mass percent of iron in the iron ore.

## SOLUTION Where are we going?

We are asked to determine the mass percent of iron in an iron ore.

## How do we get there?

$$
\text { Mass percent of iron }=\frac{\text { mass of iron }}{\text { mass of iron ore }} \times 100 \%
$$

We know that the mass of the mixture is 0.3500 g , so we change the question to "What is the mass of the iron?"

All of the iron metal is converted to $\mathrm{Fe}^{2+}$, which is reacted with a known volume and molarity of $\mathrm{MnO}_{4}^{-}$. From volume and molarity we can get moles, and by using the mole ratio in a balanced equation, we can determine the moles of iron. We convert from moles to mass using the atomic mass of iron.

From the problem it is obvious that this is a redox reaction, so we will need to balance the equation accordingly.

First, we write the unbalanced equation for the reaction:

$$
\mathrm{H}^{+}(a q)+\mathrm{MnO}_{4}^{-}(a q)+\mathrm{Fe}^{2+}(a q) \longrightarrow \mathrm{Fe}^{3+}(a q)+\mathrm{Mn}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Using the half-reaction method, we balance the equation:

$$
8 \mathrm{H}^{+}(a q)+\mathrm{MnO}_{4}^{-}(a q)+5 \mathrm{Fe}^{2+}(a q) \longrightarrow 5 \mathrm{Fe}^{3+}(a q)+\mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

The number of moles of $\mathrm{MnO}_{4}{ }^{-}$ion required in the titration is found from the volume and concentration of permanganate solution used:

$$
41.56 \mathrm{~mL} \times \frac{1 \mathrm{~L}}{1000 \mathrm{~mL}} \times \frac{1.621 \times 10^{-2} \mathrm{~mol} \mathrm{MnO}_{4}^{-}}{\mathrm{L}}=6.737 \times 10-^{4} \mathrm{~mol} \mathrm{MnO}_{4}^{-}
$$

The balanced equation shows that five times as much $\mathrm{Fe}^{2+}$ as $\mathrm{MnO}_{4}{ }^{-}$is required:

$$
6.737 \times 10^{-4} \mathrm{~mol} \mathrm{MnO}_{4}^{-} \times \frac{5 \mathrm{~mol} \mathrm{Fe}^{2+}}{1 \mathrm{~mol} \mathrm{MnO}_{4}^{-}}=3.368 \times 10^{-3} \mathrm{~mol} \mathrm{Fe}^{2+}
$$

Thus the $0.3500-\mathrm{g}$ sample of iron ore contained $3.368 \times 10^{-3}$ mole of iron. The mass of iron present is

$$
3.368 \times 10^{-3} \mathrm{~mol} \mathrm{Fe} \times \frac{55.85 \mathrm{~g} \mathrm{Fe}}{1 \mathrm{~mol} \mathrm{Fe}}=0.1881 \mathrm{~g} \mathrm{Fe}
$$

$\square$ The mass percent of iron in the iron ore is

$$
\frac{0.1881 \mathrm{~g}}{0.3500 \mathrm{~g}} \times 100 \%=53.74 \%
$$

## For Review

## Key terms

## Chemical reactions in solution are very important in everyday life.

## Water is a polar solvent that dissolves many ionic and polar substances.

## Electrolytes

> Strong electrolyte: $100 \%$ dissociated to produce separate ions; strongly conducts an electric current
》 Weak electrolyte: Only a small percentage of dissolved molecules produce ions; weakly conducts an electric current
, Nonelectrolyte: Dissolved substance produces no ions; does not conduct an electric current

## Acids and bases

> Arrhenius model
> Acid: produces $\mathrm{H}^{+}$
> Base: produces $\mathrm{OH}^{-}$
> Brønsted-Lowry model
) Acid: proton donor
> Base: proton acceptor
) Strong acid: completely dissociates into separated $\mathrm{H}^{+}$and anions
> Weak acid: dissociates to a slight extent

## Molarity

> One way to describe solution composition

$$
\operatorname{Molarity}(M)=\frac{\text { moles of solute }}{\text { volume of solution }(\mathrm{L})}
$$

> Moles solute $=$ volume of solution $(\mathrm{L}) \times$ molarity
> Standard solution: molarity is accurately known

## Dilution

> Solvent is added to reduce the molarity
> Moles of solute after dilution $=$ moles of solute before dilution

$$
M_{1} V_{1}=M_{2} V_{2}
$$

## Types of equations that describe solution reactions

, Formula equation: All reactants and products are written as complete formulas
> Complete ionic equation: All reactants and products that are strong electrolytes are written as separated ions
> Net ionic equation: Only those compounds that undergo a change are written; spectator ions are not included

## Solubility rules

> Based on experiment observation
> Help predict the outcomes of precipitation reactions

## Key terms

Section 4.9
oxidation-reduction (redox) reaction
oxidation state
oxidation
reduction
oxidizing agent (electron acceptor)
reducing agent (electron donor)

Section 4.10
half-reaction

## Important types of solution reactions

> Acid-base reactions: involve a transfer of $\mathrm{H}^{+}$ions
) Precipitation reactions: formation of a solid occurs
) Oxidation-reduction reactions: involve electron transfer

## Titrations

> Measures the volume of a standard solution (titrant) needed to react with a substance in solution
> Stoichiometric (equivalence) point: the point at which the required amount of titrant has been added to exactly react with the substance being analyzed
) Endpoint: the point at which a chemical indicator changes color

## Oxidation-reduction reactions

> Oxidation states are assigned using a set of rules to keep track of electron flow
> Oxidation: increase in oxidation state (a loss of electrons)
) Reduction: decrease in oxidation state (a gain of electrons)
> Oxidizing agent: gains electrons (is reduced)
) Reducing agent: loses electrons (is oxidized)
) Equations for oxidation-reduction reactions can be balanced by the oxidation states method

## Review Questions Answers to the Review Questions can be found on the Student website (accessible from www.cengagebrain.com).

1. The ( $a q$ ) designation listed after a solute indicates the process of hydration. Using $\mathrm{KBr}(a q)$ and $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(a q)$ as your examples, explain the process of hydration for soluble ionic compounds and for soluble covalent compounds.
2. Characterize strong electrolytes versus weak electrolytes versus nonelectrolytes. Give examples of each. How do you experimentally determine whether a soluble substance is a strong electrolyte, weak electrolyte, or nonelectrolyte?
3. Distinguish between the terms slightly soluble and weak electrolyte.
4. Molarity is a conversion factor relating moles of solute in solution to the volume of the solution. How does one use molarity as a conversion factor to convert from moles of solute to volume of solution, and from volume of solution to moles of solute present?
5. What is a dilution? What stays constant in a dilution? Explain why the equation $M_{1} V_{1}=M_{2} V_{2}$ works for dilution problems.
6. When the following beakers are mixed, draw a molecular-level representation of the product mixture (see Fig. 4.17).

7. Differentiate between the formula equation, the complete ionic equation, and the net ionic equation. For each reaction in Question 6, write all three balanced equations.
8. What is an acid-base reaction? Strong bases are soluble ionic compounds that contain the hydroxide ion. List the strong bases. When a strong base reacts with an acid, what is always produced? Explain the terms titration, stoichiometric point, neutralization, and standardization.
9. Define the terms oxidation, reduction, oxidizing agent, and reducing agent. Given a chemical reaction, how can you tell if it is a redox reaction?
10. What is a half-reaction? Why must the number of electrons lost in the oxidation half-reaction equal the number of electrons gained in the reduction half-reaction? Summarize briefly the steps in the half-reaction method for balancing redox reactions. What two items must be balanced in a redox reaction (or any reaction)?

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. Assume you have a highly magnified view of a solution of HCl that allows you to "see" the HCl . Draw this magnified view. If you dropped in a piece of magnesium, the magnesium would disappear and hydrogen gas would be released. Represent this change using symbols for the elements, and write out the balanced equation.
2. You have a solution of table salt in water. What happens to the salt concentration (increases, decreases, or stays the same) as the solution boils? Draw pictures to explain your answer.
3. You have a sugar solution (solution $A$ ) with concentration $x$. You pour one-fourth of this solution into a beaker, and add an equivalent volume of water (solution $B$ ).
a. What is the ratio of sugar in solutions $A$ and $B$ ?
b. Compare the volumes of solutions $A$ and $B$.
c. What is the ratio of the concentrations of sugar in solutions $A$ and $B$ ?
4. You add an aqueous solution of lead nitrate to an aqueous solution of potassium iodide. Draw highly magnified views of each solution individually, and the mixed solution, including any product that forms. Write the balanced equation for the reaction.
5. Order the following molecules from lowest to highest oxidation state of the nitrogen atom: $\mathrm{HNO}_{3}, \mathrm{NH}_{4} \mathrm{Cl}, \mathrm{N}_{2} \mathrm{O}, \mathrm{NO}_{2}$, $\mathrm{NaNO}_{2}$.
6. Why is it that when something gains electrons, it is said to be reduced? What is being reduced?
7. Consider separate aqueous solutions of HCl and $\mathrm{H}_{2} \mathrm{SO}_{4}$ with the same molar concentrations. You wish to neutralize an aqueous solution of NaOH . For which acid solution would you need to add more volume (in milliliters) to neutralize the base?
a. the HCl solution
b. the $\mathrm{H}_{2} \mathrm{SO}_{4}$ solution
c. You need to know the acid concentrations to answer this question.
d. You need to know the volume and concentration of the NaOH solution to answer this question.
e. cand d

Explain.
8. Draw molecular-level pictures to differentiate between concentrated and dilute solutions.
9. Draw molecular-level pictures to differentiate between two soluble compounds: one that is a strong electrolyte and one that is a nonelectrolyte.
10. On the basis of the general solubility rules given in Table 4.1, predict the identity of the precipitate that forms when the
following aqueous solutions are mixed. If no precipitate forms, indicate which rules apply.

11. You need to make 150.0 mL of a $0.10-\mathrm{M} \mathrm{NaCl}$ solution. You have solid NaCl , and your lab partner has a $2.5-M \mathrm{NaCl}$ solution. Explain how you each make the $0.10-\mathrm{M} \mathrm{NaCl}$ solution.
12. The exposed electrodes of a light bulb are placed in a solution of $\mathrm{H}_{2} \mathrm{SO}_{4}$ in an electrical circuit such that the light bulb is glowing. You add a dilute salt solution, and the bulb dims. Which of the following could be the salt in the solution?
a. $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$
b. $\mathrm{NaNO}_{3}$
c. $\mathrm{K}_{2} \mathrm{SO}_{4}$
d. $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$

Justify your choices. For those you did not choose, explain why they are incorrect.
13. You have two solutions of chemical A. To determine which has the highest concentration of A (molarity), which of the following must you know (there may be more than one answer)?
a. the mass in grams of A in each solution
b. the molar mass of A
c. the volume of water added to each solution
d. the total volume of the solution

Explain.
14. Which of the following must be known to calculate the molarity of a salt solution (there may be more than one answer)?
a. the mass of salt added
b. the molar mass of the salt
c. the volume of water added
d. the total volume of the solution

Explain.
15. The equation $\mathrm{Ag}^{+}(a q)+\mathrm{Cu}(s) \rightarrow \mathrm{Cu}^{2+}(a q)+\mathrm{Ag}(s)$ has equal numbers of each type of element on each side of the equation. This equation, however, is not balanced. Why is this equation not balanced? Balance the equation.
16. In balancing oxidation-reduction reactions, why is it permissible to add water to either side of the equation?
A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site

## Questions

17. Differentiate between what happens when the following are added to water.
a. polar solute versus nonpolar solute
b. KF versus $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$
c. RbCl versus AgCl
d. $\mathrm{HNO}_{3}$ versus CO
18. A typical solution used in general chemistry laboratories is 3.0 M HCl . Describe, in detail, the composition of 2.0 L of a $3.0-M \mathrm{HCl}$ solution. How would 2.0 L of a $3.0-M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ solution differ from the same quantity of the HCl solution?
19. Which of the following statements is(are) true? For the false statements, correct them.
a. A concentrated solution in water will always contain a strong or weak electrolyte.
b. A strong electrolyte will break up into ions when dissolved in water.
c. An acid is a strong electrolyte.
d. All ionic compounds are strong electrolytes in water.
20. A student wants to prepare 1.00 L of a $1.00-M$ solution of NaOH (molar mass $=40.00 \mathrm{~g} / \mathrm{mol}$ ). If solid NaOH is available, how would the student prepare this solution? If 2.00 M NaOH is available, how would the student prepare the solution? To help ensure three significant figures in the NaOH molarity, to how many significant figures should the volumes and mass be determined?
21. List the formulas of three soluble bromide salts and three insoluble bromide salts. Do the same exercise for sulfate salts, hydroxide salts, and phosphate salts (list three soluble salts and three insoluble salts). List the formulas for six insoluble $\mathrm{Pb}^{2+}$ salts and one soluble $\mathrm{Pb}^{2+}$ salt.
22. When 1.0 mole of solid lead nitrate is added to 2.0 moles of aqueous potassium iodide, a yellow precipitate forms. After the precipitate settles to the bottom, does the solution above the precipitate conduct electricity? Explain. Write the complete ionic equation to help you answer this question.
23. What is an acid and what is a base? An acid-base reaction is sometimes called a proton-transfer reaction. Explain.
24. A student had 1.00 L of a $1.00-M$ acid solution. Much to the surprise of the student, it took 2.00 L of 1.00 M NaOH solution to react completely with the acid. Explain why it took twice as much NaOH to react with all of the acid.

In a different experiment, a student had 10.0 mL of 0.020 M HCl . Again, much to the surprise of the student, it took only 5.00 mL of 0.020 M strong base to react completely with the HCl . Explain why it took only half as much strong base to react with all of the HCl .
25. Differentiate between the following terms.
a. species reduced versus the reducing agent
b. species oxidized versus the oxidizing agent
c. oxidation state versus actual charge
26. When balancing reactions in Chapter 3, we did not mention that reactions must be charge balanced as well as mass balanced. What do charge balance and mass balance mean? How are redox reactions charge balanced?

## Exercises

In this section similar exercises are paired.

## Aqueous Solutions: Strong and Weak Electrolytes

-27. Show how each of the following strong electrolytes "breaks up" into its component ions upon dissolving in water by drawing molecular-level pictures.
a. NaBr
f. $\mathrm{FeSO}_{4}$
b. $\mathrm{MgCl}_{2}$
g. $\mathrm{KMnO}_{4}$
c. $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$
h. $\mathrm{HClO}_{4}$
d. $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$
i. $\mathrm{NH}_{4} \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ (ammo-
e. NaOH nium acetate)
28. Match each name below with the following microscopic pictures of that compound in aqueous solution.

29. Calcium chloride is a strong electrolyte and is used to "salt" streets in the winter to melt ice and snow. Write a reaction to show how this substance breaks apart when it dissolves in water.
30. Commercial cold packs and hot packs are available for treating athletic injuries. Both types contain a pouch of water and a dry chemical. When the pack is struck, the pouch of water breaks, dissolving the chemical, and the solution becomes either hot or cold. Many hot packs use magnesium sulfate, and many cold packs use ammonium nitrate. Write reactions to show how these strong electrolytes break apart when they dissolve in water.

## Solution Concentration: Molarity

-31. Calculate the molarity of each of these solutions.
a. A $5.623-\mathrm{g}$ sample of $\mathrm{NaHCO}_{3}$ is dissolved in enough water to make 250.0 mL of solution.
b. A $184.6-\mathrm{mg}$ sample of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ is dissolved in enough water to make 500.0 mL of solution.
c. A $0.1025-\mathrm{g}$ sample of copper metal is dissolved in 35 mL of concentrated $\mathrm{HNO}_{3}$ to form $\mathrm{Cu}^{2+}$ ions and then water is added to make a total volume of 200.0 mL . (Calculate the molarity of $\mathrm{Cu}^{2+}$.)
32. A solution of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ in water is prepared by dissolving 75.0 mL of ethanol (density $=0.79 \mathrm{~g} / \mathrm{cm}^{3}$ ) in enough water to make 250.0 mL of solution. What is the molarity of the ethanol in this solution?
-33. Calculate the concentration of all ions present in each of the following solutions of strong electrolytes.
a. 0.100 mole of $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$ in 100.0 mL of solution
b. 2.5 moles of $\mathrm{Na}_{2} \mathrm{SO}_{4}$ in 1.25 L of solution
c. 5.00 g of $\mathrm{NH}_{4} \mathrm{Cl}$ in 500.0 mL of solution
d. $1.00 \mathrm{~g} \mathrm{~K}_{3} \mathrm{PO}_{4}$ in 250.0 mL of solution
34. Calculate the concentration of all ions present in each of the following solutions of strong electrolytes.
a. 0.0200 mole of sodium phosphate in 10.0 mL of solution
b. 0.300 mole of barium nitrate in 600.0 mL of solution
c. 1.00 g of potassium chloride in 0.500 L of solution
d. 132 g of ammonium sulfate in 1.50 L of solution
-35. Which of the following solutions of strong electrolytes contains the largest number of moles of chloride ions: 100.0 mL of $0.30 \mathrm{M} \mathrm{AlCl}_{3}, 50.0 \mathrm{~mL}$ of $0.60 \mathrm{M} \mathrm{MgCl}_{2}$, or 200.0 mL of 0.40 M NaCl ?
36. Which of the following solutions of strong electrolytes contains the largest number of ions: 100.0 mL of 0.100 M NaOH , 50.0 mL of $0.200 M \mathrm{BaCl}_{2}$, or 75.0 mL of $0.150 \mathrm{M} \mathrm{a}_{3} \mathrm{PO}_{4}$ ?

What mass of NaOH is contained in 250.0 mL of a 0.400 M sodium hydroxide solution?
38. If 10. g of $\mathrm{AgNO}_{3}$ is available, what volume of $0.25 \mathrm{M} \mathrm{AgNO}_{3}$ solution can be prepared?
-39. The sodium level in a patient's blood was measured at $137 \mathrm{mmol} / \mathrm{L}$. If 15.0 mL of blood is drawn from this patient, what mass of sodium would be present?
40. High-density lipoprotein (HDL) cholesterol is the "good" cholesterol because adequate levels reduce the risk of heart disease and stroke. HDL levels between 40 . and $59 \mathrm{mg} / \mathrm{dL}$ are typical for a healthy individual. What is this range of HDL cholesterol in units of $\mathrm{mol} / \mathrm{L}$ ? The formula for cholesterol is $\mathrm{C}_{27} \mathrm{H}_{46} \mathrm{O}$.
[41. Describe how you would prepare 2.00 L of each of the following solutions.
a. 0.250 M NaOH from solid NaOH
b. 0.250 M NaOH from 1.00 M NaOH stock solution
c. $0.100 \mathrm{M} \mathrm{K}_{2} \mathrm{CrO}_{4}$ from solid $\mathrm{K}_{2} \mathrm{CrO}_{4}$
d. $0.100 \mathrm{M} \mathrm{K}_{2} \mathrm{CrO}_{4}$ from $1.75 \mathrm{M} \mathrm{K}_{2} \mathrm{CrO}_{4}$ stock solution
42. How would you prepare 1.00 L of a $0.50-M$ solution of each of the following?
a. $\mathrm{H}_{2} \mathrm{SO}_{4}$ from "concentrated" $(18 \mathrm{M})$ sulfuric acid
b. HCl from "concentrated" $(12 \mathrm{M})$ reagent
c. $\mathrm{NiCl}_{2}$ from the salt $\mathrm{NiCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$
d. $\mathrm{HNO}_{3}$ from "concentrated" $(16 \mathrm{M})$ reagent
e. Sodium carbonate from the pure solid
43. A solution is prepared by dissolving 10.8 g ammonium sulfate in enough water to make 100.0 mL of stock solution. A $10.00-\mathrm{mL}$ sample of this stock solution is added to 50.00 mL of water. Calculate the concentration of ammonium ions and sulfate ions in the final solution.
-44. A solution was prepared by mixing 50.00 mL of 0.100 M $\mathrm{HNO}_{3}$ and 100.00 mL of $0.200 \mathrm{M} \mathrm{HNO}_{3}$. Calculate the molarity of the final solution of nitric acid.
-45. Calculate the sodium ion concentration when 70.0 mL of $3.0 M$ sodium carbonate is added to 30.0 mL of 1.0 M sodium bicarbonate.
46. Suppose 50.0 mL of $0.250 \mathrm{M} \mathrm{CoCl}_{2}$ solution is added to 25.0 mL of $0.350 \mathrm{M} \mathrm{NiCl}_{2}$ solution. Calculate the concentration, in moles per liter, of each of the ions present after mixing. Assume that the volumes are additive.
47. A standard solution is prepared for the analysis of fluoxymesterone $\left(\mathrm{C}_{20} \mathrm{H}_{29} \mathrm{FO}_{3}\right)$, an anabolic steroid. A stock solution is first prepared by dissolving 10.0 mg of fluoxymesterone in enough water to give a total volume of 500.0 mL . A $100.0-\mu \mathrm{L}$ aliquot (portion) of this solution is diluted to a final volume of 100.0 mL . Calculate the concentration of the final solution in terms of molarity.
48. A stock solution containing $\mathrm{Mn}^{2+}$ ions was prepared by dissolving 1.584 g pure manganese metal in nitric acid and diluting to a final volume of 1.000 L . The following solutions were then prepared by dilution:

For solution $A, 50.00 \mathrm{~mL}$ of stock solution was diluted to 1000.0 mL .

For solution $B, 10.00 \mathrm{~mL}$ of solution $A$ was diluted to 250.0 mL .

For solution $C, 10.00 \mathrm{~mL}$ of solution $B$ was diluted to 500.0 mL .

Calculate the concentrations of the stock solution and solutions $A, B$, and $C$.

## Precipitation Reactions

49. On the basis of the general solubility rules given in Table 4.1, predict which of the following substances are likely to be soluble in water.
a. aluminum nitrate
b. magnesium chloride
c. rubidium sulfate
d. nickel(II) hydroxide
e. lead(II) sulfide
f. magnesium hydroxide
g. iron(III) phosphate
50. On the basis of the general solubility rules given in Table 4.1, predict which of the following substances are likely to be soluble in water.
a. zinc chloride
e. cobalt(III) sulfide
b. lead(II) nitrate
f. chromium(III) hydroxide
c. lead(II) sulfate
g. magnesium carbonate
d. sodium iodide
h. ammonium carbonate
51. When the following solutions are mixed together, what precipitate (if any) will form?
a. $\mathrm{FeSO}_{4}(a q)+\mathrm{KCl}(a q)$
b. $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}(a q)+\mathrm{Ba}(\mathrm{OH})_{2}(a q)$
c. $\mathrm{CaCl}_{2}(a q)+\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)$
d. $\mathrm{K}_{2} \mathrm{~S}(a q)+\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2}(a q)$
52. When the following solutions are mixed together, what precipitate (if any) will form?
a. $\mathrm{Hg}_{2}\left(\mathrm{NO}_{3}\right)_{2}(a q)+\mathrm{CuSO}_{4}(a q)$
b. $\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2}(a q)+\mathrm{CaCl}_{2}(a q)$
c. $\mathrm{K}_{2} \mathrm{CO}_{3}(a q)+\mathrm{MgI}_{2}(a q)$
d. $\mathrm{Na}_{2} \mathrm{CrO}_{4}(a q)+\mathrm{AlBr}_{3}(a q)$
53. For the reactions in Exercise 51, write the balanced formula equation, complete ionic equation, and net ionic equation. If no precipitate forms, write "No reaction."
$\mathbf{5 4 .}^{\text {54 }}$ For the reactions in Exercise 52, write the balanced formula equation, complete ionic equation, and net ionic equation. If no precipitate forms, write "No reaction."
-55. Write the balanced formula and net ionic equations for the reaction that occurs when the contents of the two beakers are added together. What colors represent the spectator ions in each reaction?
a.

b.

(-) $\mathrm{Co}^{2+}$ - $\mathrm{Cl}^{-}$ ( $\mathrm{Na}^{+}$
c.

54. Give an example how each of the following insoluble ionic compounds could be produced using a precipitation reaction. Write the balanced formula equation for each reaction.
a. $\mathrm{Fe}(\mathrm{OH})_{3}(s)$
b. $\mathrm{Hg}_{2} \mathrm{Cl}_{2}(s)$
c. $\mathrm{PbSO}_{4}(s)$
d. $\mathrm{BaCrO}_{4}(s)$
-57. Write net ionic equations for the reaction, if any, that occurs when aqueous solutions of the following are mixed.
a. ammonium sulfate and barium nitrate
b. lead(II) nitrate and sodium chloride
c. sodium phosphate and potassium nitrate
d. sodium bromide and rubidium chloride
e. copper(II) chloride and sodium hydroxide
55. Write net ionic equations for the reaction, if any, that occurs when aqueous solutions of the following are mixed.
a. chromium(III) chloride and sodium hydroxide
b. silver nitrate and ammonium carbonate
c. copper(II) sulfate and mercury(I) nitrate
d. strontium nitrate and potassium iodide
-59. Separate samples of a solution of an unknown soluble ionic compound are treated with $\mathrm{KCl}, \mathrm{Na}_{2} \mathrm{SO}_{4}$, and NaOH . A precipitate forms only when $\mathrm{Na}_{2} \mathrm{SO}_{4}$ is added. Which cations could be present in the unknown soluble ionic compound?
56. A sample may contain any or all of the following ions: $\mathrm{Hg}_{2}{ }^{2+}$, $\mathrm{Ba}^{2+}$, and $\mathrm{Mn}^{2+}$.
a. No precipitate formed when an aqueous solution of NaCl was added to the sample solution.
b. No precipitate formed when an aqueous solution of $\mathrm{Na}_{2} \mathrm{SO}_{4}$ was added to the sample solution.
c. A precipitate formed when the sample solution was made basic with NaOH .
Which ion or ions are present in the sample solution?
-61. What mass of $\mathrm{Na}_{2} \mathrm{CrO}_{4}$ is required to precipitate all of the silver ions from 75.0 mL of a $0.100-\mathrm{M}$ solution of $\mathrm{AgNO}_{3}$ ?
57. What volume of $0.100 \mathrm{Ma}_{3} \mathrm{PO}_{4}$ is required to precipitate all the lead(II) ions from 150.0 mL of $0.250 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$ ?
58. What mass of iron(III) hydroxide precipitate can be produced by reacting 75.0 mL of 0.105 M iron(III) nitrate with 125 mL of 0.150 M sodium hydroxide?
59. What mass of barium sulfate can be produced when 100.0 mL of a $0.100-M$ solution of barium chloride is mixed with 100.0 mL of a $0.100-M$ solution of iron(III) sulfate?
60. What mass of solid AgBr is produced when 100.0 mL of $0.150 \mathrm{M} \mathrm{AgNO}_{3}$ is added to 20.0 mL of 1.00 M NaBr ?
61. What mass of silver chloride can be prepared by the reaction of 100.0 mL of 0.20 M silver nitrate with 100.0 mL of 0.15 M calcium chloride? Calculate the concentrations of each ion remaining in solution after precipitation is complete.
-67. A $100.0-\mathrm{mL}$ aliquot of 0.200 M aqueous potassium hydroxide is mixed with 100.0 mL of 0.200 M aqueous magnesium nitrate.
a. Write a balanced chemical equation for any reaction that occurs.
b. What precipitate forms?
c. What mass of precipitate is produced?
d. Calculate the concentration of each ion remaining in solution after precipitation is complete.
62. The drawings below represent aqueous solutions. Solution A is 2.00 L of a $2.00-M$ aqueous solution of copper(II) nitrate. Solution B is 2.00 L of a $3.00-\mathrm{M}$ aqueous solution of potassium hydroxide.

a. Draw a picture of the solution made by mixing solutions A and $B$ together after the precipitation reaction takes place. Make sure this picture shows the correct relative volume compared to solutions A and B, and the correct relative number of ions, along with the correct relative amount of solid formed.
b. Determine the concentrations (in $M$ ) of all ions left in solution (from part a) and the mass of solid formed.
63. A $1.42-\mathrm{g}$ sample of a pure compound, with formula $\mathrm{M}_{2} \mathrm{SO}_{4}$, was dissolved in water and treated with an excess of aqueous calcium chloride, resulting in the precipitation of all the sulfate ions as calcium sulfate. The precipitate was collected, dried, and found to weigh 1.36 g . Determine the atomic mass of M , and identify M .
64. You are given a $1.50-\mathrm{g}$ mixture of sodium nitrate and sodium chloride. You dissolve this mixture into 100 mL of water and then add an excess of $0.500 M$ silver nitrate solution. You produce a white solid, which you then collect, dry, and measure. The white solid has a mass of 0.641 g .
a. If you had an extremely magnified view of the solution (to the atomic-molecular level), list the species you would see (include charges, if any).
b. Write the balanced net ionic equation for the reaction that produces the solid. Include phases and charges.
c. Calculate the mass percent of sodium chloride in the original unknown mixture.

## Acid-Base Reactions

-71. Write the balanced formula, complete ionic, and net ionic equations for each of the following acid-base reactions.
a. $\mathrm{HClO}_{4}(a q)+\mathrm{Mg}(\mathrm{OH})_{2}(s) \rightarrow$
b. $\mathrm{HCN}(a q)+\mathrm{NaOH}(a q) \rightarrow$
c. $\mathrm{HCl}(a q)+\mathrm{NaOH}(a q) \rightarrow$
72. Write the balanced formula, complete ionic, and net ionic equations for each of the following acid-base reactions.
a. $\mathrm{HNO}_{3}(a q)+\mathrm{Al}(\mathrm{OH})_{3}(s) \rightarrow$
b. $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)+\mathrm{KOH}(a q) \rightarrow$
c. $\mathrm{Ca}(\mathrm{OH})_{2}(a q)+\mathrm{HCl}(a q) \rightarrow$
[73. Write the balanced formula equation for the acid-base reactions that occur when the following are mixed.
a. potassium hydroxide (aqueous) and nitric acid
b. barium hydroxide (aqueous) and hydrochloric acid
c. perchloric acid $\left[\mathrm{HClO}_{4}(a q)\right]$ and solid iron(III) hydroxide
d. solid silver hydroxide and hydrobromic acid
e. aqueous strontium hydroxide and hydroiodic acid
74. What acid and what base would react in aqueous solution so that the following salts appear as products in the formula equation? Write the balanced formula equation for each reaction.
a. potassium perchlorate
b. cesium nitrate
c. calcium iodide
[75. What volume of each of the following acids will react completely with 50.00 mL of 0.200 M NaOH ?
a. 0.100 M HCl
c. $0.200 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
b. $0.150 \mathrm{M} \mathrm{HNO}_{3}$
(1 acidic hydrogen)
76. What volume of each of the following bases will react completely with 25.00 mL of 0.200 M HCl ?
a. 0.100 M NaOH
b. $0.0500 \mathrm{M} \mathrm{Sr}(\mathrm{OH})_{2}$
c. 0.250 M KOH

Hydrochloric acid ( 75.0 mL of 0.250 M ) is added to 225.0 mL of $0.0550 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ solution. What is the concentration of the excess $\mathrm{H}^{+}$or $\mathrm{OH}^{-}$ions left in this solution?
78. A student mixes four reagents together, thinking that the solutions will neutralize each other. The solutions mixed together are 50.0 mL of 0.100 M hydrochloric acid, 100.0 mL of 0.200 M of nitric acid, 500.0 mL of 0.0100 M calcium hydroxide, and 200.0 mL of 0.100 M rubidium hydroxide. Did the acids and bases exactly neutralize each other? If not, calculate the concentration of excess $\mathrm{H}^{+}$or $\mathrm{OH}^{-}$ions left in solution.
[79. A $25.00-\mathrm{mL}$ sample of hydrochloric acid solution requires 24.16 mL of 0.106 M sodium hydroxide for complete neutralization. What is the concentration of the original hydrochloric acid solution?
80. A $10.00-\mathrm{mL}$ sample of vinegar, an aqueous solution of acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$, is titrated with 0.5062 M NaOH , and 16.58 mL is required to reach the equivalence point.
a. What is the molarity of the acetic acid?
b. If the density of the vinegar is $1.006 \mathrm{~g} / \mathrm{cm}^{3}$, what is the mass percent of acetic acid in the vinegar?
81. What volume of 0.0200 M calcium hydroxide is required to neutralize 35.00 mL of 0.0500 M nitric acid?
82. A $30.0-\mathrm{mL}$ sample of an unknown strong base is neutralized after the addition of 12.0 mL of a $0.150 \mathrm{M} \mathrm{HHN}_{3}$ solution. If the unknown base concentration is 0.0300 M , give some possible identities for the unknown base.
83. A student titrates an unknown amount of potassium hydrogen phthalate $\left(\mathrm{KHC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}\right.$, often abbreviated KHP) with 20.46 mL of a $0.1000-\mathrm{M} \mathrm{NaOH}$ solution. KHP (molar mass $=204.22 \mathrm{~g} /$ mol ) has one acidic hydrogen. What mass of KHP was titrated (reacted completely) by the sodium hydroxide solution?
84. The concentration of a certain sodium hydroxide solution was determined by using the solution to titrate a sample of potassium hydrogen phthalate (abbreviated as KHP). KHP is an acid with one acidic hydrogen and a molar mass of $204.22 \mathrm{~g} /$ mol. In the titration, 34.67 mL of the sodium hydroxide solution was required to react with 0.1082 g KHP. Calculate the molarity of the sodium hydroxide.

## Oxidation-Reduction Reactions

85. Assign oxidation states for all atoms in each of the following compounds.
a. $\mathrm{KMnO}_{4}$
b. $\mathrm{NiO}_{2}$
c. $\mathrm{Na}_{4} \mathrm{Fe}(\mathrm{OH})_{6}$
d. $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}$
e. $\mathrm{P}_{4} \mathrm{O}_{6}$
f. $\mathrm{Fe}_{3} \mathrm{O}_{4}$
g. $\mathrm{XeOF}_{4}$
h. $\mathrm{SF}_{4}$
i. CO
j. $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$
86. Assign oxidation states for all atoms in each of the following compounds.
a. $\mathrm{UO}_{2}{ }^{2+}$
b. $\mathrm{As}_{2} \mathrm{O}_{3}$
c. $\mathrm{NaBiO}_{3}$
d. $\mathrm{As}_{4}$
f. $\mathrm{Mg}_{2} \mathrm{P}_{2} \mathrm{O}_{7}$
g. $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$
h. $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$
i. $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$
-87. Assign the oxidation state for nitrogen in each of the following.
a. $\mathrm{Li}_{3} \mathrm{~N}$
b. $\mathrm{NH}_{3}$
c. $\mathrm{N}_{2} \mathrm{H}_{4}$
d. NO
e. $\mathrm{N}_{2} \mathrm{O}$
f. $\mathrm{NO}_{2}$
g. $\mathrm{NO}_{2}{ }^{-}$
h. $\mathrm{NO}_{3}{ }^{-}$
i. $\mathrm{N}_{2}$
87. Assign oxidation numbers to all the atoms in each of the following.
a. $\mathrm{SrCr}_{2} \mathrm{O}_{7}$
b. $\mathrm{CuCl}_{2}$
c. $\mathrm{O}_{2}$
d. $\mathrm{H}_{2} \mathrm{O}_{2}$
e. $\mathrm{MgCO}_{3}$
f. Ag
g. $\mathrm{PbSO}_{3}$
h. $\mathrm{PbO}_{2}$
i. $\mathrm{Na}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$
j. $\mathrm{CO}_{2}$
k. $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Ce}\left(\mathrm{SO}_{4}\right)_{3}$
l. $\mathrm{Cr}_{2} \mathrm{O}_{3}$
-89. Specify which of the following are oxidation-reduction reactions, and identify the oxidizing agent, the reducing agent, the substance being oxidized, and the substance being reduced.
a. $\mathrm{Cu}(s)+2 \mathrm{Ag}^{+}(a q) \rightarrow 2 \mathrm{Ag}(s)+\mathrm{Cu}^{2+}(a q)$
b. $\mathrm{HCl}(g)+\mathrm{NH}_{3}(g) \rightarrow \mathrm{NH}_{4} \mathrm{Cl}(s)$
c. $\mathrm{SiCl}_{4}(l)+2 \mathrm{H}_{2} \mathrm{O}(l) \rightarrow 4 \mathrm{HCl}(a q)+\mathrm{SiO}_{2}(s)$
d. $\mathrm{SiCl}_{4}(l)+2 \mathrm{Mg}(s) \rightarrow 2 \mathrm{MgCl}_{2}(s)+\mathrm{Si}(s)$
e. $\mathrm{Al}(\mathrm{OH})_{4}^{-}(a q) \rightarrow \mathrm{AlO}_{2}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)$
88. Specify which of the following equations represent oxidationreduction reactions, and indicate the oxidizing agent, the reducing agent, the species being oxidized, and the species being reduced.
a. $\mathrm{CH}_{4}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{g}) \rightarrow \mathrm{CO}(\mathrm{g})+3 \mathrm{H}_{2}(\mathrm{~g})$
b. $2 \mathrm{AgNO}_{3}(a q)+\mathrm{Cu}(s) \rightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(a q)+2 \mathrm{Ag}(s)$
c. $\mathrm{Zn}(s)+2 \mathrm{HCl}(a q) \rightarrow \mathrm{ZnCl}_{2}(a q)+\mathrm{H}_{2}(g)$
d. $2 \mathrm{H}^{+}(a q)+2 \mathrm{CrO}_{4}{ }^{2-}(a q) \rightarrow \mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
-91. Balance the following oxidation-reduction reactions that occur in acidic solution using the half-reaction method.
a. $\mathrm{I}^{-}(a q)+\mathrm{ClO}^{-}(a q) \rightarrow \mathrm{I}_{3}^{-}(a q)+\mathrm{Cl}^{-}(a q)$
b. $\mathrm{As}_{2} \mathrm{O}_{3}(s)+\mathrm{NO}_{3}^{-}(a q) \rightarrow \mathrm{H}_{3} \mathrm{AsO}_{4}(a q)+\mathrm{NO}(g)$
c. $\mathrm{Br}^{-}(a q)+\mathrm{MnO}_{4}^{-}(a q) \rightarrow \mathrm{Br}_{2}(l)+\mathrm{Mn}^{2+}(a q)$
d. $\mathrm{CH}_{3} \mathrm{OH}(a q)+\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}(a q) \rightarrow \mathrm{CH}_{2} \mathrm{O}(a q)+\mathrm{Cr}^{3+}(a q)$
89. Balance the following oxidation-reduction reactions that occur in acidic solution using the half-reaction method.
a. $\mathrm{Cu}(s)+\mathrm{NO}_{3}^{-}(a q) \rightarrow \mathrm{Cu}^{2+}(a q)+\mathrm{NO}(g)$
b. $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+\mathrm{Cl}^{-}(a q) \rightarrow \mathrm{Cr}^{3+}(a q)+\mathrm{Cl}_{2}(g)$
c. $\mathrm{Pb}(s)+\mathrm{PbO}_{2}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \rightarrow \mathrm{PbSO}_{4}(s)$
d. $\mathrm{Mn}^{2+}(a q)+\mathrm{NaBiO}_{3}(s) \rightarrow \mathrm{Bi}^{3+}(a q)+\mathrm{MnO}_{4}^{-}(a q)$
e. $\mathrm{H}_{3} \mathrm{AsO}_{4}(a q)+\mathrm{Zn}(s) \rightarrow \mathrm{AsH}_{3}(g)+\mathrm{Zn}^{2+}(a q)$
-93. Balance the following oxidation-reduction reactions that occur in basic solution.
a. $\mathrm{Al}(s)+\mathrm{MnO}_{4}^{-}(a q) \rightarrow \mathrm{MnO}_{2}(s)+\mathrm{Al}(\mathrm{OH})_{4}{ }^{-}(a q)$
b. $\mathrm{Cl}_{2}(g) \rightarrow \mathrm{Cl}^{-}(a q)+\mathrm{OCl}^{-}(a q)$
c. $\mathrm{NO}_{2}{ }^{-}(a q)+\mathrm{Al}(s) \rightarrow \mathrm{NH}_{3}(\mathrm{~g})+\mathrm{AlO}_{2}{ }^{-}(a q)$
90. Balance the following oxidation-reduction reactions that occur in basic solution.
a. $\mathrm{Cr}(s)+\mathrm{CrO}_{4}{ }^{2-}(a q) \rightarrow \mathrm{Cr}(\mathrm{OH})_{3}(s)$
b. $\mathrm{MnO}_{4}^{-}(a q)+\mathrm{S}^{2-}(a q) \rightarrow \mathrm{MnS}(s)+\mathrm{S}(s)$
c. $\mathrm{CN}^{-}(a q)+\mathrm{MnO}_{4}^{-}(a q) \rightarrow \mathrm{CNO}^{-}(a q)+\mathrm{MnO}_{2}(s)$
91. Chlorine gas was first prepared in 1774 by C. W. Scheele by oxidizing sodium chloride with manganese(IV) oxide. The reaction is

$$
\begin{aligned}
\mathrm{NaCl}(a q)+ & \mathrm{H}_{2} \mathrm{SO}_{4}(a q)+\mathrm{MnO}_{2}(s) \longrightarrow \\
& \mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+\mathrm{MnCl}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Cl}_{2}(g)
\end{aligned}
$$

Balance this equation.
96. Gold metal will not dissolve in either concentrated nitric acid or concentrated hydrochloric acid. It will dissolve, however, in aqua regia, a mixture of the two concentrated acids. The products of the reaction are the $\mathrm{AuCl}_{4}^{-}$ion and gaseous NO. Write a balanced equation for the dissolution of gold in aqua regia.
-97. A solution of permanganate is standardized by titration with oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$. It required 28.97 mL of the permanganate solution to react completely with 0.1058 g of oxalic acid. The unbalanced equation for the reaction is

$$
\mathrm{MnO}_{4}^{-}(a q)+\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q) \xrightarrow{\text { Acidic }} \mathrm{Mn}^{2+}(a q)+\mathrm{CO}_{2}(g)
$$

What is the molarity of the permanganate solution?
98. The iron content of iron ore can be determined by titration with a standard $\mathrm{KMnO}_{4}$ solution. The iron ore is dissolved in HCl , and all the iron is reduced to $\mathrm{Fe}^{2+}$ ions. This solution is then titrated with $\mathrm{KMnO}_{4}$ solution, producing $\mathrm{Fe}^{3+}$ and $\mathrm{Mn}^{2+}$ ions in acidic solution. If it required 38.37 mL of 0.0198 M $\mathrm{KMnO}_{4}$ to titrate a solution made from 0.6128 g of iron ore, what is the mass percent of iron in the iron ore?

- 99. A $50.00-\mathrm{mL}$ sample of solution containing $\mathrm{Fe}^{2+}$ ions is titrated with a $0.0216 \mathrm{M} \mathrm{KnO}_{4}$ solution. It required 20.62 mL of $\mathrm{KMnO}_{4}$ solution to oxidize all the $\mathrm{Fe}^{2+}$ ions to $\mathrm{Fe}^{3+}$ ions by the reaction
$\mathrm{MnO}_{4}^{-}(a q)+\mathrm{Fe}^{2+}(a q) \xrightarrow{\text { Acidic }} \mathrm{Mn}^{2+}(a q)+\mathrm{Fe}^{3+}(a q)$
(Unbalanced)
a. What was the concentration of $\mathrm{Fe}^{2+}$ ions in the sample solution?
b. What volume of $0.0150 M \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ solution would it take to do the same titration? The reaction is

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+\mathrm{Fe}^{2+}(a q) \xrightarrow{\text { Acidic }} \mathrm{Cr}^{3+}(a q)+\mathrm{Fe}^{3+}(a q)
$$

(Unbalanced)
100. The blood alcohol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ level can be determined by titrating a sample of blood plasma with an acidic potassium dichromate solution, resulting in the production of $\mathrm{Cr}^{3+}(a q)$ and carbon dioxide. The reaction can be monitored because the dichromate ion $\left(\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}\right)$ is orange in solution, and the $\mathrm{Cr}^{3+}$ ion is green. The unbalanced redox equation is

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(a q) \rightarrow \mathrm{Cr}^{3+}(a q)+\mathrm{CO}_{2}(g)
$$

If 31.05 mL of 0.0600 M potassium dichromate solution is required to titrate 30.0 g of blood plasma, determine the mass percent of alcohol in the blood.

## Additional Exercises

101. You wish to prepare 1 L of a $0.02-M$ potassium iodate solution. You require that the final concentration be within $1 \%$ of 0.02 M and that the concentration must be known accurately to the fourth decimal place. How would you prepare this solution? Specify the glassware you would use, the accuracy needed for the balance, and the ranges of acceptable masses of $\mathrm{KIO}_{3}$ that can be used.
102. The figures below are molecular-level representations of four aqueous solutions of the same solute. Arrange the solutions from most to least concentrated.

103. An average human being has about 5.0 L of blood in his or her body. If an average person were to eat 32.0 g of sugar (sucrose, $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}, 342.30 \mathrm{~g} / \mathrm{mol}$ ), and all that sugar were dissolved into the bloodstream, how would the molarity of the blood sugar change?
104. A $230 .-\mathrm{mL}$ sample of a $0.275-M \mathrm{CaCl}_{2}$ solution is left on a hot plate overnight; the following morning, the solution is 1.10 M . What volume of water evaporated from the $0.275 \mathrm{M} \mathrm{CaCl}_{2}$ solution?
105. Many plants are poisonous because their stems and leaves contain oxalic acid, $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$, or sodium oxalate, $\mathrm{Na}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$. When ingested, these substances cause swelling of the respiratory tract and suffocation. A standard analysis for determining the amount of oxalate ion, $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}$, in a sample is to precipitate this species as calcium oxalate, which is insoluble in water. Write the net ionic equation for the reaction between sodium oxalate and calcium chloride, $\mathrm{CaCl}_{2}$, in aqueous solution.
106. Many over-the-counter antacid tablets are now formulated using calcium carbonate as the active ingredient, which enables such tablets to also be used as dietary calcium supplements. As an antacid for gastric hyperacidity, calcium carbonate reacts by combining with hydrochloric acid found in the stomach, producing a solution of calcium chloride, converting the stomach acid to water, and releasing carbon dioxide gas (which the person suffering from stomach problems may feel as a "burp"). Write the balanced chemical equation for this process.
107. Using the general solubility rules given in Table 4.1, name three reagents that would form precipitates with each of the following ions in aqueous solution. Write the net ionic equation for each of your suggestions.
a. chloride ion
d. sulfate ion
b. calcium ion
e. mercury(I) ion, $\mathrm{Hg}_{2}{ }^{2+}$
c. iron(III) ion
f. silver ion
108. Consider a $1.50-\mathrm{g}$ mixture of magnesium nitrate and magnesium chloride. After dissolving this mixture in water, 0.500 M silver nitrate is added dropwise until precipitate formation is complete. The mass of the white precipitate formed is 0.641 g .
a. Calculate the mass percent of magnesium chloride in the mixture.
b. Determine the minimum volume of silver nitrate that must have been added to ensure complete formation of the precipitate.
109. A $1.00-\mathrm{g}$ sample of an alkaline earth metal chloride is treated with excess silver nitrate. All of the chloride is recovered as 1.38 g of silver chloride. Identify the metal.
110. A mixture contains only NaCl and $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$. A $1.45-\mathrm{g}$ sample of the mixture is dissolved in water and an excess of NaOH is added, producing a precipitate of $\mathrm{Al}(\mathrm{OH})_{3}$. The precipitate is filtered, dried, and weighed. The mass of the precipitate is 0.107 g . What is the mass percent of $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$ in the sample?
111. The thallium (present as $\mathrm{Tl}_{2} \mathrm{SO}_{4}$ ) in a $9.486-\mathrm{g}$ pesticide sample was precipitated as thallium(I) iodide. Calculate the mass percent of $\mathrm{Tl}_{2} \mathrm{SO}_{4}$ in the sample if 0.1824 g of TII was recovered.
112. A mixture contains only NaCl and $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$. A 0.456 -g sample of the mixture is dissolved in water, and an excess of NaOH is added, producing a precipitate of $\mathrm{Fe}(\mathrm{OH})_{3}$. The precipitate is filtered, dried, and weighed. Its mass is 0.107 g . Calculate the following.
a. the mass of iron in the sample
b. the mass of $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$ in the sample
c. the mass percent of $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$ in the sample
113. A student added 50.0 mL of an NaOH solution to 100.0 mL of 0.400 M HCl . The solution was then treated with an excess of aqueous chromium(III) nitrate, resulting in formation of 2.06 g of precipitate. Determine the concentration of the NaOH solution.
114. Some of the substances commonly used in stomach antacids are $\mathrm{MgO}, \mathrm{Mg}(\mathrm{OH})_{2}$, and $\mathrm{Al}(\mathrm{OH})_{3}$.
a. Write a balanced equation for the neutralization of hydrochloric acid by each of these substances.
b. Which of these substances will neutralize the greatest amount of 0.10 M HCl per gram?
115. Acetylsalicylic acid is the active ingredient in aspirin. It took 35.17 mL of 0.5065 M sodium hydroxide to react completely with 3.210 g of acetylsalicylic acid. Acetylsalicylic acid has one acidic hydrogen. What is the molar mass of acetylsalicylic acid?
116. When hydrochloric acid reacts with magnesium metal, hydrogen gas and aqueous magnesium chloride are produced. What volume of 5.0 M HCl is required to react completely with 3.00 g of magnesium?
117. A $2.20-\mathrm{g}$ sample of an unknown acid (empirical formula $=$ $\mathrm{C}_{3} \mathrm{H}_{4} \mathrm{O}_{3}$ ) is dissolved in 1.0 L of water. A titration required 25.0 mL of 0.500 M NaOH to react completely with all the acid present. Assuming the unknown acid has one acidic proton per molecule, what is the molecular formula of the unknown acid?
118. Carminic acid, a naturally occurring red pigment extracted from the cochineal insect, contains only carbon, hydrogen, and oxygen. It was commonly used as a dye in the first half of the nineteenth century. It is $53.66 \% \mathrm{C}$ and $4.09 \% \mathrm{H}$ by mass. A titration required 18.02 mL of 0.0406 M NaOH to neutralize 0.3602 g carminic acid. Assuming that there is only one acidic hydrogen per molecule, what is the molecular formula of carminic acid?
119. Chlorisondamine chloride $\left(\mathrm{C}_{14} \mathrm{H}_{20} \mathrm{Cl}_{6} \mathrm{~N}_{2}\right)$ is a drug used in the treatment of hypertension. A $1.28-\mathrm{g}$ sample of a medication containing the drug was treated to destroy the organic material and to release all the chlorine as chloride ion. When the filtered solution containing chloride ion was treated with an excess of silver nitrate, 0.104 g silver chloride was recovered. Calculate the mass percent of chlorisondamine chloride in the medication, assuming the drug is the only source of chloride.
120. Saccharin $\left(\mathrm{C}_{7} \mathrm{H}_{5} \mathrm{NO}_{3} \mathrm{~S}\right)$ is sometimes dispensed in tablet form. Ten tablets with a total mass of 0.5894 g were dissolved in water. The saccharin was oxidized to convert all the sulfur to sulfate ion, which was precipitated by adding an excess of barium chloride solution. The mass of $\mathrm{BaSO}_{4}$ obtained was 0.5032 g . What is the average mass of saccharin per tablet? What is the average mass percent of saccharin in the tablets?
121. Douglasite is a mineral with the formula $2 \mathrm{KCl} \cdot \mathrm{FeCl}_{2}$. $2 \mathrm{H}_{2} \mathrm{O}$. Calculate the mass percent of douglasite in a $455.0-\mathrm{mg}$ sample if it took 37.20 mL of a $0.1000-\mathrm{M} \mathrm{AgNO}_{3}$ solution to precipitate all the $\mathrm{Cl}^{-}$as AgCl . Assume the douglasite is the only source of chloride ion.
122. Many oxidation-reduction reactions can be balanced by inspection. Try to balance the following reactions by inspection. In each reaction, identify the substance reduced and the substance oxidized.
a. $\mathrm{Al}(s)+\mathrm{HCl}(a q) \rightarrow \mathrm{AlCl}_{3}(a q)+\mathrm{H}_{2}(g)$
b. $\mathrm{CH}_{4}(g)+\mathrm{S}(s) \rightarrow \mathrm{CS}_{2}(l)+\mathrm{H}_{2} \mathrm{~S}(g)$
c. $\mathrm{C}_{3} \mathrm{H}_{8}(g)+\mathrm{O}_{2}(g) \rightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)$
d. $\mathrm{Cu}(s)+\mathrm{Ag}^{+}(a q) \rightarrow \mathrm{Ag}(s)+\mathrm{Cu}^{2+}(a q)$
123. One of the classic methods for determining the manganese content in steel involves converting all the manganese to the deeply colored permanganate ion and then measuring the absorption of light. The steel is first dissolved in nitric acid, producing the manganese(II) ion and nitrogen dioxide gas. This solution is then reacted with an acidic solution containing the periodate ion; the products are the permanganate and iodate ions. Write balanced chemical equations for both of these steps.

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
124. Calculate the concentration of all ions present when 0.160 g of $\mathrm{MgCl}_{2}$ is dissolved in 100.0 mL of solution.
125. A solution is prepared by dissolving 0.6706 g oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ in enough water to make 100.0 mL of solution. A $10.00-\mathrm{mL}$ aliquot (portion) of this solution is then diluted to a final volume of 250.0 mL . What is the final molarity of the oxalic acid solution?
126. For the following chemical reactions, determine the precipitate produced when the two reactants listed below are mixed together. Indicate "none" if no precipitate will form.

|  | Formula of Precipitate |
| :---: | :---: |
| $\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})+\mathrm{K}_{3} \mathrm{PO}_{4}(\mathrm{aq}) \longrightarrow$ | (s) |
| $\mathrm{K}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{AgNO}_{3}(\mathrm{aq}) \longrightarrow$ | (s) |
| $\mathrm{NaCl}(\mathrm{aq})+\mathrm{KNO}_{3}(\mathrm{aq}) \longrightarrow$ | (s) |
| $\mathrm{KCl}(\mathrm{aq})+\mathrm{AgNO}_{3}(\mathrm{aq}) \longrightarrow$ | _(s) |
| $\mathrm{FeCl}_{3}(\mathrm{aq})+\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq}) \longrightarrow$ | (s) |

127. What volume of 0.100 M NaOH is required to precipitate all of the nickel(II) ions from 150.0 mL of a $0.249-M$ solution of $\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2}$ ?
128. A $500.0-\mathrm{mL}$ sample of $0.200 M$ sodium phosphate is mixed with 400.0 mL of 0.289 M barium chloride. What is the mass of the solid produced?
129. A $450.0-\mathrm{mL}$ sample of a $0.257-M$ solution of silver nitrate is mixed with 400.0 mL of 0.200 M calcium chloride. What is the concentration of $\mathrm{Cl}^{-}$in solution after the reaction is complete?
130. The zinc in a $1.343-\mathrm{g}$ sample of a foot powder was precipitated as $\mathrm{ZnNH}_{4} \mathrm{PO}_{4}$. Strong heating of the precipitate yielded $0.4089 \mathrm{~g} \mathrm{Zn}_{2} \mathrm{P}_{2} \mathrm{O}_{7}$. Calculate the mass percent of zinc in the sample of foot powder.
131. A $50.00-\mathrm{mL}$ sample of aqueous $\mathrm{Ca}(\mathrm{OH})_{2}$ requires 34.66 mL of a $0.944-M$ nitric acid for neutralization. Calculate the concentration (molarity) of the original solution of calcium hydroxide.
132. When organic compounds containing sulfur are burned, sulfur dioxide is produced. The amount of $\mathrm{SO}_{2}$ formed can be determined by the reaction with hydrogen peroxide:

$$
\mathrm{H}_{2} \mathrm{O}_{2}(a q)+\mathrm{SO}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)
$$

The resulting sulfuric acid is then titrated with a standard NaOH solution. A $1.302 \mathrm{-g}$ sample of coal is burned and the $\mathrm{SO}_{2}$ is collected in a solution of hydrogen peroxide. It took 28.44 mL of a $0.1000-\mathrm{M} \mathrm{NaOH}$ solution to titrate the resulting sulfuric acid. Calculate the mass percent of sulfur in the coal sample. Sulfuric acid has two acidic hydrogens.
133. Assign the oxidation state for the element listed in each of the following compounds:

|  | Oxidation State |
| :--- | :--- |
| S in $\mathrm{MgSO}_{4}$ |  |
| Pb in $\mathrm{PbSO}_{4}$ |  |
| O in $\mathrm{O}_{2}$ |  |
| Ag in Ag |  |
| Cu in $\mathrm{CuCl}_{2}$ |  |

## Challenge Problems

134. A $10.00-\mathrm{g}$ sample consisting of a mixture of sodium chloride and potassium sulfate is dissolved in water. This aqueous mixture then reacts with excess aqueous lead(II) nitrate to form 21.75 g of solid. Determine the mass percent of sodium chloride in the original mixture.
135. The units of parts per million (ppm) and parts per billion (ppb) are commonly used by environmental chemists. In general, 1 ppm means 1 part of solute for every $10^{6}$ parts of solution. Mathematically, by mass:

$$
\mathrm{ppm}=\frac{\mu \mathrm{g} \text { solute }}{\mathrm{g} \text { solution }}=\frac{\mathrm{mg} \text { solute }}{\mathrm{kg} \text { solution }}
$$

In the case of very dilute aqueous solutions, a concentration of 1.0 ppm is equal to $1.0 \mu \mathrm{~g}$ of solute per 1.0 mL , which equals 1.0 g solution. Parts per billion is defined in a similar fashion. Calculate the molarity of each of the following aqueous solutions.
a. 5.0 ppb Hg in $\mathrm{H}_{2} \mathrm{O}$
b. $1.0 \mathrm{ppb} \mathrm{CHCl}_{3}$ in $\mathrm{H}_{2} \mathrm{O}$
c. 10.0 ppm As in $\mathrm{H}_{2} \mathrm{O}$
d. 0.10 ppm DDT $\left(\mathrm{C}_{14} \mathrm{H}_{9} \mathrm{Cl}_{5}\right)$ in $\mathrm{H}_{2} \mathrm{O}$
136. In the spectroscopic analysis of many substances, a series of standard solutions of known concentration are measured to generate a calibration curve. How would you prepare standard solutions containing $10.0,25.0,50.0,75.0$, and 100 . ppm of copper from a commercially produced $1000.0-\mathrm{ppm}$ solution? Assume each solution has a final volume of 100.0 mL . (See Exercise 135 for definitions.)
137. In most of its ionic compounds, cobalt is either Co (II) or Co (III). One such compound, containing chloride ion and waters of hydration, was analyzed, and the following results were obtained. A $0.256-\mathrm{g}$ sample of the compound was dissolved in water, and excess silver nitrate was added. The silver chloride was filtered, dried, and weighed, and it had a mass of 0.308 g . A second sample of 0.416 g of the compound was dissolved in water, and an excess of sodium hydroxide was added. The hydroxide salt was filtered and heated in a flame, forming cobalt(III) oxide. The mass of cobalt(III) oxide formed was 0.145 g .
a. What is the percent composition, by mass, of the compound?
b. Assuming the compound contains one cobalt ion per formula unit, what is the formula?
c. Write balanced equations for the three reactions described.
138. Polychlorinated biphenyls (PCBs) have been used extensively as dielectric materials in electrical transformers. Because PCBs have been shown to be potentially harmful, analysis for their presence in the environment has become very important. PCBs are manufactured according to the following generic reaction:

$$
\mathrm{C}_{12} \mathrm{H}_{10}+n \mathrm{Cl}_{2} \rightarrow \mathrm{C}_{12} \mathrm{H}_{10-n} \mathrm{Cl}_{n}+n \mathrm{HCl}
$$

This reaction results in a mixture of PCB products. The mixture is analyzed by decomposing the PCBs and then precipitating the resulting $\mathrm{Cl}^{-}$as AgCl .
a. Develop a general equation that relates the average value of $n$ to the mass of a given mixture of PCBs and the mass of AgCl produced.
b. A $0.1947-\mathrm{g}$ sample of a commercial PCB yielded 0.4791 g of AgCl . What is the average value of $n$ for this sample?
139. Consider the reaction of 19.0 g of zinc with excess silver nitrite to produce silver metal and zinc nitrite. The reaction is stopped before all the zinc metal has reacted and 29.0 g of solid metal is present. Calculate the mass of each metal in the 29.0-g mixture.
140. A mixture contains only sodium chloride and potassium chloride. A $0.1586-\mathrm{g}$ sample of the mixture was dissolved in water. It took 22.90 mL of $0.1000 \mathrm{M} \mathrm{AgNO}_{3}$ to completely precipitate all the chloride present. What is the composition (by mass percent) of the mixture?
141. You are given a solid that is a mixture of $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and $\mathrm{K}_{2} \mathrm{SO}_{4}$. A $0.205-\mathrm{g}$ sample of the mixture is dissolved in water. An excess of an aqueous solution of $\mathrm{BaCl}_{2}$ is added. The $\mathrm{BaSO}_{4}$ that is formed is filtered, dried, and weighed. Its mass is 0.298 g . What mass of $\mathrm{SO}_{4}{ }^{2-}$ ion is in the sample? What is the mass percent of $\mathrm{SO}_{4}{ }^{2-}$ ion in the sample? What are the percent compositions by mass of $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and $\mathrm{K}_{2} \mathrm{SO}_{4}$ in the sample?
142. Zinc and magnesium metal each react with hydrochloric acid according to the following equations:

$$
\begin{aligned}
\mathrm{Zn}(s)+2 \mathrm{HCl}(a q) & \longrightarrow \mathrm{ZnCl}_{2}(a q)+\mathrm{H}_{2}(g) \\
\mathrm{Mg}(s)+2 \mathrm{HCl}(a q) & \longrightarrow \mathrm{MgCl}_{2}(a q)+\mathrm{H}_{2}(g)
\end{aligned}
$$

A $10.00-\mathrm{g}$ mixture of zinc and magnesium is reacted with the stoichiometric amount of hydrochloric acid. The reaction mixture is then reacted with 156 mL of 3.00 M silver nitrate to produce the maximum possible amount of silver chloride.
a. Determine the percent magnesium by mass in the original mixture.
b. If 78.0 mL of HCl was added, what was the concentration of the HCl ?
143. You made 100.0 mL of a lead(II) nitrate solution for lab but forgot to cap it. The next lab session you noticed that there was only 80.0 mL left (the rest had evaporated). In addition, you forgot the initial concentration of the solution. You decide to take 2.00 mL of the solution and add an excess of a concentrated sodium chloride solution. You obtain a solid with a mass of 3.407 g . What was the concentration of the original lead(II) nitrate solution?
144. Consider reacting copper(II) sulfate with iron. Two possible reactions can occur, as represented by the following equations.

$$
\begin{aligned}
& \text { copper(II) sulfate }(a q)+\operatorname{iron}(s) \longrightarrow \\
& \operatorname{copper}(s)
\end{aligned}+\operatorname{iron}(\text { II }) \text { sulfate }(a q)
$$

You place 87.7 mL of a $0.500-\mathrm{M}$ solution of copper(II) sulfate in a beaker. You then add 2.00 g of iron filings to the copper(II) sulfate solution. After one of the above reactions occurs, you isolate 2.27 g of copper. Which equation above describes the reaction that occurred? Support your answer.
145. Consider an experiment in which two burets, $Y$ and $Z$, are simultaneously draining into a beaker that initially contained 275.0 mL of 0.300 M HCl . Buret Y contains 0.150 M NaOH and buret Z contains 0.250 MKOH . The stoichiometric point in the titration is reached 60.65 minutes after Y and Z were started simultaneously. The total volume in the beaker at the stoichiometric point is 655 mL . Calculate the flow rates of burets Y and Z. Assume the flow rates remain constant during the experiment.
146. Complete and balance each acid-base reaction.
a. $\mathrm{H}_{3} \mathrm{PO}_{4}(a q)+\mathrm{NaOH}(a q) \rightarrow$

Contains three acidic hydrogens
b. $\mathrm{H}_{2} \mathrm{SO}_{4}(a q)+\mathrm{Al}(\mathrm{OH})_{3}(s) \rightarrow$ Contains two acidic hydrogens
c. $\mathrm{H}_{2} \mathrm{Se}(a q)+\mathrm{Ba}(\mathrm{OH})_{2}(a q) \rightarrow$ Contains two acidic hydrogens
d. $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q)+\mathrm{NaOH}(a q) \rightarrow$

Contains two acidic hydrogens
147. What volume of $0.0521 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ is required to neutralize exactly 14.20 mL of $0.141 \mathrm{M} \mathrm{H}_{3} \mathrm{PO}_{4}$ ? Phosphoric acid contains three acidic hydrogens.
148. A $10.00-\mathrm{mL}$ sample of sulfuric acid from an automobile battery requires 35.08 mL of 2.12 M sodium hydroxide solution for complete neutralization. What is the molarity of the sulfuric acid? Sulfuric acid contains two acidic hydrogens.
149. A $0.500-\mathrm{L}$ sample of $\mathrm{H}_{2} \mathrm{SO}_{4}$ solution was analyzed by taking a $100.0-\mathrm{mL}$ aliquot and adding 50.0 mL of 0.213 M NaOH . After the reaction occurred, an excess of $\mathrm{OH}^{-}$ions remained in the solution. The excess base required 13.21 mL of 0.103 M HCl for neutralization. Calculate the molarity of the original sample of $\mathrm{H}_{2} \mathrm{SO}_{4}$. Sulfuric acid has two acidic hydrogens.
150. A $6.50-\mathrm{g}$ sample of a diprotic acid requires 137.5 mL of a $0.750 M \mathrm{NaOH}$ solution for complete neutralization. Determine the molar mass of the acid.
151. Citric acid, which can be obtained from lemon juice, has the molecular formula $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7}$. A $0.250-\mathrm{g}$ sample of citric acid dissolved in 25.0 mL of water requires 37.2 mL of 0.105 M NaOH for complete neutralization. What number of acidic hydrogens per molecule does citric acid have?
152. A stream flows at a rate of $5.00 \times 10^{4}$ liters per second (L/s) upstream of a manufacturing plant. The plant discharges $3.50 \times 10^{3} \mathrm{~L} / \mathrm{s}$ of water that contains 65.0 ppm HCl into the stream. (See Exercise 135 for definitions.)
a. Calculate the stream's total flow rate downstream from this plant.
b. Calculate the concentration of HCl in ppm downstream from this plant.
c. Further downstream, another manufacturing plant diverts $1.80 \times 10^{4} \mathrm{~L} / \mathrm{s}$ of water from the stream for its own use. This plant must first neutralize the acid and does so by adding lime:

$$
\mathrm{CaO}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Ca}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

What mass of CaO is consumed in an 8.00 -h work day by this plant?
d. The original stream water contained $10.2 \mathrm{ppm} \mathrm{Ca}^{2+}$. Although no calcium was in the waste water from the first plant, the waste water of the second plant contains $\mathrm{Ca}^{2+}$ from the neutralization process. If $90.0 \%$ of the water used by the second plant is returned to the stream, calculate the concentration of $\mathrm{Ca}^{2+}$ in ppm downstream of the second plant.
153. It took $25.06 \pm 0.05 \mathrm{~mL}$ of a sodium hydroxide solution to titrate a 0.4016 -g sample of KHP (see Exercise 83). Calculate the concentration and uncertainty in the concentration of the sodium hydroxide solution. (See Appendix 1.5.) Neglect any uncertainty in the mass.
154. Triiodide ions are generated in solution by the following (unbalanced) reaction in acidic solution:

$$
\mathrm{IO}_{3}^{-}(a q)+\mathrm{I}^{-}(a q) \longrightarrow \mathrm{I}_{3}^{-}(a q)
$$

Triiodide ion concentration is determined by titration with a sodium thiosulfate $\left(\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}\right)$ solution. The products are iodide ion and tetrathionate ion $\left(\mathrm{S}_{4} \mathrm{O}_{6}{ }^{2-}\right)$.
a. Balance the equation for the reaction of $\mathrm{IO}_{3}^{-}$with $\mathrm{I}^{-}$ions.
b. A sample of 0.6013 g of potassium iodate was dissolved in water. Hydrochloric acid and solid potassium iodide were then added. What is the minimum mass of solid KI and the minimum volume of 3.00 M HCl required to convert all of the $\mathrm{IO}_{3}{ }^{-}$ions to $\mathrm{I}_{3}{ }^{-}$ions?
c. Write and balance the equation for the reaction of $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$ with $\mathrm{I}_{3}{ }^{-}$in acidic solution.
d. A $25.00-\mathrm{mL}$ sample of a 0.0100 M solution of $\mathrm{KIO}_{3}$ is reacted with an excess of KI. It requires 32.04 mL of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ solution to titrate the $\mathrm{I}_{3}{ }^{-}$ions present. What is the molarity of the $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ solution?
e. How would you prepare 500.0 mL of the $\mathrm{KIO}_{3}$ solution in part d using solid $\mathrm{KIO}_{3}$ ?
155. Chromium has been investigated as a coating for steel cans. The thickness of the chromium film is determined by dissolving a sample of a can in acid and oxidizing the resulting $\mathrm{Cr}^{3+}$ to $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ with the peroxydisulfate ion:

$$
\begin{aligned}
\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}(a q)+ & \mathrm{Cr}^{3+} \\
& (a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}(a q) \\
& +\mathrm{SO}_{4}{ }^{2-}(a q)+\mathrm{H}^{+}(a q) \text { (Unbalanced) }
\end{aligned}
$$

After removal of unreacted $\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}$, an excess of ferrous ammonium sulfate $\left[\mathrm{Fe}\left(\mathrm{NH}_{4}\right)_{2}\left(\mathrm{SO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}\right]$ is added, reacting with $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ produced from the first reaction. The unreacted $\mathrm{Fe}^{2+}$ from the excess ferrous ammonium sulfate is titrated with a separate $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ solution. The reaction is:

$$
\begin{aligned}
\mathrm{H}^{+}(a q)+\mathrm{Fe}^{2+}(a q) & +\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \\
+\mathrm{Cr}^{3+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) & \mathrm{Fe}^{3+}(\text { Unbalanced) }
\end{aligned}
$$

a. Write balanced chemical equations for the two reactions.
b. In one analysis, a $40.0-\mathrm{cm}^{2}$ sample of a chromium-plated can was treated according to this procedure. After dissolution and removal of excess $\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}, 3.000 \mathrm{~g}$ of $\mathrm{Fe}\left(\mathrm{NH}_{4}\right)_{2}\left(\mathrm{SO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ was added. It took 8.58 mL of $0.0520 M \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ solution to completely react with the excess $\mathrm{Fe}^{2+}$. Calculate the thickness of the chromium film on the can. (The density of chromium is $7.19 \mathrm{~g} / \mathrm{cm}^{3}$.)

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
156. Tris(pentafluorophenyl)borane, commonly known by its acronym BARF, is frequently used to initiate polymerization of ethylene or propylene in the presence of a catalytic transition metal compound. It is composed solely of C, F, and B; it is $42.23 \% \mathrm{C}$ and $55.66 \% \mathrm{~F}$ by mass.
a. What is the empirical formula of BARF?
b. A $2.251-\mathrm{g}$ sample of BARF dissolved in 347.0 mL of solution produces a $0.01267-M$ solution. What is the molecular formula of BARF?
157. In a 1-L beaker, 203 mL of 0.307 M ammonium chromate was mixed with 137 mL of 0.269 M chromium(III) nitrite to produce ammonium nitrite and chromium(III) chromate. Write the balanced chemical equation for the reaction occurring here. If the percent yield of the reaction was $88.0 \%$, what mass of chromium(III) chromate was isolated?
158. The vanadium in a sample of ore is converted to $\mathrm{VO}^{2+}$. The $\mathrm{VO}^{2+}$ ion is subsequently titrated with $\mathrm{MnO}_{4}^{-}$in acidic solution to form $\mathrm{V}(\mathrm{OH})_{4}{ }^{+}$and manganese(II) ion. To titrate the solution, 26.45 mL of $0.02250 \mathrm{M} \mathrm{MnO}_{4}{ }^{-}$was required. If the mass percent of vanadium in the ore was $58.1 \%$, what was the mass of the ore sample?
159. The unknown acid $\mathrm{H}_{2} \mathrm{X}$ can be neutralized completely by $\mathrm{OH}^{-}$according to the following (unbalanced) equation:

$$
\mathrm{H}_{2} \mathrm{X}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{X}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

The ion formed as a product, $\mathrm{X}^{2-}$, was shown to have 36 total electrons. What is element X? Propose a name for $\mathrm{H}_{2} \mathrm{X}$. To completely neutralize a sample of $\mathrm{H}_{2} \mathrm{X}, 35.6 \mathrm{~mL}$ of 0.175 M $\mathrm{OH}^{-}$solution was required. What was the mass of the $\mathrm{H}_{2} \mathrm{X}$ sample used?

## Marathon Problems

These problems are designed to incorporate several concepts and techniques into one situation.
160. Three students were asked to find the identity of the metal in a particular sulfate salt. They dissolved a $0.1472-\mathrm{g}$ sample of the salt in water and treated it with excess barium chloride, resulting in the precipitation of barium sulfate. After the precipitate had been filtered and dried, it weighed 0.2327 g .

Each student analyzed the data independently and came to different conclusions. Pat decided that the metal was titanium. Chris thought it was sodium. Randy reported that it was gallium. What formula did each student assign to the sulfate salt?

Look for information on the sulfates of gallium, sodium, and titanium in this text and reference books such as the CRC Handbook of Chemistry and Physics. What further tests would you suggest to determine which student is most likely correct?
161. You have two $500.0-\mathrm{mL}$ aqueous solutions. Solution A is a solution of a metal nitrate that is $8.246 \%$ nitrogen by mass. The ionic compound in solution B consists of potassium, chromium, and oxygen; chromium has an oxidation state of +6 and there are 2 potassiums and 1 chromium in the formula. The masses of the solutes in each of the solutions are the same. When the solutions are added together, a blood-red precipitate forms. After the reaction has gone to completion, you dry the solid and find that it has a mass of 331.8 g .
a. Identify the ionic compounds in solution A and solution B.
b. Identify the blood-red precipitate.
c. Calculate the concentration (molarity) of all ions in the original solutions.
d. Calculate the concentration (molarity) of all ions in the final solution.

The artistry of this sunset over Lamarck Col in California's Sierra Nevada mountains results from reflections on the clouds in our gaseous atmosphere. (Jerry Dodril/Aurora Photos/Getty Images)

### 5.7 Effusion and Diffusion Effusion Diffusion <br> 5.8 Real Gases <br> 5.9 Characteristics of Several Real Gases <br> 5.10 Chemistry in the Atmosphere

 relatively few substances exist in the gaseous state under typical conditions, gases are very important. For example, we live immersed in a gaseous solution. The earth's atmosphere is a mixture of gases that consists mainly of elemental nitrogen $\left(\mathrm{N}_{2}\right)$ and oxygen $\left(\mathrm{O}_{2}\right)$. The atmosphere both supports life and acts as a waste receptacle for the exhaust gases that accompany many industrial processes. The chemical reactions of these waste gases in the atmosphere lead to various types of pollution, including smog and acid rain. The gases in the atmosphere also shield us from harmful radiation from the sun and keep the earth warm by reflecting heat radiation back toward the earth. In fact, there is now great concern that an increase in atmospheric carbon dioxide, a product of the combustion of fossil fuels, is causing a dangerous warming of the earth.In this chapter we will look carefully at the properties of gases. First we will see how measurements of gas properties lead to various types of laws-statements that show how the properties are related to each other. Then we will construct a model to explain why gases behave as they do. This model will show how the behavior of the individual particles of a gas leads to the observed properties of the gas itself (a collection of many, many particles).

The study of gases provides an excellent example of the scientific method in action. It illustrates how observations lead to natural laws, which in turn can be accounted for by models.

### 5.1 Pressure

As a gas, water occupies 1200 times as much space as it does as a liquid at $25^{\circ} \mathrm{C}$ and atmospheric pressure.

FIGURE 5.1 The pressure exerted by the gases in the atmosphere can be demonstrated by boiling water in a large metal can (a) and then turning off the heat and sealing the can. As the can cools, the water vapor condenses, lowering the gas pressure inside the can. This causes the can to crumple (b).

A gas uniformly fills any container, is easily compressed, and mixes completely with any other gas. One of the most obvious properties of a gas is that it exerts pressure on its surroundings. For example, when you blow up a balloon, the air inside pushes against the elastic sides of the balloon and keeps it firm.

As mentioned earlier, the gases most familiar to us form the earth's atmosphere. The pressure exerted by this gaseous mixture that we call air can be dramatically demonstrated by the experiment shown in Fig. 5.1. A small volume of water is placed in a metal can, and the water is boiled, which fills the can with steam. The can is then sealed and allowed to cool. Why does the can collapse as it cools? It is the atmospheric pressure that crumples the can. When the can is cooled after being sealed so that no air can flow in, the water vapor (steam) condenses to a very small volume of liquid water.

FIGURE 5.2 A torricellian barometer. The tube, completely filled with mercury, is inverted in a dish of mercury. Mercury flows out of the tube until the pressure of the column of mercury (shown by the black arrow) "standing on the surface" of the mercury in the dish is equal to the pressure of the air (shown by the purple arrows) on the rest of the surface of the mercury in the dish.

Soon after Torricelli died, a German physicist named Otto von Guericke invented an air pump. In a famous demonstration for the King of Prussia in 1663, Guericke placed two hemispheres together, pumped the air out of the resulting sphere through a valve, and showed that teams of horses could not pull the hemispheres apart. Then, after secretly opening the air valve, Guericke easily separated the hemispheres by hand. The King of Prussia was so impressed that he awarded Guericke a lifetime pension!

As a gas, the water filled the can, but when it is condensed to a liquid, the liquid does not come close to filling the can. The $\mathrm{H}_{2} \mathrm{O}$ molecules formerly present as a gas are now collected in a very small volume of liquid, and there are very few molecules of gas left to exert pressure outward and counteract the air pressure. As a result, the pressure exerted by the gas molecules in the atmosphere smashes the can.

A device to measure atmospheric pressure, the barometer, was invented in 1643 by an Italian scientist named Evangelista Torricelli (1608-1647), who had been a student of Galileo. Torricelli's barometer is constructed by filling a glass tube with liquid mercury and inverting it in a dish of mercury (Fig. 5.2). Notice that a large quantity of mercury stays in the tube. In fact, at sea level the height of this column of mercury averages 760 mm . Why does this mercury stay in the tube, seemingly in defiance of gravity? Figure 5.2 illustrates how the pressure exerted by the atmospheric gases on the surface of mercury in the dish keeps the mercury in the tube.

Atmospheric pressure results from the mass of the air being pulled toward the center of the earth by gravity-in other words, it results from the weight of the air. Changing weather conditions cause the atmospheric pressure to vary, so the height of the column of Hg supported by the atmosphere at sea level varies; it is not always 760 mm . The meteorologist who says a "low" is approaching means that the atmospheric pressure is going to decrease. This condition often occurs in conjunction with a storm.

Atmospheric pressure also varies with altitude. For example, when Torricelli's experiment is done in Breckenridge, Colorado (elevation 9600 feet), the atmosphere supports a column of mercury only about 520 mm high because the air is "thinner." That is, there is less air pushing down on the earth's surface at Breckenridge than at sea level.

## Units of Pressure

Because instruments used for measuring pressure, such as the manometer (Fig. 5.3), often contain mercury, the most commonly used units for pressure are based on the height of the mercury column (in millimeters) that the gas pressure can support. The

FIGURE 5.3 A simple manometer, a device for measuring the pressure of a gas in a container. The pressure of the gas is given by $h$ (the difference in mercury levels) in units of torr (equivalent to mm Hg ). (a) Gas pressure $=$ atmospheric pressure $-h$. (b) Gas pressure $=$ atmospheric pressure $+h$.
$1 \mathrm{~atm}=760 \mathrm{~mm} \mathrm{Hg}$
$=760$ torr
$=101,325 \mathrm{~Pa}$
$=29.92 \mathrm{in} \mathrm{Hg}$
$=14.7 \mathrm{lb} / \mathrm{in}^{2}$
unit $\mathbf{~ m m ~ H g}$ (millimeter of mercury) is often called the torr in honor of Torricelli. The terms torr and mm Hg are used interchangeably by chemists. A related unit for pressure is the standard atmosphere (abbreviated atm):

$$
1 \text { standard atmosphere }=1 \mathrm{~atm}=760 \mathrm{~mm} \mathrm{Hg}=760 \text { torr }
$$

However, since pressure is defined as force per unit area,

$$
\text { Pressure }=\frac{\text { force }}{\text { area }}
$$

the fundamental units of pressure involve units of force divided by units of area. In the SI system, the unit of force is the newton ( N ) and the unit of area is meters squared $\left(\mathrm{m}^{2}\right)$. (For a review of the SI system, see Chapter 1.) Thus the unit of pressure in the SI system is newtons per meter squared ( $\mathrm{N} / \mathrm{m}^{2}$ ) and is called the pascal (Pa). In terms of pascals, the standard atmosphere is

$$
1 \text { standard atmosphere }=101,325 \mathrm{~Pa}
$$

Thus 1 atmosphere is about $10^{5}$ pascals. Since the pascal is so small, and since it is not commonly used in the United States, we will use it sparingly in this book. However, converting from torrs or atmospheres to pascals is straightforward, as shown in Example 5.1.

## INTERACTIVE EXAMPLE 5.1 Pressure Conversions

The pressure of a gas is measured as 49 torr. Represent this pressure in both atmospheres and pascals.

SOLUTION

$$
\begin{array}{r}
49 \mathrm{t} \text { orf } \times \frac{1 \mathrm{~atm}}{760 \mathrm{torf}}=6.4 \times 10^{-2} \mathrm{~atm} \\
6.4 \times 10^{-2} \mathrm{~atm} \times \frac{101,325 \mathrm{~Pa}}{1 \mathrm{~atm}}=6.5 \times 10^{3} \mathrm{~Pa}
\end{array}
$$

## See Exercises 5.41 and 5.42

### 5.2 The Gas Laws of Boyle, Charles, and Avogadro

In this section we will consider several mathematical laws that relate the properties of gases. These laws derive from experiments involving careful measurements of the relevant gas properties. From these experimental results, the mathematical relationships among the properties can be discovered. These relationships are often represented pictorially by means of graphs (plots).

We will take a historical approach to these laws to give you some perspective on the scientific method in action.

## Boyle's Law

The first quantitative experiments on gases were performed by an Irish chemist, Robert Boyle (1627-1691). Using a J-shaped tube closed at one end (Fig. 5.4), which he reportedly set up in the multistory entryway of his house, Boyle studied the relationship between the pressure of the trapped gas and its volume. Representative values from Boyle's experiments are given in Table 5.1. These data show that the product of

FIGURE 5.4 A J-tube similar to the one used by Boyle. When mercury is added to the tube, pressure on the trapped gas is increased, resulting in a decreased volume.

Boyle's law: $V \propto 1 / P$ at constant temperature

Graphing is reviewed in Appendix 1.3.

TABLE 5.1 | Actual Data from Boyle's Experiment

| Pressure (in Hg) | Volume $\left(\mathrm{in}^{3}\right)$ | Pressure $\times$ Volume <br> $\left(\right.$ in $\left.\mathrm{Hg} \times \mathrm{in}^{3}\right)$ |
| :---: | :---: | :---: |
| 117.5 | 12.0 | $14.1 \times 10^{2}$ |
| 87.2 | 16.0 | $14.0 \times 10^{2}$ |
| 70.7 | 20.0 | $14.1 \times 10^{2}$ |
| 58.8 | 24.0 | $14.1 \times 10^{2}$ |
| 44.2 | 32.0 | $14.1 \times 10^{2}$ |
| 35.3 | 40.0 | $14.1 \times 10^{2}$ |
| 29.1 | 48.0 | $14.0 \times 10^{2}$ |
|  |  |  |

the pressure and volume for the trapped air sample is constant within the accuracies of Boyle's measurements (note the third column in Table 5.1). This behavior can be represented by the equation

$$
P V=k
$$

which is called Boyle's law, where $k$ is a constant for a given sample of air at a specific temperature.

It is convenient to represent the data in Table 5.1 by using two different plots. The first type of plot, $P$ versus $V$, forms a curve called a hyperbola [Fig. 5.5(a)]. Looking at this plot, note that as the pressure drops by about half (from 58.8 to 29.1), the volume doubles (from 24.0 to 48.0). In other words, there is an inverse relationship between pressure and volume. The second type of plot can be obtained by rearranging Boyle's law to give

$$
V=\frac{k}{P}=k \frac{1}{P}
$$

which is the equation for a straight line of the type

$$
y=m x+b
$$

where $m$ represents the slope and $b$ is the intercept of the straight line. In this case, $y=V, x=1 / P, m=k$, and $b=0$. Thus a plot of $V$ versus $1 / P$ using Boyle's data gives a straight line with an intercept of zero [Fig. 5.5(b)].

FIGURE 5.5 Plotting Boyle's data from Table 5.1. (a) A plot of $P$ versus $V$ shows that the volume doubles as the pressure is halved. (b) A plot of $V$ versus $1 / P$ gives a straight line. The slope of this line equals the value of the constant $k$.

## INTERACTIVE EXAMPLE 5.2

## SOLUTION

Boyle's law also can be written as

$$
P_{1} V_{1}=P_{2} V_{2}
$$

FIGURE 5.6 A plot of $P V$ versus $P$ for several gases at pressures below 1 atm. An ideal gas is expected to have a constant value of $P V$, as shown by the dotted line. Carbon dioxide shows the largest change in $P V$, and this change is actually quite small: $P V$ changes from about $22.39 \mathrm{~L} \cdot \mathrm{~atm}$ at 0.25 atm to $22.26 \mathrm{~L} \cdot \mathrm{~atm}$ at 1.00 atm . Thus Boyle's law is a good approximation at these relatively low pressures.

In the three centuries since Boyle carried out his studies, the sophistication of measuring techniques has increased tremendously. The results of highly accurate measurements show that Boyle's law holds precisely only at very low pressures. Measurements at higher pressures reveal that $P V$ is not constant but varies as the pressure is varied. Results for several gases at pressures below 1 atm are shown in Fig. 5.6. Note the very small changes that occur in the product $P V$ as the pressure is changed at these low pressures. Such changes become more significant at much higher pressures, where the complex nature of the dependence of $P V$ on pressure becomes more obvious. We will discuss these deviations and the reasons for them in detail in Section 5.8. A gas that strictly obeys Boyle's law is called an ideal gas. We will describe the characteristics of an ideal gas more completely in Section 5.3.

One common use of Boyle's law is to predict the new volume of a gas when the pressure is changed (at constant temperature), or vice versa. Because deviations from Boyle's law are so slight at pressures close to 1 atm, in our calculations we will assume that gases obey Boyle's law (unless stated otherwise).

## Boyle's Law I

Sulfur dioxide $\left(\mathrm{SO}_{2}\right)$, a gas that plays a central role in the formation of acid rain, is found in the exhaust of automobiles and power plants. Consider a $1.53-\mathrm{L}$ sample of gaseous $\mathrm{SO}_{2}$ at a pressure of $5.6 \times 10^{3} \mathrm{~Pa}$. If the pressure is changed to $1.5 \times 10^{4} \mathrm{~Pa}$ at a constant temperature, what will be the new volume of the gas?

## Where are we going?

To calculate the new volume of gas
What do we know?

$$
\begin{array}{ll}
>P_{1}=5.6 \times 10^{3} \mathrm{~Pa} & \\
>P_{2}=1.5 \times 10^{4} \mathrm{~Pa} \\
>V_{1}=1.53 \mathrm{~L} &
\end{array} V_{2}=?
$$

What information do we need?
> Boyle's law

$$
P V=k
$$

## How do we get there?

What is Boyle's law (in a form useful with our knowns)?

$$
P_{1} V_{1}=P_{2} V_{2}
$$

What is $V_{2}$ ?

$$
V_{2}=\frac{P_{1} V_{1}}{P_{2}}=\frac{5.6 \times 10^{3} \mathrm{~Pa} \times 1.53 \mathrm{~L}}{1.5 \times 10^{4} \mathrm{~Pa}}=0.57 \mathrm{~L}
$$

■ The new volume will be 0.57 L .
Reality Check The new volume $(0.57 \mathrm{~L})$ is smaller than the original volume. As pressure increases, the volume should decrease, so our answer is reasonable.

See Exercise 5.47

The fact that the volume decreases in Example 5.2 makes sense because the pressure was increased. To help eliminate errors, make it a habit to check whether an answer to a problem makes physical (common!) sense.

We mentioned before that Boyle's law is only approximately true for real gases. To determine the significance of the deviations, studies of the effect of changing pressure on the volume of a gas are often done, as shown in Example 5.3.

## EXAMPLE 5.3 Boyle's Law II

In a study to see how closely gaseous ammonia obeys Boyle's law, several volume measurements were made at various pressures, using 1.0 mole of $\mathrm{NH}_{3}$ gas at a temperature of $0^{\circ} \mathrm{C}$. Using the results listed below, calculate the Boyle's law constant for $\mathrm{NH}_{3}$ at the various pressures.

| Experiment | Pressure (atm) | Volume (L) |
| :---: | :---: | :---: |
| 1 | 0.1300 | 172.1 |
| 2 | 0.2500 | 89.28 |
| 3 | 0.3000 | 74.35 |
| 4 | 0.5000 | 44.49 |
| 5 | 0.7500 | 29.55 |
| 6 | 1.000 | 22.08 |

## SOLUTION

FIGURE 5.7 A plot of $P V$ versus $P$ for 1 mole of ammonia. The dashed line shows the extrapolation of the data to zero pressure to give the "ideal" value of $P V$ of $22.41 \mathrm{~L} \cdot \mathrm{~atm}$.

To determine how closely $\mathrm{NH}_{3}$ gas follows Boyle's law under these conditions, we calculate the value of $k$ (in $\mathrm{L} \cdot \mathrm{atm}$ ) for each set of values:

| Experiment | 1 | 2 | 3 | 4 | 5 | 6 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $k=P V$ | 22.37 | 22.32 | 22.31 | 22.25 | 22.16 | 22.08 |

Although the deviations from true Boyle's law behavior are quite small at these low pressures, note that the value of $k$ changes regularly in one direction as the pressure is increased. Thus, to calculate the "ideal" value of $k$ for $\mathrm{NH}_{3}$, we can plot $P V$ versus $P$ (Fig. 5.7), and extrapolate (extend the line beyond the experimental points) back to zero pressure, where, for reasons we will discuss later, a gas behaves most ideally. The value of $k$ obtained by this extrapolation is $22.41 \mathrm{~L} \cdot \mathrm{~atm}$. Notice that this is the same value obtained from similar plots for the gases $\mathrm{CO}_{2}, \mathrm{O}_{2}$, and Ne at $0^{\circ} \mathrm{C}$ (see Fig. 5.6).

$$
\text { See Exercise } 5.133
$$

## Charles's Law

In the century following Boyle's findings, scientists continued to study the properties of gases. One of these scientists was a French physicist, Jacques Charles (1746-1823), who was the first person to fill a balloon with hydrogen gas and who made the first solo balloon flight. Charles found in 1787 that the volume of a gas at constant pressure increases linearly with the temperature of the gas. That is, a plot of the volume of a gas (at constant pressure) versus its temperature $\left({ }^{\circ} \mathrm{C}\right)$ gives a straight line. This behavior is shown for samples of several gases in Fig. 5.8. The slopes of the lines in this graph are different because the samples contain different numbers of moles of gas. A very interesting feature of these plots is that the volumes of all the gases extrapolate to zero at the same temperature, $-273^{\circ} \mathrm{C}$. On the Kelvin temperature scale, this point is defined

FIGURE 5.8 Plots of $V$ versus $T\left({ }^{\circ} \mathrm{C}\right)$ for several gases. The solid lines represent experimental measurements of gases. The dashed lines represent extrapolation of the data into regions where these gases would become liquids or solids. Note that the samples of the various gases contain different numbers of moles.

FIGURE 5.9 Plots of $V$ versus $T$ as in Fig. 5.8, except here the Kelvin scale is used for temperature.

Charles's law: $V \propto T$ (expressed in K ) at constant pressure.
as 0 K , which leads to the following relationship between the Kelvin and Celsius scales:

$$
\mathrm{K}={ }^{\circ} \mathrm{C}+273
$$

When the volumes of the gases shown in Fig. 5.8 are plotted versus temperature on the Kelvin scale, the plots in Fig. 5.9 result. In this case, the volume of each gas is directly proportional to temperature and extrapolates to zero when the temperature is 0 K . This behavior is represented by the equation known as Charles's law,

$$
V=b T
$$

where $T$ is in kelvins and $b$ is a proportionality constant.
Before we illustrate the uses of Charles's law, let us consider the importance of 0 K . At temperatures below this point, the extrapolated volumes would become negative. The fact that a gas cannot have a negative volume suggests that 0 K has a special significance. In fact, 0 K is called absolute zero, and there is much evidence to suggest that this temperature cannot be attained. Temperatures of approximately 0.000000001 K have been produced in laboratories, but 0 K has never been reached.

According to Charles's law, the volume of a gas is directly related to its temperature in kelvins at constant pressure and number of moles. What if the volume of a gas was directly related to its temperature in degrees Celsius at constant pressure and number of moles? What differences would you notice?

## INTERACTVE EXAMPLE 5.4 Charles's Law

A sample of gas at $15^{\circ} \mathrm{C}$ and 1 atm has a volume of 2.58 L . What volume will this gas occupy at $38^{\circ} \mathrm{C}$ and 1 atm ?

## SOLUTION Where are we going?

To calculate the new volume of gas

## What do we know?

$$
\begin{array}{ll}
>T_{1}=15^{\circ} \mathrm{C}+273=288 \mathrm{~K} & \\
>T_{2}=38^{\circ} \mathrm{C}+273=311 \mathrm{~K} \\
>V_{1}=2.58 \mathrm{~L} &
\end{array}
$$

Charles's law also can be written as

$$
\frac{V_{1}}{T_{1}}=\frac{V_{2}}{T_{2}}
$$

FIGURE 5.10 These balloons each hold 1.0 L gas at $25^{\circ} \mathrm{C}$ and 1 atm . Each balloon contains 0.041 mole of gas, or $2.5 \times 10^{22}$ molecules.

What information do we need?
》 Charles's law

$$
\frac{V}{T}=b
$$

## How do we get there?

What is Charles's law (in a form useful with our knowns)?

$$
\frac{V_{1}}{T_{1}}=\frac{V_{2}}{T_{2}}
$$

What is $V_{2}$ ?

$$
V_{2}=\left(\frac{T_{2}}{T_{1}}\right) V_{1}=\left(\frac{311 \mathrm{~K}}{288 \mathrm{~K}}\right) 2.58 \mathrm{~L}=2.79 \mathrm{~L}
$$

Reality Check The new volume is greater than the original volume, which makes physical sense because the gas will expand as it is heated.

## See Exercise 5.48

## Avogadro's Law

In Chapter 2 we noted that in 1811 the Italian chemist Avogadro postulated that equal volumes of gases at the same temperature and pressure contain the same number of "particles." This observation is called Avogadro's law, which is illustrated by Fig. 5.10. Stated mathematically, Avogadro's law is

$$
V=a n
$$

where $V$ is the volume of the gas, $n$ is the number of moles of gas particles, and $a$ is a proportionality constant. This equation states that for a gas at constant temperature and pressure, the volume is directly proportional to the number of moles of gas. This relationship is obeyed closely by gases at low pressures.

## INTERACTIVE EXAMPLE 5.5

## SOLUTION

## Avogadro's Law

Suppose we have a 12.2 -L sample containing 0.50 mole of oxygen gas $\left(\mathrm{O}_{2}\right)$ at a pressure of 1 atm and a temperature of $25^{\circ} \mathrm{C}$. If all this $\mathrm{O}_{2}$ were converted to ozone $\left(\mathrm{O}_{3}\right)$ at the same temperature and pressure, what would be the volume of the ozone?

## Where are we going?

To calculate the volume of the ozone produced by 0.50 mole of oxygen
What do we know?

$$
\begin{array}{ll}
> & n_{1}=0.50 \mathrm{~mol} \mathrm{O}_{2}
\end{array} \quad \geqslant n_{2}=? \mathrm{~mol} \mathrm{O}_{3} .
$$

What information do we need?
> Balanced equation
> Moles of $\mathrm{O}_{3}$
> Avogadro's law

$$
V=a n
$$

## How do we get there?

How many moles of $\mathrm{O}_{3}$ are produced by 0.50 mole of $\mathrm{O}_{2}$ ?
What is the balanced equation?

$$
3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{O}_{3}(\mathrm{~g})
$$

What is the mole ratio between $\mathrm{O}_{3}$ and $\mathrm{O}_{2}$ ?

$$
\frac{2 \mathrm{~mol} \mathrm{O}_{3}}{3 \mathrm{~mol} \mathrm{O}_{2}}
$$

Now we can calculate the moles of $O_{3}$ formed.

$$
0.50 \mathrm{mot}_{2} \times \frac{2 \mathrm{~mol} \mathrm{O}_{3}}{3{\mathrm{mot} \Theta_{2}}^{2}}=0.33 \mathrm{~mol} \mathrm{O}_{3}
$$

What is the volume of $O_{3}$ produced?
Avogadro's law states that $V=a n$, which can be rearranged to give

$$
\frac{V}{n}=a
$$

Since $a$ is a constant, an alternative representation is

$$
\frac{V_{1}}{n_{1}}=a=\frac{V_{2}}{n_{2}}
$$

where $V_{1}$ is the volume of $n_{1}$ moles of $\mathrm{O}_{2}$ gas and $V_{2}$ is the volume of $n_{2}$ moles of $\mathrm{O}_{3}$ gas. In this case we have

$$
\begin{array}{ll}
>n_{1}=0.50 \mathrm{~mol} & >n_{2}=0.33 \mathrm{~mol} \\
>V_{1}=12.2 \mathrm{~L} & >V_{2}=?
\end{array}
$$

Solving for $V_{2}$ gives

$$
V_{2}=\left(\frac{n_{2}}{n_{1}}\right) V_{1}=\left(\frac{0.33 \mathrm{mot}}{0.50 \mathrm{mot}}\right) 12.2 \mathrm{~L}=8.1 \mathrm{~L}
$$

Reality Check Note that the volume decreases, as it should, since fewer moles of gas molecules will be present after $\mathrm{O}_{2}$ is converted to $\mathrm{O}_{3}$.

### 5.3 The Ideal Gas Law

We have considered three laws that describe the behavior of gases as revealed by experimental observations:

$$
\begin{array}{rll}
\text { Boyle's law: } & V=\frac{k}{P} & (\text { at constant } T \text { and } n) \\
\text { Charles's law: } & V=b T & (\text { at constant } P \text { and } n) \\
\text { Avogadro's law: } & V=a n & (\text { at constant } T \text { and } P)
\end{array}
$$

These relationships, which show how the volume of a gas depends on pressure, temperature, and number of moles of gas present, can be combined as follows:

$$
V=R\left(\frac{T n}{P}\right)
$$

$R=0.08206 \frac{\mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}$

The ideal gas law applies best at pressures smaller than 1 atm.
where $R$ is the combined proportionality constant called the universal gas constant. When the pressure is expressed in atmospheres and the volume in liters, $R$ has the value $0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$. The preceding equation can be rearranged to the more familiar form of the ideal gas law:

$$
P V=n R T
$$

The ideal gas law is an equation of state for a gas, where the state of the gas is its condition at a given time. A particular state of a gas is described by its pressure, volume, temperature, and number of moles. Knowledge of any three of these properties is enough to completely define the state of a gas, since the fourth property can then be determined from the equation for the ideal gas law.

It is important to recognize that the ideal gas law is an empirical equation-it is based on experimental measurements of the properties of gases. A gas that obeys this equation is said to behave ideally. The ideal gas equation is best regarded as a limiting law-it expresses behavior that real gases approach at low pressures and high temperatures. Therefore, an ideal gas is a hypothetical substance. However, most gases obey the ideal gas equation closely enough at pressures below 1 atm that only minimal errors result from assuming ideal behavior. Unless you are given information to the contrary, you should assume ideal gas behavior when solving problems involving gases in this text.

The ideal gas law can be used to solve a variety of problems. Example 5.6 demonstrates one type, where you are asked to find one property characterizing the state of a gas, given the other three.

## INTERACTIVE EXAMPLE 5.6 Ideal Gas Law I

A sample of hydrogen gas $\left(\mathrm{H}_{2}\right)$ has a volume of 8.56 L at a temperature of $0^{\circ} \mathrm{C}$ and a pressure of 1.5 atm . Calculate the moles of $\mathrm{H}_{2}$ molecules present in this gas sample.

## SOLUTION Where are we going?

To calculate the moles of $\mathrm{H}_{2}$
What do we know?

$$
\begin{array}{ll}
> & n=? \mathrm{~mol} \mathrm{H}_{2} \\
> & V=8.56 \mathrm{~L} \\
> & P=1.5 \mathrm{~atm} \\
> & T=0^{\circ} \mathrm{C}+273=273 \mathrm{~K}
\end{array}
$$

What information do we need?
> Ideal gas law

$$
P V=n R T
$$

> $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$

## How do we get there?

## How many moles of $\mathrm{H}_{2}$ are present in the sample?

> Solve the ideal gas equation for $n$ :

$$
\square n=\frac{(1.5 \mathrm{~atm})(8.56 \mathrm{~K})}{\left(0.08206 \frac{\mathrm{~K} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(273 \mathrm{~K})}=0.57 \mathrm{~mol}
$$

Gas law problems can be solved in a variety of ways. They can be classified as a Boyle's law, Charles's law, or Avogadro's law problem and solved, but now we need to remember the specific law and when it applies. The real advantage of using the ideal gas law is that it applies to virtually any problem dealing with gases and is easy to remember.

The basic assumption we make when using the ideal gas law to describe a change in state for a gas is that the equation applies equally well to both the initial and final states. In dealing with changes in state, we always place the variables that change on one side of the equal sign and the constants on the other. Let's see how this might work in several examples.

## INTERACTIVE EXAMPLE 5.7 Ideal Gas Law II

## SOLUTION Where are we going?

To use the ideal gas equation to determine the final pressure
What do we know?

$$
\begin{array}{ll}
>P_{1}=1.68 \mathrm{am} & >P_{2}=? \\
>V_{1}=7.0 \mathrm{~mL} & >V_{2}=2.7 \mathrm{~mL}
\end{array}
$$

What information do we need?
> Ideal gas law

$$
P V=n R T
$$

) $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$

## How do we get there?

What are the variables that change?

$$
P, V
$$

What are the variables that remain constant?

$$
n, R, T
$$

Write the ideal gas law, collecting the change variables on one side of the equal sign and the variables that do not change on the other.

Since $n$ and $T$ remain the same in this case, we can write $P_{1} V_{1}=n R T$ and $P_{2} V_{2}=n R T$. Combining these gives

$$
P_{1} V_{1}=n R T=P_{2} V_{2} \quad \text { or } \quad P_{1} V_{1}=P_{2} V_{2}
$$

We are given $P_{1}=1.68 \mathrm{~atm}, V_{1}=7.0 \mathrm{~mL}$, and $V_{2}=2.7 \mathrm{~mL}$. Solving for $P_{2}$ thus gives

$$
P_{2}=\left(\frac{V_{1}}{V_{2}}\right) P_{1}=\left(\frac{7.0 \mathrm{mt}}{2.7 \mathrm{mt}}\right) 1.68 \mathrm{~atm}=4.4 \mathrm{~atm}
$$

Reality Check Does this answer make sense? The volume decreased (at constant temperature), so the pressure should increase, as the result of the calculation indicates. Note that the calculated final pressure is 4.4 atm . Most gases do not behave ideally
above 1 atm . Therefore, we might find that if we measured the pressure of this gas sample, the observed pressure would differ slightly from 4.4 atm .

## INTERACTIVE EXAMPLE 5.8

## Ideal Gas Law III

A sample of methane gas that has a volume of 3.8 L at $5^{\circ} \mathrm{C}$ is heated to $86^{\circ} \mathrm{C}$ at constant pressure. Calculate its new volume.

## SOLUTION Where are we going?

To use the ideal gas equation to determine the final volume
What do we know?

$$
\begin{array}{ll}
>T_{1}=5^{\circ} \mathrm{C}+273=278 \mathrm{~K} & , T_{2}=86^{\circ} \mathrm{C}+273=359 \mathrm{~K} \\
>V_{1}=3.8 \mathrm{~L} & , V_{2}=?
\end{array}
$$

What information do we need?
> Ideal gas law

$$
P V=n R T
$$

> $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$

## How do we get there?

What are the variables that change?

$$
V, T
$$

What are the variables that remain constant?

$$
n, R, P
$$

Write the ideal gas law, collecting the change variables on one side of the equal sign and the variables that do not change on the other.

$$
\frac{V}{T}=\frac{n R}{P}
$$

which leads to

$$
\frac{V_{1}}{T_{1}}=\frac{n R}{P} \quad \text { and } \quad \frac{V_{2}}{T_{2}}=\frac{n R}{P}
$$

Combining these gives

$$
\frac{V_{1}}{T_{1}}=\frac{n R}{P}=\frac{V_{2}}{T_{2}} \quad \text { or } \quad \frac{V_{1}}{T_{1}}=\frac{V_{2}}{T_{2}}
$$

> Solving for $V_{2}$ :

$$
V_{2}=\frac{T_{2} V_{1}}{T_{1}}=\frac{(359 \mathrm{~K})(3.8 \mathrm{~L})}{278 \mathrm{~K}}=4.9 \mathrm{~L}
$$

Reality Check Is the answer sensible? In this case the temperature increased (at constant pressure), so the volume should increase. Thus the answer makes sense.

The problem in Example 5.8 could be described as a Charles's law problem, whereas the problem in Example 5.7 might be called a Boyle's law problem. In both cases, however, we started with the ideal gas law. The real advantage of using the ideal gas law is that it applies to virtually any problem dealing with gases and is easy to remember.

## INTERACTIVE EXAMPLE 5.9

Always convert the temperature to the Kelvin scale when applying the ideal gas law.

## SOLUTION

## Ideal Gas Law IV

A sample of diborane gas $\left(\mathrm{B}_{2} \mathrm{H}_{6}\right)$, a substance that bursts into flame when exposed to air, has a pressure of 345 torr at a temperature of $-15^{\circ} \mathrm{C}$ and a volume of 3.48 L . If conditions are changed so that the temperature is $36^{\circ} \mathrm{C}$ and the pressure is 468 torr, what will be the volume of the sample?

## Where are we going?

To use the ideal gas equation to determine the final volume
What do we know?

$$
\begin{array}{ll}
>T_{1}=15^{\circ} \mathrm{C}+273=258 \mathrm{~K} & \\
>T_{2}=36^{\circ} \mathrm{C}+273=309 \mathrm{~K} \\
>V_{1}=3.48 \mathrm{~L} & , V_{2}=? \\
>P_{1}=345 \mathrm{orr} & >P_{2}=468 \text { torr }
\end{array}
$$

What information do we need?
> Ideal gas law

$$
P V=n R T
$$

> $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$

## How do we get there?

What are the variables that change?

$$
P, V, T
$$

What are the variables that remain constant?

$$
n, R
$$

Write the ideal gas law, collecting the change variables on one side of the equal sign and the variables that do not change on the other.

$$
\frac{P V}{T}=n R
$$

which leads to

$$
\frac{P_{1} V_{1}}{T_{1}}=n R=\frac{P_{2} V_{2}}{T_{2}} \quad \text { or } \quad \frac{P_{1} V_{1}}{T_{1}}=\frac{P_{2} V_{2}}{T_{2}}
$$

> Solving for $V_{2}$ :

$$
\square V_{2}=\frac{T_{2} P_{1} V_{1}}{T_{1} P_{2}}=\frac{(309 \mathrm{~K})(345 \mathrm{torr})(3.48 \mathrm{~L})}{(258 \mathrm{~K})(468 \mathrm{torf})}=3.07 \mathrm{~L}
$$

## INTERACTIVE EXAMPLE 5.10

## Ideal Gas Law V

A sample containing 0.35 mole of argon gas at a temperature of $13^{\circ} \mathrm{C}$ and a pressure of 568 torr is heated to $56^{\circ} \mathrm{C}$ and a pressure of 897 torr. Calculate the change in volume that occurs.

## SOLUTION Where are we going?

To use the ideal gas equation to determine the final volume
What do we know?

| State 1 | State 2 |
| :--- | :--- |
| $n_{1}=0.35 \mathrm{~mol}$ | $n_{2}=0.35 \mathrm{~mol}$ |
| $P_{1}=568 \mathrm{torr} \times \frac{1 \mathrm{~atm}}{760 \mathrm{torr}}=0.747 \mathrm{~atm}$ | $P_{2}=897 \mathrm{torr} \times \frac{1 \mathrm{~atm}}{760 \mathrm{torf}}=1.18 \mathrm{~atm}$ |
| $T_{1}=13^{\circ} \mathrm{C}+273=286 \mathrm{~K}$ | $T_{2}=56^{\circ} \mathrm{C}+273=329 \mathrm{~K}$ |

What information do we need?

```
> Ideal gas law \(P V=n R T\)
) \(R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}\)
) \(V_{1}\) and \(V_{2}\)
```

## How do we get there?

What is $V_{l}$ ?

$$
V_{1}=\frac{n_{1} R T_{1}}{P_{1}}=\frac{(0.35 \mathrm{mot})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \operatorname{mot})(286 \mathrm{~K})}{(0.747 \mathrm{~atm})}=11 \mathrm{~L}
$$

What is $V_{2}$ ?

$$
V_{2}=\frac{n_{2} R T_{2}}{P_{2}}=\frac{(0.35 \mathrm{mot})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \operatorname{mot})(329 \mathrm{~K})}{(1.18 \mathrm{~atm})}=8.0 \mathrm{~L}
$$

What is the change in volume $\Delta V$ ?

$$
\Delta V=V_{2}-V_{1}=8.0 \mathrm{~L}-11 \mathrm{~L}=-3 \mathrm{~L}
$$

The change in volume is negative because the volume decreases.
Note: For this problem (unlike Example 5.9), the pressures must be converted from torrs to atmospheres as required by the atmospheres part of the units for $R$ since each volume was found separately, and the conversion factor does not cancel.

## See Exercise 5.69

## When 273.15 K is used in

 this calculation, the mola volume obtained in Example 5.3 is the same value as 22.41 L .STP: $0^{\circ} \mathrm{C}$ and 1 atm

### 5.4 Gas Stoichiometry

Suppose we have 1 mole of an ideal gas at $0^{\circ} \mathrm{C}(273.2 \mathrm{~K})$ and 1 atm . From the ideal gas law, the volume of the gas is given by

$$
V=\frac{n R T}{P}=\frac{(1.000 \mathrm{mof})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mof})(273.2 \mathrm{~K})}{1.000 \mathrm{~atm}}=22.42 \mathrm{~L}
$$

This volume of 22.42 L is the molar volume of an ideal gas (at $0^{\circ} \mathrm{C}$ and 1 atm ). The measured molar volumes of several gases are listed in Table 5.2. Note that the molar volumes of some of the gases are very close to the ideal value, while others deviate significantly. Later in this chapter, we will discuss some of the reasons for the deviations.

The conditions $0^{\circ} \mathrm{C}$ and 1 atm , called standard temperature and pressure (abbreviated STP), are common reference conditions for the properties of gases. For example, the molar volume of an ideal gas is 22.42 L at STP (Fig. 5.11).

> temperature $\left(22^{\circ} \mathrm{C}\right)$ and 1 atm? How would this affect the molar volume of an ideal gas? Include an explanation and a number.

## INTERACTIVE EXAMPLE 5.11

## SOLUTION

FIGURE 5.11 22.42 Lofagas would just fit into this beach ball.

## Gas Stoichiometry I

A sample of nitrogen gas has a volume of 1.75 L at STP . How many moles of $\mathrm{N}_{2}$ are present?

We could solve this problem by using the ideal gas equation, but we can take a shortcut by using the molar volume of an ideal gas at STP. Since 1 mole of an ideal gas at STP has a volume of $22.42 \mathrm{~L}, 1.75 \mathrm{~L} \mathrm{~N}_{2}$ at STP will contain less than 1 mole. We can find how many moles using the ratio of 1.75 L to 22.42 L :

$$
1.75 \mathrm{LA}_{2} \times \frac{1 \mathrm{~mol} \mathrm{~N}_{2}}{22.42 \mathrm{LA}_{2}}=7.81 \times 10^{-2} \mathrm{~mol} \mathrm{~N}_{2}
$$

See Exercises 5.71 and 5.72

Many chemical reactions involve gases. By assuming ideal behavior for these gases, we can carry out stoichiometric calculations if the pressure, volume, and temperature of the gases are known.

TABLE 5.2 \| Molar Volumes for Various Gases at $0^{\circ} \mathrm{C}$ and 1 atm

| Gas | Molar Volume (L) |
| :--- | :---: |
| Oxygen $\left(\mathrm{O}_{2}\right)$ | 22.397 |
| Nitrogen $\left(\mathrm{N}_{2}\right)$ | 22.402 |
| Hydrogen $\left(\mathrm{H}_{2}\right)$ | 22.433 |
| Helium $(\mathrm{He})$ | 22.434 |
| Argon $(\mathrm{Ar})$ | 22.397 |
| Carbon dioxide $\left(\mathrm{CO}_{2}\right)$ | 22.260 |
| Ammonia $\left(\mathrm{NH}_{3}\right)$ | 22.079 |

## INTERACTIVE EXAMPLE 5.12 Gas Stoichiometry II

Quicklime $(\mathrm{CaO})$ is produced by the thermal decomposition of calcium carbonate $\left(\mathrm{CaCO}_{3}\right)$. Calculate the volume of $\mathrm{CO}_{2}$ at STP produced from the decomposition of $152 \mathrm{~g} \mathrm{CaCO}_{3}$ by the reaction

$$
\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

## SOLUTION

## Where are we going?

To use stoichiometry to determine the volume of $\mathrm{CO}_{2}$ produced
What do we know?

$$
>\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

What information do we need?
> Molar volume of a gas at STP is 22.42 L

## How do we get there?

We need to use the strategy for solving stoichiometry problems that we learned in Chapter 3.

1. What is the balanced equation?

$$
\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

2. What are the moles of $\mathrm{CaCO}_{3}(100.09 \mathrm{~g} / \mathrm{mol})$ ?

$$
152 \mathrm{~g} \mathrm{CaCO}_{3} \times \frac{1 \mathrm{~mol} \mathrm{CaCO}_{3}}{100.09 \mathrm{~g} \mathrm{CaCO}_{3}}=1.52 \mathrm{~mol} \mathrm{CaCO}_{3}
$$

3. What is the mole ratio between $\mathrm{CO}_{2}$ and $\mathrm{CaCO}_{3}$ in the balanced equation?

$$
\frac{1 \mathrm{~mol} \mathrm{CO}_{2}}{1 \mathrm{~mol} \mathrm{CaCO}_{3}}
$$

4. What are the moles of $\mathrm{CO}_{2}$ ?
1.52 moles of $\mathrm{CO}_{2}$, which is the same as the moles of $\mathrm{CaCO}_{3}$ because the mole ratio is 1 .
5. What is the volume of $\mathrm{CO}_{2}$ produced?

We can compute this by using the molar volume since the sample is at STP:

$$
\square 1.52 \mathrm{~mol} \mathrm{CO}_{2} \times \frac{22.42 \mathrm{~L} \mathrm{CO}_{2}}{1 \mathrm{~mol} \mathrm{CO}_{2}}=34.1 \mathrm{~L} \mathrm{CO}_{2}
$$

> Thus the decomposition of $152 \mathrm{~g} \mathrm{CaCO}_{3}$ produces $34.1 \mathrm{~L} \mathrm{CO}_{2}$ at STP.

## See Exercises 5.73 through 5.76

Remember that the molar volume of an ideal gas is 22.42 L when measured at STP.

Note that in Example 5.12 the final step involved calculation of the volume of gas from the number of moles. Since the conditions were specified as STP, we were able to use the molar volume of a gas at STP. If the conditions of a problem are different from STP, the ideal gas law must be used to compute the volume.

## INTERACTVE EXAMPLE 5.13 Gas Stoichiometry III

A sample of methane gas having a volume of 2.80 L at $25^{\circ} \mathrm{C}$ and 1.65 atm was mixed with a sample of oxygen gas having a volume of 35.0 L at $31^{\circ} \mathrm{C}$ and 1.25 atm . The
mixture was then ignited to form carbon dioxide and water. Calculate the volume of $\mathrm{CO}_{2}$ formed at a pressure of 2.50 atm and a temperature of $125^{\circ} \mathrm{C}$.

## SOLUTION

Where are we going?
To determine the volume of $\mathrm{CO}_{2}$ produced
What do we know?

|  | $\mathrm{CH}_{4}$ | $\mathrm{O}_{2}$ | $\mathrm{CO}_{2}$ |
| :--- | :--- | :--- | :--- |
| $P$ | 1.65 atm | 1.25 atm | 2.50 atm |
| $V$ | 2.80 L | 35.0 L | $?$ |
| $T$ | $25^{\circ} \mathrm{C}+273=298 \mathrm{~K}$ | $31^{\circ} \mathrm{C}+273=304 \mathrm{~K}$ | $125^{\circ} \mathrm{C}+273=398 \mathrm{~K}$ |

What information do we need?
) Balanced chemical equation for the reaction
> Ideal gas law

$$
P V=n R T
$$

> $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$

## How do we get there?

We need to use the strategy for solving stoichiometry problems that we learned in Chapter 3.

1. What is the balanced equation?

From the description of the reaction, the unbalanced equation is

$$
\mathrm{CH}_{4}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

which can be balanced to give

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

2. What is the limiting reactant?

We can determine this by using the ideal gas law to determine the moles for each reactant:

$$
\begin{aligned}
n_{\mathrm{CH}_{4}} & =\frac{P V}{R T}=\frac{(1.65 \mathrm{~atm})(2.80 \mathrm{~K})}{(0.08206 \mathrm{~K} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K})}=0.189 \mathrm{~mol} \\
n_{\mathrm{O}_{2}} & =\frac{P V}{R T}=\frac{(1.25 \mathrm{~atm})(35.0 \mathrm{~K})}{(0.08206 \mathrm{~K} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(304 \mathrm{~K})}=1.75 \mathrm{~mol}
\end{aligned}
$$

In the balanced equation for the combustion reaction, 1 mole of $\mathrm{CH}_{4}$ requires 2 moles of $\mathrm{O}_{2}$. Thus the moles of $\mathrm{O}_{2}$ required by 0.189 mole of $\mathrm{CH}_{4}$ can be calculated as follows:

$$
0.189 \mathrm{molCH}_{4} \times \frac{2 \mathrm{~mol} \mathrm{O}_{2}}{1 \mathrm{molCH}_{4}}=0.378 \mathrm{~mol} \mathrm{O} 2
$$

The limiting reactant is $\mathrm{CH}_{4}$.
3. What are the moles of $\mathrm{CO}_{2}$ ?

Since $\mathrm{CH}_{4}$ is limiting, we use the moles of $\mathrm{CH}_{4}$ to determine the moles of $\mathrm{CO}_{2}$ produced:

$$
0.189 \mathrm{molCH}_{4} \times \frac{1 \mathrm{~mol} \mathrm{CO}_{2}}{1 \mathrm{molCH}_{4}}=0.189 \mathrm{~mol} \mathrm{CO}_{2}
$$

## Density $=\frac{\text { mass }}{\text { volume }}$

## 4. What is the volume of $\mathrm{CO}_{2}$ produced?

Since the conditions stated are not STP, we must use the ideal gas law to calculate the volume:

$$
V=\frac{n R T}{P}
$$

In this case $n=0.189 \mathrm{~mol}, T=125^{\circ} \mathrm{C}+273=398 \mathrm{~K}, P=2.50 \mathrm{~atm}$, and $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$. Thus

$$
V=\frac{(0.189 \mathrm{mot})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mot})(398 \mathrm{~K})}{2.50 \mathrm{~atm}}=2.47 \mathrm{~L}
$$

This represents the volume of $\mathrm{CO}_{2}$ produced under these conditions.

## See Exercises 5.77 and 5.80

## Molar Mass of a Gas

One very important use of the ideal gas law is in the calculation of the molar mass (molecular weight) of a gas from its measured density. To see the relationship between gas density and molar mass, consider that the number of moles of gas, $n$, can be expressed as

$$
n=\frac{\text { grams of gas }}{\text { molar mass }}=\frac{\text { mass }}{\text { molar mass }}=\frac{m}{\text { molar mass }}
$$

Substitution into the ideal gas equation gives

$$
P=\frac{n R T}{V}=\frac{(m / \text { molar mass }) R T}{V}=\frac{m(R T)}{V(\text { molar mass })}
$$

However, $m / V$ is the gas density, $d$, in units of grams per liter. Thus

$$
P=\frac{d R T}{\text { molar mass }}
$$

or

$$
\begin{equation*}
\text { Molar mass }=\frac{d R T}{P} \tag{5.1}
\end{equation*}
$$

Thus, if the density of a gas at a given temperature and pressure is known, its molar mass can be calculated.

## INTERACTIVE EXAMPLE 5.14

## Gas Density/Molar Mass

The density of a gas was measured at 1.50 atm and $27^{\circ} \mathrm{C}$ and found to be $1.95 \mathrm{~g} / \mathrm{L}$. Calculate the molar mass of the gas.

## SOLUTION Where are we going?

To determine the molar mass of the gas
What do we know?
> $P=1.50 \mathrm{~atm}$
) $T=27^{\circ} \mathrm{C}+273=300 . \mathrm{K}$
) $d=1.95 \mathrm{~g} / \mathrm{L}$

What information do we need?
, Molar mass $=\frac{d R T}{P}$
> $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$
How do we get there?
Molar mass $=\frac{d R T}{P}=\frac{\left(1.95 \frac{\mathrm{~g}}{\mathrm{~L}}\right)\left(0.08206 \frac{\mathrm{~K} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(300 . \mathrm{K})}{1.50 \mathrm{~atm}}=32.0 \mathrm{~g} / \mathrm{mol}$
Reality Check These are the units expected for molar mass.

## See Exercises 5.83 through 5.86

You could memorize the equation involving gas density and molar mass, but it is better simply to remember the ideal gas equation, the definition of density, and the relationship between number of moles and molar mass. You can then derive the appropriate equation when you need it. This approach ensures that you understand the concepts and means one less equation to memorize.

## 5. 5 Dalton's Law of Partial Pressures

Among the experiments that led John Dalton to propose the atomic theory were his studies of mixtures of gases. In 1803 Dalton summarized his observations as follows: For a mixture of gases in a container, the total pressure exerted is the sum of the pressures that each gas would exert if it were alone. This statement, known as Dalton's law of partial pressures, can be expressed as follows:

$$
P_{\mathrm{TOTAL}}=P_{1}+P_{2}+P_{3}+\cdots
$$

where the subscripts refer to the individual gases (gas 1 , gas 2 , and so on). The symbols $P_{1}, P_{2}, P_{3}$, and so on represent each partial pressure, the pressure that a particular gas would exert if it were alone in the container.

Assuming that each gas behaves ideally, the partial pressure of each gas can be calculated from the ideal gas law:

$$
P_{1}=\frac{n_{1} R T}{V}, \quad P_{2}=\frac{n_{2} R T}{V}, \quad P_{3}=\frac{n_{3} R T}{V}
$$

The total pressure of the mixture $P_{\text {TOTAL }}$ can be represented as

$$
\begin{aligned}
P_{\mathrm{TOTAL}}=P_{1}+P_{2}+P_{3}+\cdots & =\frac{n_{1} R T}{V}+\frac{n_{2} R T}{V}+\frac{n_{3} R T}{V}+\cdots \\
& =\left(n_{1}+n_{2}+n_{3}+\cdots\right)\left(\frac{R T}{V}\right) \\
& =n_{\mathrm{TOTAL}}\left(\frac{R T}{V}\right)
\end{aligned}
$$

where $n_{\text {TOTAL }}$ is the sum of the numbers of moles of the various gases. Thus, for a mixture of ideal gases, it is the total number of moles of particles that is important, not the identity or composition of the involved gas particles. This idea is illustrated in Fig. 5.12.

This important observation indicates some fundamental characteristics of an ideal gas. The fact that the pressure exerted by an ideal gas is not affected by the identity

FIGURE 5.12 The partial pressure of each gas in a mixture of gases in a container depends on the number of moles of that gas. The total pressure is the sum of the partial pressures and depends on the total moles of gas particles present, no matter what they are. Note that the volume remains constant.

(composition) of the gas particles reveals two things about ideal gases: (1) the volume of the individual gas particle must not be important, and (2) the forces among the particles must not be important. If these factors were important, the pressure exerted by the gas would depend on the nature of the individual particles. These observations will strongly influence the model that we will eventually construct to explain ideal gas behavior.

## INTERACTIVE EXAMPLE 5.15

## SOLUTION

## Dalton's Law I

Mixtures of helium and oxygen can be used in scuba diving tanks to help prevent "the bends." For a particular dive, 46 L He at $25^{\circ} \mathrm{C}$ and 1.0 atm and $12 \mathrm{~L} \mathrm{O}_{2}$ at $25^{\circ} \mathrm{C}$ and 1.0 atm were pumped into a tank with a volume of 5.0 L . Calculate the partial pressure of each gas and the total pressure in the tank at $25^{\circ} \mathrm{C}$.

## Where are we going?

To determine the partial pressure of each gas To determine the total pressure in the tank at $25^{\circ} \mathrm{C}$

What do we know?

|  | He | $\mathbf{O}_{\mathbf{2}}$ | Tank |
| :--- | :--- | :--- | :--- |
| $P$ | 1.00 atm | 1.00 atm | ? atm |
| $V$ | 46 L | 12 L | 5.0 L |
| $T$ | $25^{\circ} \mathrm{C}+273=298 \mathrm{~K}$ | $25^{\circ} \mathrm{C}+273=298 \mathrm{~K}$ | $25^{\circ} \mathrm{C}+273=298 \mathrm{~K}$ |

What information do we need?
> Ideal gas law

$$
P V=n R T
$$

> $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$

## How do we get there?

How many moles are present for each gas?

$$
\begin{aligned}
n & =\frac{P V}{R T} \\
n_{\mathrm{He}} & =\frac{(1.0 \mathrm{~atm})(46 \mathrm{~K})}{(0.08206 \mathrm{~K} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K})}=1.9 \mathrm{~mol} \\
n_{\mathrm{O}_{2}} & =\frac{(1.0 \mathrm{~atm})(12 \mathrm{~K})}{(0.08206 \mathrm{~K} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K})}=0.49 \mathrm{~mol}
\end{aligned}
$$

## CHEMICAL CDNNECTIDNS

## Separating Gases

A
ssume you work for an oil company that owns a huge natural gas reservoir containing a mixture of methane and nitrogen gases. In fact, the gas mixture contains so much nitrogen that it is unusable as a fuel. Your job is to separate the nitrogen $\left(\mathrm{N}_{2}\right)$ from the methane $\left(\mathrm{CH}_{4}\right)$. How might you accomplish this task? You clearly need some sort of "molecular filter" that will stop the slightly larger methane molecules (size $\approx 430 \mathrm{pm}$ ) and allow the nitrogen molecules (size $\approx 410 \mathrm{pm}$ ) to pass through. To accomplish the separation of molecules so similar in size will require a very precise "filter."

The good news is that such a filter exists. Work by Steven Kuznicki and Valerie Bell at Engelhard Corporation in New Jersey and Michael Tsapatsis
at the University of Massachusetts has produced a "molecular sieve" in which the pore (passage) sizes can be adjusted precisely enough to separate $\mathrm{N}_{2}$ molecules from $\mathrm{CH}_{4}$ molecules. The material involved is a special hydrated titanosilicate (contains $\mathrm{H}_{2} \mathrm{O}, \mathrm{Ti}, \mathrm{Si}, \mathrm{O}$, and Sr ) compound patented by Engelhard known as ETS-4 (Engelhard TitanoSilicate-4). When sodium ions are substituted for the strontium ions
in ETS-4 and the new material is carefully dehydrated, a uniform and controllable pore-size reduction occurs (see figure). The researchers have shown that the material can be used to separate $\mathrm{N}_{2}(\approx 410 \mathrm{pm})$ from $\mathrm{O}_{2}$ ( $\approx 390 \mathrm{pm}$ ). They have also shown that it is possible to reduce the nitrogen content of natural gas from $18 \%$ to less than $5 \%$ with a $90 \%$ recovery of methane.

Molecular sieve framework of titanium (blue), silicon (green), and oxygen (red) atoms contracts on heating-at room temperature (left), $\mathrm{d}=4.27 \AA \AA$; at $250^{\circ} \mathrm{C}$ (right), $\mathrm{d}=3.94 \AA$.

What is the partial pressure for each gas in the tank?
The tank containing the mixture has a volume of 5.0 L , and the temperature is $25^{\circ} \mathrm{C}$. We can use these data and the ideal gas law to calculate the partial pressure of each gas:

$$
\begin{aligned}
P & =\frac{n R T}{V} \\
P_{\mathrm{He}} & =\frac{(1.9 \mathrm{mot})(0.08206 \mathrm{~K} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mot})(298 \mathrm{~K})}{5.0 \mathrm{~K}}=9.3 \mathrm{~atm} \\
P_{\mathrm{O}_{2}} & =\frac{(0.49 \mathrm{mot})(0.08206 \mathrm{~K} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mot})(298 \mathrm{~K})}{5.0 \mathrm{~K}}=2.4 \mathrm{~atm}
\end{aligned}
$$

What is the total pressure of the mixture of gases in the tank?
The total pressure is the sum of the partial pressures:

$$
P_{\mathrm{TOTAL}}=P_{\mathrm{He}}+P_{\mathrm{O}_{2}}=9.3 \mathrm{~atm}+2.4 \mathrm{~atm}=11.7 \mathrm{~atm}
$$

## See Exercises 5.89 and 5.90

At this point we need to define the mole fraction: the ratio of the number of moles of a given component in a mixture to the total number of moles in the mixture. The Greek lowercase letter chi $(\chi)$ is used to symbolize the mole fraction. For example, for a given component in a mixture, the mole fraction $\chi_{1}$ is

$$
\chi_{1}=\frac{n_{1}}{n_{\mathrm{TOTAL}}}=\frac{n_{1}}{n_{1}+n_{2}+n_{3}+\cdots}
$$

## CHEMICAL CONNECTIONS

## The Chemistry of Air Bags

T:he inclusion of air bags in modern automobiles has led to a significant reduction in the number of injuries as a result of car crashes. Air bags are stored in the steering wheel and dashboard of all cars, and many autos now have additional air bags that protect the occupant's knees, head, and shoulders. In fact, some auto manufacturers now include air bags in the seat belts. Also, because deployment of an air bag can severely injure a child, all cars now have "smart" air bags that deploy with an inflation force that is proportional to the seat occupant's weight.

The term "air bag" is really a misnomer because air is not involved in the inflation process. Rather, an air bag inflates rapidly (in about 30 ms ) due to the explosive production of $\mathrm{N}_{2}$ gas.

Originally, sodium azide, which decomposes to produce $\mathrm{N}_{2}$,

$$
2 \mathrm{NaN}_{3}(s) \rightarrow 2 \mathrm{Na}(s)+3 \mathrm{~N}_{2}(g)
$$

was used, but it has now been replaced by less toxic materials.

The sensing devices that trigger the air bags must react very rapidly. For example, consider a car hitting a concrete bridge abutment. When this happens, an internal accelerometer sends a message to the control module that a collision possibly is occurring. The microprocessor then analyzes the measured deceleration from several accelerometers and door pressure sensors and decides whether air bag deployment is appropriate. All this happens within 8 to 40 ms of the initial impact.

Because an air bag must provide the appropriate cushioning effect, the bag
begins to vent even as it is being filled. In fact, the maximum pressure in the bag is 5 pounds per square inch (psi), even in the middle of a collision event. Air bags represent a case where an explosive chemical reaction saves lives rather than the reverse.

Inflated air bags.

From the ideal gas equation, we know that the number of moles of a gas is directly proportional to the pressure of the gas, since

$$
n=P\left(\frac{V}{R T}\right)
$$

That is, for each component in the mixture,

$$
n_{1}=P_{1}\left(\frac{V}{R T}\right), \quad n_{2}=P_{2}\left(\frac{V}{R T}\right), \quad \cdots
$$

Therefore, we can represent the mole fraction in terms of pressures:

$$
\begin{aligned}
\chi_{1}=\frac{n_{1}}{n_{\mathrm{TOTAL}}} & =\frac{\overbrace{P_{1}(V / R T)}^{n_{1}}}{\underbrace{P_{1}(V / R T)}_{n_{1}}+\underbrace{P_{2}(V / R T)}_{n_{2}}+\underbrace{P_{3}(V / R T)}_{n_{3}}+\cdots} \\
& =\frac{(V / R T) P_{1}}{(V / R T)\left(P_{1}+P_{2}+P_{3}+\cdots\right)} \\
& =\frac{P_{1}}{P_{1}+P_{2}+P_{3}+\cdots}=\frac{P_{1}}{P_{\text {TOTAL }}}
\end{aligned}
$$

In fact, the mole fraction of each component in a mixture of ideal gases is directly related to its partial pressure:

$$
\chi_{2}=\frac{n_{2}}{n_{\mathrm{TOTAL}}}=\frac{P_{2}}{P_{\mathrm{TOTAL}}}
$$

## INTERACTIVE EXAMPLE 5.16 Dalton's Law II

The partial pressure of oxygen was observed to be 156 torr in air with a total atmospheric pressure of 743 torr. Calculate the mole fraction of $\mathrm{O}_{2}$ present.

## SOLUTION Where are we going?

To determine the mole fraction of $\mathrm{O}_{2}$
What do we know?

$$
\begin{aligned}
& >P_{\mathrm{O}_{2}}=156 \text { torr } \\
& >P_{\mathrm{TOTAL}}=743 \text { torr }
\end{aligned}
$$

## How do we get there?

The mole fraction of $\mathrm{O}_{2}$ can be calculated from the equation

$$
\chi_{\mathrm{O}_{2}}=\frac{P_{\mathrm{O}_{2}}}{P_{\mathrm{TOTAL}}}=\frac{156 \text { torf }}{743 \text { torf }}=0.210
$$

Note that the mole fraction has no units.

The expression for the mole fraction,

$$
\chi_{1}=\frac{P_{1}}{P_{\mathrm{TOTAL}}}
$$

can be rearranged to give

$$
P_{1}=\chi_{1} \times P_{\mathrm{TOTAL}}
$$

That is, the partial pressure of a particular component of a gaseous mixture is the mole fraction of that component times the total pressure.

## INTERACTVE EXAMPLE 5.17 Dalton's Law III

The mole fraction of nitrogen in the air is 0.7808 . Calculate the partial pressure of $\mathrm{N}_{2}$ in air when the atmospheric pressure is 760 . torr.

SOLUTION The partial pressure of $\mathrm{N}_{2}$ can be calculated as follows:

$$
\square P_{\mathrm{N}_{2}}=\chi_{\mathrm{N}_{2}} \times P_{\mathrm{TOTAL}}=0.7808 \times 760 . \text { torr }=593 \text { torr }
$$

## Collecting a Gas over Water

A mixture of gases results whenever a gas is collected by displacement of water. For example, Fig. 5.13 shows the collection of oxygen gas produced by the decomposition of solid potassium chlorate. In this situation, the gas in the bottle is a mixture of water vapor and the oxygen being collected. Water vapor is present because molecules of water escape from the surface of the liquid and collect in the space above the liquid. Molecules of water also return to the liquid. When the rate of escape equals the rate of

FIGURE 5.13 The production of oxygen by thermal decomposition of $\mathrm{KClO}_{3}$. The $\mathrm{MnO}_{2}$ is mixed with the $\mathrm{KClO}_{3}$ to make the reaction faster.

Vapor pressure will be discussed in detail in Chapter 10. A table of water vapor pressure values is given in Section 10.8.

return, the number of water molecules in the vapor state remains constant, and thus the pressure of water vapor remains constant. This pressure, which depends on temperature, is called the vapor pressure of water.

## INTERACTIVE EXAMPLE 5.18 Gas Collection over Water

A sample of solid potassium chlorate $\left(\mathrm{KClO}_{3}\right)$ was heated in a test tube (see Fig. 5.13) and decomposed by the following reaction:

$$
2 \mathrm{KClO}_{3}(s) \longrightarrow 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g)
$$

The oxygen produced was collected by displacement of water at $22^{\circ} \mathrm{C}$ at a total pressure of 754 torr. The volume of the gas collected was 0.650 L , and the vapor pressure of water at $22^{\circ} \mathrm{C}$ is 21 torr. Calculate the partial pressure of $\mathrm{O}_{2}$ in the gas collected and the mass of $\mathrm{KClO}_{3}$ in the sample that was decomposed.

## SOLUTION Where are we going?

To determine the partial pressure of $\mathrm{O}_{2}$ in the gas collected Calculate the mass of $\mathrm{KClO}_{3}$ in the original sample

What do we know?

|  | Gas Collected | Water Vapor |
| :---: | :--- | :--- |
| $P$ | 754 torr | 21 torr |
| $V$ | 0.650 L |  |
| $T$ | $22^{\circ} \mathrm{C}+273=295 \mathrm{~K}$ | $22^{\circ} \mathrm{C}+273=295 \mathrm{~K}$ |

## How do we get there?

What is the partial pressure of $\mathrm{O}_{2}$ ?

$$
\begin{aligned}
P_{\mathrm{TOTAL}} & =P_{\mathrm{O}_{2}}+P_{\mathrm{H}_{2} \mathrm{O}}=P_{\mathrm{O}_{2}}+21 \text { torr }=754 \text { torr } \\
P_{\mathrm{O}_{2}} & =754 \text { torr }-21 \text { torr }=733 \text { torr }
\end{aligned}
$$

What is the number of moles of $\mathrm{O}_{2}$ ?
Now we use the ideal gas law to find the number of moles of $\mathrm{O}_{2}$ :

$$
n_{\mathrm{O}_{2}}=\frac{P_{\mathrm{O}_{2}} V}{R T}
$$

In this case, the partial pressure of the $\mathrm{O}_{2}$ is

$$
P_{\mathrm{O}_{2}}=733 \text { torr }=\frac{733 \mathrm{torr}}{760 \mathrm{torr} / \mathrm{atm}}=0.964 \mathrm{~atm}
$$

To find the moles of $\mathrm{O}_{2}$ produced, we use

$$
\begin{gathered}
V=0.650 \mathrm{~L} \\
T=22^{\circ} \mathrm{C}+273=295 \mathrm{~K} \\
R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol} \\
n_{\mathrm{O}_{2}}=\frac{(0.964 \mathrm{~atm})(0.650 \mathrm{~K})}{(0.08206 \mathrm{~K} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(295 \mathrm{~K})}=2.59 \times 10^{-2} \mathrm{~mol}
\end{gathered}
$$

How many moles of $\mathrm{KClO}_{3}$ are required to produce this amount of $\mathrm{O}_{2}$ ?
Use the stoichiometry problem-solving strategy:

1. What is the balanced equation?

$$
2 \mathrm{KClO}_{3}(s) \longrightarrow 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g)
$$

2. What is the mole ratio between $\mathrm{KClO}_{3}$ and $\mathrm{O}_{2}$ in the balanced equation?

$$
\frac{2 \mathrm{~mol} \mathrm{KClO}_{3}}{3 \mathrm{~mol} \mathrm{O}_{2}}
$$

3. What are the moles of $\mathrm{KClO}_{3}$ ?

$$
2.59 \times 10^{-2} \mathrm{~mol}_{2} \times \frac{2 \mathrm{~mol} \mathrm{KClO}_{3}}{3 \mathrm{~mol}_{2}}=1.73 \times 10^{-2} \mathrm{~mol} \mathrm{KClO}_{3}
$$

4. What is the mass of $\mathrm{KClO}_{3}$ (molar mass $122.6 \mathrm{~g} / \mathrm{mol}$ ) in the original sample?

$$
1.73 \times 10^{-2}{\mathrm{~mol} \mathrm{KClO}_{3}}^{\square} \times \frac{122.6 \mathrm{~g} \mathrm{KClO}_{3}}{1 \mathrm{~mol} \mathrm{KCl}_{3}}=2.12 \mathrm{~g} \mathrm{KClO}_{3}
$$

Thus the original sample contained $2.12 \mathrm{~g} \mathrm{KClO}_{3}$.

## See Exercises 5.99 through 5.101

### 5.6 The Kinetic Molecular Theory of Gases

We have so far considered the behavior of gases from an experimental point of view. Based on observations from different types of experiments, we know that at pressures of less than 1 atm most gases closely approach the behavior described by the ideal gas law. Now we want to construct a model to explain this behavior.

Before we do this, let's briefly review the scientific method. Recall that a law is a way of generalizing behavior that has been observed in many experiments. Laws are very useful, since they allow us to predict the behavior of similar systems. For example, if a chemist prepares a new gaseous compound, a measurement of the gas density at known pressure and temperature can provide a reliable value for the compound's molar mass.

However, although laws summarize observed behavior, they do not tell us why nature behaves in the observed fashion. This is the central question for scientists. To try to answer this question, we construct theories (build models). The models in chemistry consist of speculations about what the individual atoms or molecules
(microscopic particles) might be doing to cause the observed behavior of the macroscopic systems (collections of very large numbers of atoms and molecules).

A model is considered successful if it explains the observed behavior in question and predicts correctly the results of future experiments. It is important to understand that a model can never be proved absolutely true. In fact, any model is an approximation by its very nature and is bound to fail at some point. Models range from the simple to the extraordinarily complex. We use simple models to predict approximate behavior and more complicated models to account very precisely for observed quantitative behavior. In this text we will stress simple models that provide an approximate picture of what might be happening and that fit the most important experimental results.

An example of this type of model is the kinetic molecular theory (KMT), a simple model that attempts to explain the properties of an ideal gas. This model is based on speculations about the behavior of the individual gas particles (atoms or molecules). The postulates of the kinetic molecular theory as they relate to the particles of an ideal gas can be stated as follows:

## Postulates of the Kinetic Molecular Theory

1. The particles are so small compared with the distances between them that the volume of the individual particles can be assumed to be negligible (zero) (Fig. 5.14).
2. The particles are in constant motion. The collisions of the particles with the walls of the container are the cause of the pressure exerted by the gas.
3. The particles are assumed to exert no forces on each other; they are assumed neither to attract nor to repel each other.
4. The average kinetic energy of a collection of gas particles is assumed to be directly proportional to the Kelvin temperature of the gas.

Of course, the molecules in a real gas have finite volumes and do exert forces on each other. Thus real gases do not conform to these assumptions. However, we will see that these postulates do indeed explain ideal gas behavior.

The true test of a model is how well its predictions fit the experimental observations. The postulates of the kinetic molecular model picture an ideal gas as consisting of particles having no volume and no attractions for each other, and the model assumes that the gas produces pressure on its container by collisions with the walls.

Let's consider how this model accounts for the properties of gases as summarized by the ideal gas law: $P V=n R T$.

FIGURE 5.14 (a) One mole of $\mathrm{N}_{2}(I)$ has a volume of approximately 35 mL and a density of $0.81 \mathrm{~g} / \mathrm{mL}$. (b) One mole of $\mathrm{N}_{2}(\mathrm{~g})$ has a volume of 22.42 L (STP) and a density of $1.2 \times 10^{-3} \mathrm{~g} / \mathrm{mL}$. Thus the ratio of the volumes of gaseous $\mathrm{N}_{2}$ and liquid $\mathrm{N}_{2}$ is $22.42 / 0.035=640$, and the spacing of the molecules is 9 times farther apart in $\mathrm{N}_{2}(\mathrm{~g})$.

FIGURE 5.15 The effects of decreasing the volume of a sample of gas at constant temperature.

FIGURE 5.16 The effects of increasing the temperature of a sample of gas at constant volume.

## Pressure and Volume (Boyle's Law]

We have seen that for a given sample of gas at a given temperature ( $n$ and $T$ are constant) that if the volume of a gas is decreased, the pressure increases:

$$
P=\underbrace{(n R T)}_{\substack{\uparrow \\ \text { Constant }}} \frac{1}{V}
$$

This makes sense based on the kinetic molecular theory because a decrease in volume means that the gas particles will hit the wall more often, thus increasing pressure (Fig. 5.15).

## Pressure and Temperature

From the ideal gas law, we can predict that for a given sample of an ideal gas at a constant volume, the pressure will be directly proportional to the temperature:

$$
P=\underbrace{\left(\frac{n R}{V}\right)}_{\substack{\uparrow \\ \text { Constant }}} T
$$

The KMT accounts for this behavior because when the temperature of a gas increases, the speeds of its particles increase, the particles hitting the wall with greater force and greater frequency. Since the volume remains the same, this would result in increased gas pressure (Fig. 5.16).

> KMT. What if we could not assume the third postulate to be true? How would this affect the measured pressure of a gas?

## Volume and Temperature (Charles's Law)

The ideal gas law indicates that for a given sample of gas at a constant pressure, the volume of the gas is directly proportional to the temperature in kelvins:

$$
V=\underbrace{\left(\frac{n R}{P}\right)}_{\substack{\uparrow \\ \text { Constant }}} T
$$

This can be visualized from the KMT (Fig. 5.17). When the gas is heated to a higher temperature, the speeds of its molecules increase and thus they hit the walls more

FIGURE 5.17 The effects of increasing the temperature of a sample of gas at constant pressure.

FIGURE 5.18 The effects of increasing the number of moles of gas particles at constant temperature and pressure.

often and with more force. The only way to keep the pressure constant in this situation is to increase the volume of the container. This compensates for the increased particle speeds.

## Volume and Number of Moles (Avogadro's Law)

The ideal gas law predicts that the volume of a gas at a constant temperature and pressure depends directly on the number of gas particles present:

$$
V=\underbrace{\left(\frac{R T}{P}\right)}_{\substack{\uparrow \\ \text { Constant }}} n
$$

This makes sense in terms of the KMT because an increase in the number of gas particles at the same temperature would cause the pressure to increase if the volume were held constant (Fig. 5.18). The only way to return the pressure to its original value is to increase the volume.

It is important to recognize that the volume of a gas (at constant $P$ and $T$ ) depends only on the number of gas particles present. The individual volumes of the particles are not a factor because the particle volumes are so small compared with the distances between the particles (for a gas behaving ideally).

## Mixture of Gases (Dalton's Law)

The observation that the total pressure exerted by a mixture of gases is the sum of the pressures of the individual gases is expected because the KMT assumes that all gas particles are independent of each other and that the volumes of the individual particles are unimportant. Thus the identities of the gas particles do not matter.

Kinetic energy (KE) given by the equation $\mathrm{KE}=\frac{1}{2} m \overline{u^{2}}$ is the energy due to the motion of a particle. We will discuss this further in Section 6.1.

## Deriving the Ideal Gas Law

We have shown qualitatively that the assumptions of the KMT successfully account for the observed behavior of an ideal gas. We can go further. By applying the principles of physics to the assumptions of the KMT, we can in effect derive the ideal gas law.

As shown in detail in Appendix 2, we can apply the definitions of velocity, momentum, force, and pressure to the collection of particles in an ideal gas and derive the following expression for pressure:

$$
P=\frac{2}{3}\left[\frac{n N_{\mathrm{A}}\left(\frac{1}{2} m \overline{u^{2}}\right)}{V}\right]
$$

where $P$ is the pressure of the gas, $n$ is the number of moles of gas, $N_{\mathrm{A}}$ is Avogadro's number, $m$ is the mass of each particle, $\overline{u^{2}}$ is the average of the square of the velocities of the particles, and $V$ is the volume of the container.

The quantity $\frac{1}{2} m \overline{u^{2}}$ represents the average kinetic energy of a gas particle. If the average kinetic energy of an individual particle is multiplied by $N_{\mathrm{A}}$, the number of particles in a mole, we get the average kinetic energy for a mole of gas particles:

$$
(\mathrm{KE})_{\mathrm{avg}}=N_{\mathrm{A}}\left(\frac{1}{2} m \overline{u^{2}}\right)
$$

Using this definition, we can rewrite the expression for pressure as

$$
P=\frac{2}{3}\left[\frac{n(\mathrm{KE})_{\mathrm{avg}}}{V}\right] \quad \text { or } \quad \frac{P V}{n}=\frac{2}{3}(\mathrm{KE})_{\mathrm{avg}}
$$

The fourth postulate of the kinetic molecular theory is that the average kinetic energy of the particles in the gas sample is directly proportional to the temperature in kelvin. Thus, since $(\mathrm{KE})_{\text {avg }} \propto T$, we can write

$$
\frac{P V}{n}=\frac{2}{3}(\mathrm{KE})_{\mathrm{avg}} \propto T \quad \text { or } \quad \frac{P V}{n} \propto T
$$

Note that this expression has been derived from the assumptions of the kinetic molecular theory. How does it compare to the ideal gas law-the equation obtained from experiment? Compare the ideal gas law,

$$
\frac{P V}{n}=R T \quad \text { From experiment }
$$

with the result from the kinetic molecular theory,

$$
\frac{P V}{n} \propto T \quad \text { From theory }
$$

These expressions have exactly the same form if $R$, the universal gas constant, is considered the proportionality constant in the second case.

The agreement between the ideal gas law and the predictions of the kinetic molecular theory gives us confidence in the validity of the model. The characteristics we have assumed for ideal gas particles must agree, at least under certain conditions, with their actual behavior.

## The Meaning of Temperature

We have seen from the kinetic molecular theory that the Kelvin temperature indicates the average kinetic energy of the gas particles. The exact relationship between temperature and average kinetic energy can be obtained by combining the equations:

$$
\frac{P V}{n}=R T=\frac{2}{3}(\mathrm{KE})_{\mathrm{avg}}
$$

which yields the expression

$$
(\mathrm{KE})_{\mathrm{avg}}=\frac{3}{2} K^{\prime} T
$$

This is a very important relationship. It summarizes the meaning of the Kelvin temperature of a gas: The Kelvin temperature is an index of the random motions of the particles of a gas, with higher temperature meaning greater motion. (As we will see in Chapter 10, temperature is an index of the random motions in solids and liquids as well as in gases.)

## Root Mean Square Velocity

In the equation from the kinetic molecular theory, the average velocity of the gas particles is a special kind of average. The symbol $\overline{u^{2}}$ means the average of the squares of the particle velocities. The square root of $\overline{u^{2}}$ is called the root mean square velocity and is symbolized by $u_{\mathrm{rms}}$ :

$$
u_{\mathrm{rms}}=\sqrt{\overline{\overline{u^{2}}}}
$$

We can obtain an expression for $u_{\mathrm{rms}}$ from the equations

$$
(\mathrm{KE})_{\mathrm{avg}}=N_{\mathrm{A}}\left(\frac{1}{2} m \overline{u^{2}}\right) \quad \text { and } \quad(\mathrm{KE})_{\mathrm{avg}}=\frac{3}{2} R T
$$

Combination of these equations gives

$$
N_{\mathrm{A}}\left(\frac{1}{2} m \overline{u^{2}}\right)=\frac{3}{2} R T \quad \text { or } \quad \overline{u^{2}}=\frac{3 R T}{N_{\mathrm{A}} m}
$$

Taking the square root of both sides of the last equation produces

$$
\sqrt{\overline{u^{2}}}=u_{\mathrm{rms}}=\sqrt{\frac{3 R T}{N_{\mathrm{A}} m}}
$$

> $R=0.08206 \frac{\mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}$
> $R=8.3145 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}$

In this expression $m$ represents the mass in kilograms of a single gas particle. When $N_{\mathrm{A}}$, the number of particles in a mole, is multiplied by $m$, the product is the mass of a mole of gas particles in kilograms. We will call this quantity $M$. Substituting $M$ for $N_{\mathrm{A}} m$ in the equation for $u_{\mathrm{rms}}$, we obtain

$$
u_{\mathrm{rms}}=\sqrt{\frac{3 R T}{M}}
$$

Before we can use this equation, we need to consider the units for $R$. So far we have used $0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$ as the value of $R$. But to obtain the desired units (meters per second) for $u_{\text {rms }}, R$ must be expressed in different units. As we will see in more detail in Chapter 6, the energy unit most often used in the SI system is the joule (J). A joule is defined as a kilogram meter squared per second squared $\left(\mathrm{kg} \cdot \mathrm{m}^{2} / \mathrm{s}^{2}\right)$. When $R$ is converted to include the unit of joules, it has the value $8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. When $R$ in these units is used in the expression $\sqrt{3 R T / M}, u_{\mathrm{rms}}$ is obtained in the units of meters per second as desired.

## INTERACTIVE EXAMPLE 5.19 Root Mean Square Velocity

Calculate the root mean square velocity for the atoms in a sample of helium gas at $25^{\circ} \mathrm{C}$.

## SOLUTION Where are we going?

To determine the root mean square velocity for the atoms of He

## What do we know?

$$
\begin{aligned}
& \text { > } T=25^{\circ} \mathrm{C}+273=298 \mathrm{~K} \\
& >R=8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
$$

What information do we need?
, Root mean square velocity is $u_{\mathrm{rms}}=\sqrt{\frac{3 R T}{M}}$

## How do we get there?

What is the mass of a mole of He in kilograms?

$$
M=4.00 \frac{\mathrm{~g}}{\mathrm{~mol}} \times \frac{1 \mathrm{~kg}}{1000 \mathrm{~g}}=4.00 \times 10^{-3} \mathrm{~kg} / \mathrm{mol}
$$

What is the root mean square velocity for the atoms of He?

$$
u_{\mathrm{rms}}=\sqrt{\frac{3\left(8.3145 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{mot}}\right)(298 \mathrm{~K})}{4.00 \times 10^{-3} \frac{\mathrm{~kg}}{\mathrm{mot}}}}=\sqrt{1.86 \times 10^{6} \frac{\mathrm{~J}}{\mathrm{~kg}}}
$$

Since the units of J are $\mathrm{kg} \cdot \mathrm{m}^{2} / \mathrm{s}^{2}$, this expression gives

$$
u_{\mathrm{rms}}=\sqrt{1.86 \times 10^{6} \frac{\mathrm{~kg} \cdot \mathrm{~m}^{2}}{\mathrm{~kg} \cdot \mathrm{~s}^{2}}}=1.36 \times 10^{3} \mathrm{~m} / \mathrm{s}
$$

Reality Check The resulting units are appropriate for velocity.

FIGURE 5.19 Path of one particle in a gas. Any given particle will continuously change its course as a result of collisions with other particles, as well as with the walls of the container.

FIGURE 5.20 A plot of the relative number of $\mathrm{O}_{2}$ molecules that have a given velocity at STP.

FIGURE 5.21 A plot of the relative number of $\mathrm{N}_{2}$ molecules that have a given velocity at three temperatures. Note that as the temperature increases, both the average velocity and the spread of velocities increase.

So far we have said nothing about the range of velocities actually found in a gas sample. In a real gas, there are large numbers of collisions between particles. For example, as we will see in the next section, when an odorous gas such as ammonia is released in a room, it takes some time for the odor to permeate the air. This delay results from collisions between the $\mathrm{NH}_{3}$ molecules and the $\mathrm{O}_{2}$ and $\mathrm{N}_{2}$ molecules in the air, which greatly slow the mixing process.

If the path of a particular gas particle could be monitored, it would look very erratic, something like that shown in Fig. 5.19. The average distance a particle travels between collisions in a particular gas sample is called the mean free path. It is typically a very small distance ( $1 \times 10^{-7} \mathrm{~m}$ for $\mathrm{O}_{2}$ at STP). One effect of the many collisions among gas particles is to produce a large range of velocities as the particles collide and exchange kinetic energy. Although $u_{\mathrm{rms}}$ for oxygen gas at STP is approximately $500 \mathrm{~m} / \mathrm{s}$, the majority of $\mathrm{O}_{2}$ molecules do not have this velocity. The actual distribution of molecular velocities for oxygen gas at STP is shown in Fig. 5.20. This figure shows the relative number of gas molecules having each particular velocity.

We are also interested in the effect of temperature on the velocity distribution in a gas. Figure 5.21 shows the velocity distribution (called the Maxwell-Boltzmann distribution) for nitrogen gas at three temperatures. Note that as the temperature is increased, the curve peak moves toward higher values and the range of velocities becomes much larger. The peak of the curve reflects the most probable velocity (the velocity found most often as we sample the movement of the various particles in the gas). Because the kinetic energy increases with temperature, it makes sense that the peak of the curve should move to higher values as the temperature of the gas is increased.

### 5.7 Effusion and Diffusion

We have seen that the postulates of the kinetic molecular theory, when combined with the appropriate physical principles, produce an equation that successfully fits the experimentally observed behavior of gases as they approach ideal behavior. Two phenomena involving gases provide further tests of this model.

Diffusion is the term used to describe the mixing of gases. When a small amount of pungent-smelling ammonia is released at the front of a classroom, it takes some time before everyone in the room can smell it, because time is required for the ammonia to mix with the air. The rate of diffusion is the rate of the mixing of gases. Effusion is the

FIGURE 5.22 The effusion of a gas into an evacuated chamber. The rate of effusion (the rate at which the gas is transferred across the barrier through the pin hole) is inversely proportional to the square root of the mass of the gas molecules.

In Graham's law the units for molar mass can be $\mathrm{g} / \mathrm{mol}$ or $\mathrm{kg} / \mathrm{mol}$, since the units cancel in the ratio $\frac{\sqrt{M_{2}}}{\sqrt{M_{1}}}$

term used to describe the passage of a gas through a tiny orifice into an evacuated chamber, as shown in Fig. 5.22. The rate of effusion measures the speed at which the gas is transferred into the chamber.

## Effusion

Thomas Graham (1805-1869), a Scottish chemist, found experimentally that the rate of effusion of a gas is inversely proportional to the square root of the mass of its particles. Stated in another way, the relative rates of effusion of two gases at the same temperature and pressure are given by the inverse ratio of the square roots of the masses of the gas particles:

$$
\frac{\text { Rate of effusion for gas } 1}{\text { Rate of effusion for gas } 2}=\frac{\sqrt{M_{2}}}{\sqrt{M_{1}}}
$$

where $M_{1}$ and $M_{2}$ represent the molar masses of the gases. This equation is called Graham's law of effusion.

## INTERACTIVE EXAMPLE 5.20

FIGURE 5.23 Relative molecular speed distribution of $\mathrm{H}_{2}$ and $\mathrm{UF}_{6}$.

## Effusion Rates

Calculate the ratio of the effusion rates of hydrogen gas $\left(\mathrm{H}_{2}\right)$ and uranium hexafluoride $\left(\mathrm{UF}_{6}\right)$, a gas used in the enrichment process to produce fuel for nuclear reactors (Fig. 5.23).

SOLUTION First we need to compute the molar masses: Molar mass of $\mathrm{H}_{2}=2.016 \mathrm{~g} / \mathrm{mol}$, and molar mass of $\mathrm{UF}_{6}=352.02 \mathrm{~g} / \mathrm{mol}$. Using Graham's law,

$$
\square \frac{\text { Rate of effusion for } \mathrm{H}_{2}}{\text { Rate of effusion for } \mathrm{UF}_{6}}=\frac{\sqrt{M_{\mathrm{UF}_{6}}}}{\sqrt{M_{\mathrm{H}_{2}}}}=\sqrt{\frac{352.02}{2.016}}=13.2
$$

The effusion rate of the very light $\mathrm{H}_{2}$ molecules is about 13 times that of the massive $\mathrm{UF}_{6}$ molecules.

## See Exeraises 5.119 through 5.122

Does the kinetic molecular model for gases correctly predict the relative effusion rates of gases summarized by Graham's law? To answer this question, we must recognize that the effusion rate for a gas depends directly on the average velocity of its particles. The faster the gas particles are moving, the more likely they are to pass

FIGURE 5.24 (above left) A demonstration of the relative diffusion rates of $\mathrm{NH}_{3}$ and HCl molecules through air. Two cotton plugs, one dipped in $\mathrm{HCl}(a q)$ and one dipped in $\mathrm{NH}_{3}(a q)$, are simultaneously inserted into the ends of the tube. Gaseous $\mathrm{NH}_{3}$ and HCl vaporizing from the cotton plugs diffuse toward each other and, where they meet, react to form $\mathrm{NH}_{4} \mathrm{Cl}(s)$. (above right) When $\mathrm{HCl}(g)$ and $\mathrm{NH}_{3}(g)$ meet in the tube, a white ring of $\mathrm{NH}_{4} \mathrm{Cl}(s)$ forms.
through the effusion orifice. This reasoning leads to the following prediction for two gases at the same pressure and temperature ( $T$ ):

$$
\frac{\text { Effusion rate for gas } 1}{\text { Effusion rate for gas } 2}=\frac{u_{\mathrm{rms}} \text { for gas } 1}{u_{\mathrm{rms}} \text { for gas } 2}=\frac{\sqrt{\frac{3 R T}{M_{1}}}}{\sqrt{\frac{3 R T}{M_{2}}}}=\frac{\sqrt{M_{2}}}{\sqrt{M_{1}}}
$$

This equation is identical to Graham's law. Thus the kinetic molecular model does fit the experimental results for the effusion of gases.

## Diffusion

Diffusion is frequently illustrated by the lecture demonstration represented in Fig. 5.24, in which two cotton plugs soaked in ammonia and hydrochloric acid are simultaneously placed at the ends of a long tube. A white ring of ammonium chloride $\left(\mathrm{NH}_{4} \mathrm{Cl}\right)$ forms where the $\mathrm{NH}_{3}$ and HCl molecules meet several minutes later:

$$
\mathrm{NH}_{3}(g)+\mathrm{HCl}(g) \longrightarrow \underset{\text { White solid }}{\mathrm{NH}_{4} \mathrm{Cl}(s)}
$$

As a first approximation, we might expect that the distances traveled by the two gases are related to the relative velocities of the gas molecules:

$$
\frac{\text { Distance traveled by } \mathrm{NH}_{3}}{\text { Distance traveled by } \mathrm{HCl}}=\frac{u_{\mathrm{rms}} \text { for } \mathrm{NH}_{3}}{u_{\mathrm{rms}} \text { for } \mathrm{HCl}}=\sqrt{\frac{M_{\mathrm{HCl}}}{M_{\mathrm{NH}_{3}}}}=\sqrt{\frac{36.5}{17}}=1.5
$$

However, careful experiments produce an observed ratio of less than 1.5 , indicating that a quantitative analysis of diffusion requires a more complex analysis.

The diffusion of the gases through the tube is surprisingly slow in light of the fact that the velocities of HCl and $\mathrm{NH}_{3}$ molecules at $25^{\circ} \mathrm{C}$ are about 450 and $660 \mathrm{~m} /$, respectively. Why does it take several minutes for the $\mathrm{NH}_{3}$ and HCl molecules to meet? The answer is that the tube contains air and thus the $\mathrm{NH}_{3}$ and HCl molecules undergo many collisions with $\mathrm{O}_{2}$ and $\mathrm{N}_{2}$ molecules as they travel through the tube. Because so many collisions occur when gases mix, diffusion is quite complicated to describe theoretically.

### 5.8 Real Gases

An ideal gas is a hypothetical concept. No gas exactly follows the ideal gas law, although many gases come very close at low pressures and/or high temperatures. Thus ideal gas behavior can best be thought of as the behavior approached by real gases under certain conditions.

FIGURE 5.25 Plots of $P V / n R T$ versus $P$ for several gases ( 200 K ). Note the significant deviations from ideal behavior $(P V / n R T=1)$. The behavior is close to ideal only at low pressures (less than 1 atm ).

FIGURE 5.26 Plots of $P V / n R T$ versus $P$ for nitrogen gas at three temperatures. Note that although nonideal behavior is evident in each case, the deviations are smaller at the higher temperatures.
$P^{\prime}$ is corrected for the finite volume of the particles. The attractive forces have not yet been taken into account.

The attractive forces among molecules will be discussed in Chapter 10.

We have seen that a very simple model, the kinetic molecular theory, by making some rather drastic assumptions (no interparticle interactions and zero volume for the gas particles), successfully explains ideal behavior. However, it is important that we examine real gas behavior to see how it differs from that predicted by the ideal gas law and to determine what modifications are needed in the kinetic molecular theory to explain the observed behavior. Since a model is an approximation and will inevitably fail, we must be ready to learn from such failures. In fact, we often learn more about nature from the failures of our models than from their successes.

We will examine the experimentally observed behavior of real gases by measuring the pressure, volume, temperature, and number of moles for a gas and noting how the quantity $P V / n R T$ depends on pressure. Plots of $P V / n R T$ versus $P$ are shown for several gases in Fig. 5.25. For an ideal gas, $P V / n R T$ equals 1 under all conditions, but notice that for real gases, $P V / n R T$ approaches 1 only at very low pressures (typically below 1 atm ). To illustrate the effect of temperature, $P V / n R T$ is plotted versus $P$ for nitrogen gas at several temperatures in Fig. 5.26. Note that the behavior of the gas appears to become more nearly ideal as the temperature is increased. The most important conclusion to be drawn from these figures is that a real gas typically exhibits behavior that is closest to ideal behavior at low pressures and high temperatures.

One of the most important procedures in science is correcting our models as we collect more data. We will understand more clearly how gases actually behave if we can figure out how to correct the simple model that explains the ideal gas law so that the new model fits the behavior we actually observe for gases. So the question is: How can we modify the assumptions of the kinetic molecular theory to fit the behavior of real gases? The first person to do important work in this area was Johannes van der Waals (1837-1923), a physics professor at the University of Amsterdam who in 1910 received a Nobel Prize for his work. To follow his analysis, we start with the ideal gas law,

$$
P=\frac{n R T}{V}
$$

Remember that this equation describes the behavior of a hypothetical gas consisting of volumeless entities that do not interact with each other. In contrast, a real gas consists of atoms or molecules that have finite volumes. Therefore, the volume available to a given particle in a real gas is less than the volume of the container because the gas particles themselves take up some of the space. To account for this discrepancy, van der Waals represented the actual volume as the volume of the container $V$ minus a correction factor for the volume of the molecules $n b$, where $n$ is the number of moles of gas and $b$ is an empirical constant (one determined by fitting the equation to the experimental results). Thus the volume actually available to a given gas molecule is given by the difference $V-n b$.

This modification of the ideal gas equation leads to the equation

$$
P^{\prime}=\frac{n R T}{V-n b}
$$

The volume of the gas particles has now been taken into account.
The next step is to allow for the attractions that occur among the particles in a real gas. The effect of these attractions is to make the observed pressure $P_{\text {obs }}$ smaller than it would be if the gas particles did not interact:

$$
P_{\mathrm{obs}}=\left(P^{\prime}-\text { correction factor }\right)=\left(\frac{n R T}{V-n b}-\text { correction factor }\right)
$$

This effect can be understood using the following model. When gas particles come close together, attractive forces occur, which cause the particles to hit the wall very slightly less often than they would in the absence of these interactions (Fig. 5.27).

The size of the correction factor depends on the concentration of gas molecules defined in terms of moles of gas particles per liter $(n / V)$. The higher the concentration,

FIGURE 5.27 (a) Gas at low concentration-relatively few interactions between particles. The indicated gas particle exerts a pressure on the wall close to that predicted for an ideal gas.
(b) Gas at high concentration-many more interactions between particles. The indicated gas particle exerts a much lower pressure on the wall than would be expected in the absence of interactions.
We have now corrected for both the finite volume and the attractive forces of the particles.
$P_{\text {obs }}$ is usually called just $P$.

Gas sample with 10 particles
the more likely a pair of gas particles will be close enough to attract each other. For large numbers of particles, the number of interacting pairs of particles depends on the square of the number of particles and thus on the square of the concentration, or $(n / V)^{2}$. This can be justified as follows: In a gas sample containing $N$ particles, there are $N-1$ partners available for each particle (Fig. 5.28). Since the $1 \cdots 2$ pair is the same as the $2 \cdots 1$ pair, this analysis counts each pair twice. Thus, for $N$ particles, there are $N(N-1) / 2$ pairs. If $N$ is a very large number, $N-1$ approximately equals $N$, giving $N^{2} / 2$ possible pairs. Thus the pressure, corrected for the attractions of the particles, has the form

$$
P_{\mathrm{obs}}=P^{\prime}-a\left(\frac{n}{V}\right)^{2}
$$

where $a$ is a proportionality constant (which includes the factor of $\frac{1}{2}$ from $N^{2} / 2$ ). The value of $a$ for a given real gas can be determined from observing the actual behavior of that gas. Inserting the corrections for both the volume of the particles and the attractions of the particles gives the equation

This equation can be rearranged to give the van der Waals equation:

$$
\underbrace{\left[P_{\mathrm{obs}}+a\left(\frac{n}{V}\right)^{2}\right] \times \underbrace{\text { Corrected pressure }}_{V_{\text {ideal }}} \times \underbrace{(V-n b)}_{\text {Corrected volume }}=n R T}_{P_{\text {ideal }}}
$$

The values of the weighting factors $a$ and $b$ are determined for a given gas by fitting experimental behavior. That is, $a$ and $b$ are varied until the best fit of the observed pressure is obtained under all conditions. The values of $a$ and $b$ for various gases are given in Table 5.3.

Experimental studies indicate that the changes van der Waals made in the basic assumptions of the kinetic molecular theory correct the major flaws in the model. First, consider the effects of volume. For a gas at low pressure (large volume), the volume of the container is very large compared with the volumes of the gas particles. That is, in this case the volume available to the gas is essentially equal to the volume of the container, and the gas behaves ideally. On the other hand, for a gas at high pressure (small container volume), the volume of the particles becomes significant so that the volume available to the gas is significantly less than the container volume. These cases are illustrated in Fig. 5.29. Note from Table 5.3 that the volume correction constant $b$ generally increases with the size of the gas molecule, which gives further support to these arguments.

The fact that a real gas tends to behave more ideally at high temperatures also can be explained in terms of the van der Waals model. At high temperatures the particles are moving so rapidly that the effects of interparticle interactions are not very important.

FIGURE 5.28 Illustration of pairwise interactions among gas particles. In a sample with 10 particles, each particle has 9 possible partners, to give $10(9) / 2=45$ distinct pairs. The factor of $\frac{1}{2}$ arises because when particle (1) is the particle of interest, we count the (1) . 2 pair, and when particle (2) is the particle of interest, we count the (2) $\cdots$ (1) pair. However, (1) $\cdots$ (2) and (2) $\cdots$ (1) are the same pair, which we thus have counted twice. Therefore, we must divide by 2 to get the correct number of pairs.

TABLE 5.3| Values of the van der Waals Constants for Some Common Gases

| Gas | $a\left(\frac{a t m \cdot L^{2}}{m o l^{2}}\right)$ | $b\left(\frac{L}{m o l}\right)$ |
| :--- | :--- | :--- |
| He | 0.0341 | 0.0237 |

| $\mathrm{H}_{2} \mathrm{O}$ | 5.46 | 0.0305 |

FIGURE 5.29 The volume taken up by the gas particles themselves is less important at (a) large container volume (low pressure) than at (b) small container volume (high pressure).

The corrections to the kinetic molecular theory that van der Waals found necessary to explain real gas behavior make physical sense, which makes us confident that we understand the fundamentals of gas behavior at the particle level. This is significant because so much important chemistry takes place in the gas phase. In fact, the mixture of gases called the atmosphere is vital to our existence. In Section 5.10 we consider some of the important reactions that occur in the atmosphere.

### 5.8 Characteristics of Several Real Gases

We can understand gas behavior more completely if we examine the characteristics of several common gases. Note from Fig. 5.25 that the gases $\mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{CH}_{4}$, and $\mathrm{CO}_{2}$ show different behavior when the compressibility $\left(\frac{P V}{n R T}\right)$ is plotted versus $P$. For example, notice that the plot for $\mathrm{H}_{2}(g)$ never drops below the ideal value (1.0) in contrast to all the other gases. What is special about $\mathrm{H}_{2}$ compared to these other gases? Recall from Section 5.8 that the reason that the compressibility of a real gas falls below 1.0 is that the actual (observed) pressure is lower than the pressure expected for an ideal gas due to the intermolecular attractions that occur in real gases. This must mean that $\mathrm{H}_{2}$ molecules have very low attractive forces for each other. This idea is borne out by looking at the van der Waals $a$ value for $\mathrm{H}_{2}$ in Table 5.3. Note that $\mathrm{H}_{2}$ has the lowest value among the gases $\mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{CH}_{4}$, and $\mathrm{CO}_{2}$. Remember that the value of $a$ reflects how much of a correction must be made to adjust the observed pressure up to the expected ideal pressure:

$$
P_{\mathrm{ideal}}=P_{\mathrm{observed}}+a\left(\frac{n}{V}\right)^{2}
$$

A low value for $a$ reflects weak intermolecular forces among the gas molecules.
Also notice that although the compressibility for $\mathrm{N}_{2}$ dips below 1.0, it does not show as much deviation as that for $\mathrm{CH}_{4}$, which in turn does not show as much deviation as the compressibility for $\mathrm{CO}_{2}$. Based on this behavior, we can surmise that the importance of intermolecular interactions increases in this order:

$$
\mathrm{H}_{2}<\mathrm{N}_{2}<\mathrm{CH}_{4}<\mathrm{CO}_{2}
$$

This order is reflected by the relative $a$ values for these gases in Table 5.3. In Section 10.1, we will see how these variations in intermolecular interactions can be explained. The main point to be made here is that real gas behavior can tell us about the relative importance of intermolecular attractions among gas molecules.

CEATICAL ThHINKINC You have learned that no gases behave perfectly ideally, but under conditions of high temperature and low pressure (high volume), gases behave more ideally. What if all gases always behaved perfectly ideally? How would the world be different?

### 5.10 Chemistry in the Atmosphere

TABLE 5.4 | Atmospheric Composition Near Sea Level (Dry Air)*

| Component | Mole Fraction |
| :--- | :--- |
| $\mathrm{N}_{2}$ | 0.78084 |
| $\mathrm{O}_{2}$ | 0.20948 |

| Xe | 0.000000087 |

*The atmosphere contains various amounts of water vapor depending on conditions.

The most important gases to us are those in the atmosphere that surrounds the earth's surface. The principal components are $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$, but many other important gases, such as $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$, are also present. The average composition of the earth's atmosphere near sea level, with the water vapor removed, is shown in Table 5.4. Because of gravitational effects, the composition of the earth's atmosphere is not constant; heavier molecules tend to be near the earth's surface, and light molecules tend to migrate to higher altitudes, with some eventually escaping into space. The atmosphere is a highly complex and dynamic system, but for convenience we divide it into several layers. Fig. 5.30 shows how the temperature changes with altitude.

The chemistry occurring in the higher levels of the atmosphere is mostly determined by the effects of high-energy radiation and particles from the sun and other sources in space. In fact, the upper atmosphere serves as an important shield to prevent this high-energy radiation from reaching the earth, where it would damage the relatively fragile molecules sustaining life. In particular, the ozone in the upper atmosphere helps prevent high-energy ultraviolet radiation from penetrating to the earth. Intensive research is in progress to determine the natural factors that control the ozone concentration and how it is affected by chemicals released into the atmosphere.

The chemistry occurring in the troposphere, the layer of atmosphere closest to the earth's surface, is strongly influenced by human activities. Millions of tons of gases and particulates are released into the troposphere by our highly industrial civilization. Actually, it is amazing that the atmosphere can absorb so much material with relatively small permanent changes (so far).

FIGURE 5.30 The variation of temperature with altitude.

FIGURE 5.31 Concentration (in molecules per million molecules of "air") for some smog components versus time of day. (Source: P.A. Leighton, "Photochemistry of Air Pollution," in Physical Chemistry: A Series of Monographs, edited by Eric Hutchinson and P. Van Rysselberghe, Vol. IX. New York: Academic Press, 1961.)

The OH radical has no charge [it has one fewer electron than the hydroxide ion $\left.\left(\mathrm{OH}^{-}\right)\right]$.

Although represented here as $\mathrm{O}_{2}$, the actual oxidant for NO is OH or an organic peroxide such as $\mathrm{CH}_{3} \mathrm{COO}$, formed by oxidation of organic pollutants.

Significant changes, however, are occurring. Severe air pollution is found around many large cities, and it is probable that long-range changes in our planet's weather are taking place. We will discuss some of the long-range effects of pollution in Chapter 6. In this section we will deal with short-term, localized effects of pollution.

The two main sources of pollution are transportation and the production of electricity. The combustion of petroleum in vehicles produces $\mathrm{CO}, \mathrm{CO}_{2}, \mathrm{NO}$, and $\mathrm{NO}_{2}$, along with unburned molecules from petroleum. When this mixture is trapped close to the ground in stagnant air, reactions occur, producing chemicals that are potentially irritating and harmful to living systems.

The complex chemistry of polluted air appears to center around the nitrogen oxides $\left(\mathrm{NO}_{x}\right)$. At the high temperatures found in the gasoline and diesel engines of cars and trucks, $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ react to form a small quantity of NO that is emitted into the air with the exhaust gases (Fig. 5.31). This NO is immediately oxidized in air to $\mathrm{NO}_{2}$, which, in turn, absorbs energy from sunlight and breaks up into nitric oxide and free oxygen atoms:

$$
\mathrm{NO}_{2}(g) \xrightarrow[\text { energy }]{\text { Radiant }} \mathrm{NO}(g)+\mathrm{O}(g)
$$

Oxygen atoms are very reactive and can combine with $\mathrm{O}_{2}$ to form ozone:

$$
\mathrm{O}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{O}_{3}(g)
$$

Ozone is also very reactive and can react directly with other pollutants, or the ozone can absorb light and break up to form an energetically excited $\mathrm{O}_{2}$ molecule $\left(\mathrm{O}_{2}{ }^{*}\right)$ and an energetically excited oxygen atom $\left(\mathrm{O}^{*}\right)$. The latter species readily reacts with a water molecule to form two hydroxyl radicals $(\mathrm{OH})$ :

$$
\mathrm{O}^{*}+\mathrm{H}_{2} \mathrm{O} \longrightarrow 2 \mathrm{OH}
$$

The hydroxyl radical is a very reactive oxidizing agent. For example, OH can react with $\mathrm{NO}_{2}$ to form nitric acid:

$$
\mathrm{OH}+\mathrm{NO}_{2} \longrightarrow \mathrm{HNO}_{3}
$$

The OH radical also can react with the unburned hydrocarbons in the polluted air to produce chemicals that cause the eyes to water and burn and are harmful to the respiratory system.

The end product of this whole process is often referred to as photochemical smog, so called because light is required to initiate some of the reactions. The production of photochemical smog can be understood more clearly by examining as a group the reactions discussed above:

$$
\begin{aligned}
& \mathrm{NO}_{2}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{O}(g) \\
& \mathrm{O}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{O}_{3}(g) \\
& \text { Net reaction: } \begin{aligned}
\mathrm{NO}(g)+\frac{1}{2} \mathrm{O}_{2}(g) & \longrightarrow \mathrm{NO}_{2}(g) \\
\frac{3}{2} \mathrm{O}_{2}(g) & \longrightarrow \mathrm{O}_{3}(g)
\end{aligned}
\end{aligned}
$$

Note that the $\mathrm{NO}_{2}$ molecules assist in the formation of ozone without being themselves used up. The ozone formed then leads to the formation of OH and other pollutants.

We can observe this process by analyzing polluted air at various times during a day (see Fig. 5.31). As people drive to work between 6 and 8 a.m., the amounts of NO, $\mathrm{NO}_{2}$, and unburned molecules from petroleum increase. Later, as the decomposition of $\mathrm{NO}_{2}$ occurs, the concentration of ozone and other pollutants builds up. Current efforts to combat the formation of photochemical smog are focused on cutting down the amounts of molecules from unburned fuel in automobile exhaust and designing engines that produce less nitric oxide.

The other major source of pollution results from burning coal to produce electricity. Much of the coal found in the Midwest contains significant quantities of sulfur, which, when burned, produces sulfur dioxide:

$$
\mathrm{S}(\text { in coal })+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g)
$$

FIGURE 5.32 Testing for acid rain in Wilderness Lake, Colorado.

FIGURE 5.33 A schematic diagram of the process for scrubbing sulfur dioxide from stack gases in power plants.

A further oxidation reaction occurs when sulfur dioxide is changed to sulfur trioxide in the air:*

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)
$$

The production of sulfur trioxide is significant because it can combine with droplets of water in the air to form sulfuric acid:

$$
\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)
$$

Sulfuric acid is very corrosive to both living things and building materials. Another result of this type of pollution is acid rain. In many parts of the northeastern United States and southeastern Canada, acid rain has caused some freshwater lakes to become too acidic to support any life (Fig. 5.32).

The problem of sulfur dioxide pollution is made more complicated by the energy crisis. As petroleum supplies dwindle and the price increases, our dependence on coal will probably grow. As supplies of low-sulfur coal are used up, high-sulfur coal will be utilized. One way to use high-sulfur coal without further harming the air quality is to remove the sulfur dioxide from the exhaust gas by means of a system called a scrubber before it is emitted from the power plant stack. A common method of scrubbing is to blow powdered limestone $\left(\mathrm{CaCO}_{3}\right)$ into the combustion chamber, where it is decomposed to lime and carbon dioxide:

$$
\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

The lime then combines with the sulfur dioxide to form calcium sulfite:

$$
\mathrm{CaO}(s)+\mathrm{SO}_{2}(g) \longrightarrow \mathrm{CaSO}_{3}(s)
$$

To remove the calcium sulfite and any remaining unreacted sulfur dioxide, an aqueous suspension of lime is injected into the exhaust gases to produce a slurry (a thick suspension) (Fig. 5.33).

Unfortunately, there are many problems associated with scrubbing. The systems are complicated and expensive and consume a great deal of energy. The large quantities of calcium sulfite produced in the process present a disposal problem. With a typical scrubber, approximately 1 ton of calcium sulfite per year is produced per person served by the power plant. Since no use has yet been found for this calcium sulfite, it is usually buried in a landfill. As a result of these difficulties, air pollution by sulfur dioxide continues to be a major problem, one that is expensive in terms of damage to the environment and human health as well as in monetary terms.

》 The average kinetic energy of the gas particles is directly proportional to the temperature of the gas in kelvins

## Gas properties

＞The particles in any gas sample have a range of velocities
＞The root mean square（rms）velocity for a gas represents the average of the squares of the particle velocities

$$
u_{\mathrm{rms}}=\sqrt{\frac{3 R T}{M}}
$$

》 Diffusion：the mixing of two or more gases
＞Effusion：the process in which a gas passes through a small hole into an empty chamber

## Real gas behavior

＞Real gases behave ideally only at high temperatures and low pressures
＞Understanding how the ideal gas equation must be modified to account for real gas behavior helps us understand how gases behave on a molecular level
）Van der Waals found that to describe real gas behavior we must consider particle interactions and particle volumes

## Review Questions Answers to the Review Questions can be found on the Student website (accessible from wwww.cengagebrain.com).

1. Explain how a barometer and a manometer work to measure the pressure of the atmosphere or the pressure of a gas in a container.
2. What are Boyle's law, Charles's law, and Avogadro's law? What plots do you make to show a linear relationship for each law?
3. Show how Boyle's law, Charles's law, and Avogadro's law are special cases of the ideal gas law. Using the ideal gas law, determine the relationship between $P$ and $n$ (at constant $V$ and $T$ ) and between $P$ and $T$ (at constant $V$ and $n$ ).
4. Rationalize the following observations.
a. Aerosol cans will explode if heated.
b. You can drink through a soda straw.
c. A thin-walled can will collapse when the air inside is removed by a vacuum pump.
d. Manufacturers produce different types of tennis balls for high and low elevations.
5. Consider the following balanced equation in which gas $X$ forms gas $\mathrm{X}_{2}$ :

$$
2 \mathrm{X}(\mathrm{~g}) \longrightarrow \mathrm{X}_{2}(\mathrm{~g})
$$

Equal moles of X are placed in two separate containers. One container is rigid so the volume cannot change; the other container is flexible so the volume changes to keep the internal pressure equal to the external pressure. The above reaction is run in each container. What happens to the pressure and density of the gas inside each container as reactants are converted to products?
6. Use the postulates of the kinetic molecular theory (KMT) to explain why Boyle's law, Charles's law, Avogadro's law, and Dalton's law of partial pressures hold true for ideal gases. Use the KMT to explain the $P$ versus $n$ (at

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. Consider the following apparatus: a test tube covered with a nonpermeable elastic membrane inside a container that is closed with a cork. A syringe goes through the cork.
a. As you push down on the syringe, how does the membrane covering the test tube change?
b. You stop pushing the syringe but continue to hold it down. In a few seconds, what happens to the membrane?
constant $V$ and $T$ ) relationship and the $P$ versus $T$ (at constant $V$ and $n$ ) relationship.
2. Consider the following velocity distribution curves $A$ and $B$.

a. If the plots represent the velocity distribution of 1.0 L of $\mathrm{He}(g)$ at STP versus 1.0 L of $\mathrm{Cl}_{2}(g)$ at STP, which plot corresponds to each gas? Explain your reasoning.
b. If the plots represent the velocity distribution of 1.0 L of $\mathrm{O}_{2}(\mathrm{~g})$ at temperatures of 273 K versus 1273 K , which plot corresponds to each temperature? Explain your reasoning. Under which temperature condition would the $\mathrm{O}_{2}(\mathrm{~g})$ sample behave most ideally? Explain.
3. Briefly describe two methods one might use to find the molar mass of a newly synthesized gas for which a molecular formula was not known.
4. In the van der Waals equation, why is a term added to the observed pressure and why is a term subtracted from the container volume to correct for nonideal gas behavior?
5. Why do real gases not always behave ideally? Under what conditions does a real gas behave most ideally? Why?
6. Figure 5.2 shows a picture of a barometer. Which of the following statements is the best explanation of how this barometer works?
a. Air pressure outside the tube causes the mercury to move in the tube until the air pressure inside and outside the tube is equal.
b. Air pressure inside the tube causes the mercury to move in the tube until the air pressure inside and outside the tube is equal.
c. Air pressure outside the tube counterbalances the weight of the mercury in the tube.
d. Capillary action of the mercury causes the mercury to go up the tube.
e. The vacuum that is formed at the top of the tube holds up the mercury.

Justify your choice, and for the choices you did not pick, explain what is wrong with them. Pictures help!
3. The barometer below shows the level of mercury at a given atmospheric pressure. Fill all the other barometers with mercury for that same atmospheric pressure. Explain your answer.

4. As you increase the temperature of a gas in a sealed, rigid container, what happens to the density of the gas? Would the results be the same if you did the same experiment in a container with a piston at constant pressure? (See Fig. 5.17.)
5. A diagram in a chemistry book shows a magnified view of a flask of air as follows:

What do you suppose is between the dots (the dots represent air molecules)?
a. air
b. dust
c. pollutants
d. oxygen
e. nothing
6. If you put a drinking straw in water, place your finger over the opening, and lift the straw out of the water, some water stays in the straw. Explain.
7. A chemistry student relates the following story: I noticed my tires were a bit low and went to the gas station. As I was filling the tires, I thought about the kinetic molecular theory (KMT). I noticed the tires because the volume was low, and I realized that I was increasing both the pressure and volume of the tires. "Hmmm," I thought, "that goes against what I learned in chemistry, where I was told pressure and volume are inversely proportional." What is the fault in the logic of the chemistry student in this situation? Explain why we think pressure and volume to be inversely related (draw pictures and use the KMT).
8. Chemicals $X$ and $Y$ (both gases) react to form the gas $X Y$, but it takes a bit of time for the reaction to occur. Both $X$ and $Y$ are placed in a container with a piston (free to move), and you note the volume. As the reaction occurs, what happens to the volume of the container? (See Fig. 5.18.)
9. Which statement best explains why a hot-air balloon rises when the air in the balloon is heated?
a. According to Charles's law, the temperature of a gas is directly related to its volume. Thus the volume of the balloon increases, making the density smaller. This lifts the balloon.
b. Hot air rises inside the balloon, and this lifts the balloon.
c. The temperature of a gas is directly related to its pressure. The pressure therefore increases, and this lifts the balloon.
d. Some of the gas escapes from the bottom of the balloon, thus decreasing the mass of gas in the balloon. This decreases the density of the gas in the balloon, which lifts the balloon.
e. Temperature is related to the root mean square velocity of the gas molecules. Thus the molecules are moving faster, hitting the balloon more, and thus lifting the balloon.
Justify your choice, and for the choices you did not pick, explain what is wrong with them.
10. Draw a highly magnified view of a sealed, rigid container filled with a gas. Then draw what it would look like if you cooled the gas significantly but kept the temperature above the boiling point of the substance in the container. Also draw what it would look like if you heated the gas significantly. Finally, draw what each situation would look like if you evacuated enough of the gas to decrease the pressure by a factor of 2 .
11. If you release a helium balloon, it soars upward and eventually pops. Explain this behavior.
12. If you have any two gases in different containers that are the same size at the same pressure and same temperature, what is true about the moles of each gas? Why is this true?
13. Explain how Boyle's law, Charles's law, and Avogadro's law are special cases of the ideal gas law.
14. You have helium gas in a two-bulbed container connected by a valve as shown below. Initially the valve is closed. When the valve is opened, will the total pressure in the apparatus be less than 5.00 atm , equal to 5.00 atm , or greater than 5.00 atm ? Explain your answer.

15. Explain the following seeming contradiction: You have two gases, $A$ and $B$, in two separate containers of equal volume and at equal pressure and temperature. Therefore, you must have the same number of moles of each gas. Because the two temperatures are equal, the average kinetic energies of the two samples are equal. Therefore, since the energy given such a system will be converted to translational motion (that is, move the molecules), the root mean square velocities of the two are equal, and thus the particles in each sample move, on average, with the same relative speed. Since $A$ and $B$ are different gases, they each must have a different molar mass. If $A$ has a higher molar mass than $B$, the particles of $A$ must be hitting the sides of the container with more force. Thus the pressure in the container of gas $A$ must be higher than that in the container with gas $B$. However, one of our initial assumptions was that the pressures were equal.
16. You have a balloon covering the mouth of a flask filled with air at 1 atm . You apply heat to the bottom of the flask until the volume of the balloon is equal to that of the flask.
a. Which has more air in it, the balloon or the flask? Or do both have the same amount? Explain.
b. In which is the pressure greater, the balloon or the flask? Or is the pressure the same? Explain.
17. How does Dalton's law of partial pressures help us with our model of ideal gases? That is, what postulates of the kinetic molecular theory does it support?
18. At the same conditions of pressure and temperature, ammonia gas is less dense than air. Why is this true?
19. For each of the quantities listed below, explain which of the following properties (mass of the molecule, density of the gas sample, temperature of the gas sample, size of the molecule, and number of moles of gas) must be known to calculate the quantity.
a. average kinetic energy
b. average number of collisions per second with other gas molecules
c. average force of each impact with the wall of the container
d. root mean square velocity
e. average number of collisions with a given area of the container
f. distance between collisions
20. You have two containers each with 1 mole of xenon gas at $15^{\circ} \mathrm{C}$. Container A has a volume of 3.0 L , and container B has a volume of 1.0 L . Explain how the following quantities compare between the two containers.
a. the average kinetic energy of the Xe atoms
b. the force with which the Xe atoms collide with the container walls
c. the root mean square velocity of the Xe atoms
d. the collision frequency of the Xe atoms (with other atoms)
e. the pressure of the Xe sample
21. Draw molecular-level views that show the differences among solids, liquids, and gases.

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of the book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

22. At room temperature, water is a liquid with a molar volume of 18 mL . At $105^{\circ} \mathrm{C}$ and 1 atm pressure, water is a gas and has a molar volume of over 30 L . Explain the large difference in molar volumes.
23. If a barometer were built using water $\left(d=1.0 \mathrm{~g} / \mathrm{cm}^{3}\right)$ instead of mercury ( $d=13.6 \mathrm{~g} / \mathrm{cm}^{3}$ ), would the column of water be higher than, lower than, or the same as the column of mercury at 1.00 atm ? If the level is different, by what factor? Explain.
24. A bag of potato chips is packed and sealed in Los Angeles, California, and then shipped to Lake Tahoe, Nevada, during ski season. It is noticed that the volume of the bag of potato chips has increased upon its arrival in Lake Tahoe. What external conditions would most likely cause the volume increase?
25. Boyle's law can be represented graphically in several ways. Which of the following plots does not correctly represent Boyle's law (assuming constant $T$ and $n$ )? Explain.

26. As weather balloons rise from the earth's surface, the pressure of the atmosphere becomes less, tending to cause the volume of the balloons to expand. However, the temperature is much lower in the upper atmosphere than at sea level. Would this temperature effect tend to make such a balloon expand or contract? Weather balloons do, in fact, expand as they rise. What does this tell you?
27. Which noble gas has the smallest density at STP? Explain.
28. Consider two different containers, each filled with 2 moles of $\mathrm{Ne}(g)$. One of the containers is rigid and has constant volume. The other container is flexible (like a balloon) and is capable of changing its volume to keep the external pressure and internal pressure equal to each other. If you raise the temperature in both containers, what happens to the pressure and density of the gas inside each container? Assume a constant external pressure.
29. In Example 5.11 of the text, the molar volume of $\mathrm{N}_{2}(g)$ at STP is given as $22.42 \mathrm{~L} / \mathrm{mol} \mathrm{N}_{2}$. How is this number calculated? How does the molar volume of $\operatorname{He}(g)$ at STP compare to the molar volume of $\mathrm{N}_{2}(g)$ at STP (assuming ideal gas behavior)? Is the molar volume of $\mathrm{N}_{2}(\mathrm{~g})$ at 1.000 atm and $25.0^{\circ} \mathrm{C}$ equal to, less than, or greater than $22.42 \mathrm{~L} / \mathrm{mol}$ ? Explain. Is the molar volume of $\mathrm{N}_{2}(g)$ collected over water at a total pressure of 1.000 atm and $0.0^{\circ} \mathrm{C}$ equal to, less than, or greater than $22.42 \mathrm{~L} / \mathrm{mol}$ ? Explain.
30. You are holding two balloons of equal volume; one contains argon and the other contains neon. What is the approximate mass ratio between Ar and Ne in the two balloons?
31. Consider a sample of ideal gas molecules for the following question.
a. How is the average kinetic energy of the gas molecules related to temperature?
b. How is the average velocity of the gas molecules related to temperature?
c. How is the average velocity of the gas molecules related to the molar mass of the gas at constant temperature?
32. Consider the flasks in the following diagrams.

Assuming the connecting tube has negligible volume, draw what each diagram will look like after the stopcock between the two flasks is opened. Also, solve for the final pressure in each case, in terms of the original pressure. Assume temperature is constant.
33. Do all the molecules in a 1-mole sample of $\mathrm{CH}_{4}(\mathrm{~g})$ have the same kinetic energy at 273 K ? Do all molecules in a 1-mole sample of $\mathrm{N}_{2}(\mathrm{~g})$ have the same velocity at 546 K ? Explain.
34. Consider the following samples of gases at the same temperature.

Arrange each of these samples in order from lowest to highest:
a. pressure
b. average kinetic energy
c. density
d. root mean square velocity

Note: Some samples of gases may have equal values for these attributes. Assume the larger containers have a volume twice the volume of the smaller containers, and assume the mass of an argon atom is twice the mass of a neon atom.
35. As $\mathrm{NH}_{3}(g)$ is decomposed into nitrogen gas and hydrogen gas at constant pressure and temperature, the volume of the product gases collected is twice the volume of $\mathrm{NH}_{3}$ reacted. Explain. As $\mathrm{NH}_{3}(g)$ is decomposed into nitrogen gas and hydrogen gas at constant volume and temperature, the total pressure increases by some factor. Why the increase in pressure and by what factor does the total pressure increase when reactants are completely converted into products? How do the partial pressures of the product gases compare to each other and to the initial pressure of $\mathrm{NH}_{3}$ ?
36. Which of the following statements is(are) true? For the false statements, correct them.
a. At constant temperature, the lighter the gas molecules, the faster the average velocity of the gas molecules.
b. At constant temperature, the heavier the gas molecules, the larger the average kinetic energy of the gas molecules.
c. A real gas behaves most ideally when the container volume is relatively large and the gas molecules are moving relatively quickly.
d. As temperature increases, the effect of interparticle interactions on gas behavior is increased.
e. At constant $V$ and $T$, as gas molecules are added into a container, the number of collisions per unit area increases resulting in a higher pressure.
f. The kinetic molecular theory predicts that pressure is inversely proportional to temperature at constant volume and moles of gas.
37. From the values in Table 5.3 for the van der Waals constant $a$ for the gases $\mathrm{H}_{2}, \mathrm{CO}_{2}, \mathrm{~N}_{2}$, and $\mathrm{CH}_{4}$, predict which of these gas molecules show the strongest intermolecular attractions.
38. Without looking at a table of values, which of the following gases would you expect to have the largest value of the van der Waals constant $b$ : $\mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{CH}_{4}, \mathrm{C}_{2} \mathrm{H}_{6}$, or $\mathrm{C}_{3} \mathrm{H}_{8}$ ?
39. Figure 5.6 shows the $P V$ versus $P$ plot for three different gases. Which gas behaves most ideally? Explain.
40. Ideal gas particles are assumed to be volumeless and to neither attract nor repel each other. Why are these assumptions crucial to the validity of Dalton's law of partial pressures?

## Exercises

In this section similar exercises are paired.

## Pressure

-41. Freon-12 $\left(\mathrm{CF}_{2} \mathrm{Cl}_{2}\right)$ is commonly used as the refrigerant in central home air conditioners. The system is initially charged to a pressure of 4.8 atm . Express this pressure in each of the following units ( $1 \mathrm{~atm}=14.7 \mathrm{psi}$ ).
a. mm Hg
b. torr
c. Pa
d. psi
42. A gauge on a compressed gas cylinder reads 2200 psi (pounds per square inch; $1 \mathrm{~atm}=14.7 \mathrm{psi}$ ). Express this pressure in each of the following units.
a. standard atmospheres
b. megapascals (MPa)
c. torr
43. A sealed-tube manometer (as shown below) can be used to measure pressures below atmospheric pressure. The tube above the mercury is evacuated. When there is a vacuum in the flask, the mercury levels in both arms of the U-tube are equal. If a gaseous sample is introduced into the flask, the mercury levels are different. The difference $h$ is a measure of the pressure of the gas inside the flask. If $h$ is equal to 6.5 cm , calculate the pressure in the flask in torr, pascals, and atmospheres.

44. If the sealed-tube manometer in Exercise 43 had a height difference of 20.0 inches between the mercury levels, what is the pressure in the flask in torr and atmospheres?

A diagram for an open-tube manometer is shown below.

If the flask is open to the atmosphere, the mercury levels are equal. For each of the following situations where a gas is contained in the flask, calculate the pressure in the flask in torr, atmospheres, and pascals.

c. Calculate the pressures in the flask in parts a and b (in torr) if the atmospheric pressure is 635 torr.
46. a. If the open-tube manometer in Exercise 45 contains a nonvolatile silicone oil (density $=1.30 \mathrm{~g} / \mathrm{cm}^{3}$ ) instead of mercury (density $=13.6 \mathrm{~g} / \mathrm{cm}^{3}$ ), what are the pressures in the flask as shown in parts a and b in torr, atmospheres, and pascals?
b. What advantage would there be in using a less dense fluid than mercury in a manometer used to measure relatively small differences in pressure?

## Gas Laws

An aerosol can contains 400 . mL of compressed gas at 5.20 atm . When all of the gas is sprayed into a large plastic bag, the bag inflates to a volume of 2.14 L . What is the pressure of gas in the plastic bag? Assume a constant temperature.
48. A balloon is filled to a volume of $7.00 \times 10^{2} \mathrm{~mL}$ at a temperature of $20.0^{\circ} \mathrm{C}$. The balloon is then cooled at constant pressure to a temperature of $1.00 \times 10^{2} \mathrm{~K}$. What is the final volume of the balloon?
. If 27.1 g of $\operatorname{Ar}(g)$ occupies a volume of 4.21 L , what volume will 1.29 moles of $\mathrm{Ne}(g)$ occupy at the same temperature and pressure?
50. Consider the following chemical equation.

$$
2 \mathrm{NO}_{2}(\mathrm{~g}) \longrightarrow \mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})
$$

If $25.0 \mathrm{~mL} \mathrm{NO}_{2}$ gas is completely converted to $\mathrm{N}_{2} \mathrm{O}_{4}$ gas under the same conditions, what volume will the $\mathrm{N}_{2} \mathrm{O}_{4}$ occupy?
-51. Complete the following table for an ideal gas.

|  | $\boldsymbol{P}(\mathrm{atm})$ | $\boldsymbol{V}(\mathrm{L})$ | $\boldsymbol{n}(\mathrm{mol})$ | $\boldsymbol{T}$ |
| :--- | :--- | :---: | :---: | :---: |
| a. | 5.00 |  | 2.00 | $155^{\circ} \mathrm{C}$ |
| b. | 0.300 | 2.00 |  | 155 K |
| c. | 4.47 | 25.0 | 2.01 |  |
| d. |  | 2.25 | 10.5 | $75^{\circ} \mathrm{C}$ |
|  |  |  |  |  |

52. Complete the following table for an ideal gas.

|  | $\boldsymbol{P}$ | $\boldsymbol{V}$ | $\boldsymbol{n}$ | $\boldsymbol{T}$ |
| :--- | :--- | :--- | :--- | ---: |
| a. | $7.74 \times 10^{3} \mathrm{~Pa}$ | 12.2 mL |  | $25^{\circ} \mathrm{C}$ |
| b. |  | 43.0 mL | 0.421 mol | 223 K |
| c. | 455 torr |  | $4.4 \times 10^{-2} \mathrm{~mol}$ | $331^{\circ} \mathrm{C}$ |
| d. | 745 mm Hg | 11.2 L | 0.401 mol |  |

. Suppose two 200.0-L tanks are to be filled separately with the gases helium and hydrogen. What mass of each gas is needed to produce a pressure of 2.70 atm in its respective tank at $24^{\circ} \mathrm{C}$ ?
54. The average lung capacity of a human is 6.0 L . How many moles of air are in your lungs when you are in the following situations?
a. At sea level $(T=298 \mathrm{~K}, P=1.00 \mathrm{~atm})$.
b. 10. m below water $(T=298 \mathrm{~K}, P=1.97 \mathrm{~atm})$.
c. At the top of Mount Everest ( $T=200$. K, $P=0.296 \mathrm{~atm}$ ).
55. The steel reaction vessel of a bomb calorimeter, which has a volume of 75.0 mL , is charged with oxygen gas to a pressure of 14.5 atm at $22^{\circ} \mathrm{C}$. Calculate the moles of oxygen in the reaction vessel.
56. A 5.0-L flask contains $0.60 \mathrm{~g} \mathrm{O}_{2}$ at a temperature of $22^{\circ} \mathrm{C}$. What is the pressure (in atm) inside the flask?
-57. A 2.50-L container is filled with 175 g argon.
a. If the pressure is 10.0 atm , what is the temperature?
b. If the temperature is 225 K , what is the pressure?
58. A person accidentally swallows a drop of liquid oxygen, $\mathrm{O}_{2}(l)$, which has a density of $1.149 \mathrm{~g} / \mathrm{mL}$. Assuming the drop has a volume of 0.050 mL , what volume of gas will be produced in the person's stomach at body temperature $\left(37^{\circ} \mathrm{C}\right)$ and a pressure of 1.0 atm ?
59. A typical adult inhales 450 mL of air in any one breath. How many air particles are in a typical breath at 745 torr and $22^{\circ} \mathrm{C}$ ?
60. $\mathrm{N}_{2} \mathrm{O}$ is a gas commonly used to help sedate patients in medicine and dentistry due to its mild anesthetic and analgesic properties; it is also nonflammable. If a cylinder of $\mathrm{N}_{2} \mathrm{O}$ is at 10.5 atm and has a volume of 5.00 L at 298 K , how many moles of $\mathrm{N}_{2} \mathrm{O}$ gas are present? The gas from the cylinder is emptied into a large balloon at 745 torr. What is the volume of the balloon at 298 K ?
61. A gas sample containing 1.50 moles at $25^{\circ} \mathrm{C}$ exerts a pressure of 400 . torr. Some gas is added to the same container and the temperature is increased to $50 .{ }^{\circ} \mathrm{C}$. If the pressure increases to 800. torr, how many moles of gas were added to the container? Assume a constant-volume container.
62. A bicycle tire is filled with air to a pressure of 75 psi at a temperature of $19^{\circ} \mathrm{C}$. Riding the bike on asphalt on a hot day increases the temperature of the tire to $58^{\circ} \mathrm{C}$. The volume of the tire increases by $4.0 \%$. What is the new pressure in the bicycle tire?
63. Consider two separate gas containers at the following conditions:

| Container $\mathbf{A}$ | Container B |
| :--- | :--- |
| Contents: $\mathrm{SO}_{2}(g)$ | Contents: unknown gas |
| Pressure $=P_{\mathrm{A}}$ | Pressure $=P_{\mathrm{B}}$ |
| Moles of gas $=1.0 \mathrm{~mol}$ | Moles of gas $=2.0 \mathrm{~mol}$ |
| Volume $=1.0 \mathrm{~L}$ | Volume $=2.0 \mathrm{~L}$ |
| Temperature $=7^{\circ} \mathrm{C}$ | Temperature $=287^{\circ} \mathrm{C}$ |

How is the pressure in container B related to the pressure in container A?
64. What will be the effect on the volume of an ideal gas if the pressure is doubled and the absolute temperature is halved?
655. A container is filled with an ideal gas to a pressure of 11.0 atm at $0^{\circ} \mathrm{C}$.
a. What will be the pressure in the container if it is heated to $45^{\circ} \mathrm{C}$ ?
b. At what temperature would the pressure be 6.50 atm ?
c. At what temperature would the pressure be 25.0 atm ?
66. An ideal gas at $7^{\circ} \mathrm{C}$ is in a spherical flexible container having a radius of 1.00 cm . The gas is heated at constant pressure to $88^{\circ} \mathrm{C}$. Determine the radius of the spherical container after the gas is heated. [Volume of a sphere $=(4 / 3) \pi r^{3}$.]
67. An ideal gas is contained in a cylinder with a volume of $5.0 \times$ $10^{2} \mathrm{~mL}$ at a temperature of $30 .{ }^{\circ} \mathrm{C}$ and a pressure of 710 . torr. The gas is then compressed to a volume of 25 mL , and the temperature is raised to $820 .{ }^{\circ} \mathrm{C}$. What is the new pressure of the gas?
68. A compressed gas cylinder contains $1.00 \times 10^{3} \mathrm{~g}$ argon gas. The pressure inside the cylinder is 2050. psi (pounds per square inch) at a temperature of $18^{\circ} \mathrm{C}$. How much gas remains in the cylinder if the pressure is decreased to 650. psi at a temperature of $26^{\circ} \mathrm{C}$ ?
-69. A sealed balloon is filled with 1.00 L helium at $23^{\circ} \mathrm{C}$ and 1.00 atm . The balloon rises to a point in the atmosphere where the pressure is 220 . torr and the temperature is $-31^{\circ} \mathrm{C}$. What is the change in volume of the balloon as it ascends from 1.00 atm to a pressure of 220 . torr?
70. A hot-air balloon is filled with air to a volume of $4.00 \times$ $10^{3} \mathrm{~m}^{3}$ at 745 torr and $21^{\circ} \mathrm{C}$. The air in the balloon is then heated to $62^{\circ} \mathrm{C}$, causing the balloon to expand to a volume of $4.20 \times 10^{3} \mathrm{~m}^{3}$. What is the ratio of the number of moles of air in the heated balloon to the original number of moles of air in the balloon? (Hint: Openings in the balloon allow air to flow in and out. Thus the pressure in the balloon is always the same as that of the atmosphere.)

## Gas Density, Molar Mass, and Reaction Stoichiometry

-71. Consider the following reaction:

$$
4 \mathrm{Al}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Al}_{2} \mathrm{O}_{3}(s)
$$

It takes 2.00 L of pure oxygen gas at STP to react completely with a certain sample of aluminum. What is the mass of aluminum reacted?
72. A student adds 4.00 g of dry ice (solid $\mathrm{CO}_{2}$ ) to an empty balloon. What will be the volume of the balloon at STP after all the dry ice sublimes (converts to gaseous $\mathrm{CO}_{2}$ )?
-73. Air bags are activated when a severe impact causes a steel ball to compress a spring and electrically ignite a detonator cap. This causes sodium azide $\left(\mathrm{NaN}_{3}\right)$ to decompose explosively according to the following reaction:

$$
2 \mathrm{NaN}_{3}(s) \longrightarrow 2 \mathrm{Na}(s)+3 \mathrm{~N}_{2}(g)
$$

What mass of $\mathrm{NaN}_{3}(s)$ must be reacted to inflate an air bag to 70.0 L at STP?
74. Concentrated hydrogen peroxide solutions are explosively decomposed by traces of transition metal ions (such as Mn or Fe ):

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
$$

What volume of pure $\mathrm{O}_{2}(\mathrm{~g})$, collected at $27^{\circ} \mathrm{C}$ and 746 torr, would be generated by decomposition of 125 g of a $50.0 \%$ by mass hydrogen peroxide solution? Ignore any water vapor that may be present.

In 1897 the Swedish explorer Andreé tried to reach the North Pole in a balloon. The balloon was filled with hydrogen gas. The hydrogen gas was prepared from iron splints and diluted sulfuric acid. The reaction is

$$
\mathrm{Fe}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{FeSO}_{4}(a q)+\mathrm{H}_{2}(g)
$$

The volume of the balloon was $4800 \mathrm{~m}^{3}$ and the loss of hydrogen gas during filling was estimated at $20 . \%$. What mass of iron splints and $98 \%$ (by mass) $\mathrm{H}_{2} \mathrm{SO}_{4}$ were needed to ensure the complete filling of the balloon? Assume a temperature of $0^{\circ} \mathrm{C}$, a pressure of 1.0 atm during filling, and $100 \%$ yield.
76. Sulfur trioxide, $\mathrm{SO}_{3}$, is produced in enormous quantities each year for use in the synthesis of sulfuric acid.

$$
\begin{gathered}
\mathrm{S}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g) \\
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)
\end{gathered}
$$

What volume of $\mathrm{O}_{2}(\mathrm{~g})$ at $350 .{ }^{\circ} \mathrm{C}$ and a pressure of 5.25 atm is needed to completely convert 5.00 g sulfur to sulfur trioxide?
77. A 15.0-L rigid container was charged with 0.500 atm of krypton gas and 1.50 atm of chlorine gas at $350 .{ }^{\circ} \mathrm{C}$. The krypton and chlorine react to form krypton tetrachloride. What mass of krypton tetrachloride can be produced assuming $100 \%$ yield?
78. An important process for the production of acrylonitrile $\left(\mathrm{C}_{3} \mathrm{H}_{3} \mathrm{~N}\right)$ is given by the following equation:
$2 \mathrm{C}_{3} \mathrm{H}_{6}(\mathrm{~g})+2 \mathrm{NH}_{3}(\mathrm{~g})+3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{C}_{3} \mathrm{H}_{3} \mathrm{~N}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ A 150.-L reactor is charged to the following partial pressures at $25^{\circ} \mathrm{C}$ :

$$
\begin{aligned}
P_{\mathrm{C}_{3} \mathrm{H}_{6}} & =0.500 \mathrm{MPa} \\
P_{\mathrm{NH}_{3}} & =0.800 \mathrm{MPa} \\
P_{\mathrm{O}_{2}} & =1.500 \mathrm{MPa}
\end{aligned}
$$

What mass of acrylonitrile can be produced from this mixture $\left(\mathrm{MPa}=10^{6} \mathrm{~Pa}\right)$ ?
-79. Consider the reaction between 50.0 mL liquid methanol, $\mathrm{CH}_{3} \mathrm{OH}$ (density $=0.850 \mathrm{~g} / \mathrm{mL}$ ), and $22.8 \mathrm{~L} \mathrm{O}_{2}$ at $27^{\circ} \mathrm{C}$ and a pressure of 2.00 atm . The products of the reaction are $\mathrm{CO}_{2}(\mathrm{~g})$ and $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$. Calculate the number of moles of $\mathrm{H}_{2} \mathrm{O}$ formed if the reaction goes to completion.
80. Urea $\left(\mathrm{H}_{2} \mathrm{NCONH}_{2}\right)$ is used extensively as a nitrogen source in fertilizers. It is produced commercially from the reaction of ammonia and carbon dioxide:

$$
2 \mathrm{NH}_{3}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g}) \xrightarrow[\text { Pressure }]{\text { Heat }} \mathrm{H}_{2} \mathrm{NCONH}_{2}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

Ammonia gas at $223^{\circ} \mathrm{C}$ and 90 . atm flows into a reactor at a rate of $500 . \mathrm{L} / \mathrm{min}$. Carbon dioxide at $223^{\circ} \mathrm{C}$ and 45 atm flows into the reactor at a rate of $600 \mathrm{~L} / \mathrm{min}$. What mass of urea is produced per minute by this reaction assuming $100 \%$ yield?
-81. Hydrogen cyanide is prepared commercially by the reaction of methane, $\mathrm{CH}_{4}(\mathrm{~g})$, ammonia, $\mathrm{NH}_{3}(\mathrm{~g})$, and oxygen, $\mathrm{O}_{2}(\mathrm{~g})$, at high temperature. The other product is gaseous water.
a. Write a chemical equation for the reaction.
b. What volume of $\mathrm{HCN}(g)$ can be obtained from the reaction of $20.0 \mathrm{~L} \mathrm{CH}_{4}(g)$, 20.0 $\mathrm{L} \mathrm{NH}_{3}(g)$, and $20.0 \mathrm{~L} \mathrm{O}_{2}(g)$ ? The volumes of all gases are measured at the same temperature and pressure.
82. Ethene is converted to ethane by the reaction

$$
\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g}) \xrightarrow{\text { Catalyst }} \mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})
$$

$\mathrm{C}_{2} \mathrm{H}_{4}$ flows into a catalytic reactor at 25.0 atm and $300 .{ }^{\circ} \mathrm{C}$ with a flow rate of $1000 . \mathrm{L} / \mathrm{min}$. Hydrogen at 25.0 atm and $300 .{ }^{\circ} \mathrm{C}$ flows into the reactor at a flow rate of $1500 . \mathrm{L} / \mathrm{min}$. If 15.0 kg $\mathrm{C}_{2} \mathrm{H}_{6}$ is collected per minute, what is the percent yield of the reaction?
83. An unknown diatomic gas has a density of $3.164 \mathrm{~g} / \mathrm{L}$ at STP. What is the identity of the gas?
84. A compound has the empirical formula CHCl . A $256-\mathrm{mL}$ flask, at 373 K and 750 . torr, contains 0.800 g of the gaseous compound. Give the molecular formula.
85. Uranium hexafluoride is a solid at room temperature, but it boils at $56^{\circ} \mathrm{C}$. Determine the density of uranium hexafluoride at $60 .{ }^{\circ} \mathrm{C}$ and 745 torr.
86. Silicon tetrachloride $\left(\mathrm{SiCl}_{4}\right)$ and trichlorosilane $\left(\mathrm{SiHCl}_{3}\right)$ are both starting materials for the production of electronics-grade silicon. Calculate the densities of pure $\mathrm{SiCl}_{4}$ and pure $\mathrm{SiHCl}_{4}$ vapor at $85^{\circ} \mathrm{C}$ and 635 torr.

## Partial Pressure

Determine the partial pressure of each gas as shown in the figure below. Note: The relative numbers of each type of gas are depicted in the figure.

88. Consider the flasks in the following diagrams.

a. Which is greater, the initial pressure of helium or the initial pressure of neon? How much greater?
b. Assuming the connecting tube has negligible volume, draw what each diagram will look like after the stopcock between the two flasks is opened.
c. Solve for the final pressure in terms of the original pressures of helium and neon. Assume temperature is constant.
d. Solve for the final partial pressures of helium and neon in terms of their original pressures. Assume the temperature is constant.
89. For scuba dives below 150 ft , helium is often used to replace nitrogen in the scuba tank. If 15.2 g of $\mathrm{He}(\mathrm{g})$ and 30.6 g of $\mathrm{O}_{2}(g)$ are added to a previously evacuated 5.00 L tank at $22^{\circ} \mathrm{C}$, calculate the partial pressure of each gas present as well as the total pressure in the tank.
90. A mixture of $1.00 \mathrm{~g} \mathrm{H}_{2}$ and 1.00 g He is placed in a $1.00-\mathrm{L}$ container at $27^{\circ} \mathrm{C}$. Calculate the partial pressure of each gas and the total pressure.
-91. Consider the flasks in the following diagram. What are the final partial pressures of $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ after the stopcock between the two flasks is opened? (Assume the final volume is 3.00 L .) What is the total pressure (in torr)?

92. Consider the flask apparatus in Exercise 91, which now contains $2.00 \mathrm{~L} \mathrm{H}_{2}$ at a pressure of 360 . torr and $1.00 \mathrm{~L} \mathrm{~N}_{2}$ at an unknown pressure. If the total pressure in the flasks is 320 . torr after the stopcock is opened, determine the initial pressure of $\mathrm{N}_{2}$ in the 1.00-L flask.
93. Consider the three flasks in the diagram below. Assuming the connecting tubes have negligible volume, what is the partial pressure of each gas and the total pressure after all the stopcocks are opened?

94. At $0^{\circ} \mathrm{C}$ a 1.0-L flask contains $5.0 \times 10^{-2}$ mole of $\mathrm{N}_{2}, 1.5 \times$ $10^{2} \mathrm{mg} \mathrm{O}_{2}$, and $5.0 \times 10^{21}$ molecules of $\mathrm{NH}_{3}$. What is the partial pressure of each gas, and what is the total pressure in the flask?
95. A mixture of cyclopropane and oxygen is sometimes used as a general anesthetic. Consider a balloon with an anesthetic mixture of cyclopropane and oxygen at 170 . torr and 570. torr, respectively. Calculate the mole fraction of cyclopropane in the mixture.
96. A $1: 1$ mixture by moles of nitrous oxide and oxygen is often used as a sedative in dentistry. If the total pressure of this mixture in a cylinder is 2.50 atm , what is the partial pressure of each gas?
97. The partial pressure of $\mathrm{CH}_{4}(g)$ is 0.175 atm and that of $\mathrm{O}_{2}(g)$ is 0.250 atm in a mixture of the two gases.
a. What is the mole fraction of each gas in the mixture?
b. If the mixture occupies a volume of 10.5 L at $65^{\circ} \mathrm{C}$, calculate the total number of moles of gas in the mixture.
c. Calculate the number of grams of each gas in the mixture.
98. A tank contains a mixture of 52.5 g oxygen gas and 65.1 g carbon dioxide gas at $27^{\circ} \mathrm{C}$. The total pressure in the tank is 9.21 atm . Calculate the partial pressures of each gas in the container.
99. Small quantities of hydrogen gas can be prepared in the laboratory by the addition of aqueous hydrochloric acid to metallic zinc.

$$
\mathrm{Zn}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{ZnCl}_{2}(a q)+\mathrm{H}_{2}(g)
$$

Typically, the hydrogen gas is bubbled through water for collection and becomes saturated with water vapor. Suppose 240. mL of hydrogen gas is collected at $30 .{ }^{\circ} \mathrm{C}$ and has a total pressure of 1.032 atm by this process. What is the partial pressure of hydrogen gas in the sample? How many grams of zinc must have reacted to produce this quantity of hydrogen? (The vapor pressure of water is 32 torr at $30^{\circ} \mathrm{C}$.)
100. Helium is collected over water at $25^{\circ} \mathrm{C}$ and 1.00 atm total pressure. What total volume of gas must be collected to obtain 0.586 g helium? (At $25^{\circ} \mathrm{C}$ the vapor pressure of water is 23.8 torr.)
-101. At elevated temperatures, sodium chlorate decomposes to produce sodium chloride and oxygen gas. A $0.8765-\mathrm{g}$ sample of impure sodium chlorate was heated until the production of oxygen gas ceased. The oxygen gas collected over water occupied 57.2 mL at a temperature of $22^{\circ} \mathrm{C}$ and a pressure of 734 torr. Calculate the mass percent of $\mathrm{NaClO}_{3}$ in the original sample. (At $22^{\circ} \mathrm{C}$ the vapor pressure of water is 19.8 torr.)
102. Xenon and fluorine will react to form binary compounds when a mixture of these two gases is heated to $400^{\circ} \mathrm{C}$ in a nickel reaction vessel. A $100.0-\mathrm{mL}$ nickel container is filled with xenon and fluorine, giving partial pressures of 1.24 atm and 10.10 atm , respectively, at a temperature of $25^{\circ} \mathrm{C}$. The reaction vessel is heated to $400^{\circ} \mathrm{C}$ to cause a reaction to occur and then cooled to a temperature at which $F_{2}$ is a gas and the xenon fluoride compound produced is a nonvolatile solid. The remaining $\mathrm{F}_{2}$ gas is transferred to another $100.0-\mathrm{mL}$ nickel container, where the pressure of $\mathrm{F}_{2}$ at $25^{\circ} \mathrm{C}$ is 7.62 atm . Assuming all of the xenon has reacted, what is the formula of the product?
103. Methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ can be produced by the following reaction:

$$
\mathrm{CO}(\mathrm{~g})+2 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(\mathrm{~g})
$$

Hydrogen at STP flows into a reactor at a rate of $16.0 \mathrm{~L} / \mathrm{min}$. Carbon monoxide at STP flows into the reactor at a rate of $25.0 \mathrm{~L} / \mathrm{min}$. If 5.30 g methanol is produced per minute, what is the percent yield of the reaction?
104. In the "Méthode Champenoise," grape juice is fermented in a wine bottle to produce sparkling wine. The reaction is

$$
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q) \longrightarrow 2 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(a q)+2 \mathrm{CO}_{2}(g)
$$

Fermentation of $750 . \mathrm{mL}$ grape juice (density $=1.0 \mathrm{~g} / \mathrm{cm}^{3}$ ) is allowed to take place in a bottle with a total volume of 825 mL until $12 \%$ by volume is ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$. Assuming that the $\mathrm{CO}_{2}$ is insoluble in $\mathrm{H}_{2} \mathrm{O}$ (actually, a wrong assumption), what would be the pressure of $\mathrm{CO}_{2}$ inside the wine bottle at $25^{\circ} \mathrm{C}$ ? (The density of ethanol is $0.79 \mathrm{~g} / \mathrm{cm}^{3}$.)
-105. Hydrogen azide, $\mathrm{HN}_{3}$, decomposes on heating by the following unbalanced equation:

$$
\mathrm{HN}_{3}(g) \longrightarrow \mathrm{N}_{2}(g)+\mathrm{H}_{2}(g)
$$

If 3.0 atm of pure $\mathrm{HN}_{3}(\mathrm{~g})$ is decomposed initially, what is the final total pressure in the reaction container? What are the partial pressures of nitrogen and hydrogen gas? Assume the volume and temperature of the reaction container are constant.
-106. Equal moles of sulfur dioxide gas and oxygen gas are mixed in a flexible reaction vessel and then sparked to initiate the formation of gaseous sulfur trioxide. Assuming that the reaction goes to completion, what is the ratio of the final volume of the gas mixture to the initial volume of the gas mixture if both volumes are measured at the same temperature and pressure?
-107. Some very effective rocket fuels are composed of lightweight liquids. The fuel composed of dimethylhydrazine $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~N}_{2} \mathrm{H}_{2}\right]$ mixed with dinitrogen tetroxide was used to power the Lunar Lander in its missions to the moon. The two components react according to the following equation:
$\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~N}_{2} \mathrm{H}_{2}(l)+2 \mathrm{~N}_{2} \mathrm{O}_{4}(l) \longrightarrow 3 \mathrm{~N}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(g)+2 \mathrm{CO}_{2}(g)$
If 150 g dimethylhydrazine reacts with excess dinitrogen tetroxide and the product gases are collected at $127^{\circ} \mathrm{C}$ in an evacuated 250-L tank, what is the partial pressure of nitrogen gas produced and what is the total pressure in the tank assuming the reaction has $100 \%$ yield?
108. The oxides of Group 2A metals (symbolized by M here) react with carbon dioxide according to the following reaction:

$$
\mathrm{MO}(s)+\mathrm{CO}_{2}(\mathrm{~g}) \longrightarrow \mathrm{MCO}_{3}(s)
$$

A $2.85-\mathrm{g}$ sample containing only MgO and CuO is placed in a $3.00-\mathrm{L}$ container. The container is filled with $\mathrm{CO}_{2}$ to a pressure of 740 . torr at $20 .{ }^{\circ} \mathrm{C}$. After the reaction has gone to completion, the pressure inside the flask is 390 . torr at $20 .{ }^{\circ} \mathrm{C}$. What is the mass percent of MgO in the mixture? Assume that only the MgO reacts with $\mathrm{CO}_{2}$.

## Kinetic Molecular Theory and Real Gases

-109. Calculate the average kinetic energies of $\mathrm{CH}_{4}(g)$ and $\mathrm{N}_{2}(g)$ molecules at 273 K and 546 K .
110. A 100.-L flask contains a mixture of methane $\left(\mathrm{CH}_{4}\right)$ and argon gases at $25^{\circ} \mathrm{C}$. The mass of argon present is 228 g and the mole fraction of methane in the mixture is 0.650 . Calculate the total kinetic energy of the gaseous mixture.
-111. Calculate the root mean square velocities of $\mathrm{CH}_{4}(g)$ and $\mathrm{N}_{2}(g)$ molecules at 273 K and 546 K .
112. Consider separate $1.0-\mathrm{L}$ samples of $\operatorname{He}(g)$ and $\mathrm{UF}_{6}(g)$, both at 1.00 atm and containing the same number of moles. What ratio of temperatures for the two samples would produce the same root mean square velocity?
-113. You have a gas in a container fitted with a piston and you change one of the conditions of the gas such that a change takes place, as shown below:
1.00 atm

State two distinct changes you can make to accomplish this, and explain why each would work.
114. You have a gas in a container fitted with a piston and you change one of the conditions of the gas such that a change takes place, as shown below:

State three distinct changes you can make to accomplish this, and explain why each would work.
-115. Consider a $1.0-\mathrm{L}$ container of neon gas at STP. Will the average kinetic energy, average velocity, and frequency of collisions of gas molecules with the walls of the container increase, decrease, or remain the same under each of the following conditions?
a. The temperature is increased to $100^{\circ} \mathrm{C}$.
b. The temperature is decreased to $-50^{\circ} \mathrm{C}$.
c. The volume is decreased to 0.5 L .
d. The number of moles of neon is doubled.
116. Consider two gases, $A$ and $B$, each in a $1.0-\mathrm{L}$ container with both gases at the same temperature and pressure. The mass of gas A in the container is 0.34 g and the mass of gas B in the container is 0.48 g .

a. Which gas sample has the most molecules present? Explain.
b. Which gas sample has the largest average kinetic energy? Explain.
c. Which gas sample has the fastest average velocity? Explain.
d. How can the pressure in the two containers be equal to each other since the larger gas B molecules collide with the container walls more forcefully?
$\Gamma^{117 .}$ Consider three identical flasks filled with different gases. Flask A: CO at 760 torr and $0^{\circ} \mathrm{C}$
Flask B: $\mathrm{N}_{2}$ at 250 torr and $0^{\circ} \mathrm{C}$
Flask C: $\mathrm{H}_{2}$ at 100 torr and $0^{\circ} \mathrm{C}$
a. In which flask will the molecules have the greatest average kinetic energy?
b. In which flask will the molecules have the greatest average velocity?
118. Consider separate 1.0-L gaseous samples of $\mathrm{H}_{2}, \mathrm{Xe}, \mathrm{Cl}_{2}$, and $\mathrm{O}_{2}$ all at STP.
a. Rank the gases in order of increasing average kinetic energy.
b. Rank the gases in order of increasing average velocity.
c. How can separate 1.0-L samples of $\mathrm{O}_{2}$ and $\mathrm{H}_{2}$ each have the same average velocity?
119. The effusion rate of an unknown gas is measured and found to be $31.50 \mathrm{~mL} / \mathrm{min}$. Under identical experimental conditions, the effusion rate of $\mathrm{O}_{2}(\mathrm{~g})$ is found to be $30.50 \mathrm{~mL} / \mathrm{min}$. If the choices for the unknown gas are $\mathrm{CH}_{4}, \mathrm{CO}, \mathrm{NO}, \mathrm{CO}_{2}$, and $\mathrm{NO}_{2}$, what is the identity of the gas?
120. The rate of effusion of a particular gas was measured and found to be $24.0 \mathrm{~mL} / \mathrm{min}$. Under the same conditions, the rate of effusion of pure methane $\left(\mathrm{CH}_{4}\right)$ gas is $47.8 \mathrm{~mL} / \mathrm{min}$. What is the molar mass of the unknown gas?
${ }^{121}$. One way of separating oxygen isotopes is by gaseous diffusion of carbon monoxide. The gaseous diffusion process behaves like an effusion process. Calculate the relative rates of effusion of ${ }^{12} \mathrm{C}^{16} \mathrm{O},{ }^{12} \mathrm{C}^{17} \mathrm{O}$, and ${ }^{12} \mathrm{C}^{18} \mathrm{O}$. Name some advantages and disadvantages of separating oxygen isotopes by gaseous diffusion of carbon dioxide instead of carbon monoxide.
122. It took 4.5 minutes for 1.0 L helium to effuse through a porous barrier. How long will it take for $1.0 \mathrm{LCl}_{2}$ gas to effuse under identical conditions?
-123. Calculate the pressure exerted by 0.5000 mole of $\mathrm{N}_{2}$ in a $1.0000-\mathrm{L}$ container at $25.0^{\circ} \mathrm{C}$
a. using the ideal gas law.
b. using the van der Waals equation.
c. Compare the results.
124. Calculate the pressure exerted by 0.5000 mole of $\mathrm{N}_{2}$ in a $10.000-\mathrm{L}$ container at $25.0^{\circ} \mathrm{C}$
a. using the ideal gas law.
b. using the van der Waals equation.
c. Compare the results.
d. Compare the results with those in Exercise 123.

## Atmosphere Chemistry

-125. Use the data in Table 5.4 to calculate the partial pressure of He in dry air assuming that the total pressure is 1.0 atm . Assuming a temperature of $25^{\circ} \mathrm{C}$, calculate the number of He atoms per cubic centimeter.
126. A $1.0-\mathrm{L}$ sample of air is collected at $25^{\circ} \mathrm{C}$ at sea level ( 1.00 atm ). Estimate the volume this sample of air would have at an altitude of 15 km (see Fig. 5.30). At 15 km , the pressure is about 0.1 atm .
-127. Write an equation to show how sulfuric acid is produced in the atmosphere.
128. Write an equation to show how sulfuric acids in acid rain reacts with marble and limestone. (Both marble and limestone are primarily calcium carbonate.)
-129. Atmospheric scientists often use mixing ratios to express the concentrations of trace compounds in air. Mixing ratios are often expressed as ppmv (parts per million volume):

$$
\text { ppmv of } X=\frac{\text { vol of } X \text { at STP }}{\text { total vol of air at STP }} \times 10^{6}
$$

On a certain November day, the concentration of carbon monoxide in the air in downtown Denver, Colorado, reached $3.0 \times 10^{2} \mathrm{ppmv}$. The atmospheric pressure at that time was 628 torr and the temperature was $0^{\circ} \mathrm{C}$.
a. What was the partial pressure of CO ?
b. What was the concentration of CO in molecules per cubic meter?
c. What was the concentration of CO in molecules per cubic centimeter?
130. Trace organic compounds in the atmosphere are first concentrated and then measured by gas chromatography. In the concentration step, several liters of air are pumped through a tube containing a porous substance that traps organic compounds. The tube is then connected to a gas chromatograph and heated to release the trapped compounds. The organic compounds are separated in the column and the amounts are measured. In an analysis for benzene and toluene in air, a 3.00-L sample of air at 748 torr and $23^{\circ} \mathrm{C}$ was passed through the trap. The gas chromatography analysis showed that this air sample contained 89.6 ng benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ and 153 ng toluene $\left(\mathrm{C}_{7} \mathrm{H}_{8}\right)$. Calculate the mixing ratio (see Exercise 129) and number of molecules per cubic centimeter for both benzene and toluene.

## Additional Exercises

131. Draw a qualitative graph to show how the first property varies with the second in each of the following (assume 1 mole of an ideal gas and $T$ in kelvin).
a. $P V$ versus $V$ with constant $T$
b. $P$ versus $T$ with constant $V$
c. $T$ versus $V$ with constant $P$
d. $P$ versus $V$ with constant $T$
e. $P$ versus $1 / V$ with constant $T$
f. $P V / T$ versus $P$
132. At STP, $1.0 \mathrm{~L} \mathrm{Br}_{2}$ reacts completely with $3.0 \mathrm{~L}_{2}$, producing 2.0 L of a product. What is the formula of the product? (All substances are gases.)
133. A form of Boyle's law is $P V=k$ (at constant $T$ and $n$ ). Table 5.1 contains actual data from pressure-volume experiments conducted by Robert Boyle. The value of $k$ in most experiments is $14.1 \times 10^{2} \mathrm{in} \mathrm{Hg} \cdot \mathrm{in}^{3}$. Express $k$ in units of atm $\cdot \mathrm{L}$. In Example 5.3, $k$ was determined for $\mathrm{NH}_{3}$ at various pressures and volumes. Give some reasons why the $k$ values differ so dramatically between Example 5.3 and Table 5.1.
134. A 2.747 -g sample of manganese metal is reacted with excess HCl gas to produce $3.22 \mathrm{~L}_{2}(g)$ at 373 K and 0.951 atm and a manganese chloride compound $\left(\mathrm{MnCl}_{x}\right)$. What is the formula of the manganese chloride compound produced in the reaction?
135. A $1.00-\mathrm{L}$ gas sample at $100 .{ }^{\circ} \mathrm{C}$ and 600 . torr contains $50.0 \%$ helium and $50.0 \%$ xenon by mass. What are the partial pressures of the individual gases?
136. Cyclopropane, a gas that when mixed with oxygen is used as a general anesthetic, is composed of $85.7 \% \mathrm{C}$ and $14.3 \% \mathrm{H}$ by mass. If the density of cyclopropane is $1.88 \mathrm{~g} / \mathrm{L}$ at STP, what is the molecular formula of cyclopropane?
137. The nitrogen content of organic compounds can be determined by the Dumas method. The compound in question is first reacted by passage over hot $\mathrm{CuO}(s)$ :

$$
\text { Compound } \xrightarrow[\mathrm{CuO}(s)]{\mathrm{Hot}} \mathrm{~N}_{2}(g)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

The product gas is then passed through a concentrated solution of KOH to remove the $\mathrm{CO}_{2}$. After passage through the KOH solution, the gas contains $\mathrm{N}_{2}$ and is saturated with water vapor. In a given experiment a $0.253-\mathrm{g}$ sample of a compound produced $31.8 \mathrm{~mL} \mathrm{~N}_{2}$ saturated with water vapor at $25^{\circ} \mathrm{C}$ and 726 torr. What is the mass percent of nitrogen in the compound? (The vapor pressure of water at $25^{\circ} \mathrm{C}$ is 23.8 torr.)
138. Hyperbaric oxygen therapy is used to treat patients with carbon monoxide poisoning as well as to treat divers with the bends. In hyperbaric oxygen therapy, a patient is placed inside a $7.0-\mathrm{ft}$ cylinder with a $3.0-\mathrm{ft}$ diameter, which is then filled with oxygen gas to a total pressure of 2.50 atm . Assuming the patient takes up $32.0 \%$ of the chamber's volume, what volume of $\mathrm{O}_{2}(g)$ from a gas cylinder at $25^{\circ} \mathrm{C}$ and 95 atm is required to fill the chamber to a total pressure of 2.50 atm at $25^{\circ} \mathrm{C}$ ? Assume the hyperbaric chamber initially contains air at 1.00 atm before $\mathrm{O}_{2}(g)$ is added.
139. A $15.0-\mathrm{L}$ tank is filled with $\mathrm{H}_{2}$ to a pressure of $2.00 \times 10^{2} \mathrm{~atm}$. How many balloons (each 2.00 L ) can be inflated to a pressure of 1.00 atm from the tank? Assume that there is no temperature change and that the tank cannot be emptied below 1.00 atm pressure.
140. A spherical glass container of unknown volume contains helium gas at $25^{\circ} \mathrm{C}$ and 1.960 atm . When a portion of the helium is withdrawn and adjusted to 1.00 atm at $25^{\circ} \mathrm{C}$, it is found to have a volume of $1.75 \mathrm{~cm}^{3}$. The gas remaining in the first container shows a pressure of 1.710 atm . Calculate the volume of the spherical container.
141. A 2.00-L sample of $\mathrm{O}_{2}(g)$ was collected over water at a total pressure of 785 torr and $25^{\circ} \mathrm{C}$. When the $\mathrm{O}_{2}(g)$ was dried (water vapor removed), the gas had a volume of 1.94 L at $25^{\circ} \mathrm{C}$ and 785 torr. Calculate the vapor pressure of water at $25^{\circ} \mathrm{C}$.
142. A $20.0-\mathrm{L}$ stainless steel container at $25^{\circ} \mathrm{C}$ was charged with 2.00 atm of hydrogen gas and 3.00 atm of oxygen gas. A spark ignited the mixture, producing water. What is the pressure in the tank at $25^{\circ} \mathrm{C}$ ? If the exact same experiment were performed, but the temperature was $125^{\circ} \mathrm{C}$ instead of $25^{\circ} \mathrm{C}$, what would be the pressure in the tank?
143. Metallic molybdenum can be produced from the mineral molybdenite, $\mathrm{MoS}_{2}$. The mineral is first oxidized in air to molybdenum trioxide and sulfur dioxide. Molybdenum
trioxide is then reduced to metallic molybdenum using hydrogen gas. The balanced equations are

$$
\begin{aligned}
\operatorname{MoS}_{2}(s)+\frac{7}{2} \mathrm{O}_{2}(g) & \longrightarrow \mathrm{MoO}_{3}(s)+2 \mathrm{SO}_{2}(g) \\
\mathrm{MoO}_{3}(s)+3 \mathrm{H}_{2}(g) & \longrightarrow \mathrm{Mo}(s)+3 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

Calculate the volumes of air and hydrogen gas at $17^{\circ} \mathrm{C}$ and 1.00 atm that are necessary to produce $1.00 \times 10^{3} \mathrm{~kg}$ pure molybdenum from $\mathrm{MoS}_{2}$. Assume air contains $21 \%$ oxygen by volume, and assume $100 \%$ yield for each reaction.
144. Nitric acid is produced commercially by the Ostwald process. In the first step ammonia is oxidized to nitric oxide:

$$
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
$$

Assume this reaction is carried out in the apparatus diagramed below.

The stopcock between the two reaction containers is opened, and the reaction proceeds using proper catalysts. Calculate the partial pressure of NO after the reaction is complete. Assume $100 \%$ yield for the reaction, assume the final container volume is 3.00 L , and assume the temperature is constant.
145. A compound contains only $\mathrm{C}, \mathrm{H}$, and N . It is $58.51 \% \mathrm{C}$ and $7.37 \% \mathrm{H}$ by mass. Helium effuses through a porous frit 3.20 times as fast as the compound does. Determine the empirical and molecular formulas of this compound.
146. One of the chemical controversies of the nineteenth century concerned the element beryllium (Be). Berzelius originally claimed that beryllium was a trivalent element (forming $\mathrm{Be}^{3+}$ ions) and that it gave an oxide with the formula $\mathrm{Be}_{2} \mathrm{O}_{3}$. This resulted in a calculated atomic mass of 13.5 for beryllium. In formulating his periodic table, Mendeleev proposed that beryllium was divalent (forming $\mathrm{Be}^{2+}$ ions) and that it gave an oxide with the formula BeO . This assumption gives an atomic mass of 9.0. In 1894, A. Combes (Comptes Rendus 1894, p. 1221) reacted beryllium with the anion $\mathrm{C}_{5} \mathrm{H}_{7} \mathrm{O}_{2}^{-}$and measured the density of the gaseous product. Combes's data for two different experiments are as follows:

|  |  | II |
| :--- | :--- | :--- |
| Mass | 0.2022 g | 0.2224 g |
| Volume | $22.6 \mathrm{~cm}^{3}$ | $26.0 \mathrm{~cm}^{3}$ |
| Temperature | $13^{\circ} \mathrm{C}$ | $17^{\circ} \mathrm{C}$ |
| Pressure | 765.2 mm Hg | 764.6 mm |

If beryllium is a divalent metal, the molecular formula of the product will be $\mathrm{Be}\left(\mathrm{C}_{5} \mathrm{H}_{7} \mathrm{O}_{2}\right)_{2}$; if it is trivalent, the formula will be $\mathrm{Be}\left(\mathrm{C}_{5} \mathrm{H}_{7} \mathrm{O}_{2}\right)_{3}$. Show how Combes's data help to confirm that beryllium is a divalent metal.
147. An organic compound contains $\mathrm{C}, \mathrm{H}, \mathrm{N}$, and O . Combustion of 0.1023 g of the compound in excess oxygen yielded $0.2766 \mathrm{~g} \mathrm{CO}_{2}$ and $0.0991 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$. A sample of 0.4831 g of the compound was analyzed for nitrogen by the Dumas method (see Exercise 137). At STP, 27.6 mL of dry $\mathrm{N}_{2}$ was obtained. In a third experiment, the density of the compound as a gas was found to be $4.02 \mathrm{~g} / \mathrm{L}$ at $127^{\circ} \mathrm{C}$ and 256 torr. What are the empirical and molecular formulas of the compound?
148. Consider the following diagram:

Container A (with porous walls) is filled with air at STP. It is then inserted into a large enclosed container (B), which is then flushed with $\mathrm{H}_{2}(g)$. What will happen to the pressure inside container A? Explain your answer.

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
149. A glass vessel contains 28 g of nitrogen gas. Assuming ideal behavior, which of the processes listed below would double the pressure exerted on the walls of the vessel?
a. Adding 28 g of oxygen gas
b. Raising the temperature of the container from $-73^{\circ} \mathrm{C}$ to $127^{\circ} \mathrm{C}$
c. Adding enough mercury to fill one-half the container
d. Adding 32 g of oxygen gas
e. Raising the temperature of the container from $30 .{ }^{\circ} \mathrm{C}$ to $60 .{ }^{\circ} \mathrm{C}$
150. A steel cylinder contains 150.0 moles of argon gas at a temperature of $25^{\circ} \mathrm{C}$ and a pressure of 8.93 MPa . After some argon has been used, the pressure is 2.00 MPa at a temperature of $19^{\circ} \mathrm{C}$. What mass of argon remains in the cylinder?
151. A certain flexible weather balloon contains helium gas at a volume of 855 L . Initially, the balloon is at sea level where the temperature is $25^{\circ} \mathrm{C}$ and the barometric pressure is 730 torr. The balloon then rises to an altitude of 6000 ft , where the pressure is 605 torr and the temperature is $15^{\circ} \mathrm{C}$. What is the change in volume of the balloon as it ascends from sea level to 6000 ft ?
152. A large flask with a volume of 936 mL is evacuated and found to have a mass of 134.66 g . It is then filled to a pressure of 0.967 atm at $31^{\circ} \mathrm{C}$ with a gas of unknown molar mass and then reweighed to give a new mass of 135.87 g . What is the molar mass of this gas?
153. A 20.0 -L nickel container was charged with 0.859 atm of xenon gas and 1.37 atm of fluorine gas at $400^{\circ} \mathrm{C}$. The xenon
and fluorine react to form xenon tetrafluoride. What mass of xenon tetrafluoride can be produced assuming $100 \%$ yield?
154. Consider the unbalanced chemical equation below:

$$
\mathrm{CaSiO}_{3}(s)+\mathrm{HF}(g) \longrightarrow \mathrm{CaF}_{2}(a q)+\mathrm{SiF}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Suppose a $32.9-\mathrm{g}$ sample of $\mathrm{CaSiO}_{3}$ is reacted with 31.8 L of HF at $27.0^{\circ} \mathrm{C}$ and 1.00 atm . Assuming the reaction goes to completion, calculate the mass of the $\mathrm{SiF}_{4}$ and $\mathrm{H}_{2} \mathrm{O}$ produced in the reaction.
155. Consider separate 2.5-L gaseous samples of $\mathrm{He}, \mathrm{N}_{2}$, and $\mathrm{F}_{2}$, all at STP and all acting ideally. Rank the gases in order of increasing average kinetic energy and in order of increasing average velocity.
156. Which of the following statements is(are) true?
a. If the number of moles of a gas is doubled, the volume will double, assuming the pressure and temperature of the gas remain constant.
b. If the temperature of a gas increases from $25^{\circ} \mathrm{C}$ to $50^{\circ} \mathrm{C}$, the volume of the gas would double, assuming that the pressure and the number of moles of gas remain constant.
c. The device that measures atmospheric pressure is called a barometer.
d. If the volume of a gas decreases by one half, then the pressure would double, assuming that the number of moles and the temperature of the gas remain constant.

## Challenge Problems

157. A chemist weighed out 5.14 g of a mixture containing unknown amounts of $\mathrm{BaO}(s)$ and $\mathrm{CaO}(s)$ and placed the sample in a $1.50-\mathrm{L}$ flask containing $\mathrm{CO}_{2}(\mathrm{~g})$ at $30.0^{\circ} \mathrm{C}$ and 750 . torr. After the reaction to form $\mathrm{BaCO}_{3}(s)$ and $\mathrm{CaCO}_{3}(s)$ was completed, the pressure of $\mathrm{CO}_{2}(\mathrm{~g})$ remaining was 230. torr. Calculate the mass percentages of $\mathrm{CaO}(s)$ and $\mathrm{BaO}(s)$ in the mixture.
158. A mixture of chromium and zinc weighing 0.362 g was reacted with an excess of hydrochloric acid. After all the metals in the mixture reacted, 225 mL dry of hydrogen gas was collected at $27^{\circ} \mathrm{C}$ and 750 . torr. Determine the mass percent of Zn in the metal sample. [Zinc reacts with hydrochloric acid to produce zinc chloride and hydrogen gas; chromium reacts with hydrochloric acid to produce chromium(III) chloride and hydrogen gas.]
159. Consider a sample of a hydrocarbon (a compound consisting of only carbon and hydrogen) at 0.959 atm and 298 K . Upon combusting the entire sample in oxygen, you collect a mixture of gaseous carbon dioxide and water vapor at 1.51 atm and 375 K . This mixture has a density of $1.391 \mathrm{~g} / \mathrm{L}$ and occupies a volume four times as large as that of the pure hydrocarbon. Determine the molecular formula of the hydrocarbon.
160. You have an equimolar mixture of the gases $\mathrm{SO}_{2}$ and $\mathrm{O}_{2}$, along with some He , in a container fitted with a piston. The density of this mixture at STP is $1.924 \mathrm{~g} / \mathrm{L}$. Assume ideal behavior and constant temperature and pressure.
a. What is the mole fraction of He in the original mixture?
b. The $\mathrm{SO}_{2}$ and $\mathrm{O}_{2}$ react to completion to form $\mathrm{SO}_{3}$. What is the density of the gas mixture after the reaction is complete?
161. Methane $\left(\mathrm{CH}_{4}\right)$ gas flows into a combustion chamber at a rate of $200 \mathrm{~L} / \mathrm{min}$ at 1.50 atm and ambient temperature. Air is added to the chamber at 1.00 atm and the same temperature, and the gases are ignited.
a. To ensure complete combustion of $\mathrm{CH}_{4}$ to $\mathrm{CO}_{2}(g)$ and $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$, three times as much oxygen as is necessary is reacted. Assuming air is 21 mole percent $\mathrm{O}_{2}$ and 79 mole percent $\mathrm{N}_{2}$, calculate the flow rate of air necessary to deliver the required amount of oxygen.
b. Under the conditions in part a, combustion of methane was not complete as a mixture of $\mathrm{CO}_{2}(g)$ and $\mathrm{CO}(g)$ was produced. It was determined that $95.0 \%$ of the carbon in the exhaust gas was present in $\mathrm{CO}_{2}$. The remainder was present as carbon in CO . Calculate the composition of the exhaust gas in terms of mole fraction of $\mathrm{CO}, \mathrm{CO}_{2}, \mathrm{O}_{2}, \mathrm{~N}_{2}$, and $\mathrm{H}_{2} \mathrm{O}$. Assume $\mathrm{CH}_{4}$ is completely reacted and $\mathrm{N}_{2}$ is unreacted.
162. A steel cylinder contains 5.00 mole of graphite (pure carbon) and 5.00 moles of $\mathrm{O}_{2}$. The mixture is ignited and all the graphite reacts. Combustion produces a mixture of CO gas and $\mathrm{CO}_{2}$ gas. After the cylinder has cooled to its original temperature, it is found that the pressure of the cylinder has increased by $17.0 \%$. Calculate the mole fractions of $\mathrm{CO}, \mathrm{CO}_{2}$, and $\mathrm{O}_{2}$ in the final gaseous mixture.
163. The total mass that can be lifted by a balloon is given by the difference between the mass of air displaced by the balloon and the mass of the gas inside the balloon. Consider a hot-air balloon that approximates a sphere 5.00 m in diameter and contains air heated to $65^{\circ} \mathrm{C}$. The surrounding air temperature is $21^{\circ} \mathrm{C}$. The pressure in the balloon is equal to the atmospheric pressure, which is 745 torr.
a. What total mass can the balloon lift? Assume that the average molar mass of air is $29.0 \mathrm{~g} / \mathrm{mol}$. (Hint: Heated air is less dense than cool air.)
b. If the balloon is filled with enough helium at $21^{\circ} \mathrm{C}$ and 745 torr to achieve the same volume as in part a, what total mass can the balloon lift?
c. What mass could the hot-air balloon in part a lift if it were on the ground in Denver, Colorado, where a typical atmospheric pressure is 630 . torr?
164. Consider a children's cartoon illustrating a child holding the strings of several helium balloons and being lifted into the sky.
a. Estimate the minimum number of 10 .-L balloons it would take to lift a 50.-lb child. Assume air has an average molar mass of $29 \mathrm{~g} / \mathrm{mol}$, and assume the masses of the balloons and strings are negligible.
b. Explain why the balloons can lift the child.
165. You have a helium balloon at 1.00 atm and $25^{\circ} \mathrm{C}$. You want to make a hot-air balloon with the same volume and same lift as the helium balloon. Assume air is $79.0 \%$ nitrogen and $21.0 \%$ oxygen by volume. The "lift" of a balloon is given by the difference between the mass of air displaced by the balloon and the mass of gas inside the balloon.
a. Will the temperature in the hot-air balloon have to be higher or lower than $25^{\circ} \mathrm{C}$ ? Explain.
b. Calculate the temperature of the air required for the hotair balloon to provide the same lift as the helium balloon at 1.00 atm and $25^{\circ} \mathrm{C}$. Assume atmospheric conditions are 1.00 atm and $25^{\circ} \mathrm{C}$.
166. We state that the ideal gas law tends to hold best at low pressures and high temperatures. Show how the van der Waals equation simplifies to the ideal gas law under these conditions.
167. You are given an unknown gaseous binary compound (that is, a compound consisting of two different elements). When 10.0 g of the compound is burned in excess oxygen, 16.3 g of water is produced. The compound has a density 1.38 times that of oxygen gas at the same conditions of temperature and pressure. Give a possible identity for the unknown compound.
168. Nitrogen gas $\left(\mathrm{N}_{2}\right)$ reacts with hydrogen gas $\left(\mathrm{H}_{2}\right)$ to form ammonia gas $\left(\mathrm{NH}_{3}\right)$. You have nitrogen and hydrogen gases in a $15.0-\mathrm{L}$ container fitted with a movable piston (the piston allows the container volume to change so as to keep the pressure constant inside the container). Initially the partial pressure of each reactant gas is 1.00 atm . Assume the temperature is constant and that the reaction goes to completion.
a. Calculate the partial pressure of ammonia in the container after the reaction has reached completion.
b. Calculate the volume of the container after the reaction has reached completion.
169. Consider a classroom containing ten evenly spaced rows of students. If a student in row 1 releases laughing gas $\left(\mathrm{N}_{2} \mathrm{O}\right)$ and a student in row 10 simultaneously releases a lachrymator (a gas that causes tears) with molar mass of $176 \mathrm{~g} / \mathrm{mol}$, in which row do the students first laugh and cry at the same time?

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
170. A compound containing only $\mathrm{C}, \mathrm{H}$, and N yields the following data:
i. Complete combustion of 35.0 mg of the compound produced 33.5 mg of $\mathrm{CO}_{2}$ and 41.1 mg of $\mathrm{H}_{2} \mathrm{O}$.
ii. A $65.2-\mathrm{mg}$ sample of the compound was analyzed for nitrogen by the Dumas method (see Exercise 137), giving 35.6 mL of dry $\mathrm{N}_{2}$ at 740 . torr and $25^{\circ} \mathrm{C}$.
iii. The effusion rate of the compound as a gas was measured and found to be $24.6 \mathrm{~mL} / \mathrm{min}$. The effusion rate of argon gas, under identical conditions, is $26.4 \mathrm{~mL} / \mathrm{min}$.
What is the molecular formula of the compound?
171. In the presence of nitric acid, $\mathrm{UO}^{2+}$ undergoes a redox process. It is converted to $\mathrm{UO}_{2}{ }^{2+}$ and nitric oxide (NO) gas is produced according to the following unbalanced equation:

$$
\begin{gathered}
\mathrm{H}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q)+\mathrm{UO}^{2+}(a q) \longrightarrow \\
\mathrm{NO}(g)+\mathrm{UO}_{2}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
\end{gathered}
$$

If $2.55 \times 10^{2} \mathrm{~mL} \mathrm{NO}(g)$ is isolated at $29^{\circ} \mathrm{C}$ and 1.5 atm , what amount (moles) of $\mathrm{UO}^{2+}$ was used in the reaction?
172. Silane, $\mathrm{SiH}_{4}$, is the silicon analogue of methane, $\mathrm{CH}_{4}$. It is prepared industrially according to the following equations:

$$
\begin{gathered}
\mathrm{Si}(s)+3 \mathrm{HCl}(g) \longrightarrow \mathrm{HSiCl}_{3}(l)+\mathrm{H}_{2}(g) \\
4 \mathrm{HSiCl}_{3}(l) \longrightarrow \mathrm{SiH}_{4}(g)+3 \mathrm{SiCl}_{4}(l)
\end{gathered}
$$

a. If $156 \mathrm{~mL} \mathrm{HSiCl}_{3}(d=1.34 \mathrm{~g} / \mathrm{mL})$ is isolated when 15.0 L HCl at 10.0 atm and $35^{\circ} \mathrm{C}$ is used, what is the percent yield of $\mathrm{HSiCl}_{3}$ ?
b. When $156 \mathrm{~mL} \mathrm{HSiCl}_{3}$ is heated, what volume of $\mathrm{SiH}_{4}$ at 10.0 atm and $35^{\circ} \mathrm{C}$ will be obtained if the percent yield of the reaction is $93.1 \%$ ?
173. Solid thorium(IV) fluoride has a boiling point of $1680^{\circ} \mathrm{C}$. What is the density of a sample of gaseous thorium(IV) fluoride at its boiling point under a pressure of 2.5 atm in a $1.7-\mathrm{L}$ container? Which gas will effuse faster at $1680^{\circ} \mathrm{C}$, thorium(IV) fluoride or uranium(III) fluoride? How much faster?
174. Natural gas is a mixture of hydrocarbons, primarily methane $\left(\mathrm{CH}_{4}\right)$ and ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$. A typical mixture might have $\chi_{\text {methane }}=0.915$ and $\chi_{\text {ethane }}=0.085$. What are the partial pressures of the two gases in a 15.00-L container of natural gas at $20 .{ }^{\circ} \mathrm{C}$ and 1.44 atm ? Assuming complete combustion of both gases in the natural gas sample, what is the total mass of water formed?

## Marathon Problem <br> This problem is designed to incorporate several concepts and techniques into one situation.

175. Consider an equimolar mixture (equal number of moles) of two diatomic gases ( $\mathrm{A}_{2}$ and $\mathrm{B}_{2}$ ) in a container fitted with a piston. The gases react to form one product (which is also a gas) with the formula $\mathrm{A}_{x} \mathrm{~B}_{y}$. The density of the sample after the reaction is complete (and the temperature returns to its original state) is 1.50 times greater than the density of the reactant mixture.
a. Specify the formula of the product, and explain if more than one answer is possible based on the given data.
b. Can you determine the molecular formula of the product with the information given or only the empirical formula?

A burning match is an example of exothermic reaction. This double exposure shows the match lit and the match blown out. (© Caren Brinkema/Science Faction/Corbis)

### 6.6 New Energy Sources

Coal Conversion
Hydrogen as a Fuel
Other Energy Alternatives

Energy is the essence of our very existence as individuals and as a society. The food that we eat furnishes the energy to live, work, and play, just as the coal and oil consumed by manufacturing and transportation systems power our modern industrialized civilization.

In the past, huge quantities of carbon-based fossil fuels have been available for the taking. This abundance of fuels has led to a world society with a voracious appetite for energy, consuming millions of barrels of petroleum every day. We are now dangerously dependent on the dwindling supplies of oil, and this dependence is an important source of tension among nations in today's world. In an incredibly short time, we have moved from a period of ample and cheap supplies of petroleum to one of high prices and uncertain supplies. If our present standard of living is to be maintained, we must find alternatives to petroleum. To do this, we need to know the relationship between chemistry and energy, which we explore in this chapter.

There are additional problems with fossil fuels. The waste products from burning fossil fuels significantly affect our environment. For example, when a carbon-based fuel is burned, the carbon reacts with oxygen to form carbon dioxide, which is released into the atmosphere. Although much of this carbon dioxide is consumed in various natural processes such as photosynthesis and the formation of carbonate materials, the amount of carbon dioxide in the atmosphere is steadily increasing. This increase is significant because atmospheric carbon dioxide absorbs heat radiated from the earth's surface and radiates it back toward the earth. Since this is an important mechanism for controlling the earth's temperature, many scientists fear that an increase in the concentration of carbon dioxide will warm the earth, causing significant changes in climate. In addition, impurities in the fossil fuels react with components of the air to produce air pollution. We discussed some aspects of this problem in Chapter 5.

Just as energy is important to our society on a macroscopic scale, it is critically important to each living organism on a microscopic scale. The living cell is a miniature chemical factory powered by energy from chemical reactions. The process of cellular respiration extracts the energy stored in sugars and other nutrients to drive the various tasks of the cell. Although the extraction process is more complex and more subtle, the energy obtained from "fuel" molecules by the cell is the same as would be obtained from burning the fuel to power an internal combustion engine.

Whether it is an engine or a cell that is converting energy from one form to another, the processes are all governed by the same principles, which we will begin to explore in this chapter. Additional aspects of energy transformation will be covered in Chapter 17.

### 6.1 The Nature of Energy

Although the concept of energy is quite familiar, energy itself is rather difficult to define precisely. We will define energy as the capacity to do work or to produce heat. In this chapter we will concentrate specifically on the heat transfer that accompanies chemical processes.

One of the most important characteristics of energy is that it is conserved. The law of conservation of energy states that energy can be converted from one form to another but can be neither created nor destroyed. That is, the energy of the universe is constant. Energy can be classified as either potential or kinetic energy. Potential energy is energy due to position or composition. For example, water behind a dam has potential energy that can be converted to work when the water flows down through turbines, thereby creating electricity. Attractive and repulsive forces also lead to potential energy. The energy released when gasoline is burned results from differences in attractive forces between the nuclei and electrons in the reactants and products. The kinetic energy of an object is energy due to the motion of the object and depends on the mass of the object $m$ and its velocity $v: \mathrm{KE}=\frac{1}{2} m v^{2}$.

-a
Initial

FIGURE 6.1 (a) In the initial positions, ball $A$ has a higher potential energy than ball B. (b) After $A$ has rolled down the hill, the potential energy lost by $A$ has been converted to random motions of the components of the hill (frictional heating) and to the increase in the potential energy of $B$.

Heat involves a transfer of energy.

$\Delta$
This infrared photo of a house shows where energy leaks occur. The more red the color, the more energy (heat) is leaving the house.

[^8]Energy can be converted from one form to another. For example, consider the two balls in Fig. 6.1(a). Ball A, because of its higher position initially, has more potential energy than ball B. When A is released, it moves down the hill and strikes B. Eventually, the arrangement shown in Fig. 6.1(b) is achieved. What has happened in going from the initial to the final arrangement? The potential energy of A has decreased, but since energy is conserved, all the energy lost by A must be accounted for. How is this energy distributed?

Initially, the potential energy of A is changed to kinetic energy as the ball rolls down the hill. Part of this kinetic energy is then transferred to B , causing it to be raised to a higher final position. Thus the potential energy of $B$ has been increased. However, since the final position of B is lower than the original position of A , some of the energy is still unaccounted for. Both balls in their final positions are at rest, so the missing energy cannot be due to their motions. What has happened to the remaining energy?

The answer lies in the interaction between the hill's surface and the ball. As ball A rolls down the hill, some of its kinetic energy is transferred to the surface of the hill as heat. This transfer of energy is called frictional heating. The temperature of the hill increases very slightly as the ball rolls down.

Before we proceed further, it is important to recognize that heat and temperature are decidedly different. As we saw in Chapter 5, temperature is a property that reflects the random motions of the particles in a particular substance. Heat, on the other hand, involves the transfer of energy between two objects due to a temperature difference. Heat is not a substance contained by an object, although we often talk of heat as if this were true. We will discuss the concept of heat in more detail shortly.

Note that in going from the initial to the final arrangements in Fig. 6.1, ball B gains potential energy because work was done by ball A on B. Work is defined as force acting over a distance. Work is required to raise B from its original position to its final one. Part of the original energy stored as potential energy in A has been transferred through work to B, thereby increasing B's potential energy. Thus there are two ways to transfer energy: through work and through heat.

In rolling to the bottom of the hill shown in Fig. 6.1, ball A will always lose the same amount of potential energy. However, the way that this energy transfer is divided between work and heat depends on the specific conditions-the pathway. For example, the surface of the hill might be so rough that the energy of A is expended completely through frictional heating; A is moving so slowly when it hits $B$ that it cannot move B to the next level. In this case, no work is done. Regardless of the condition of the hill's surface, the total energy transferred will be constant. However, the amounts of heat and work will differ. Energy change is independent of the pathway; however, work and heat are both dependent on the pathway.

This brings us to a very important concept: the state function or state property. A state function refers to a property of the system that depends only on its present state. A state function (property) does not depend in any way on the system's past (or future). In other words, the value of a state function does not depend on how the system arrived at the present state; it depends only on the characteristics of the present state. This leads to a very important characteristic of a state function: A change in this function (property) in going from one state to another state is independent of the particular pathway taken between the two states.

A nonscientific analogy that illustrates the difference between a state function and a nonstate function is elevation on the earth's surface and distance between two points. In traveling from Chicago (elevation 674 ft ) to Denver (elevation 5280 ft ), the change in elevation is always $5280-674=4606 \mathrm{ft}$ regardless of the route taken between the two cities. The distance traveled, however, depends on how you make the trip. Thus elevation is a function that does not depend on the route (pathway), but distance is pathway dependent. Elevation is a state function and distance is not.

Of the functions considered in our present example, energy is a state function, but work and heat are not state functions.

## The Process of Heat

We have defined heat as a transfer of energy between two objects due to a temperature difference. Experience shows that when two objects at different temperatures are in contact, they will eventually reach the same intermediate temperature. For example, suppose you and a friend are each enjoying a beverage. You are drinking a cold glass of lemonade while your friend has a hot cup of tea. If you allow the drinks to sit for a long enough period of time, the temperature of the tea will decrease and the temperature of the lemonade will increase. Eventually the temperatures of tea and the lemonade will be the same as room temperature. Energy is transferred in the form of heat from the hot tea to the surroundings (air in the room) and from the surroundings to the cold lemonade. Thus, we see that energy is always transferred from the "hot body" to the "cold body." How does this process occur?

To answer this, let's consider a relatively simple system-two samples of gases, each at a different temperature and in contact as shown below. The wall separating the two samples is a thin membrane.

Recall from Chapter 5 that temperature is a measure of the kinetic energy of a sample of gas. That is, temperature is an index of the random motions of the particles of the gas. A higher temperature means that the gas has a greater average kinetic energy, which gives rise to a higher average velocity of the gas particles.

The gas particles in the left side of the container are at a higher temperature and thus moving at a greater average velocity than the particles in the right side (velocity is represented by the "tails" on the particles in Fig. 6.2). Consider what happens when a particle in the left side ("hot") collides with the membrane at the same time and on the exact opposite side as a particle on the right side ("cold"). Energy will be transferred from the faster-moving particle on the left side to the slower-moving particle on the right side. The particle with the higher initial velocity will slow down, while the particle with the lower initial velocity will speed up. As this process continues, the average kinetic energy on the left side will decrease and the average kinetic energy on the right side will increase. Eventually, the average kinetic energy on each side will be equal, and the temperature of the gas samples will be the same. When this happens, the particles will still be in motion, but they will be moving with the same average velocity.

Although this is perhaps easier to visualize with gas particles striking a shared wall, a similar process occurs with solids and liquids. Atoms and molecules are always in constant motion (even if that motion is merely vibrating such as in a solid lattice). Temperature is a measure of the average kinetic energy of particles in solids and liquids as well as in gases. For any "hot body" in thermal contact with a "cold body," energy is transferred as the initially faster particles decrease in motion and the initially slower molecules increase in motion. Therefore, the samples will eventually reach thermal equilibrium. That is, the particles will have the same average kinetic energy and thus the same temperature.

FIGURE 6.2 Particles at different temperatures in adjoining chambers.

## Chemical Energy

The ideas we have illustrated using mechanical examples also apply to chemical systems. The combustion of methane, for example, is used to heat many homes in the United States:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)+\text { energy (heat) }
$$

To discuss this reaction, we divide the universe into two parts: the system and the surroundings. The system is the part of the universe on which we wish to focus attention; the surroundings include everything else in the universe. In this case we define the system as the reactants and products of the reaction. The surroundings consist of the reaction container (a furnace, for example), the room, and anything else other than the reactants and products.

When a reaction results in the evolution of heat, it is said to be exothermic (exo- is a prefix meaning "out of"); that is, energy flows out of the system. For example, in the combustion of methane, energy flows out of the system as heat. Reactions that absorb energy from the surroundings are said to be endothermic. When the heat flow is into a system, the process is endothermic. For example, the formation of nitric oxide from nitrogen and oxygen is endothermic:

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g)+\text { energy (heat) } \longrightarrow 2 \mathrm{NO}(g)
$$

Where does the energy, released as heat, come from in an exothermic reaction? The answer lies in the difference in potential energies between the products and the reactants. Which has lower potential energy, the reactants or the products? We know that total energy is conserved and that energy flows from the system into the surroundings in an exothermic reaction. This means that the energy gained by the surroundings must be equal to the energy lost by the system. In the combustion of methane, the energy content of the system decreases, which means that 1 mole of $\mathrm{CO}_{2}$ and 2 moles of $\mathrm{H}_{2} \mathrm{O}$ molecules (the products) possess less potential energy than do 1 mole of $\mathrm{CH}_{4}$ and 2 moles of $\mathrm{O}_{2}$ molecules (the reactants). The heat flow into the surroundings results from a lowering of the potential energy of the reaction system. This always holds true. In any exothermic reaction, some of the potential energy stored in the chemical bonds is being converted to thermal energy (random kinetic energy) via heat.

The energy diagram for the combustion of methane is shown in Fig. 6.3, where $\Delta(\mathrm{PE})$ represents the change in potential energy stored in the bonds of the products as compared with the bonds of the reactants. In other words, this quantity represents the difference between the energy required to break the bonds in the reactants and the energy released when the bonds in the products are formed. In an exothermic process, the bonds in the products are stronger (on average) than those of the reactants. That is, more energy is released by forming the new bonds in the products than is consumed to

FIGURE 6.3 The combustion of methane releases the quantity of energy $\Delta(\mathrm{PE})$ to the surroundings via heat flow. This is an exothermic process.

FIGURE 6.4 The energy diagram for the reaction of nitrogen and oxygen to form nitric oxide. This is an endothermic process: Heat [equal in magnitude to $\Delta(\mathrm{PE})]$ flows into the system from the surroundings.

break the bonds in the reactants. The net result is that the quantity of energy $\Delta(\mathrm{PE})$ is transferred to the surroundings through heat.

For an endothermic reaction, the situation is reversed, as shown in Fig. 6.4. Energy that flows into the system as heat is used to increase the potential energy of the system. In this case the products have higher potential energy (weaker bonds on average) than the reactants.

The study of energy and its interconversions is called thermodynamics. The law of conservation of energy is often called the first law of thermodynamics and is stated as follows: The energy of the universe is constant.

The internal energy $E$ of a system can be defined most precisely as the sum of the kinetic and potential energies of all the "particles" in the system. The internal energy of a system can be changed by a flow of work, heat, or both. That is,

$$
\Delta E=q+w
$$

where $\Delta E$ represents the change in the system's internal energy, $q$ represents heat, and $w$ represents work.

Thermodynamic quantities always consist of two parts: a number, giving the magnitude of the change, and a sign, indicating the direction of the flow. The sign reflects the system's point of view. For example, if a quantity of energy flows into the system via heat (an endothermic process), $q$ is equal to $+x$, where the positive sign indicates that the system's energy is increasing. On the other hand, when energy flows out of the system via heat (an exothermic process), $q$ is equal to $-x$, where the negative sign indicates that the system's energy is decreasing.

In this text the same conventions also apply to the flow of work. If the system does work on the surroundings (energy flows out of the system), $w$ is negative. If the surroundings do work on the system (energy flows into the system), $w$ is positive. We define work from the system's point of view to be consistent for all thermodynamic quantities. That is, in this convention the signs of both $q$ and $w$ reflect what happens to the system; thus we use $\Delta E=q+w$.

The convention in this text is to take the system's point of view; $q=-x$ denotes an exothermic process, and $q=+x$ denotes an endothermic one.

In this text we always take the system's point of view. This convention is not followed in every area of science. For example, engineers are in the business of designing machines to do work, that is, to make the system (the machine) transfer energy to its surroundings through work. Consequently, engineers define work from the surroundings' point of view. In their convention, work that flows out of the system is treated as positive because the energy of the surroundings has increased. The first law of thermodynamics is then written $\Delta E=q-w^{\prime}$, where $w^{\prime}$ signifies work from the surroundings' point of view.

## INTERACTIVE EXAMPLE 6.1

## SOLUTION

FIGURE 6.5 (a) The piston, moving a distance $\Delta h$ against a pressure $P$, does work on the surroundings. (b) Since the volume of a cylinder is the area of the base times its height, the change in volume of the gas is given by $\Delta h \times A=\Delta V$.

## Internal Energy

Calculate $\Delta E$ for a system undergoing an endothermic process in which 15.6 kJ of heat flows and where 1.4 kJ of work is done on the system.

We use the equation

$$
\Delta E=q+w
$$

where $q=+15.6 \mathrm{~kJ}$, since the process is endothermic, and $w=+1.4 \mathrm{~kJ}$, since work is done on the system. Thus

$$
\Delta E=15.6 \mathrm{~kJ}+1.4 \mathrm{~kJ}=17.0 \mathrm{~kJ}
$$

■ The system has gained 17.0 kJ of energy.

See Exercises 6.33 through 6.35

A common type of work associated with chemical processes is work done by a gas (through expansion) or work done to a gas (through compression). For example, in an automobile engine, the heat from the combustion of the gasoline expands the gases in the cylinder to push back the piston, and this motion is then translated into the motion of the car.

Suppose we have a gas confined to a cylindrical container with a movable piston as shown in Fig. 6.5, where $F$ is the force acting on a piston of area $A$. Since pressure is defined as force per unit area, the pressure of the gas is

$$
P=\frac{F}{A}
$$

Work is defined as force applied over a distance, so if the piston moves a distance $\Delta h$, as shown in Fig. 6.5, then the work done is

$$
\text { Work }=\text { force } \times \text { distance }=F \times \Delta h
$$

Since $P=F / A$ or $F=P \times A$, then

$$
\text { Work }=F \times \Delta h=P \times A \times \Delta h
$$

Since the volume of a cylinder equals the area of the piston times the height of the cylinder (see Fig. 6.5), the change in volume $\Delta V$ resulting from the piston moving a distance $\Delta h$ is

$$
\Delta V=\text { final volume }- \text { initial volume }=A \times \Delta h
$$

Substituting $\Delta V=A \times \Delta h$ into the expression for work gives

$$
\text { Work }=P \times A \times \Delta h=P \Delta V
$$

This gives us the magnitude (size) of the work required to expand a gas $\Delta V$ against a pressure $P$.

What about the sign of the work? The gas (the system) is expanding, moving the piston against the pressure. Thus the system is doing work on the surroundings, so from the system's point of view the sign of the work should be negative.
$w$ and $P \Delta V$ have opposite signs because when the gas expands ( $\Delta V$ is positive), work flows into the surroundings ( $w$ is negative).

Calculate the work associated with the expansion of a gas from 46 L to 64 L at a constant external pressure of 15 atm .

$$
w=-P \Delta V
$$

For an ideal gas, work can occur only when its volume changes. Thus, if a gas is heated at constant volume, the pressure increases but no work occurs.

For an expanding gas, $\Delta V$ is a positive quantity because the volume is increasing. Thus $\Delta V$ and $w$ must have opposite signs, which leads to the equation

$$
w=-P \Delta V
$$

Note that for a gas expanding against an external pressure $P, w$ is a negative quantity as required, since work flows out of the system. When a gas is compressed, $\Delta V$ is a negative quantity (the volume decreases), which makes $w$ a positive quantity (work flows into the system).

You are calculating $\Delta E$ in a chemistry problem. What if you confuse the system and the surroundings? How would this affect the magnitude of the answer you calculate? The sign?

## INTERACTIVE EXAMPLE 6.2 PV Work

SOLUTION For a gas at constant pressure,

In this case $P=15 \mathrm{~atm}$ and $\Delta V=64-46=18 \mathrm{~L}$. Hence
■ $w=-15 \mathrm{~atm} \times 18 \mathrm{~L}=-270 \mathrm{~L} \cdot \mathrm{~atm}$
Note that since the gas expands, it does work on its surroundings.
Reality Check Energy flows out of the gas, so $w$ is a negative quantity.

## See Exercises 6.39 through 6.41

In dealing with " $P V$ work," keep in mind that the $P$ in $P \Delta V$ always refers to the external pressure-the pressure that causes a compression or that resists an expansion.

## INTERACTIVE EXAMPLE 6.3 Internal Energy, Heat, and Work

A balloon is being inflated to its full extent by heating the air inside it. In the final stages of this process, the volume of the balloon changes from $4.00 \times 10^{6} \mathrm{~L}$ to $4.50 \times 10^{6} \mathrm{~L}$ by the addition of $1.3 \times 10^{8} \mathrm{~J}$ of energy as heat. Assuming that the balloon expands against a constant pressure of 1.0 atm , calculate $\Delta E$ for the process. (To convert between $\mathrm{L} \cdot \mathrm{atm}$ and J , use $1 \mathrm{~L} \cdot \operatorname{atm}=101.3 \mathrm{~J}$.)

## SOLUTION Where are we going?

To calculate $\Delta E$
What do we know?

$$
\begin{array}{ll}
\Rightarrow & V_{1}=4.00 \times 10^{6} \mathrm{~L} \\
\Rightarrow & q=+1.3 \times 10^{8} \mathrm{~J} \\
\Rightarrow & P=1.0 \mathrm{~atm} \\
\Rightarrow & 1 \mathrm{~L} \cdot \mathrm{~atm}=101.3 \mathrm{~J} \\
\Rightarrow & V_{2}=4.50 \times 10^{6} \mathrm{~L}
\end{array}
$$

A
A propane burner is used to heat the air in a hot-air balloon.

What do we need?

$$
\Delta E=q+w
$$

How do we get there?
What is the work done on the gas?

$$
w=-P \Delta V
$$

What is $\Delta V$ ?

$$
\Delta V=V_{2}-V_{1}=4.50 \times 10^{6} \mathrm{~L}-4.00 \times 10^{6} \mathrm{~L}=5.0 \times 10^{5} \mathrm{~L}
$$

What is the work?

$$
w=-P \Delta V=-1.0 \mathrm{~atm} \times 5.0 \times 10^{5} \mathrm{~L}=-5.0 \times 10^{5} \mathrm{~L} \cdot \mathrm{~atm}
$$

The negative sign makes sense because the gas is expanding and doing work on the surroundings. To calculate $\Delta E$, we must sum $q$ and $w$. However, since $q$ is given in units of J and $w$ is given in units of $\mathrm{L} \cdot \mathrm{atm}$, we must change the work to units of joules:

$$
w=-5.0 \times 10^{5} \mathrm{~L} \cdot \mathrm{~atm} \times \frac{101.3 \mathrm{~J}}{\mathrm{~L} \cdot \mathrm{~atm}}=-5.1 \times 10^{7} \mathrm{~J}
$$

Then

$$
\Delta E=q+w=\left(+1.3 \times 10^{8} \mathrm{~J}\right)+\left(-5.1 \times 10^{7} \mathrm{~J}\right)=8 \times 10^{7} \mathrm{~J}
$$

Reality Check Since more energy is added through heating than the gas expends doing work, there is a net increase in the internal energy of the gas in the balloon. Hence $\Delta E$ is positive.

## See Exercises 6.42 through 6.44

### 6.2 Enthalpy and Calorimetry

## Enthalpy

So far we have discussed the internal energy of a system. A less familiar property of a system is its enthalpy $H$, which is defined as

$$
H=E+P V
$$

where $E$ is the internal energy of the system, $P$ is the pressure of the system, and $V$ is the volume of the system.

Since internal energy, pressure, and volume are all state functions, enthalpy is also a state function. But what exactly is enthalpy? To help answer this question, consider a process carried out at constant pressure and where the only work allowed is pressurevolume work ( $w=-P \Delta V$ ). Under these conditions, the expression

$$
\Delta E=q_{P}+w
$$

becomes

$$
\Delta E=q_{P}-P \Delta V
$$

or

$$
q_{P}=\Delta E+P \Delta V
$$

where $q_{P}$ is the heat at constant pressure.
$\Delta H=q$ only at constant pressure.

The change in enthalpy of a system has no easily interpreted meaning except at constant pressure, where $\Delta H=$ heat.

At constant pressure, exothermic means $\Delta H$ is negative; endothermic means $\Delta H$ is positive.

We will now relate $q_{P}$ to a change in enthalpy. The definition of enthalpy is $H=E+P V$. Therefore, we can say

$$
\text { Change in } H=(\text { change in } E)+(\text { change in } P V)
$$

or

$$
\Delta H=\Delta E+\Delta(P V)
$$

Since $P$ is constant, the change in $P V$ is due only to a change in volume. Thus

$$
\Delta(P V)=P \Delta V
$$

and

$$
\Delta H=\Delta E+P \Delta V
$$

This expression is identical to the one we obtained for $q_{P}$ :

$$
q_{P}=\Delta E+P \Delta V
$$

Thus, for a process carried out at constant pressure and where the only work allowed is that from a volume change, we have

$$
\Delta H=q_{P}
$$

At constant pressure (where only PV work is allowed), the change in enthalpy $\Delta H$ of the system is equal to the energy flow as heat. This means that for a reaction studied at constant pressure, the flow of heat is a measure of the change in enthalpy for the system. For this reason, the terms heat of reaction and change in enthalpy are used interchangeably for reactions studied at constant pressure.

For a chemical reaction, the enthalpy change is given by the equation

$$
\Delta H=H_{\text {products }}-H_{\text {reactants }}
$$

In a case in which the products of a reaction have a greater enthalpy than the reactants, $\Delta H$ will be positive. Thus heat will be absorbed by the system, and the reaction is endothermic. On the other hand, if the enthalpy of the products is less than that of the reactants, $\Delta H$ will be negative. In this case the overall decrease in enthalpy is achieved by the generation of heat, and the reaction is exothermic.

## INTERACTIVE EXAMPLE 6.4 Enthalpy

When 1 mole of methane $\left(\mathrm{CH}_{4}\right)$ is burned at constant pressure, 890 kJ of energy is released as heat. Calculate $\Delta H$ for a process in which a $5.8-\mathrm{g}$ sample of methane is burned at constant pressure.

## SOLUTION Where are we going?

To calculate $\Delta H$
What do we know?
) $q_{P}=\Delta H=-890 \mathrm{~kJ} / \mathrm{mol} \mathrm{CH}_{4}$
) Mass $=5.8 \mathrm{~g} \mathrm{CH}_{4}$
) Molar mass $\mathrm{CH}_{4}=16.04 \mathrm{~g}$
How do we get there?
What are the moles of $\mathrm{CH}_{4}$ burned?

$$
5.8 \mathrm{gCH}_{4} \times \frac{1 \mathrm{~mol} \mathrm{CH}_{4}}{16.04 \mathrm{gCH}_{4}}=0.36 \mathrm{~mol} \mathrm{CH}_{4}
$$

What is $\Delta H$ ?

$$
\Delta H=0.36 \mathrm{molCH}_{4} \times \frac{-890 \mathrm{~kJ}}{\mathrm{molCH}_{4}}=-320 \mathrm{~kJ}
$$

Thus, when a $5.8-\mathrm{g}$ sample of $\mathrm{CH}_{4}$ is burned at constant pressure,

$$
\Delta H=\text { heat flow }=-320 \mathrm{~kJ}
$$

Reality Check In this case, a $5.8-\mathrm{g}$ sample of $\mathrm{CH}_{4}$ is burned. Since this amount is smaller than 1 mole, less than 890 kJ will be released as heat.

## See Exercises 6.49 through 6.52

## TABLE 6.1 | The Specific Heat Capacities of Some Common Substances

| Substance | Specific Heat <br> Capacity $\left(\mathrm{J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}\right)$ |
| :--- | :---: |
| $\mathrm{H}_{2} \mathrm{O}(I)$ | 4.18 |
| $\mathrm{H}_{2} \mathrm{O}(s)$ | 2.03 |
| $\mathrm{Al}(s)$ | 0.89 |
| $\mathrm{Fe}(s)$ | 0.45 |
| $\mathrm{Hg}(I)$ | 0.14 |
| $\mathrm{C}(\mathrm{s})$ | 0.71 |

Specific heat capacity: the energy required to raise the temperature of one gram of a substance by one degree Celsius.

Molar heat capacity: the energy required to raise the temperature of one mole of a substance by one degree Celsius.

FIGURE 6.6 A coffee-cup calorimeter made of two Styrofoam cups.

## Calorimetry

The device used experimentally to determine the heat associated with a chemical reaction is called a calorimeter. Calorimetry, the science of measuring heat, is based on observing the temperature change when a body absorbs or discharges energy as heat. Substances respond differently to being heated. One substance might require a great deal of heat energy to raise its temperature by one degree, whereas another will exhibit the same temperature change after absorbing relatively little heat. The heat capacity $C$ of a substance, which is a measure of this property, is defined as

$$
C=\frac{\text { heat absorbed }}{\text { increase in temperature }}
$$

When an element or a compound is heated, the energy required will depend on the amount of the substance present (for example, it takes twice as much energy to raise the temperature of 2 g of water by one degree than it takes to raise the temperature of 1 g of water by one degree). Thus, in defining the heat capacity of a substance, the amount of substance must be specified. If the heat capacity is given per gram of substance, it is called the specific heat capacity, and its units are $\mathrm{J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$ or $\mathrm{J} / \mathrm{K} \cdot \mathrm{g}$. If the heat capacity is given per mole of the substance, it is called the molar heat capacity, and it has the units $\mathrm{J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{mol}$ or $\mathrm{J} / \mathrm{K} \cdot \mathrm{mol}$. The specific heat capacities of some common substances are given in Table 6.1. Note from this table that the heat capacities of metals are very different from that of water. It takes much less energy to change the temperature of a gram of a metal by $1^{\circ} \mathrm{C}$ than for a gram of water.

Although the calorimeters used for highly accurate work are precision instruments, a very simple calorimeter can be used to examine the fundamentals of calorimetry. All we need are two nested Styrofoam cups with a cover through which a stirrer and thermometer can be inserted (Fig. 6.6). This device is called a "coffee-cup calorimeter." The outer cup is used to provide extra insulation. The inner cup holds the solution in which the reaction occurs.

The measurement of heat using a simple calorimeter such as that shown in Fig. 6.6 is an example of constant-pressure calorimetry, since the pressure (atmospheric pressure) remains constant during the process. Constant-pressure calorimetry is used in determining the changes in enthalpy (heats of reactions) for reactions occurring in solution. Recall that under these conditions, the change in enthalpy equals the heat; that is, $\Delta H=q_{P}$.

For example, suppose we mix 50.0 mL of 1.0 M HCl at $25.0^{\circ} \mathrm{C}$ with 50.0 mL of 1.0 M NaOH also at $25^{\circ} \mathrm{C}$ in a calorimeter. After the reactants are mixed by stirring, the temperature is observed to increase to $31.9^{\circ} \mathrm{C}$. As we saw in Section 4.8 , the net ionic equation for this reaction is

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

When these reactants (each originally at the same temperature) are mixed, the temperature of the mixed solution is observed to increase. Therefore, the chemical

## CHEMICAL CDNNECTIDNS

## Nature Has Hot Plants

The voodoo lily is a beautiful, seductive-and foul-smellingplant. The exotic-looking lily features an elaborate reproductive mechanisma purple spike that can reach nearly 3 feet in length and is cloaked by a hoodlike leaf. But approach to the plant reveals bad news-it smells terrible!

Despite its antisocial odor, this putrid plant has fascinated biologists for many years because of its ability to generate heat. At the peak of its metabolic activity, the plant's blossom can be as much as $15^{\circ} \mathrm{C}$ above its ambient temperature. To generate this much heat, the metabolic rate of the plant must be close to that of a flying hummingbird!

What's the purpose of this intense heat production? For a plant faced with limited food supplies in the very competitive tropical climate where it grows, heat production seems like a great waste of energy. The answer to this mystery is that the voodoo lily is pollinated mainly by carrion-loving insects. Thus the lily prepares a malodorous mixture of chemicals characteristic of rotting meat, which it then "cooks" off into the surrounding air to attract flesh-feeding beetles and flies. Then, once the insects enter the
pollination chamber, the high temperatures there (as high as $110^{\circ} \mathrm{F}$ ) cause the insects to remain very active to better carry out their pollination duties.

The voodoo lily is only one of many such thermogenic (heat-producing) plants. Another interesting example is the eastern skunk cabbage, which produces enough heat to bloom inside of a snow bank by creating its own ice caves. These plants are of special interest to biologists because they provide opportunities to study metabolic reactions that are quite subtle in "normal" plants. For example, recent studies have shown that salicylic acid, the active form of aspirin, is probably very important in producing the metabolic bursts in thermogenic plants.

Besides studying the dramatic heat effects in thermogenic plants, biologists are also interested in calorimetric studies of regular plants. For example, very precise calorimeters have been designed that can be used to study the heat produced, and thus the metabolic activities, of clumps of cells no larger than a bread crumb. Several scientists have suggested that a single calorimetric measurement taking just a few minutes on a tiny plant
might be useful in predicting the growth rate of the mature plant throughout its lifetime. If true, this would provide a very efficient method for selecting the plants most likely to thrive as adults.

Because the study of the heat production by plants is an excellent way to learn about plant metabolism, this continues to be a "hot" area of research.

The voodoo lily attracts pollinating insects with its foul odor.

[^9]reaction must be releasing energy as heat. This released energy increases the random motions of the solution components, which in turn increases the temperature. The quantity of energy released can be determined from the temperature increase, the mass of solution, and the specific heat capacity of the solution. For an approximate result, we will assume that the calorimeter does not absorb or leak any heat and that the solution can be treated as if it were pure water with a density of $1.0 \mathrm{~g} / \mathrm{mL}$.

We also need to know the heat required to raise the temperature of a given amount of water by $1^{\circ} \mathrm{C}$. Table 6.1 lists the specific heat capacity of water as $4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$. This means that 4.18 J of energy is required to raise the temperature of 1 g of water by $1^{\circ} \mathrm{C}$.

From these assumptions and definitions, we can calculate the heat (change in enthalpy) for the neutralization reaction:
Energy (as heat) released by the reaction

$$
\begin{aligned}
& =\text { energy (as heat) absorbed by the solution } \\
& =\text { specific heat capacity } \times \text { mass of solution } \times \text { increase in temperature } \\
& =s \times m \times \Delta T
\end{aligned}
$$

Notice that in this example we mentally keep track of the direction of the energy flow and assign the correct sign at the end of the calculation.

In this case the increase in temperature $(\Delta T)=31.9^{\circ} \mathrm{C}-25.0^{\circ} \mathrm{C}=6.9^{\circ} \mathrm{C}$, and the mass of solution $(m)=100.0 \mathrm{~mL} \times 1.0 \mathrm{~g} / \mathrm{mL}=1.0 \times 10^{2} \mathrm{~g}$. Thus

$$
\begin{aligned}
\text { Energyr eleased (as heat) } & =s \times m \times \Delta T \\
& =\left(4.18 \frac{\mathrm{~J}}{{ }^{\circ} \mathrm{C} \cdot \mathrm{~g}}\right)\left(1.0 \times 10^{2} \mathrm{~g}\right)\left(6.9^{\circ} \mathrm{C}\right) \\
& =2.9 \times 10^{3} \mathrm{~J}
\end{aligned}
$$

How much energy would have been released if twice these amounts of solutions had been mixed? The answer is that twice as much heat would have been produced. The heat of a reaction is an extensive property; it depends directly on the amount of substance, in this case on the amounts of reactants. In contrast, an intensive property is not related to the amount of a substance. For example, temperature is an intensive property.

Enthalpies of reaction are often expressed in terms of moles of reacting substances. The number of moles of $\mathrm{H}^{+}$ions consumed in the preceding experiment is

$$
50.0 \mathrm{mG} \times \frac{1 \mathrm{~K}}{1000 \mathrm{mt}} \times \frac{1.0 \mathrm{~mol} \mathrm{H}^{+}}{\mathrm{L}}=5.0 \times 10^{-2} \mathrm{~mol} \mathrm{H}^{+}
$$

Thus $2.9 \times 10^{3} \mathrm{~J}$ heat was released when $5.0 \times 10^{-2}$ mole of $\mathrm{H}^{+}$ions reacted, or

$$
\frac{2.9 \times 10^{3} \mathrm{~J}}{5.0 \times 10^{-2} \mathrm{~mol} \mathrm{H}^{+}}=5.8 \times 10^{4} \mathrm{~J} / \mathrm{mol}
$$

of heat released per 1.0 mole of $\mathrm{H}^{+}$ions neutralized. Thus the magnitude of the enthalpy change per mole for the reaction

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

is $58 \mathrm{~kJ} / \mathrm{mol}$. Since heat is evolved, $\Delta H=-58 \mathrm{~kJ} / \mathrm{mol}$.
To summarize, we have found that when an object changes temperature, the heat can be calculated from the equation

$$
q=s \times m \times \Delta T
$$

where $s$ is the specific heat capacity, $m$ is the mass, and $\Delta T$ is the change in temperature. Note that when $\Delta T$ is positive, $q$ also has a positive sign. The object has absorbed heat, so its temperature increases.

## INTERACTVE EXAMPLE 6.5 Constant-Pressure Calorimetry

When 1.00 L of $1.00 \mathrm{M} \mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$ solution at $25.0^{\circ} \mathrm{C}$ is mixed with 1.00 L of 1.00 M $\mathrm{Na}_{2} \mathrm{SO}_{4}$ solution at $25.0^{\circ} \mathrm{C}$ in a calorimeter, the white solid $\mathrm{BaSO}_{4}$ forms, and the temperature of the mixture increases to $28.1^{\circ} \mathrm{C}$. Assuming that the calorimeter absorbs only a negligible quantity of heat, the specific heat capacity of the solution is $4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$, and the density of the final solution is $1.0 \mathrm{~g} / \mathrm{mL}$, calculate the enthalpy change per mole of $\mathrm{BaSO}_{4}$ formed.

## SOLUTION

## Where are we going?

To calculate $\Delta H$ per mole of $\mathrm{BaSO}_{4}$ formed
What do we know?

$$
\begin{array}{ll}
> & 1.00 \mathrm{~L} \text { of } 1.00 \mathrm{M} \mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2} \\
> & 1.00 \mathrm{~L} \text { of } 1.00 \mathrm{M} \mathrm{Na}_{2} \mathrm{SO}_{4} \\
> & T_{\text {initial }}=25.0^{\circ} \mathrm{C} \\
> & T_{\text {final }}=28.1^{\circ} \mathrm{C} \\
> & \text { Heat capacity of solution }=4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{~g} \\
> & \text { Density of final solution }=1.0 \mathrm{~g} / \mathrm{mL}
\end{array}
$$

What do we need?
) Net ionic equation for the reaction
The ions present before any reaction occurs are $\mathrm{Ba}^{2+}, \mathrm{NO}_{3}{ }^{-}, \mathrm{Na}^{+}$, and $\mathrm{SO}_{4}{ }^{2-}$. The $\mathrm{Na}^{+}$ and $\mathrm{NO}_{3}{ }^{-}$ions are spectator ions, since $\mathrm{NaNO}_{3}$ is very soluble in water and will not precipitate under these conditions. The net ionic equation for the reaction is therefore

$$
\mathrm{Ba}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q) \longrightarrow \mathrm{BaSO}_{4}(s)
$$

## How do we get there?

What is $\Delta H$ ?
Since the temperature increases, formation of solid $\mathrm{BaSO}_{4}$ must be exothermic; $\Delta H$ is negative.
Heat evolved by the reaction
$=$ heat absorbed by the solution
$=$ specific heat capacity $\times$ mass of solution $\times$ increase in temperature
What is the mass of the final solution?

$$
\text { Mass of solution }=2.00 \mathrm{E} \times \frac{1000 \mathrm{mt}}{1 \mathrm{~L}} \times \frac{1.0 \mathrm{~g}}{\mathrm{~m}}=2.0 \times 10^{3} \mathrm{~g}
$$

What is the temperature increase?

$$
\Delta T=T_{\text {final }}-T_{\text {initial }}=28.1^{\circ} \mathrm{C}-25.0^{\circ} \mathrm{C}=3.1^{\circ} \mathrm{C}
$$

How much heat is evolved by the reaction?

$$
\text { Heat evolved }=\left(4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{~g}\right)\left(2.0 \times 10^{3} \mathrm{~g}\right)\left(3.1^{\circ} \mathrm{C}\right)=2.6 \times 10^{4} \mathrm{~J}
$$

Thus

$$
q=q_{P}=\Delta H=-2.6 \times 10^{4} \mathrm{~J}
$$

What is $\Delta H$ per mole of $\mathrm{BaSO}_{4}$ formed?
Since 1.0 L of $1.0 \mathrm{M} \mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$ contains 1 mole of $\mathrm{Ba}^{2+}$ ions and 1.0 L of 1.0 M $\mathrm{Na}_{2} \mathrm{SO}_{4}$ contains 1.0 mole of $\mathrm{SO}_{4}{ }^{2-}$ ions, 1.0 mole of solid $\mathrm{BaSO}_{4}$ is formed in this experiment. Thus the enthalpy change per mole of $\mathrm{BaSO}_{4}$ formed is

$$
\Delta H=-2.6 \times 10^{4} \mathrm{~J} / \mathrm{mol}=-26 \mathrm{~kJ} / \mathrm{mol}
$$

## See Exercises 6.65 through 6.68

Constant-volume calorimetry experiments can also be performed. For example, when a photographic flashbulb flashes, the bulb becomes very hot, because the reaction of the zirconium or magnesium wire with the oxygen inside the bulb is exothermic. The reaction occurs inside the flashbulb, which is rigid and does not change volume. Under these conditions, no work is done (because the volume must change for pressure-volume work to be performed). To study the energy changes in reactions under conditions of constant volume, a "bomb calorimeter" (Fig. 6.7) is used. Weighed reactants are placed inside a rigid steel container (the "bomb") and ignited. The energy change is determined by measuring the increase in the temperature of the water and other calorimeter parts. For a constant-volume process, the change in volume $\Delta V$ is equal to zero, so work (which is $-P \Delta V$ ) is also equal to zero. Therefore,

$$
\Delta E=q+w=q=q_{V} \quad \text { (constant volume) }
$$

Suppose we wish to measure the energy of combustion of octane $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$, a component of gasoline. A $0.5269-\mathrm{g}$ sample of octane is placed in a bomb calorimeter known to have a heat capacity of $11.3 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$. This means that 11.3 kJ of energy is required to

FIGURE 6.7 A bomb calorimeter. The reaction is carried out inside a rigid steel "bomb" (photo of actual disassembled "bomb" shown on right), and the heat evolved is absorbed by the surrounding water and other calorimeter parts. The quantity of energy produced by the reaction can be calculated from the temperature increase.
raise the temperature of the water and other parts of the calorimeter by $1^{\circ} \mathrm{C}$. The octane is ignited in the presence of excess oxygen, and the temperature increase of the calorimeter is $2.25^{\circ} \mathrm{C}$. The amount of energy released is calculated as follows:

Energy released by the reaction

$$
\begin{aligned}
& =\text { temperature increase } \times \text { energy required to change the temperature by } 1^{\circ} \mathrm{C} \\
& =\Delta T \times \text { heat capacity of calorimeter } \\
& =2.25^{\circ} \ell \times 11.3 \mathrm{~kJ} /{ }^{\circ} \ell=25.4 \mathrm{~kJ}
\end{aligned}
$$

This means that 25.4 kJ of energy was released by the combustion of 0.5269 g octane. The number of moles of octane is

$$
0.5269 \text { g octane } \times \frac{1 \mathrm{~mol} \text { octane }}{114.2 \text { goctane }}=4.614 \times 10^{-3} \mathrm{~mol} \text { octane }
$$

Since 25.4 kJ of energy was released for $4.614 \times 10^{-3}$ mole of octane, the energy released per mole is

$$
\frac{25.4 \mathrm{~kJ}}{4.614 \times 10^{-3} \mathrm{~mol}}=5.50 \times 10^{3} \mathrm{~kJ} / \mathrm{mol}
$$

Since the reaction is exothermic, $\Delta E$ is negative:

$$
\Delta E_{\text {combustion }}=-5.50 \times 10^{3} \mathrm{~kJ} / \mathrm{mol}
$$

Note that since no work is done in this case, $\Delta E$ is equal to the heat.

$$
\Delta E=q+w=q \quad \text { since } w=0
$$

Thus $q=-5.50 \times 10^{3} \mathrm{~kJ} / \mathrm{mol}$.

## EXAMPLE 6.6

Hydrogen's potential as a fuel is discussed in Section 6.6.

## Constant-Volume Calorimetry

It has been suggested that hydrogen gas obtained by the decomposition of water might be a substitute for natural gas (principally methane). To compare the energies of combustion of these fuels, the following experiment was carried out using a bomb calorimeter with a heat capacity of $11.3 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$. When a $1.50-\mathrm{g}$ sample of methane gas was

## SOLUTION

The direction of energy flow is indicated by words in this example. Using signs to designate the direction of energy flow:
$\Delta E_{\text {combustion }}=-55 \mathrm{~kJ} / \mathrm{g}$
for methane and
$\Delta E_{\text {combustion }}=-141 \mathrm{~kJ} / \mathrm{g}$
for hydrogen.
burned with excess oxygen in the calorimeter, the temperature increased by $7.3^{\circ} \mathrm{C}$. When a $1.15-\mathrm{g}$ sample of hydrogen gas was burned with excess oxygen, the temperature increase was $14.3^{\circ} \mathrm{C}$. Compare the energies of combustion (per gram) for hydrogen and methane.

## Where are we going?

To calculate $\Delta H$ of combustion per gram for $\mathrm{H}_{2}$ and $\mathrm{CH}_{4}$

## What do we know?

$$
\begin{aligned}
& >1.50 \mathrm{~g} \mathrm{CH}_{4} \Rightarrow \Delta T=7.3^{\circ} \mathrm{C} \\
& >1.15 \mathrm{~g} \mathrm{H}_{2} \Rightarrow \Delta T=14.3^{\circ} \mathrm{C} \\
& >\text { Heat capacity of calorimeter }=11.3 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}
\end{aligned}
$$

## What do we need?

> $\Delta E=\Delta T \times$ heat capacity of calorimeter

## How do we get there?

What is the energy released for each combustion?
For $\mathrm{CH}_{4}$, we calculate the energy of combustion for methane using the heat capacity of the calorimeter $\left(11.3 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}\right)$ and the observed temperature increase of $7.3^{\circ} \mathrm{C}$ :

$$
\text { Energy released in the combustion of } \begin{aligned}
1.5 \mathrm{~g} \mathrm{CH}_{4} & =\left(11.3 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}\right)\left(7.3^{\circ} \mathrm{C}\right) \\
& =83 \mathrm{~kJ}
\end{aligned}
$$

Energy released in the combustion of $1 \mathrm{~g} \mathrm{CH}_{4}=\frac{83 \mathrm{~kJ}}{1.5 \mathrm{~g}}=55 \mathrm{~kJ} / \mathrm{g}$
For $\mathrm{H}_{2}$,
Energy released in the combustion of $1.15 \mathrm{~g} \mathrm{H}_{2}=\left(11.3 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}\right)\left(14.3^{\circ} \mathrm{C}\right)$

$$
=162 \mathrm{~kJ}
$$

Energy released in the combustion of $1 \mathrm{~g} \mathrm{H}_{2}=\frac{162 \mathrm{~kJ}}{1.15 \mathrm{~g}}=141 \mathrm{~kJ} / \mathrm{g}$
How do the energies of combustion compare?

- The energy released in the combustion of 1 g hydrogen is approximately 2.5 times that for 1 g methane, indicating that hydrogen gas is a potentially useful fuel.

## See Exercises 6.71 and 6.74

### 6.3 Hess's Law

$\Delta H$ is not dependent on the reaction pathway.

Since enthalpy is a state function, the change in enthalpy in going from some initial state to some final state is independent of the pathway. This means that in going from a particular set of reactants to a particular set of products, the change in enthalpy is the same whether the reaction takes place in one step or in a series of steps. This principle is known as Hess's law and can be illustrated by examining the oxidation of nitrogen to produce nitrogen dioxide. The overall reaction can be written in one step, where the enthalpy change is represented by $\Delta H_{1}$.

$$
\mathrm{N}_{2}(g)+2 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g) \quad \Delta H_{1}=68 \mathrm{~kJ}
$$

FIGURE 6.8 The principle of Hess's law. The same change in enthalpy occurs when nitrogen and oxygen react to form nitrogen dioxide, regardless of whether the reaction occurs in one (red) or two (blue) steps.

Reversing the direction of a reaction changes the sign of $\Delta H$.

A
Crystals of xenon tetrafluoride, the first reported binary compound containing a noble gas element.

This reaction also can be carried out in two distinct steps, with enthalpy changes designated by $\Delta H_{2}$ and $\Delta H_{3}$ :

$$
\begin{array}{rlr}
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g) & \Delta H_{2}=180 \mathrm{~kJ} \\
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g) & \Delta H_{3}=-112 \mathrm{~kJ} \\
\hline \text { Netr eaction: } & \mathrm{N}_{2}(g)+2 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g) & \Delta H_{2}+\Delta H_{3}
\end{array}=68 \mathrm{~kJ}
$$

Note that the sum of the two steps gives the net, or overall, reaction and that

$$
\Delta H_{1}=\Delta H_{2}+\Delta H_{3}=68 \mathrm{~kJ}
$$

The principle of Hess's law is shown schematically in Fig. 6.8.

## Characteristics of Enthalpy Changes

To use Hess's law to compute enthalpy changes for reactions, it is important to understand two characteristics of $\Delta H$ for a reaction:

## Characteristics of $\boldsymbol{\Delta H}$ for a Reaction

" If a reaction is reversed, the sign of $\Delta H$ is also reversed.
" The magnitude of $\Delta H$ is directly proportional to the quantities of reactants and products in a reaction. If the coefficients in a balanced reaction are multiplied by an integer, the value of $\Delta H$ is multiplied by the same integer.

Both these rules follow in a straightforward way from the properties of enthalpy changes. The first rule can be explained by recalling that the sign of $\Delta H$ indicates the direction of the heat flow at constant pressure. If the direction of the reaction is reversed, the direction of the heat flow also will be reversed. To see this, consider the preparation of xenon tetrafluoride, which was the first binary compound made from a noble gas:

$$
\mathrm{Xe}(g)+2 \mathrm{~F}_{2}(g) \longrightarrow \mathrm{XeF}_{4}(s) \quad \Delta H=-251 \mathrm{~kJ}
$$

This reaction is exothermic, and 251 kJ of energy flows into the surroundings as heat. On the other hand, if the colorless $\mathrm{XeF}_{4}$ crystals are decomposed into the elements, according to the equation

$$
\mathrm{XeF}_{4}(s) \longrightarrow \mathrm{Xe}(g)+2 \mathrm{~F}_{2}(g)
$$

the opposite energy flow occurs because 251 kJ of energy must be added to the system to produce this endothermic reaction. Thus, for this reaction, $\Delta H=+251 \mathrm{~kJ}$.

The second rule comes from the fact that $\Delta H$ is an extensive property, depending on the amount of substances reacting. For example, since 251 kJ of energy is evolved for the reaction

$$
\mathrm{Xe}(g)+2 \mathrm{~F}_{2}(g) \longrightarrow \mathrm{XeF}_{4}(s)
$$

then for a preparation involving twice the quantities of reactants and products, or

$$
2 \mathrm{Xe}(g)+4 \mathrm{~F}_{2}(g) \longrightarrow 2 \mathrm{XeF}_{4}(s)
$$

twice as much heat would be evolved:

$$
\Delta H=2(-251 \mathrm{~kJ})=-502 \mathrm{~kJ}
$$

##  some possible repercussions this would have?

## INTERACTIVE EXAMPLE 6.7 Hess's Law I

Two forms of carbon are graphite, the soft, black, slippery material used in "lead" pencils and as a lubricant for locks, and diamond, the brilliant, hard gemstone. Using the enthalpies of combustion for graphite ( $-394 \mathrm{~kJ} / \mathrm{mol}$ ) and diamond ( $-396 \mathrm{~kJ} / \mathrm{mol}$ ), calculate $\Delta H$ for the conversion of graphite to diamond:

$$
\mathrm{C}_{\text {graphite }}(s) \longrightarrow \mathrm{C}_{\text {diamond }}(s)
$$

## SOLUTION Where are we going?

To calculate $\Delta H$ for the conversion of graphite to diamond

## What do we know?

The combustion reactions are

$$
\begin{array}{lll}
> & \mathrm{C}_{\text {graphite }}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta H=-394 \mathrm{~kJ} \\
> & \mathrm{C}_{\text {diamond }}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta H=-396 \mathrm{~kJ}
\end{array}
$$

How do we get there?
How do we combine the combustion equations to obtain the equation for the conversion of graphite to diamond?
Note that if we reverse the second reaction (which means we must change the sign of $\Delta H)$ and sum the two reactions, we obtain the desired reaction:

$$
\begin{aligned}
\mathrm{C}_{\text {graphite }}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta H=-394 \mathrm{~kJ} \\
\mathrm{CO}_{2}(g) \longrightarrow \mathrm{C}_{\text {diamond }}(s)+\mathrm{O}_{2}(g) & \Delta H=-(-396 \mathrm{~kJ}) \\
\hline \mathrm{C}_{\text {graphite }}(s) \longrightarrow \mathrm{C}_{\text {diamond }}(s) & \Delta H=2 \mathrm{~kJ}
\end{aligned}
$$

$\square$ The $\Delta H$ for the conversion of graphite to diamond is

$$
\Delta H=2 \mathrm{~kJ} / \mathrm{mol} \text { graphite }
$$

We obtain this value by summing the $\Delta H$ values for the equations as shown above. This process is endothermic since the sign of $\Delta H$ is positive.

## INTERACTIVE EXAMPLE 6.8

## Hess's Law II

Diborane $\left(\mathrm{B}_{2} \mathrm{H}_{6}\right)$ is a highly reactive boron hydride that was once considered as a possible rocket fuel for the U.S. space program. Calculate $\Delta H$ for the synthesis of diborane from its elements, according to the equation

$$
2 \mathrm{~B}(s)+3 \mathrm{H}_{2}(g) \longrightarrow \mathrm{B}_{2} \mathrm{H}_{6}(g)
$$

using the following data:

## Reaction $\Delta H$

(a) $2 \mathrm{~B}(s)++\frac{3}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{B}_{2} \mathrm{O}_{3}(s) \quad-1273 \mathrm{~kJ}$
(b) $\mathrm{B}_{2} \mathrm{H}_{6}(g)+3 \mathrm{O}_{2}(g) \longrightarrow \mathrm{B}_{2} \mathrm{O}_{3}(s)+3 \mathrm{H}_{2} \mathrm{O}(g) \quad-2035 \mathrm{~kJ}$
(c) $\mathrm{H}_{2}(g)++\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad-286 \mathrm{~kJ}$
(d) $\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g) \quad 44 \mathrm{~kJ}$

SOLUTION To obtain $\Delta H$ for the required reaction, we must somehow combine equations (a), (b), (c), and (d) to produce that reaction and add the corresponding $\Delta H$ values. This can best be done by focusing on the reactants and products of the required reaction. The reactants are $\mathrm{B}(s)$ and $\mathrm{H}_{2}(g)$, and the product is $\mathrm{B}_{2} \mathrm{H}_{6}(g)$. How can we obtain the correct equation? Reaction (a) has $\mathrm{B}(s)$ as a reactant, as needed in the required equation. Thus reaction (a) will be used as it is. Reaction (b) has $\mathrm{B}_{2} \mathrm{H}_{6}(g)$ as a reactant, but this
substance is needed as a product. Thus reaction (b) must be reversed, and the sign of $\Delta H$ must be changed accordingly. Up to this point we have

$$
\left.\begin{array}{cll}
\text { (a) } & 2 \mathrm{~B}(s)+\frac{3}{2} \mathrm{O}_{2}(g) & \longrightarrow \mathrm{B}_{2} \mathrm{O}_{3}(s) \\
-(\mathrm{b}) & B_{2} \mathrm{O}_{3}(s)+3 \mathrm{H}_{2} \mathrm{O}(g) & \longrightarrow \mathrm{B}_{2} \mathrm{H}_{6}(g)+3 \mathrm{O}_{2}(g)
\end{array}\right) \Delta H=-1273 \mathrm{~kJ},(-2035 \mathrm{~kJ}) .
$$

Deleting the species that occur on both sides gives

$$
2 \mathrm{~B}(s)+3 \mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{B}_{2} \mathrm{H}_{6}(g)+\frac{3}{2} \mathrm{O}_{2}(g) \quad \Delta H=762 \mathrm{~kJ}
$$

We are closer to the required reaction, but we still need to remove $\mathrm{H}_{2} \mathrm{O}(g)$ and $\mathrm{O}_{2}(g)$ and introduce $\mathrm{H}_{2}(g)$ as a reactant. We can do this using reactions (c) and (d). If we multiply reaction (c) and its $\Delta H$ value by 3 and add the result to the preceding equation, we have

| $2 \mathrm{~B}(s)+3 \mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{B}_{2} \mathrm{H}_{6}(g)+\frac{3}{2} \mathrm{O}_{2}(g)$ | $\Delta H=762 \mathrm{~kJ}$ |
| :--- | :--- |
| $3\left[\mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)\right]$ | $\Delta H=3(-286 \mathrm{~kJ})$ |
| Sum: $2 \mathrm{~B}(s)+3 \mathrm{H}_{2}(g)+\frac{3}{2} \mathrm{O}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{B}_{2} \mathrm{H}_{6}(g)+\frac{3}{2} \mathrm{O}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(l)$ | $\Delta H=-96 \mathrm{~kJ}$ |

We can cancel the $\frac{3}{2} \mathrm{O}_{2}(g)$ on both sides, but we cannot cancel the $\mathrm{H}_{2} \mathrm{O}$ because it is gaseous on one side and liquid on the other. This can be solved by adding reaction (d), multiplied by 3 :

$$
\begin{aligned}
& 2 \mathrm{~B}(s)+3 \mathrm{H}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{B}_{2} \mathrm{H}_{6}(g)+3 \mathrm{H}_{2} \mathrm{O}(l) \Delta H=-96 \mathrm{~kJ} \\
& 3\left[\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g)\right] \Delta H=3(44 \mathrm{~kJ}) \\
& \hline 3 \times(\mathrm{d}) \mathrm{B}_{2} \mathrm{H}_{6}(g)+3 \mathrm{H}_{2} \mathrm{O}(l)+3 \mathrm{H}_{2} \mathrm{O}(g) \\
& \hline 2 \mathrm{~B}(\mathrm{~s})+3 \mathrm{H}_{2}(\mathrm{~g})+3 \mathrm{H}_{2} \mathrm{O}(g)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow+36 \mathrm{~kJ}
\end{aligned}
$$

This gives the reaction required by the problem:

$$
2 \mathrm{~B}(s)+3 \mathrm{H}_{2}(g) \longrightarrow \mathrm{B}_{2} \mathrm{H}_{6}(g) \quad \Delta H=+36 \mathrm{~kJ}
$$

$\square$ Thus $\Delta H$ for the synthesis of 1 mole of diborane from the elements is +36 kJ .

## See Exercises 6.77 through 6.82

## PROBLEM-SOLVING STRATEGY

## Hess's Law

Calculations involving Hess's law typically require that several reactions be manipulated and combined to finally give the reaction of interest. In doing this procedure you should
" Work backward from the required reaction, using the reactants and products to decide how to manipulate the other given reactions at your disposal
" Reverse any reactions as needed to give the required reactants and products
» Multiply reactions to give the correct numbers of reactants and products
This process involves some trial and error, but it can be very systematic if you always allow the final reaction to guide you.

### 6.4 Standard Enthalpies of Formation

For a reaction studied under conditions of constant pressure, we can obtain the enthalpy change using a calorimeter. However, this process can be very difficult. In fact, in some cases it is impossible, since certain reactions do not lend themselves to such

The International Union of Pure and Applied Chemists (IUPAC) has adopted 1 bar ( $100,000 \mathrm{~Pa}$ ) as the standard pressure instead of 1 atm (101,305 Pa). Both standards are now in wide use.

Standard state is not the same as the standard temperature and pressure (STP) for a gas (discussed in Section 5.4).

Brown nitrogen dioxide gas.
study. An example is the conversion of solid carbon from its graphite form to its diamond form:

$$
\mathrm{C}_{\text {graphite }}(s) \longrightarrow \mathrm{C}_{\text {diamond }}(s)
$$

The value of $\Delta H$ for this process cannot be obtained by direct measurement in a calorimeter because the process is much too slow under normal conditions. However, as we saw in Example 6.7, $\Delta H$ for this process can be calculated from heats of combustion. This is only one example of how useful it is to be able to calculate $\Delta H$ values for chemical reactions. We will next show how to do this using standard enthalpies of formation.

The standard enthalpy of formation $\left(\Delta H_{\mathrm{f}}^{\circ}\right)$ of a compound is defined as the change in enthalpy that accompanies the formation of 1 mole of a compound from its elements with all substances in their standard states.

A degree symbol on a thermodynamic function, for example, $\Delta H^{\circ}$, indicates that the corresponding process has been carried out under standard conditions. The standard state for a substance is a precisely defined reference state. Because thermodynamic functions often depend on the concentrations (or pressures) of the substances involved, we must use a common reference state to properly compare the thermodynamic properties of two substances. This is especially important because, for most thermodynamic properties, we can measure only changes in the property. For example, we have no method for determining absolute values of enthalpy. We can measure enthalpy changes ( $\Delta H$ values) only by performing heat-flow experiments.

## Conventional Definitions of Standard States

## For a Compound

\# The standard state of a gaseous substance is a pressure of exactly 1 atmosphere.
") For a pure substance in a condensed state (liquid or solid), the standard state is the pure liquid or solid.
» For a substance present in a solution, the standard state is a concentration of exactly 1 M .

## For an Element

» The standard state of an element is the form in which the element exists under conditions of 1 atmosphere and $25^{\circ} \mathrm{C}$. (The standard state for oxygen is $\mathrm{O}_{2}(\mathrm{~g})$ at a pressure of 1 atmosphere; the standard state for sodium is $\mathrm{Na}(\mathrm{s})$; the standard state for mercury is $\mathrm{Hg}(\mathrm{l}$; and so on.)

Several important characteristics of the definition of the enthalpy of formation will become clearer if we again consider the formation of nitrogen dioxide from the elements in their standard states:

$$
\frac{1}{2} \mathrm{~N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{NO}_{2}(g) \quad \Delta H_{\mathrm{f}}^{\circ}=34 \mathrm{~kJ} / \mathrm{mol}
$$

Note that the reaction is written so that both elements are in their standard states, and 1 mole of product is formed. Enthalpies of formation are always given per mole of product with the product in its standard state.

The formation reaction for methanol is written as

$$
\mathrm{C}(s)+2 \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(l) \quad \Delta H_{\mathrm{f}}^{\circ}=-239 \mathrm{~kJ} / \mathrm{mol}
$$

The standard state of carbon is graphite, the standard states for oxygen and hydrogen are the diatomic gases, and the standard state for methanol is the liquid.

TABLE 6.2 \| Standard Enthalpies of Formation for Several Compounds at $25^{\circ} \mathrm{C}$

| Compound | $\Delta H_{f}^{\circ}(\mathrm{kJ} / \mathrm{mol})$ |
| :--- | ---: |
| $\mathrm{NH}_{3}(\mathrm{~g})$ | -46 |
| $\mathrm{NO}_{2}(\mathrm{~g})$ | 34 |
| $\mathrm{H}_{2} \mathrm{O}(l)$ | -286 |
| $\mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{~s})$ | -1676 |
| $\mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})$ | -826 |
| $\mathrm{CO}_{2}(g)$ | -394 |
| $\mathrm{CH}_{3} \mathrm{OH}(I)$ | -239 |
| $\mathrm{C}_{8} \mathrm{H}_{18}(l)$ | -269 |

FIGURE 6.9 In this pathway for the combustion of methane, the reactants are first taken apart in reactions (a) and (b) to form the constituent elements in their standard states, which are then used to assemble the products in reactions (c) and (d).

The $\Delta H_{\mathrm{f}}^{\circ}$ values for some common substances are shown in Table 6.2. More values are found in Appendix 4. The importance of the tabulated $\Delta H_{\mathrm{f}}^{\circ}$ values is that enthalpies for many reactions can be calculated using these numbers. To see how this is done, we will calculate the standard enthalpy change for the combustion of methane:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Enthalpy is a state function, so we can invoke Hess's law and choose any convenient pathway from reactants to products and then sum the enthalpy changes along the chosen pathway. A convenient pathway, shown in Fig. 6.9, involves taking the reactants apart to the respective elements in their standard states in reactions (a) and (b) and then forming the products from these elements in reactions (c) and (d). This general pathway will work for any reaction, since atoms are conserved in a chemical reaction.

Note from Fig. 6.9 that reaction (a), where methane is taken apart into its elements,

$$
\mathrm{CH}_{4}(\mathrm{~g}) \longrightarrow \mathrm{C}(s)+2 \mathrm{H}_{2}(g)
$$

is just the reverse of the formation reaction for methane:

$$
\mathrm{C}(s)+2 \mathrm{H}_{2}(g) \longrightarrow \mathrm{CH}_{4}(g) \quad \Delta H_{\mathrm{f}}^{\circ}=-75 \mathrm{~kJ} / \mathrm{mol}
$$

Since reversing a reaction means changing the sign of $\Delta H$ but keeping the magnitude the same, $\Delta H$ for reaction (a) is $-\Delta H_{\mathrm{f}}^{\circ}$, or 75 kJ . Thus $\Delta H_{(\mathrm{a})}^{\circ}=75 \mathrm{~kJ}$.

Next we consider reaction (b). Here oxygen is already an element in its standard state, so no change is needed. Thus $\Delta H_{(\mathrm{b})}^{\circ}=0$.

The next steps, reactions (c) and (d), use the elements formed in reactions (a) and (b) to form the products. Note that reaction (c) is simply the formation reaction for carbon dioxide:

$$
\mathrm{C}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) \quad \Delta H_{\mathrm{f}}^{\circ}=-394 \mathrm{~kJ} / \mathrm{mol}
$$

and

$$
\Delta H_{(\mathrm{c})}^{\circ}=\Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{CO}_{2}(g)=-394 \mathrm{~kJ}
$$

Reaction (d) is the formation reaction for water:

$$
\mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H_{\mathrm{f}}^{\circ}=-286 \mathrm{~kJ} / \mathrm{mol}
$$

However, since 2 moles of water are required in the balanced equation, we must form 2 moles of water from the elements:

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

## Reactants

FIGURE 6.10 A schematic diagram of the energy changes for the reaction $\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$.

Subtraction means to reverse the sign and add.

Elements in their standard states are not included in enthalpy calculations using $\Delta H_{\mathrm{f}}^{\circ}$ values.

Thus

$$
\Delta H_{(\mathrm{d})}^{\circ}=2 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{H}_{2} \mathrm{O}(l)=2(-286 \mathrm{~kJ})=-572 \mathrm{~kJ}
$$

We have now completed the pathway from the reactants to the products. The change in enthalpy for the reaction is the sum of the $\Delta H$ values (including their signs) for the steps:
$\Delta H^{\circ}{ }_{\text {reaction }}$

$$
\begin{aligned}
& =\Delta H_{(\mathrm{a})}^{\circ}+\Delta H_{(\mathrm{b})}^{\circ}+\Delta H_{(\mathrm{c})}^{\circ}+\Delta H_{(\mathrm{d})}^{\circ} \\
& =\left[-\Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{CH}_{4}(g)\right]+0+\left[\Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{CO}_{2}(g)\right]+\left[2 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{H}_{2} \mathrm{O}(l)\right] \\
& =-(-75 \mathrm{~kJ})+0+(-394 \mathrm{~kJ})+(-572 \mathrm{~kJ}) \\
& =-891 \mathrm{~kJ}
\end{aligned}
$$

This process is diagramed in Fig. 6.10. Notice that the reactants are taken apart and converted to elements [not necessary for $\mathrm{O}_{2}(g)$ ] that are then used to form products. You can see that this is a very exothermic reaction because very little energy is required to convert the reactants to the respective elements but a great deal of energy is released when these elements form the products. This is why this reaction is so useful for producing heat to warm homes and offices.

Let's examine carefully the pathway we used in this example. First, the reactants were broken down into the elements in their standard states. This process involved reversing the formation reactions and thus switching the signs of the enthalpies of formation. The products were then constructed from these elements. This involved formation reactions and thus enthalpies of formation. We can summarize this entire process as follows: The enthalpy change for a given reaction can be calculated by subtracting the enthalpies of formation of the reactants from the enthalpies of formation of the products. Remember to multiply the enthalpies of formation by integers as required by the balanced equation. This statement can be represented symbolically as follows:

$$
\begin{equation*}
\Delta H_{\text {reaction }}^{\circ}=\Sigma n_{\mathrm{p}} \Delta H_{\mathrm{f}}^{\circ}(\text { products })-\Sigma n_{\mathrm{r}} \Delta H_{\mathrm{f}}^{\circ}(\text { reactants }) \tag{6.1}
\end{equation*}
$$

where the symbol $\Sigma$ (sigma) means "to take the sum of the terms," and $n_{\mathrm{p}}$ and $n_{\mathrm{r}}$ represent the moles of each product or reactant, respectively.

Elements are not included in the calculation because elements require no change in form. We have in effect defined the enthalpy of formation of an element in its standard state as zero, since we have chosen this as our reference point for calculating enthalpy changes in reactions.

## PROBLEM-SOLVING STRATEGY

## Enthalpy Calculations

" When a reaction is reversed, the magnitude of $\Delta H$ remains the same, but its sign changes.
" When the balanced equation for a reaction is multiplied by an integer, the value of $\Delta H$ for that reaction must be multiplied by the same integer.
") The change in enthalpy for a given reaction can be calculated from the enthalpies of formation of the reactants and products:

$$
\Delta H_{\text {reaction }}^{\circ}=\Sigma n_{\mathrm{p}} \Delta H_{\mathrm{f}}^{\circ}(\text { products })-\Sigma n_{\mathrm{r}} \Delta H_{\mathrm{f}}^{\circ}(\text { reactants })
$$

» Elements in their standard states are not included in the $\Delta H_{\text {reaction }}$ calculations. That is, $\Delta H_{\mathrm{f}}^{\circ}$ for an element in its standard state is zero.

## INTERACTIVE EXAMPLE 6.9

## SOLUTION

## Enthalpies from Standard Enthalpies of Formation I

Using the standard enthalpies of formation listed in Table 6.2, calculate the standard enthalpy change for the overall reaction that occurs when ammonia is burned in air to form nitrogen dioxide and water. This is the first step in the manufacture of nitric acid.

$$
4 \mathrm{NH}_{3}(g)+7 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)
$$

We will use the pathway in which the reactants are broken down into elements in their standard states, which are then used to form the products (Fig. 6.11).
> Decomposition of $\mathrm{NH}_{3}(\mathrm{~g})$ into elements [reaction (a) in Fig. 6.11]. The first step is to decompose 4 moles of $\mathrm{NH}_{3}$ into $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ :

$$
4 \mathrm{NH}_{3}(g) \longrightarrow 2 \mathrm{~N}_{2}(g)+6 \mathrm{H}_{2}(g)
$$

The preceding reaction is 4 times the reverse of the formation reaction for $\mathrm{NH}_{3}$ :

$$
\frac{1}{2} \mathrm{~N}_{2}(g)+\frac{3}{2} \mathrm{H}_{2}(g) \longrightarrow \mathrm{NH}_{3}(g) \quad \Delta H_{\mathrm{f}}^{\circ}=-46 \mathrm{~kJ} / \mathrm{mol}
$$

Thus

FIGURE 6.11 A pathway for the combustion of ammonia.

$$
\Delta H^{\circ}{ }_{(\mathrm{a})}=4 \mathrm{~mol}[-(-46 \mathrm{~kJ} / \mathrm{mol})]=184 \mathrm{~kJ}
$$

> Elemental oxygen [reaction (b) in Fig. 6.11]. Since $\mathrm{O}_{2}(g)$ is an element in its standard state, $\Delta H^{\circ}{ }_{(\mathrm{b})}=0$.

We now have the elements $\mathrm{N}_{2}(g), \mathrm{H}_{2}(g)$, and $\mathrm{O}_{2}(g)$, which can be combined to form the products of the overall reaction.
> Synthesis of $\mathrm{NO}_{2}(\mathrm{~g})$ from elements [reaction (c) in Fig. 6.11]. The overall reaction equation has 4 moles of $\mathrm{NO}_{2}$. Thus the required reaction is 4 times the formation reaction for $\mathrm{NO}_{2}$ :

$$
4 \times\left[\frac{1}{2} \mathrm{~N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{NO}_{2}(g)\right]
$$

and

$$
\Delta H^{\circ}{ }_{(\mathrm{c})}=4 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{NO}_{2}(g)
$$

From Table 6.2, $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{NO}_{2}(g)=34 \mathrm{~kJ} / \mathrm{mol}$ and

$$
\Delta H_{(\mathrm{c})}^{\circ}=4 \mathrm{~mol} \times 34 \mathrm{~kJ} / \mathrm{mol}=136 \mathrm{~kJ}
$$

》 Synthesis of $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ from elements [reaction (d) in Fig. 6.11]. Since the overall equation for the reaction has 6 moles of $\mathrm{H}_{2} \mathrm{O}(l)$, the required reaction is 6 times the formation reaction for $\mathrm{H}_{2} \mathrm{O}(l)$ :

$$
6 \times\left[\mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)\right]
$$

and

$$
\Delta H_{(\mathrm{d})}^{\circ}=6 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{H}_{2} \mathrm{O}(l)
$$

From Table 6.2, $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{H}_{2} \mathrm{O}(l)=-286 \mathrm{~kJ} / \mathrm{mol}$ and

$$
\Delta H_{(\mathrm{d})}^{\circ}=6 \mathrm{~mol}(-286 \mathrm{~kJ} / \mathrm{mol})=-1716 \mathrm{~kJ}
$$

To summarize, we have done the following:

We add the $\Delta H^{\circ}$ values for the steps to get $\Delta H^{\circ}$ for the overall reaction:

$$
\begin{aligned}
\Delta H_{\text {reaction }}^{\circ}= & \Delta H_{(\mathrm{a})}^{\circ}+\Delta H_{(\mathrm{b})}^{\circ}+\Delta H_{(\mathrm{c})}^{\circ}+\Delta H_{(\mathrm{d})}^{\circ} \\
= & {\left[4 \times-\Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{NH}_{3}(\mathrm{~g})\right]+0+\left[4 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{NO}_{2}(g)\right] } \\
& \quad+\left[6 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{H}_{2} \mathrm{O}(l)\right] \\
= & {\left[4 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{NO}_{2}(g)\right]+\left[6 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{H}_{2} \mathrm{O}(l)\right] } \\
& \quad-\left[4 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{NH}_{3}(g)\right] \\
= & \Sigma n_{\mathrm{p}} \Delta H_{\mathrm{f}}^{\circ}(\text { products })-\Sigma n_{\mathrm{r}} \Delta H_{\mathrm{f}}^{\circ}(\text { reactants })
\end{aligned}
$$

Remember that elemental reactants and products do not need to be included, since $\Delta H_{\mathrm{f}}^{\circ}$ for an element in its standard state is zero. Note that we have again obtained Equation (6.1). The final solution is

$$
\begin{aligned}
\square \Delta H_{\text {reaction }}^{\circ} & =[4 \times(34 \mathrm{~kJ})]+[6 \times(-286 \mathrm{~kJ})]-[4 \times(-46 \mathrm{~kJ})] \\
& =-1396 \mathrm{~kJ}
\end{aligned}
$$

## See Exercises 6.85 and 6.86

Now that we have shown the basis for Equation (6.1), we will make direct use of it to calculate $\Delta H$ for reactions in succeeding exercises.

## INTERACTIVE EXAMPLE 6.10 Enthalpies from Standard Enthalpies of Formation II

Using enthalpies of formation, calculate the standard change in enthalpy for the thermite reaction:

$$
2 \mathrm{Al}(s)+\mathrm{Fe}_{2} \mathrm{O}_{3}(s) \longrightarrow \mathrm{Al}_{2} \mathrm{O}_{3}(s)+2 \mathrm{Fe}(s)
$$

This reaction occurs when a mixture of powdered aluminum and iron(III) oxide is ignited with a magnesium fuse.

## SOLUTION

## Where are we going?

To calculate $\Delta H$ for the reaction
What do we know?
》 $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{Fe}_{2} \mathrm{O}_{3}(s)=-826 \mathrm{~kJ} / \mathrm{mol}$
> $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{Al}_{2} \mathrm{O}_{3}(s)=-1676 \mathrm{~kJ} / \mathrm{mol}$
> $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{Al}(s)=\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{Fe}(s)=0$
What do we need?
> We use Equation (6.1):

$$
\Delta H^{\circ}=\Sigma n_{\mathrm{p}} \Delta H_{\mathrm{f}}^{\circ}(\text { products })-\Sigma n_{\mathrm{r}} \Delta H_{\mathrm{f}}^{\circ}(\text { reactants })
$$

## How do we get there?

$$
\begin{aligned}
\Delta H_{\text {reaction }}^{\circ} & =\Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{Al}_{2} \mathrm{O}_{3}(s)-\Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{Fe}_{2} \mathrm{O}_{3}(s) \\
& =-1676 \mathrm{~kJ}-(-826 \mathrm{~kJ})=-850 . \mathrm{kJ}
\end{aligned}
$$

This reaction is so highly exothermic that the iron produced is initially molten. This process is often used as a lecture demonstration and also has been used in welding massive steel objects such as ships' propellers.

## See Exercises 6.89 and 6.90

The thermite reaction is one of the most energetic chemical reactions known.

## EXAMPLE 6.11

## SOLUTION

## Enthalpies from Standard Enthalpies of Formation III

Until recently, methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ was used as a fuel in high-performance engines in race cars. Using the data in Table 6.2, compare the standard enthalpy of combustion per gram of methanol with that per gram of gasoline. Gasoline is actually a mixture of compounds, but assume for this problem that gasoline is pure liquid octane $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$.

## Where are we going?

To compare $\Delta H$ of combustion for methanol and octane
What do we know?
> Standard enthalpies of formation from Table 6.2

In the cars used in the Indianapolis 500, ethanol is now used instead of methanol.

## How do we get there?

For methanol:
What is the combustion reaction?

$$
2 \mathrm{CH}_{3} \mathrm{OH}(l)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

What is the $\Delta H^{\circ}{ }_{\text {reaction }}$ ?
Using the standard enthalpies of formation from Table 6.2 and Equation (6.1), we have

$$
\begin{aligned}
\Delta H_{\text {reaction }}^{\circ}= & 2 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{CO}_{2}(g)+4 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{H}_{2} \mathrm{O}(l) \\
& \quad-2 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{CH}_{3} \mathrm{OH}(l) \\
= & 2 \times(-394 \mathrm{~kJ})+4 \times(-286 \mathrm{~kJ})-2 \times(-239 \mathrm{~kJ}) \\
= & -1.45 \times 10^{3} \mathrm{~kJ}
\end{aligned}
$$

What is the enthalpy of combustion per gram?
Thus $1.45 \times 10^{3} \mathrm{~kJ}$ of heat is evolved when 2 moles of methanol burn. The molar mass of methanol is $32.04 \mathrm{~g} / \mathrm{mol}$. This means that $1.45 \times 10^{3} \mathrm{~kJ}$ of energy is produced when 64.08 g methanol burns. The enthalpy of combustion per gram of methanol is

$$
\frac{-1.45 \times 10^{3} \mathrm{~kJ}}{64.08 \mathrm{~g}}=-22.6 \mathrm{~kJ} / \mathrm{g}
$$

For octane:
What is the combustion reaction?

$$
2 \mathrm{C}_{8} \mathrm{H}_{18}(l)+25 \mathrm{O}_{2}(g) \longrightarrow 16 \mathrm{CO}_{2}(g)+18 \mathrm{H}_{2} \mathrm{O}(l)
$$

What is the $\Delta H^{\circ}{ }_{\text {reaction }}$ ?
Using the standard enthalpies of formation from Table 6.2 and Equation (6.1), we have

$$
\begin{aligned}
\Delta H_{\text {reaction }}^{\circ}= & 16 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{CO}_{2}(g)+18 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{H}_{2} \mathrm{O}(l) \\
& \quad-2 \times \Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{C}_{8} \mathrm{H}_{18}(l) \\
= & 16 \times(-394 \mathrm{~kJ})+18 \times(-286 \mathrm{~kJ})-2 \times(-269 \mathrm{~kJ}) \\
= & -1.09 \times 10^{4} \mathrm{~kJ}
\end{aligned}
$$

What is the enthalpy of combustion per gram?
This is the amount of heat evolved when 2 moles of octane burn. Since the molar mass of octane is $114.22 \mathrm{~g} / \mathrm{mol}$, the enthalpy of combustion per gram of octane is

$$
\frac{-1.09 \times 10^{4} \mathrm{~kJ}}{2(114.22 \mathrm{~g})}=-47.7 \mathrm{~kJ} / \mathrm{g}
$$

- The enthalpy of combustion per gram of octane is approximately twice that per gram of methanol. On this basis, gasoline appears to be superior to methanol for use in a racing car, where weight considerations are usually very important. Why, then, was methanol used in racing cars? The answer is that methanol burns much more smoothly than gasoline in high-performance engines, and this advantage more than compensates for its weight disadvantage.

### 6.5 Present Sources of Energy

Woody plants, coal, petroleum, and natural gas hold a vast amount of energy that originally came from the sun. By the process of photosynthesis, plants store energy that can be claimed by burning the plants themselves or the decay products that have been

FIGURE 6.12 Energy sources used in the United States.

TABLE 6.3 | Names and Formulas for Some Common Hydrocarbons

A
Oil rig in Gulf of Mexico.
converted over millions of years to fossil fuels. Although the United States currently depends heavily on petroleum for energy, this dependency is a relatively recent phenomenon, as shown in Fig. 6.12. In this section we will discuss some sources of energy and their effects on the environment.

## Petroleum and Natural Gas

Although how they were produced is not completely understood, petroleum and natural gas were most likely formed from the remains of marine organisms that lived approximately 500 million years ago. Petroleum is a thick, dark liquid composed mostly of compounds called hydrocarbons that contain carbon and hydrogen. (Carbon is unique among elements in the extent to which it can bond to itself to form chains of various lengths.) Table 6.3 gives the formulas and names for several common hydrocarbons. Natural gas, usually associated with petroleum deposits, consists mostly of methane, but it also contains significant amounts of ethane, propane, and butane. Over the last several years it has become clear that there are tremendous reserves of natural gas deep in shale deposits. Estimates indicate that there may be as much as 200 trillion cubic meters of recoverable natural gas in these deposits around the globe. In the eastern United States, the 1-mile-deep Marsellus Shale deposit may contain as much as two trillion cubic meters of recoverable gas. The problem with these gas deposits is that the shale is very impermeable, and the gas does not flow out into wells on its own. A technique called hydraulic fracturing, or "fracking," is now being used to access these gas deposits. Fracking involves injecting a slurry of water, sand, and chemical additives under pressure through a well bore drilled into the shale. This produces fractures in the rock that allow the gas to flow out into wells. With the increased use of fracking has come environmental concerns, including potential contamination of ground water, risks to air quality, and possible mishandling of wastes associated with the process. However, even in view of these potential hazards, it is expected that natural gas obtained from fracking may supply as much as half of the U.S. natural gas supply by the year 2020 .

The composition of petroleum varies somewhat, but it consists mostly of hydrocarbons having chains that contain from 5 to more than 25 carbons. To be used efficiently, the petroleum must be separated into fractions by boiling. The lighter molecules (having the lowest boiling points) can be boiled off, leaving the heavier ones behind. The commercial uses of various petroleum fractions are shown in Table 6.4.

The petroleum era began when the demand for lamp oil during the Industrial Revolution outstripped the traditional sources: animal fats and whale oil. In response to this increased demand, Edwin Drake drilled the first oil well in 1859 at Titusville, Pennsylvania. The petroleum from this well was refined to produce kerosene (fraction $\mathrm{C}_{10}-\mathrm{C}_{18}$ ),

## TABLE 6.4 \| Uses of the Various Petroleum Fractions

| Petroleum <br> Fraction in Terms <br> of Numbers of <br> Carbon Atoms | Major Uses |
| :---: | :--- |
| $\mathrm{C}_{5}-\mathrm{C}_{10}$ | Gasoline |
| $\mathrm{C}_{10}-\mathrm{C}_{18}$ | Kerosene <br> Jet fuel |
| $\mathrm{C}_{15}-\mathrm{C}_{25}$ | Diesel fuel <br> Heating oil <br> Lubricating oil |
| $>\mathrm{C}_{25}$ | Asphalt |

[^10]which served as an excellent lamp oil. Gasoline (fraction $\mathrm{C}_{5}-\mathrm{C}_{10}$ ) had limited use and was often discarded. However, this situation soon changed. The development of the electric light decreased the need for kerosene, and the advent of the "horseless carriage" with its gasoline-powered engine signaled the birth of the gasoline age.

As gasoline became more important, new ways were sought to increase the yield of gasoline obtained from each barrel of petroleum. William Burton invented a process at Standard Oil of Indiana called pyrolytic (high-temperature) cracking. In this process, the heavier molecules of the kerosene fraction are heated to about $700^{\circ} \mathrm{C}$, causing them to break (crack) into the smaller molecules of hydrocarbons in the gasoline fraction. As cars became larger, more efficient internal combustion engines were designed. Because of the uneven burning of the gasoline then available, these engines "knocked," producing unwanted noise and even engine damage. Intensive research to find additives that would promote smoother burning produced tetraethyl lead, $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{~Pb}$, a very effective "antiknock" agent.

The addition of tetraethyl lead to gasoline became a common practice, and by 1960, gasoline contained as much as 3 grams of lead per gallon. As we have discovered so often in recent years, technological advances can produce environmental problems. To prevent air pollution from automobile exhaust, catalytic converters have been added to car exhaust systems. The effectiveness of these converters, however, is destroyed by lead. The use of leaded gasoline also greatly increased the amount of lead in the environment, where it can be ingested by animals and humans. For these reasons, the use of lead in gasoline has been phased out, requiring extensive (and expensive) modifications of engines and of the gasoline refining process.

## Coal

Coal was formed from the remains of plants that were buried and subjected to high pressure and heat over long periods of time. Plant materials have a high content of cellulose, a complex molecule whose empirical formula is $\mathrm{CH}_{2} \mathrm{O}$ but whose molar mass is around $500,000 \mathrm{~g} / \mathrm{mol}$. After the plants and trees that flourished on the earth at various times and places died and were buried, chemical changes gradually lowered the oxygen and hydrogen content of the cellulose molecules. Coal "matures" through four stages: lignite, subbituminous, bituminous, and anthracite. Each stage has a higher carbon-to-oxygen and carbon-to-hydrogen ratio; that is, the relative carbon content gradually increases. Typical elemental compositions of the various coals are given in Table 6.5. The energy available from the combustion of a given mass of coal increases as the carbon content increases. Therefore, anthracite is the most valuable coal and lignite the least valuable.

Coal is an important and plentiful fuel in the United States, currently furnishing approximately $23 \%$ of our energy. As the supply of petroleum dwindles, the share of the energy supply from coal is expected to increase. However, coal is expensive and dangerous to mine underground, and the strip mining of fertile farmland in the Midwest or of scenic land in the West causes obvious problems. In addition, the burning of coal, especially high-sulfur coal, yields air pollutants such as sulfur dioxide, which, in

## TABLE 6.5 | Elemental Composition of Various Types of Coal

|  | Mass Percent of Fach Element |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Type of Coal | C | H | 0 | N | S |
| Lignite | 71 | 4 | 23 | 1 | 1 |
| Subbituminous | 77 | 5 | 16 | 1 | 1 |
| Bituminous | 80 | 6 | 8 | 1 | 5 |
| Anthracite | 92 | 3 | 3 | 1 | 1 |

The electromagnetic spectrum, including visible and infrared radiation, is discussed in Chapter 7.

FIGURE 6. 13 The earth's atmosphere is transparent to visible light from the sun. This visible light strikes the earth, and part of it is changed to infrared radiation. The infrared radiation from the earth's surface is strongly absorbed by $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and other molecules present in smaller amounts (for example, $\mathrm{CH}_{4}$ and $\mathrm{N}_{2} \mathrm{O}$ ) in the atmosphere. In effect, the atmosphere traps some of the energy, acting like the glass in a greenhouse and keeping the earth warmer than it would otherwise be.

The average temperature of the earth's surface is 298 K . It would be 255 K without the "greenhouse gases."
turn, can lead to acid rain, as we learned in Chapter 5. However, even if coal were pure carbon, the carbon dioxide produced when it was burned would still have significant effects on the earth's climate.

## Effects of Carbon Dioxide on Climate

The earth receives a tremendous quantity of radiant energy from the sun, about $30 \%$ of which is reflected back into space by the earth's atmosphere. The remaining energy passes through the atmosphere to the earth's surface. Some of this energy is absorbed by plants for photosynthesis and some by the oceans to evaporate water, but most of it is absorbed by soil, rocks, and water, increasing the temperature of the earth's surface. This energy is in turn radiated from the heated surface mainly as infrared radiation, often called heat radiation.

The atmosphere, like window glass, is transparent to visible light but does not allow all the infrared radiation to pass back into space. Molecules in the atmosphere, principally $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$, strongly absorb infrared radiation and radiate it back toward the earth (Fig. 6.13), so a net amount of thermal energy is retained by the earth's atmosphere, causing the earth to be much warmer than it would be without its atmosphere. In a way, the atmosphere acts like the glass of a greenhouse, which is transparent to visible light but absorbs infrared radiation, thus raising the temperature inside the building. This greenhouse effect is seen even more spectacularly on Venus, where the dense atmosphere is thought to be responsible for the high surface temperature of that planet.

Thus the temperature of the earth's surface is controlled to a significant extent by the water content of the atmosphere as well as greenhouse gases such as carbon dioxide. The effect of atmospheric moisture (humidity) is apparent in the Midwest. In summer, when the humidity is high, the heat of the sun is retained well into the night, giving very high nighttime temperatures. On the other hand, in winter, the coldest temperatures always occur on clear nights, when the low humidity allows efficient radiation of energy back into space.

The atmosphere's water content is controlled by the water cycle (evaporation and precipitation), and the average remains constant over the years. However, as fossil fuels have been used more extensively, the carbon dioxide concentration has increased by about $16 \%$ from 1880 to 1980 . Comparisons of satellite data have now produced evidence that the increase in carbon dioxide concentration has contributed to the warming of the earth's atmosphere. The data compare the same areas in both 1979 and 1997. The analysis shows that more infrared radiation was blocked by $\mathrm{CO}_{2}$, methane, and other greenhouse gases. This could increase the earth's average temperature by as much as $3^{\circ} \mathrm{C}$, causing dramatic changes in climate and greatly affecting the growth of food crops.

How well can we predict long-term effects? Because weather has been studied for a period of time that is minuscule compared with the age of the earth, the factors that control the earth's climate in the long range, such as changes in the sun, are not clearly understood. For example, we do not understand what causes the earth's periodic ice ages. So it is difficult to estimate the impact of the increasing carbon dioxide levels.

In fact, the variation in the earth's average temperature over the past century is somewhat confusing. In the northern latitudes during the past century, the average temperature rose by $0.8^{\circ} \mathrm{C}$ over a period of 60 years, then cooled by $0.5^{\circ} \mathrm{C}$ during the next 25 years, and finally warmed by $0.2^{\circ} \mathrm{C}$ in the succeeding 15 years. Such fluctuations do not match the steady increase in carbon dioxide. However, in southern latitudes and near the equator during the past century, the average temperature showed a steady rise totaling $0.4^{\circ} \mathrm{C}$. This figure is in reasonable agreement with the predicted effect of the increasing carbon dioxide concentration over that period. Another significant fact is that the past 10 years constitute the warmest decade on record, although the warming has not been as great as the models predicted for the increase in carbon dioxide concentration.

FIGURE 6.14 The atmospheric $\mathrm{CO}_{2}$ concentration and the average global temperature over the last 250 years. Note the significant increase in $\mathrm{CO}_{2}$ concentration in the last 50 years.
(Source: National Assessment Synthesis Team, Climate Change Impacts on the United States: The Potential Consequences of Climate, Variability and Change, Overview, Report for the U.S. Global Change Research Program, Cambridge University Press, Cambridge, UK, p. 13, 2000.)

Although the relationship between the carbon dioxide concentration in the atmosphere and the earth's temperature is not known at present, one thing is clear: The increase in the atmospheric concentration of carbon dioxide is quite dramatic (Fig. 6.14). We must consider the implications of this increase as we consider our future energy needs.

Methane is another greenhouse gas that is 21 times more potent than carbon dioxide. This fact is particularly significant for countries with lots of animals, because methane is produced by methanogenic archae that live in the animals' rumen. For example, sheep and cattle produce about $14 \%$ of Australia's total greenhouse emissions. To reduce this level, Australia has initiated a program to vaccinate sheep and cattle to lower the number of archae present in their digestive systems. It is hoped that this effort will reduce by $20 \%$ the amount of methane emitted by these animals.

### 6.6 New Energy Sources

As we search for the energy sources of the future, we need to consider economic, climatic, and supply factors. There are several potential energy sources: the sun (solar), nuclear processes (fission and fusion), biomass (plants), and synthetic fuels. Direct use of the sun's radiant energy to heat our homes and run our factories and transportation systems seems a sensible long-term goal. But what do we do now? Conservation of fossil fuels is one obvious step, but substitutes for fossil fuels also must be found. We will discuss some alternative sources of energy here. Nuclear power will be considered in Chapter 19.

## Coal Conversion

One alternative energy source involves using a traditional fuel-coal-in new ways. Since transportation costs for solid coal are high, more energy-efficient fuels are being developed from coal. One possibility is to produce a gaseous fuel. Substances like coal that contain large molecules have high boiling points and tend to be solids or thick liquids. To convert coal from a solid to a gas therefore requires reducing the size of the molecules; the coal structure must be broken down in a process called coal gasification. This is done by treating the coal with oxygen and steam at high temperatures to break many of the carbon-carbon bonds. These bonds are replaced by carbonhydrogen and carbon-oxygen bonds as the coal fragments react with the water and oxygen. The process is represented in Fig. 6.15. The desired product is a mixture of carbon monoxide and hydrogen called synthesis gas, or syngas, and methane $\left(\mathrm{CH}_{4}\right)$ gas. Since all the components of this product can react with oxygen to release heat in a combustion reaction, this gas is a useful fuel.

One of the most important considerations in designing an industrial process is efficient use of energy. In coal gasification, some of the reactions are exothermic:

$$
\begin{aligned}
\mathrm{C}(s)+2 \mathrm{H}_{2}(g) & \longrightarrow \mathrm{CH}_{4}(g) \\
\mathrm{C}(s)+\frac{1}{2} \mathrm{O}_{2}(g) & \Delta H^{\circ}=-75 \mathrm{~kJ} \\
\mathrm{CO}(g)+\mathrm{O}_{2}(g) & \longrightarrow H^{\circ}=-111 \mathrm{~kJ} \\
\mathrm{CO}_{2}(g) & \Delta H^{\circ}=-394 \mathrm{~kJ}
\end{aligned}
$$

Other gasification reactions are endothermic, for example:

$$
\mathrm{C}(s)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{CO}(g) \quad \Delta H^{\circ}=131 \mathrm{~kJ}
$$

FIGURE 6. 15 Coal gasification. Reaction of coal with a mixture of steam and air breaks down the large hydrocarbon molecules in the coal to smaller gaseous molecules, which can be used as fuels.

## An industrial process must be energy

 efficient.

A
A hydrogen powered bus in Reykjavik, Iceland

If such conditions as the rate of feed of coal, air, and steam are carefully controlled, the correct temperature can be maintained in the process without using any external energy source. That is, an energy balance is maintained.

Presently only a few plants in the United States use syngas produced on site to produce electricity. These plants are being used to evaluate the economic feasibility of producing electrical power by coal gasification.

Although syngas can be used directly as a fuel, it is also important as a raw material to produce other fuels. For example, syngas can be converted directly to methanol:

$$
\mathrm{CO}(g)+2 \mathrm{H}_{2}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(l)
$$

Methanol is used in the production of synthetic fibers and plastics and also can be used as a fuel. In addition, it can be converted directly to gasoline. Approximately half of South Africa's gasoline supply comes from methanol produced from syngas.

In addition to coal gasification, the formation of coal slurries is another new use of coal. A slurry is a suspension of fine particles in a liquid, and coal must be pulverized and mixed with water to form a slurry. The slurry can be handled, stored, and burned in ways similar to those used for residual oil, a heavy fuel oil from petroleum accounting for almost $15 \%$ of U.S. petroleum imports. One hope is that coal slurries might replace solid coal and residual oil as fuels for electricity-generating power plants. However, the water needed for slurries might place an unacceptable burden on water resources, especially in the western states.

## Hydrogen as a Fuel

If you have ever seen a lecture demonstration where hydrogen-oxygen mixtures were ignited, you have witnessed a demonstration of hydrogen's potential as a fuel. The combustion reaction is

$$
\mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H^{\circ}=-286 \mathrm{~kJ}
$$

As we saw in Example 6.6, the heat of combustion of $\mathrm{H}_{2}(g)$ per gram is approximately 2.5 times that of natural gas. In addition, hydrogen has a real advantage over fossil fuels in that the only product of hydrogen combustion is water; fossil fuels also produce carbon dioxide. However, even though it appears that hydrogen is a very logical

## CHEMICAL CONNECTIONS

## Farming the Wind

n the Midwest the wind blows across fields of corn, soybeans, wheat, and wind turbines-wind turbines? It turns out that the wind that seems to blow almost continuously across the plains is now becoming the latest cash crop. One of these new-breed wind farmers is Daniel Juhl, who recently erected 17 wind turbines on six acres of land near Woodstock, Minnesota. These turbines can generate as much as 10 megawatts (MW) of electricity, which Juhl sells to the local electrical utility.

There is plenty of untapped wind power in the United States. Wind mappers rate regions on a scale of 1 to 6 (with 6 being the best) to indicate the quality of the wind resource. Wind farms are now being developed in areas rated from 4 to 6 . The farmers who own the land welcome the increased income derived from the wind blowing across their land. Economists estimate that each acre devoted to wind turbines can pay royalties to the farmers of as much as $\$ 8000$ per year, or many times the revenue from growing corn on that same land. Juhl claims that farmers who construct the turbines themselves can realize as much as $\$ 20,000$ per year per turbine. Globally, wind generation of electricity has nearly quadrupled in the last five
years and is expected to increase by about 60\% per year in the United States. The economic feasibility of windgenerated electricity has greatly improved in the past 30 years as the wind turbines have become more efficient. Today's turbines can produce electricity that costs about the same as that from other sources. The most impressive thing about wind power is the magnitude of the supply. According to the American Wind Energy Association in Washington, D.C., the wind-power potential in the United States is comparable or larger than the energy resources under the sands of Saudi Arabia.

The biggest hurdle that must be overcome before wind power can become a significant electricity producer in the United States is construction of the transmission infrastructure-the power lines needed to move the electricity from the rural areas to the cities where most of the power is used. For example, the hundreds of turbines planned in southwest Minnesota in a development called Buffalo Ridge could supply enough electricity to power 1 million homes if transmission problems can be solved.

Another possible scenario for wind farms is to use the electrical power

This State Line Wind Project along the Oregon-Washington border uses approximately 399 wind turbines to create enough electricity to power some 70,000 households.
generated to decompose water to produce hydrogen gas that could be carried to cities by pipelines and used as a fuel. One real benefit of hydrogen is that it produces water as its only combustion product. Thus, it is essentially pollution-free.

Within a few years, wind power could be a major source of electricity. There could be a fresh wind blowing across the energy landscape of the United States in the near future.
choice as a major fuel for the future, there are three main problems: the cost of production, storage, and transport.

First let's look at the production problem. Although hydrogen is very abundant on the earth, virtually none of it exists as the free gas. Currently, the main source of hydrogen gas is from the treatment of natural gas with steam:

$$
\mathrm{CH}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow 3 \mathrm{H}_{2}(g)+\mathrm{CO}(g)
$$

We can calculate $\Delta H$ for this reaction using Equation (6.1):

$$
\begin{aligned}
\Delta H^{\circ} & =\Sigma n_{\mathrm{p}} \Delta H_{\mathrm{f}}^{\circ}(\text { products })-\Sigma n_{\mathrm{r}} \Delta H_{\mathrm{f}}^{\circ}(\text { reactants }) \\
& =\Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{CO}(g)-\Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{CH}_{4}(g)-\Delta H_{\mathrm{f}}^{\circ} \text { for } \mathrm{H}_{2} \mathrm{O}(g) \\
& =-111 \mathrm{~kJ}-(-75 \mathrm{~kJ})-(-242 \mathrm{~kJ})=206 \mathrm{~kJ}
\end{aligned}
$$

## Electrolysis will be discussed in Chapter 18.

Note that this reaction is highly endothermic; treating methane with steam is not an efficient way to obtain hydrogen for fuel. It would be much more economical to burn the methane directly.

A virtually inexhaustible supply of hydrogen exists in the waters of the world's oceans. However, the reaction

$$
\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g)
$$

requires 286 kJ of energy per mole of liquid water, and under current circumstances, large-scale production of hydrogen from water is not economically feasible. However, several methods for such production are currently being studied: electrolysis of water, thermal decomposition of water, thermochemical decomposition of water, and biological decomposition of water.

Electrolysis of water involves passing an electric current through it. The present cost of electricity makes the hydrogen produced by electrolysis too expensive to be competitive as a fuel. However, if in the future we develop more efficient sources of electricity, this situation could change.

Recent research at the University of Minnesota by Lanny Schmidt and his coworkers suggests that corn could be a feasible source of hydrogen. In this process the starch from the corn is fermented to produce alcohol, which is then decomposed in a special reactor at $140^{\circ} \mathrm{C}$ with a rhodium and cerium oxide catalyst to give hydrogen. These scientists indicate that enough hydrogen gas can be obtained from a few ounces of ethanol to generate electricity to run six 60 -watt bulbs for an hour.

Thermal decomposition is another method for producing hydrogen from water. This involves heating the water to several thousand degrees, where it spontaneously decomposes into hydrogen and oxygen. However, attaining temperatures in this range would be very expensive even if a practical heat source and a suitable reaction container were available.

In the thermochemical decomposition of water, chemical reactions, as well as heat, are used to "split" water into its components. One such system involves the following reactions (the temperature required for each is given in parentheses):

$$
\begin{array}{rlr}
2 \mathrm{HI} & \longrightarrow \mathrm{I}_{2}+\mathrm{H}_{2} & \left(425^{\circ} \mathrm{C}\right) \\
2 \mathrm{H}_{2} \mathrm{O}+\mathrm{SO}_{2}+\mathrm{I}_{2} & \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}+2 \mathrm{HI} & \left(90^{\circ} \mathrm{C}\right) \\
\mathrm{H}_{2} \mathrm{SO}_{4} & \longrightarrow \mathrm{SO}_{2}+\mathrm{H}_{2} \mathrm{O}+\frac{1}{2} \mathrm{O}_{2} & \left(825^{\circ} \mathrm{C}\right) \\
\hline \text { Net reaction: } \mathrm{H}_{2} \mathrm{O} & \longrightarrow \mathrm{H}_{2}+\frac{1}{2} \mathrm{O}_{2} &
\end{array}
$$

Note that the HI is not consumed in the net reaction. Note also that the maximum temperature required is $825^{\circ} \mathrm{C}$, a temperature that is feasible if a nuclear reactor is used as a heat source. A current research goal is to find a system for which the required temperatures are low enough that sunlight can be used as the energy source.

But what about the organisms that decompose water without the aid of electricity or high temperatures? In the process of photosynthesis, green plants absorb carbon dioxide and water and use them along with energy from the sun to produce the substances needed for growth. Scientists have studied photosynthesis for years, hoping to get answers to humanity's food and energy shortages. At present, much of this research involves attempts to modify the photosynthetic process so that plants will release hydrogen gas from water instead of using the hydrogen to produce complex compounds. Small-scale experiments have shown that under certain conditions plants do produce hydrogen gas, but the yields are far from being commercially useful. At this point the economical production of hydrogen gas remains unrealized.

The storage and transportation of hydrogen also present problems. First, on metal surfaces the $\mathrm{H}_{2}$ molecule decomposes to atoms. Since the atoms are so small, they can migrate into the metal, causing structural changes that make it brittle. This might lead to a pipeline failure if hydrogen were pumped under high pressure.

An additional problem is the relatively small amount of energy that is available per unit volume of hydrogen gas. Although the energy available per gram of hydrogen is
significantly greater than that per gram of methane, the energy available per given volume of hydrogen is about one-third that available from the same volume of methane. This is demonstrated in Example 6.12.

Although the use of hydrogen as a fuel solves some of the problems associated with fossil fuels, it does present some potential environmental problems of its own. Studies by John M. Eiler and his colleagues at California Institute of Technology indicate that, if hydrogen becomes a major source of energy, accidental leakage of the gas into the atmosphere could pose a threat. The Cal Tech scientists calculate that leakage could raise the concentration of $\mathrm{H}_{2}$ in the atmosphere from its natural level of 0.5 part per million to more than 2 parts per million. As some of the $\mathrm{H}_{2}$ eventually finds its way into the upper atmosphere, it would react with $\mathrm{O}_{2}$ to form water, which would increase the number of ice crystals. This could lead to the destruction of some of the protective ozone because many of the chemical reactions that destroy ozone occur on the surfaces of ice crystals. However, as is the usual case with environmental issues, the situation is complicated. The scenario suggested by Eiler's team may not happen because the leaked $\mathrm{H}_{2}$ could be consumed by soil microbes that use hydrogen as a nutrient. In fact, Eiler's studies show that $90 \%$ of the $\mathrm{H}_{2}$ emitted into the atmosphere today from sources such as motor vehicles and forest fires is eventually absorbed by soil organisms.

The evaluation of hydrogen as a fuel illustrates how complex and interconnected the economic and environmental issues are.

## EXAMPLE 6.12

## Enthalpies of Combustion

Compare the energy available from the combustion of a given volume of methane and the same volume of hydrogen at the same temperature and pressure.

## SOLUTION

In Example 6.6 we calculated the heat released for the combustion of methane and hydrogen: $55 \mathrm{~kJ} / \mathrm{g} \mathrm{CH}_{4}$ and $141 \mathrm{~kJ} / \mathrm{g} \mathrm{H}_{2}$. We also know from our study of gases that 1 mole of $\mathrm{H}_{2}(\mathrm{~g})$ has the same volume as 1 mole of $\mathrm{CH}_{4}(g)$ at the same temperature and pressure (assuming ideal behavior). Thus, for molar volumes of both gases under the same conditions of temperature and pressure,

Enthalpy of combustion of 1 molar volume of $\mathrm{H}_{2}(\mathrm{~g})$
Enthalpy of combustion of 1 molar volume of $\mathrm{CH}_{4}(\mathrm{~g})$

$$
\begin{aligned}
& =\frac{\text { enthalpy of combustion per mole of } \mathrm{H}_{2}}{\text { enthalpy of combustion per mole of } \mathrm{CH}_{4}} \\
& =\frac{(-141 \mathrm{~kJ} / \mathrm{g})\left(2.02 \mathrm{gH}_{2} / \mathrm{mot} \mathrm{H}_{2}\right)}{(-55 \mathrm{~kJ} / \mathrm{g})\left(16.04 g \mathrm{GH}_{4} / \mathrm{mot} \mathrm{CH}_{4}\right)} \\
& =\frac{-285}{-882} \approx \frac{1}{3}
\end{aligned}
$$

- Thus about three times the volume of hydrogen gas is needed to furnish the same energy as a given volume of methane.

## See Exercise 6.98

Could hydrogen be considered as a potential fuel for automobiles? This is an intriguing question. The internal combustion engines in automobiles can be easily adapted to burn hydrogen. In fact, BMW is now experimenting with a fleet of cars powered by hydrogen-burning internal combustion engines. However, the primary difficulty is the storage of enough hydrogen to give an automobile a reasonable range. This is illustrated by Example 6.13.

## INTERACTIVE EXAMPLE 6.13 Comparing Enthalpies of Combustion

Assuming that the combustion of hydrogen gas provides three times as much energy per gram as gasoline, calculate the volume of liquid $\mathrm{H}_{2}$ (density $=0.0710 \mathrm{~g} / \mathrm{mL}$ ) required to furnish the energy contained in 80.0 L (about 20 gal ) of gasoline (density $=0.740 \mathrm{~g} / \mathrm{mL}$ ). Calculate also the volume that this hydrogen would occupy as a gas at 1.00 atm and $25^{\circ} \mathrm{C}$.

## SOLUTION Where are we going?

To calculate the volume of $\mathrm{H}_{2}(l)$ required and its volume as a gas at the given conditions
What do we know?
> Density for $\mathrm{H}_{2}(l)=0.0710 \mathrm{~g} / \mathrm{mL}$
> 80.0 L gasoline
) Density for gasoline $=0.740 \mathrm{~g} / \mathrm{mL}$
) $\mathrm{H}_{2}(g) \Rightarrow P=1.00 \mathrm{~atm}, T=25^{\circ} \mathrm{C}=298 \mathrm{~K}$
How do we get there?
What is the mass of gasoline?

$$
80.0 \mathrm{~L} \times \frac{1000 \mathrm{mG}}{1 \mathrm{E}} \times \frac{0.740 \mathrm{~g}}{\mathrm{mG}}=59,200 \mathrm{~g}
$$

How much $H_{2}(l)$ is needed?
Since $\mathrm{H}_{2}$ furnishes three times as much energy per gram as gasoline, only a third as much liquid hydrogen is needed to furnish the same energy:

$$
\text { Mass of } \mathrm{H}_{2}(l) \text { needed }=\frac{59,200 \mathrm{~g}}{3}=19,700 \mathrm{~g}
$$

Since density $=$ mass/volume, then volume $=$ mass/density, and the volume of $\mathrm{H}_{2}(l)$ needed is

$$
\begin{aligned}
V & =\frac{19,700 \mathrm{~g}}{0.0710 \mathrm{~g} / \mathrm{mL}} \\
& =2.77 \times 10^{5} \mathrm{~mL}=277 \mathrm{~L}
\end{aligned}
$$

■ Thus 277 L of liquid $\mathrm{H}_{2}$ is needed to furnish the same energy of combustion as 80.0 L of gasoline.

What is the volume of the $\mathrm{H}_{2}(\mathrm{~g})$ ?
To calculate the volume that this hydrogen would occupy as a gas at 1.00 atm and $25^{\circ} \mathrm{C}$, we use the ideal gas law:

$$
P V=n R T
$$

In this case

$$
P=1.00 \mathrm{~atm}, T=273+25^{\circ} \mathrm{C}=298 \mathrm{~K}, \text { and } R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol}
$$

What are the moles of $\mathrm{H}_{2}(\mathrm{~g})$ ?

$$
n=19,700 \mathrm{~g} \mathrm{H}_{2} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2}}{2.016 \mathrm{gH}_{2}}=9.77 \times 10^{3} \mathrm{~mol} \mathrm{H}_{2}
$$

Thus

$$
\begin{aligned}
V=\frac{n R T}{P} & =\frac{\left(9.77 \times 10^{3} \mathrm{mot}\right)(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mot})(298 \mathrm{~K})}{1.00 \mathrm{~atm}} \\
& =2.39 \times 10^{5} \mathrm{~L}=239,000 \mathrm{~L}
\end{aligned}
$$

Metal hydrides are discussed in Chapter 20.

- At 1 atm and $25^{\circ} \mathrm{C}$, the hydrogen gas needed to replace 20 gal of gasoline occupies a volume of $239,000 \mathrm{~L}$.

See Exercises 6.99 and 6.100

You can see from Example 6.13 that an automobile would need a huge tank to hold enough hydrogen gas (at 1 atm ) to have a typical mileage range. Clearly, hydrogen must be stored as a liquid or in some other way. Is this feasible? Because of its very low boiling point ( 20 K ), storage of liquid hydrogen requires a superinsulated container that can withstand high pressures. Storage in this manner would be both expensive and hazardous because of the potential for explosion. Thus storage of hydrogen in the individual automobile as a liquid does not seem practical.

A much better alternative seems to be the use of metals that absorb hydrogen to form solid metal hydrides:

$$
\mathrm{H}_{2}(g)+\mathrm{M}(s) \longrightarrow \mathrm{MH}_{2}(s)
$$

To use this method of storage, hydrogen gas would be pumped into a tank containing the solid metal in powdered form, where it would be absorbed to form the hydride, whose volume would be little more than that of the metal alone. This hydrogen would then be available for combustion in the engine by release of $\mathrm{H}_{2}(g)$ from the hydride as needed:

$$
\mathrm{MH}_{2}(s) \longrightarrow \mathrm{M}(s)+\mathrm{H}_{2}(g)
$$

Several types of solids that absorb hydrogen to form hydrides are being studied for use in hydrogen-powered vehicles. The most likely use of hydrogen in automobiles will be to power fuel cells. Ford, Honda, and Toyota are all experimenting with cars powered by hydrogen fuel cells.

## Other Energy Alternatives

Many other energy sources are being considered for future use. The western states, especially Colorado, contain huge deposits of oil shale, which consists of a complex carbon-based material called kerogen contained in porous rock formations. These deposits have the potential of being a larger energy source than the vast petroleum deposits of the Middle East. The main problem with oil shale is that the trapped fuel is not fluid and cannot be pumped. To recover the fuel, the rock must be heated to a temperature of $250^{\circ} \mathrm{C}$ or higher to decompose the kerogen to smaller molecules that produce gaseous and liquid products. This process is expensive and yields large quantities of waste rock, which have a negative environmental impact.

Ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ is another fuel used to supplement gasoline. The most common method of producing ethanol is fermentation, a process in which sugar is changed to alcohol by the action of yeast. The sugar can come from virtually any source, including fruits and grains, although fuel-grade ethanol would probably come mostly from corn. Car engines can burn pure alcohol or gasohol, an alcohol-gasoline mixture ( $10 \%$ ethanol in gasoline), with little modification. Gasohol is now widely available in the United States. A fuel called E85, which is $85 \%$ ethanol and $15 \%$ gasoline, is also widely available for cars with "flex-fuel" engines. The use of pure alcohol as a motor fuel is not feasible in most of the United States because it does not vaporize easily when temperatures are low. However, pure ethanol could be a very practical fuel in warm climates. For example, in Brazil, large quantities of ethanol fuel are being produced for cars. It is hoped that in the future ethanol can be derived from sources of cellulose, such as switch grass, so that corn, which is a valuable food source, would not have to be used. However, the process to efficiently convert cellulose to ethanol has proved very difficult to develop.

A
Castor seed oil is one of the raw materials used in the production of biofuels.

Methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$, an alcohol similar to ethanol, which was used successfully for many years in race cars, is now being evaluated as a motor fuel in California. A major gasoline retailer has agreed to install pumps at 25 locations to dispense a fuel that is $85 \%$ methanol and $15 \%$ gasoline for use in specially prepared automobiles. The California Energy Commission feels that methanol has great potential for providing a secure, long-term energy supply that would alleviate air quality problems. Arizona and Colorado are also considering methanol as a source of portable energy.

Another potential source of liquid fuels is oil squeezed from seeds (seed oil). For example, some farmers in North Dakota, South Africa, and Australia are now using sunflower oil to replace diesel fuel. Oil seeds, found in a wide variety of plants, can be processed to produce an oil composed mainly of carbon and hydrogen, which of course reacts with oxygen to produce carbon dioxide, water, and heat. It is hoped that oil-seed plants can be developed that will thrive under soil and climatic conditions unsuitable for corn and wheat. The main advantage of seed oil as a fuel is that it is renewable. Ideally, fuel would be grown just like food crops.

## For Review

## Key terms

Section 6.1
energy
law of conservation of energy
potential energy
kinetic energy
heat
work
pathway
state function (property)
system
surroundings
exothermic
endothermic
thermodynamics
first law of thermodynamics
internal energy
Section 6.2

calorimeter
calorimetry
heat capacity
specific heat capacity
molar heat capacity
constant-pressure calorimetry
constant-volume calorimetry
Section 6.3
Hess's law

## Energy

> The capacity to do work or produce heat
> Is conserved (first law of thermodynamics)
> Can be converted from one form to another
) Is a state function
> Potential energy: stored energy
> Kinetic energy: energy due to motion
) The internal energy for a system is the sum of its potential and kinetic energies
> The internal energy of a system can be changed by work and heat:

$$
\Delta E=q+w
$$

## Work

> Force applied over a distance
> For an expanding/contracting gas
> Not a state function

$$
w=-P \Delta V
$$

## Heat

) Energy flow due to a temperature difference
) Exothermic: energy as heat flows out of a system
) Endothermic: energy as heat flows into a system
> Not a state function
> Measured for chemical reactions by calorimetry

## Key terms

fossil fuels petroleum natural gas
coal
greenhouse effect
Section 6.6
syngas

## Enthalpy

) $H=E+P V$
> Is a state function
> Hess's law: the change in enthalpy in going from a given set of reactants to a given set of products is the same whether the process takes place in one step or a series of steps
> Standard enthalpies of formation $\left(\Delta H_{\mathrm{f}}\right)$ can be used to calculate $\Delta H$ for a chemical reaction

$$
\Delta H_{\text {reaction }}^{\circ}=\Sigma n_{\mathrm{p}} \Delta H_{\mathrm{f}}^{\circ}(\text { products })-\Sigma n_{\mathrm{r}} \Delta H^{\circ}(\text { reactants })
$$

## Energy use

> Energy sources from fossil fuels are associated with difficult supply and environmental impact issues
> The greenhouse effect results from release into the atmosphere of gases, including carbon dioxide, that strongly absorb infrared radiation, thus warming the earth
> Alternative fuels are being sought to replace fossil fuels:
> Hydrogen
> Syngas from coal
> Biofuels from plants such as corn and certain seed-producing plants

Review Questions Answers to the Review Questions can be found on the Student website (accessible from wwww.cengagehrain.com).

1. Define the following terms: potential energy, kinetic energy, path-dependent function, state function, system, surroundings.
2. Consider the following potential energy diagrams for two different reactions.

Which plot represents an exothermic reaction? In plot a, do the reactants on average have stronger or weaker bonds than the products? In plot $b$, reactants must gain potential energy to convert to products. How does this occur?
3. What is the first law of thermodynamics? How can a system change its internal energy, $E$ ? What are the sign conventions for thermodynamic quantities used in this text?
4. When a gas expands, what is the sign of $w$ ? Why? When a gas contracts, what is the sign of $w$ ? Why? What are the signs of $q$ and $w$ for the process of boiling water?
5. What is the heat gained/released at constant pressure equal to ( $q_{P}=$ ?)? What is the heat gained/released at constant volume equal to ( $q_{V}=$ ? )? Explain why $\Delta H$ is obtained directly from a coffee-cup calorimeter, whereas $\Delta E$ is obtained directly from a bomb calorimeter.
6. High-quality audio amplifiers generate large amounts of heat. To dissipate the heat and prevent damage to the electronic components, heat-radiating metal fins are used. Would it be better to make these fins out of iron or aluminum? Why? (See Table 6.1 for specific heat capacities.)
7. Explain how calorimetry works to calculate $\Delta H$ or $\Delta E$ for a reaction. Does the temperature of the calorimeter increase or decrease for an endothermic reaction? For an exothermic reaction? Explain.
8. What is Hess's law? When a reaction is reversed, what happens to the sign and magnitude of $\Delta H$ for that reversed reaction? When the coefficients in a balanced reaction are multiplied by a factor $n$, what happens to the sign and magnitude of $\Delta H$ for that multiplied reaction?
9. Define the standard enthalpy of formation. What are standard states for elements and for compounds? Using Hess's law, illustrate why the formula $\Delta H_{\text {reaction }}^{\circ}=$ $\Sigma n_{\mathrm{p}} \Delta H_{\mathrm{f}}^{\circ}$ (products) $-\Sigma n_{\mathrm{r}} \Delta H_{\mathrm{f}}^{\circ}$ (reactants) works to calculate $\Delta H^{\circ}$ for a reaction.
10. What are some of the problems associated with the world's dependence on fossil fuels? What are some alternative fuels for petroleum products?

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. Objects placed together eventually reach the same temperature. When you go into a room and touch a piece of metal in that room, it feels colder than a piece of plastic. Explain.
2. What is meant by the term lower in energy? Which is lower in energy, a mixture of hydrogen and oxygen gases or liquid water? How do you know? Which of the two is more stable? How do you know?
3. A fire is started in a fireplace by striking a match and lighting crumpled paper under some logs. Explain all the energy transfers in this scenario using the terms exothermic, endothermic, system, surroundings, potential energy, and kinetic energy in the discussion.
4. Liquid water turns to ice. Is this process endothermic or exothermic? Explain what is occurring using the terms system, surroundings, heat, potential energy, and kinetic energy in the discussion.
5. Consider the following statements: "Heat is a form of energy, and energy is conserved. The heat lost by a system must be equal to the amount of heat gained by the surroundings. Therefore, heat is conserved." Indicate everything you think is correct in these statements. Indicate everything you think is incorrect. Correct the incorrect statements and explain.
6. Consider 5.5 L of a gas at a pressure of 3.0 atm in a cylinder with a movable piston. The external pressure is changed so that the volume changes to 10.5 L .
a. Calculate the work done, and indicate the correct sign.
b. Use the preceding data but consider the process to occur in two steps. At the end of the first step, the volume is 7.0 L . The second step results in a final volume of 10.5 L . Calculate the work done, and indicate the correct sign.
c. Calculate the work done if after the first step the volume is 8.0 L and the second step leads to a volume of 10.5 L . Does the work differ from that in part b? Explain.
7. In Question 6 the work calculated for the different conditions in the various parts of the question was different even though the system had the same initial and final conditions. Based on this information, is work a state function?
a. Explain how you know that work is not a state function.
b. Why does the work increase with an increase in the number of steps?
c. Which two-step process resulted in more work, when the first step had the bigger change in volume or when the second step had the bigger change in volume? Explain.
8. What if energy was not conserved? How would this affect our lives?
9. Hess's law is really just another statement of the first law of thermodynamics. Explain.
10. In the equation $w=-P \Delta V$, why is there a negative sign?
11. Explain why aluminum cans are good storage containers for soft drinks. Styrofoam cups can be used to keep coffee hot and cola cold. Why is this?
12. For each of the following situations a-c, use choices $i$ - iii to complete the statement: "The final temperature of the water should be . . ."
i. between $50^{\circ} \mathrm{C}$ and $90^{\circ} \mathrm{C}$.
ii. $50^{\circ} \mathrm{C}$.
iii. between $10^{\circ} \mathrm{C}$ and $50^{\circ} \mathrm{C}$.
a. A $100.0-\mathrm{g}$ sample of water at $90^{\circ} \mathrm{C}$ is added to a $100.0-\mathrm{g}$ sample of water at $10^{\circ} \mathrm{C}$.
b. A $100.0-\mathrm{g}$ sample of water at $90^{\circ} \mathrm{C}$ is added to a $500.0-\mathrm{g}$ sample of water at $10^{\circ} \mathrm{C}$.
c. You have a Styrofoam cup with 50.0 g of water at $10^{\circ} \mathrm{C}$. You add a $50.0-\mathrm{g}$ iron ball at $90^{\circ} \mathrm{C}$ to the water.

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

13. Consider an airplane trip from Chicago, Illinois, to Denver, Colorado. List some path-dependent functions and some state functions for the plane trip.
14. How is average bond strength related to relative potential energies of the reactants and the products?
15. Assuming gasoline is pure $\mathrm{C}_{8} \mathrm{H}_{18}(l)$, predict the signs of $q$ and $w$ for the process of combusting gasoline into $\mathrm{CO}_{2}(g)$ and $\mathrm{H}_{2} \mathrm{O}(g)$.
16. What is the difference between $\Delta H$ and $\Delta E$ ?
17. The enthalpy change for the reaction

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

is -891 kJ for the reaction as written.
a. What quantity of heat is released for each mole of water formed?
b. What quantity of heat is released for each mole of oxygen reacted?
18. Explain why oceanfront areas generally have smaller temperature fluctuations than inland areas.
19. The equation for the fermentation of glucose to alcohol and carbon dioxide is:

$$
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q) \longrightarrow 2 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(a q)+2 \mathrm{CO}_{2}(g)
$$

The enthalpy change for the reaction is -67 kJ . Is this reaction exothermic or endothermic? Is energy, in the form of heat, absorbed or evolved as the reaction occurs?
20. Explain why $\Delta H$ is obtained directly from coffee-cup calorimeters, whereas $\Delta E$ is obtained directly from bomb calorimeters.
21. The enthalpy of combustion of $\mathrm{CH}_{4}(g)$ when $\mathrm{H}_{2} \mathrm{O}(l)$ is formed is $-891 \mathrm{~kJ} / \mathrm{mol}$ and the enthalpy of combustion of $\mathrm{CH}_{4}(\mathrm{~g})$ when $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ is formed is $-803 \mathrm{~kJ} / \mathrm{mol}$. Use these data and Hess's law to determine the enthalpy of vaporization for water.
22. The enthalpy change for a reaction is a state function and it is an extensive property. Explain.
23. Standard enthalpies of formation are relative values. What are $\Delta H_{\mathrm{f}}^{\circ}$ values relative to?
24. The combustion of methane can be represented as follows:

a. Use the information given above to determine the value of $\Delta H$ for the combustion of methane to form $\mathrm{CO}_{2}(g)$ and $2 \mathrm{H}_{2} \mathrm{O}(l)$.
b. What is $\Delta H_{\mathrm{f}}^{\circ}$ for an element in its standard state? Why is this? Use the figure above to support your answer.
c. How does $\Delta H$ for the reaction $\mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \rightarrow$ $\mathrm{CH}_{4}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})$ compare to that of the combustion of methane? Why is this?
25. Why is it a good idea to rinse your thermos bottle with hot water before filling it with hot coffee?
26. Photosynthetic plants use the following reaction to produce glucose, cellulose, and so forth:

$$
6 \mathrm{CO}_{2}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \xrightarrow{\text { Sunlight }} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(\mathrm{~g})
$$

How might extensive destruction of forests exacerbate the greenhouse effect?
27. What is incomplete combustion of fossil fuels? Why can this be a problem?
28. Explain the advantages and disadvantages of hydrogen as an alternative fuel.

## Exercises

## In this section similar exercises are paired.

## Potential and Kinetic Energy

29. Calculate the kinetic energy of a baseball (mass $=5.25 \mathrm{oz}$ ) with a velocity of $1.0 \times 10^{2} \mathrm{mi} / \mathrm{h}$.
30. Which has the greater kinetic energy, an object with a mass of 2.0 kg and a velocity of $1.0 \mathrm{~m} / \mathrm{s}$ or an object with a mass of 1.0 kg and a velocity of $2.0 \mathrm{~m} / \mathrm{s}$ ?
-31. Consider the following diagram when answering the questions below.

a. Compare balls A and B in terms of potential energy in both the initial and final setups.
b. Ball A has stopped moving in the figure on the right above, but energy must be conserved. What happened to the potential energy of ball A?
31. Consider the accompanying diagram. Ball A is allowed to fall and strike ball B. Assume that all of ball A's energy is transferred to ball B at point I, and that there is no loss of energy to other sources. What is the kinetic energy and the potential energy of ball B at point II? The potential energy is given by $\mathrm{PE}=m g z$, where $m$ is the mass in kilograms, $g$ is the gravitational constant $\left(9.81 \mathrm{~m} / \mathrm{s}^{2}\right)$, and $z$ is the distance in meters.

## Heat and Work

. A gas absorbs 45 kJ of heat and does 29 kJ of work. Calculate $\Delta E$.
34. Calculate $\Delta E$ for each of the following.
a. $q=-47 \mathrm{~kJ}, w=+88 \mathrm{~kJ}$
b. $q=+82 \mathrm{~kJ}, w=-47 \mathrm{~kJ}$
c. $q=+47 \mathrm{~kJ}, w=0$
d. In which of these cases do the surroundings do work on the system?
-35. A system undergoes a process consisting of the following two steps:
Step 1: The system absorbs 72 J of heat while 35 J of work is done on it.
Step 2: The system absorbs 35 J of heat while performing 72 J of work.
Calculate $\Delta E$ for the overall process.
36. A system absorbs 35 J of heat and has 25 J of work performed on it. The system then returns to its initial state by a second step. If 5 J of heat are given off in the second step, how much work is done by the system in the second step?
-37. If the internal energy of a thermodynamic system is increased by 300 . J while 75 J of expansion work is done, how much heat was transferred and in which direction, to or from the system?
38. Calculate the internal energy change for each of the following.
a. One hundred (100.) joules of work is required to compress a gas. At the same time, the gas releases 23 J of heat.
b. A piston is compressed from a volume of 8.30 L to 2.80 L against a constant pressure of 1.90 atm . In the process, there is a heat gain by the system of 350 . J.
c. A piston expands against 1.00 atm of pressure from 11.2 L to 29.1 L . In the process, 1037 J of heat is absorbed.
-39. A sample of an ideal gas at 15.0 atm and 10.0 L is allowed to expand against a constant external pressure of 2.00 atm at a constant temperature. Calculate the work in units of kJ for the gas expansion. (Hint: Boyle's law applies.)
40. A piston performs work of $210 . \mathrm{L} \cdot \mathrm{atm}$ on the surroundings, while the cylinder in which it is placed expands from $10 . \mathrm{L}$ to 25 L . At the same time, 45 J of heat is transferred from the surroundings to the system. Against what pressure was the piston working?
-41. Consider a mixture of air and gasoline vapor in a cylinder with a piston. The original volume is $40 . \mathrm{cm}^{3}$. If the combustion of this mixture releases 950 . J of energy, to what volume will the gases expand against a constant pressure of 650. torr if all the energy of combustion is converted into work to push back the piston?
42. As a system increases in volume, it absorbs 52.5 J of energy in the form of heat from the surroundings. The piston is working against a pressure of 0.500 atm . The final volume of the system is 58.0 L . What was the initial volume of the system if the internal energy of the system decreased by 102.5 J ?
43. A balloon filled with 39.1 moles of helium has a volume of 876 L at $0.0^{\circ} \mathrm{C}$ and 1.00 atm pressure. The temperature of the balloon is increased to $38.0^{\circ} \mathrm{C}$ as it expands to a volume of 998 L , the pressure remaining constant. Calculate $q, w$, and $\Delta E$ for the helium in the balloon. (The molar heat capacity for helium gas is $20.8 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{mol}$.)
44. One mole of $\mathrm{H}_{2} \mathrm{O}(g)$ at 1.00 atm and $100 .{ }^{\circ} \mathrm{C}$ occupies a volume of 30.6 L . When 1 mole of $\mathrm{H}_{2} \mathrm{O}(g)$ is condensed to 1 mole of $\mathrm{H}_{2} \mathrm{O}(l)$ at 1.00 atm and $100 .{ }^{\circ} \mathrm{C}, 40.66 \mathrm{~kJ}$ of heat is released. If the density of $\mathrm{H}_{2} \mathrm{O}(l)$ at this temperature and pressure is $0.996 \mathrm{~g} / \mathrm{cm}^{3}$, calculate $\Delta E$ for the condensation of 1 mole of water at 1.00 atm and $100 .{ }^{\circ} \mathrm{C}$.

## Properties of Enthalpy

One of the components of polluted air is NO. It is formed in the high-temperature environment of internal combustion engines by the following reaction:

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g) \quad \Delta H=180 \mathrm{~kJ}
$$

Why are high temperatures needed to convert $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ to NO ?
46. The reaction

$$
\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)
$$

is the last step in the commercial production of sulfuric acid. The enthalpy change for this reaction is -227 kJ . In designing a sulfuric acid plant, is it necessary to provide for heating or cooling of the reaction mixture? Explain.
-47. Are the following processes exothermic or endothermic?
a. When solid KBr is dissolved in water, the solution gets colder.
b. Natural gas $\left(\mathrm{CH}_{4}\right)$ is burned in a furnace.
c. When concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$ is added to water, the solution gets very hot.
d. Water is boiled in a teakettle.
48. Are the following processes exothermic or endothermic?
a. the combustion of gasoline in a car engine
b. water condensing on a cold pipe
c. $\mathrm{CO}_{2}(s) \longrightarrow \mathrm{CO}_{2}(g)$
d. $\mathrm{F}_{2}(g) \longrightarrow 2 \mathrm{~F}(g)$
-49. The overall reaction in a commercial heat pack can be represented as

$$
4 \mathrm{Fe}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Fe}_{2} \mathrm{O}_{3}(s) \quad \Delta H=-1652 \mathrm{~kJ}
$$

a. How much heat is released when 4.00 moles of iron are reacted with excess $\mathrm{O}_{2}$ ?
b. How much heat is released when 1.00 mole of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ is produced?
c. How much heat is released when 1.00 g iron is reacted with excess $\mathrm{O}_{2}$ ?
d. How much heat is released when 10.0 g Fe and $2.00 \mathrm{~g} \mathrm{O}_{2}$ are reacted?
50. Consider the following reaction:

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H=-572 \mathrm{~kJ}
$$

a. How much heat is evolved for the production of 1.00 mole of $\mathrm{H}_{2} \mathrm{O}(l)$ ?
b. How much heat is evolved when 4.03 g hydrogen are reacted with excess oxygen?
c. How much heat is evolved when 186 g oxygen are reacted with excess hydrogen?
d. The total volume of hydrogen gas needed to fill the Hindenburg was $2.0 \times 10^{8} \mathrm{~L}$ at 1.0 atm and $25^{\circ} \mathrm{C}$. How much heat was evolved when the Hindenburg exploded, assuming all of the hydrogen reacted?
-51. Consider the combustion of propane:

$$
\mathrm{C}_{3} \mathrm{H}_{8}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 3 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

$$
\Delta H=-2221 \mathrm{~kJ}
$$

Assume that all the heat in Example 6.3 comes from the combustion of propane. What mass of propane must be burned to furnish this amount of energy assuming the heat transfer process is $60 . \%$ efficient?
52. Consider the following reaction:
$\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$

$$
\Delta H=-891 \mathrm{~kJ}
$$

Calculate the enthalpy change for each of the following cases:
a. 1.00 g methane is burned in excess oxygen.
b. $1.00 \times 10^{3} \mathrm{~L}$ methane gas at 740 . torr and $25^{\circ} \mathrm{C}$ are burned in excess oxygen.
-53. For the process $\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g)$ at 298 K and 1.0 atm , $\Delta H$ is more positive than $\Delta E$ by $2.5 \mathrm{~kJ} / \mathrm{mol}$. What does the $2.5 \mathrm{~kJ} / \mathrm{mol}$ quantity represent?
54. For the following reactions at constant pressure, predict if $\Delta H>\Delta E, \Delta H<\Delta E$, or $\Delta H=\Delta E$.
a. $2 \mathrm{HF}(g) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{F}_{2}(g)$
b. $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)$
c. $4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)$

## Calorimetry and Heat Capacity

-55. Consider the substances in Table 6.1. Which substance requires the largest amount of energy to raise the temperature of 25.0 g of the substance from $15.0^{\circ} \mathrm{C}$ to $37.0^{\circ} \mathrm{C}$ ? Calculate the energy. Which substance in Table 6.1 has the largest temperature change when 550 . g of the substance absorbs 10.7 kJ of energy? Calculate the temperature change.
56. The specific heat capacity of silver is $0.24 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$.
a. Calculate the energy required to raise the temperature of 150.0 g Ag from 273 K to 298 K .
b. Calculate the energy required to raise the temperature of 1.0 mole of Ag by $1.0^{\circ} \mathrm{C}$ (called the molar heat capacity of silver).
c. It takes 1.25 kJ of energy to heat a sample of pure silver from $12.0^{\circ} \mathrm{C}$ to $15.2^{\circ} \mathrm{C}$. Calculate the mass of the sample of silver.
$\Gamma^{57}$. A $5.00-\mathrm{g}$ sample of one of the substances listed in Table 6.1 was heated from $25.2^{\circ} \mathrm{C}$ to $55.1^{\circ} \mathrm{C}$, requiring 133 J to do so. Which substance was it?
58. It takes 585 J of energy to raise the temperature of 125.6 g mercury from $20.0^{\circ} \mathrm{C}$ to $53.5^{\circ} \mathrm{C}$. Calculate the specific heat capacity and the molar heat capacity of mercury.
[59. A $30.0-\mathrm{g}$ sample of water at $280 . \mathrm{K}$ is mixed with 50.0 g water at 330 . K. Calculate the final temperature of the mixture assuming no heat loss to the surroundings.
60. A biology experiment requires the preparation of a water bath at $37.0^{\circ} \mathrm{C}$ (body temperature). The temperature of the cold tap water is $22.0^{\circ} \mathrm{C}$, and the temperature of the hot tap water is $55.0^{\circ} \mathrm{C}$. If a student starts with 90.0 g cold water, what mass of hot water must be added to reach $37.0^{\circ} \mathrm{C}$ ?
61. A $5.00-\mathrm{g}$ sample of aluminum pellets (specific heat capacity $=$ $0.89 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$ ) and a $10.00-\mathrm{g}$ sample of iron pellets (specific heat capacity $=0.45 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$ ) are heated to $100.0^{\circ} \mathrm{C}$. The mixture of hot iron and aluminum is then dropped into 97.3 g water at $22.0^{\circ} \mathrm{C}$. Calculate the final temperature of the metal and water mixture, assuming no heat loss to the surroundings.
62. Hydrogen gives off $120 \mathrm{~J} / \mathrm{g}$ of energy when burned in oxygen, and methane gives off $50 \mathrm{~J} / \mathrm{g}$ under the same circumstances. If a mixture of 5.0 g hydrogen and 10 g methane is burned, and the heat released is transferred to 50.0 g water at $25.0^{\circ} \mathrm{C}$, what final temperature will be reached by the water?
63. A $150.0-\mathrm{g}$ sample of a metal at $75.0^{\circ} \mathrm{C}$ is added to $150.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$ at $15.0^{\circ} \mathrm{C}$. The temperature of the water rises to $18.3^{\circ} \mathrm{C}$. Calculate the specific heat capacity of the metal, assuming that all the heat lost by the metal is gained by the water.
64. A 110.-g sample of copper (specific heat capacity $=0.20 \mathrm{~J} /{ }^{\circ} \mathrm{C}$ $\cdot \mathrm{g}$ ) is heated to $82.4^{\circ} \mathrm{C}$ and then placed in a container of water at $22.3^{\circ} \mathrm{C}$. The final temperature of the water and copper is $24.9^{\circ} \mathrm{C}$. What is the mass of the water in the container, assuming that all the heat lost by the copper is gained by the water?

In a coffee-cup calorimeter, 50.0 mL of $0.100 \mathrm{M} \mathrm{AgNO}_{3}$ and 50.0 mL of 0.100 M HCl are mixed to yield the following reaction:

$$
\mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{AgCl}(s)
$$

The two solutions were initially at $22.60^{\circ} \mathrm{C}$, and the final temperature is $23.40^{\circ} \mathrm{C}$. Calculate the heat that accompanies this reaction in $\mathrm{kJ} / \mathrm{mol}$ of AgCl formed. Assume that the combined solution has a mass of 100.0 g and a specific heat capacity of $4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$.
66. In a coffee-cup calorimeter, 100.0 mL of 1.0 M NaOH and 100.0 mL of 1.0 M HCl are mixed. Both solutions were originally at $24.6^{\circ} \mathrm{C}$. After the reaction, the final temperature is $31.3^{\circ} \mathrm{C}$. Assuming that all the solutions have a density of $1.0 \mathrm{~g} / \mathrm{cm}^{3}$ and a specific heat capacity of $4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$, calculate the enthalpy change for the neutralization of HCl by NaOH . Assume that no heat is lost to the surroundings or to the calorimeter.
7. A coffee-cup calorimeter initially contains 125 g water at $24.2^{\circ} \mathrm{C}$. Potassium bromide ( 10.5 g ), also at $24.2^{\circ} \mathrm{C}$, is added to the water, and after the KBr dissolves, the final temperature is $21.1^{\circ} \mathrm{C}$. Calculate the enthalpy change for dissolving the salt in $\mathrm{J} / \mathrm{g}$ and $\mathrm{kJ} / \mathrm{mol}$. Assume that the specific heat capacity of the solution is $4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$ and that no heat is transferred to the surroundings or to the calorimeter.
68. In a coffee-cup calorimeter, $1.60 \mathrm{~g} \mathrm{NH}_{4} \mathrm{NO}_{3}$ is mixed with 75.0 g water at an initial temperature of $25.00^{\circ} \mathrm{C}$. After dissolution of the salt, the final temperature of the calorimeter contents is $23.34^{\circ} \mathrm{C}$. Assuming the solution has a heat capacity of $4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$ and assuming no heat loss to the calorimeter, calculate the enthalpy change for the dissolution of $\mathrm{NH}_{4} \mathrm{NO}_{3}$ in units of $\mathrm{kJ} / \mathrm{mol}$.
69. Consider the dissolution of $\mathrm{CaCl}_{2}$ :

$$
\mathrm{CaCl}_{2}(s) \longrightarrow \mathrm{Ca}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q) \quad \Delta H=-81.5 \mathrm{~kJ}
$$

An $11.0-\mathrm{g}$ sample of $\mathrm{CaCl}_{2}$ is dissolved in 125 g water, with both substances at $25.0^{\circ} \mathrm{C}$. Calculate the final temperature of the solution assuming no heat loss to the surroundings and assuming the solution has a specific heat capacity of $4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$.
70. Consider the reaction

$$
2 \mathrm{HCl}(a q)+\mathrm{Ba}(\mathrm{OH})_{2}(a q) \longrightarrow \mathrm{BaCl}_{2}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

$$
\Delta H=-118 \mathrm{~kJ}
$$

Calculate the heat when 100.0 mL of 0.500 M HCl is mixed with 300.0 mL of $0.100 \mathrm{MBa}(\mathrm{OH})_{2}$. Assuming that the temperature of both solutions was initially $25.0^{\circ} \mathrm{C}$ and that the final mixture has a mass of 400.0 g and a specific heat capacity of $4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$, calculate the final temperature of the mixture.
-71. Quinone is an important type of molecule that is involved in photosynthesis. The transport of electrons mediated by quinone in certain enzymes allows plants to take water, carbon dioxide, and the energy of sunlight to create glucose. A 0.1964 -g sample of quinone $\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{O}_{2}\right)$ is burned in a bomb calorimeter with a heat capacity of $1.56 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$. The temperature of the calorimeter increases by $3.2^{\circ} \mathrm{C}$. Calculate the energy of combustion of quinone per gram and per mole.
72. The energy content of food is typically determined using a bomb calorimeter. Consider the combustion of a $0.30-\mathrm{g} \mathrm{sam}-$ ple of butter in a bomb calorimeter having a heat capacity of $2.67 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$. If the temperature of the calorimeter increases from $23.5^{\circ} \mathrm{C}$ to $27.3^{\circ} \mathrm{C}$, calculate the energy of combustion per gram of butter.
[73. The heat capacity of a bomb calorimeter was determined by burning 6.79 g methane (energy of combustion $=-802 \mathrm{~kJ} /$ $\mathrm{mol} \mathrm{CH} 4)$ in the bomb. The temperature changed by $10.8^{\circ} \mathrm{C}$.
a. What is the heat capacity of the bomb?
b. A 12.6-g sample of acetylene, $\mathrm{C}_{2} \mathrm{H}_{2}$, produced a temperature increase of $16.9^{\circ} \mathrm{C}$ in the same calorimeter. What is the energy of combustion of acetylene (in $\mathrm{kJ} / \mathrm{mol}$ )?
74. The combustion of 0.1584 g benzoic acid increases the temperature of a bomb calorimeter by $2.54^{\circ} \mathrm{C}$. Calculate the heat capacity of this calorimeter. (The energy released by combustion of benzoic acid is $26.42 \mathrm{~kJ} / \mathrm{g}$.) A $0.2130-\mathrm{g}$ sample of vanillin $\left(\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{O}_{3}\right)$ is then burned in the same calorimeter, and the temperature increases by $3.25^{\circ} \mathrm{C}$. What is the energy of combustion per gram of vanillin? Per mole of vanillin?

## Hess's Law

75. The enthalpy of combustion of solid carbon to form carbon dioxide is $-393.7 \mathrm{~kJ} / \mathrm{mol}$ carbon, and the enthalpy of combustion of carbon monoxide to form carbon dioxide is $-283.3 \mathrm{~kJ} /$ mol CO . Use these data to calculate $\Delta H$ for the reaction

$$
2 \mathrm{C}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}(g)
$$

76. Combustion reactions involve reacting a substance with oxygen. When compounds containing carbon and hydrogen are combusted, carbon dioxide and water are the products. Using the enthalpies of combustion for $\mathrm{C}_{4} \mathrm{H}_{4}(-2341 \mathrm{~kJ} / \mathrm{mol}), \mathrm{C}_{4} \mathrm{H}_{8}$ ( $-2755 \mathrm{~kJ} / \mathrm{mol}$ ), and $\mathrm{H}_{2}(-286 \mathrm{~kJ} / \mathrm{mol})$, calculate $\Delta H$ for the reaction

$$
\mathrm{C}_{4} \mathrm{H}_{4}(\mathrm{~g})+2 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow \mathrm{C}_{4} \mathrm{H}_{8}(\mathrm{~g})
$$

77. Given the following data

calculate $\Delta H$ for the reaction

On the basis of the enthalpy change, is this a useful reaction for the synthesis of ammonia?
78. Given the following data

$$
\begin{aligned}
2 \mathrm{ClF}(g)+\mathrm{O}_{2}(g) & \longrightarrow \mathrm{Cl}_{2} \mathrm{O}(g)+\mathrm{F}_{2} \mathrm{O}(g) & \Delta H & =167.4 \mathrm{~kJ} \\
2 \mathrm{ClF}_{3}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) & \longrightarrow \mathrm{Cl}_{2} \mathrm{O}(\mathrm{~g})+3 \mathrm{~F}_{2} \mathrm{O}(\mathrm{~g}) & \Delta H & =341.4 \mathrm{~kJ} \\
2 \mathrm{~F}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) & \longrightarrow 2 \mathrm{~F}_{2} \mathrm{O}(\mathrm{~g}) & \Delta H & =-43.4 \mathrm{~kJ}
\end{aligned}
$$

calculate $\Delta H$ for the reaction

$$
\mathrm{ClF}(g)+\mathrm{F}_{2}(g) \longrightarrow \mathrm{ClF}_{3}(g)
$$

-79. The bombardier beetle uses an explosive discharge as a defensive measure. The chemical reaction involved is the oxidation of hydroquinone by hydrogen peroxide to produce quinone and water:

$$
\mathrm{C}_{6} \mathrm{H}_{4}(\mathrm{OH})_{2}(a q)+\mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{O}_{2}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Calculate $\Delta H$ for this reaction from the following data:

$$
\begin{array}{rlrl}
\mathrm{C}_{6} \mathrm{H}_{4}(\mathrm{OH})_{2}(a q) & \longrightarrow \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{O}_{2}(a q)+\mathrm{H}_{2}(g) \\
& \Delta H & =177.4 \mathrm{~kJ} \\
\mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) & \longrightarrow \mathrm{H}_{2} \mathrm{O}_{2}(a q) & \Delta H & =-191.2 \mathrm{~kJ} \\
\mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) & \longrightarrow \mathrm{H}_{2} \mathrm{O}(g) & \Delta H & =-241.8 \mathrm{~kJ} \\
\mathrm{H}_{2} \mathrm{O}(g) & \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) & \Delta H & =-43.8 \mathrm{~kJ}
\end{array}
$$

80. Calculate $\Delta H$ for the reaction:

$$
2 \mathrm{NH}_{3}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{N}_{2} \mathrm{H}_{4}(l)+\mathrm{H}_{2} \mathrm{O}(l)
$$

given the following data:

$$
\begin{aligned}
& 2 \mathrm{NH}_{3}(g)+3 \mathrm{~N}_{2} \mathrm{O}(g) \longrightarrow 4 \mathrm{~N}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(l) \\
& \Delta H=-1010 . \mathrm{kJ} \\
& \mathrm{~N}_{2} \mathrm{O}(g)+3 \mathrm{H}_{2}(g) \longrightarrow \mathrm{N}_{2} \mathrm{H}_{4}(l)+\mathrm{H}_{2} \mathrm{O}(l) \\
& \Delta H=-317 \mathrm{~kJ} \\
& \mathrm{~N}_{2} \mathrm{H}_{4}(l)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \\
& \Delta H=-623 \mathrm{~kJ} \\
& \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \Delta \mathrm{H}_{2} \mathrm{O}(l) \quad
\end{aligned}
$$

81. Given the following data

$$
\begin{aligned}
& \mathrm{Ca}(s)+2 \mathrm{C}(\text { graphite }) \longrightarrow \mathrm{CaC}_{2}(s) \\
& \Delta H=-62.8 \mathrm{~kJ} \\
& \mathrm{Ca}(s)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CaO}(s) \\
& \Delta H=-635.5 \mathrm{~kJ} \\
& \mathrm{CaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(a q) \\
& \Delta H=-653.1 \mathrm{~kJ} \\
& \mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g})+\frac{5}{2} \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \Delta H=-1300 . \mathrm{kJ} \\
& \mathrm{C} \text { (graphite) }+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g}) \\
& \Delta H=-393.5 \mathrm{~kJ}
\end{aligned}
$$

calculate $\Delta H$ for the reaction

$$
\mathrm{CaC}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(a q)+\mathrm{C}_{2} \mathrm{H}_{2}(g)
$$

82. Given the following data

$$
\begin{aligned}
\mathrm{P}_{4}(s)+6 \mathrm{Cl}_{2}(g) \longrightarrow 4 \mathrm{PCl}_{3}(g) & \Delta H \\
\mathrm{P}_{4}(s)+5 \mathrm{O}_{2}(g) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{10}(s) & \Delta H=-2967.3 \mathrm{~kJ} \\
\mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{PCl}_{5}(\mathrm{~g}) & \Delta H=-84.2 \mathrm{~kJ} \\
\mathrm{PCl}_{3}(g)+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{Cl}_{3} \mathrm{PO}(\mathrm{~g}) & \Delta H=-285.7 \mathrm{~kJ}
\end{aligned}
$$

calculate $\Delta H$ for the reaction

$$
\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{PCl}_{5}(\mathrm{~g}) \longrightarrow 10 \mathrm{Cl}_{3} \mathrm{PO}(\mathrm{~g})
$$

## Standard Enthalpies of Formation

83. Give the definition of the standard enthalpy of formation for a substance. Write separate reactions for the formation of NaCl , $\mathrm{H}_{2} \mathrm{O}, \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$, and $\mathrm{PbSO}_{4}$ that have $\Delta H^{\circ}$ values equal to $\Delta H_{\mathrm{f}}^{\circ}$ for each compound.
84. Write reactions for which the enthalpy change will be
a. $\Delta H_{\mathrm{f}}^{\circ}$ for solid aluminum oxide.
b. the standard enthalpy of combustion of liquid ethanol, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)$.
c. the standard enthalpy of neutralization of sodium hydroxide solution by hydrochloric acid.
d. $\Delta H_{\mathrm{f}}^{\circ}$ for gaseous vinyl chloride, $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{Cl}(g)$.
e. the enthalpy of combustion of liquid benzene, $\mathrm{C}_{6} \mathrm{H}_{6}(l)$.
f. the enthalpy of solution of solid ammonium bromide.
-85. Use the values of $\Delta H_{\mathrm{f}}^{\circ}$ in Appendix 4 to calculate $\Delta H^{\circ}$ for the following reactions.

b. $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)+3 \mathrm{H}_{2} \mathrm{SO}_{4}(l) \longrightarrow 3 \mathrm{CaSO}_{4}(s)+2 \mathrm{H}_{3} \mathrm{PO}_{4}(l)$
c. $\mathrm{NH}_{3}(g)+\mathrm{HCl}(g) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(s)$
85. Use the values of $\Delta H_{\mathrm{f}}^{\circ}$ in Appendix 4 to calculate $\Delta H^{\circ}$ for the following reactions. (See Exercise 85.)

b. $\mathrm{SiCl}_{4}(l)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{SiO}_{2}(s)+4 \mathrm{HCl}(a q)$
c. $\mathrm{MgO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Mg}(\mathrm{OH})_{2}(s)$
-87. The Ostwald process for the commercial production of nitric acid from ammonia and oxygen involves the following steps:

$$
\begin{aligned}
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) & \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g) \\
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) & \longrightarrow 2 \mathrm{NO}_{2}(g) \\
3 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{HNO}_{3}(a q)+\mathrm{NO}(g)
\end{aligned}
$$

a. Use the values of $\Delta H_{\mathrm{f}}^{\circ}$ in Appendix 4 to calculate the value of $\Delta H^{\circ}$ for each of the preceding reactions.
b. Write the overall equation for the production of nitric acid by the Ostwald process by combining the preceding equations. (Water is also a product.) Is the overall reaction exothermic or endothermic?
88. Calculate $\Delta H^{\circ}$ for each of the following reactions using the data in Appendix 4:

$$
\begin{aligned}
4 \mathrm{Na}(s)+\mathrm{O}_{2}(g) & \longrightarrow 2 \mathrm{Na}_{2} \mathrm{O}(s) \\
2 \mathrm{Na}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{NaOH}^{2}(a q)+\mathrm{H}_{2}(g) \\
2 \mathrm{Na}(s)+\mathrm{CO}_{2}(g) & \longrightarrow \mathrm{Na}_{2} \mathrm{O}(s)+\mathrm{CO}(g)
\end{aligned}
$$

Explain why a water or carbon dioxide fire extinguisher might not be effective in putting out a sodium fire.
89. The reusable booster rockets of the space shuttle use a mixture of aluminum and ammonium perchlorate as fuel. A possible reaction is

$$
\begin{aligned}
& 3 \mathrm{Al}(s)+3 \mathrm{NH}_{4} \mathrm{ClO}_{4}(s) \longrightarrow \\
& \mathrm{Al}_{2} \mathrm{O}_{3}(s)+\mathrm{AlCl}_{3}(s)+3 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
\end{aligned}
$$

Calculate $\Delta H^{\circ}$ for this reaction.
90. The space shuttle Orbiter utilizes the oxidation of methylhydrazine by dinitrogen tetroxide for propulsion:

$$
4 \mathrm{~N}_{2} \mathrm{H}_{3} \mathrm{CH}_{3}(l)+5 \mathrm{~N}_{2} \mathrm{O}_{4}(l) \longrightarrow \underset{12 \mathrm{H}_{2} \mathrm{O}(g)+9 \mathrm{~N}_{2}(g)+4 \mathrm{CO}_{2}(g)}{ }
$$

Calculate $\Delta H^{\circ}$ for this reaction.
-91. Consider the reaction

$$
\begin{array}{r}
2 \mathrm{ClF}_{3}(g)+2 \mathrm{NH}_{3}(g) \longrightarrow \mathrm{N}_{2}(g)+6 \mathrm{HF}(g)+\mathrm{Cl}_{2}(g) \\
\Delta H^{\circ}=-1196 \mathrm{~kJ}
\end{array}
$$

Calculate $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{ClF}_{3}(\mathrm{~g})$.
92. The standard enthalpy of combustion of ethene gas, $\mathrm{C}_{2} \mathrm{H}_{4}(g)$, is $-1411.1 \mathrm{~kJ} / \mathrm{mol}$ at 298 K . Given the following enthalpies of formation, calculate $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{C}_{2} \mathrm{H}_{4}(g)$.

$$
\begin{array}{ll}
\mathrm{CO}_{2}(\mathrm{~g}) & -393.5 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{H}_{2} \mathrm{O}(l) & -285.8 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

## Energy Consumption and Sources

-93. Water gas is produced from the reaction of steam with coal:

$$
\mathrm{C}(s)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{CO}(g)
$$

Assuming that coal is pure graphite, calculate $\Delta H^{\circ}$ for this reaction.
94. Syngas can be burned directly or converted to methanol. Calculate $\Delta H^{\circ}$ for the reaction

$$
\mathrm{CO}(g)+2 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(l)
$$

-95. Ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ has been proposed as an alternative fuel. Calculate the standard enthalpy of combustion per gram of liquid ethanol.
96. Methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ has also been proposed as an alternative fuel. Calculate the standard enthalpy of combustion per gram of liquid methanol, and compare this answer to that for ethanol in Exercise 95.
-97. Some automobiles and buses have been equipped to burn propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$. Compare the amounts of energy that can be obtained per gram of $\mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})$ and per gram of gasoline, assuming that gasoline is pure octane, $\mathrm{C}_{8} \mathrm{H}_{18}(l)$. (See Example 6.11.) Look up the boiling point of propane. What disadvantages are there to using propane instead of gasoline as a fuel?
98. Acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ and butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ are gaseous fuels with enthalpies of combustion of $-49.9 \mathrm{~kJ} / \mathrm{g}$ and $-49.5 \mathrm{~kJ} / \mathrm{g}$, respectively. Compare the energy available from the combustion of a given volume of acetylene to the combustion energy from the same volume of butane at the same temperature and pressure.
-99. Assume that $4.19 \times 10^{6} \mathrm{~kJ}$ of energy is needed to heat a home. If this energy is derived from the combustion of methane $\left(\mathrm{CH}_{4}\right)$, what volume of methane, measured at STP, must be burned? $\left(\Delta H_{\text {combustion }}^{\circ}\right.$ for $\left.\mathrm{CH}_{4}=-891 \mathrm{~kJ} / \mathrm{mol}\right)$
100. The complete combustion of acetylene, $\mathrm{C}_{2} \mathrm{H}_{2}(g)$, produces 1300. kJ of energy per mole of acetylene consumed. How many grams of acetylene must be burned to produce enough heat to raise the temperature of 1.00 gal water by $10.0^{\circ} \mathrm{C}$ if the process is $80.0 \%$ efficient? Assume the density of water is $1.00 \mathrm{~g} / \mathrm{cm}^{3}$.

## Additional Exercises

101. It has been determined that the body can generate 5500 kJ of energy during one hour of strenuous exercise. Perspiration is the body's mechanism for eliminating this heat. What mass of water would have to be evaporated through perspiration to rid the body of the heat generated during 2 hours of exercise? (The heat of vaporization of water is $40.6 \mathrm{~kJ} / \mathrm{mol}$.)
102. One way to lose weight is to exercise! Walking briskly at 4.0 miles per hour for an hour consumes about 400 kcal of energy. How many hours would you have to walk at 4.0 miles per hour to lose one pound of body fat? One gram of body fat is equivalent to 7.7 kcal of energy. There are 454 g in 1 lb .
103. Three gas-phase reactions were run in a constant-pressure piston apparatus as shown in the following illustration. For each reaction, give the balanced reaction and predict the sign of $w$ (the work done) for the reaction.

If just the balanced reactions were given, how could you predict the sign of $w$ for a reaction?
104. Nitrogen gas $\bigcirc$ reacts with hydrogen gas $\boxtimes$ to form ammonia gas . Consider the reaction between nitrogen and hydrogen as depicted below:

a. Draw what the container will look like after the reaction has gone to completion. Assume a constant pressure of 1 atm .
b. Is the sign of work positive or negative, or is the value of work equal to zero for the reaction? Explain your answer.
105. Combustion of table sugar produces $\mathrm{CO}_{2}(g)$ and $\mathrm{H}_{2} \mathrm{O}(l)$. When 1.46 g table sugar is combusted in a constant-volume (bomb) calorimeter, 24.00 kJ of heat is liberated.
a. Assuming that table sugar is pure sucrose, $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(s)$, write the balanced equation for the combustion reaction.
b. Calculate $\Delta E$ in $\mathrm{kJ} / \mathrm{mol} \mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$ for the combustion reaction of sucrose.
106. Consider the following changes:
a. $\mathrm{N}_{2}(g) \longrightarrow \mathrm{N}_{2}(l)$
b. $\mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g)$
c. $\mathrm{Ca}_{3} \mathrm{P}_{2}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 3 \mathrm{Ca}(\mathrm{OH})_{2}(s)+2 \mathrm{PH}_{3}(g)$
d. $2 \mathrm{CH}_{3} \mathrm{OH}(l)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)$
e. $\mathrm{I}_{2}(s) \longrightarrow \mathrm{I}_{2}(\mathrm{~g})$

At constant temperature and pressure, in which of these changes is work done by the system on the surroundings? By the surroundings on the system? In which of them is no work done?
107. A serving size of six cookies contains 4 g of fat, 20 g of carbohydrates, and 2 g of protein. If walking 1.0 mile consumes 170 kJ of energy, how many miles must you walk to burn off enough calories to eat six cookies? Assume the energy content of fats, carbohydrates, and proteins are $8 \mathrm{kcal} / \mathrm{g}, 4 \mathrm{kcal} / \mathrm{g}$, and $4 \mathrm{kcal} / \mathrm{g}$, respectively.
108. Calculate $\Delta H^{\circ}$ for the reaction

$$
2 \mathrm{~K}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{KOH}(a q)+\mathrm{H}_{2}(g)
$$

A $5.00-\mathrm{g}$ chunk of potassium is dropped into 1.00 kg water at $24.0^{\circ} \mathrm{C}$. What is the final temperature of the water after the preceding reaction occurs? Assume that all the heat is used to raise the temperature of the water. (Never run this reaction. It is very dangerous; it bursts into flame!)
109. The enthalpy of neutralization for the reaction of a strong acid with a strong base is $-56 \mathrm{~kJ} / \mathrm{mol}$ water produced. How much energy will be released when 200.0 mL of 0.400 M HNO 3 is mixed with 150.0 mL of 0.500 M KOH ?
110. Given the following data:

\[

\]

Calculate the bond energy for the $\mathrm{O}_{2}$ bond, that is, calculate $\Delta H$ for:

$$
\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{O}(g) \quad \Delta H=?
$$

111. If a student performs an endothermic reaction in a calorimeter, how does the calculated value of $\Delta H$ differ from the actual value if the heat exchanged with the calorimeter is not taken into account?
112. In a bomb calorimeter, the reaction vessel is surrounded by water that must be added for each experiment. Since the amount of water is not constant from experiment to experiment, the mass of water must be measured in each case. The heat capacity of the calorimeter is broken down into two parts: the water and the calorimeter components. If a calorimeter contains 1.00 kg water and has a total heat capacity of $10.84 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$, what is the heat capacity of the calorimeter components?
113. The bomb calorimeter in Exercise 112 is filled with 987 g water. The initial temperature of the calorimeter contents is $23.32^{\circ} \mathrm{C}$. A $1.056-\mathrm{g}$ sample of benzoic acid $\left(\Delta E_{\text {comb }}=\right.$ $-26.42 \mathrm{~kJ} / \mathrm{g}$ ) is combusted in the calorimeter. What is the final temperature of the calorimeter contents?
114. Consider the two space shuttle fuel reactions in Exercises 89 and 90 . Which reaction produces more energy per kilogram of reactant mixture (stoichiometric amounts)?
115. Consider the following equations:

$$
\begin{aligned}
3 \mathrm{~A}+6 \mathrm{~B} & \longrightarrow 3 \mathrm{D} & \Delta H & =-403 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{E}+2 \mathrm{~F} & \longrightarrow \mathrm{~A} & \Delta H & =-105.2 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{C} & \longrightarrow \mathrm{E}+3 \mathrm{D} & \Delta H & =64.8 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Suppose the first equation is reversed and multiplied by $\frac{1}{6}$, the second and third equations are divided by 2 , and the three adjusted equations are added. What is the net reaction and what is the overall heat of this reaction?
116. Given the following data

$$
\begin{aligned}
\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+3 \mathrm{CO}(g) \longrightarrow 2 \mathrm{Fe}(s)+3 \mathrm{CO}_{2}(g) & \Delta H^{\circ}=-23 \mathrm{~kJ} \\
3 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+\mathrm{CO}(g) \longrightarrow 2 \mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{CO}_{2}(g) & \Delta H^{\circ}=-39 \mathrm{~kJ} \\
\mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{CO}(g) \longrightarrow 3 \mathrm{FeO}(s)+\mathrm{CO}_{2}(g) & \Delta H^{\circ}=18 \mathrm{~kJ}
\end{aligned}
$$

calculate $\Delta H^{\circ}$ for the reaction

$$
\mathrm{FeO}(s)+\mathrm{CO}(g) \longrightarrow \mathrm{Fe}(s)+\mathrm{CO}_{2}(g)
$$

117. At 298 K , the standard enthalpies of formation for $\mathrm{C}_{2} \mathrm{H}_{2}(g)$ and $\mathrm{C}_{6} \mathrm{H}_{6}(l)$ are $227 \mathrm{~kJ} / \mathrm{mol}$ and $49 \mathrm{~kJ} / \mathrm{mol}$, respectively.
a. Calculate $\Delta H^{\circ}$ for

$$
\mathrm{C}_{6} \mathrm{H}_{6}(l) \longrightarrow 3 \mathrm{C}_{2} \mathrm{H}_{2}(g)
$$

b. Both acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ and benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ can be used as fuels. Which compound would liberate more energy per gram when combusted in air?
118. Using the following data, calculate the standard heat of formation of $\mathrm{ICl}(g)$ in $\mathrm{kJ} / \mathrm{mol}$ :

$$
\begin{aligned}
\mathrm{Cl}_{2}(g) & \longrightarrow 2 \mathrm{Cl}(g) \\
\mathrm{I}_{2}(g) & \Delta H^{\circ}=242.3 \mathrm{~kJ} \\
\mathrm{ICl}(g) & \Delta H^{\circ}=151.0 \mathrm{~kJ} \\
\mathrm{I}_{2}(s) & \mathrm{I}(g)+\mathrm{Cl}(g) \\
\mathrm{I}_{2}(g) & \Delta H^{\circ}=211.3 \mathrm{~kJ} \\
& \Delta H^{\circ}=62.8 \mathrm{~kJ}
\end{aligned}
$$

119. A sample of nickel is heated to $99.8^{\circ} \mathrm{C}$ and placed in a coffeecup calorimeter containing 150.0 g water at $23.5^{\circ} \mathrm{C}$. After the metal cools, the final temperature of metal and water mixture is $25.0^{\circ} \mathrm{C}$. If the specific heat capacity of nickel is $0.444 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$, what mass of nickel was originally heated? Assume no heat loss to the surroundings.
120. Given:

$$
\begin{array}{rll}
2 \mathrm{Cu}_{2} \mathrm{O}(s)+\mathrm{O}_{2}(g) & \Delta 4 \mathrm{CuO}(s) & \Delta H^{\circ}=-288 \mathrm{~kJ} \\
\mathrm{Cu}_{2} \mathrm{O}(s) & \longrightarrow \mathrm{CuO}(s)+\mathrm{Cu}(s) & \Delta H^{\circ}=11 \mathrm{~kJ}
\end{array}
$$

Calculate the standard enthalpy of formation $\left(\Delta H_{f}^{\circ}\right)$ for $\mathrm{CuO}(s)$.
121. Calculate $\Delta H^{\circ}$ for each of the following reactions, which occur in the atmosphere.
a. $\mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{CHO}(g)+\mathrm{O}_{2}(g)$
b. $\mathrm{O}_{3}(g)+\mathrm{NO}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$
c. $\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)$
d. $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
122. Consider a balloon filled with helium at the following conditions.

$$
\begin{aligned}
& 313 \mathrm{~g} \mathrm{He} \\
& 1.00 \mathrm{~atm} \\
& 1910 \mathrm{~L} \\
& \text { Molar Heat Capacity }=20.8 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{~mol}
\end{aligned}
$$

The temperature of this balloon is decreased by $41.6^{\circ} \mathrm{C}$ as the volume decreases to 1643 L , with the pressure remaining constant. Determine $q, w$, and $\Delta E$ (in kJ ) for the compression of the balloon.
123. In which of the following systems is(are) work done by the surroundings on the system? Assume pressure and temperature are constant.
a. $2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)$
b. $\mathrm{CO}_{2}(s) \longrightarrow \mathrm{CO}_{2}(g)$
c. $4 \mathrm{NH}_{3}(g)+7 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)$
d. $\mathrm{N}_{2} \mathrm{O}_{4}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$
e. $\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaCO}(s)+\mathrm{CO}_{2}(g)$
124. Which of the following processes are exothermic?
a. $\mathrm{N}_{2}(g) \longrightarrow 2 \mathrm{~N}(g)$
b. $\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(s)$
c. $\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{Cl}(g)$
d. $2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g)$
e. $\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{O}(g)$
125. Consider the reaction
$\mathrm{B}_{2} \mathrm{H}_{6}(g)+3 \mathrm{O}_{2}(g) \longrightarrow \mathrm{B}_{2} \mathrm{O}_{3}(\mathrm{~s})+3 \mathrm{H}_{2} \mathrm{O}(g) \quad \Delta H=-2035 \mathrm{~kJ}$
Calculate the amount of heat released when 54.0 g of diborane is combusted.
126. A swimming pool, 10.0 m by 4.0 m , is filled with water to a depth of 3.0 m at a temperature of $20.2^{\circ} \mathrm{C}$. How much energy is required to raise the temperature of the water to $24.6^{\circ} \mathrm{C}$ ?
127. In a coffee-cup calorimeter, 150.0 mL of 0.50 M HCl is added to 50.0 mL of 1.00 M NaOH to make 200.0 g solution at an initial temperature of $48.2^{\circ} \mathrm{C}$. If the enthalpy of neutralization for the reaction between a strong acid and a strong base is $-56 \mathrm{~kJ} / \mathrm{mol}$, calculate the final temperature of the calorimeter contents. Assume the specific heat capacity of the solution is $4.184 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$ and assume no heat loss to the surroundings.
128. Calculate $\Delta H$ for the reaction

$$
\mathrm{N}_{2} \mathrm{H}_{4}(l)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

given the following data:

| Equation | $\begin{gathered} \Delta H \\ (\mathrm{~kJ}) \end{gathered}$ |
| :---: | :---: |
| $2 \mathrm{NH}_{3}(\mathrm{~g})+3 \mathrm{~N}_{2} \mathrm{O}(\mathrm{g}) \longrightarrow 4 \mathrm{~N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | -1010 |
| $\mathrm{N}_{2} \mathrm{O}(\mathrm{g})+3 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow \mathrm{N}_{2} \mathrm{H}_{4}(\mathrm{I})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | -317 |
| $2 \mathrm{NH}_{3}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{N}_{2} \mathrm{H}_{4}(\mathrm{I})+\mathrm{H}_{2} \mathrm{O}(I)$ | -143 |
| $\mathrm{H}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | -286 |

129. Which of the following substances have an enthalpy of formation equal to zero?
a. $\mathrm{Cl}_{2}(g)$
b. $\mathrm{H}_{2}(g)$
c. $\mathrm{N}_{2}(l)$
d. $\mathrm{Cl}(g)$

## Challenge Problems

130. Consider 2.00 moles of an ideal gas that are taken from state $A$ $\left(P_{A}=2.00 \mathrm{~atm}, V_{A}=10.0 \mathrm{~L}\right)$ to state $B\left(P_{B}=1.00 \mathrm{~atm}, V_{B}=\right.$ 30.0 L ) by two different pathways:

State A $\quad 1 /\binom{V_{C}=30.0 \mathrm{~L}}{P_{C}=2.00 \mathrm{~atm}}>2 \quad$ State B

$$
\begin{aligned}
\binom{V_{A}=10.0 \mathrm{~L}}{P_{A}=2.00 \mathrm{~atm}} & \binom{V_{B}=30.0 \mathrm{~L}}{P_{B}=1.00 \mathrm{~atm}} \\
& 3
\end{aligned}
$$

These pathways are summarized on the following graph of $P$ versus $V$ :

Calculate the work (in units of J ) associated with the two pathways. Is work a state function? Explain.
131. Calculate $w$ and $\Delta E$ when 1 mole of a liquid is vaporized at its boiling point $\left(80 .{ }^{\circ} \mathrm{C}\right)$ and 1.00 atm pressure. $\Delta H_{\text {vap }}$ for the liquid is $30.7 \mathrm{~kJ} / \mathrm{mol}$ at $80 .{ }^{\circ} \mathrm{C}$.
132. The sun supplies energy at a rate of about 1.0 kilowatt per square meter of surface area ( 1 watt $=1 \mathrm{~J} / \mathrm{s}$ ). The plants in an agricultural field produce the equivalent of $20 . \mathrm{kg}$ sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ per hour per hectare ( $1 \mathrm{ha}=10,000 \mathrm{~m}^{2}$ ). Assuming that sucrose is produced by the reaction

$$
\begin{aligned}
& 12 \mathrm{CO}_{2}(g)+11 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(s)+ 12 \mathrm{O}_{2}(g) \\
& \Delta H=5640 \mathrm{~kJ}
\end{aligned}
$$

calculate the percentage of sunlight used to produce the sucrose-that is, determine the efficiency of photosynthesis.
133. The best solar panels currently available are about $19 \%$ efficient in converting sunlight to electricity. A typical home will use about $40 . \mathrm{kWh}$ of electricity per day $(1 \mathrm{kWh}=1$ kilowatt hour; $1 \mathrm{~kW}=1000 \mathrm{~J} / \mathrm{s}$ ). Assuming 8.0 hours of useful sunlight per day, calculate the minimum solar panel surface area necessary to provide all of a typical home's electricity. (See Exercise 132 for the energy rate supplied by the sun.)
134. On Easter Sunday, April 3, 1983, nitric acid spilled from a tank car near downtown Denver, Colorado. The spill was neutralized with sodium carbonate:
$2 \mathrm{HNO}_{3}(a q)+\mathrm{Na}_{2} \mathrm{CO}_{3}(s) \longrightarrow 2 \mathrm{NaNO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)$
a. Calculate $\Delta H^{\circ}$ for this reaction. Approximately $2.0 \times$ $10^{4}$ gal nitric acid was spilled. Assume that the acid was an aqueous solution containing $70.0 \% \mathrm{HNO}_{3}$ by mass with a density of $1.42 \mathrm{~g} / \mathrm{cm}^{3}$. What mass of sodium carbonate was required for complete neutralization of the spill, and what quantity of heat was evolved? $\left(\Delta H_{\mathrm{f}}^{\circ}\right.$ for $\left.\mathrm{NaNO}_{3}(a q)=-467 \mathrm{~kJ} / \mathrm{mol}\right)$
b. According to The Denver Post for April 4, 1983, authorities feared that dangerous air pollution might occur during the neutralization. Considering the magnitude of $\Delta H^{\circ}$, what was their major concern?
135. A piece of chocolate cake contains about 400 Calories. A nutritional Calorie is equal to 1000 calories (thermochemical calories), which is equal to 4.184 kJ . How many 8 -in-high steps must a $180-\mathrm{lb}$ man climb to expend the 400 Cal from the piece of cake? See Exercise 32 for the formula for potential energy.
136. The standard enthalpy of formation of $\mathrm{H}_{2} \mathrm{O}(l)$ at 298 K is $-285.8 \mathrm{~kJ} / \mathrm{mol}$. Calculate the change in internal energy for the following process at 298 K and 1 atm :

$$
\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \quad \Delta E^{\circ}=?
$$

(Hint: Using the ideal gas equation, derive an expression for work in terms of $n, R$, and $T$.)
137. You have a 1.00 -mole sample of water at $-30 .{ }^{\circ} \mathrm{C}$ and you heat it until you have gaseous water at $140 .{ }^{\circ} \mathrm{C}$. Calculate $q$ for the entire process. Use the following data.

$$
\begin{aligned}
\text { Specific heat capacity of ice } & =2.03 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{~g} \\
\text { Specific heat capacity of water } & =4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{~g} \\
\text { Specific heat capacity of steam } & =2.02 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{~g}
\end{aligned}
$$

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) & \Delta H_{\text {fusion }}=6.02 \mathrm{~kJ} / \mathrm{mol}\left(\text { at } 0^{\circ} \mathrm{C}\right) \\
\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g) & \Delta H_{\text {vaporization }}=40.7 \mathrm{~kJ} / \mathrm{mol}\left(\text { at } 100 .^{\circ} \mathrm{C}\right)
\end{aligned}
$$

138. A $500.0-\mathrm{g}$ sample of an element at $195^{\circ} \mathrm{C}$ is dropped into an ice-water mixture; 109.5 g ice melts and an ice-water mixture remains. Calculate the specific heat of the element. See Exercise 137 for pertinent information.
139. Calculate $q, w, \Delta E$, and $\Delta H$ for the process in which 88.0 g of nitrous oxide (laughing gas, $\mathrm{N}_{2} \mathrm{O}$ ) is cooled from $165^{\circ} \mathrm{C}$ to $55^{\circ} \mathrm{C}$ at a constant pressure of 5.00 atm . The molar heat capacity for $\mathrm{N}_{2} \mathrm{O}(g)$ is $38.7 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{mol}$.

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
140. When 1.00 L of $2.00 \mathrm{M} \mathrm{Na}_{2} \mathrm{SO}_{4}$ solution at $30.0^{\circ} \mathrm{C}$ is added to 2.00 L of $0.750 \mathrm{M} \mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$ solution at $30.0^{\circ} \mathrm{C}$ in a calorimeter, a white solid $\left(\mathrm{BaSO}_{4}\right)$ forms. The temperature of the mixture increases to $42.0^{\circ} \mathrm{C}$. Assuming that the specific heat capacity of the solution is $6.37 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$ and that the density of the final solution is $2.00 \mathrm{~g} / \mathrm{mL}$, calculate the enthalpy change per mole of $\mathrm{BaSO}_{4}$ formed.
141. The preparation of $\mathrm{NO}_{2}(g)$ from $\mathrm{N}_{2}(g)$ and $\mathrm{O}_{2}(g)$ is an endothermic reaction:

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{NO}_{2}(g) \text { (unbalanced) }
$$

The enthalpy change of reaction for the balanced equation (with lowest whole-number coefficients) is $\Delta H=67.7 \mathrm{~kJ}$. If $2.50 \times 10^{2} \mathrm{~mL} \mathrm{~N}_{2}(\mathrm{~g})$ at $100 .{ }^{\circ} \mathrm{C}$ and 3.50 atm and $4.50 \times$ $10^{2} \mathrm{~mL} \mathrm{O}_{2}(\mathrm{~g})$ at $100 .{ }^{\circ} \mathrm{C}$ and 3.50 atm are mixed, what amount of heat is necessary to synthesize the maximum yield of $\mathrm{NO}_{2}(g)$ ?
142. Nitromethane, $\mathrm{CH}_{3} \mathrm{NO}_{2}$, can be used as a fuel. When the liquid is burned, the (unbalanced) reaction is mainly

$$
\mathrm{CH}_{3} \mathrm{NO}_{2}(l)+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+\mathrm{N}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(g)
$$

a. The standard enthalpy change of reaction $\left(\Delta H_{\mathrm{rxn}}^{\circ}\right)$ for the balanced reaction (with lowest whole-number coefficients) is -1288.5 kJ . Calculate $\Delta H_{\mathrm{f}}^{\circ}$ for nitromethane.
b. A 15.0-L flask containing a sample of nitromethane is filled with $\mathrm{O}_{2}$ and the flask is heated to $100 .{ }^{\circ} \mathrm{C}$. At this temperature, and after the reaction is complete, the total pressure of all the gases inside the flask is 950 . torr. If the mole fraction of nitrogen $\left(\chi_{\text {nitrogen }}\right)$ is 0.134 after the reaction is complete, what mass of nitrogen was produced?
143. A cubic piece of uranium metal (specific heat capacity $=$ $0.117 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$ ) at $200.0^{\circ} \mathrm{C}$ is dropped into 1.00 L deuterium oxide ("heavy water," specific heat capacity $=4.211 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$ ) at $25.5^{\circ} \mathrm{C}$. The final temperature of the uranium and deuterium oxide mixture is $28.5^{\circ} \mathrm{C}$. Given the densities of uranium $\left(19.05 \mathrm{~g} / \mathrm{cm}^{3}\right)$ and deuterium oxide $(1.11 \mathrm{~g} / \mathrm{mL})$, what is the edge length of the cube of uranium?

## Marathon Problems

These problems are designed to incorporate several concepts and techniques into one situation.
144. Consider a sample containing 5.00 moles of a monatomic ideal gas that is taken from state A to state B by the following two pathways:

$$
\begin{array}{ll}
\text { Pathway one: } & \begin{array}{l}
P_{\mathrm{A}}=3.00 \mathrm{~atm} \\
V_{\mathrm{A}}=15.0 \mathrm{~L}
\end{array} \\
& \\
\text { Pathway two: } & \begin{array}{l}
1 \\
P_{\mathrm{A}}=3.00 \mathrm{~atm} \\
V_{\mathrm{A}}=15.0 \mathrm{~L} \\
P_{\mathrm{C}}=3.00 \mathrm{~atm} \\
V_{\mathrm{C}}=55.0 \mathrm{~L} \\
P_{\mathrm{B}}=6.00 \mathrm{~atm}
\end{array} \\
V_{\mathrm{B}}=20.0 \mathrm{~L} \\
& \\
& \\
P_{\mathrm{D}}=6.00 \mathrm{~atm}
\end{array}
$$

For each step, assume that the external pressure is constant and equals the final pressure of the gas for that step. Calculate $q, w, \Delta E$, and $\Delta H$ for each step in kJ , and calculate overall values for each pathway. Explain how the overall values for the two pathways illustrate that $\Delta E$ and $\Delta H$ are state functions, whereas $q$ and $w$ are path functions. Hint: In a more rigorous study of thermochemistry, it can be shown that for an ideal gas:

$$
\begin{aligned}
\Delta E & =\mathrm{nC}_{\mathrm{v}} \Delta T \text { and } \\
\Delta H & =\mathrm{nC}_{\mathrm{p}} \Delta T
\end{aligned}
$$

where $\mathrm{C}_{\mathrm{v}}$ is the molar heat capacity at constant volume and $\mathrm{C}_{\mathrm{p}}$ is the molar heat capacity at constant pressure. In addition, for a monotomic ideal gas, $\mathrm{C}_{\mathrm{v}}=\frac{3}{2} \mathrm{R}$ and $\mathrm{C}_{\mathrm{p}}=\frac{5}{2} \mathrm{R}$.
145. A gaseous hydrocarbon reacts completely with oxygen gas to form carbon dioxide and water vapor. Given the following data, determine $\Delta H_{\mathrm{f}}^{\circ}$ for the hydrocarbon:

$$
\begin{aligned}
\Delta H_{\text {reaction }}^{\circ} & =-2044.5 \mathrm{~kJ} / \mathrm{mol} \text { hydrocarbon } \\
\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{CO}_{2}\right) & =-393.5 \mathrm{~kJ} / \mathrm{mol} \\
\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{H}_{2} \mathrm{O}\right) & =-242 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Density of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ product mixture at 1.00 atm, $200 .{ }^{\circ} \mathrm{C}=0.751 \mathrm{~g} / \mathrm{L}$.
The density of the hydrocarbon is less than the density of Kr at the same conditions.

Scientists at the Swiss Federal Institute of Technology in Lausanne have designed an experiment to simultaneously show the wave and particle nature of light. This photograph is the result of that experiment. (see http://actu.epfl.ch/news/the-first-ever-photograph-of-light-as-both-a-parti/) (Fabrizio Carbone/EPFL)

Information Contained in the Periodic Table
The Alkali Metals
n the past 200 years, a great deal of experimental evidence has accumulated to support the atomic model. This theory has proved to be both extremely useful and physically reasonable. When atoms were first suggested by the Greek philosophers Democritus and Leucippus about 400 в.c., the concept was based mostly on intuition. In fact, for the following 20 centuries, no convincing experimental evidence was available to support the existence of atoms. The first real scientific data were gathered by Lavoisier and others from quantitative measurements of chemical reactions. The results of these stoichiometric experiments led John Dalton to propose the first systematic atomic theory. Dalton's theory, although crude, has stood the test of time extremely well.

Once we came to "believe in" atoms, it was logical to ask: What is the nature of an atom? Does an atom have parts, and if so, what are they? In Chapter 2 we considered some of the experiments most important for shedding light on the nature of the atom. Now we will see how the atomic theory has evolved to its present state.

One of the most striking things about the chemistry of the elements is the periodic repetition of properties. There are several groups of elements that show great similarities in chemical behavior. As we saw in Chapter 2, these similarities led to the development of the periodic table of the elements. In this chapter we will see that the modern theory of atomic structure accounts for periodicity in terms of the electron arrangements in atoms.

However, before we examine atomic structure, we must consider the revolution that took place in physics in the first 30 years of the twentieth century. During that time, experiments were carried out, the results of which could not be explained by the theories of classical physics developed by Isaac Newton and many others who followed him. A radical new theory called quantum mechanics was developed to account for the behavior of light and atoms. This "new physics" provides many surprises for humans who are used to the macroscopic world, but it seems to account flawlessly (within the bounds of necessary approximations) for the behavior of matter.

As the first step in our exploration of this revolution in science, we will consider the properties of light, more properly called electromagnetic radiation.

### 7.1 Electromagnetic Radiation

One of the ways that energy travels through space is by electromagnetic radiation. The light from the sun, the energy used to cook food in a microwave oven, the X rays used by dentists, and the radiant heat from a fireplace are all examples of electromagnetic radiation. Although these forms of radiant energy seem quite different, they all exhibit the same type of wavelike behavior and travel at the speed of light in a vacuum.

Waves have three primary characteristics: wavelength, frequency, and speed. Wavelength (symbolized by the lowercase Greek letter lambda, $\lambda$ ) is the distance between two consecutive peaks or troughs in a wave (Fig. 7.1). The frequency (symbolized by the lowercase Greek letter nu, $\nu$ ) is defined as the number of waves (cycles) per second that pass a given point in space. Since all types of electromagnetic radiation travel at the speed of light, short-wavelength radiation must have a high frequency. You can see this in Fig. 7.1, where three waves are shown traveling between two points at constant speed. Note that the wave with the shortest wavelength $\left(\lambda_{3}\right)$ has the highest frequency and the wave with the longest wavelength $\left(\lambda_{1}\right)$ has the lowest frequency.This implies an inverse relationship between wavelength and frequency, that is, $\lambda \propto 1 / \nu$, or

$$
\lambda \nu=c
$$

where $\lambda$ is the wavelength in meters, $\nu$ is the frequency in cycles per second, and $c$ is the speed of light ( $2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}$ ). In the SI system, cycles are understood, and the unit per second becomes $1 / \mathrm{s}$, or s ${ }^{-1}$, which is called the hertz (abbreviated Hz ).

[^11]

FIGURE 7.1 The nature of waves. Many of the properties of ocean waves are the same as those of light waves. Note that the radiation with the shortest wavelength has the highest frequency.

FIGURE 7.2 Classification of electromagnetic radiation.

Electromagnetic radiation is classified as shown in Fig. 7.2. Radiation provides an important means of energy transfer. For example, the energy from the sun reaches the earth mainly in the form of visible and ultraviolet radiation, whereas the glowing coals of a fireplace transmit heat energy by infrared radiation. In a microwave oven, the water molecules in food absorb microwave radiation, which increases their motions. This energy is then transferred to other types of molecules via collisions, causing an increase in the food's temperature. As we proceed in the study of chemistry, we will consider many of the classes of electromagnetic radiation and the ways in which they affect matter.

## INTERACTIVE EXAMPLE 1.1

## Frequency of Electromagnetic Radiation

The brilliant red colors seen in fireworks are due to the emission of light with wavelengths around 650 nm when strontium salts such as $\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}$ and $\mathrm{SrCO}_{3}$ are heated. (This can be easily demonstrated in the lab by dissolving one of these salts in methanol that contains a little water and igniting the mixture in an evaporating dish.) Calculate the frequency of red light of wavelength $6.50 \times 10^{2} \mathrm{~nm}$.

## SOLUTION

-
When a strontium salt is dissolved in methanol (with a little water) and ignited, it gives a brilliant red flame. The red color is produced by emission of light when electrons, excited by the energy of the burning methanol, fall back to their ground states.

### 7.2 The Nature of Matter

## -

When alternating current at 110 volts is applied to a dill pickle, a glowing discharge occurs. The current flowing between the electrodes (forks), which is supported by the $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions present, apparently causes some sodium atoms to form in an excited state. When these atoms relax to the ground state, they emit visible light at 589 nm , producing the yellow glow reminiscent of sodium vapor lamps.

We can convert wavelength to frequency using the equation

$$
\lambda \nu=c \quad \text { or } \quad \nu=\frac{c}{\lambda}
$$

where $c=2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}$. In this case $\lambda=6.50 \times 10^{2} \mathrm{~nm}$. Changing the wavelength to meters, we have

$$
6.50 \times 10^{2} \mathrm{~nm} \times \frac{1 \mathrm{~m}}{10^{9} \mathrm{~nm}}=6.50 \times 10^{-7} \mathrm{~m}
$$

and

$$
\nu=\frac{c}{\lambda}=\frac{2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}}{6.50 \times 10^{-7} \mathrm{~m}}=4.61 \times 10^{14} \mathrm{~s}^{-1}=4.61 \times 10^{14} \mathrm{~Hz}
$$

It is probably fair to say that at the end of the nineteenth century, physicists were feeling rather smug. Theories could explain phenomena as diverse as the motions of the planets and the dispersion of visible light by a prism. Rumor has it that students were being discouraged from pursuing physics as a career because it was felt that all the major problems had been solved, or at least described in terms of the current physical theories.

At the end of the nineteenth century, the idea prevailed that matter and energy were distinct. Matter was thought to consist of particles, whereas energy in the form of light (electromagnetic radiation) was described as a wave. Particles were things that had mass and whose position in space could be specified. Waves were described as massless and delocalized; that is, their position in space could not be specified. It also was assumed that there was no intermingling of matter and light. Everything known before 1900 seemed to fit neatly into this view.

At the beginning of the twentieth century, however, certain experimental results suggested that this picture was incorrect. The first important advance came in 1900 from the German physicist Max Planck (1858-1947). Studying the radiation profiles emitted by solid bodies heated to incandescence, Planck found that the results could not be explained in terms of the physics of his day, which held that matter could absorb or emit any quantity of energy. Planck could account for these observations only by postulating that energy can be gained or lost only in whole-number multiples of the quantity $h \nu$, where $h$ is a constant called Planck's constant, determined by experiment to have the value $6.626 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}$. That is, the change in energy for a system, $\Delta E$, can be represented by the equation

$$
\Delta E=n h \nu
$$

## See Exercises 7.45 and 7.46

where $n$ is an integer $(1,2,3, \ldots), h$ is Planck's constant, and $\nu$ is the frequency of the electromagnetic radiation absorbed or emitted.

Planck's result was a real surprise. It had always been assumed that the energy of matter was continuous, which meant that the transfer of any quantity of energy was possible. Now it seemed clear that energy is in fact quantized and can occur only in discrete units of size $h \nu$. Each of these small "packets" of energy is called a quantum. A system can transfer energy only in whole quanta. Thus energy seems to have particulate properties.

## INTERACTIVE EXAMPLE 7.2 The Energy of a Photon

## SOLUTION

The blue color in fireworks is often achieved by heating copper $(\mathrm{I})$ chloride $(\mathrm{CuCl})$ to about $1200^{\circ} \mathrm{C}$. Then the compound emits blue light having a wavelength of 450 nm . What is the increment of energy (the quantum) that is emitted at $4.50 \times 10^{2} \mathrm{~nm}$ by CuCl ?

The quantum of energy can be calculated from the equation

$$
\Delta E=h \nu
$$

The frequency $\nu$ for this case can be calculated as follows:

$$
\nu=\frac{c}{\lambda}=\frac{2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}}{4.50 \times 10^{-7} \mathrm{~m}}=6.66 \times 10^{14} \mathrm{~s}^{-1}
$$

So

$$
\Delta E=h \nu=\left(6.626 \times 10^{-34} \mathrm{~J} \cdot 8\right)\left(6.66 \times 10^{14} \mathrm{~s}^{-1}\right)=4.41 \times 10^{-19} \mathrm{~J}
$$

A sample of CuCl emitting light at 450 nm can lose energy only in increments of $4.41 \times 10^{-19} \mathrm{~J}$, the size of the quantum in this case.

## See Exercises 7.47 and 7.48

The next important development in the knowledge of atomic structure came when Albert Einstein (Fig. 7.3) proposed that electromagnetic radiation is itself quantized. Einstein suggested that electromagnetic radiation can be viewed as a stream of "particles" called photons. The energy of each photon is given by the expression

$$
E_{\text {photon }}=h \nu=\frac{h c}{\lambda}
$$

where $h$ is Planck's constant, $\nu$ is the frequency of the radiation, and $\lambda$ is the wavelength of the radiation.

## The Photoelectric Effect

Einstein arrived at this conclusion through his analysis of the photoelectric effect (for which he later was awarded the Nobel Prize). The photoelectric effect refers to the

FIGURE 7.3 Albert Einstein (1879-1955) was born in Germany. Nothing in his early development suggested genius; even at the age of 9 he did not speak clearly, and his parents feared that he might be handicapped. When asked what profession Einstein should follow, his school principal replied, "It doesn't matter; he'll never make a success of anything." When he was 10, Einstein entered the Luitpold Gymnasium (high school), which was typical of German schools of that time in being harshly disciplinarian. There he developed a deep suspicion of authority and a skepticism that encouraged him to question and doubt-valuable qualities in a scientist. In 1905, while a patent clerk in Switzerland, Einstein published a paper explaining the photoelectric effect via the quantum theory. For this revolutionary thinking, he received a Nobel Prize in 1921. Highly regarded by this time, he worked in Germany until 1933, when Hitler's persecution of the Jews forced him to come to the United States. He worked at the Institute for Advanced Studies in Princeton, New Jersey, until his death in 1955.

Einstein was undoubtedly the greatest physicist of our age. Even if someone else had derived the theory of relativity, his other work would have ensured his ranking as the second greatest physicist of his time. Our concepts of space and time were radically changed by ideas he first proposed when he was 26 years old. From then until the end of his life, he attempted unsuccessfully to find a single unifying theory that would explain all physical events.

## CHEMICAL CONNECTIONS

## Fireworks

The art of using mixtures of chemicals to produce explosives is an ancient one. Black powder-a mixture of potassium nitrate, charcoal, and sulfur-was being used in China well before 1000 A.D. and has been used subsequently through the centuries in military explosives, in construction blasting, and for fireworks. The du Pont Company, now a major chemical manufacturer, started out as a manufacturer of black powder. In fact, the founder, Eleuthère du Pont, learned the manufacturing technique from none other than Lavoisier.

Before the nineteenth century, fireworks were confined mainly to rockets and loud bangs. Orange and yellow colors came from the presence of charcoal and iron filings. However, with the great advances in chemistry in the nineteenth century, new compounds found their way into fireworks. Salts of copper, strontium, and barium added brilliant colors. Magnesium and aluminum metals gave a dazzling white light. Fireworks, in fact, have changed very little since then.

How do fireworks produce their brilliant colors and loud bangs? Actually, only a handful of different chemicals are responsible for most of the spectacular effects. To produce the noise and flashes, an oxidizer (an oxidizing agent) and a fuel (a reducing agent) are used. A common mixture involves potassium perchlorate $\left(\mathrm{KClO}_{4}\right)$ as the oxidizer and aluminum and sulfur as the fuel. The perchlorate oxidizes the fuel in a very

exothermic reaction, which produces a brilliant flash, due to the aluminum, and a loud report from the rapidly expanding gases produced. For a color effect, an element with a colored emission spectrum is included. Recall that the electrons in atoms can be raised to higher-energy orbitals when the atoms absorb energy. The excited atoms can then release this excess energy by emitting light of specific wavelengths, often in the visible region. In fireworks, the energy to excite the electrons comes from the reaction between the oxidizer and fuel.

Yellow colors in fireworks are due to the $589-\mathrm{nm}$ emission of sodium ions. Red colors come from strontium salts

A typical aerial shell used in fireworks displays. Time-delayed fuses cause a shell to explode in stages. In this case a red starburst occurs first, followed by a blue starburst, and finally a flash and loud report.
emitting at 606 nm and from 636 to 688 nm . This red color is familiar from highway safety flares. Barium salts give a green color in fireworks, due to a series of emission lines between 505 and 535 nm . A really good blue color, however, is hard to obtain. Copper salts give a blue color, emitting in the 420- to $460-\mathrm{nm}$ region. But difficulties occur because the oxidizing agent, potassium chlorate $\left(\mathrm{KClO}_{3}\right)$, reacts with copper salts to form copper chlorate, a highly explosive compound that is dangerous to store. (The use of $\mathrm{KClO}_{3}$ in fireworks has been largely abandoned because
phenomenon in which electrons are emitted from the surface of a metal when light strikes it. The following observations characterize the photoelectric effect.

1. Studies in which the frequency of the light is varied show that no electrons are emitted by a given metal below a specific threshold frequency, $\nu_{0}$.
2. For light with frequency lower than the threshold frequency, no electrons are emitted regardless of the intensity of the light.
3. For light with frequency greater than the threshold frequency, the number of electrons emitted increases with the intensity of the light.
of its explosive hazards.) Paris green, a copper salt containing arsenic, was once used extensively but is now considered to be too toxic.

In recent years the colors produced by fireworks have become more intense because of the formation of metal chlorides during the burning process. These gaseous metal chloride molecules produce colors much more brilliant than do the metal atoms by themselves. For example, strontium chloride produces a much brighter red than do strontium atoms. Thus, chlorine-donating compounds are now included in many fireworks shells.

A typical aerial shell is shown in the diagram. The shell is launched from a mortar (a steel cylinder) using black powder as the propellant. Time-delayed fuses are used to fire the shell in stages. A list of chemicals commonly used in fireworks is given in the table.

Although you might think that the chemistry of fireworks is simple, the achievement of the vivid white flashes
and the brilliant colors requires complex combinations of chemicals. For example, because the white flashes produce high flame temperatures, the colors tend to wash out. Thus oxidizers such as $\mathrm{KClO}_{4}$ are commonly used with fuels that produce relatively low flame temperatures. An added difficulty, however, is that perchlorates are very sensitive to accidental ignition and are therefore quite hazardous. Another problem arises from the use of sodium salts. Because sodium produces an extremely bright yellow emission, sodium salts cannot be used when other colors are desired. Carbon-based fuels also give a yellow flame that masks other colors, and this limits the use of organic compounds as fuels. You can see that the manufacture of fireworks that produce the desired effects and are also safe to handle requires careful selection of chemicals. And, of course, there is still the dream of a deep blue flame.

Fireworks in Washington, D.C.

Chemicals Commonly Used in the Manufacture of Fireworks

| Oxidizers | Fuels | Special Effects |
| :--- | :--- | :--- |
| Potassium nitrate | Aluminum | Red flame: strontium nitrate, strontium carbonate |
| Potassium chlorate | Magnesium | Green flame: barium nitrate, barium chlorate |
| Potassium perchlorate | Titanium | Blue flame: copper carbonate, copper sulfate, copper oxide |
| Ammonium perchlorate | Charcoal | Yellow flame: sodium oxalate, cryolite $\left(\mathrm{Na}_{3} \mathrm{AlF}_{6}\right)$ |
| Barium nitrate | Sulfur | White flame: magnesium, aluminum |
| Barium chlorate | Antimony sulfide | Gold sparks: iron filings, charcoal |
| Strontium nitrate | Dextrin | White sparks: aluminum, magnesium, aluminum-magnesium alloy, titanium |
|  | Red gum | Whistle effect: potassium benzoate or sodium salicylate |
|  | Polyvinyl chloride | White smoke: mixture of potassium nitrate and sulfur |
|  |  | Colored smoke: mixture of potassium chlorate, sulfur, and organic dye |

4. For light with frequency greater than the threshold frequency, the kinetic energy of the emitted electrons increases linearly with the frequency of the light.

These observations can be explained by assuming that electromagnetic radiation is quantized (consists of photons), and that the threshold frequency represents the minimum energy required to remove the electron from the metal's surface.

Minimum energy required to remove an electron $=E_{0}=h \nu_{0}$

a
 b
FIGURE 7.4 The photoelectric effect. (a) Light with frequency less than the threshold frequency produces no electrons. (b) Light with frequency higher than the threshold frequency causes electrons to be emitted from the metal.

Note that the apparent mass of a photon depends on its wavelength. A photon does not have mass in a classical sense.

Light as a wave phenomenon

Light as a stream of photons

FIGURE 7.5 Electromagnetic radiation exhibits wave properties and particulate properties. The energy of each photon of the radiation is related to the wavelength and frequency by the equation $E_{\text {photon }}=h \nu=h c / \lambda$.

Because a photon with energy less than $E_{0}\left(\nu<\nu_{0}\right)$ cannot remove an electron, light with a frequency less than the threshold frequency produces no electrons (Fig. 7.4). On the other hand, for light where $\nu>\nu_{0}$, the energy in excess of that required to remove the electron is given to the electron as kinetic energy (KE):

$$
\mathrm{KE}_{\text {electron }}=\begin{aligned}
& \begin{array}{r}
\text { Velocity } \\
\text { of } \\
\text { electron } \\
\downarrow
\end{array} \begin{array}{l}
\text { Energy } \\
\text { of incident } \\
\text { photon } \\
\downarrow \\
\downarrow
\end{array} \\
& \begin{array}{c}
\text { Mass } \\
\text { of } \\
\text { electron }
\end{array} h \nu-h \nu_{0} \\
& \text { energy required to } \\
& \text { remove electron from } \\
& \text { metal's surface }
\end{aligned}
$$

Because in this picture the intensity of light is a measure of the number of photons present in a given part of the beam, a greater intensity means that more photons are available to release electrons (as long as $\nu>\nu_{0}$ for the radiation).

In a related development, Einstein derived the famous equation

$$
E=m c^{2}
$$

in his special theory of relativity published in 1905. The main significance of this equation is that energy has mass. This is more apparent if we rearrange the equation in the following form:

$$
\begin{aligned}
\underset{\uparrow}{m}= & \frac{E}{c^{2}} \leftarrow \text { Energy } \\
\text { Mass } \uparrow & \\
& \text { Speed of light }
\end{aligned}
$$

Using this form of the equation, we can calculate the mass associated with a given quantity of energy. For example, we can calculate the apparent mass of a photon. For electromagnetic radiation of wavelength $\lambda$, the energy of each photon is given by the expression

$$
E_{\text {photon }}=\frac{h c}{\lambda}
$$

Then the apparent mass of a photon of light with wavelength $\lambda$ is given by

$$
m=\frac{E}{c^{2}}=\frac{h c / \lambda}{c^{2}}=\frac{h}{\lambda c}
$$

The photon behaves as if it has mass under certain circumstances. In 1922 American physicist Arthur Compton (1892-1962) performed experiments involving collisions of X rays and electrons that showed that photons do exhibit the apparent mass calculated from the preceding equation. However, it is clear that photons do not have mass in the classical sense. A photon has mass only in a relativistic sense-it has no rest mass.

We can summarize the important conclusions from the work of Planck and Einstein as follows:

Energy is quantized. It can occur only in discrete units called quanta.
Electromagnetic radiation, which was previously thought to exhibit only wave properties, seems to show certain characteristics of particulate matter as well. This phenomenon is sometimes referred to as the dual nature of light (Fig. 7.5).
Thus light, which previously was thought to be purely wavelike, was found to have certain characteristics of particulate matter. But is the opposite also true? That is, does matter that is normally assumed to be particulate exhibit wave properties? This question was raised in 1923 by a young French physicist named Louis de Broglie (1892-1987). To see how de Broglie supplied the answer to this question, recall that the relationship

Do not confuse $\nu$ (frequency) with $v$ (velocity).
between mass and wavelength for electromagnetic radiation is $m=h / \lambda c$. For a particle with velocity $v$, the corresponding expression is

$$
m=\frac{h}{\lambda v}
$$

Rearranging to solve for $\lambda$, we have

$$
\lambda=\frac{h}{m v}
$$

This equation, called de Broglie's equation, allows us to calculate the wavelength for a particle, as shown in Example 7.3.

## INTERACTIVE EXAMPLE 7.3 Calculations of Wavelength

Compare the wavelength for an electron (mass $=9.11 \times 10^{-31} \mathrm{~kg}$ ) traveling at a speed of $1.0 \times 10^{7} \mathrm{~m} / \mathrm{s}$ with that for a ball (mass $=0.10 \mathrm{~kg}$ ) traveling at $35 \mathrm{~m} / \mathrm{s}$.

SOLUTION We use the equation $\lambda=h / m v$, where

$$
h=6.626 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s} \quad \text { or } \quad 6.626 \times 10^{-34} \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}
$$

since

$$
1 \mathrm{~J}=1 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2}
$$

For the electron,

$$
\lambda_{\mathrm{e}}=\frac{6.626 \times 10^{-34} \frac{\mathrm{~kg} \cdot \mathrm{mK} \cdot \mathrm{~m}}{8}}{\left(9.11 \times 10^{-31} \mathrm{~kg}\right)\left(1.0 \times 10^{7} \mathrm{~m} / 8\right)}=7.27 \times 10^{-11} \mathrm{~m}
$$

For the ball,

$$
\lambda_{\mathrm{b}}=\frac{6.626 \times 10^{-34} \frac{\mathrm{~kg} \cdot \mathrm{~m} \cdot \mathrm{~m}}{8}}{(0.10 \mathrm{~kg})(35 \mathrm{~m} / \mathrm{s})}=1.9 \times 10^{-34} \mathrm{~m}
$$

## See Exercises 7.59 through 7.62

Notice from Example 7.3 that the wavelength associated with the ball is incredibly short. On the other hand, the wavelength of the electron, although still quite small, happens to be on the same order as the spacing between the atoms in a typical crystal. This is important because, as we will see presently, it provides a means for testing de Broglie's equation.

Diffraction results when light is scattered from a regular array of points or lines. You may have noticed the diffraction of light from the ridges and grooves of a compact disc. The colors result because the various wavelengths of visible light are not all scattered in the same way. The colors are "separated," giving the same effect as light passing through a prism. Just as a regular arrangement of ridges and grooves produces diffraction, so does a regular array of atoms or ions in a crystal, as shown in Figure 7.6. For example, when X rays are directed onto a crystal of a particular nickel/titanium alloy, the scattered radiation produces a diffraction pattern of bright spots and dark areas on a photographic plate (Fig. 7.6). This occurs because the scattered light can interfere constructively (the peaks and troughs of the beams are in phase) to produce a bright area [Fig. 7.6(a)] or destructively (the peaks and troughs are out of phase) to produce a dark spot [Fig. 7.6(b)].

FIGURE 7.6 A diffraction pattern of a beryl crystal. (a) A light area results from constructive interference of the waves. (b) A dark area arises from destructive interference of the waves.

## Constructive interference

b

A diffraction pattern can be explained only in terms of waves. Thus, this phenomenon provides a test for the postulate that particles such as electrons have wavelengths. As we saw in Example 7.3, an electron with a velocity of $10^{7} \mathrm{~m} / \mathrm{s}$ (easily achieved by acceleration of the electron in an electric field) has a wavelength of about $10^{-10} \mathrm{~m}$, which is roughly the distance between the ions in a crystal such as sodium chloride. This is important because diffraction occurs most efficiently when the spacing between the scattering points is about the same as the wavelength of the wave being diffracted. Thus, if electrons really do have an associated wavelength, a crystal should diffract electrons. An experiment to test this idea was carried out in 1927 by C. J. Davisson and L. H. Germer at Bell Laboratories. When they directed a beam of electrons at a nickel crystal, they observed a diffraction pattern similar to that seen from the diffraction of X rays. This result verified de Broglie's relationship, at least for electrons. Larger chunks of matter, such as balls, have such small wavelengths (see Example 7.3) that they are impossible to verify experimentally. However, we believe that all matter obeys de Broglie's equation.

Now we have come full circle. Electromagnetic radiation, which at the turn of the twentieth century was thought to be a pure waveform, was found to possess particulate properties. Conversely, electrons, which were thought to be particles, were found to have a wavelength associated with them. The significance of these results is that matter and energy are not distinct. Energy is really a form of matter, and all matter shows the same types of properties. That is, all matter exhibits both particulate and wave properties. Large pieces of matter, such as baseballs, exhibit predominantly particulate properties. The associated wavelength is so small that it is not observed. Very small "bits of matter," such as photons, while showing some particulate properties, exhibit predominantly wave properties. Pieces of matter with intermediate mass, such as electrons, show clearly both the particulate and wave properties of matter.

### 7.3 The Atomic Spectrum of Hydrogen

As we saw in Chapter 2, key information about the atom came from several experiments carried out in the early twentieth century, in particular Thomson's discovery of the electron and Rutherford's discovery of the nucleus. Another important experiment was the study of the emission of light by excited hydrogen atoms. When a sample of

A
The line spectra of a number of gases. Each spectrum is unique and allows the identification of the elements.

FIGURE 7.7 (a) A continuous spectrum containing all wavelengths of visible light (indicated by the initial letters of the colors of the rainbow). (b) The hydrogen line spectrum contains only a few discrete wavelengths.
Spectrum adapted by permission from C. W. Keenan, D. C. Kleinfelter, and J. H. Wood, General College Chemistry, Sixth Edition (New York: Harper \& Row, 1980).

FIGURE 7.8 A change between two discrete energy levels emits a photon of light.
hydrogen gas receives a high-energy spark, the $\mathrm{H}_{2}$ molecules absorb energy, and some of the $\mathrm{H}-\mathrm{H}$ bonds are broken. The resulting hydrogen atoms are excited; that is, they contain excess energy, which they release by emitting light of various wavelengths to produce what is called the emission spectrum of the hydrogen atom.

To understand the significance of the hydrogen emission spectrum, we must first describe the continuous spectrum that results when white light is passed through a prism [Fig. 7.7(a)]. This spectrum, like the rainbow produced when sunlight is dispersed by raindrops, contains all the wavelengths of visible light. In contrast, when the hydrogen emission spectrum in the visible region is passed through a prism [Fig. 7.7(b)], we see only a few lines, each of which corresponds to a discrete wavelength. The hydrogen emission spectrum is called a line spectrum.

What is the significance of the line spectrum of hydrogen? It indicates that only certain energies are allowed for the electron in the hydrogen atom. In other words, the energy of the electron in the hydrogen atom is quantized. This observation ties in perfectly with the postulates of Max Planck discussed in Section 7.2. Changes in energy between discrete energy levels in hydrogen will produce only certain wavelengths of emitted light (Fig. 7.8). For example, a given change in energy from a high to a lower level would give a wavelength of light that can be calculated from Planck's equation:

$$
\Delta \dot{C}=h \nu=\frac{h c}{\lambda} \quad \begin{aligned}
& \text { Wavelength of } \\
& \text { Change in } \\
& \text { energy }
\end{aligned} \underset{\substack{\text { Frequency of } \\
\text { light emitted }}}{\text { light emitted }}
$$

The discrete line spectrum of hydrogen shows that only certain energies are possible; that is, the electron energy levels are quantized. In contrast, if any energy level were allowed, the emission spectrum would be continuous.
 -a

## 

 energy levels in the atoms are quantized. Some of this evidence is discussed in this chapter. What if energy levels in atoms were not quantized? What are some differences we would notice?
### 7.4 The Bohr Model

The J in Equation (7.1) stands for joules.
In 1913, a Danish physicist named Niels Bohr (1885-1962), aware of the experimental results we have just discussed, developed a quantum model for the hydrogen atom. Bohr proposed that the electron in a hydrogen atom moves around the nucleus only in certain allowed circular orbits. He calculated the radii for these allowed orbits by using the theories of classical physics and by making some new assumptions.

From classical physics Bohr knew that a particle in motion tends to move in a straight line and can be made to travel in a circle only by application of a force toward the center of the circle. Thus Bohr reasoned that the tendency of the revolving electron to fly off the atom must be just balanced by its attraction for the positively charged nucleus. But classical physics also decreed that a charged particle under acceleration should radiate energy. Since an electron revolving around the nucleus constantly changes its direction, it is constantly accelerating. Therefore, the electron should emit light and lose energy-and thus be drawn into the nucleus. This, of course, does not correlate with the existence of stable atoms.

Clearly, an atomic model based solely on the theories of classical physics was untenable. Bohr also knew that the correct model had to account for the experimental spectrum of hydrogen, which showed that only certain electron energies were allowed. The experimental data were absolutely clear on this point. Bohr found that his model would fit the experimental results if he assumed that the angular momentum of the electron (angular momentum equals the product of mass, velocity, and orbital radius) could occur only in certain increments. It was not clear why this should be true, but with this assumption, Bohr's model gave hydrogen atom energy levels consistent with the hydrogen emission spectrum. The model is represented pictorially in Fig. 7.9.

Although we will not show the derivation here, the most important equation to come from Bohr's model is the expression for the energy levels available to the electron in the hydrogen atom:

$$
\begin{equation*}
E=-2.178 \times 10^{-18} \mathrm{~J}\left(\frac{Z^{2}}{n^{2}}\right) \tag{7.1}
\end{equation*}
$$

in which $n$ is an integer (the larger the value of $n$, the larger the orbit radius) and $Z$ is the nuclear charge. Using Equation (7.1), Bohr was able to calculate hydrogen atom energy levels that exactly matched the values obtained by experiment.

The negative sign in Equation (7.1) simply means that the energy of the electron bound to the nucleus is lower than it would be if the electron were at an infinite distance $(n=\infty)$ from the nucleus, where there is no interaction and the energy is zero:

$$
E=-2.178 \times 10^{-18} \mathrm{~J}\left(\frac{Z^{2}}{\infty}\right)=0
$$

The energy of the electron in any orbit is negative relative to this reference state.
Equation (7.1) can be used to calculate the change in energy of an electron when the electron changes orbits. For example, suppose an electron in level $n=6$ of an excited hydrogen atom falls back to level $n=1$ as the hydrogen atom returns to its lowest possible energy state, its ground state. We use Equation (7.1) with $Z=1$, since the

FIGURE 7.9 Electronic transitions in the Bohr model for the hydrogen atom. (a) An energy-level diagram for electronic transitions. (b) An orbit-transition diagram, which accounts for the experimental spectrum. (Note that the orbits shown are schematic. They are not drawn to scale.) (c) The resulting line spectrum on a photographic plate is shown. Note that the lines in the visible region of the spectrum correspond to transitions from higher levels to the $n=2$ level.

-
Niels Hendrik David Bohr (1885-1962) as a boy lived in the shadow of his younger brother Harald, who played on the 1908 Danish Olympic Soccer Team and later became a distinguished mathematician. In school, Bohr received his poorest marks in composition and struggled with writing during his entire life. In fact, he wrote so poorly that he was forced to dictate his Ph.D. thesis to his mother. Nevertheless, Bohr was a brilliant physicist. After receiving his Ph.D. in Denmark, he constructed a quantum model for the hydrogen atom by the time he was 27 . Even though his model later proved to be incorrect, Bohr remained a central figure in the drive to understand the atom. He was awarded the Nobel Prize in physics in 1922.

hydrogen nucleus contains a single proton. The energies corresponding to the two states are as follows:

$$
\begin{array}{ll}
\text { For } n=6: & E_{6}=-2.178 \times 10^{-18} \mathrm{~J}\left(\frac{1^{2}}{6^{2}}\right)=-6.050 \times 10^{-20} \mathrm{~J} \\
\text { For } n=1: & E_{1}=-2.178 \times 10^{-18} \mathrm{~J}\left(\frac{1^{2}}{1^{2}}\right)=-2.178 \times 10^{-18} \mathrm{~J}
\end{array}
$$

Note that for $n=1$ the electron has a more negative energy than it does for $n=6$, which means that the electron is more tightly bound in the smallest allowed orbit.

The change in energy, $\Delta E$, when the electron falls from $n=6$ to $n=1$ is

$$
\begin{aligned}
\Delta E & =\text { energy of final state }- \text { energy of initial state } \\
& =E_{1}-E_{6}=\left(-2.178 \times 10^{-18} \mathrm{~J}\right)-\left(-6.050 \times 10^{-20} \mathrm{~J}\right) \\
& =-2.117 \times 10^{-18} \mathrm{~J}
\end{aligned}
$$

The negative sign for the change in energy indicates that the atom has lost energy and is now in a more stable state. The energy is carried away from the atom by the production (emission) of a photon.

The wavelength of the emitted photon can be calculated from the equation

$$
\Delta E=h\left(\frac{c}{\lambda}\right) \quad \text { or } \quad \lambda=\frac{h c}{\Delta E}
$$

where $\Delta E$ represents the change in energy of the atom, which equals the energy of the emitted photon. We have

$$
\lambda=\frac{h c}{\Delta E}=\frac{\left(6.626 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}\right)\left(2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)}{2.117 \times 10^{-18} \mathrm{~J}}=9.383 \times 10^{-8} \mathrm{~m}
$$

Note that for this calculation the absolute value of $\Delta E$ is used (we have not included the negative sign). In this case we indicate the direction of energy flow by saying that a photon of wavelength $9.383 \times 10^{-8} \mathrm{~m}$ has been emitted from the hydrogen atom. Simply plugging the negative value of $\Delta E$ into the equation would produce a negative value for $\lambda$, which is physically meaningless.

## INTERACTIVE EXAMPLE 7.4 Energy Quantization in Hydrogen

## SOLUTION

Note from Fig. 7.2 that the light required to produce the transition from the $n=1$ to $n=2$ level in hydrogen lies in the ultraviolet region.

Calculate the energy required to excite the hydrogen electron from level $n=1$ to level $n=2$. Also calculate the wavelength of light that must be absorbed by a hydrogen atom in its ground state to reach this excited state.*

Using Equation (7.1) with $Z=1$, we have

$$
\begin{gathered}
E_{1}=-2.178 \times 10^{-18} \mathrm{~J}\left(\frac{1^{2}}{1^{2}}\right)=-2.178 \times 10^{-18} \mathrm{~J} \\
E_{2}=-2.178 \times 10^{-18} \mathrm{~J}\left(\frac{1^{2}}{2^{2}}\right)=-5.445 \times 10^{-19} \mathrm{~J} \\
\Delta E=E_{2}-E_{1}=\left(-5.445 \times 10^{-19} \mathrm{~J}\right)-\left(-2.178 \times 10^{-18} \mathrm{~J}\right)=1.633 \times 10^{-18} \mathrm{~J}
\end{gathered}
$$

The positive value for $\Delta E$ indicates that the system has gained energy. The wavelength of light that must be absorbed to produce this change is

$$
\begin{aligned}
\lambda & =\frac{h c}{\Delta E}=\frac{\left(6.626 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}\right)\left(2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)}{1.633 \times 10^{-18} \mathrm{~J}} \\
& =1.216 \times 10^{-7} \mathrm{~m}
\end{aligned}
$$

## See Exercises 7.63 and 7.64

At this time we must emphasize two important points about the Bohr model:

1. The model correctly fits the quantized energy levels of the hydrogen atom and postulates only certain allowed circular orbits for the electron.
2. As the electron becomes more tightly bound, its energy becomes more negative relative to the zero-energy reference state (corresponding to the electron being at infinite distance from the nucleus). As the electron is brought closer to the nucleus, energy is released from the system.

Using Equation (7.1), we can derive a general equation for the electron moving from one level ( $n_{\text {initial }}$ ) to another level ( $n_{\text {final }}$ ):

$$
\begin{align*}
\Delta E & =\text { energy of level } n_{\text {final }}-\text { energy of level } n_{\text {initial }} \\
& =E_{\text {final }}-E_{\text {initial }} \\
& =\left(-2.178 \times 10^{-18} \mathrm{~J}\right)\left(\frac{1^{2}}{n_{\text {final }^{2}}}\right)-\left(-2.178 \times 10^{-18} \mathrm{~J}\right)\left(\frac{1^{2}}{n_{\text {initial }^{2}}}\right) \\
& =-2.178 \times 10^{-18} \mathrm{~J}\left(\frac{1}{n_{\text {final }^{2}}}-\frac{1}{n_{\text {initial }^{2}}}\right) \tag{7.2}
\end{align*}
$$

Equation (7.2) can be used to calculate the energy change between any two energy levels in a hydrogen atom, as shown in Example 7.5.

[^12]
## CHEMICAL CDNNECTIDNS

### 0.035 Femtometer Is a Big Deal

The long-accepted value for the radius of the proton is 0.8768 fm $\left(\mathrm{fm}=10^{-15} \mathrm{~m}\right)$. However, new experiments suggest that this value might be about $4 \%$ too large. This doesn't sound like much, but if proven correct it will raise havoc in the scientific community.

The possible problem with the currently accepted value of the proton radius results from work done by Randolf Pohl and his coworkers at the Max Planck Institute of Quantum Optics in Garching, Germany. These scientists created an exotic form of hydrogen in which they replaced the hydrogen electron by a muon. A muon is a particle that has the same charge as an electron but is 200 times more
massive than the electron. Because of its greater mass, the muon has orbitals with smaller average radii than those of an electron. The German team attempted to excite the muon to higher energy levels using laser pulses. They set their laser to detect muon transitions assuming the proton radius was in the range from 0.87 to 0.91 femtometers ( fm ), the value expected from current theories. After years of failing to see the expected energy transitions, the German scientists were within weeks of shutting down the experiment when they decided to assume a smaller value for the proton radius. They saw the expected transition when they tuned their laser at a
value corresponding to a proton radius of 0.84184 fm . Although this value doesn't seem too different from 0.8768 fm , it has tremendous implications. A change in the radius of the proton will affect the value of the charge density of the proton, a value that affects the values of all of the fundamental physical constants since all of these constants are interrelated. Thus, more experiments are needed to determine the correct value of the proton radius. If the new, smaller value proves to be correct, it has important implications for the fundamental theory (quantum electrodynamics) of matter. Perhaps this will lead to a better understanding of nature.

## EXAMPLE 7.5 Electron Energies

Calculate the energy required to remove the electron from a hydrogen atom in its ground state.
SOLUTION Removing the electron from a hydrogen atom in its ground state corresponds to taking the electron from $n_{\text {initial }}=1$ to $n_{\text {final }}=\infty$. Thus

$$
\begin{aligned}
\Delta E & =-2.178 \times 10^{-18} \mathrm{~J}\left(\frac{1}{n_{\text {final }}^{2}}-\frac{1}{n_{\text {initial }}{ }^{2}}\right) \\
& =-2.178 \times 10^{-18} \mathrm{~J}\left(\frac{1}{\infty}-\frac{1}{1^{2}}\right) \\
& =-2.178 \times 10^{-18} \mathrm{~J}(0-1)=2.178 \times 10^{-18} \mathrm{~J}
\end{aligned}
$$

The energy required to remove the electron from a hydrogen atom in its ground state is $2.178 \times 10^{-18} \mathrm{~J}$.

See Exercises 7.71 and 7.72
At first Bohr's model appeared to be very promising. The energy levels calculated by Bohr closely agreed with the values obtained from the hydrogen emission spectrum. However, when Bohr's model was applied to atoms other than hydrogen, it did not work at all. Although some attempts were made to adapt the model using elliptical orbits, it was concluded that Bohr's model is fundamentally incorrect. The model is, however, very important historically, because it showed that the observed quantization of energy in atoms could be explained by making rather simple assumptions. Bohr's

Although Bohr's model fits the energy levels for hydrogen, it is a fundamentally incorrect model for the hydrogen atom. model paved the way for later theories. It is important to realize, however, that the current theory of atomic structure is in no way derived from the Bohr model. Electrons do not move around the nucleus in circular orbits, as we shall see later in this chapter.

### 7.5 The Quantum Mechanical Model of the Atom

Unplucked string

1 half-wavelength

2 half-wavelengths

FIGURE 7.10 The standing waves caused by the vibration of a guitar string fastened at both ends. Each dot represents a node (a point of zero displacement).

By the mid-1920s it had become apparent that the Bohr model could not be made to work. A totally new approach was needed. Three physicists were at the forefront of this effort: Werner Heisenberg (1901-1976), Louis de Broglie (1892-1987), and Erwin Schrödinger (1887-1961). The approach they developed became known as wave mechanics or, more commonly, quantum mechanics. As we have already seen, de Broglie originated the idea that the electron, previously considered to be a particle, also shows wave properties. Pursuing this line of reasoning, Schrödinger, an Austrian physicist, decided to attack the problem of atomic structure by giving emphasis to the wave properties of the electron. To Schrödinger and de Broglie, the electron bound to the nucleus seemed similar to a standing wave, and they began research on a wave mechanical description of the atom.

The most familiar example of standing waves occurs in association with musical instruments such as guitars or violins, where a string attached at both ends vibrates to produce a musical tone. The waves are described as "standing" because they are stationary; the waves do not travel along the length of the string. The motions of the string can be explained as a combination of simple waves of the type shown in Fig. 7.10. The dots in this figure indicate the nodes, or points of zero lateral (sideways) displacement, for a given wave. Note that there are limitations on the allowed wavelengths of the standing wave. Each end of the string is fixed, so there is always a node at each end. This means that there must be a whole number of half wavelengths in any of the allowed motions of the string (see Fig. 7.10). Standing waves can be illustrated using the wave generator shown in the photo.

A similar situation results when the electron in the hydrogen atom is imagined to be a standing wave. As shown in Fig. 7.11, only certain circular orbits have a circumference into which a whole number of wavelengths of the standing electron wave will "fit." All other orbits would produce destructive interference of the standing electron wave and are not allowed. This seemed like a possible explanation for the observed quantization of the hydrogen atom, so Schrödinger worked out a model for the hydrogen atom in which the electron was assumed to behave as a standing wave.

It is important to recognize that Schrödinger could not be sure that this idea would work. The test had to be whether or not the model would correctly fit the experimental data on hydrogen and other atoms. The physical principles for describing standing waves were well known in 1925 when Schrödinger decided to treat the electron in this way. His mathematical treatment is too complicated to be detailed here. However, the form of Schrödinger's equation is

$$
\hat{H} \psi=E \psi
$$

where $\psi$, called the wave function, is a function of the coordinates ( $x, y$, and $z$ ) of the electron's position in three-dimensional space and $\hat{H}$ represents a set of mathematical instructions called an operator. In this case, the operator contains mathematical terms that produce the total energy of the atom when they are applied to the wave function. $E$ represents the total energy of the atom (the sum of the potential energy due to the attraction between the proton and electron and the kinetic energy of the moving electron). When this equation is analyzed, many solutions are found.

a

$-\mathrm{b}$

## c

FIGURE 7.11 The hydrogen electron visualized as a standing wave around the nucleus. The circumference of a particular circular orbit would have to correspond to a whole number of wavelengths, as shown in (a) and (b), or else destructive interference occurs, as shown in (c). This is consistent with the fact that only certain electron energies are allowed; the atom is quantized. (Although this idea encouraged scientists to use a wave theory, it does not mean that the electron really travels in circular orbits.)

## Probability is the likelihood, or odds, that

 something will occur.Each solution consists of a wave function, $\psi$, that is characterized by a particular value of $E$. A specific wave function is often called an orbital.

To illustrate the most important ideas of the quantum (wave) mechanical model of the atom, we will first concentrate on the wave function corresponding to the lowest energy for the hydrogen atom. This wave function is called the $1 s$ orbital. The first point of interest is to explore the meaning of the word orbital. As we will see, this is not a trivial matter. One thing is clear: An orbital is not a Bohr orbit. The electron in the hydrogen $1 s$ orbital is not moving around the nucleus in a circular orbit. How, then, is the electron moving? The answer is quite surprising: We do not know. The wave function gives us no information about the detailed pathway of the electron. This is somewhat disturbing. When we solve problems involving the motions of particles in the macroscopic world, we are able to predict their pathways. For example, when two billiard balls with known velocities collide, we can predict their motions after the collision. However, we cannot predict the electron's motion from the $1 s$ orbital function. Does this mean that the theory is wrong? Not necessarily: We have already learned that an electron does not behave much like a billiard ball, so we must examine the situation closely before we discard the theory.

To help us understand the nature of an orbital, we need to consider a principle discovered by Werner Heisenberg, one of the primary developers of quantum mechanics. Heisenberg's mathematical analysis led him to a surprising conclusion: There is a fundamental limitation to just how precisely we can know both the position and momentum of a particle at a given time. This is a statement of the Heisenberg uncertainty principle. Stated mathematically, the uncertainty principle is

$$
\Delta x \cdot \Delta(m v) \geq \frac{h}{4 \pi}
$$

where $\Delta x$ is the uncertainty in a particle's position, $\Delta(m v)$ is the uncertainty in a particle's momentum, and $h$ is Planck's constant. Thus the minimum uncertainty in the product $\Delta x \cdot \Delta(m v)$ is $h / 4 \pi$. What this equation really says is that the more accurately we know a particle's position, the less accurately we can know its momentum, and vice versa. This limitation is so small for large particles such as baseballs or billiard balls that it is unnoticed. However, for a small particle such as the electron, the limitation becomes quite important. Applied to the electron, the uncertainty principle implies that we cannot know the exact motion of the electron as it moves around the nucleus. It is therefore not appropriate to assume that the electron is moving around the nucleus in a well-defined orbit, as in the Bohr model.

## The Physical Meaning of a Wave Function

Given the limitations indicated by the uncertainty principle, what then is the physical meaning of a wave function for an electron? That is, what is an atomic orbital? Although the wave function itself has no easily visualized meaning, the square of the function does have a definite physical significance. The square of the function indicates the probability of finding an electron near a particular point in space. For example, suppose we have two positions in space, one defined by the coordinates $x_{1}, y_{1}$, and $z_{1}$ and the other by the coordinates $x_{2}, y_{2}$, and $z_{2}$. The relative probability of finding the electron at positions 1 and 2 is given by substituting the values of $x, y$, and $z$ for the two positions into the wave function, squaring the function value, and computing the following ratio:

$$
\frac{\left[\psi\left(x_{1}, y_{1}, z_{1}\right)\right]^{2}}{\left[\psi\left(x_{2}, y_{2}, z_{2}\right)\right]^{2}}=\frac{N_{1}}{N_{2}}
$$

The quotient $N_{1} / N_{2}$ is the ratio of the probabilities of finding the electron at positions 1 and 2. For example, if the value of the ratio $N_{1} / N_{2}$ is 100 , the electron is 100 times more likely to be found at position 1 than at position 2 . The model gives no information concerning when the electron will be at either position or how it moves between
a

$1 \AA=10^{-10} \mathrm{~m}$; the angstrom is most often used as the unit for atomic radius because of its convenient size. Another convenient unit is the picometer:

$$
1 \mathrm{pm}=10^{-12} \mathrm{~m}
$$

FIGURE 7.13 (a) Cross section of the hydrogen $1 s$ orbital probability distribution divided into successive thin spherical shells. (b) The radial probability distribution. A plot of the total probability of finding the electron in each thin spherical shell as a function of distance from the nucleus.
the positions. This vagueness is consistent with the concept of the Heisenberg uncertainty principle.

The square of the wave function is most conveniently represented as a probability distribution, in which the intensity of color is used to indicate the probability value near a given point in space. The probability distribution for the hydrogen $1 s$ wave function (orbital) is shown in Fig. 7.12(a). The best way to think about this diagram is as a three-dimensional time exposure with the electron as a tiny moving light. The more times the electron visits a particular point, the darker the negative becomes. Thus the darkness of a point indicates the probability of finding an electron at that position. This diagram is also known as an electron density map; electron density and electron probability mean the same thing. When a chemist uses the term atomic orbital, he or she is probably picturing an electron density map of this type.

Another way of representing the electron probability distribution for the $1 s$ wave function is to calculate the probability at points along a line drawn outward in any direction from the nucleus. The result is shown in Fig. 7.12(b). Note that the probability of finding the electron at a particular position is greatest close to the nucleus and drops off rapidly as the distance from the nucleus increases. We are also interested in knowing the total probability of finding the electron in the hydrogen atom at a particular distance from the nucleus. Imagine that the space around the hydrogen nucleus is made up of a series of thin, spherical shells (rather like layers in an onion), as shown in Fig. 7.13(a). When the total probability of finding the electron in each spherical shell is plotted versus the distance from the nucleus, the plot in Fig. 7.13(b) is obtained. This graph is called the radial probability distribution.

The maximum in the curve occurs because of two opposing effects. The probability of finding an electron at a particular position is greatest near the nucleus, but the volume of the spherical shell increases with distance from the nucleus. Therefore, as we move away from the nucleus, the probability of finding the electron at a given position decreases, but we are summing more positions. Thus the total probability increases to a certain radius and then decreases as the electron probability at each position becomes very small. For the hydrogen $1 s$ orbital, the maximum radial probability (the distance at which the electron is most likely to be found) occurs at a distance of $5.29 \times 10^{-2} \mathrm{~nm}$ or $0.529 \AA$ from the nucleus. Interestingly, this is exactly the radius of the innermost orbit in the Bohr model. Note that in Bohr's model the electron is assumed to have a circular path and so is always found at this distance. In the quantum mechanical model, the specific electron motions are unknown, and this is the most probable distance at which the electron is found.

One more characteristic of the hydrogen $1 s$ orbital that we must consider is its size. As we can see from Fig. 7.12, the size of this orbital cannot be defined precisely, since the probability never becomes zero (although it drops to an extremely small value at large values of $r$ ). So, in fact, the hydrogen $1 s$ orbital has no distinct size. However, it is useful to have a definition of relative orbital size. The definition most often used by chemists to describe the size of the hydrogen 1s orbital is the radius of the sphere that encloses $90 \%$ of the total electron probability. That is, $90 \%$ of the time the electron is inside this sphere.

### 7.6 Quantum Numbers

When we solve the Schrödinger equation for the hydrogen atom, we find many wave functions (orbitals) that satisfy it. Each of these orbitals is characterized by a series of numbers called quantum numbers, which describe various properties of the orbital:

The principal quantum number $(n)$ has integral values: $1,2,3, \ldots$ The principal quantum number is related to the size and energy of the orbital. As $n$ increases, the orbital becomes larger and the electron spends more time farther from the nucleus. An increase in $n$ also means higher energy, because the electron is less tightly bound to the nucleus, and the energy is less negative.

The angular momentum quantum number $(\ell)$ has integral values from 0 to $n-1$ for each value of $n$. This quantum number is related to the shape of atomic orbitals. The value of $\ell$ for a particular orbital is commonly assigned a letter: $\ell=0$ is called $s ; \ell=1$ is called $p ; \ell=2$ is called $d ; \ell=3$ is called $f$. This system arises from early spectral studies and is summarized in Table 7.1.
The magnetic quantum number ( $m_{\ell}$ ) has integral values between $\ell$ and $-\ell$, including zero. The value of $m_{\ell}$ is related to the orientation of the orbital in space relative to the other orbitals in the atom.

The first four levels of orbitals in the hydrogen atom are listed with their quantum numbers in Table 7.2. Note that each set of orbitals with a given value of $\ell$ (sometimes called a subshell) is designated by giving the value of $n$ and the letter for $\ell$. Thus an orbital where $n=2$ and $\ell=1$ is symbolized as $2 p$. There are three $2 p$ orbitals, which have different orientations in space. We will describe these orbitals in the next section.

TABLE 7.2 | Quantum Numbers for the First Four Levels of Orbitals in the Hydrogen Atom

| $n$ | $\ell$ | Sublevel <br> Designation | $m_{\ell}$ | Number of <br> Orbitals |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 0 | $1 s$ | 0 | 1 |
| 2 | 0 | $2 s$ | 0 | 1 |
|  | 1 | $2 p$ | $-1,0,+1$ | 3 |
| 3 | 0 | $3 s$ | 0 | 1 |
|  | 1 | $3 p$ | $-1,0,1$ | 3 |
|  | 2 | $3 d$ | $-2,-1,0,1,2$ | 5 |
| 4 | 0 | $4 s$ | 0 | 1 |
|  | 1 | $4 p$ | $-1,0,1$ | 3 |
|  | 2 | $4 d$ | $-2,-1,0,1,2$ | 5 |
|  | $3 f$ | $-3,-2,-1,0,1,2,3$ | 7 |  |

## INTERACTIVE EXAMPLE 7.6 Electron Subshells

SOLUTION For $n=5$, the allowed values of $\ell$ run from 0 to $4(n-1=5-1)$. Thus, the subshells and their designations are

| $\ell=0$ | $\ell=1$ | $\ell=2$ | $\ell=3$ | $\ell=4$ |
| :---: | :---: | :---: | :---: | :---: |
| $5 s$ | $5 p$ | $5 d$ | $5 f$ | $5 g$ |

See Exercises 7.77 and 7.79

### 7.1 Orbital Shapes and Energies

We have seen that the meaning of an orbital is represented most clearly by a probability distribution. Each orbital in the hydrogen atom has a unique probability distribution. We also saw that another means of representing an orbital is by the surface that surrounds $90 \%$ of the total electron probability. These three types of representations for the hydrogen $1 s, 2 s$, and $3 s$ orbitals are shown in Fig. 7.14. Note the characteristic spherical shape of each of the $s$ orbitals. Note also that the $2 s$ and $3 s$ orbitals contain areas of high probability separated by areas of zero probability. These latter areas are called nodal surfaces, or simply nodes. The number of nodes increases as $n$ increases.

Note that the signs inside the surface indicate the phases (signs) of the orbital in that region of space.

## $n$ value <br> $2 p_{x} \leftarrow$ orientation in space <br> $\ell$ value

For $s$ orbitals, the number of nodes is given by $n-1$. For our purposes, however, we will think of $s$ orbitals only in terms of their overall spherical shape, which becomes larger as the value of $n$ increases.

The two types of representations for the $2 p$ orbitals (there are no $1 p$ orbitals) are shown in Fig. 7.15. Note that the $p$ orbitals are not spherical like $s$ orbitals but have two lobes separated by a node at the nucleus. The $p$ orbitals are labeled according to the axis of the $x y z$ coordinate system along which the lobes lie. For example, the $2 p$ orbital with lobes centered along the $x$ axis is called the $2 p_{x}$ orbital.

At this point it is useful to remember that mathematical functions have signs. For example, a simple sine wave (see Fig. 7.1) oscillates from positive to negative and repeats this pattern. Atomic orbital functions also have signs. The functions for $s$ orbitals are positive everywhere in three-dimensional space. That is, when the $s$ orbital function is evaluated at any point in space, it results in a positive number. In contrast, the $p$ orbital functions have different signs in different regions of space. For example, the $p_{z}$ orbital has a positive sign in all the regions of space in which $z$ is positive and has a negative sign when $z$ is negative. This behavior is indicated in Fig. 7.15(b) by the positive and negative signs inside their boundary surfaces. It is important to understand that these are mathematical signs, not charges. Just as a sine wave has alternating positive and negative phases, so too $p$ orbitals have positive and negative phases. The phases of the $p_{x}, p_{y}$, and $p_{z}$ orbitals are indicated in Fig. 7.15(b).

As you might expect from our discussion of the $s$ orbitals, the $3 p$ orbitals have a more complex probability distribution than that of the $2 p$ orbitals (Fig. 7.16), but they can still be represented by the same boundary surface shapes. The surfaces just grow larger as the value of $n$ increases.

There are no $d$ orbitals that correspond to principal quantum levels $n=1$ and $n=2$. The $d$ orbitals $(\ell=2)$ first occur in level $n=3$. The five $3 d$ orbitals have the shapes shown in Fig. 7.17. The $d$ orbitals have two different fundamental shapes. Four of the orbitals ( $d_{x z}, d_{y z}, d_{x y}$, and $d_{x^{2}-y^{2}}$ ) have four lobes centered in the plane indicated in the orbital label. Note that $d_{x y}$ and $d_{x^{2}-y^{2}}$ are both centered in the $x y$ plane; however, the lobes of $d_{x^{2}-y^{2}}$ lie along the $x$ and $y$ axes, while the lobes of $d_{x y}$ lie between the axes. The fifth orbital, $d_{z^{2}}$, has a unique shape with two lobes along the $z$ axis and a belt centered in the $x y$ plane. The $d$ orbitals for levels $n>3$ look like the $3 d$ orbitals but have larger lobes.

The $f$ orbitals first occur in level $n=4$, and as might be expected, they have shapes even more complex than those of the $d$ orbitals. Figure 7.18 shows representations of the $4 f$ orbitals $(\ell=3)$ along with their designations. These orbitals are not involved in the bonding in any of the compounds we will consider in this text. Their shapes and labels are simply included for completeness.

FIGURE 7.18 Representation of the $4 f$ orbitals in terms of their boundary surfaces.

So far we have talked about the shapes of the hydrogen atomic orbitals but not about their energies. For the hydrogen atom, the energy of a particular orbital is determined by its value of $n$. Thus all orbitals with the same value of $n$ have the same energy -they are said to be degenerate. This is shown in Fig. 7.19, where the energies for the orbitals in the first three quantum levels for hydrogen are shown.

Hydrogen's single electron can occupy any of its atomic orbitals. However, in the lowest energy state, the ground state, the electron resides in the $1 s$ orbital. If energy is put into the atom, the electron can be transferred to a higher-energy orbital, producing an excited state.

$f_{x\left(z^{2}-y^{2}\right)}$

## LET'S REVIEW A Summary of the Hydrogen Atom

" In the quantum (wave) mechanical model, the electron is viewed as a standing wave. This representation leads to a series of wave functions (orbitals) that describe the possible energies and spatial distributions available to the electron.
» In agreement with the Heisenberg uncertainty principle, the model cannot specify the detailed electron motions. Instead, the square of the wave function represents the probability distribution of the electron in that orbital. This allows us to picture orbitals in terms of probability distributions, or electron density maps.
\# The size of an orbital is arbitrarily defined as the surface that contains $90 \%$ of the total electron probability.
" The hydrogen atom has many types of orbitals. In the ground state, the single electron resides in the $1 s$ orbital. The electron can be excited to higher-energy orbitals if energy is put into the atom.

### 7.8 Electron Spin and the Pauli Principle

The concept of electron spin was developed by Samuel Goudsmit and George Uhlenbeck while they were graduate students at the University of Leyden in the Netherlands. They found that a fourth quantum number (in addition to $n, \ell$, and $m_{\ell}$ ) was necessary to account for the details of the emission spectra of atoms. The spectral data indicate that the electron has a magnetic moment with two possible orientations when the atom is placed in an external magnetic field. Since they knew from classical physics that a spinning charge produces a magnetic moment, it seemed reasonable to assume that the electron could have two spin states, thus producing the two oppositely directed magnetic moments (Fig. 7.20). The new quantum number adopted to describe this phenomenon, called the electron spin quantum number $\left(m_{s}\right)$, can have only one of two values, $+\frac{1}{2}$ and $-\frac{1}{2}$. We can interpret this to mean that the electron can spin in one of two opposite directions, although other interpretations also have been suggested.

For our purposes, the main significance of electron spin is connected with the postulate of Austrian physicist Wolfgang Pauli (1900-1958): In a given atom no two electrons can have the same set of four quantum numbers $\left(\mathbf{n}, \ell, \mathrm{m}_{\ell}\right.$, and $\left.\mathrm{m}_{s}\right)$. This is called the Pauli exclusion principle. Since electrons in the same orbital have the same values of $n, \ell$, and $m_{\ell}$, this postulate says that they must have different values of $m_{s}$. Then, since only two values of $m_{s}$ are allowed, an orbital can hold only two electrons, and they must have opposite spins. This principle will have important consequences as we use the atomic model to account for the electron arrangements of the atoms in the periodic table.

FIGURE 7.20 A picture of the spinning electron. Spinning in one direction, the electron produces the magnetic field oriented as shown in (a). Spinning in the opposite direction, it gives a magnetic field of the opposite orientation, as shown in (b).

### 7.8 Polyelectronic Atoms

The quantum mechanical model gives a description of the hydrogen atom that agrees very well with experimental data. However, the model would not be very useful if it did not account for the properties of all the other atoms as well.

To see how the model applies to polyelectronic atoms, that is, atoms with more than one electron, let's consider helium, which has two protons in its nucleus and two electrons:

$$
2+\mathrm{e}^{-}
$$

Three energy contributions must be considered in the description of the helium atom: (1) the kinetic energy of the electrons as they move around the nucleus, (2) the potential energy of attraction between the nucleus and the electrons, and (3) the potential energy of repulsion between the two electrons.

Although the helium atom can be readily described in terms of the quantum mechanical model, the Schrödinger equation that results cannot be solved exactly. The difficulty arises in dealing with the repulsions between the electrons. Since the electron pathways are unknown, the electron repulsions cannot be calculated exactly. This is called the electron correlation problem.

The electron correlation problem occurs with all polyelectronic atoms. To treat these systems using the quantum mechanical model, we must make approximations. Most commonly, the approximation used is to treat each electron as if it were moving in a field of charge that is the net result of the nuclear attraction and the average repulsions of all the other electrons.

For example, consider the sodium atom, which has 11 electrons:

Now let's single out the outermost electron and consider the forces this electron feels. The electron clearly is attracted to the highly charged nucleus. However, the electron also feels the repulsions caused by the other 10 electrons. The net effect is that the electron is not bound nearly as tightly to the nucleus as it would be if the other electrons were not present. We say that the electron is screened or shielded from the nuclear charge by the repulsions of the other electrons.

This picture of polyelectronic atoms leads to hydrogen-like orbitals for these atoms. They have the same general shapes as the orbitals for hydrogen, but their sizes and energies are different. The differences occur because of the interplay between nuclear attraction and the electron repulsions.

One especially important difference between polyelectronic atoms and the hydrogen atom is that for hydrogen all the orbitals in a given principal quantum level have the same energy (they are said to be degenerate). This is not the case for polyelectronic atoms, where we find that for a given principal quantum level the orbitals vary in energy as follows:

$$
E_{n s}<E_{n p}<E_{n d}<E_{n f}
$$

In other words, when electrons are placed in a particular quantum level, they "prefer" the orbitals in the order $s, p, d$, and then $f$. Why does this happen? Although the concept of orbital energies is a complicated matter, we can qualitatively understand

Distance from nucleus
FIGURE 7.21 A comparison of the radial probability distributions of the $2 s$ and $2 p$ orbitals.
why the $2 s$ orbital has a lower energy than the $2 p$ orbital in a polyelectronic atom by looking at the probability profiles of these orbitals (Fig. 7.21). Notice that the $2 p$ orbital has its maximum probability closer to the nucleus than for the $2 s$. This might lead us to predict that the $2 p$ would be preferable (lower energy) to the $2 s$ orbital. However, notice the small hump of electron density that occurs in the $2 s$ profile very near the nucleus. This means that although an electron in the $2 s$ orbital spends most of its time a little farther from the nucleus than does an electron in the $2 p$ orbital, it spends a small but very significant amount of time very near the nucleus. We say that the $2 s$ electron penetrates to the nucleus more than once in the $2 p$ orbital. This penetration effect causes an electron in a $2 s$ orbital to be attracted to the nucleus more strongly than an electron in a $2 p$ orbital. That is, the $2 s$ orbital is lower in energy than the $2 p$ orbitals in a polyelectronic atom.

The same thing happens in the other principal quantum levels as well. Figure 7.22 shows the radial probability profiles for the $3 s, 3 p$, and $3 d$ orbitals. Note again the hump in the $3 s$ profile very near the nucleus. The innermost hump for the $3 p$ is farther out, which causes the energy of the $3 s$ orbital to be lower than that of the $3 p$. Notice that the $3 d$ orbital has its maximum probability closer to the nucleus than either the $3 s$ or $3 p$ does, but its absence of probability near the nucleus causes it to be highest in energy of the three orbitals. The relative energies of the orbitals for $n=3$ are

$$
E_{3 s}<E_{3 p}<E_{3 d}
$$

In general, the more effectively an orbital allows its electron to penetrate the shielding electrons to be close to the nuclear charge, the lower is the energy of that orbital.

A summary diagram of the orders of the orbital energies for polyelectronic atoms is represented in Fig. 7.23. We will use these orbitals in Section 7.11 to show how the electrons are arranged in polyelectronic atoms.
 would this affect the radial probability profiles as shown in Figs. 7.21 and 7.22?

FIGURE 7.22 (a) The radial probability distribution for an electron in a $3 s$ orbital. Although a 3 s electron is mostly found far from the nucleus, there is a small but significant probability (shown by the arrows) of its being found close to the nucleus. The $3 s$ electron penetrates the shield of inner electrons. (b) The radial probability distribution for the $3 s, 3 p$, and 3d orbitals. The arrows indicate that the $s$ orbital (red arrow) allows greater electron penetration than the $p$ orbital (yellow arrow) does; the $d$ orbital allows minimal electron penetration.

FIGURE 7.23 The orders of the energies of the orbitals in the first three levels of polyelectronic atoms.

### 7.10 The History of the Periodic Table

The modern periodic table contains a tremendous amount of useful information. In this section we will discuss the origin of this valuable tool; later we will see how the quantum mechanical model for the atom explains the periodicity of chemical properties. Certainly the greatest triumph of the quantum mechanical model is its ability to account for the arrangement of the elements in the periodic table.

The periodic table was originally constructed to represent the patterns observed in the chemical properties of the elements. As chemistry progressed during the eighteenth and nineteenth centuries, it became evident that the earth is composed of a great many elements with very different properties. Things are much more complicated than the simple model of earth, air, fire, and water suggested by the ancients. At first, the array of elements and properties was bewildering. Gradually, however, patterns were noticed.

The first chemist to recognize patterns was Johann Dobereiner (1780-1849), who found several groups of three elements that have similar properties, for example, chlorine, bromine, and iodine. However, as Dobereiner attempted to expand this model of triads (as he called them) to the rest of the known elements, it became clear that it was severely limited.

The next notable attempt was made by the English chemist John Newlands, who in 1864 suggested that elements should be arranged in octaves, based on the idea that certain properties seemed to repeat for every eighth element in a way similar to the musical scale, which repeats for every eighth tone. Even though this model managed to group several elements with similar properties, it was not generally successful.

The present form of the periodic table was conceived independently by two chemists: the German Julius Lothar Meyer (1830-1895) and Dmitri Ivanovich Mendeleev (1834-1907), a Russian (Fig. 7.24). Usually Mendeleev is given most of the credit, because it was he who emphasized how useful the table could be in predicting the existence and properties of still unknown elements. For example, in 1872 when Mendeleev first published his table (Fig. 7.25), the elements gallium, scandium, and germanium were unknown. Mendeleev correctly predicted the existence and properties of these elements from gaps in his periodic table. The data for germanium (which Mendeleev called ekasilicon) are shown in Table 7.3. Note the excellent agreement between the actual values and Mendeleev's predictions, which were based on the properties of other members in the group of elements similar to germanium.

Using his table, Mendeleev also was able to correct several values for atomic masses. For example, the original atomic mass of 76 for indium was based on the assumption that indium oxide had the formula InO. This atomic mass placed indium, which has metallic properties, among the nonmetals. Mendeleev assumed the atomic mass was probably incorrect and proposed that the formula of indium oxide was

FIGURE 7.24 Dmitri Ivanovich Mendeleev (1834-1907), born in Siberia as the youngest of 17 children, taught chemistry at the University of St. Petersburg. In 1860 Mendeleev heard the Italian chemist Cannizzaro lecture on a reliable method for determining the correct atomic masses of the elements. This important development paved the way for Mendeleev's own brilliant contribution to chemistry -the periodic table. In 1861 Mendeleev returned to St. Petersburg, where he wrote a book on organic chemistry. Later Mendeleev also wrote a book on inorganic chemistry, and he was struck by the fact that the systematic approach characterizing organic chemistry was lacking in inorganic chemistry. In attempting to systematize inorganic chemistry, he eventually arranged the elements in the form of the periodic table.

Mendeleev was a versatile genius who was interested in many fields of science. He worked on many problems associated with Russia's natural resources, such as coal, salt, and various metals. Being particularly interested in the petroleum industry, he visited the United States in 1876 to study the Pennsylvania oil fields. His interests also included meteorology and hot-air balloons. In 1887 he made an ascent in a balloon to study a total eclipse of the sun.

FIGURE 7.25 Mendeleev's early periodic table, published in 1872. Note the spaces left for missing elements with atomic masses $44,68,72$, and 100 .
(From Annalen der Chemie und Pharmacie, VIII, Supplementary Volume for 1872, page 511.)
really $\operatorname{In}_{2} \mathrm{O}_{3}$. Based on this correct formula, indium has an atomic mass of approximately 113 , placing the element among the metals. Mendeleev also corrected the atomic masses of beryllium and uranium.

Because of its obvious usefulness, Mendeleev's periodic table was almost universally adopted, and it remains one of the most valuable tools at the chemist's disposal. For example, it is still used to predict the properties of elements recently discovered, as shown in Table 7.4.

A current version of the periodic table is shown inside the front cover of this book. The only fundamental difference between this table and that of Mendeleev is that it lists the elements in order by atomic number rather than by atomic mass. The reason for this will become clear later in this chapter as we explore the electron arrangements of the atom. Another recent format of the table is discussed in the following section.

TABLE 7.3 | Comparison of the Properties of Germanium as Predicted by Mendeleev and as Actually Observed

| Properties of Germanium | Predicted <br> in 1871 | Observed <br> in 1886 |

### 7.11 The Aufbau Principle and the Periodic Table

```
Aufbau is German for "building up."
\(H(Z=1)\)
\(\mathrm{He}(Z=2)\)
\(\mathrm{Li}(Z=3)\)
\(\operatorname{Be}(Z=4)\)
B ( \(Z=5\) )
etc.
( \(Z=\) atomic number)
```

For an atom with unfilled subshells, the lowest energy is achieved by electrons occupying separate orbitals with parallel spins, as far as allowed by the Pauli exclusion principle.

We can use the quantum mechanical model of the atom to show how the electron arrangements in the hydrogen-like atomic orbitals of the various atoms account for the organization of the periodic table. Our main assumption here is that all atoms have the same type of orbitals as have been described for the hydrogen atom. As protons are added one by one to the nucleus to build up the elements, electrons are similarly added to these hydrogen-like orbitals. This is called the aufbau principle.

Hydrogen has one electron, which occupies the $1 s$ orbital in its ground state. The configuration for hydrogen is written as $1 s^{1}$, which can be represented by the following orbital diagram:

The arrow represents an electron spinning in a particular direction.
The next element, helium, has two electrons. Since two electrons with opposite spins can occupy an orbital, according to the Pauli exclusion principle, the electrons for helium are in the $1 s$ orbital with opposite spins, producing a $1 s^{2}$ configuration:

Lithium has three electrons, two of which can go into the $1 s$ orbital before the orbital is filled. Since the $1 s$ orbital is the only orbital for $n=1$, the third electron will occupy the lowest-energy orbital with $n=2$, or the $2 s$ orbital, giving a $1 s^{2} 2 s^{1}$ configuration:

The next element, beryllium, has four electrons, which occupy the $1 s$ and $2 s$ orbitals:

Boron has five electrons, four of which occupy the $1 s$ and $2 s$ orbitals. The fifth electron goes into the second type of orbital with $n=2$, the $2 p$ orbitals:

Since all the $2 p$ orbitals have the same energy (are degenerate), it does not matter which $2 p$ orbital the electron occupies.

Carbon is the next element and has six electrons. Two electrons occupy the $1 s$ orbital, two occupy the $2 s$ orbital, and two occupy $2 p$ orbitals. Since there are three $2 p$ orbitals with the same energy, the mutually repulsive electrons will occupy separate $2 p$ orbitals. This behavior is summarized by Hund's rule (named for the German physicist F. H. Hund): The lowest energy configuration for an atom is the one having the maximum number of unpaired electrons allowed by the Pauli principle in a particular set of degenerate orbitals. By convention, the unpaired electrons are represented as having parallel spins (with spin "up").

The configuration for carbon could be written $1 s^{2} 2 s^{2} 2 p^{1} 2 p^{1}$ to indicate that the electrons occupy separate $2 p$ orbitals. However, the configuration is usually given as

## CHEMICAL CDNNECTIDNS

## The Chemistry of Copernicium

A
Ithough element 112 is not exactly a newborn (it was discovered in 1996), it has recently been given a name. The International Union of Pure and Applied Chemistry announced on February 19,2010 , that the official name of 112 is Copernicium (pronounced koh-pur-NEE-see-um) and has the symbol Cn. The name honors Nicolaus Copernicus, who is best known for first recognizing that the planetary
$[\mathrm{Ne}]$ is shorthand for $1 s^{2} 2 s^{2} 2 p^{6}$.

$\Delta$
Sodium metal is so reactive that it is stored in kerosene to protect it from the oxygen in the air.
system is sun-centered rather than Earth-centered.

Now scientists from the Paul Sherrer Institute in Switzerland and the Joint Institute for Nuclear Research in Russia have studied the properties of Cn . By firing a beam of ${ }^{48} \mathrm{Ca}$ projectiles at a target of ${ }^{242} \mathrm{Pu}$ (doped with $\mathrm{Nd}_{2} \mathrm{O}_{3}$ ), these scientists have produced just two atoms of Cn . Given the relatively long lifetime of Cn atoms (a few seconds), the researchers have been able to compare
the properties of $\mathrm{Cn}, \mathrm{Hg}$, and Ar atoms. When these atoms were injected into a series of gold-covered detectors, it was found that, similar to Hg (and in contrast to Ar), Cn atoms were "mildly" volatile and readily formed bonds with gold. Thus, as predicted by the periodic table, the element Cn , which has an expected electron configuration of $[\mathrm{Rn}] 7 \mathrm{~s}^{2} 6 d^{10}$, fits with the $\mathrm{Zn}, \mathrm{Cd}$, and Hg group of elements, all of which have the $n s^{2}(n-1) d^{10}$ configuration.

FIGURE 7.26 The electron configurations in the type of orbital occupied last for the first 18 elements.

A
A vial containing potassium metal. The sealed vial contains an inert gas to protect the potassium from reacting with oxygen.

A
Calcium metal.

Chromium is often used to plate bumpers and hood ornaments, such as this statue of Mercury found on a 1929 Buick.

At this point it is useful to introduce the concept of valence electrons, the electrons in the outermost principal quantum level of an atom. The valence electrons of the nitrogen atom, for example, are the $2 s$ and $2 p$ electrons. For the sodium atom, the valence electron is the electron in the $3 s$ orbital, and so on. Valence electrons are the most important electrons to chemists because they are involved in bonding, as we will see in the next two chapters. The inner electrons are known as core electrons.

Note in Fig. 7.26 that a very important pattern is developing: The elements in the same group (vertical column of the periodic table) have the same valence electron configuration. Remember that Mendeleev originally placed the elements in groups based on similarities in chemical properties. Now we understand the reason behind these groupings. Elements with the same valence electron configuration show similar chemical behavior.

The element after argon is potassium. Since the $3 p$ orbitals are fully occupied in argon, we might expect the next electron to go into a $3 d$ orbital (recall that for $n=3$ the orbitals are $3 s, 3 p$, and $3 d$ ). However, the chemistry of potassium is clearly very similar to that of lithium and sodium, indicating that the last electron in potassium occupies the $4 s$ orbital instead of one of the $3 d$ orbitals, a conclusion confirmed by many types of experiments. The electron configuration of potassium is

$$
\mathrm{K}: \quad 1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{1} \quad \text { or } \quad[\mathrm{Ar}] 4 s^{1}
$$

The next element is calcium:

$$
\mathrm{Ca}: \quad[\mathrm{Ar}] 4 s^{2}
$$

The next element, scandium, begins a series of 10 elements (scandium through zinc) called the transition metals, whose configurations are obtained by adding electrons to the five $3 d$ orbitals. The configuration of scandium is

$$
\mathrm{Sc}: \quad[\mathrm{Ar}] 4 s^{2} 3 d^{1}
$$

That of titanium is

$$
\mathrm{Ti}: \quad[\mathrm{Ar}] 4 s^{2} 3 d^{2}
$$

And that of vanadium is

$$
\mathrm{V}: \quad[\mathrm{Ar}] 4 s^{2} 3 d^{3}
$$

Chromium is the next element. The expected configuration is [ Ar$] 4 s^{2} 3 d^{4}$. However, the observed configuration is

$$
\mathrm{Cr}: \quad[\mathrm{Ar}] 4 s^{1} 3 d^{5}
$$

The explanation for this configuration of chromium is beyond the scope of this book. In fact, chemists are still disagreeing over the exact cause of this anomaly. Note, however, that the observed configuration has both the $4 s$ and $3 d$ orbitals half-filled. This is a good way to remember the correct configuration.

The next four elements, manganese through nickel, have the expected configurations:

$$
\begin{array}{llll}
\mathrm{Mn}: & {[\mathrm{Ar}] 4 s^{2} 3 d^{5}} & \mathrm{Co}: & {[\mathrm{Ar}] 4 s^{2} 3 d^{7}} \\
\mathrm{Fe}: & {[\mathrm{Ar}] 4 s^{2} 3 d^{6}} & \mathrm{Ni}: & {[\mathrm{Ar}] 4 s^{2} 3 d^{8}}
\end{array}
$$

FIGURE 7.27 Valence electron configurations for potassium through krypton. The transition metals (scandium through zinc) have the general configuration $[\mathrm{Ar}] 4 s^{2} 3 d^{n}$, except for chromium and copper.

The $(n+1)$ s orbitals fill before the nd orbitals.

FIGURE 7.28 The orbitals being filled for elements in various parts of the periodic table. Note that in going along a horizontal row (a period), the $(n+1)$ s orbital fills before the $n d$ orbital. The group labels indicate the number of valence electrons (ns plus $n p$ electrons) for the elements in each group.

The configuration for copper is expected to be $[\mathrm{Ar}] 4 s^{2} 3 d^{9}$. However, the observed configuration is

$$
\mathrm{Cu}: \quad[\mathrm{Ar}] 4 s^{1} 3 d^{10}
$$

In this case, a half-filled $4 s$ orbital and a filled set of $3 d$ orbitals characterize the actual configuration.

Zinc has the expected configuration:

$$
\mathrm{Zn}: \quad[\mathrm{Ar}] 4 s^{2} 3 d^{10}
$$

The configurations of the transition metals are shown in Fig. 7.27. After that, the next six elements, gallium through krypton, have configurations that correspond to filling the $4 p$ orbitals (Fig. 7.27).

The entire periodic table is represented in Fig. 7.28 in terms of which orbitals are being filled. The valence electron configurations are given in Fig. 7.29. From these two figures, note the following additional points:

1. The $(n+1) s$ orbitals always fill before the $n d$ orbitals. For example, the $5 s$ orbitals fill in rubidium and strontium before the $4 d$ orbitals fill in the second row of transition metals (yttrium through cadmium). This early filling of the $s$ orbitals

## $f$-Transition Elements

*Lanthanides
**Actinides

|  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 91 Pa $7 s^{2} 5 f^{26 d 1}$ |  |  |  |  |  |  |  |  |  |  |  |  |

FIGURE 7.29 The periodic table with atomic symbols, atomic numbers, and partial electron configurations.

Lanthanides are elements in which the $4 f$ orbitals are being filled.

Actinides are elements in which the $5 f$ orbitals are being filled.

The group label tells the total number of valence electrons for that group.
can be explained by the penetration effect. For example, the $4 s$ orbital allows for so much more penetration to the vicinity of the nucleus that it becomes lower in energy than the $3 d$ orbital. Thus, the $4 s$ fills before the $3 d$. The same things can be said about the $5 s$ and $4 d$, the $6 s$ and $5 d$, and the $7 s$ and $6 d$ orbitals.
2. After lanthanum, which has the configuration $[\mathrm{Xe}] 6 s^{2} 5 d^{1}$, a group of 14 elements called the lanthanide series, or the lanthanides, occurs. This series of elements corresponds to the filling of the seven $4 f$ orbitals. Note that sometimes an electron occupies a $5 d$ orbital instead of a $4 f$ orbital. This occurs because the energies of the $4 f$ and $5 d$ orbitals are very similar.
3. After actinium, which has the configuration $[\mathrm{Rn}] 7 s^{2} 6 d^{1}$, a group of 14 elements called the actinide series, or the actinides, occurs. This series corresponds to the filling of the seven $5 f$ orbitals. Note that sometimes one or two electrons occupy the $6 d$ orbitals instead of the $5 f$ orbitals, because these orbitals have very similar energies.
4. The group labels for Groups $1 \mathrm{~A}, 2 \mathrm{~A}, 3 \mathrm{~A}, 4 \mathrm{~A}, 5 \mathrm{~A}, 6 \mathrm{~A}, 7 \mathrm{~A}$, and 8 A indicate the total number of valence electrons for the atoms in these groups. For example, all
the elements in Group 5A have the configuration $n s^{2} n p^{3}$. (The $d$ electrons fill one period late and are usually not counted as valence electrons.) The meaning of the group labels for the transition metals is not as clear as for the Group A elements, and these will not be used in this text.
5. The groups labeled $1 \mathrm{~A}, 2 \mathrm{~A}, 3 \mathrm{~A}, 4 \mathrm{~A}, 5 \mathrm{~A}, 6 \mathrm{~A}, 7 \mathrm{~A}$, and 8 A are often called the main-group, or representative, elements. Every member of these groups has the same valence electron configuration.

> is allowed two electrons, and this pattern is evident on the periodic table. What if each orbital was allowed three electrons? How would this change the appearance of the periodic table?

The International Union of Pure and Applied Chemistry (IUPAC), a body of scientists organized to standardize scientific conventions, has recommended a new form for the periodic table, which the American Chemical Society has adopted (see the blue numbers in Fig. 7.29). In this new version, the group number indicates the number of $s, p$, and $d$ electrons added since the last noble gas. We will not use the new format in this book, but you should be aware that the familiar periodic table may be soon replaced by this or a similar format.

The results considered in this section are very important. We have seen that the quantum mechanical model can be used to explain the arrangement of the elements in the periodic table. This model allows us to understand that the similar chemistry exhibited by the members of a given group arises from the fact that they all have the same valence electron configuration. Only the principal quantum number of the valence orbitals changes in going down a particular group.

It is important to be able to give the electron configuration for each of the maingroup elements. This is most easily done by using the periodic table. If you understand how the table is organized, it is not necessary to memorize the order in which the orbitals fill. Review Figs. 7.28 and 7.29 to make sure that you understand the correspondence between the orbitals and the periods and groups.

Predicting the configurations of the transition metals ( $3 d, 4 d$, and $5 d$ elements), the lanthanides ( $4 f$ elements), and the actinides ( $5 f$ elements) is somewhat more difficult because there are many exceptions of the type encountered in the first-row transition metals (the $3 d$ elements). You should memorize the configurations of chromium and copper, the two exceptions in the first-row transition metals, since these elements are often encountered.

## INTERACTIVE EXAMPLE 7.7

## Electron Configurations

Give the electron configurations for sulfur (S), cadmium (Cd), hafnium (Hf), and radium $(\mathrm{Ra})$ using the periodic table inside the front cover of this book.

SOLUTION Sulfur is element 16 and resides in Period 3, where the $3 p$ orbitals are being filled (Fig. 7.30). Since sulfur is the fourth among the " $3 p$ elements," it must have four $3 p$ electrons. Its configuration is

$$
\mathrm{S}: \quad 1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{4} \quad \text { or } \quad[\mathrm{Ne}] 3 s^{2} 3 p^{4}
$$

Cadmium is element 48 and is located in Period 5 at the end of the $4 d$ transition metals (Fig. 7.30). It is the tenth element in the series and thus has 10 electrons in the $4 d$ orbitals, in addition to the 2 electrons in the $5 s$ orbital. The configuration is

$$
\mathrm{Cd}: \quad 1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6} 5 s^{2} 4 d^{10} \quad \text { or } \quad[\mathrm{Kr}] 5 s^{2} 4 d^{10}
$$

FIGURE $\mathbf{7 . 3 0}$ The positions of the elements considered in Example 7.7.

Hafnium is element 72 and is found in Period 6 (Fig. 7.30). Note that it occurs just after the lanthanide series. Thus the $4 f$ orbitals are already filled. Hafnium is the second member of the $5 d$ transition series and has two $5 d$ electrons. The configuration is
$\square$ Hf: $\quad 1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6} 5 s^{2} 4 d^{10} 5 p^{6} 6 s^{2} 4 f^{14} 5 d^{2} \quad$ or $\quad[\mathrm{Xe}] 6 s^{2} 4 f^{14} 5 d^{2}$
Radium is element 88 and is in Period 7 (and Group 2A) (Fig. 7.30). Thus radium has two electrons in the $7 s$ orbital, and the configuration is

Ra: $\quad 1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6} 5 s^{2} 4 d^{10} 5 p^{6} 6 s^{2} 4 f^{14} 5 d^{10} 6 p^{6} 7 s^{2} \quad$ or $\quad[\mathrm{Rn}] 7 s^{2}$

See Exercises 7.91 and 7.92

### 1.12 Periodic Trends in Atomic

 PropertiesWe have developed a fairly complete picture of polyelectronic atoms. Although the model is rather crude because the nuclear attractions and electron repulsions are simply lumped together, it is very successful in accounting for the periodic table of elements. We will next use the model to account for the observed trends in several important atomic properties: ionization energy, electron affinity, and atomic size.

## Ionization Energy

Ionization energy is the energy required to remove an electron from a gaseous atom or ion:

$$
\mathrm{X}(g) \longrightarrow \mathrm{X}^{+}(g)+\mathrm{e}^{-}
$$

where the atom or ion is assumed to be in its ground state.
To introduce some of the characteristics of ionization energy, we will consider the energy required to remove several electrons in succession from aluminum in the gaseous state. The ionization energies are

$$
\begin{aligned}
\mathrm{Al}(g) & \longrightarrow \mathrm{Al}^{+}(g)+\mathrm{e}^{-} \\
\mathrm{Al}^{+}(g) & I_{1}=580 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{Al}^{2+}(g)+\mathrm{e}^{-} & I_{2}=1815 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{Al}^{2+}(g) & \longrightarrow \mathrm{Al}^{3+}(g)+\mathrm{e}^{-} \\
\mathrm{Al}^{3+}(g) & I_{3}=2740 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{Al}^{4+}(g)+\mathrm{e}^{-} & I_{4}=11,600 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

TABLE 7.5 | Successive lonization Energies (kJ/mol) for the Elements in Period 3

| Element | $I_{1}$ | $I_{2}$ | $I_{3}$ | $I_{4}$ | $I_{5}$ | $I_{6}$ | $I_{7}$ |

| Ar | 1527 | 2665 | 3945 | 5770 | 7230 | 8780 | 12,000 |

*Note the large jump in ionization energy in going from removal of valence electrons to removal of core electrons.

Several important points can be illustrated from these results. In a stepwise ionization process, it is always the highest-energy electron (the one bound least tightly) that is removed first. The first ionization energy $I_{1}$ is the energy required to remove the highest-energy electron of an atom. The first electron removed from the aluminum atom comes from the $3 p$ orbital ( Al has the electron configuration $[\mathrm{Ne}] 3 s^{2} 3 p^{1}$ ). The second electron comes from the $3 s$ orbital (since $\mathrm{Al}^{+}$has the configuration $[\mathrm{Ne}] 3 s^{2}$ ). Note that the value of $I_{1}$ is considerably smaller than the value of $I_{2}$, the second ionization energy.

This makes sense for several reasons. The primary factor is simply charge. Note that the first electron is removed from a neutral atom $(\mathrm{Al})$, whereas the second electron is removed from a $1+$ ion $\left(\mathrm{Al}^{+}\right)$. The increase in positive charge binds the electrons more firmly, and the ionization energy increases. The observation that the attraction between charged species is related to the magnitude of their charges is known as Coulomb's law, and we will revisit this law when we discuss the formation of ionic compounds in Chapter 8. The same trend shows up in the third $\left(I_{3}\right)$ and fourth $\left(I_{4}\right)$ ionization energies, where the electron is removed from the $\mathrm{Al}^{2+}$ and $\mathrm{Al}^{3+}$ ions, respectively.

The increase in successive ionization energies for an atom also can be interpreted using our simple model for polyelectronic atoms. The increase in ionization energy from $I_{1}$ to $I_{2}$ makes sense because the first electron is removed from a $3 p$ orbital that is higher in energy than the $3 s$ orbital from which the second electron is removed. The largest jump in ionization energy by far occurs in going from the third ionization energy $\left(I_{3}\right)$ to the fourth $\left(I_{4}\right)$. This is so because $I_{4}$ corresponds to removing a core electron ( $\mathrm{Al}^{3+}$ has the configuration $1 s^{2} 2 s^{2} 2 p^{6}$ ), and core electrons are bound much more tightly than valence electrons.

Table 7.5 gives the values of ionization energies for all the Period 3 elements. Note the large jump in energy in each case in going from removal of valence electrons to removal of core electrons.

The values of the first ionization energies for the elements in the first six periods of the periodic table are graphed in Fig. 7.31. Note that in general as we go across a period from left to right, the first ionization energy increases. This is consistent with the idea that electrons added in the same principal quantum level do not completely shield the increasing nuclear charge caused by the added protons. With an increasing nuclear charge, the attraction for electrons is greater, as predicted by Coulomb's law. Thus electrons in the same principal quantum level are generally more strongly bound as we move to the right on the periodic table, and there is a general increase in ionization energy values as electrons are added to a given principal quantum level.

First ionization energy increases across a period and decreases down a group.

FIGURE 7.32 Trends in ionization energies ( $\mathrm{kJ} / \mathrm{mol}$ ) for the representative elements.

FIGURE 7.31 The values of first ionization energy for the elements in the first six periods. In general, ionization energy decreases in going down a group. For example, note the decrease in values for Group 1A and Group 8A. In general, ionization energy increases in going left to right across a period. For example, note the sharp increase going across Period 2 from lithium through neon.

On the other hand, first ionization energy decreases in going down a group. This can be seen most clearly by focusing on the Group 1A elements (the alkali metals) and the Group 8A elements (the noble gases), as shown in Table 7.6. The main reason for the decrease in ionization energy in going down a group is that the electrons being removed are, on average, farther from the nucleus. As $n$ increases, the size of the orbital increases, and the electron is easier to remove.

In Fig. 7.31 we see that there are some discontinuities in ionization energy in going across a period. For example, for Period 2, discontinuities occur in going from beryllium to boron and from nitrogen to oxygen. These exceptions to the normal trend can be explained in terms of electron repulsions. The decrease in ionization energy in going from beryllium to boron reflects the fact that the electrons in the filled $2 s$ orbital provide some shielding for electrons in the $2 p$ orbital from the nuclear charge. The decrease in ionization energy in going from nitrogen to oxygen reflects the extra electron repulsions in the doubly occupied oxygen $2 p$ orbital.

The ionization energies for the representative elements are summarized in Fig. 7.32.

## EXAMPLE 7.8 Trends in lonization Energies

The first ionization energy for phosphorus is $1060 \mathrm{~kJ} / \mathrm{mol}$, and that for sulfur is $1005 \mathrm{~kJ} / \mathrm{mol}$. Why?

SOLUTION Phosphorus and sulfur are neighboring elements in Period 3 of the periodic table and have the following valence electron configurations: Phosphorus is $3 s^{2} 3 p^{3}$, and sulfur is $3 s^{2} 3 p^{4}$.

Ordinarily, the first ionization energy increases as we go across a period, so we might expect sulfur to have a greater ionization energy than phosphorus. However, in this case the fourth $p$ electron in sulfur must be placed in an already occupied orbital. The electron-electron repulsions that result cause this electron to be more easily removed than might be expected.

## INTERACTVE EXAMPLE 7.9 Ionization Energies

Consider atoms with the following electron configurations:

$$
\begin{aligned}
& 1 s^{2} 2 s^{2} 2 p^{6} \\
& 1 s^{2} 2 s^{2} 2 p^{6} 3 s^{1} \\
& 1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2}
\end{aligned}
$$

Which atom has the largest first ionization energy, and which one has the smallest second ionization energy? Explain your choices.

SOLUTION The atom with the largest value of $I_{1}$ is the one with the configuration $1 s^{2} 2 s^{2} 2 p^{6}$ (this is the neon atom), because this element is found at the right end of Period 2. Since the $2 p$ electrons do not shield each other very effectively, $I_{1}$ will be relatively large. The other configurations given include $3 s$ electrons. These electrons are effectively shielded by the core electrons and are farther from the nucleus than the $2 p$ electrons in neon. Thus $I_{1}$ for these atoms will be smaller than for neon.

The atom with the smallest value of $I_{2}$ is the one with the configuration $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2}$ (the magnesium atom). For magnesium, both $I_{1}$ and $I_{2}$ involve valence electrons. For the atom with the configuration $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{1}$ (sodium), the second electron lost (corresponding to $I_{2}$ ) is a core electron (from a $2 p$ orbital).

## Photoelectron Spectroscopy (PES) for Atoms

We have seen general trends in ionization energy across rows and down columns of the periodic table. But how do we measure ionization energies? Recall from our discussion of the photoelectric effect (see Section 7.2) that electrons can be ejected from a metal by shining light of sufficient energy on its surface. By gradually increasing the energy of the light used, we can determine the exact energy of the photon required to eject an electron and thus determine the binding energy of the electrons in the solid metal. A similar technique, called photoelectron spectroscopy (PES), can be used to determine the relative energies of electrons in individual atoms (as well as in molecules). In this technique, high-energy photons are directed at the sample, and the

FIGURE 7.33 The idealized PES spectrum of phosphorus.

See Appendix 3 for further discussion on spectroscopy and various spectroscopic techniques.

Electron affinity is associated with the production of a negative ion.

[^13]

FIGURE 7.34 The idealized PES spectra of boron and fluorine.
kinetic energies of the ejected electrons are measured. From this information we can determine the energy of the electron in the atom or molecule since:

Energy of electron = energy of photons used - kinetic energy of the electron
or

$$
E_{\text {electron }}=h \nu-\mathrm{KE}
$$

Helium gas usually is used as the source of high-energy photons in PES because, when excited, helium atoms emit photons with a wavelength of $58.4 \mathrm{~nm}(21.2 \mathrm{eV})$. These very-high-energy photons are energetic enough to eject electrons from many common atoms and molecules.

PES is useful for studying the electron energy levels of atoms. Usually PES is used to analyze for the presence of specific elements in samples by identifying known binding energies. For example, the $\mathrm{O}_{1 s}$ electrons occur in the PES spectrum at 530 eV and $\mathrm{C}_{1 s}$ appears at 285 eV . We can imagine an idealized schematic PES spectrum of an element such as phosphorus shown in Fig. 7.33. Because the actual spectrum is very complex and hard for a nonexpert to interpret, we have represented the data from the PES spectrum in a very simple manner. Note that the area of each peak is proportional to the number of electrons that have that particular energy.

The first ionization energies we have reported (such as shown in Fig. 7.32), are the binding energies of the most easily removed electron from a given atom. We can see how the trends we have discussed are consistent with PES data by considering an overlay of idealized spectra of boron and fluorine as shown in Fig. 7.34. Notice that the binding energy of the most easily removed electron from boron is less than that for fluorine, which matches the expected trend. In addition, the values of these binding energies are the same as the first ionization energies we have reported.

## Electron Affinity

Electron affinity is the energy change associated with the addition of an electron to a gaseous atom:

$$
\mathrm{X}(g)+\mathrm{e}^{-} \longrightarrow \mathrm{X}^{-}(g)
$$

Because two different conventions have been used, there is a good deal of confusion in the chemical literature about the signs for electron affinity values. Electron affinity has been defined in many textbooks as the energy released when an electron is added to a gaseous atom. This convention requires that a positive sign be attached to an exothermic addition of an electron to an atom, which opposes normal thermodynamic

FIGURE 7.35 The electron affinity values for atoms among the first 20 elements that form stable, isolated $X^{-}$ions. The lines shown connect adjacent elements. The absence of a line indicates missing elements ( $\mathrm{He}, \mathrm{Be}, \mathrm{N}, \mathrm{Ne}$, Mg , and Ar ) whose atoms do not add an electron exothermically and thus do not form stable, isolated $\mathrm{X}^{-}$ions.

TABLE 7.7 | Electron Affinities of the Halogens

| Atom | Electron Affinity <br> (kJ/mol) |
| :---: | :---: |
| F | -327.8 |
| Cl | -348.7 |
| Br | -324.5 |
| I | -295.2 |

conventions. Therefore, in this book we define electron affinity as a change in energy, which means that if the addition of the electron is exothermic, the corresponding value for electron affinity will carry a negative sign.

Figure 7.35 shows the electron affinity values for the atoms among the first 20 elements that form stable, isolated negative ions-that is, the atoms that undergo the addition of an electron as shown above. As expected, all these elements have negative (exothermic) electron affinities. Note that the more negative the energy, the greater the quantity of energy released. Although electron affinities generally become more negative from left to right across a period, there are several exceptions to this rule in each period. The dependence of electron affinity on atomic number can be explained by considering the changes in electron repulsions as a function of electron configurations. For example, the fact that the nitrogen atom does not form a stable, isolated $\mathrm{N}^{-}(g)$ ion, whereas carbon forms $\mathrm{C}^{-}(g)$, reflects the difference in the electron configurations of these atoms. An electron added to nitrogen $\left(1 s^{2} 2 s^{2} 2 p^{3}\right)$ to form the $\mathrm{N}^{-}(g)$ ion $\left(1 s^{2} 2 s^{2} 2 p^{4}\right)$ would have to occupy a $2 p$ orbital that already contains one electron. The extra repulsion between the electrons in this doubly occupied orbital causes $\mathrm{N}^{-}(g)$ to be unstable. When an electron is added to carbon $\left(1 s^{2} 2 s^{2} 2 p^{2}\right)$ to form the $\mathrm{C}^{-}(g)$ ion $\left(1 s^{2} 2 s^{2} 2 p^{3}\right)$, no such extra repulsions occur.

In contrast to the nitrogen atom, the oxygen atom can add one electron to form the stable $\mathrm{O}^{-}(g)$ ion. Presumably oxygen's greater nuclear charge compared with that of nitrogen is sufficient to overcome the repulsion associated with putting a second electron into an already occupied $2 p$ orbital. However, it should be noted that a second electron cannot be added to an oxygen atom $\left[\mathrm{O}^{-}(g)+\mathrm{e}^{-} / \rightarrow \mathrm{O}^{2-}(g)\right]$ to form an isolated oxide ion. This outcome seems strange in view of the many stable oxide compounds ( $\mathrm{MgO}, \mathrm{Fe}_{2} \mathrm{O}_{3}$, and so on) that are known. As we will discuss in detail in Chapter 8 , the $\mathrm{O}^{2-}$ ion is stabilized in ionic compounds by the large attractions that occur among the positive ions and the oxide ions.

When we go down a group, electron affinity should become more positive (less energy released), since the electron is added at increasing distances from the nucleus. Although this is generally the case, the changes in electron affinity in going down most groups are relatively small, and numerous exceptions occur. This behavior is demonstrated by the electron affinities of the Group 7A elements (the halogens) shown in Table 7.7. Note that the range of values is quite small compared with the changes that typically occur across a period. Also note that although chlorine, bromine, and iodine show the expected trend, the energy released when an electron is added to fluorine is smaller than might be expected. This smaller energy release has been attributed to the small size of the $2 p$ orbitals. Because the electrons must be very close together in these orbitals, there are unusually large electron-electron repulsions. In the other halogens with their larger orbitals, the repulsions are not as severe.

## Atomic Radius

Just as the size of an orbital cannot be specified exactly, neither can the size of an atom. We must make some arbitrary choices to obtain values for atomic radii. These values can be obtained by measuring the distances between atoms in chemical compounds.

FIGURE $\mathbf{7 . 3 6}$ The radius of an atom $(r)$ is defined as half the distance between the nuclei in a molecule consisting of identical atoms.

For example, in the bromine molecule, the distance between the two nuclei is known to be 228 pm . The bromine atomic radius is assumed to be half this distance, or 114 pm (Fig. 7.36). These radii are often called covalent atomic radii because of the way they are determined (from the distances between atoms in covalent bonds).

For nonmetallic atoms that do not form diatomic molecules, the atomic radii are estimated from their various covalent compounds. The radii for metal atoms (called metallic radii) are obtained from half the distance between metal atoms in solid metal crystals.

The values of the atomic radii for the representative elements are shown in Fig. 7.37. Note that these values are significantly smaller than might be expected from the $90 \%$ electron density volumes of isolated atoms, because when atoms form bonds, their electron "clouds" interpenetrate. However, these values form a self-consistent data set that can be used to discuss the trends in atomic radii.

Note from Fig. 7.37 that the atomic radii decrease in going from left to right across a period. This decrease can be explained in terms of the increasing effective nuclear charge (decreasing shielding) in going from left to right. This means that the valence electrons are drawn closer to the nucleus, decreasing the size of the atom.

Atomic radius increases down a group, because of the increases in the orbital sizes in successive principal quantum levels.

FIGURE 7.37 Atomic radii (in picometers) for selected atoms. Note that atomic radius decreases going across a period and increases going down a group. The values for the noble gases are estimated, because data from bonded atoms are lacking.

## INTERACTIVE EXAMPLE 7.10 Trends in Radii

## SOLUTION

All these ions are formed by removing two electrons from an atom of a Group 2A element. In going from beryllium to strontium, we are going down the group, so the sizes increase:

### 7.13 The Properties of a Group: The Alkali Metals

We have seen that the periodic table originated as a way to portray the systematic properties of the elements. Mendeleev was primarily responsible for first showing its usefulness in correlating and predicting the elemental properties. In this section we will summarize much of the information available from the table. We also will illustrate the usefulness of the table by discussing the properties of a representative group, the alkali metals.

## Information Contained in the Periodic Table

1. The essence of the periodic table is that the groups of representative elements exhibit similar chemical properties that change in a regular way. The quantum mechanical model of the atom has allowed us to understand the basis for the similarity of properties in a group-that each group member has the same valence electron configuration. It is the number and type of valence electrons that primarily determine an atom's chemistry.
2. One of the most valuable types of information available from the periodic table is the electron configuration of any representative element. If you understand the organization of the table, you will not need to memorize electron configurations for these elements. Although the predicted electron configurations for transition metals are sometimes incorrect, this is not a serious problem. You should, however, memorize the configurations of two exceptions, chromium and copper, since these $3 d$ transition elements are found in many important compounds.
3. As we mentioned in Chapter 2, certain groups in the periodic table have special names. These are summarized in Fig. 7.38. Groups are often referred to by these names, so you should learn them.
4. The most basic division of the elements in the periodic table is into metals and nonmetals. The most important chemical property of a metal atom is the tendency to give up one or more electrons to form a positive ion; metals tend to have low ionization energies. The metallic elements are found on the left side of the table, as shown in Fig. 7.38. The most chemically reactive metals are found on the lower left-hand portion of the table, where the ionization energies are smallest. The most distinctive chemical property of a nonmetal atom is the ability to gain one or more electrons to form an anion when reacting with a metal. Thus nonmetals are elements with large ionization energies and the most negative electron affinities. The nonmetals are found on the right side of the table, with the

FIGURE $\mathbf{7 . 3 8}$ Special names for groups in the periodic table.

Hydrogen will be discussed further in Chapter 20.

most reactive ones in the upper right-hand corner, except for the noble gas elements, which are quite unreactive. The division into metals and nonmetals shown in Fig. 7.38 is only approximate. Many elements along the division line exhibit both metallic and nonmetallic properties under certain circumstances. These elements are often called metalloids, or sometimes semimetals.

## The Alkali Metals

The metals of Group 1A, the alkali metals, illustrate very well the relationships among the properties of the elements in a group. Lithium, sodium, potassium, rubidium, cesium, and francium are the most chemically reactive of the metals. We will not discuss francium here because it occurs in nature in only very small quantities. Although hydrogen is found in Group 1A of the periodic table, it behaves as a nonmetal, in contrast to the other members of that group. The fundamental reason for hydrogen's nonmetallic character is its very small size (see Fig. 7.37). The electron in the small $1 s$ orbital is bound tightly to the nucleus.

Some important properties of the first five alkali metals are shown in Table 7.8. The data in Table 7.8 show that in going down the group, the first ionization energy decreases and the atomic radius increases. This agrees with the general trends discussed in Section 7.12.

## CHEMICAL CDNNECTIDNS

## Potassium -Too Much of a Good Thing Can Kill you

Potassium is widely recognized as an essential element. In fact, our daily requirement for potassium is more than twice that for sodium. Because most foods contain potassium, serious deficiency of this element in humans is rare. However, potassium deficiency can be caused by kidney malfunction or by the use of certain diuretics. Potassium deficiency leads to muscle weakness, irregular heartbeat, and depression.

Potassium is found in the fluids of the body as the $\mathrm{K}^{+}$ion, and its presence is essential to the operation of our nervous system. The passage of impulses along the nerves requires the flow of $\mathrm{K}^{+}$(and $\mathrm{Na}^{+}$) through channels in the membranes of the nerve cells. Failure of this ion flow prevents nerve transmissions and results in death. For example, the black mamba snake kills its victims by injecting a venom that blocks the potassium channels in the nerve cells.

Although a steady intake of potassium is essential to preserve life, ironically, too much potassium can be lethal. In fact, the deadly ingredient in the

The black mamba snake's venom kills by blocking the potassium channels in the nerve cells of victims.
drug mixture used for executing criminals is potassium chloride. Injection of a large amount of a potassium chloride solution produces an excess of $\mathrm{K}^{+}$ion in the fluids surrounding the cells and prevents the essential flow of $\mathrm{K}^{+}$out the cells to allow nerve impulses to occur. This causes the heart to stop
beating. Unlike other forms of execution, death by lethal injection of potassium chloride does not harm the organs of the body. Thus condemned criminals who are executed in this manner could potentially donate their organs for transplants. However, this idea is very controversial.

The overall increase in density in going down Group 1A is typical of all groups. This occurs because atomic mass generally increases more rapidly than atomic size. Thus there is more mass per unit volume for each succeeding element.

The smooth decrease in melting point and boiling point in going down Group 1A is not typical; in most other groups, more complicated behavior occurs. Note that the

TABLE 7.8 | Properties of Five Alkali Metals

| Element | Valence Electron Configuration | Density at $25^{\circ} \mathrm{C}$ ( $\mathrm{g} / \mathrm{cm}^{3}$ ) | $\mathrm{mp}\left({ }^{\circ} \mathrm{C}\right)$ | bp ( ${ }^{\circ} \mathrm{C}$ ) | First lonization Energy (kJ/mol) | Atomic (covalent) Radius (pm) | Ionic ( ${ }^{+}$) <br> Radius (pm) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Oxidation-reduction reactions were

 discussed in Chapter 4.
-
Potassium reacts vigorously with water.

TABLE 7.9 | Hydration Energies for $\mathrm{Li}^{+}, \mathrm{Na}^{+}$, and K+ ${ }^{+}$lons

| Ion | Hydration Energy <br> $(\mathrm{kJ} / \mathrm{mol})$ |
| :--- | :---: |
| $\mathrm{Li}^{+}$ | -510 |
| $\mathrm{Na}^{+}$ | -402 |
| $\mathrm{~K}^{+}$ | -314 |

melting point of cesium is only $29^{\circ} \mathrm{C}$. Cesium can be melted readily using only the heat from your hand. This is very unusual-metals typically have rather high melting points. For example, tungsten melts at $3410^{\circ} \mathrm{C}$. The only other metals with low melting points are mercury $\left(\mathrm{mp}-38^{\circ} \mathrm{C}\right)$ and gallium ( $\mathrm{mp} 30^{\circ} \mathrm{C}$ ).

The chemical property most characteristic of a metal is the ability to lose its valence electrons. The Group 1A elements are very reactive. They have low ionization energies and react with nonmetals to form ionic solids. A typical example involves the reaction of sodium with chlorine to form sodium chloride:

$$
2 \mathrm{Na}(s)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NaCl}(s)
$$

where sodium chloride contains $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions. This is an oxidation-reduction reaction in which chlorine oxidizes sodium. In the reactions between metals and nonmetals, it is typical for the nonmetal to behave as the oxidizing agent and the metal to behave as the reducing agent, as shown by the following reactions:

$$
\left.\begin{array}{rl}
2 \mathrm{Na}(s)+\mathrm{S}(s) \longrightarrow & \mathrm{Na}_{2} \mathrm{~S}(s) \\
\text { Contains } \mathrm{Na}^{+} \text {and } \mathrm{S}^{2-} \text { ions }
\end{array}\right\} \begin{aligned}
& 2 \mathrm{Li}_{3} \mathrm{~N}(s) \\
& 6 \mathrm{Li}(s)+\mathrm{N}_{2}(g) \longrightarrow{\mathrm{Contains} \mathrm{Li}^{+} \text {and } \mathrm{N}^{3-} \text { ions }}^{2 \mathrm{Na}}{ }_{2} \mathrm{O}_{2}(s)
\end{aligned}
$$

For reactions of the types just shown, the relative reducing powers of the alkali metals can be predicted from the first ionization energies listed in Table 7.8. Since it is much easier to remove an electron from a cesium atom than from a lithium atom, cesium should be the better reducing agent. The expected trend in reducing ability is

$$
\mathrm{Cs}>\mathrm{Rb}>\mathrm{K}>\mathrm{Na}>\mathrm{Li}
$$

This order is observed experimentally for direct reactions between the solid alkali metals and nonmetals. However, this is not the order for reducing ability found when the alkali metals react in aqueous solution. For example, the reduction of water by an alkali metal is very vigorous and exothermic:

$$
2 \mathrm{M}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{M}^{+}(a q)+2 \mathrm{OH}^{-}(a q)+\text { energy }
$$

The order of reducing abilities observed for this reaction for the first three group members is

$$
\mathrm{Li}>\mathrm{K}>\mathrm{Na}
$$

In the gas phase, potassium loses an electron more easily than sodium, and sodium more easily than lithium. Thus it is surprising that lithium is the best reducing agent toward water.

This reversal occurs because the formation of the $\mathrm{M}^{+}$ions in aqueous solution is strongly influenced by the hydration of these ions by the polar water molecules. The hydration energy of an ion represents the change in energy that occurs when water molecules attach to the $\mathrm{M}^{+}$ion. The hydration energies for the $\mathrm{Li}^{+}, \mathrm{Na}^{+}$, and $\mathrm{K}^{+}$ions (Table 7.9) indicate that the process is exothermic in each case. However, nearly twice as much energy is released by the hydration of the $\mathrm{Li}^{+}$ion as for the $\mathrm{K}^{+}$ion. This difference is caused by size effects; the $\mathrm{Li}^{+}$ion is much smaller than the $\mathrm{K}^{+}$ion, and thus its charge density (charge per unit volume) is also much greater. This means that the polar water molecules are more strongly attracted to the small $\mathrm{Li}^{+}$ion. Because the $\mathrm{Li}^{+}$ion is so strongly hydrated, its formation from the lithium atom occurs more readily than the formation of the $\mathrm{K}^{+}$ion from the potassium atom. Although a potassium atom in the gas phase loses its valence electron more readily than a lithium atom in the gas phase, the opposite is true in aqueous solution. This anomaly is an example of the importance of the polarity of the water molecule in aqueous reactions.

There is one more surprise involving the highly exothermic reactions of the alkali metals with water. Experiments show that in water lithium is the best reducing agent, so we might expect that lithium should react the most vigorously with water. However, this is not true. Sodium and potassium react much more vigorously. Why is this so? The answer lies in the relatively high melting point of lithium. When sodium and potassium react with water, the heat evolved causes them to melt, giving a larger area of contact with water. Lithium, on the other hand, does not melt under these conditions and reacts more slowly. This illustrates the important principle (which we will discuss in detail in Chapter 12) that the energy change for a reaction and the rate at which it occurs are not necessarily related.

In this section we have seen that the trends in atomic properties summarized by the periodic table can be a great help in understanding the chemical behavior of the elements. This fact will be emphasized over and over as we proceed in our study of chemistry.

## For Review

## Electromagnetic radiation

> Characterized by its wavelength $(\lambda)$, frequency $(\nu)$, and speed $\left(c=2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)$

$$
\lambda \nu=c
$$

> Can be viewed as a stream of "particles" called photons, each with energy $h \nu$, where $h$ is Planck's constant ( $6.626 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}$ )

## Photoelectric effect

) When light strikes a metal surface, electrons are emitted
) Analysis of the kinetic energy and numbers of the emitted electrons led Einstein to suggest that electromagnetic radiation can be viewed as a stream of photons

## Hydrogen spectrum

> The emission spectrum of hydrogen shows discrete wavelengths
> Indicates that hydrogen has discrete energy levels

## Bohr model of the hydrogen atom

> Using the data from the hydrogen spectrum and assuming angular momentum to be quantized, Bohr devised a model in which the electron traveled in circular orbits
> Although an important pioneering effort, this model proved to be entirely incorrect

## Wave (quantum) mechanical model

> An electron is described as a standing wave
) The square of the wave function (often called an orbital) gives a probability distribution for the electron position
> The exact position of the electron is never known, which is consistent with the Heisenberg uncertainty principle: It is impossible to know accurately both the position and the momentum of a particle simultaneously
> Probability maps are used to define orbital shapes
) Orbitals are characterized by the quantum numbers $n, \ell$, and $m_{\ell}$

## Key terms

## Electron spin

) Described by the spin quantum number $m_{s}$, which can have values of $\pm \frac{1}{2}$
> Pauli exclusion principle: No two electrons in a given atom can have the same set of quantum numbers $n, \ell, m_{\ell}$, and $m_{s}$
> Only two electrons with opposite spins can occupy a given orbital

## Periodic table

> By populating the orbitals from the wave mechanical model (the aufbau principle), the form of the periodic table can be explained
> According to the wave mechanical model, atoms in a given group have the same valence (outer) electron configuration
) The trends in properties such as ionization energies and atomic radii can be explained in terms of the concepts of nuclear attraction, electron repulsions, shielding, and penetration

## Review Questions Answers to the Review Questions can be found on the Student website (accessible from www.cengagebrain.com).

1. Four types of electromagnetic radiation (EMR) are ultraviolet, microwaves, gamma rays, and visible. All of these types of EMR can be characterized by wavelength, frequency, photon energy, and speed of travel. Define these terms, and rank the four types of electromagnetic radiation in order of increasing wavelength, frequency, photon energy, and speed.
2. Characterize the Bohr model of the atom. In the Bohr model, what do we mean when we say something is quantized? How does the Bohr model of the hydrogen atom explain the hydrogen emission spectrum? Why is the Bohr model fundamentally incorrect?
3. What experimental evidence supports the quantum theory of light? Explain the wave-particle duality of all matter. For what size particles must one consider both the wave and the particle properties?
4. List the most important ideas of the quantum mechanical model of the atom. Include in your discussion the terms or names wave function, orbital, Heisenberg uncertainty principle, de Broglie, Schrödinger, and probability distribution.
5. What are quantum numbers? What information do we get from the quantum numbers $n, \ell$, and $m_{\ell}$ ? We define a spin quantum number $\left(m_{s}\right)$, but do we know that an electron literally spins?
6. How do $2 p$ orbitals differ from each other? How do $2 p$ and $3 p$ orbitals differ from each other? What is a nodal surface in an atomic orbital? What is wrong with $1 p, 1 d$, $2 d, 1 f, 2 f$, and $3 f$ orbitals? Explain what we mean when we say that a $4 s$ electron is more penetrating than a $3 d$ electron.
7. Four blocks of elements in a periodic table refer to various atomic orbitals being filled. What are the four blocks and the corresponding orbitals? How do you get the energy ordering of the atomic orbitals from the periodic table? What is the aufbau principle? Hund's rule? The Pauli exclusion principle? There are two common exceptions to the ground-state electron configuration for elements $1-36$ as predicted by the periodic table. What are they?
8. What is the difference between core electrons and valence electrons? Why do we emphasize the valence electrons in an atom when discussing atomic properties? What is the relationship between valence electrons and elements in the same group of the periodic table?

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. What does it mean for something to have wavelike properties? Particulate properties? Electromagnetic radiation can be discussed in terms of both particles and waves. Explain the experimental verification for each of these views.
2. Defend and criticize Bohr's model. Why was it reasonable that such a model was proposed, and what evidence was there that it "works"? Why do we no longer "believe" in it?
3. The first four ionization energies for the elements $X$ and $Y$ are shown below. The units are not $\mathrm{kJ} / \mathrm{mol}$.

|  | $X$ | $\boldsymbol{Y}$ |
| :--- | ---: | ---: |
| First | 170 | 200 |
| Second | 350 | 400 |
| Third | 1800 | 3500 |
| Fourth | 2500 | 5000 |

Identify the elements $X$ and $Y$. There may be more than one correct answer, so explain completely.
4. Compare the first ionization energy of helium to its second ionization energy, remembering that both electrons come from the $1 s$ orbital. Explain the difference without using actual numbers from the text.
5. Which has the larger second ionization energy, lithium or beryllium? Why?
6. Explain why a graph of ionization energy versus atomic number (across a row) is not linear. Where are the exceptions? Why are there exceptions?
9. Using the element phosphorus as an example, write the equation for a process in which the energy change will correspond to the ionization energy and to the electron affinity.

Explain why the first ionization energy tends to increase as one proceeds from left to right across a period. Why is the first ionization energy of aluminum lower than that of magnesium, and the first ionization energy of sulfur lower than that of phosphorus?

Why do the successive ionization energies of an atom always increase? Note the successive ionization energies for silicon given in Table 7.5. Would you expect to see any large jumps between successive ionization energies of silicon as you removed all the electrons, one by one, beyond those shown in the table?
10. The radius trend and the ionization energy trend are exact opposites. Does this make sense? Define electron affinity. Electron affinity values are both exothermic (negative) and endothermic (positive). However, ionization energy values are always endothermic (positive). Explain.
7. Without referring to your text, predict the trend of second ionization energies for the elements sodium through argon. Compare your answer with Table 7.5. Explain any differences.
8. Account for the fact that the line that separates the metals from the nonmetals on the periodic table is diagonal downward to the right instead of horizontal or vertical.
9. Make sense of the fact that metals tend to lose electrons and nonmetals tend to gain electrons.
10. Explain electron from a quantum mechanical perspective, including a discussion of atomic radii, probabilities, and orbitals.
11. Which is larger, the H $1 s$ orbital or the Li $1 s$ orbital? Why? Which has the larger radius, the H atom or the Li atom? Why?
12. There are an infinite number of allowed electronic transitions in the hydrogen atom. Why don't we see more lines in the hydrogen emission spectrum?
13. Explain what is meant by the term "excited state" as it applies to an electron. Is an electron in an excited state higher or lower in energy than an electron in the ground state? Is an electron in an excited state more or less stable than an electron in the ground state?
14. Choose the best response for the following: The ionization energy for the chlorine atom is equal in magnitude to the electron affinity for
a. the Cl atom.
b. the $\mathrm{Cl}^{-}$ion.
c. the $\mathrm{Cl}^{+}$ion.
d. the F atom.
e. none of these.

Explain each choice. Justify your choice, and for the choices you did not select, explain what is incorrect about them.
15. Consider the following statement: "The ionization energy for the potassium atom is negative, because when K loses an electron to become $\mathrm{K}^{+}$, it achieves a noble gas electron configuration." Indicate everything that is correct in this statement. Indicate everything that is incorrect. Correct the incorrect information, and explain.
16. In going across a row of the periodic table, electrons are added and ionization energy generally increases. In going down a column of the periodic table, electrons are also being added but ionization energy decreases. Explain.
17. How does probability fit into the description of the atom?
18. What is meant by an orbital?
19. Explain the difference between the probability density distribution for an orbital and its radial probability.
20. Is the following statement true or false? The hydrogen atom has a $3 s$ orbital. Explain.
21. Which is higher in energy: the $2 s$ or $2 p$ orbital in hydrogen? Is this also true for helium? Explain.
22. Prove mathematically that it is more energetically favorable for a fluorine atom to take an electron from a sodium atom than for a fluorine atom to take an electron from another fluorine atom.

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of the book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

23. What type of relationship (direct or inverse) exists between wavelength, frequency, and photon energy? What does a photon energy unit of a joule equal?
24. What do we mean by the frequency of electromagnetic radiation? Is the frequency the same as the speed of the electromagnetic radiation?
25. Explain the photoelectric effect.
26. Describe briefly why the study of electromagnetic radiation has been important to our understanding of the arrangement of electrons in atoms.
27. How does the wavelength of a fast-pitched baseball compare to the wavelength of an electron traveling at $1 / 10$ the speed of light? What is the significance of this comparison? See Example 7.3.
28. The following is an energy-level diagram for electronic transitions in the Bohr hydrogen atom.

a. Explain why the energy levels get closer together as they increase. Provide mathematical support for this.
b. Verify that the colors given in the diagram are correct. Provide mathematical support.
29. The Bohr model only works for one electron species. Why do we discuss it in this text (what's good about it)?
30. We can represent both probability and radial probability versus distance from the nucleus for a hydrogen $1 s$ orbital as depicted below.

What does each graph tell us about the electron in a hydrogen $1 s$ orbital? Describe the significance of the radial probability distribution.
31. Consider the representations of the $p$ and $d$ atomic orbitals in Figs. 7.15 and 7.17. What do the + and - signs indicate?
32. The periodic table consists of four blocks of elements that correspond to $s, p, d$, and $f$ orbitals being filled. After $f$ orbitals come $g$ and $h$ orbitals. In theory, if a $g$ block and an $h$ block of elements existed, how long would the rows of $g$ and $h$ elements be in this theoretical periodic table?
33. Which quantum number is related to
a. the orientation of the orbital in space?
b. the size of the orbital?
c. the magnetic moment produced by an electron
d. the shape of the orbital?
34. What is the difference between a ground state and an excited state? How many ground state electron configurations are possible for an element? How many excited states are possible?
35. Many times the claim is made that subshells half-filled with electrons are particularly stable. Can you suggest a possible physical basis for this claim?
36. Diagonal relationships in the periodic table exist as well as the vertical relationships. For example, Be and Al are similar in some of their properties, as are B and Si. Rationalize why these diagonal relationships hold for properties such as size, ionization energy, and electron affinity.
37. Elements with very large ionization energies also tend to have highly exothermic electron affinities. Explain. Which group of elements would you expect to be an exception to this statement?
38. The changes in electron affinity as one goes down a group in the periodic table are not nearly as large as the variations in ionization energies. Why?
39. Why is it much harder to explain the line spectra of polyelectronic atoms and ions than it is to explain the line spectra of hydrogen and hydrogen-like ions?
40. Scientists use emission spectra to confirm the presence of an element in materials of unknown composition. Why is this possible?
41. Does the minimization of electron-electron repulsions correlate with Hund's rule?
42. In the hydrogen atom, what is the physical significance of the state for which $n=\infty$ and $E=0$ ?
43. On which quantum numbers does the energy of an electron depend in each of the following?
a. a one-electron atom or ion
b. an atom or ion with more than one electron
44. Although Mendeleev predicted the existence of several undiscovered elements, he did not predict the existence of the noble gases, the lanthanides, or the actinides. Propose reasons why Mendeleev was not able to predict the existence of the noble gases.

## Exercises

In this section similar exercises are paired.

## Light and Matter

45. Photosynthesis uses $660-\mathrm{nm}$ light to convert $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ into glucose and $\mathrm{O}_{2}$. Calculate the frequency of this light.
46. An FM radio station broadcasts at 99.5 MHz . Calculate the wavelength of the corresponding radio waves.
47. Microwave radiation has a wavelength on the order of 1.0 cm . Calculate the frequency and the energy of a single photon of this radiation. Calculate the energy of an Avogadro's number of photons (called an einstein) of this radiation.
48. A photon of ultraviolet (UV) light possesses enough energy to mutate a strand of human DNA. What is the energy of a single UV photon and a mole of UV photons having a wavelength of 25 nm ?
49. Octyl methoxycinnamate and oxybenzone are common ingredients in sunscreen applications. These compounds work by absorbing ultraviolet (UV) B light (wavelength 280-320 nm), the UV light most associated with sunburn symptoms. What frequency range of light do these compounds absorb?
50. Human color vision is "produced" by the nervous system based on how three different cone receptors interact with photons of light in the eye. These three different types of cones interact with photons of different frequency light, as indicated in the following chart:

| Cone Type | Range of Light <br> Frequency <br> Detected |
| :---: | :---: |
| S | $6.00-7.49 \times 10^{14} \mathrm{~s}^{-1}$ |
| M | $4.76-6.62 \times 10^{14} \mathrm{~s}^{-1}$ |
| L | $4.28-6.00 \times 10^{14} \mathrm{~s}^{-1}$ |

What wavelength ranges (and corresponding colors) do the three types of cones detect?
-51. Consider the following waves representing electromagnetic radiation:

Which wave has the longer wavelength? Calculate the wavelength. Which wave has the higher frequency and larger photon energy? Calculate these values. Which wave has the greater velocity? What type of electromagnetic radiation does each wave represent?
52. One type of electromagnetic radiation has a frequency of 107.1 MHz , another type has a wavelength of $2.12 \times 10^{-10} \mathrm{~m}$, and another type of electromagnetic radiation has photons with energy equal to $3.97 \times 10^{-19} \mathrm{~J} /$ photon. Identify each type of electromagnetic radiation and place them in order of increasing photon energy and increasing frequency.
-53. Carbon absorbs energy at a wavelength of 150 . nm. The total amount of energy emitted by a carbon sample is $1.98 \times 10^{5} \mathrm{~J}$. Calculate the number of carbon atoms present in the sample, assuming that each atom emits one photon.
54. X rays have wavelengths on the order of $1 \times 10^{-10} \mathrm{~m}$. Calculate the energy of $1.0 \times 10^{-10} \mathrm{~m} \mathrm{X}$ rays in units of kilojoules per mole of X rays. AM radio waves have wavelengths on the order of $1 \times 10^{4} \mathrm{~m}$. Calculate the energy of $1.0 \times 10^{4} \mathrm{~m}$ radio waves in units of kilojoules per mole of radio waves. Consider that the bond energy of a carbon-carbon single bond found in organic compounds is $347 \mathrm{~kJ} / \mathrm{mol}$. Would X rays and/or radio waves be able to disrupt organic compounds by breaking carbon-carbon single bonds?
-55. The work function of an element is the energy required to remove an electron from the surface of the solid element. The work function for lithium is $279.7 \mathrm{~kJ} / \mathrm{mol}$ (that is, it takes 279.7 kJ of energy to remove one mole of electrons from one mole of Li atoms on the surface of Li metal). What is the maximum wavelength of light that can remove an electron from an atom on the surface of lithium metal?
56. It takes 208.4 kJ of energy to remove 1 mole of electrons from an atom on the surface of rubidium metal. How much energy does it take to remove a single electron from an atom on the surface of solid rubidium? What is the maximum wavelength of light capable of doing this?
-57. It takes $7.21 \times 10^{-19} \mathrm{~J}$ of energy to remove an electron from an iron atom. What is the maximum wavelength of light that can do this?
58. Ionization energy is the energy required to remove an electron from an atom in the gas phase. The ionization energy of gold is $890.1 \mathrm{~kJ} / \mathrm{mol}$. Is light with a wavelength of 225 nm capable of ionizing a gold atom (removing an electron) in the gas phase?
59. Calculate the de Broglie wavelength for each of the following.
a. an electron with a velocity $10 . \%$ of the speed of light
b. a tennis ball $(55 \mathrm{~g})$ served at $35 \mathrm{~m} / \mathrm{s}(\sim 80 \mathrm{mi} / \mathrm{h})$
60. Neutron diffraction is used in determining the structures of molecules.
a. Calculate the de Broglie wavelength of a neutron moving at $1.00 \%$ of the speed of light.
b. Calculate the velocity of a neutron with a wavelength of $75 \mathrm{pm}\left(1 \mathrm{pm}=10^{-12} \mathrm{~m}\right)$.
61. A particle has a velocity that is $90 . \%$ of the speed of light. If the wavelength of the particle is $1.5 \times 10^{-15} \mathrm{~m}$, calculate the mass of the particle.
62. In the 1930s, electron microscopes were first used to provide structural details of human cells. If an electron microscope uses electrons having a wavelength of 0.1 nm , calculate the velocity of the electrons in this microscope.

## Hydrogen Atom: The Bohr Model

63. Calculate the wavelength of light emitted when each of the following transitions occur in the hydrogen atom. What type of electromagnetic radiation is emitted in each transition?
a. $n=3 \rightarrow n=2$
b. $n=4 \rightarrow n=2$
c. $n=2 \rightarrow n=1$
64. Calculate the wavelength of light emitted when each of the following transitions occur in the hydrogen atom. What type of electromagnetic radiation is emitted in each transition?
a. $n=4 \rightarrow n=3$
b. $n=5 \rightarrow n=4$
c. $n=5 \rightarrow n=3$
$\Gamma^{65}$. Using vertical lines, indicate the transitions from Exercise 63 on an energy-level diagram for the hydrogen atom (see Fig. 7.9).
65. Using vertical lines, indicate the transitions from Exercise 64 on an energy-level diagram for the hydrogen atom (see Fig. 7.9).

Consider only the transitions involving the first four energy levels for a hydrogen atom:

a. How many emissions are possible for an electron in the $n=4$ level as it goes to the ground state?
b. Which electronic transition is the lowest energy?
c. Which electronic transition corresponds to the shortest wavelength emission?
68. Assume that a hydrogen atom's electron has been excited to the $n=5$ level. How many different wavelengths of light can be emitted as this excited atom loses energy?
69. Does a photon of visible light ( $\lambda \approx 400$ to 700 nm ) have sufficient energy to excite an electron in a hydrogen atom from the $n=1$ to the $n=5$ energy state? from the $n=2$ to the $n=6$ energy state?
70. An electron is excited from the $n=1$ ground state to the $n=$ 3 state in a hydrogen atom. Which of the following statements are true? Correct the false statements to make them true.
a. It takes more energy to ionize (completely remove) the electron from $n=3$ than from the ground state.
b. The electron is farther from the nucleus on average in the $n=3$ state than in the $n=1$ state.
c. The wavelength of light emitted if the electron drops from $n=3$ to $n=2$ will be shorter than the wavelength of light emitted if the electron falls from $n=3$ to $n=1$.
d. The wavelength of light emitted when the electron returns to the ground state from $n=3$ will be the same as the wavelength of light absorbed to go from $n=1$ to $n=3$.
e. For $n=3$, the electron is in the first excited state.
[71. Calculate the maximum wavelength of light capable of removing an electron for a hydrogen atom from the energy state characterized by $n=1$, by $n=2$.
72. Consider an electron for a hydrogen atom in an excited state. The maximum wavelength of electromagnetic radiation that can completely remove (ionize) the electron from the H atom is 1460 nm . What is the initial excited state for the electron ( $n=$ ? )?
-73. An excited hydrogen atom with an electron in the $n=5$ state emits light having a frequency of $6.90 \times 10^{14} \mathrm{~s}^{-1}$. Determine the principal quantum level for the final state in this electronic transition.
74. An excited hydrogen atom emits light with a wavelength of 397.2 nm to reach the energy level for which $n=2$. In which principal quantum level did the electron begin?

## Quantum Mechanics, Quantum Numbers, and Orbitals

75. Using the Heisenberg uncertainty principle, calculate $\Delta x$ for each of the following.
a. an electron with $\Delta v=0.100 \mathrm{~m} / \mathrm{s}$
b. a baseball (mass $=145 \mathrm{~g}$ ) with $\Delta v=0.100 \mathrm{~m} / \mathrm{s}$
c. How does the answer in part a compare with the size of a hydrogen atom?
d. How does the answer in part $b$ correspond to the size of $a$ baseball?
76. The Heisenberg uncertainty principle can be expressed in the form

$$
\Delta E \cdot \Delta t \geq \frac{h}{4 \pi}
$$

where $E$ represents energy and $t$ represents time. Show that the units for this form are the same as the units for the form used in this chapter:

$$
\Delta x \cdot \Delta(m v) \geq \frac{h}{4 \pi}
$$

[77. What are the possible values for the quantum numbers $n, \ell$, and $m_{\ell}$ ?
78. Identify each of the following orbitals and determine the $n$ and $l$ quantum numbers. Explain your answers.

b.

c.

-79. Which of the following sets of quantum numbers are not allowed in the hydrogen atom? For the sets of quantum numbers that are incorrect, state what is wrong in each set.
a. $n=3, \ell=2, m_{\ell}=2$
b. $n=4, \ell=3, m_{\ell}=4$
c. $n=0, \ell=0, m_{\ell}=0$
d. $n=2, \ell=-1, m_{\ell}=1$
80. Which of the following sets of quantum numbers are not allowed? For each incorrect set, state why it is incorrect.
a. $n=3, \ell=3, m_{\ell}=0, m_{s}=-\frac{1}{2}$
b. $n=4, \ell=3, m_{\ell}=2, m_{s}=-\frac{1}{2}$
c. $n=4, \ell=1, m_{\ell}=1, m_{s}=+\frac{1}{2}$
d. $n=2, \ell=1, m_{\ell}=-1, m_{s}=-1$
e. $n=5, \ell=-4, m_{\ell}=2, m_{s}=+\frac{1}{2}$
f. $n=3, \ell=1, m_{\ell}=2, m_{s}=-\frac{1}{2}$
81. What is the physical significance of the value of $\psi^{2}$ at a particular point in an atomic orbital?
82. In defining the sizes of orbitals, why must we use an arbitrary value, such as $90 \%$ of the probability of finding an electron in that region?

## Polyelectronic Atoms

Total radial probability distributions for the helium, neon, and argon atoms are shown in the following graph. How can one interpret the shapes of these curves in terms of electron configurations, quantum numbers, and nuclear charges?

84. The relative orbital levels for the hydrogen atom can be represented as

Draw the relative orbital energy levels for atoms with more than one electron, and explain your answer. Also explain how the following radial probability distributions support your answer.

Distance from the nucleus

Distance from the nucleus
85. How many orbitals in an atom can have the designation $5 p$, $3 d_{z^{2}}, 4 d, n=5, n=4$ ?
86. How many electrons in an atom can have the designation $1 p$, $6 d_{x^{2}-y^{2}}, 4 f, 7 p_{y}, 2 s, n=3$ ?
87. Give the maximum number of electrons in an atom that can have these quantum numbers:
a. $n=4$
b. $n=5, m_{\ell}=+1$
c. $n=5, m_{s}=+\frac{1}{2}$
d. $n=3, \ell=2$
e. $n=2, \ell=1$
88. Give the maximum number of electrons in an atom that can have these quantum numbers:
a. $n=0, \ell=0, m_{\ell}=0$
b. $n=2, \ell=1, m_{\ell}=-1, m_{s}=-\frac{1}{2}$
c. $n=3, m_{s}=+\frac{1}{2}$
d. $n=2, \ell=2$
e. $n=1, \ell=0, m_{\ell}=0$
-89. Draw atomic orbital diagrams representing the ground-state electron configuration for each of the following elements.
a. Na
b. Co
c. Kr

How many unpaired electrons are present in each element?
90. For elements $1-36$, there are two exceptions to the filling order as predicted from the periodic table. Draw the atomic orbital diagrams for the two exceptions and indicate how many unpaired electrons are present.
-91. The elements $\mathrm{Si}, \mathrm{Ga}, \mathrm{As}, \mathrm{Ge}, \mathrm{Al}, \mathrm{Cd}, \mathrm{S}$, and Se are all used in the manufacture of various semiconductor devices. Write the expected electron configuration for these atoms.
92. Write the expected electron configurations for each of the following atoms: $\mathrm{Cl}, \mathrm{Sb}, \mathrm{Sr}, \mathrm{W}, \mathrm{Pb}, \mathrm{Cf}$.
-93. How many $4 d$ electrons would be predicted in the ground state for the following elements?
a. zirconium
b. cadmium
c. iridium
d. iron
94. For each of the following elements, which set of orbitals is last to fill in the ground state?
a. radium
b. iodine
c. gold
d. uranium
95. Write the expected ground-state electron configuration for the following:
a. the element with one unpaired $5 p$ electron that forms a covalent with compound fluorine
b. the (as yet undiscovered) alkaline earth metal after radium
c. the noble gas with electrons occupying $4 f$ orbitals
d. the first-row transition metal with the most unpaired electrons
96. Using only the periodic table inside the front cover of the text, write the expected ground-state electron configurations for
a. the third element in Group 5A.
b. element number 116 .
c. an element with three unpaired $5 d$ electrons.
d. the halogen with electrons in the $6 p$ atomic orbitals.
97. Given the valence electron orbital level diagram and the description, identify the element or ion.
a. a ground-state atom

b. an atom in an excited state (assume two electrons occupy the $1 s$ orbital)

c. a ground-state ion with a charge of -1

98. Identify the following elements.
a. An excited state of this element has the electron configuration $1 s^{2} 2 s^{2} 2 p^{5} 3 s^{1}$.
b. The ground-state electron configuration is $[\mathrm{Ne}] 3 s^{2} 3 p^{4}$.
c. An excited state of this element has the electron configuration $[\mathrm{Kr}] 5 s^{2} 4 d^{6} 5 p^{2} 6 s^{1}$.
d. The ground-state electron configuration contains three unpaired $6 p$ electrons.
99. In the ground state of mercury, Hg ,
a. how many electrons occupy atomic orbitals with $n=3$ ?
b. how many electrons occupy $d$ atomic orbitals?
c. how many electrons occupy $p_{z}$ atomic orbitals?
d. how many electrons have spin "up" ( $m_{s}=+\frac{1}{2}$ ) ?
100. In the ground state of element 115 , Uup,
a. how many electrons have $n=5$ as one of their quantum numbers?
b. how many electrons have $\ell=3$ as one of their quantum numbers?
c. how many electrons have $m_{\ell}=1$ as one of their quantum numbers?
d. how many electrons have $m_{s}=-\frac{1}{2}$ as one of their quantum numbers?
-101. Give a possible set of values of the four quantum numbers for all the electrons in a boron atom and a nitrogen atom if each is in the ground state.
102. Give a possible set of values of the four quantum numbers for the $4 s$ and $3 d$ electrons in titanium.
-103. Valence electrons are those electrons in the outermost principal quantum level (highest $n$ level) of an atom in its ground state. Groups 1A to 8 A have from 1 to 8 valence electrons. For each group of the representative elements ( $1 \mathrm{~A}-8 \mathrm{~A}$ ), give the number of valence electrons, the general valence electron configuration, a sample element in that group, and the specific valence electron configuration for that element.
104. How many valence electrons do each of the following elements have, and what are the specific valence electrons for each element?
a. Ca
b. O
c. element 117
d. In
e. Ar
f. Bi
-105. A certain oxygen atom has the electron configuration $1 s^{2} 2 s^{2} 2 p_{x}{ }^{2} 2 p_{y}{ }^{2}$. How many unpaired electrons are present? Is this an excited state of oxygen? In going from this state to the ground state, would energy be released or absorbed?
106. Which of the following electron configurations correspond to an excited state? Identify the atoms and write the ground-state electron configuration where appropriate.
a. $1 s^{2} 2 s^{2} 3 p^{1}$
b. $1 s^{2} 2 s^{2} 2 p^{6}$
c. $1 s^{2} 2 s^{2} 2 p^{4} 3 s^{1}$
d. $[\mathrm{Ar}] 4 s^{2} 3 d^{5} 4 p^{1}$

How many unpaired electrons are present in each of these species?
-107 . Which of elements $1-36$ have two unpaired electrons in the ground state?
108. The first-row transition metals from chromium through zinc all have some biological function in the human body (see Table 21.18). How many unpaired electrons are present in each of these first-row transition metals?
-109. One bit of evidence that the quantum mechanical model is "correct" lies in the magnetic properties of matter. Atoms with unpaired electrons are attracted by magnetic fields and thus are said to exhibit paramagnetism. The degree to which this effect is observed is directly related to the number of unpaired electrons present in the atom. Consider the ground-state electron configurations for $\mathrm{Li}, \mathrm{N}, \mathrm{Ni}, \mathrm{Te}, \mathrm{Ba}$, and Hg . Which of these atoms would be expected to be paramagnetic, and how many unpaired electrons are present in each paramagnetic atom?
110. How many unpaired electrons are present in each of the following in the ground state: $\mathrm{O}, \mathrm{O}^{+}, \mathrm{O}^{-}, \mathrm{Os}, \mathrm{Zr}, \mathrm{S}, \mathrm{F}, \mathrm{Ar}$ ?

## The Periodic Table and Periodic Properties

-111. Arrange the following groups of atoms in order of increasing size.
a. $\mathrm{Te}, \mathrm{S}, \mathrm{Se}$
b. $\mathrm{K}, \mathrm{Br}, \mathrm{Ni}$
c. $\mathrm{Ba}, \mathrm{Si}, \mathrm{F}$
112. Arrange the following groups of atoms in order of increasing size.
a. $\mathrm{Rb}, \mathrm{Na}, \mathrm{Be}$
b. $\mathrm{Sr}, \mathrm{Se}, \mathrm{Ne}$
c. $\mathrm{Fe}, \mathrm{P}, \mathrm{O}$
113. Arrange the atoms in Exercise 111 in order of increasing first ionization energy.
114. Arrange the atoms in Exercise 112 in order of increasing first ionization energy.
-115. In each of the following sets, which atom or ion has the smallest radius?
a. $\mathrm{H}, \mathrm{He}$
b. $\mathrm{Cl}, \mathrm{In}, \mathrm{Se}$
c. element 120 , element 119 , element 116
d. $\mathrm{Nb}, \mathrm{Zn}, \mathrm{Si}$
e. $\mathrm{Na}^{-}, \mathrm{Na}, \mathrm{Na}^{+}$
116. In each of the following sets, which atom or ion has the smallest ionization energy?
a. $\mathrm{Ca}, \mathrm{Sr}, \mathrm{Ba}$
b. $\mathrm{K}, \mathrm{Mn}, \mathrm{Ga}$
c. $\mathrm{N}, \mathrm{O}, \mathrm{F}$
d. $\mathrm{S}^{2-}, \mathrm{S}, \mathrm{S}^{2+}$
e. $\mathrm{Cs}, \mathrm{Ge}, \mathrm{Ar}$
-117. Element 106 has been named seaborgium, Sg , in honor of Glenn Seaborg, discoverer of the first transuranium element.
a. Write the expected electron configuration for element 106.
b. What other element would be most like element 106 in its properties?
c. Predict the formula for a possible oxide and a possible oxyanion of element 106.
118. Predict some of the properties of element 117 (the symbol is Uus, following conventions proposed by the International Union of Pure and Applied Chemistry, or IUPAC).
a. What will be its electron configuration?
b. What element will it most resemble chemically?
c. What will be the formula of the neutral binary compounds it forms with sodium, magnesium, carbon, and oxygen?
d. What oxyanions would you expect Uus to form?
-119. The first ionization energies of As and Se are 0.947 and $0.941 \mathrm{MJ} / \mathrm{mol}$, respectively. Rationalize these values in terms of electron configurations.
120. Rank the elements $\mathrm{Be}, \mathrm{B}, \mathrm{C}, \mathrm{N}$, and O in order of increasing first ionization energy. Explain your reasoning.
-121. Consider the following ionization energies for aluminum:

$$
\begin{aligned}
& \mathrm{Al}(g) \longrightarrow \mathrm{Al}^{+}(g)+\mathrm{e}^{-} \quad I_{1}=580 \mathrm{~kJ} / \mathrm{mol} \\
& \mathrm{Al}^{+}(\mathrm{g}) \longrightarrow \mathrm{Al}^{2+}(\mathrm{g})+\mathrm{e}^{-} I_{2}=1815 \mathrm{~kJ} / \mathrm{mol} \\
& \mathrm{Al}^{2+}(g) \longrightarrow \mathrm{Al}^{3+}(g)+\mathrm{e}^{-} \quad I_{3}=2740 \mathrm{~kJ} / \mathrm{mol} \\
& \mathrm{Al}^{3+}(g) \longrightarrow \mathrm{Al}^{4+}(g)+\mathrm{e}^{-} \quad I_{4}=11,600 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

a. Account for the trend in the values of the ionization energies.
b. Explain the large increase between $I_{3}$ and $I_{4}$.
122. The following graph plots the first, second, and third ionization energies for $\mathrm{Mg}, \mathrm{Al}$, and Si .

Without referencing the text, which plot corresponds to which element? In one of the plots, there is a huge jump in energy between $I_{2}$ and $I_{3}$, unlike in the other two plots. Explain this phenomenon.
123. For each of the following pairs of elements

$$
(\mathrm{C} \text { and } \mathrm{N}) \quad(\mathrm{Ar} \text { and } \mathrm{Br})
$$

pick the atom with
a. more favorable (exothermic) electron affinity.
b. higher ionization energy.
c. larger size.
124. For each of the following pairs of elements

$$
(\mathrm{Mg} \text { and } \mathrm{K}) \quad(\mathrm{F} \text { and } \mathrm{Cl})
$$

pick the atom with
a. more favorable (exothermic) electron affinity.
b. higher ionization energy.
c. larger size.
-125. The electron affinities of the elements from aluminum to chlorine are $-44,-120,-74,-200.4$, and $-384.7 \mathrm{~kJ} / \mathrm{mol}$, respectively. Rationalize the trend in these values.
126. In the second row of the periodic table, $\mathrm{Be}, \mathrm{N}$, and Ne all have endothermic (unfavorable) electron affinities, whereas the other second-row elements have exothermic (favorable) electron affinities. Rationalize why $\mathrm{Be}, \mathrm{N}$, and Ne have unfavorable electron affinities.
-127. Order the atoms in each of the following sets from the least exothermic electron affinity to the most.
a. $\mathrm{S}, \mathrm{Se}$
b. $\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I}$
128. Order the atoms in each of the following sets from the least exothermic electron affinity to the most.
a. $\mathrm{N}, \mathrm{O}, \mathrm{F}$
b. $\mathrm{Al}, \mathrm{Si}, \mathrm{P}$
129. The electron affinity for sulfur is more exothermic than that for oxygen. How do you account for this?
130. Which has the more negative electron affinity, the oxygen atom or the $\mathrm{O}^{-}$ion? Explain your answer.
-131. Write equations corresponding to the following.
a. the fourth ionization energy of Se
b. the electron affinity of $\mathrm{S}^{-}$
c. the electron affinity of $\mathrm{Fe}^{3+}$
d. the ionization energy of Mg
132. Using data from the text, determine the following values (justify your answer):
a. the electron affinity of $\mathrm{Mg}^{2+}$
b. the ionization energy of $\mathrm{Cl}^{-}$
c. the electron affinity of $\mathrm{Cl}^{+}$
d. the ionization energy of $\mathrm{Mg}^{-}$(Electron affinity of $\mathrm{Mg}=$ $230 \mathrm{~kJ} / \mathrm{mol}$ )
133. Consider the following idealized PES spectrum for carbon:

Explain the location and relative intensities of the various peaks.
134. Consider the following idealized PES spectrum for an element:

What is the identity of the element?

## Alkali Metals

135. An ionic compound of potassium and oxygen has the empirical formula KO. Would you expect this compound to be potassium(II) oxide or potassium peroxide? Explain.
136. Give the name and formula of each of the binary compounds formed from the following elements.
a. Li and N
b. Na and Br
c. K and S
-137. Cesium was discovered in natural mineral waters in 1860 by R. W. Bunsen and G. R. Kirchhoff using the spectroscope they invented in 1859. The name came from the Latin caesius ("sky blue") because of the prominent blue line observed for this element at 455.5 nm . Calculate the frequency and energy of a photon of this light.
137. The bright yellow light emitted by a sodium vapor lamp consists of two emission lines at 589.0 and 589.6 nm . What are the frequency and the energy of a photon of light at each of these wavelengths? What are the energies in $\mathrm{kJ} / \mathrm{mol}$ ?
-139. Does the information on alkali metals in Table 7.8 of the text confirm the general periodic trends in ionization energy and atomic radius? Explain.
138. Predict the atomic number of the next alkali metal after francium and give its ground-state electron configuration.
-141. Lithium is often prescribed as a mood-stabilizing drug. Do you think the lithium prescribed is in the elemental form? What is the more likely form of the lithium to be prescribed as a drug?
139. Small daily doses of lithium carbonate taken orally are often given to treat manic-depressive psychoses. This dosage maintains the level of lithium ion in the blood at about $1 \times 10^{-3} \mathrm{~mol} / \mathrm{L}$.
a. What is the formula of lithium carbonate?
b. What mass of lithium ion is present per liter of blood in these patients?
140. Complete and balance the equations for the following reactions.
a. $\mathrm{Li}(s)+\mathrm{N}_{2}(g) \rightarrow$
b. $\mathrm{Rb}(s)+\mathrm{S}(s) \rightarrow$
141. Complete and balance the equations for the following reactions.
a. $\mathrm{Cs}(s)+\mathrm{H}_{2} \mathrm{O}(l) \rightarrow$
b. $\mathrm{Na}(s)+\mathrm{Cl}_{2}(g) \rightarrow$

## Additional Exercises

145. An unknown element is a nonmetal and has a valence electron configuration of $n s^{2} n p^{4}$.
a. How many valence electrons does this element have?
b. What are some possible identities for this element?
c. What is the formula of the compound this element would form with potassium?
d. Would this element have a larger or smaller radius than barium?
e. Would this element have a greater or smaller ionization energy than fluorine?
146. A carbon-oxygen double bond in a certain organic molecule absorbs radiation that has a frequency of $6.0 \times 10^{13} \mathrm{~s}^{-1}$.
a. What is the wavelength of this radiation?
b. To what region of the spectrum does this radiation belong?
c. What is the energy of this radiation per photon? per mole of photons?
d. A carbon-oxygen bond in a different molecule absorbs radiation with frequency equal to $5.4 \times 10^{13} \mathrm{~s}^{-1}$. Is this radiation more or less energetic?
147. Photogray lenses incorporate small amounts of silver chloride in the glass of the lens. When light hits the AgCl particles, the following reaction occurs:

$$
\mathrm{AgCl} \xrightarrow{h v} \mathrm{Ag}+\mathrm{Cl}
$$

The silver metal that is formed causes the lenses to darken. The enthalpy change for this reaction is $3.10 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}$. Assuming all this energy must be supplied by light, what is the maximum wavelength of light that can cause this reaction?
148. A certain microwave oven delivers 750 . watts $(\mathrm{J} / \mathrm{s})$ of power to a coffee cup containing 50.0 g water at $25.0^{\circ} \mathrm{C}$. If the wavelength of microwaves in the oven is 9.75 cm , how long does it take, and how many photons must be absorbed, to make the water boil? The specific heat capacity of water is $4.18 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g}$, and assume only the water absorbs the energy of the microwaves.
149. Mars is roughly 60 million km from Earth. How long does it take for a radio signal originating from Earth to reach Mars?
150. Consider the following approximate visible light spectrum:

Barium emits light in the visible region of the spectrum. If each photon of light emitted from barium has an energy of $3.59 \times 10^{-19} \mathrm{~J}$, what color of visible light is emitted?
151. One of the visible lines in the hydrogen emission spectrum corresponds to the $n=6$ to $n=2$ electronic transition. What color light is this transition? See Exercise 150.
152. Using Fig. 7.29, list the elements (ignore the lanthanides and actinides) that have ground-state electron configurations that differ from those we would expect from their positions in the periodic table.
153. Are the following statements true for the hydrogen atom only, true for all atoms, or not true for any atoms?
a. The principal quantum number completely determines the energy of a given electron.
b. The angular momentum quantum number, $\ell$, determines the shapes of the atomic orbitals.
c. The magnetic quantum number, $m_{\ell}$, determines the direction that the atomic orbitals point in space.
154. Although no currently known elements contain electrons in $g$ orbitals in the ground state, it is possible that these elements will be found or that electrons in excited states of known elements could be in $g$ orbitals. For $g$ orbitals, the value of $\ell$ is 4 . What is the lowest value of $n$ for which $g$ orbitals could exist? What are the possible values of $m_{\ell}$ ? How many electrons could a set of $g$ orbitals hold?
155. Which of the following orbital designations are incorrect: $1 s$, $1 p, 7 d, 9 s, 3 f, 4 f, 2 d$ ?
156. The four most abundant elements by mass in the human body are oxygen, carbon, hydrogen, and nitrogen. These four elements make up about $96 \%$ of the human body. The next four most abundant elements are calcium, phosphorus, magnesium, and potassium. Write the expected ground-state electron configurations for these eight most abundant elements in the human body.
157. Consider the eight most abundant elements in the human body, as outlined in Exercise 156. Excluding hydrogen, which of these elements would have the smallest size? largest size? smallest first ionization energy? largest first ionization energy?
158. An ion having a $4+$ charge and a mass of 49.9 u has 2 electrons with principal quantum number $n=1,8$ electrons with $n=2$, and 10 electrons with $n=3$. Supply as many of the properties for the ion as possible from the information given. (Hint: In forming ions for this species, the $4 s$ electrons are lost before the $3 d$ electrons.)
a. the atomic number
b. total number of $s$ electrons
c. total number of $p$ electrons
d. total number of $d$ electrons
e. the number of neutrons in the nucleus
f. the ground-state electron configuration of the neutral atom
159. The successive ionization energies for an unknown element are

$$
\begin{aligned}
& I_{1}=896 \mathrm{~kJ} / \mathrm{mol} \\
& I_{2}=1752 \mathrm{~kJ} / \mathrm{mol} \\
& I_{3}=14,807 \mathrm{~kJ} / \mathrm{mol} \\
& I_{4}=17,948 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

To which family in the periodic table does the unknown element most likely belong?
160. In the ground state of cadmium, Cd ,
a. how many electrons have $\ell=2$ as one of their quantum numbers?
b. how many electrons have $n=4$ as one of their quantum numbers?
c. how many electrons have $m_{\ell}=-1$ as one of their quantum numbers?
d. how many electrons hav $m_{s}=-\frac{1}{2}$ as one of their quantum numbers?
161. Using data from this chapter, calculate the change in energy expected for each of the following processes.
a. $\mathrm{Na}(g)+\mathrm{Cl}(g) \rightarrow \mathrm{Na}^{+}(g)+\mathrm{Cl}^{-}(g)$
b. $\mathrm{Mg}(g)+\mathrm{F}(g) \rightarrow \mathrm{Mg}^{+}(g)+\mathrm{F}^{-}(g)$
c. $\mathrm{Mg}^{+}(g)+\mathrm{F}(g) \rightarrow \mathrm{Mg}^{2+}(g)+\mathrm{F}^{-}(g)$
d. $\mathrm{Mg}(g)+2 \mathrm{~F}(g) \rightarrow \mathrm{Mg}^{2+}(g)+2 \mathrm{~F}^{-}(g)$
162. Consider the following idealized PES spectrum for potassium:

Explain the location and relative intensities of the various peaks.

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
163. It takes 476 kJ to remove 1 mole of electrons from the atoms at the surface of a solid metal. What is the maximum wavelength of light that can remove a single electron from an atom at the surface of this solid metal?
164. Calculate, to four significant figures, the longest and shortest wavelengths of light emitted by electrons in the hydrogen atom that begin in the $n=5$ state and then fall to states with smaller values of $n$.
165. Assume that a hydrogen atom's electron has been excited to the $n=6$ level. How many different wavelengths of light can be emitted as this excited atom loses energy?
166. Determine the maximum number of electrons that can have each of the following designations: $2 f, 2 d_{x y}, 3 p, 5 d_{y z}$, and $4 p$.
167. Consider the ground state of arsenic, As. How many electrons have $\ell=1$ as one of their quantum numbers? How many electrons have $m_{\ell}=0$ ? How many electrons have $m_{\ell}=+1$ ?
168. Which of the following statements is(are) true?
a. The $2 s$ orbital in the hydrogen atom is larger than the $3 s$ orbital also in the hydrogen atom.
b. The Bohr model of the hydrogen atom has been found to be incorrect.
c. The hydrogen atom has quantized energy levels.
d. An orbital is the same as a Bohr orbit.
e. The third energy level has three sublevels, the $s, p$, and $d$ sublevels.
169. Identify the following three elements.
a. The ground-state electron configuration is $[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{4}$.
b. The ground-state electron configuration is $[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{2}$.
c. An excited state of this element has the electron configuration $1 s^{2} 2 s^{2} 2 p^{4} 3 s^{1}$.
170. For each of the following pairs of elements, choose the one that correctly completes the following table.

|  | K and Cs | Te and Br | Ge and Se |  |
| :--- | :--- | :--- | :--- | :--- |
| The more <br> favorable <br> (exothermic) <br> electron affinity | - |  |  |  |
| The higher <br> ionization energy | - |  |  |  |
| The larger size <br> (atomic radius) | - |  |  |  |

171. Which of the following statements is(are) true?
a. F has a larger first ionization energy than does Li .
b. Cations are larger than their parent atoms.
c. The removal of the first electron from a lithium atom (electron configuration is $1 s^{2} 2 s^{1}$ ) is exothermic-that is, removing this electron gives off energy.
d. The He atom is larger than the $\mathrm{H}^{+}$ion.
e. The Al atom is smaller than the Li atom.
172. Three elements have the electron configurations $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2}$, $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{4}$, and $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2}$. The first ionization energies of these elements (not in the same order) are 0.590 , 0.999 , and $0.738 \mathrm{MJ} / \mathrm{mol}$. The atomic radii are 104,160 , and 197 pm . Identify the three elements, and match the appropriate values of ionization energy and atomic radius to each configuration. Complete the following table with the correct information.
$\left.\begin{array}{llll} & & \begin{array}{c}\text { First } \\ \text { Ionization } \\ \text { Energy } \\ \text { Electron } \\ \text { Configuration }\end{array} & \begin{array}{c}\text { Element } \\ \text { Symbol }\end{array}\end{array} \begin{array}{c}\text { Atomic } \\ \text { Radius } \\ \text { (pm) }\end{array}\right]$

## Challenge Problems

173. An atom moving at its root mean square velocity at $100 .{ }^{\circ} \mathrm{C}$ has a wavelength of $2.31 \times 10^{-11} \mathrm{~m}$. Which atom is it?
174. One of the emission spectral lines for $\mathrm{Be}^{3+}$ has a wavelength of 253.4 nm for an electronic transition that begins in the state with $n=5$. What is the principal quantum number of the lower-energy state corresponding to this emission? (Hint: The Bohr model can be applied to one-electron ions. Don't forget the $Z$ factor: $Z=$ nuclear charge $=$ atomic number.)
175. The figure below represents part of the emission spectrum for a one-electron ion in the gas phase. All the lines result from electronic transitions from excited states to the $n=3$ state. (See Exercise 174.)

a. What electronic transitions correspond to lines $A$ and $B$ ?
b. If the wavelength of line $B$ is 142.5 nm , calculate the wavelength of line $A$.
176. When the excited electron in a hydrogen atom falls from $n=5$ to $n=2$, a photon of blue light is emitted. If an excited electron in $\mathrm{He}^{+}$falls from $n=4$, to which energy level must it fall so that a similar blue light (as with the hydrogen) is emitted? Prove it. (See Exercise 174.)
177. The ground state ionization energy for the one electron ion $X^{m+}$ is $4.72 \times 10^{4} \mathrm{~kJ} / \mathrm{mol}$. Identify X and $m$. (See Exercise 174.)
178. For hydrogen atoms, the wave function for the state $n=3$, $\ell=0, m_{\ell}=0$ is

$$
\psi_{300}=\frac{1}{81 \sqrt{3 \pi}}\left(\frac{1}{a_{0}}\right)^{3 / 2}\left(27-18 \sigma+2 \sigma^{2}\right) e^{-\sigma / \beta}
$$

where $\sigma=r / a_{0}$ and $a_{0}$ is the Bohr radius $\left(5.29 \times 10^{-11} \mathrm{~m}\right)$. Calculate the position of the nodes for this wave function.
179. The wave function for the $2 p_{z}$ orbital in the hydrogen atom is

$$
\psi_{2 p_{z}}=\frac{1}{4 \sqrt{2 \pi}}\left(\frac{Z}{a_{0}}\right)^{3 / 2} \sigma \mathrm{e}^{-\sigma / 2} \cos \theta
$$

where $a_{0}$ is the value for the radius of the first Bohr orbit in meters $\left(5.29 \times 10^{-11}\right), \sigma$ is $Z\left(r / a_{0}\right), r$ is the value for the distance from the nucleus in meters, and $\theta$ is an angle. Calculate the value of $\psi_{2 p_{z}}{ }^{2}$ at $r=a_{0}$ for $\theta=0^{\circ}(z$ axis $)$ and for $\theta=90^{\circ}$ (xy plane).
180. Answer the following questions assuming that $m_{s}$ could have three values rather than two and that the rules for $n, \ell$, and $m_{\ell}$ are the normal ones.
a. How many electrons would an orbital be able to hold?
b. How many elements would the first and second periods in the periodic table contain?
c. How many elements would be contained in the first transition metal series?
d. How many electrons would the set of $4 f$ orbitals be able to hold?
181. Assume that we are in another universe with different physical laws. Electrons in this universe are described by four quantum numbers with meanings similar to those we use. We will call these quantum numbers $p, q, r$, and $s$. The rules for these quantum numbers are as follows:
$p=1,2,3,4,5, \ldots$
$q$ takes on positive odd integers and $q \leq p$.
$r$ takes on all even integer values from $-q$ to $+q$. (Zero is considered an even number.)

$$
s=+\frac{1}{2} \text { or }-\frac{1}{2}
$$

a. Sketch what the first four periods of the periodic table will look like in this universe.
b. What are the atomic numbers of the first four elements you would expect to be least reactive?
c. Give an example, using elements in the first four rows, of ionic compounds with the formulas $\mathrm{XY}, \mathrm{XY}_{2}, \mathrm{X}_{2} \mathrm{Y}, \mathrm{XY}_{3}$, and $X_{2} Y_{3}$.
d. How many electrons can have $p=4, q=3$ ?
e. How many electrons can have $p=3, q=0, r=0$ ?
f. How many electrons can have $p=6$ ?
182. Without looking at data in the text, sketch a qualitative graph of the third ionization energy versus atomic number for the elements Na through Ar, and explain your graph.
183. The following numbers are the ratios of second ionization energy to first ionization energy:

| $\mathrm{Na}:$ | 9.2 | $\mathrm{P}:$ | 1.8 |
| :--- | :--- | :--- | :--- |
| $\mathrm{Mg}:$ | 2.0 | $\mathrm{~S}:$ | 2.3 |
| $\mathrm{Al}:$ | 3.1 | $\mathrm{Cl}:$ | 1.8 |
| $\mathrm{Si}:$ | 2.0 | $\mathrm{Ar}:$ | 1.8 |

Explain these relative numbers.
184. We expect the atomic radius to increase going down a group in the periodic table. Can you suggest why the atomic radius of hafnium breaks this rule? (See data below.)

| Atomic Radif (in pm) |  |  |  |
| :---: | :---: | :---: | :---: |
| Sc | 157 | Ti | 147.7 |
| Y | 169.3 | Zr | 159.3 |
| La | 191.5 | Hf | 147.6 |

185. The ionization energy for a $1 s$ electron in a silver atom is $2.462 \times 10^{6} \mathrm{~kJ} / \mathrm{mol}$.
a. Determine an approximate value for $Z_{\text {eff }}$ for the $\mathrm{Ag} 1 s$ electron. Assume the Bohr model applies to the $1 s$ electron. $Z_{\text {eff }}$ is the apparent nuclear charge experienced by the electrons.
b. How does $Z_{\text {eff }}$ from part a compare to $Z$ for Ag ? Rationalize the relative numbers.
186. Consider the following idealized PES spectrum for an element:

What is the identity of the element? Explain the relative positions of the various peaks.
187. An atom of a particular element is traveling at $1.00 \%$ of the speed of light. The de Broglie wavelength is found to be $3.31 \times 10^{-3} \mathrm{pm}$. Which element is this? Prove it.

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
188. As the weapons officer aboard the Starship Chemistry, it is your duty to configure a photon torpedo to remove an electron from the outer hull of an enemy vessel. You know that the
work function (the binding energy of the electron) of the hull of the enemy ship is $7.52 \times 10^{-19} \mathrm{~J}$.
a. What wavelength does your photon torpedo need to be to eject an electron?
b. You find an extra photon torpedo with a wavelength of 259 nm and fire it at the enemy vessel. Does this photon torpedo do any damage to the ship (does it eject an electron)?
c. If the hull of the enemy vessel is made of the element with an electron configuration of $[\mathrm{Ar}] 4 s^{1} 3 d^{10}$, what metal is this?
189. Francium, Fr, is a radioactive element found in some uranium minerals and is formed as a result of the decay of actinium.
a. What are the electron configurations of francium and its predicted most common ion?
b. It has been estimated that at any one time, there is only one (1.0) ounce of francium on earth. Assuming this is true, what number of francium atoms exist on earth?
c. The longest-lived isotope of francium is ${ }^{223} \mathrm{Fr}$. What is the total mass in grams of the neutrons in one atom of this isotope?
190. Answer the following questions based on the given electron configurations, and identify the elements.
a. Arrange these atoms in order of increasing size: $[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{6} ;[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{1} ;[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{3}$.
b. Arrange these atoms in order of decreasing first ionization energy: $[\mathrm{Ne}] 3 s^{2} 3 p^{5} ;[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{3} ;[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{5}$.

The nudibranch uses a particular molecule (called an allomone) to defend itself against predators. The structure of the molecule is specific to its purpose. (Cesare Naidi/National Geographic Creative)

A
Quartz grows in beautiful, regular crystals.

A s we examine the world around us, we find it to be composed almost entirely of compounds and mixtures of compounds: Rocks, coal, soil, petroleum, trees, and human bodies are all complex mixtures of chemical compounds in which different kinds of atoms are bound together. Substances composed of unbound atoms do exist in nature, but they are very rare. Examples are the argon in the atmosphere and the helium mixed with natural gas reserves.

The manner in which atoms are bound together has a profound effect on chemical and physical properties. For example, graphite is a soft, slippery material used as a lubricant in locks, and diamond is one of the hardest materials known, valuable both as a gemstone and in industrial cutting tools. Why do these materials, both composed solely of carbon atoms, have such different properties? The answer, as we will see, lies in the bonding in these substances.

Silicon and carbon are next to each other in Group 4A of the periodic table. From our knowledge of periodic trends, we might expect $\mathrm{SiO}_{2}$ and $\mathrm{CO}_{2}$ to be very similar. But $\mathrm{SiO}_{2}$ is the empirical formula of silica, which is found in sand and quartz, and carbon dioxide is a gas, a product of respiration. Why are they so different? We will be able to answer this question after we have developed models for bonding.

Molecular bonding and structure play the central role in determining the course of all chemical reactions, many of which are vital to our survival. Later in this book we will demonstrate their importance by showing how enzymes facilitate complex chemical reactions, how genetic characteristics are transferred, and how hemoglobin in the blood carries oxygen throughout the body. All of these fundamental biological reactions hinge on the geometric structures of molecules, sometimes depending on very subtle differences in molecular shape to channel the chemical reaction one way rather than another.

Many of the world's current problems require fundamentally chemical answers: disease and pollution control, the search for new energy sources, the development of new fertilizers to increase crop yields, the improvement of the protein content in various staple grains, and many more. To understand the behavior of natural materials, we must understand the nature of chemical bonding and the factors that control the structures of compounds. In this chapter we will present various classes of compounds that illustrate the different types of bonds and then develop models to describe the structure and bonding that characterize materials found in nature. Later these models will be useful in understanding chemical reactions.

### 8.1 Types of Chemical Bonds

What is a chemical bond? There is no simple and yet complete answer to this question. In Chapter 2 we defined bonds as forces that hold groups of atoms together and make them function as a unit.

There are many types of experiments we can perform to determine the fundamental nature of materials. For example, we can study physical properties such as melting point, hardness, and electrical and thermal conductivity. We can also study solubility characteristics and the properties of the resulting solutions. To determine the charge distribution in a molecule, we can study its behavior in an electric field. We can obtain information about the strength of a bonding interaction by measuring the bond energy, which is the energy required to break the bond.

There are several ways in which atoms can interact with one another to form aggregates. We will consider several specific examples to illustrate the various types of chemical bonds.

Earlier, we saw that when solid sodium chloride is dissolved in water, the resulting solution conducts electricity, a fact that helps to convince us that sodium chloride is composed of $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions. Therefore, when sodium and chlorine react to form sodium chloride, electrons are transferred from the sodium atoms to the chlorine atoms to form $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions, which then aggregate to form solid sodium chloride. Why does this happen? The best simple answer is that the system can achieve the lowest possible energy

by behaving in this way. The attraction of a chlorine atom for the extra electron and the very strong mutual attractions of the oppositely charged ions provide the driving forces for the process. The resulting solid sodium chloride is a very sturdy material; it has a melting point of approximately $800^{\circ} \mathrm{C}$. The bonding forces that produce this great thermal stability result from the electrostatic attractions of the closely packed, oppositely charged ions. This is an example of ionic bonding. Ionic substances are formed when an atom that loses electrons relatively easily reacts with an atom that has a high affinity for electrons. That is, an ionic compound results when a metal reacts with a nonmetal.

The energy of interaction between a pair of ions can be calculated using Coulomb's law in the form

$$
E=\left(2.31 \times 10^{-19} \mathrm{~J} \cdot \mathrm{~nm}\right)\left(\frac{Q_{1} Q_{2}}{r}\right)
$$

where $E$ has units of joules, $r$ is the distance between the ion centers in nanometers, and $Q_{1}$ and $Q_{2}$ are the numerical ion charges.

For example, in solid sodium chloride the distance between the centers of the $\mathrm{Na}^{+}$ and $\mathrm{Cl}^{-}$ions is $2.76 \AA(0.276 \mathrm{~nm})$, and the ionic energy per pair of ions is

$$
E=\left(2.31 \times 10^{-19} \mathrm{~J} \cdot \mathrm{~nm}\right)\left[\frac{(+1)(-1)}{0.276 \mathrm{~nm}}\right]=-8.37 \times 10^{-19} \mathrm{~J}
$$

where the negative sign indicates an attractive force. That is, the ion pair has lower energy than the separated ions.

Coulomb's law also can be used to calculate the repulsive energy when two likecharged ions are brought together. In this case the calculated value of the energy will have a positive sign.

We have seen that a bonding force develops when two different types of atoms react to form oppositely charged ions. But how does a bonding force develop between two identical atoms? Let's explore this situation from a very simple point of view by considering the energy terms that result when two hydrogen atoms are brought close together, as shown in Fig. 8.1(a). When hydrogen atoms are brought close together,

FIGURE 8.1 (a) The interaction of two hydrogen atoms. (b) Energy profile as a function of the distance between the nuclei of the hydrogen atoms. As the atoms approach each other (right side of graph), the energy decreases until the distance reaches $0.074 \mathrm{~nm}(74 \mathrm{pm})$ and then begins to increase again due to repulsions.

## CHEMICAL CDNNECTIDNS

## No Lead Pencils

Did you ever wonder why the part of a pencil that makes the mark is called the "lead"? Pencils have no lead in them now-and they never have. Apparently the association between writing and the element lead arose during the Roman Empire, when lead rods were used as writing utensils because they leave a gray mark on paper. Many centuries later, in 1564, a deposit of a black substance found to be very useful for writing was discovered in Borrowdale, England. This substance, originally called "black lead," was shown in 1879 by Swedish chemist Carl Scheele to be a form of carbon and was subsequently named graphite (after the Greek graphein, meaning"to write").

Originally, chunks of graphite from Borrowdale, called marking stones, were used as writing instruments. Later, sticks of graphite were used. Because graphite is brittle, the sticks needed reinforcement. At first they were wrapped in string, which was unwound as the core wore down. Eventually, graphite rods were tied between two wooden slats or inserted into hollowed-out wooden sticks to form the first crude pencils.

Although Borrowdale graphite was pure enough to use directly, most graphite must be mixed with other materials to be useful for writing instruments. In 1795 , the French chemist Nicolas-Jaques Conté invented a process in which graphite is mixed with clay and water to produce pencil "lead," a recipe that is still used today. In modern pencil manufacture, graphite and clay are mixed and crushed into a fine powder to which water is added. After the gray sludge is blended for several days, it is dried, ground up again, and mixed with more water to give a gray paste. The paste is extruded through a metal tube to form thin rods, which are then cut into pencil-length pieces called "leads." These leads are heated in

an oven to $1000^{\circ} \mathrm{C}$ until they are smooth and hard. The ratio of clay to graphite is adjusted to vary the hardness of the lead-the more clay in the mix, the harder the lead and the lighter the line it makes.

Pencils are made from a slat of wood with several grooves cut in it to hold the leads. A similar grooved slat is then placed on top and glued to form a "sandwich" from which individual pencils are cut, sanded smooth, and painted. Although many types of wood have been used over the years to make pencils, the current favorite is incense cedar from the Sierra Nevada Mountains of California.

Modern pencils are simple but amazing instruments. The average pencil can write approximately 45,000 words, which is equivalent to a line 35 miles long. The graphite in a pencil is easily transferred to paper because
graphite contains layers of carbon atoms bound together in a "chickenwire" structure. Although the bonding within each layer is very strong, the bonding between layers is weak, giving graphite its slippery, soft nature. In this way, graphite is much different from diamond, the other common elemental form of carbon. In diamond the carbon atoms are bound tightly in all three dimensions, making it extremely hard-the hardest natural substance.

Pencils are very useful-especially for doing chemistry problems-because we can erase our mistakes. Most pencils used in the United States have erasers (first attached to pencils in 1858), although most European pencils do not. Laid end to end, the number of pencils made in the United States each year would circle the earth about 15 times. Pencils illustrate how useful a simple substance like graphite can be.

A bond will form if the energy of the aggregate is lower than that of the separated atoms.

Potential energy was discussed in Chapter 6.

Ionic and covalent bonds are the extreme bond types.
there are two unfavorable potential energy terms, proton-proton repulsion and electronelectron repulsion, and one favorable term, proton-electron attraction. Under what conditions will the $\mathrm{H}_{2}$ molecule be favored over the separated hydrogen atoms? That is, what conditions will favor bond formation? The answer lies in the strong tendency in nature for any system to achieve the lowest possible energy. A bond will form (that is, the two hydrogen atoms will exist as a molecular unit) if the system can lower its total energy in the process.

In this case, then, the hydrogen atoms will position themselves so that the system will achieve the lowest possible energy; the system will act to minimize the sum of the positive (repulsive) energy terms and the negative (attractive) energy term. The distance where the energy is minimal is called the bond length. The total energy of this system as a function of distance between the hydrogen nuclei is shown in Fig. 8.1(b). Note several important features of this diagram:

The energy terms involved are the net potential energy that results from the attractions and repulsions among the charged particles and the kinetic energy due to the motions of the electrons.

The zero point of energy is defined with the atoms at infinite separation.
At very short distances the energy rises steeply because of the importance of the repulsive forces when the atoms are very close together.
The bond length is the distance at which the system has minimum energy.
In the $\mathrm{H}_{2}$ molecule, the electrons reside primarily in the space between the two nuclei, where they are attracted simultaneously by both protons. This positioning is precisely what leads to the stability of the $\mathrm{H}_{2}$ molecule compared with two separated hydrogen atoms. The potential energy of each electron is lowered because of the increased attractive forces in this area. When we say that a bond is formed between the hydrogen atoms, we mean that the $\mathrm{H}_{2}$ molecule is more stable than two separated hydrogen atoms by a certain quantity of energy (the bond energy).

We can also think of a bond in terms of forces. The simultaneous attraction of each electron by the protons generates a force that pulls the protons toward each other and that just balances the proton-proton and electron-electron repulsive forces at the distance corresponding to the bond length.

The type of bonding we encounter in the hydrogen molecule and in many other molecules in which electrons are shared by nuclei is called covalent bonding.

So far we have considered two extreme types of bonding. In ionic bonding the participating atoms are so different that one or more electrons are transferred to form oppositely charged ions, which then attract each other. In covalent bonding two identical atoms share electrons equally. The bonding results from the mutual attraction of the two nuclei for the shared electrons. Between these extremes are intermediate cases in which the atoms are not so different that electrons are completely transferred but are different enough that unequal sharing results, forming what is called a polar covalent bond. An example of this type of bond occurs in the hydrogen fluoride (HF) molecule. When a sample of hydrogen fluoride gas is placed in an electric field, the molecules tend to orient themselves as shown in Fig. 8.2, with the fluoride end closest to the positive pole and the hydrogen end closest to the negative pole. This result implies that the HF molecule has the following charge distribution:

$$
\mathrm{H}-\mathrm{F}
$$

where $\delta$ (lowercase delta) is used to indicate a fractional charge. This same effect was noted in Chapter 4, where many of water's unusual properties were attributed to the polar $\mathrm{O}-\mathrm{H}$ bonds in the $\mathrm{H}_{2} \mathrm{O}$ molecule.

The most logical explanation for the development of the partial positive and negative charges on the atoms (bond polarity) in such molecules as HF and $\mathrm{H}_{2} \mathrm{O}$ is that the electrons in the bonds are not shared equally. For example, we can account for the

FIGURE 8.2 The effect of an electric field on hydrogen fluoride molecules. (a) When no electric field is present, the molecules are randomly oriented. (b) When the field is turned on, the molecules tend to line up with their negative ends toward the positive pole and their positive ends toward the negative pole.

polarity of the HF molecule by assuming that the fluorine atom has a stronger attraction for the shared electrons than the hydrogen atom. Likewise, in the $\mathrm{H}_{2} \mathrm{O}$ molecule the oxygen atom appears to attract the shared electrons more strongly than the hydrogen atoms do. Because bond polarity has important chemical implications, we find it useful to quantify the ability of an atom to attract shared electrons. In the next section we show how this is done.

### 8.2 Electronegativity

The different affinities of atoms for the electrons in a bond are described by a property called electronegativity: the ability of an atom in a molecule to attract shared electrons to itself.

The most widely accepted method for determining values of electronegativity is that of Linus Pauling (1901-1995), an American scientist who won the Nobel Prizes for both chemistry and peace. To understand Pauling's model, consider a hypothetical molecule HX . The relative electronegativities of the H and X atoms are determined by comparing the measured $\mathrm{H}-\mathrm{X}$ bond energy with the "expected" $\mathrm{H}-\mathrm{X}$ bond energy, which is an average of the $\mathrm{H}-\mathrm{H}$ and $\mathrm{X}-\mathrm{X}$ bond energies:

$$
\text { Expected } H-X \text { bond energy }=\frac{H-H \text { bond energy }+X-X \text { bond energy }}{2}
$$

The difference $(\Delta)$ between the actual (measured) and expected bond energies is

$$
\Delta=(\mathrm{H}-\mathrm{X})_{\mathrm{act}}-(\mathrm{H}-\mathrm{X})_{\mathrm{exp}}
$$

If H and X have identical electronegativities, $(\mathrm{H}-\mathrm{X})_{\text {act }}$ and $(\mathrm{H}-\mathrm{X})_{\text {exp }}$ are the same, and $\Delta$ is 0 . On the other hand, if X has a greater electronegativity than H , the shared electron(s) will tend to be closer to the X atom. The molecule will be polar, with the following charge distribution:

$$
\mathrm{H}-\mathrm{X}
$$

Note that this bond can be viewed as having an ionic as well as a covalent component. The attraction between the partially (and oppositely) charged H and X atoms will lead to a greater bond strength. Thus $(\mathrm{H}-\mathrm{X})_{\text {act }}$ will be larger than $(\mathrm{H}-\mathrm{X})_{\text {exp. }}$. The greater the difference in the electronegativities of the atoms, the greater is the ionic component of the bond and the greater is the value of $\Delta$. Thus the relative electronegativities of H and X can be assigned from the $\Delta$ values.

Increasing electronegativity

FIGURE 8.3 The Pauling electronegativity values. Electronegativity generally increases across a period and decreases down a group.

Electronegativity values have been determined by this process for virtually all the elements; the results are given in Fig. 8.3. Note that electronegativity generally increases going from left to right across a period and decreases going down a group for the representative elements. The range of electronegativity values is from 4.0 for fluorine to 0.7 for cesium.

The relationship between electronegativity and bond type is shown in Table 8.1. For identical atoms (an electronegativity difference of zero), the electrons in the bond are shared equally, and no polarity develops. When two atoms with very different electronegativities interact, electron transfer can occur to form the ions that make up an ionic substance. Intermediate cases give polar covalent bonds with unequal electron sharing.

## INTERACTIVE EXAMPLE 8.1

## SOLUTION

## Relative Bond Polarities

Order the following bonds according to polarity: $\mathrm{H}-\mathrm{H}, \mathrm{O}-\mathrm{H}, \mathrm{Cl}-\mathrm{H}, \mathrm{S}-\mathrm{H}$, and $\mathrm{F}-\mathrm{H}$.

The polarity of the bond increases as the difference in electronegativity increases. From the electronegativity values in Fig. 8.3, the following variation in bond polarity is expected (the electronegativity value appears in parentheses below each element):

$$
\underset{(2.1)(2.1)}{\mathrm{H}-\mathrm{H}}<\underset{(2.5)(2.1)}{\mathrm{S}} \mathrm{H} \underset{(3.0)(2.1)}{\mathrm{Cl}-\mathrm{H}}<\underset{(3.5)(2.1)}{\mathrm{O}}-\mathrm{H}<\underset{(4.0)(2.1)}{\mathrm{F}-\mathrm{H}}
$$

Electronegativity difference

## See Exercises 8.41 and 8.42

 to account for certain properties of bonds. What if all atoms had the same electronegativity values? How would bonding between atoms be affected? What are some differences we would notice?

# TABLE 8.1 | The Relationship Between Electronegativity and Bond Type 

### 8.3 Bond Polarity and Dipole Moments

We have seen that when hydrogen fluoride is placed in an electric field, the molecules have a preferential orientation (see Fig. 8.2). This follows from the charge distribution in the HF molecule, which has a positive end and a negative end. A molecule such as HF that has a center of positive charge and a center of negative charge is said to be dipolar, or to have a dipole moment. The dipolar character of a molecule is often represented by an arrow pointing to the negative charge center with the tail of the arrow indicating the positive center of charge:

Another way to represent the charge distribution in HF is by an electrostatic potential diagram (Fig. 8.4). For this representation the colors of visible light are used to show the variation in charge distribution. Red indicates the most electron-rich region of the molecule, and blue indicates the most electron-poor region.

Of course, any diatomic (two-atom) molecule that has a polar bond also will show a molecular dipole moment. Table 8.2 shows the dipole moments (in Debye units) of the various HX molecules. Note how the dipole moment depends on the electronegativity of X.

Polyatomic molecules also can exhibit dipolar behavior. For example, because the oxygen atom in the water molecule has a greater electronegativity than the hydrogen atoms, the molecular charge distribution is that shown in Fig. 8.5(a). Because of this charge distribution, the water molecule behaves in an electric field as if it had two centers of charge-one positive and one negative-as shown in Fig. 8.5(b). The water

## TABLE 8.2 | Dipole Moments of Hydrogen Halides

| Molecule | Electronegativity of Halogen | Dipole Moment (Debyes) |
| :---: | :---: | :---: |
| HF | 4.0 | 1.86 |

molecule has a dipole moment. The same type of behavior is observed for the $\mathrm{NH}_{3}$ molecule (Fig. 8.6). Some molecules have polar bonds but do not have a dipole moment. This occurs when the individual bond polarities are arranged in such a way that they cancel each other out. An example is the $\mathrm{CO}_{2}$ molecule, which is a linear molecule that has the charge distribution shown in Fig. 8.7. In this case the opposing bond polarities cancel out, and the carbon dioxide molecule does not have a dipole moment. There is no preferential way for this molecule to line up in an electric field. (Try to find a preferred orientation to make sure you understand this concept.)

There are many cases besides that of carbon dioxide where the bond polarities oppose and exactly cancel each other. Some common types of molecules with polar bonds but no dipole moment are shown in Table 8.3.

TABLE 8.3 | Types of Molecules with Polar Bonds but No Resulting Dipole Moment

FIGURE 8.7 (a) The carbon dioxide molecule. (b) The opposed bond polarities cancel out, and the carbon dioxide molecule has no dipole moment. (c) The electrostatic potential diagram for carbon dioxide.

## EXAMPLE 8.2 Bond Polarity and Dipole Moment

For each of the following molecules, show the direction of the bond polarities and indicate which ones have a dipole moment: $\mathrm{HCl}, \mathrm{Cl}_{2}, \mathrm{SO}_{3}$ (a planar molecule with the oxygen atoms spaced evenly around the central sulfur atom), $\mathrm{CH}_{4}$ [tetrahedral (see Table 8.3) with the carbon atom at the center], and $\mathrm{H}_{2} \mathrm{~S}$ (V-shaped with the sulfur atom at the point).

## SOLUTION

Recall that a blue color is an electron-poor region and red is an electron-rich region.

The HCl molecule: In Fig. 8.3, we see that the electronegativity of chlorine (3.0) is greater than that of hydrogen (2.1). Thus the chlorine will be partially negative, and the hydrogen will be partially positive. The HCl molecule has a dipole moment:

The $\mathrm{Cl}_{2}$ molecule: The two chlorine atoms share the electrons equally. No bond polarity occurs, and the $\mathrm{Cl}_{2}$ molecule has no dipole moment.

The $\mathrm{SO}_{3}$ molecule: The electronegativity of oxygen (3.5) is greater than that of sulfur (2.5). This means that each oxygen will have a partial negative charge, and the sulfur will have a partial positive charge:

The bond polarities arranged symmetrically as shown cancel, and the molecule has no dipole moment. This molecule is the second type shown in Table 8.3.

The presence of polar bonds does not always yield a polar molecule.

The $\mathrm{CH}_{4}$ molecule: Carbon has a slightly higher electronegativity (2.5) than does hydrogen (2.1). This leads to small partial positive charges on the hydrogen atoms and a small partial negative charge on the carbon:

This case is similar to the third type in Table 8.3, and the bond polarities cancel. The molecule has no dipole moment.

The $\mathrm{H}_{2} \mathrm{~S}$ molecule: Since the electronegativity of sulfur (2.5) is slightly greater than that of hydrogen (2.1), the sulfur will have a partial negative charge, and the hydrogen atoms will have a partial positive charge, which can be represented as

This case is analogous to the water molecule, and the polar bonds result in a dipole moment oriented as shown:

Atoms in stable compounds usually have a noble gas electron configuration.

### 8.4 Ions: Electron Configurations and Sizes

The description of the electron arrangements in atoms that emerged from the quantum mechanical model has helped a great deal in our understanding of what constitutes a stable compound. In virtually every case, the atoms in a stable compound have a noble gas arrangement of electrons. Nonmetallic elements achieve a noble gas electron configuration either by sharing electrons with other nonmetals to form covalent bonds or by taking electrons from metals to form ions. In the second case, the nonmetals form anions, and the metals form cations. The generalizations that apply to electron configurations in stable compounds are as follows:

## Electron Configuration of Compounds

") When two nonmetals react to form a covalent bond, they share electrons in a way that completes the valence electron configurations of both atoms. That is, both nonmetals attain noble gas electron configurations.
" When a nonmetal and a representative-group metal react to form a binary ionic compound, the ions form so that the valence electron configuration of the nonmetal achieves the electron configuration of the next noble gas atom and the valence orbitals of the metal are emptied. In this way both ions achieve noble gas electron configurations.

In the solid state of an ionic compound, the ions are relatively close together and many ions are simultaneously interacting:

In the gas phase of an ionic substance, the ions would be relatively far apart and would not contain large groups of ions:

A
A bauxite mine. Bauxite contains $\mathrm{Al}_{2} \mathrm{O}_{3}$, the main source of aluminum.

These generalizations apply to the vast majority of compounds and are important to remember. We will deal with covalent bonds more thoroughly later, but now we will consider what implications these rules hold for ionic compounds.

## Predicting Formulas of Ionic Compounds

At the beginning of this discussion, it should be emphasized that when chemists use the term ionic compound, they are usually referring to the solid state of that compound. In the solid state, the ions are close together. That is, solid ionic compounds contain a large collection of positive and negative ions packed together in a way that minimizes the $\Theta \cdot \ominus$ and $\oplus \cdots \oplus$ repulsions and maximizes the $\oplus \cdot \ominus$ attractions. This situation stands in contrast to the gas phase of an ionic substance, where the ions are quite far apart on average. In the gas phase, a pair of ions may get close enough to interact, but large collections of ions do not exist. Thus, when we speak in this text of the stability of an ionic compound, we are referring to the solid state, where the large attractive forces present among oppositely charged ions tend to stabilize (favor the formation of) the ions. For example, as we mentioned in the preceding chapter, the $\mathrm{O}^{2-}$ ion is not stable as an isolated, gas-phase species but, of course, is very stable in many solid ionic compounds. That is, $\mathrm{MgO}(s)$, which contains $\mathrm{Mg}^{2+}$ and $\mathrm{O}^{2-}$ ions, is very stable, but the isolated, gas-phase ion pair $\mathrm{Mg}^{2+} \cdot \cdot \mathrm{O}^{2-}$ is not energetically favorable in comparison with the separate neutral gaseous atoms. Thus you should keep in mind that in this section, and in most other cases where we are describing the nature of ionic compounds, the discussion usually refers to the solid state, where many ions are simultaneously interacting.

To illustrate the principles of electron configurations in stable, solid ionic compounds, we will consider the formation of an ionic compound from calcium and oxygen. We can predict what compound will form by considering the valence electron configurations of the two atoms:

$$
\begin{array}{ll}
\mathrm{Ca} & {[\mathrm{Ar}] 4 s^{2}} \\
\mathrm{O} & {[\mathrm{He}] 2 s^{2} 2 p^{4}}
\end{array}
$$

From Fig. 8.3 we see that the electronegativity of oxygen (3.5) is much greater than that of calcium (1.0). Because of this large difference, electrons will be transferred from calcium to oxygen to form oxygen anions and calcium cations in the compound. How many electrons are transferred? We can base our prediction on the observation that noble gas configurations are generally the most stable. Note that oxygen needs two electrons to fill its $2 s$ and $2 p$ valence orbitals and to achieve the configuration of neon ( $1 s^{2} 2 s^{2} 2 p^{6}$ ). And by losing two electrons, calcium can achieve the configuration of argon. Two electrons therefore transferred:

$$
\underset{2 \mathrm{e}^{-}}{\mathrm{Ca}+\mathrm{O}} \longrightarrow \mathrm{Ca}^{2+}+\mathrm{O}^{2-}
$$

To predict the formula of the ionic compound, we simply recognize that chemical compounds are always electrically neutral-they have the same quantities of positive and negative charges. In this case we have equal numbers of $\mathrm{Ca}^{2+}$ and $\mathrm{O}^{2-}$ ions, and the empirical formula of the compound is CaO .

The same principles can be applied to many other cases. For example, consider the compound formed between aluminum and oxygen. Because aluminum has the configuration $[\mathrm{Ne}] 3 s^{2} 3 p^{1}$, it loses three electrons to form the $\mathrm{Al}^{3+}$ ion and thus achieves the neon configuration. Therefore, the $\mathrm{Al}^{3+}$ and $\mathrm{O}^{2-}$ ions form in this case. Since the compound must be electrically neutral, there must be three $\mathrm{O}^{2-}$ ions for every two $\mathrm{Al}^{3+}$ ions, and the compound has the empirical formula $\mathrm{Al}_{2} \mathrm{O}_{3}$.

Table 8.4 shows common elements that form ions with noble gas electron configurations in ionic compounds. In losing electrons to form cations, metals in Group 1A lose one electron, those in Group 2A lose two electrons, and those in Group 3A lose

## TABLE 8.4 | Common Ions with Noble Gas Configurations in Ionic Compounds

| Group 1A | Group 2A | Group 3A | Group 6A | Group 7A | Electron <br> Configuration |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{H}^{-}, \mathrm{Li}^{+}$ | $\mathrm{Be}^{2+}$ |  |  |  | $[\mathrm{He}]$ |
| $\mathrm{Na}^{+}$ | $\mathrm{Mg}^{2+}$ | $\mathrm{Al}^{3+}$ | $\mathrm{O}^{2-}$ | $\mathrm{F}^{-}$ | $[\mathrm{Ne}]$ |
| $\mathrm{K}^{+}$ | $\mathrm{Ca}^{2+}$ |  | $\mathrm{S}^{2-}$ | $\mathrm{Cl}^{-}$ | $[\mathrm{Ar}]$ |
| $\mathrm{Rb}^{+}$ | $\mathrm{Sr}^{2+}$ |  | $\mathrm{Se}^{2-}$ | $\mathrm{Br}^{-}$ | $[\mathrm{Kr}]$ |
| $\mathrm{Cs}^{+}$ | $\mathrm{Ba}^{2+}$ |  | $\mathrm{Te}^{2-}$ | $\mathrm{I}^{-}$ | $[\mathrm{Xe}]$ |

three electrons. In gaining electrons to form anions, nonmetals in Group 7A (the halogens) gain one electron, and those in Group 6A gain two electrons. Hydrogen typically behaves as a nonmetal and can gain one electron to form the hydride ion $\left(\mathrm{H}^{-}\right)$, which has the electron configuration of helium.

There are some important exceptions to the rules discussed here. For example, tin forms both $\mathrm{Sn}^{2+}$ and $\mathrm{Sn}^{4+}$ ions, and lead forms both $\mathrm{Pb}^{2+}$ and $\mathrm{Pb}^{4+}$ ions. Also, bismuth forms $\mathrm{Bi}^{3+}$ and $\mathrm{Bi}^{5+}$ ions, and thallium forms $\mathrm{Tl}^{+}$and $\mathrm{Tl}^{3+}$ ions. There are no simple explanations for the behavior of these ions. For now, just note them as exceptions to the very useful rule that ions generally adopt noble gas electron configurations in ionic compounds. Our discussion here refers to representative metals. The transition metals exhibit more complicated behavior, forming a variety of ions that will be considered in Chapter 21.

## Sizes of lons

Ion size plays an important role in determining the structure and stability of ionic solids, the properties of ions in aqueous solution, and the biologic effects of ions. As with atoms, it is impossible to define precisely the sizes of ions. Most often, ionic radii are determined from the measured distances between ion centers in ionic compounds. This method, of course, involves an assumption about how the distance should be divided up between the two ions. Thus you will note considerable disagreement among ionic sizes given in various sources. Here we are mainly interested in trends and will be less concerned with absolute ion sizes.

Various factors influence ionic size. We will first consider the relative sizes of an ion and its parent atom. Since a positive ion is formed by removing one or more electrons from a neutral atom, the resulting cation is smaller than its parent atom. The opposite is true for negative ions; the addition of electrons to a neutral atom produces an anion significantly larger than its parent atom.

It is also important to know how the sizes of ions vary depending on the positions of the parent elements in the periodic table. Figure 8.8 shows the sizes of the most important ions (each with a noble gas configuration) and their position in the periodic table. Note that ion size increases down a group. The changes that occur horizontally are complicated because of the change from predominantly metals on the left-hand side of the periodic table to nonmetals on the right-hand side. A given period thus contains both elements that give up electrons to form cations and ones that accept electrons to form anions.

One trend worth noting involves the relative sizes of a set of isoelectronic ionsions containing the same number of electrons. Consider the ions $\mathrm{O}^{2-}, \mathrm{F}^{-}, \mathrm{Na}^{+}, \mathrm{Mg}^{2+}$, and $\mathrm{Al}^{3+}$. Each of these ions has the neon electron configuration. How do the sizes of these ions vary? In general, there are two important facts to consider in predicting the relative sizes of ions: the number of electrons and the number of protons. Since these

FIGURE 8.8 Sizes of ions related to positions of the elements on the periodic table. Note that size generally increases down a group. Also note that in a series of isoelectronic ions, size decreases with increasing atomic number. The ionic radii are given in units of picometers.

For isoelectronic ions, size decreases as $Z$ increases.

133

148

148

184

198

ions are isoelectronic, the number of electrons is 10 in each case. Electron repulsions therefore should be about the same in all cases. However, the number of protons increases from 8 to 13 as we go from the $\mathrm{O}^{2-}$ ion to the $\mathrm{Al}^{3+}$ ion. Thus, in going from $\mathrm{O}^{2-}$ to $\mathrm{Al}^{3+}$, the 10 electrons experience a greater attraction as the positive charge on the nucleus increases. This causes the ions to become smaller. You can confirm this by looking at Fig. 8.8. In general, for a series of isoelectronic ions, the size decreases as the nuclear charge $Z$ increases.
 atoms. What if ions stayed the same size as their parent atoms? How would this affect ionic bonding in compounds?

## INTERACTIVE EXAMPLE 8.3

## Relative Ion Size I

Arrange the ions $\mathrm{Se}^{2-}, \mathrm{Br}^{-}, \mathrm{Rb}^{+}$, and $\mathrm{Sr}^{2+}$ in order of decreasing size.

## SOLUTION

This is an isoelectronic series of ions with the krypton electron configuration. Since these ions all have the same number of electrons, their sizes will depend on the nuclear charge. The $Z$ values are 34 for $\mathrm{Se}^{2-}, 35$ for $\mathrm{Br}^{-}, 37$ for $\mathrm{Rb}^{+}$, and 38 for $\mathrm{Sr}^{2+}$. Since the nuclear charge is greatest for $\mathrm{Sr}^{2+}$, it is the smallest of these ions. The $\mathrm{Se}^{2-}$ ion is largest:

## INTERACTIVE EXAMPLE 8.4 Relative Ion Size II

## SOLUTION

a. The ions are all from Group 1A elements. Since size increases down a group (the ion with the greatest number of electrons is largest), $\mathrm{Cs}^{+}$is the largest ion.
b. This is an isoelectronic series of ions, all of which have the xenon electron configuration. The ion with the smallest nuclear charge is largest:

$$
\begin{gathered}
\mathrm{Te}^{2-}>\mathrm{I}^{-} \quad>\mathrm{Cs}^{+} \quad>\mathrm{Ba}^{2+} \\
Z=52 \quad Z=53 \quad Z=55 \quad Z=56
\end{gathered}
$$

The structures of ionic solids will be discussed in detail in Chapter 10.

A
Lithium fluoride.

### 8.5 Energy Effects in Binary Ionic Compounds

In this section we will introduce the factors that influence the stability and the structures of solid binary ionic compounds. We know that metals and nonmetals react by transferring electrons to form cations and anions that are mutually attractive. The resulting ionic solid forms because the aggregated oppositely charged ions have a lower energy than the original elements. Just how strongly the ions attract each other in the solid state is indicated by the lattice energy-the change in energy that takes place when separated gaseous ions are packed together to form an ionic solid:

$$
\mathrm{M}^{+}(g)+\mathrm{X}^{-}(g) \longrightarrow \mathrm{MX}(s)
$$

The lattice energy is often defined as the energy released when an ionic solid forms from its ions. However, in this book the sign of an energy term is always determined from the system's point of view: negative if the process is exothermic, positive if endothermic. Thus, using this convention, the lattice energy has a negative sign.

We can illustrate the energy changes involved in the formation of an ionic solid by considering the formation of solid lithium fluoride from its elements:

$$
\mathrm{Li}(s)+\frac{1}{2} \mathrm{~F}_{2}(g) \longrightarrow \mathrm{LiF}(s)
$$

To see the energy terms associated with this process, we take advantage of the fact that energy is a state function and break this reaction into steps, the sum of which gives the overall reaction.

1. Sublimation of solid lithium. Sublimation involves taking a substance from the solid state to the gaseous state:

$$
\mathrm{Li}(s) \longrightarrow \mathrm{Li}(g)
$$

The enthalpy of sublimation for $\mathrm{Li}(s)$ is $161 \mathrm{~kJ} / \mathrm{mol}$.
2. Ionization of lithium atoms to form $\mathrm{Li}^{+}$ions in the gas phase:

$$
\mathrm{Li}(g) \longrightarrow \mathrm{Li}^{+}(g)+\mathrm{e}^{-}
$$

This process corresponds to the first ionization energy for lithium, which is $520 \mathrm{~kJ} / \mathrm{mol}$.
3. Dissociation of fluorine molecules. We need to form a mole of fluorine atoms by breaking the $\mathrm{F}-\mathrm{F}$ bonds in a half mole of $\mathrm{F}_{2}$ molecules:

$$
\frac{1}{2} \mathrm{~F}_{2}(g) \longrightarrow \mathrm{F}(g)
$$

The energy required to break this bond is $154 \mathrm{~kJ} / \mathrm{mol}$. In this case we are breaking the bonds in a half mole of fluorine, so the energy required for this step is $(154 \mathrm{~kJ}) / 2$, or 77 kJ .
4. Formation of $\mathrm{F}^{-}$ions from fluorine atoms in the gas phase:

$$
\mathrm{F}(g)+\mathrm{e}^{-} \longrightarrow \mathrm{F}^{-}(g)
$$

The energy change for this process corresponds to the electron affinity of fluorine, which is $-328 \mathrm{~kJ} / \mathrm{mol}$.
5. Formation of solid lithium fluoride from the gaseous $\mathrm{Li}^{+}$and $\mathrm{F}^{-}$ions:

$$
\mathrm{Li}^{+}(g)+\mathrm{F}^{-}(g) \longrightarrow \mathrm{LiF}(s)
$$

This corresponds to the lattice energy for LiF , which is $-1047 \mathrm{~kJ} / \mathrm{mol}$.
Since the sum of these five processes yields the desired overall reaction, the sum of the individual energy changes gives the overall energy change:

This process is summarized by the energy diagram in Fig. 8.9. Note that the formation of solid lithium fluoride from its elements is highly exothermic, mainly because of the very large negative lattice energy. A great deal of energy is released when the ions combine to form the solid. In fact, note that the energy released when an electron is added to a fluorine atom to form the $\mathrm{F}^{-}$ion ( $328 \mathrm{~kJ} / \mathrm{mol}$ ) is not enough to remove an electron from lithium ( $520 \mathrm{~kJ} / \mathrm{mol}$ ). That is, when a metallic lithium atom reacts with a nonmetallic fluorine atom to form separated ions,

$$
\mathrm{Li}(g)+\mathrm{F}(g) \longrightarrow \mathrm{Li}^{+}(g)+\mathrm{F}^{-}(g)
$$

the process is endothermic and thus unfavorable. Clearly, then, the main impetus for the formation of an ionic compound rather than a covalent compound results from the

FIGURE 8.10 The structure of lithium fluoride. (a) Represented by ball-and-stick model. Note that each $\mathrm{Li}^{+}$ion is surrounded by six $\mathrm{F}^{-}$ions, and each $\mathrm{F}^{-}$ion is surrounded by six $\mathrm{Li}^{+}$ions. (b) Represented with the ions shown as spheres. The structure is determined by packing the spherical ions in a way that both maximizes the ionic attractions and minimizes the ionic repulsions.
strong mutual attractions among the $\mathrm{Li}^{+}$and $\mathrm{F}^{-}$ions in the solid. The lattice energy is the dominant energy term.

The structure of solid lithium fluoride is represented in Fig. 8.10. Note the alternating arrangement of the $\mathrm{Li}^{+}$and $\mathrm{F}^{-}$ions. Also note that each $\mathrm{Li}^{+}$is surrounded by six $\mathrm{F}^{-}$ions, and each $\mathrm{F}^{-}$ion is surrounded by six $\mathrm{Li}^{+}$ions. This structure can be rationalized by assuming that the ions behave as hard spheres that pack together in a way that both maximizes the attractions among the oppositely charged ions and minimizes the repulsions among the identically charged ions.

All the binary ionic compounds formed by an alkali metal and a halogen have the structure shown in Fig. 8.10, except for the cesium salts. The arrangement of ions shown in Fig. 8.10 is often called the sodium chloride structure, after the most common substance that possesses it.

## Lattice Energy Calculations

In discussing the energetics of the formation of solid lithium fluoride, we emphasized the importance of lattice energy in contributing to the stability of the ionic solid. Lattice energy can be represented by a modified form of Coulomb's law:

$$
\text { Lattice energy }=k\left(\frac{Q_{1} Q_{2}}{r}\right)
$$

where $k$ is a proportionality constant that depends on the structure of the solid and the electron configurations of the ions, $Q_{1}$ and $Q_{2}$ are the charges on the ions, and $r$ is the shortest distance between the centers of the cations and anions. Note that the lattice energy has a negative sign when $Q_{1}$ and $Q_{2}$ have opposite signs. This result is expected, since bringing cations and anions together is an exothermic process. Also note that the process becomes more exothermic as the ionic charges increase and as the distances between the ions in the solid decrease.

The importance of the charges in ionic solids can be illustrated by comparing the energies involved in the formation of $\mathrm{NaF}(s)$ and $\mathrm{MgO}(s)$. These solids contain the isoelectronic ions $\mathrm{Na}^{+}, \mathrm{F}^{-}, \mathrm{Mg}^{2+}$, and $\mathrm{O}^{2-}$. The energy diagram for the formation of the two solids is given in Fig. 8.11. Note several important features:

The energy released when the gaseous $\mathrm{Mg}^{2+}$ and $\mathrm{O}^{2-}$ ions combine to form solid MgO is much greater (more than four times greater) than that released when the gaseous $\mathrm{Na}^{+}$and $\mathrm{F}^{-}$ions combine to form solid NaF .
The energy required to remove two electrons from the magnesium atom ( $735 \mathrm{~kJ} / \mathrm{mol}$ for the first and $1445 \mathrm{~kJ} / \mathrm{mol}$ for the second, yielding a total of $2180 \mathrm{~kJ} / \mathrm{mol}$ ) is much greater than the energy required to remove one electron from a sodium atom ( $495 \mathrm{~kJ} / \mathrm{mol}$ ).

Energy ( $737 \mathrm{~kJ} / \mathrm{mol}$ ) is required to add two electrons to the oxygen atom in the gas phase. Addition of the first electron is exothermic $(-141 \mathrm{~kJ} / \mathrm{mol})$, but addition of the second electron is quite endothermic ( $878 \mathrm{~kJ} / \mathrm{mol}$ ). This latter energy must be obtained indirectly, since the $\mathrm{O}^{2-}(g)$ ion is not stable.

In view of the facts that twice as much energy is required to remove the second electron from magnesium as to remove the first and that addition of an electron to the gaseous $\mathrm{O}^{-}$ion is quite endothermic, it seems puzzling that magnesium oxide contains $\mathrm{Mg}^{2+}$ and $\mathrm{O}^{2-}$ ions rather than $\mathrm{Mg}^{+}$and $\mathrm{O}^{-}$ions. The answer lies in the lattice energy. Note that the lattice energy for combining gaseous $\mathrm{Mg}^{2+}$ and $\mathrm{O}^{2-}$ ions to form $\mathrm{MgO}(s)$ is $3000 \mathrm{~kJ} / \mathrm{mol}$ more negative than that for combining gaseous $\mathrm{Na}^{+}$and $\mathrm{F}^{-}$ions to form $\mathrm{NaF}(s)$. Thus the energy released in forming a solid containing $\mathrm{Mg}^{2+}$ and $\mathrm{O}^{2-}$ ions rather than $\mathrm{Mg}^{+}$and $\mathrm{O}^{-}$ions more than compensates for the energies required for the processes that produce the $\mathrm{Mg}^{2+}$ and $\mathrm{O}^{2-}$ ions.

If there is so much lattice energy to be gained in going from singly charged to doubly charged ions in the case of magnesium oxide, why then does solid sodium fluoride

FIGURE 8.11 Comparison of the energy changes involved in the formation of solid sodium fluoride and solid magnesium oxide. Note the large lattice energy for magnesium oxide (where doubly charged ions are combining) compared with that for sodium fluoride (where singly charged ions are combining).
contain $\mathrm{Na}^{+}$and $\mathrm{F}^{-}$ions rather than $\mathrm{Na}^{2+}$ and $\mathrm{F}^{2-}$ ions? We can answer this question by recognizing that both $\mathrm{Na}^{+}$and $\mathrm{F}^{-}$ions have the neon electron configuration. Removal of an electron from $\mathrm{Na}^{+}$requires an extremely large quantity of energy ( $4560 \mathrm{~kJ} / \mathrm{mol}$ ) because a $2 p$ electron must be removed. Conversely, the addition of an electron to $\mathrm{F}^{-}$ would require use of the relatively high-energy $3 s$ orbital, which is also an unfavorable process. Thus we can say that for sodium fluoride the extra energy required to form the doubly charged ions is greater than the gain in lattice energy that would result.

This discussion of the energies involved in the formation of solid ionic compounds illustrates that a variety of factors operate to determine the composition and structure of these compounds. The most important of these factors involve the balancing of the energies required to form highly charged ions and the energy released when highly charged ions combine to form the solid.

b

FIGURE 8.12 The three possible types of bonds: (a) a covalent bond formed between identical F atoms; (b) the polar covalent bond of HF , with both ionic and covalent components; and (c) an ionic bond with no electron sharing.

$\Delta$

### 8.6 Partial Ionic Character

 of Covalent BondsRecall that when atoms with different electronegativities react to form molecules, the electrons are not shared equally. The possible result is a polar covalent bond or, in the case of a large electronegativity difference, a complete transfer of one or more electrons to form ions. The cases are summarized in Fig. 8.12.

How well can we tell the difference between an ionic bond and a polar covalent bond? The only honest answer to this question is that there are probably no totally ionic bonds between discrete pairs of atoms. The evidence for this statement comes from calculations of the percent ionic character for the bonds of various binary compounds in the gas phase. These calculations are based on comparisons of the measured dipole moments for molecules of the type $\mathrm{X}-\mathrm{Y}$ with the calculated dipole moments for the completely ionic case, $\mathrm{X}^{+} \mathrm{Y}^{-}$. The percent ionic character of a bond can be defined as

Percent ionic character of a bond $=\left(\frac{\text { measured dipole moment of } \mathrm{X}-\mathrm{Y}}{\text { calculated dipole moment of } \mathrm{X}^{+} \mathrm{Y}^{-}}\right) \times 100 \%$
Application of this definition to various compounds (in the gas phase) gives the results shown in Fig. 8.13, where percent ionic character is plotted versus the difference in the electronegativity values of X and Y . Note from this plot that ionic character increases with electronegativity difference, as expected. However, none of the bonds reaches $100 \%$ ionic character, even though compounds with the maximum possible electronegativity differences are considered. Thus, according to this definition, no individual bonds are completely ionic. This conclusion is in contrast to the usual classification of many of these compounds (as ionic solids). All the compounds shown in Fig. 8.13 with more than $50 \%$ ionic character are normally considered to be ionic solids. Recall, however, the results in Fig. 8.13 are for the gas phase, where individual XY molecules exist. These results cannot necessarily be assumed to apply to the solid state, where the existence of ions is favored by the multiple ion interactions.

Another complication in identifying ionic compounds is that many substances contain polyatomic ions. For example, $\mathrm{NH}_{4} \mathrm{Cl}$ contains $\mathrm{NH}_{4}^{+}$and $\mathrm{Cl}^{-}$ions, and $\mathrm{Na}_{2} \mathrm{SO}_{4}$ contains $\mathrm{Na}^{+}$and $\mathrm{SO}_{4}{ }^{2-}$ ions. The bonds within the ammonium and sulfate ions are covalent bonds.

We will avoid these problems by adopting an operational definition of ionic compounds: Any compound that conducts an electric current when melted will be classified as ionic.

FIGURE 8.13 The relationship between the ionic character of a covalent bond and the electronegativity difference of the bonded atoms. Note that the compounds with ionic character greater than $50 \%$ (red) are normally considered to be ionic compounds.

### 8.7 The Covalent Chemical Bond: <br> A Model

Before we develop specific models for covalent chemical bonding, it will be helpful to summarize some of the concepts introduced in this chapter.

What is a chemical bond? Chemical bonds can be viewed as forces that cause a group of atoms to behave as a unit.

Why do chemical bonds occur? There is no principle of nature that states that bonds are favored or disfavored. Bonds are neither inherently "good" nor inherently "bad" as far as nature is concerned; bonds result from the tendency of a system to seek its lowest possible energy. From a simplistic point of view, bonds occur when collections of atoms are more stable (lower in energy) than the separate atoms. For example, approximately 1652 kJ of energy is required to break a mole of methane $\left(\mathrm{CH}_{4}\right)$ molecules into separate C and H atoms. Or, taking the opposite view, 1652 kJ of energy is released when 1 mole of methane is formed from 1 mole of gaseous C atoms and 4 moles of gaseous H atoms. Thus we can say that 1 mole of $\mathrm{CH}_{4}$ molecules in the gas phase is 1652 kJ lower in energy than 1 mole of carbon atoms plus 4 moles of hydrogen atoms. Methane is therefore a stable molecule relative to its separated atoms.

We find it useful to interpret molecular stability in terms of a model called a chemical bond. To understand why this model was invented, let's continue with methane, which consists of four hydrogen atoms arranged at the corners of a tetrahedron around a carbon atom:

Given this structure, it is natural to envision four individual C - H interactions (we call them bonds). The energy of stabilization of $\mathrm{CH}_{4}$ is divided equally among the four bonds to give an average $\mathrm{C}-\mathrm{H}$ bond energy per mole of $\mathrm{C}-\mathrm{H}$ bonds:

$$
\frac{1652 \mathrm{~kJ} / \mathrm{mol}}{4}=413 \mathrm{~kJ} / \mathrm{mol}
$$

Next, consider methyl chloride, which consists of $\mathrm{CH}_{3} \mathrm{Cl}$ molecules having the structure

Experiments have shown that approximately 1578 kJ of energy is required to break down 1 mole of gaseous $\mathrm{CH}_{3} \mathrm{Cl}$ molecules into gaseous carbon, chlorine, and hydrogen atoms. The reverse process can be represented as

$$
\mathrm{C}(g)+\mathrm{Cl}(g)+3 \mathrm{H}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{Cl}(g)+1578 \mathrm{~kJ} / \mathrm{mol}
$$

A mole of gaseous methyl chloride is lower in energy by 1578 kJ than its separate gaseous atoms. Thus a mole of methyl chloride is held together by 1578 kJ of energy. Again, it is very useful to divide this energy into individual bonds. Methyl chloride can be visualized as containing one $\mathrm{C}-\mathrm{Cl}$ bond and three $\mathrm{C}-\mathrm{H}$ bonds. If we assume arbitrarily that a $\mathrm{C}-\mathrm{H}$ interaction represents the same quantity of energy in any situ-

## Bonding is a model proposed to explain molecular stability.

ation (that is, that the strength of a $\mathrm{C}-\mathrm{H}$ bond is independent of its molecular environment), we can do the following bookkeeping:

$$
1 \mathrm{~mol} \mathrm{C}-\mathrm{Cl} \text { bonds plus } 3 \mathrm{~mol} \mathrm{C}-\mathrm{H} \text { bonds }=1578 \mathrm{~kJ}
$$

$$
\mathrm{C}-\mathrm{Cl} \text { bond energy }+3(\text { average } \mathrm{C}-\mathrm{H} \text { bond energy })=1578 \mathrm{~kJ}
$$

$$
\mathrm{C}-\mathrm{Cl} \text { bond energy }+3(413 \mathrm{~kJ} / \mathrm{mol})=1578 \mathrm{~kJ}
$$

$$
\mathrm{C}-\mathrm{Cl} \text { bond energy }=1578-1239=339 \mathrm{~kJ} / \mathrm{mol}
$$

These assumptions allow us to associate given quantities of energy with $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}-\mathrm{Cl}$ bonds.

It is important to note that the bond concept is a human invention. Bonds provide a method for dividing up the energy evolved when a stable molecule is formed from its component atoms. Thus in this context a bond represents a quantity of energy obtained from the overall molecular energy of stabilization in a rather arbitrary way. This is not to say that the concept of individual bonds is a bad idea. In fact, the modern concept of the chemical bond, conceived by the American chemists G. N. Lewis and Linus Pauling, is one of the most useful ideas chemists have ever developed.

## Models: An Overview

The framework of chemistry, like that of any science, consists of models-attempts to explain how nature operates on the microscopic level based on experiences in the macroscopic world. To understand chemistry, one must understand its models and how they are used. We will use the concept of bonding to reemphasize the important characteristics of models, including their origin, structure, and uses.

Models originate from our observations of the properties of nature. For example, the concept of bonds arose from the observations that most chemical processes involve collections of atoms and that chemical reactions involve rearrangements of the ways the atoms are grouped. Therefore, to understand reactions, we must understand the forces that bind atoms together.

In natural processes there is a tendency toward lower energy. Collections of atoms therefore occur because the aggregated state has lower energy than the separated atoms. Why? As we saw earlier in this chapter, the best explanations for the energy change involve atoms sharing electrons or atoms transferring electrons to become ions. In the case of electron sharing, we find it convenient to assume that individual bonds occur between pairs of atoms. Let's explore the validity of this assumption and see how it is useful.

In a diatomic molecule such as $\mathrm{H}_{2}$, it is natural to assume that a bond exists between the atoms, holding them together. It is also useful to assume that individual bonds are present in polyatomic molecules such as $\mathrm{CH}_{4}$. Therefore, instead of thinking of $\mathrm{CH}_{4}$ as a unit with a stabilization energy of 1652 kJ per mole, we choose to think of $\mathrm{CH}_{4}$ as containing four $\mathrm{C}-\mathrm{H}$ bonds, each worth 413 kJ of energy per mole of bonds. Without this concept of individual bonds in molecules, chemistry would be hopelessly complicated. There are millions of different chemical compounds, and if each of these compounds had to be considered as an entirely new entity, the task of understanding chemical behavior would be overwhelming.

The bonding model provides a framework to systematize chemical behavior by enabling us to think of molecules as collections of common fundamental components. For example, a typical biomolecule, such as a protein, contains hundreds of atoms and might seem discouragingly complex. However, if we think of a protein as constructed of individual bonds, $\mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{H}, \mathrm{C}-\mathrm{N}, \mathrm{C}-\mathrm{O}, \mathrm{N}-\mathrm{H}$, and so on, it helps tremendously in predicting and understanding the protein's behavior. The essential idea is that we expect a given bond to behave about the same in any molecular environment. Used in this way, the model of the chemical bond has helped chemists to systematize the reactions of the millions of existing compounds.

In addition to being useful, the bonding model is physically sensible. It makes sense that atoms can form stable groups by sharing electrons; shared electrons give a lower energy state because they are simultaneously attracted by two nuclei.

The concept of individual bonds makes it much easier to deal with complex molecules such as DNA. Segments of several DNA molecules are shown here.

Also, as we will see in the next section, bond energy data support the existence of discrete bonds that are relatively independent of the molecular environment. It is very important to remember, however, that the chemical bond is only a model. Although our concept of discrete bonds in molecules agrees with many of our observations, some molecular properties require that we think of a molecule as a whole, with the electrons free to move through the entire molecule. This is called delocalization of the electrons, a concept that will be discussed more completely in the next chapter.

## LET'S REVIEW Fundamental Properties of Models

» Models are human inventions, always based on an incomplete understanding of how nature works. A model does not equal reality.
» Models are often wrong. This property derives from the first property. Models are based on speculation and are always oversimplifications.
» Models tend to become more complicated as they age. As flaws are discovered in our models, we "patch" them and thus add more detail.
» It is very important to understand the assumptions inherent in a particular model before you use it to interpret observations or to make predictions. Simple models usually involve very restrictive assumptions and can be expected to yield only qualitative information. Asking for a sophisticated explanation from a simple model is like expecting to get an accurate mass for a diamond using a bathroom scale.

For a model to be used effectively, we must understand its strengths and weaknesses and ask only appropriate questions. An illustration of this point is the simple aufbau principle used to account for the electron configurations of the elements. Although this model correctly predicts the configuration for most atoms, chromium and copper, for example, do not agree with the predictions. Detailed studies show that the configurations of chromium and copper result from complex electron interactions that are not taken into account in the simple model. However, this does not mean that we should discard the simple model that is so useful for most atoms. Instead, we must apply it with caution and not expect it to be correct in every case.
» When a model is wrong, we often learn much more than when it is right. If a model makes a wrong prediction, it usually means we do not understand some fundamental characteristics of nature. We often learn by making mistakes. (Try to remember this when you get back your next chemistry test.)

### 8.8 Covalent Bond Energies and Chemical Reactions

In this section we will consider the energies associated with various types of bonds and see how the bonding concept is useful in dealing with the energies of chemical reactions. One important consideration is to establish the sensitivity of a particular type of bond to its molecular environment. For example, consider the stepwise decomposition of methane:

## Process

$$
\begin{array}{lr}
\mathrm{CH}_{4}(g) \rightarrow \mathrm{CH}_{3}(g)+\mathrm{H}(g) & 435 \\
\mathrm{CH}_{3}(g) \rightarrow \mathrm{CH}_{2}(g)+\mathrm{H}(g) & 453 \\
\mathrm{CH}_{2}(g) \rightarrow \mathrm{CH}(g)+\mathrm{H}(g) & 425 \\
\mathrm{CH}(g) \rightarrow \mathrm{C}(g)+\mathrm{H}(g) & \\
& \\
& \text { Total }=1652 \\
& \text { Average }=\frac{1652}{4}=413
\end{array}
$$

Although a $\mathrm{C}-\mathrm{H}$ bond is broken in each case, the energy required varies in a nonsystematic way. This example shows that the $\mathrm{C}-\mathrm{H}$ bond is somewhat sensitive to its environment. We use the average of these individual bond dissociation energies even though this quantity only approximates the energy associated with a $\mathrm{C}-\mathrm{H}$ bond in a particular molecule. The degree of sensitivity of a bond to its environment also can be seen from experimental measurements of the energy required to break the $\mathrm{C}-\mathrm{H}$ bond in the following molecules:

Measured C-H Bond Energy

| Molecule | $(\mathbf{k J} / \mathbf{m o l})$ |
| :--- | :---: |
| $\mathrm{HCBr}_{3}$ | 380 |
| $\mathrm{HCCl}_{3}$ | 380 |
| $\mathrm{HCF}_{3}$ | 430 |
| $\mathrm{C}_{2} \mathrm{H}_{6}$ | 410 |

These data show that the $\mathrm{C}-\mathrm{H}$ bond strength varies significantly with its environment, but the concept of an average $\mathrm{C}-\mathrm{H}$ bond strength remains useful to chemists. The average values of bond energies for various types of bonds are listed in Table 8.5.

So far we have discussed bonds in which one pair of electrons is shared. This type of bond is called a single bond. As we will see in more detail later, atoms sometimes share two pairs of electrons, forming a double bond, or share three pairs of electrons, forming a triple bond. The bond energies for these multiple bonds are also given in Table 8.5.

A relationship also exists between the number of shared electron pairs and the bond length. As the number of shared electrons increases, the bond length shortens. This relationship is shown for selected bonds in Table 8.6.

## Bond Energy and Enthalpy

In this discussion we are ignoring the small difference between enthalpy and energy.

Bond energy values can be used to calculate approximate energies for reactions. To illustrate how this is done, we will calculate the change in energy that accompanies the following reaction:

$$
\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \longrightarrow 2 \mathrm{HF}(g)
$$

This reaction involves breaking one $\mathrm{H}-\mathrm{H}$ and one $\mathrm{F}-\mathrm{F}$ bond and forming two $\mathrm{H}-\mathrm{F}$ bonds. For bonds to be broken, energy must be added to the system-an endothermic process. Consequently, the energy terms associated with bond breaking have

TABLE 8.5 | Average Bond Energies ( $\mathrm{kJ} / \mathrm{mol}$ )

|  | Single Bonds |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{H}-\mathrm{H}$ | 432 | $\mathrm{~N}-\mathrm{H}$ | 391 | $\mathrm{I}-\mathrm{I}$ | 149 | $\mathrm{C}=\mathrm{C}$ | 614 |  |
| $\mathrm{H}-\mathrm{F}$ | 565 | $\mathrm{~N}-\mathrm{N}$ | 160 | $\mathrm{I}-\mathrm{Cl}$ | 208 | $\mathrm{C} \equiv \mathrm{C}$ | 839 |  |
| $\mathrm{H}-\mathrm{Cl}$ | 427 | $\mathrm{~N}-\mathrm{F}$ | 272 | $\mathrm{I}-\mathrm{Br}$ | 175 | $\mathrm{O}=\mathrm{O}$ | 495 |  |
| $\mathrm{H}-\mathrm{Br}$ | 363 | $\mathrm{~N}-\mathrm{Cl}$ | 200 |  |  | $\mathrm{C}=\mathrm{O}^{*}$ | 745 |  |
| $\mathrm{H}-\mathrm{I}$ | 295 | $\mathrm{~N}-\mathrm{Br}$ | 243 | $\mathrm{~S}-\mathrm{H}$ | 347 | $\mathrm{C} \equiv \mathrm{O}$ | 1072 |  |
|  |  | $\mathrm{~N}-\mathrm{O}$ | 201 | $\mathrm{~S}-\mathrm{F}$ | 327 | $\mathrm{~N}=\mathrm{O}$ | 607 |  |
| $\mathrm{C}-\mathrm{H}$ | 413 | $\mathrm{O}-\mathrm{H}$ | 467 | $\mathrm{~S}-\mathrm{Cl}$ | 253 | $\mathrm{~N}=\mathrm{N}$ | 418 |  |
| $\mathrm{C}-\mathrm{C}$ | 347 | $\mathrm{O}-\mathrm{O}$ | 146 | $\mathrm{~S}-\mathrm{Br}$ | 218 | $\mathrm{~N} \equiv \mathrm{~N}$ | 941 |  |
| $\mathrm{C}-\mathrm{N}$ | 305 | $\mathrm{O}-\mathrm{F}$ | 190 | $\mathrm{~S}-\mathrm{S}$ | 266 | $\mathrm{C} \equiv \mathrm{N}$ | 891 |  |
| $\mathrm{C}-\mathrm{O}$ | 358 | $\mathrm{O}-\mathrm{Cl}$ | 203 |  |  | $\mathrm{C}=\mathrm{N}$ | 615 |  |
| $\mathrm{C}-\mathrm{F}$ | 485 | $\mathrm{O}-\mathrm{I}$ | 234 | $\mathrm{Si}-\mathrm{Si}$ | 340 |  |  |  |
| $\mathrm{C}-\mathrm{Cl}$ | 339 |  |  | $\mathrm{Si}-\mathrm{H}$ | 393 |  |  |  |
| $\mathrm{C}-\mathrm{Br}$ | 276 | $\mathrm{~F}-\mathrm{F}$ | 154 | $\mathrm{Si}-\mathrm{C}$ | 360 |  |  |  |
| $\mathrm{C}-\mathrm{I}$ | 240 | $\mathrm{~F}-\mathrm{Cl}$ | 253 | $\mathrm{Si}-\mathrm{O}$ | 452 |  |  |  |
| $\mathrm{C}-\mathrm{S}$ | 259 | $\mathrm{~F}-\mathrm{Br}$ | 237 |  |  |  |  |  |
|  | $\mathrm{Cl}-\mathrm{Cl}$ | 239 |  |  |  |  |  |  |
|  | $\mathrm{Cl}-\mathrm{Br}$ | 218 |  |  |  |  |  |  |
|  | $\mathrm{Br}-\mathrm{Br}$ | 193 |  |  |  |  |  |  |

${ }^{*} \mathrm{C}=\mathrm{O}\left(\mathrm{CO}_{2}\right)=799$
positive signs. The formation of a bond releases energy, an exothermic process, so the energy terms associated with bond making carry a negative sign. We can write the enthalpy change for a reaction as follows:

$$
\begin{aligned}
\Delta H= & \text { sum of the energies required to break old bonds (positive signs) } \\
& \text { plus the sum of the energies released in the formation of new } \\
& \text { bonds (negative signs) }
\end{aligned}
$$

This leads to the expression

$$
\Delta H=\underbrace{\Sigma n \times D(\text { bonds broken })}_{\text {Energy required }}-\underbrace{\Sigma n \times D(\text { bonds formed })}_{\text {Energy released }}
$$

where $\Sigma$ represents the sum of terms, $D$ represents the bond energy per mole of bonds ( $D$ always has a positive sign), and $n$ represents the moles of a particular type of bond.

TABLE 8.6 | Bond Lengths and Bond Energies for Selected Bonds

| Bond | Bond Type | Bond Length (pm) | Bond Energy (kJ/mol) |
| :--- | :--- | :--- | :---: |
| $\mathrm{C}-\mathrm{C}$ | Single | 154 | 347 |
| $\mathrm{C}=\mathrm{C}$ | Double | 134 | 614 |
| $\mathrm{C} \equiv \mathrm{C}$ | Triple | 120 | 839 |
| $\mathrm{C}-\mathrm{O}$ | Single | 143 | 358 |
| $\mathrm{C}=\mathrm{O}$ | Double | 123 | 745 |
| $\mathrm{C}-\mathrm{N}$ | Single | 143 | 305 |
| $\mathrm{C}=\mathrm{N}$ | Double | 138 | 615 |
| $\mathrm{C} \equiv \mathrm{N}$ | Triple | 116 | 891 |

In the case of the formation of HF,

$$
\begin{aligned}
\Delta H & =D_{\mathrm{H}-\mathrm{H}}+D_{\mathrm{F}-\mathrm{F}}-2 D_{\mathrm{H}-\mathrm{F}} \\
& =1 \mathrm{~mol} \times \frac{432 \mathrm{~kJ}}{\mathrm{~mol}}+1 \mathrm{~mol} \times \frac{154 \mathrm{~kJ}}{\mathrm{~mol}}-2 \mathrm{~mol} \times \frac{565 \mathrm{~kJ}}{\mathrm{~mol}} \\
& =-544 \mathrm{~kJ}
\end{aligned}
$$

Thus, when 1 mole of $\mathrm{H}_{2}(g)$ and 1 mole of $\mathrm{F}_{2}(g)$ react to form 2 moles of $\mathrm{HF}(g)$, 544 kJ of energy should be released.

This result can be compared with the calculation of $\Delta H$ for this reaction from the standard enthalpy of formation for $\mathrm{HF}(-271 \mathrm{~kJ} / \mathrm{mol})$ :

$$
\Delta H^{\circ}=2 \mathrm{~mol} \times(-271 \mathrm{~kJ} / \mathrm{mol})=-542 \mathrm{~kJ}
$$

Thus the use of bond energies to calculate $\Delta H$ works quite well in this case.

## INTERACTIVE EXAMPLE 8.5

## SOLUTION

## $\Delta H$ from Bond Energies

Using the bond energies listed in Table 8.5, calculate $\Delta H$ for the reaction of methane with chlorine and fluorine to give Freon-12 $\left(\mathrm{CF}_{2} \mathrm{Cl}_{2}\right)$.

$$
\mathrm{CH}_{4}(g)+2 \mathrm{Cl}_{2}(g)+2 \mathrm{~F}_{2}(g) \longrightarrow \mathrm{CF}_{2} \mathrm{Cl}_{2}(g)+2 \mathrm{HF}(g)+2 \mathrm{HCl}(g)
$$

The idea here is to break the bonds in the gaseous reactants to give individual atoms and then assemble these atoms into the gaseous products by forming new bonds:

$$
\text { Reactants } \xrightarrow[\text { required }]{\text { Energy }} \text { atoms } \xrightarrow[\text { Eeleased }]{\text { Energy }} \text { products }
$$

We then combine the energy changes to calculate $\Delta H$ :
$\Delta H=$ energy required to break bonds - energy released when bonds form
where the minus sign gives the correct sign to the energy terms for the exothermic processes.

## Reactant Bonds Broken:

$$
\begin{array}{lll}
\mathrm{CH}_{4}: & 4 \mathrm{~mol} \mathrm{C}-\mathrm{H} & 4 \mathrm{~mol} \times \frac{413 \mathrm{~kJ}}{\mathrm{~mol}}=1652 \mathrm{~kJ} \\
2 \mathrm{Cl}_{2}: & 2 \mathrm{~mol} \mathrm{Cl}-\mathrm{Cl} & 2 \mathrm{~mol} \times \frac{239 \mathrm{~kJ}}{\mathrm{~mol}}=478 \mathrm{~kJ} \\
2 \mathrm{~F}_{2}: & 2 \mathrm{~mol} \mathrm{~F}-\mathrm{F} & 2 \mathrm{~mol} \times \frac{154 \mathrm{~kJ}}{\mathrm{~mol}}=308 \mathrm{~kJ} \\
\hline & \text { Total energy required }=2438 \mathrm{~kJ}
\end{array}
$$

## Product Bonds Formed:

$$
\begin{array}{rlr}
\mathrm{CF}_{2} \mathrm{Cl}_{2}: & 2 \mathrm{~mol} \mathrm{C}-\mathrm{F} & 2 \mathrm{~mol} \times \frac{485 \mathrm{~kJ}}{\mathrm{~mol}}=970 \mathrm{~kJ} \\
\text { and } & \\
& 2 \mathrm{~mol} \mathrm{C}-\mathrm{Cl} & 2 \mathrm{~mol} \times \frac{339 \mathrm{~kJ}}{\mathrm{~mol}}=678 \mathrm{~kJ} \\
2 \mathrm{HF}: & 2 \mathrm{~mol} \mathrm{H}-\mathrm{F} & 2 \mathrm{~mol} \times \frac{565 \mathrm{~kJ}}{\mathrm{~mol}}=1130 \mathrm{~kJ} \\
2 \mathrm{HCl}: & 2 \mathrm{~mol} \mathrm{H}-\mathrm{Cl} & 2 \mathrm{~mol} \times \frac{427 \mathrm{~kJ}}{\mathrm{~mol}}=854 \mathrm{~kJ} \\
\hline & & \text { Total energy released }=3632 \mathrm{~kJ}
\end{array}
$$

We now can calculate $\Delta H$ :

$$
\begin{aligned}
\Delta H & =\text { energy required to break bonds }- \text { energy released when bonds form } \\
& =2438 \mathrm{~kJ}-3632 \mathrm{~kJ} \\
& =-1194 \mathrm{~kJ}
\end{aligned}
$$

Since the sign of the value for the enthalpy change is negative, this means that 1194 kJ of energy is released per mole of $\mathrm{CF}_{2} \mathrm{Cl}_{2}$ formed.

See Exercises 8.69 through 8.76

### 8.9 The Localized Electron Bonding Model

So far we have discussed the general characteristics of the chemical bonding model and have seen that properties such as bond strength and polarity can be assigned to individual bonds. In this section we introduce a specific model used to describe covalent bonds. We need a simple model that can be applied easily even to very complicated molecules and that can be used routinely by chemists to interpret and organize the wide variety of chemical phenomena. The model that serves this purpose is the localized electron (LE) model, which assumes that a molecule is composed of atoms that are bound together by sharing pairs of electrons using the atomic orbitals of the bound atoms. Electron pairs in the molecule are assumed to be localized on a particular atom or in the space between two atoms. Those pairs of electrons localized on an atom are called lone pairs, and those found in the space between the atoms are called bonding pairs.

As we will apply it, the LE model has three parts:

1. Description of the valence electron arrangement in the molecule using Lewis structures (will be discussed in the next section).
2. Prediction of the geometry of the molecule using the valence shell electron-pair repulsion (VSEPR) model (will be discussed in Section 8.13).
3. Description of the type of atomic orbitals used by the atoms to share electrons or hold lone pairs (will be discussed in Chapter 9).

### 8.10 Lewis Structures

Lewis structures show only valence electrons.

FIGURE 8. 14 G.N.Lewis (1875-1946).

The Lewis structure of a molecule shows how the valence electrons are arranged among the atoms in the molecule. These representations are named after G. N. Lewis (Fig. 8.14). The rules for writing Lewis structures are based on observations of thousands of molecules. From experiment, chemists have learned that the most important requirement for the formation of a stable compound is that the atoms achieve noble gas electron configurations.

We have already seen that when metals and nonmetals react to form binary ionic compounds, electrons are transferred and the resulting ions typically have noble gas electron configurations. An example is the formation of KBr , where the $\mathrm{K}^{+}$ion has the [Ar] electron configuration and the $\mathrm{Br}^{-}$ion has the [ Kr ] electron configuration. In writing Lewis structures, the rule is that only the valence electrons are included. Using dots to represent electrons, the Lewis structure for KBr is

No dots are shown on the $\mathrm{K}^{+}$ion because it has no valence electrons. The $\mathrm{Br}^{-}$ion is shown with eight electrons because it has a filled valence shell.

Carbon, nitrogen, oxygen, and fluorine always obey the octet rule in stable molecules.

Next we will consider Lewis structures for molecules with covalent bonds, involving elements in the first and second periods. The principle of achieving a noble gas electron configuration applies to these elements as follows:

- Hydrogen forms stable molecules where it shares two electrons. That is, it follows a duet rule. For example, when two hydrogen atoms, each with one electron, combine to form the $\mathrm{H}_{2}$ molecule, we have

By sharing electrons, each hydrogen in $\mathrm{H}_{2}$, in effect, has two electrons; that is, each hydrogen has a filled valence shell.

- Helium does not form bonds because its valence orbital is already filled; it is a noble gas. Helium has the electron configuration $1 s^{2}$ and can be represented by the Lewis structure

He :

- The second-row nonmetals carbon through fluorine form stable molecules when they are surrounded by enough electrons to fill the valence orbitals, that is, the $2 s$ and the three $2 p$ orbitals. Since eight electrons are required to fill these orbitals, these elements typically obey the octet rule; they are surrounded by eight electrons. An example is the $\mathrm{F}_{2}$ molecule, which has the following Lewis structure:

$\mathrm{F}_{2}$

Note that each fluorine atom in $\mathrm{F}_{2}$ is, in effect, surrounded by eight electrons, two of which are shared with the other atom. This is a bonding pair of electrons, as discussed earlier. Each fluorine atom also has three pairs of electrons not involved in bonding. These are the lone pairs.

- Neon does not form bonds because it already has an octet of valence electrons (it is a noble gas). The Lewis structure is
:Ṇe:

Note that only the valence electrons of the neon atom ( $2 s^{2} 2 p^{6}$ ) are represented by the Lewis structure. The $1 s^{2}$ electrons are core electrons and are not shown.

From the preceding discussion we can formulate the following rules for writing the Lewis structures of molecules containing atoms from the first two periods.

## PROBLEM-SOLVING STRATEGY

## Steps for Writing Lewis Structures

1. Sum the valence electrons from all the atoms. Do not worry about keeping track of which electrons come from which atoms. It is the total number of electrons that is important.
2. Use a pair of electrons to form a bond between each pair of bound atoms.
3. Arrange the remaining electrons to satisfy the duet rule for hydrogen and the octet rule for the second-row elements.

To see how these steps are applied, we will draw the Lewis structures of a few molecules. We will first consider the water molecule and follow the previous steps.

1. We sum the valence electrons for $\mathrm{H}_{2} \mathrm{O}$ as shown:
2. Using a pair of electrons per bond, we draw in the two $\mathrm{O}-\mathrm{H}$ single bonds:

$$
\mathrm{H}-\mathrm{O}-\mathrm{H}
$$

Note that a line instead of a pair of dots is used to indicate each pair of bonding electrons. This is the standard notation.
3. We distribute the remaining electrons to achieve a noble gas electron configuration for each atom. Since four electrons have been used in forming the two bonds, four electrons $(8-4)$ remain to be distributed. Hydrogen is satisfied with two electrons (duet rule), but oxygen needs eight electrons to have a noble gas configuration. Thus the remaining four electrons are added to oxygen as two lone pairs. Dots are used to represent the lone pairs:

This is the correct Lewis structure for the water molecule. Each hydrogen has two electrons and the oxygen has eight, as shown below:

As a second example, let's write the Lewis structure for carbon dioxide.

1. Summing the valence electrons gives

$$
\begin{aligned}
& 4+6+6=16 \\
& \uparrow \uparrow \uparrow \uparrow \\
& C
\end{aligned}
$$

2. Parts of electrons are used to form a bond between the carbon and each oxygen,

$$
\mathrm{O}-\mathrm{C}-\mathrm{O}
$$

the remaining electrons are distributed to achieve noble gas configurations on each atom. In this case we have 12 electrons $(16-4)$ remaining after the bonds are drawn. The distribution of these electrons is determined by a trial-and-error process. We have 6 pairs of electrons to distribute. Suppose we try 3 pairs on each oxygen to give

$$
: \ddot{\mathrm{O}}-\mathrm{C}-\ddot{\mathrm{O}}:
$$

3. Is this correct? To answer this question, we need to check two things:
4. The total number of electrons. There are 16 valence electrons in this structure, which is the correct number.
5. The octet rule for each atom. Each oxygen has 8 electrons, but the carbon has only 4 . This cannot be the correct Lewis structure.

How can we arrange the 16 available electrons to achieve an octet for each atom? Suppose there are 2 shared pairs between the carbon and each oxygen:

$\mathrm{CO}_{2}$

$\ddot{\mathrm{O}}=\mathrm{C}=\ddot{\mathrm{O}}$ represents $\ddot{\mathrm{O}}:: \mathrm{C}: \ddot{\mathrm{O}}$

Now each atom is surrounded by 8 electrons, and the total number of electrons is 16 , as required. This is the correct Lewis structure for carbon dioxide, which has two double bonds and four lone pairs.

Finally, let's consider the Lewis structure of the $\mathrm{CN}^{-}$(cyanide) ion. Summing the valence electrons, we have

Note that the negative charge means an extra electron is present. After drawing a single bond ( $\mathrm{C}-\mathrm{N}$ ), we distribute the remaining electrons to achieve a noble gas configuration for each atom. Eight electrons remain to be distributed. We can try various possibilities, for example:

$$
\ddot{\mathrm{C}}-\dot{\mathrm{Y}}
$$

This structure is incorrect because C and N have only six electrons each instead of eight. The correct arrangement is

$$
[: \mathrm{C} \equiv \mathrm{~N}:]^{-}
$$

(Satisfy yourself that both carbon and nitrogen have eight electrons.)

## INTERACTIVE EXAMPLE 8.6

## Writing Lewis Structures

Give the Lewis structure for each of the following.
a. HF
b. $\mathrm{N}_{2}$
c. $\mathrm{NH}_{3}$
d. $\mathrm{CH}_{4}$
e. $\mathrm{CF}_{4}$
f. $\mathrm{NO}^{+}$

## SOLUTION

In each case we apply the three steps for writing Lewis structures. Recall that lines are used to indicate shared electron pairs and that dots are used to indicate nonbonding pairs (lone pairs). We have the following tabulated results:

|  | Total Valence Electrons | Draw Single Bonds | Calculate <br> Number of <br> Electrons <br> Remaining | Use Remaining Electrons to Achieve Noble Gas Configurations | Check <br> Number of Electrons |
| :---: | :---: | :---: | :---: | :---: | :---: |
| a. HF | $1+7=8$ | H-F | 6 | $\mathrm{H}-\stackrel{\mathrm{F}}{\mathrm{F}}$ : | $\begin{aligned} & \mathrm{H}, 2 \\ & \mathrm{~F}, 8 \end{aligned}$ |
| b. $\mathrm{N}_{2}$ | $5+5=10$ | N - N | 8 | $\mathrm{N} \equiv \mathrm{N}$ : | N, 8 |
| c. $\mathrm{NH}_{3}$ | $5+3(1)=8$ |  | 2 |  | $\begin{aligned} & \mathrm{H}, 2 \\ & \mathrm{~N}, 8 \end{aligned}$ |
| d. $\mathrm{CH}_{4}$ | $4+4(1)=8$ |  | 0 |  | $\begin{aligned} & \mathrm{H}, 2 \\ & \mathrm{C}, 8 \end{aligned}$ |
| e. $\mathrm{CF}_{4}$ | $4+4(7)=32$ |  | 24 |  | $\begin{aligned} & \text { F, } 8 \\ & \text { C, } 8 \end{aligned}$ |
| f. $\mathrm{NO}^{+}$ | $5+6-1=10$ | $\mathrm{N}-\mathrm{O}$ | 8 | $[: \mathrm{N} \equiv \mathrm{O}:]^{+}$ | $\mathrm{N}, 8$ |

## CHEMICAL CDNNECTIDNS

## Nitrogen Under Pressure

The element nitrogen exists at normal temperatures and pressures as a gas containing $\mathrm{N}_{2}$, a molecule with a very strong triple bond. In the gas phase, the diatomic molecules move around independently with almost no tendency to associate with each other. Under intense pressure, however, nitrogen changes to a dramatically different form. This conclusion was reached at the Carnegie Institution in Washington, D.C., by Mikhail Erements and his colleagues, who subjected nitrogen to a pressure of 2.4 million atmospheres in a special diamond anvil press. Under this tremendous pressure, the bonds of the $\mathrm{N}_{2}$ molecules break and a substance containing an aggregate of nitrogen atoms forms. In other words, under great pressure elemental nitrogen changes from a substance containing diatomic molecules to one containing many nitrogen atoms bonded to each other. Interestingly, this substance remains intact even after the pressure is released-as long as the temperature remains at 100 K . This new form of nitrogen has a very high potential energy relative to $\mathrm{N}_{2}$. Thus this substance would be an

A diamond anvil cell used to study materials at very high pressures.
extraordinarily powerful propellant or explosive if enough of it could be made. This new form of nitrogen is also a semiconductor for electricity; normal nitrogen gas is an insulator.

The newly discovered form of nitrogen is significant for several reasons. For one thing, it may help us understand the nature of the interiors of the giant gas planets such as Jupiter. Also, their success in changing nitrogen
to an atomic solid encourages highpressure scientists who are trying to accomplish the same goal with hydrogen. It is surprising that nitrogen, which has diatomic molecules containing bonds more than twice as strong as those in hydrogen, will form an atomic solid at these pressures but hydrogen does not. Hydrogen remains a molecular solid at far greater pressures than nitrogen can endure.

When writing Lewis structures, do not worry about which electrons come from which atoms in a molecule. The best way to look at a molecule is to regard it as a new entity that uses all the available valence electrons of the atoms to achieve the lowest possible energy.* The valence electrons belong to the molecule, rather than to the individual atoms. Simply distribute all valence electrons so that the various rules are satisfied, without regard for the origin of each particular electron.

### 8.11 Exceptions to the Octet Rule

The localized electron model is a simple but very successful model, and the rules we have used for Lewis structures apply to most molecules. However, with such a simple model, some exceptions are inevitable. Boron, for example, tends to form compounds

[^14]
$\mathrm{BF}_{3}$
in which the boron atom has fewer than eight electrons around it-it does not have a complete octet. Boron trifluoride $\left(\mathrm{BF}_{3}\right)$, a gas at normal temperatures and pressures, reacts very energetically with molecules such as water and ammonia that have available electron pairs (lone pairs). The violent reactivity of $\mathrm{BF}_{3}$ with electron-rich molecules arises because the boron atom is electron-deficient. Boron trifluoride has 24 valence electrons. The Lewis structure often drawn for $\mathrm{BF}_{3}$ is

Note that in this structure boron has only 6 electrons around it. The octet rule for boron can be satisfied by drawing a structure with a double bond, such as

Recent studies indicate that double bonding may be important in $\mathrm{BF}_{3}$. However, the boron atom in $\mathrm{BF}_{3}$ certainly behaves as if it is electron-deficient, as indicated by the reactivity of $\mathrm{BF}_{3}$ toward electron-rich molecules, for example, toward $\mathrm{NH}_{3}$ to form $\mathrm{H}_{3} \mathrm{NBF}_{3}$ :

In this stable compound, boron has an octet of electrons.
It is characteristic of boron to form molecules in which the boron atom is electrondeficient. On the other hand, carbon, nitrogen, oxygen, and fluorine can be counted on to obey the octet rule.

Some atoms exceed the octet rule. This behavior is observed only for those elements in Period 3 of the periodic table and beyond. To see how this arises, we will consider the Lewis structure for sulfur hexafluoride $\left(\mathrm{SF}_{6}\right)$, a well-known and very stable molecule. The sum of the valence electrons is

$$
6+6(7)=48 \text { electrons }
$$

Indicating the single bonds gives the structure on the left below:

We have used 12 electrons to form the S-F bonds, which leaves 36 electrons. Since fluorine always follows the octet rule, we complete the six fluorine octets to give the structure on the right above. This structure uses all 48 valence electrons for $\mathrm{SF}_{6}$, but sulfur has 12 electrons around it; that is, sulfur exceeds the octet rule. How can this happen?

To answer this question, we need to consider the different types of valence orbitals characteristic of second- and third-period elements. The second-row elements have $2 s$ and $2 p$ valence orbitals, and the third-row elements have $3 s, 3 p$, and $3 d$ orbitals. The $3 s$ and $3 p$ orbitals fill with electrons in going from sodium to argon, but the $3 d$ orbitals remain empty. For example, the valence orbital diagram for a sulfur atom is

Third-row elements can exceed the octet rule.

Whether the atoms that exceed the octet rule actually place the extra electrons in their $d$ orbitals is a matter of controversy among theoretical chemists. We will not consider this issue in this text.

The localized electron model assumes that the empty $3 d$ orbitals can be used to accommodate extra electrons. Thus the sulfur atom in $\mathrm{SF}_{6}$ can have 12 electrons around it by using the $3 s$ and $3 p$ orbitals to hold 8 electrons, with the extra 4 electrons placed in the formerly empty $3 d$ orbitals.

## LET'S REVIEW Lewis Structures: Comments About the Octet Rule

" The second-row elements C, N, O, and F should always be assumed to obey the octet rule.
» The second-row elements B and Be often have fewer than eight electrons around them in their compounds. These electron-deficient compounds are very reactive.
» The second-row elements never exceed the octet rule, since their valence orbitals ( $2 s$ and $2 p$ ) can accommodate only eight electrons.
\# Third-row and heavier elements often satisfy the octet rule but can exceed the octet rule by using their empty valence $d$ orbitals.
\# When writing the Lewis structure for a molecule, satisfy the octet rule for the atoms first. If electrons remain after the octet rule has been satisfied, then place them on the elements having available $d$ orbitals (elements in Period 3 or beyond).

## INTERACTIVE EXAMPLE 8.7 Lewis Structures for Molecules That Violate

 the Octet Rule IWrite the Lewis structure for $\mathrm{PCl}_{5}$.
SOLUTION We can follow the same stepwise procedure we used above for sulfur hexafluoride.

1. Sum the valence electrons.

$$
\begin{aligned}
& 5 \\
& \underset{\mathrm{P}}{5} \underset{\uparrow}{\mathrm{Cl}} \mathrm{Cl}
\end{aligned}
$$

2. Indicate single bonds between bound atoms.

3. Distribute the remaining electrons. In this case, 30 electrons $(40-10)$ remain. These are used to satisfy the octet rule for each chlorine atom. The final Lewis structure is

Note that phosphorus, which is a third-row element, has exceeded the octet rule by two electrons.

## See Exercises 8.91 and 8.92

In the $\mathrm{PCl}_{5}$ and $\mathrm{SF}_{6}$ molecules, the central atoms ( P and S , respectively) must have the extra electrons. However, in molecules having more than one atom that can exceed
the octet rule, it is not always clear which atom should have the extra electrons. Consider the Lewis structure for the triiodide ion $\left(\mathrm{I}_{3}{ }^{-}\right)$, which has

$$
\begin{gathered}
3(7) \\
\underset{\uparrow}{3}+\underset{\uparrow}{1}=22 \text { valence electrons } \\
-1 \text { charge }
\end{gathered}
$$

Indicating the single bonds gives I-I-I. At this point, 18 electrons (22-4) remain. Trial and error will convince you that one of the iodine atoms must exceed the octet rule, but which one?

The rule we will follow is that when it is necessary to exceed the octet rule for one of several third-row (or higher) elements, assume that the extra electrons should be placed on the central atom.

Thus for $\mathrm{I}_{3}{ }^{-}$the Lewis structure is

$$
[\because \ddot{\mathrm{I}}-\ddot{\mathrm{I}}-\ddot{\mathrm{I}}:]^{-}
$$

where the central iodine exceeds the octet rule. This structure agrees with known properties of $\mathrm{I}_{3}{ }^{-}$.

## INTERACTIVE EXAMPLE 8.8

## Lewis Structures for Molecules That Violate the Octet Rule II

Write the Lewis structure for each molecule or ion.
a. $\mathrm{ClF}_{3}$
b. $\mathrm{XeO}_{3}$
c. $\mathrm{RnCl}_{2}$
d. $\mathrm{BeCl}_{2}$
e. $\mathrm{ICl}_{4}^{-}$

## SOLUTION

a. The chlorine atom (third row) accepts the extra electrons.

b. All atoms obey the octet rule.

c. Radon, a noble gas in Period 6, accepts the extra electrons.

$$
: \ddot{\mathrm{C}}-\mathrm{R} \dot{\mathrm{n}}-\dot{\mathrm{C}}:
$$

d. Beryllium is electron-deficient.

$$
: \ddot{\mathrm{C}}-\mathrm{Be}-\dot{\mathrm{C}} \dot{l}:
$$

e. Iodine exceeds the octet rule.

### 8.12 Resonance

$\mathrm{NO}_{3}^{-}$

Sometimes more than one valid Lewis structure (one that obeys the rules we have outlined) is possible for a given molecule. Consider the Lewis structure for the nitrate ion $\left(\mathrm{NO}_{3}^{-}\right)$, which has 24 valence electrons. To achieve an octet of electrons around each atom, a structure like this is required:

If this structure accurately represents the bonding in $\mathrm{NO}_{3}{ }^{-}$, there should be two types of $\mathrm{N}-\mathrm{O}$ bonds observed in the molecule: one shorter bond (the double bond) and two identical longer ones (the two single bonds). However, experiments clearly show that $\mathrm{NO}_{3}{ }^{-}$exhibits only one type of $\mathrm{N}-\mathrm{O}$ bond with a length and strength between those expected for a single bond and a double bond. Thus, although the structure we have shown above is a valid Lewis structure, it does not correctly represent the bonding in $\mathrm{NO}_{3}{ }^{-}$. This is a serious problem, and it means that the model must be modified.

Look again at the proposed Lewis structure for $\mathrm{NO}_{3}{ }^{-}$. There is no reason for choosing a particular oxygen atom to have the double bond. There are really three valid Lewis structures:

Is any of these structures a correct description of the bonding in $\mathrm{NO}_{3}{ }^{-}$? No, because $\mathrm{NO}_{3}{ }^{-}$does not have one double and two single bonds-it has three equivalent bonds. We can solve this problem by making the following assumption: The correct description of $\mathrm{NO}_{3}{ }^{-}$is not given by any one of the three Lewis structures but is given only by the superposition of all three.

The nitrate ion does not exist as any of the three extreme structures but exists as an average of all three. Resonance is invoked when more than one valid Lewis structure can be written for a particular molecule. The resulting electron structure of the molecule is given by the average of these resonance structures. This situation is usually represented by double-headed arrows as follows:

Note that in all these resonance structures the arrangement of the nuclei is the same. Only the placement of the electrons differs. The arrows do not mean that the molecule "flips" from one resonance to another. They simply show that the actual structure is an average of the three resonance structures.

The concept of resonance is necessary because the localized electron model postulates that electrons are localized between a given pair of atoms. However, nature does not really operate this way. Electrons are really delocalized-they can move around the entire molecule. The valence electrons in the $\mathrm{NO}_{3}{ }^{-}$molecule distribute themselves to provide equivalent $\mathrm{N}-\mathrm{O}$ bonds. Resonance is necessary to compensate for the defective assumption of the localized electron model. However, this model is so useful that we retain the concept of localized electrons and add resonance to allow the model to treat species such as $\mathrm{NO}_{3}{ }^{-}$.

## EXAMPLE 8.9 Resonance Structures

SOLUTION

$\mathrm{NO}_{2}^{-}$

Describe the electron arrangement in the nitrite anion $\left(\mathrm{NO}_{2}{ }^{-}\right)$using the localized electron model.

We will follow the usual procedure for obtaining the Lewis structure for the $\mathrm{NO}_{2}{ }^{-}$ion. In $\mathrm{NO}_{2}{ }^{-}$there are $5+2(6)+1=18$ valence electrons. Indicating the single bonds gives the structure

$$
\mathrm{O}-\mathrm{N}-\mathrm{O}
$$

The remaining 14 electrons $(18-4)$ can be distributed to produce these structures:

This is a resonance situation. Two equivalent Lewis structures can be drawn. The electronic structure of the molecule is correctly represented not by either resonance structure but by the average of the two. There are two equivalent $\mathrm{N}-\mathrm{O}$ bonds, each one intermediate between a single and a double bond.

$$
\text { See Exercises 8.98 through } 8.98
$$

## Odd-Electron Molecules

Relatively few molecules formed from nonmetals contain odd numbers of electrons. One common example is nitric oxide (NO), which is formed when nitrogen and oxygen gases react at the high temperatures in automobile engines. Nitric oxide is emitted into the air, where it immediately reacts with oxygen to form gaseous nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$, another odd-electron molecule.

Since the localized electron model is based on pairs of electrons, it does not handle odd-electron cases in a natural way. To treat odd-electron molecules, a more sophisticated model is needed.

## Formal Charge

Molecules or polyatomic ions containing atoms that can exceed the octet rule often have many nonequivalent Lewis structures (see margin note), all of which obey the rules for writing Lewis structures. For example, as we will see in detail below, the sulfate ion has a Lewis structure with all single bonds and several Lewis structures that contain double bonds. How do we decide which of the many possible Lewis structures best describes the actual bonding in sulfate? One method is to estimate the charge on each atom in the various possible Lewis structures and use these charges to select the most appropriate structure(s). We will see below how this is done, but first we must decide on a method to assign atomic charges in molecules.

In Chapter 4 we discussed one system for obtaining charges, called oxidation states. However, in assigning oxidation states, we always count both the shared electrons as belonging to the more electronegative atom in a bond. This practice leads to highly exaggerated estimates of charge. In other words, although oxidation states are useful for bookkeeping electrons in redox reactions, they are not realistic estimates of the actual charges on individual atoms in a molecule, so they are not suitable for judging the appropriateness of Lewis structures. Another definition of the charge on an atom in a molecule, the formal charge, can, however, be used to evaluate Lewis structures. As we will see below, the formal charge of an atom in a molecule is the difference between the number of valence electrons on the free atom and the number of valence electrons assigned to the atom in the molecule.

Therefore, to determine the formal charge of a given atom in a molecule, we need to know two things:

1. The number of valence electrons on the free neutral atom (which has zero net charge because the number of electrons equals the number of protons)
2. The number of valence electrons "belonging" to the atom in a molecule

We then compare these numbers. If in the molecule the atom has the same number of valence electrons as it does in the free state, the positive and negative charges just balance, and it has a formal charge of zero. If the atom has one more valence electron in a molecule than it has as a free atom, it has a formal charge of -1 , and so on. Thus the formal charge on an atom in a molecule is defined as

Formal charge $=$ (number of valence electrons on free atom)

- (number of valence electrons assigned to the atom in the molecule)

To compute the formal charge of an atom in a molecule, we assign the valence electrons in the molecule to the various atoms, making the following assumptions:

1. Lone pair electrons belong entirely to the atom in question.
2. Shared electrons are divided equally between the two sharing atoms.

Thus the number of valence electrons assigned to a given atom is calculated as follows:
(Valence electrons) $)_{\text {assigned }}=$ (number of lone pair electrons)

$$
+\frac{1}{2} \text { (number of shared electrons) }
$$

We will illustrate the procedure for calculating formal charges by considering two of the possible Lewis structures for the sulfate ion, which has 32 valence electrons. For the Lewis structure

$\mathrm{SO}_{4}{ }^{2-}$

each oxygen atom has 6 lone pair electrons and shares 2 electrons with the sulfur atom. Thus, using the preceding assumptions, each oxygen is assigned 7 valence electrons.

The formal charge on each oxygen is -1 .
For the sulfur atom there are no lone pair electrons, and eight electrons are shared with the oxygen atoms. Thus, for sulfur,

$$
\begin{array}{r}
\text { Valence electrons assigned to sulfur }=\underset{\uparrow}{0} \text { plus } \underset{\uparrow}{\underset{2}{2}(8)=4} \begin{array}{c}
\text { Lone } \quad \underset{\uparrow}{\text { Shared }} \\
\text { pair } \\
\text { electrons }
\end{array} \text { electrons }
\end{array}
$$

A second possible Lewis structure is

In this case the formal charges are as follows:
For oxygen atoms with single bonds:
Valence electrons assigned $=6+\frac{1}{2}(2)=7$
Formalc harge $=6-7=-1$
For oxygen atoms with double bonds:

> Valence electrons assigned $=4+\frac{1}{2}(4)=6$ $\uparrow$ Each double bond has 4 electrons

Formal charge $=6-6=0$
For the sulfur atom:
Valence electrons assigned $=0+\frac{1}{2}(12)=6$
Formalc harge $=6-6=0$
We will use two fundamental assumptions about formal charges to evaluate Lewis structures:

1. Atoms in molecules try to achieve formal charges as close to zero as possible.
2. Any negative formal charges are expected to reside on the most electronegative atoms.

We can use these principles to evaluate the two nonequivalent Lewis structures for sulfate given previously. Notice that in the structure with only single bonds, each oxygen has a formal charge of -1 , while the sulfur has a formal charge of +2 . In contrast, in the structure with two double bonds and two single bonds, the sulfur and two oxygen atoms have a formal charge of 0 , while two oxygens have a formal charge of -1 . Based on the assumptions given above, the structure with two double bonds is preferred-it has lower formal charges and the -1 formal charges are on electronegative oxygen atoms. Thus, for the sulfate ion, we might expect resonance structures such as

to more closely describe the bonding than the Lewis structure with only single bonds.

## Rules Governing Formal Charge

" To calculate the formal charge on an atom:

1. Take the sum of the lone pair electrons and one-half the shared electrons. This is the number of valence electrons assigned to the atom in the molecule.
2. Subtract the number of assigned electrons from the number of valence electrons on the free, neutral atom to obtain the formal charge.
» The sum of the formal charges of all atoms in a given molecule or ion must equal the overall charge on that species.
» If nonequivalent Lewis structures exist for a species, those with formal charges closest to zero and with any negative formal charges on the most electronegative atoms are considered to best describe the bonding in the molecule or ion.

## EXAMPLE $8.10 \quad$ Formal Charges

Give possible Lewis structures for $\mathrm{XeO}_{3}$, an explosive compound of xenon. Which Lewis structure or structures are most appropriate according to the formal charges?

## SOLUTION

For $\mathrm{XeO}_{3}$ (26 valence electrons) we can draw the following possible Lewis structures (formal charges are indicated in parentheses):

(0)

(-1)

(0)

(0)

Based on the ideas of formal charge, we would predict that the Lewis structures with the lower values of formal charge would be most appropriate for describing the bonding in $\mathrm{XeO}_{3}$.

## See Exercises 8.105 and 8.106

As a final note, there are a couple of cautions about formal charge to keep in mind. First, although formal charges are closer to actual atomic charges in molecules than are oxidation states, formal charges still provide only estimates of charge-they should not be taken as actual atomic charges. Second, the evaluation of Lewis structures using formal charge ideas can lead to erroneous predictions. Tests based on experiments must be used to make the final decisions on the correct description of the bonding in a molecule or polyatomic ion.

### 8.13 Molecular Structure: The VSEPR Model

The structures of molecules play a very important role in determining their chemical properties. As we will see later, this is particularly important for biological molecules; a slight change in the structure of a large biomolecule can completely destroy its usefulness to a cell or may even change the cell from a normal one to a cancerous one.
$\mathrm{BeCl}_{2}$ has only four electrons around Be and is expected to be very reactive with electron-pair donors.

Many accurate methods now exist for determining molecular structure, the threedimensional arrangement of the atoms in a molecule. These methods must be used if precise information about structure is required. However, it is often useful to be able to predict the approximate molecular structure of a molecule. In this section we consider a simple model that allows us to do this. This model, called the valence shell electron-pair repulsion (VSEPR) model, is useful in predicting the geometries of molecules formed from nonmetals. The main postulate of this model is that the structure around a given atom is determined principally by minimizing electron-pair repulsions. The idea here is that the bonding and nonbonding pairs around a given atom will be positioned as far apart as possible. To see how this model works, we will first consider the molecule $\mathrm{BeCl}_{2}$, which has the Lewis structure

$$
: \ddot{\mathrm{C}}-\mathrm{Be}-\dot{\mathrm{C}} \dot{l}:
$$

Note that there are two pairs of electrons around the beryllium atom. What arrangement of these electron pairs allows them to be as far apart as possible to minimize the repulsions? Clearly, the best arrangement places the pairs on opposite sides of the beryllium atom at 180 degrees from each other:

This is the maximum possible separation for two electron pairs. Once we have determined the optimal arrangement of the electron pairs around the central atom, we can specify the molecular structure of $\mathrm{BeCl}_{2}$, that is, the positions of the atoms. Since each electron pair on beryllium is shared with a chlorine atom, the molecule has a linear structure with a 180-degree bond angle:

Next, let's consider $\mathrm{BF}_{3}$, which has the Lewis structure

Here the boron atom is surrounded by three pairs of electrons. What arrangement will minimize the repulsions? The electron pairs are farthest apart at angles of 120 degrees:

Since each of the electron pairs is shared with a fluorine atom, the molecular structure will be

This is a planar (flat) and triangular molecule, which is commonly described as a trigonal planar structure.

Next, let's consider the methane molecule, which has the Lewis structure

There are four pairs of electrons around the central carbon atom. What arrangement of these electron pairs best minimizes the repulsions? First, let's try a square planar arrangement:

The carbon atom and the electron pairs are centered in the plane of the paper, and the angles between the pairs are all 90 degrees.

Is there another arrangement with angles greater than 90 degrees that would put the electron pairs even farther away from each other? The answer is yes. The tetrahedral structure has angles of 109.5 degrees:

It can be shown that this is the maximum possible separation of four pairs around a given atom. This means that whenever four pairs of electrons are present around an atom, they should always be arranged tetrahedrally.

Now that we have the electron-pair arrangement that gives the least repulsion, we can determine the positions of the atoms and thus the molecular structure of $\mathrm{CH}_{4}$. In methane, each of the four electron pairs is shared between the carbon atom and a hydrogen atom. Thus the hydrogen atoms are placed as in Fig. 8.15, and the molecule has a tetrahedral structure with the carbon atom at the center.

Recall that the main idea of the VSEPR model is to find the arrangement of electron pairs around the central atom that minimizes the repulsions. Then we can determine the molecular structure from knowing how the electron pairs are shared with the peripheral atoms. Use the following steps to predict the structure of a molecule using the VSEPR model.

## PROBLEM-SOLVING STRATEGY

## Steps to Apply the VSEPR Model

1. Draw the Lewis structure for the molecule.
2. Count the electron pairs and arrange them in the way that minimizes repulsion (that is, put the pairs as far apart as possible).
3. Determine the positions of the atoms from the way the electron pairs are shared.
4. Determine the name of the molecular structure from the positions of the atoms.

FIGURE 8.16 (a) The tetrahedral arrangement of electron pairs around the nitrogen atom in the ammonia molecule. (b) Three of the electron pairs around nitrogen are shared with hydrogen atoms as shown and one is a lone pair. Although the arrangement of electron pairs is tetrahedral, as in the methane molecule, the hydrogen atoms in the ammonia molecule occupy only three corners of the tetrahedron. A lone pair occupies the fourth corner. (c) Note that molecular geometry is trigonal pyramidal, not tetrahedral.

We will predict the structure of ammonia $\left(\mathrm{NH}_{3}\right)$ using this stepwise approach.

1. Draw the Lewis structure:

2. Count the pairs of electrons and arrange them to minimize repulsions. The $\mathrm{NH}_{3}$ molecule has four pairs of electrons: three bonding pairs and one nonbonding pair. From the discussion of the methane molecule, we know that the best arrangement of four electron pairs is a tetrahedral array [Fig. 8.16(a)].
3. Determine the positions of the atoms. The three H atoms share electron pairs [Fig. 8.16(b)].
4. Name the molecular structure. It is very important to recognize that the name of the molecular structure is always based on the positions of the atoms. The placement of the electron pairs determines the structure, but the name is based on the positions of the atoms. Thus it is incorrect to say that the $\mathrm{NH}_{3}$ molecule is tetrahedral. It has a tetrahedral arrangement of electron pairs but not a tetrahedral arrangement of atoms. The molecular structure of ammonia is a trigonal pyramid (one side is different from the other three) rather than a tetrahedron [Fig. 8.16(c)].

## EXAMPLE 8.11

SOLUTION

## Prediction of Molecular Structure I

Describe the molecular structure of the water molecule.
The Lewis structure for water is

$$
\mathrm{H}-\ddot{\mathrm{O}}-\mathrm{H}
$$

There are four pairs of electrons: two bonding pairs and two nonbonding pairs. To minimize repulsions, these are best arranged in a tetrahedral array [Fig. 8.17(a)]. Although $\mathrm{H}_{2} \mathrm{O}$ has a tetrahedral arrangement of electron pairs, it is not a tetrahedral molecule. The atoms in the $\mathrm{H}_{2} \mathrm{O}$ molecule form a V shape [Fig. 8.17(b) and (c)].

## See Exercises 8.119 and 8.120

From Example 8.11 we see that the $\mathrm{H}_{2} \mathrm{O}$ molecule is V-shaped, or bent, because of the presence of the lone pairs. If no lone pairs were present, the molecule would be linear, the polar bonds would cancel, and the molecule would have no dipole moment. This would make water very different from the polar substance so familiar to us.

FIGURE 8.17 (a) The tetrahedral arrangement of the four electron pairs around oxygen in the water molecule.
(b) Two of the electron pairs are shared between oxygen and the hydrogen atoms and two are lone pairs. (c) The V-shaped molecular structure of the water molecule.

FIGURE 8.18 The bond angles in the $\mathrm{CH}_{4}, \mathrm{NH}_{3}$, and $\mathrm{H}_{2} \mathrm{O}$ molecules. Note that the bond angle between bonding pairs decreases as the number of lone pairs increases. Note that all of the angles in $\mathrm{CH}_{4}$ are 109.5 degrees and all of the angles in $\mathrm{NH}_{3}$ are 107 degrees.

-a

b
FIGURE 8.19 (a) In a bonding pair of electrons, the electrons are shared by two nuclei. (b) In a lone pair, both electrons must be close to a single nucleus and tend to take up more of the space around that atom.

a

b

Ammonia
Water

From the previous discussion, we would predict that the $\mathrm{H}-\mathrm{X}-\mathrm{H}$ bond angle (where X is the central atom) in $\mathrm{CH}_{4}, \mathrm{NH}_{3}$, and $\mathrm{H}_{2} \mathrm{O}$ should be the tetrahedral angle of 109.5 degrees. Experimental studies, however, show that the actual bond angles are those given in Fig. 8.18. What significance do these results have for the VSEPR model? One possible point of view is that we should be pleased to have the observed angles so close to the tetrahedral angle. The opposite view is that the deviations are significant enough to require modification of the simple model so that it can more accurately handle similar cases. We will take the latter view.

Let us examine the following data:

|  | $\mathrm{CH}_{4}$ | $\mathrm{NH}_{3}$ | $\mathrm{H}_{2} \mathrm{O}$ |
| :--- | :---: | :---: | :---: |
| Number of lone pairs | 0 | 1 | 2 |
| Bond angle | $109.5^{\circ}$ | $107^{\circ}$ | $104.5^{\circ}$ |

One interpretation of the trend observed here is that lone pairs require more space than bonding pairs; in other words, as the number of lone pairs increases, the bonding pairs are increasingly squeezed together.

This interpretation seems to make physical sense if we think in the following terms. A bonding pair is shared between two nuclei, and the electrons can be close to either nucleus. They are relatively confined between the two nuclei. A lone pair is localized on only one nucleus, and both electrons will be close only to that nucleus, as shown schematically in Fig. 8.19. These pictures help us understand why a lone pair may require more space near an atom than a bonding pair.

As a result of these observations, we make the following addition to the original postulate of the VSEPR model: Lone pairs require more room than bonding pairs and tend to compress the angles between the bonding pairs.

So far we have considered cases with two, three, and four electron pairs around the central atom. These are summarized in Table 8.7.

Table 8.8 summarizes the structures possible for molecules in which there are four electron pairs around the central atom with various numbers of atoms bonded to it. Note that molecules with four pairs of electrons around the central atom can be tetrahedral $\left(\mathrm{AB}_{4}\right)$, trigonal pyramidal $\left(\mathrm{AB}_{3}\right)$, and V -shaped $\left(\mathrm{AB}_{2}\right)$.

## TABLE 8.7 | Arrangements of Electron Pairs Around an Atom Yielding Minimum Repulsion

| dioll |  |  |  |
| :---: | :---: | :---: | :---: |
|  |  | OQ | 000 |
|  | Tromompenat | $8$ | $0$ |
|  | Tesematar | $g$ | $2$ |
| 5 |  | $\theta^{\circ}$ | $\begin{aligned} & 9 \\ & 0 \\ & 0 \end{aligned}$ |
| 。 | atar | $\frac{0+8}{}$ | $\cos _{8}^{8}$ |

For five pairs of electrons, there are several possible choices. The one that produces minimum repulsion is a trigonal bipyramid. Note from Table 8.7 that this arrangement has two different angles, 90 degrees and 120 degrees. As the name suggests, the structure formed by this arrangement of pairs consists of two trigonal-based pyramids that share a common base. Table 8.9 summarizes the structures possible for molecules in which there are five electron pairs around the central atom with various numbers of atoms bonded to it. Note that molecules with five pairs of electrons around the central atom can be trigonal bipyramidal $\left(\mathrm{AB}_{5}\right)$, see-saw $\left(\mathrm{AB}_{4}\right)$, T-shaped $\left(\mathrm{AB}_{3}\right)$, and linear $\left(\mathrm{AB}_{2}\right)$.

Six pairs of electrons can best be arranged around a given atom with 90-degree angles to form an octahedral structure, as shown in Table 8.7.

To use the VSEPR model to determine the geometric structures of molecules, you should memorize the relationships between the number of electron pairs and their best arrangement.
 chemistry exam. What if your friend tells you that all molecules with polar bonds are polar molecules? How would you explain to your friend that this is not correct? Provide two examples to support your answer.

## TABLE 8.8 | Structures of Molecules with Four Electron Pairs Around the Central Atom

TABLE 8.9 | Structures of Molecules with Five Electron Pairs Around the Central Atom

## INTERACTIVE EXAMPLE 8.12 Prediction of Molecular Structure II

When phosphorus reacts with excess chlorine gas, the compound phosphorus pentachloride $\left(\mathrm{PCl}_{5}\right)$ is formed. In the gaseous and liquid states, this substance consists of $\mathrm{PCl}_{5}$ molecules, but in the solid state it consists of a $1: 1$ mixture of $\mathrm{PCl}_{4}{ }^{+}$and $\mathrm{PCl}_{6}{ }^{-}$ ions. Predict the geometric structures of $\mathrm{PCl}_{5}, \mathrm{PCl}_{4}{ }^{+}$, and $\mathrm{PCl}_{6}{ }^{-}$.

## SOLUTION

The Lewis structure for $\mathrm{PCl}_{5}$ is shown. Five pairs of electrons around the phosphorus atom require a trigonal bipyramidal arrangement (see Table 8.7). When the chlorine atoms are included, a trigonal bipyramidal molecule results:

The Lewis structure for the $\mathrm{PCl}_{4}{ }^{+}$ion $[5+4(7)-1=32$ valence electrons] is shown below. There are four pairs of electrons surrounding the phosphorus atom in the $\mathrm{PCl}_{4}{ }^{+}$ion, which requires a tetrahedral arrangement of the pairs. Since each pair is shared with a chlorine atom, a tetrahedral $\mathrm{PCl}_{4}{ }^{+}$cation results.

The Lewis structure for $\mathrm{PCl}_{6}{ }^{-}[5+6(7)+1=48$ valence electrons] is shown below. Since phosphorus is surrounded by six pairs of electrons, an octahedral arrangement is required to minimize repulsions, as shown below in the center. Since each electron pair is shared with a chlorine atom, an octahedral $\mathrm{PCl}_{6}{ }^{-}$anion is predicted.

## INTERACTIVE EXAMPLE 8.13

## SOLUTION

The Lewis structure for $\mathrm{XeF}_{4}$ is

The xenon atom in this molecule is surrounded by six pairs of electrons, which means an octahedral arrangement.

The structure predicted for this molecule will depend on how the lone pairs and bonding pairs are arranged. Consider the two possibilities shown in Fig. 8.20. The bonding pairs are indicated by the presence of the fluorine atoms. Since the structure predicted differs in the two cases, we must decide which of these arrangements is

$\square$

b

FIGURE 8.20 Possible electron-pair arrangements for $\mathrm{XeF}_{4}$. Since arrangement (a) has lone pairs at 90 degrees from each other, it is less favorable than arrangement (b), where the lone pairs are at 180 degrees.

preferable. The key is to look at the lone pairs. In the structure in part (a), the lone pair-lone pair angle is 90 degrees; in the structure in part (b), the lone pairs are separated by 180 degrees. Since lone pairs require more room than bonding pairs, a structure with two lone pairs at 90 degrees is unfavorable. Thus the arrangement in Fig. 8.20 (b) is preferred, and the molecular structure is predicted to be square planar. Note that this molecule is not described as being octahedral. There is an octahedral arrangement of electron pairs, but the atoms form a square planar structure.

Although each $\mathrm{Xe}-\mathrm{F}$ bond is polar (fluorine has a greater electronegativity than xenon), the square planar arrangement of these bonds causes the polarities to cancel.

Thus $\mathrm{XeF}_{4}$ has no dipole moment, as shown in the margin.

See Exeraises 8.123 through 8.126

We can further illustrate the use of the VSEPR model for molecules or ions with lone pairs by considering the triiodide ion $\left(\mathrm{I}_{3}{ }^{-}\right)$.

The central iodine atom has five pairs around it, which requires a trigonal bipyramidal arrangement. Several possible arrangements of lone pairs are shown in Fig. 8.21. Note that structures (a) and (b) have lone pairs at 90 degrees, whereas in (c) all lone pairs are at 120 degrees. Thus structure (c) is preferred. The resulting molecular structure for $\mathrm{I}_{3}{ }^{-}$is linear:

$$
[\mathrm{I}-\mathrm{I}-\mathrm{I}]^{-}
$$

FIGURE 8.21 Three possible arrangements of the electron pairs in the $I_{3}{ }^{-}$ion. Arrangement (c) is preferred because there are no 90 -degree lone pair-lone pair interactions.

## CHEMICAL CONNECTIONS

## Chemical Structure and Communication: Semiochemicals

| n this chapter we have stressed the importance of being able to predict the three-dimensional structure of a molecule. Molecular structure is important because of its effect on chemical reactivity. This is especially true in biological systems, where reactions must be efficient and highly specific. Among the hundreds of types of molecules in the fluids of a typical biological system, the appropriate reactants must find and react only with each other-they must be very discriminating. This specificity depends largely on structure. The molecules are constructed so that only the appropriate partners can approach each other in a way that allows reaction.

Another area where molecular structure is central is in the use of molecules as a means of communication. Examples of a chemical communication occur in humans in the conduction of nerve impulses across synapses, the control of the manufacture and storage of key chemicals in cells, and the senses of smell and taste. Plants and animals also use chemical communication. For example, ants lay down a chemical trail so that other ants can find a particular food supply. Ants
also warn their fellow workers of approaching danger by emitting certain chemicals.

Molecules convey messages by fitting into appropriate receptor sites in a very specific way, which is determined by their structure. When a molecule occupies a receptor site, chemical processes are stimulated that produce the appropriate response. Sometimes receptors can be fooled, as in the use of artificial sweeteners-molecules fit the sites on the taste buds that stimulate a "sweet" response in the brain, but they are not metabolized in the same way as natural sugars. Similar deception is useful in insect control. If an area is sprayed with synthetic female sex attractant molecules, the males of that species become so confused that mating does not occur.

A semiochemical is a molecule that delivers a message between members of the same or different species of plant or animal. There are three groups of these chemical messengers: allomones, kairomones, and pheromones. Each is of great ecological importance.

An allomone is defined as a chemical that somehow gives adaptive advantage to the producer. For
example, leaves of the black walnut tree contain an herbicide, juglone, that appears after the leaves fall to the ground. Juglone is not toxic to grass or certain grains, but it is effective against plants such as apple trees that would compete for the available water and food supplies.

Antibiotics are also allomones, since the microorganisms produce them to inhibit other species from growing near them.

Many plants produce bad-tasting chemicals to protect themselves from plant-eating insects and animals. The familiar compound nicotine deters animals from eating the tobacco plant. The millipede sends an unmistakable "back off" message by squirting a predator with benzaldehyde and hydrogen cyanide.

Defense is not the only use of allomones, however. Flowers use scent as a way to attract pollinating insects. Honeybees, for instance, are guided to alfalfa and flowers by a series of sweetscented compounds.

Kairomones are chemical messengers that bring advantageous news to the receiver, and the floral scents are kairomones from the honeybees'

## The VSEPR Model and Multiple Bonds

So far in our treatment of the VSEPR model we have not considered any molecules with multiple bonds. To see how these molecules are handled by this model, let's consider the $\mathrm{NO}_{3}{ }^{-}$ion, which requires three resonance structures to describe its electronic structure:

The queen bee secretes a chemical that prevents the worker bees from raising a competitive sovereign.
viewpoint. Many predators are guided by kairomones emitted by their food. For example, apple skins exude a chemical that attracts the codling moth larva. In some cases kairomones help the underdog. Certain marine mollusks can pick up the "scent" of their predators, the sea stars, and make their escape.

Pheromones are chemicals that affect receptors of the same species as the donor. That is, they are specific within a species. Releaser pheromones
cause an immediate reaction in the receptor, and primer pheromones cause long-term effects. Examples of releaser pheromones are sex attractants of insects, generated in some species by the males and in others by the females. Sex pheromones also have been found in plants and mammals.

Alarm pheromones are highly volatile compounds (ones easily changed to a gas) released to warn of danger. Honeybees produce isoamyl acetate $\left(\mathrm{C}_{7} \mathrm{H}_{14} \mathrm{O}_{2}\right)$ in their sting glands. Because
of its high volatility, this compound does not linger after the state of alert is over. Social behavior in insects is characterized by the use of trail pheromones, which are used to indicate a food source. Social insects such as bees, ants, wasps, and termites use these substances. Since trail pheromones are less volatile compounds, the indicators persist for some time.

Primer pheromones, which cause long-term behavioral changes, are harder to isolate and identify. One example, however, is the "queen substance" produced by queen honeybees. All the eggs in a colony are laid by one queen bee. If she is removed from the hive or dies, the worker bees are activated by the absence of the queen substance and begin to feed royal jelly to bee larvae so as to raise a new queen. The queen substance also prevents the development of the workers' ovaries so that only the queen herself can produce eggs.

Many studies of insect pheromones are now under way in the hope that they will provide a method of controlling insects that is more efficient and safer than the current chemical pesticides.

The $\mathrm{NO}_{3}{ }^{-}$ion is known to be planar with 120-degree bond angles:

This planar structure is the one expected for three pairs of electrons around a central atom, which means that a double bond should be counted as one effective pair in

## INTERACTIVE EXAMPLE 8.14 Structures of Molecules with Multiple Bonds

## SOLUTION

$\mathrm{SO}_{2}$

##  <br> 00

using the VSEPR model. This makes sense because the two pairs of electrons involved in the double bond are not independent pairs. Both the electron pairs must be in the space between the nuclei of the two atoms to form the double bond. In other words, the double bond acts as one center of electron density to repel the other pairs of electrons. The same holds true for triple bonds. This leads us to another general rule: For the VSEPR model, multiple bonds count as one effective electron pair.

The molecular structure of nitrate also shows us one more important point: When a molecule exhibits resonance, any one of the resonance structures can be used to predict the molecular structure using the VSEPR model. These rules are illustrated in Example 8.14.

Predict the molecular structure of the sulfur dioxide molecule. Is this molecule expected to have a dipole moment?

First, we must determine the Lewis structure for the $\mathrm{SO}_{2}$ molecule, which has 18 valence electrons. The expected resonance structures are

To determine the molecular structure, we must count the electron pairs around the sulfur atom. In each resonance structure the sulfur has one lone pair, one pair in a single bond, and one double bond. Counting the double bond as one pair yields three effective pairs around the sulfur. According to Table 8.7, a trigonal planar arrangement is required, which yields a V -shaped molecule:

$$
\mathrm{O} \stackrel{120^{\circ}}{\mathrm{S}^{-}} \mathrm{O}
$$

Thus the structure of the $\mathrm{SO}_{2}$ molecule is expected to be V-shaped, with a 120-degree bond angle. The molecule has a dipole moment directed as shown:

Since the molecule is V-shaped, the polar bonds do not cancel.

## See Exercises 8.127 and 8.128

It should be noted at this point that lone pairs that are oriented at least 120 degrees from other pairs do not produce significant distortions of bond angles. For example, the angle in the $\mathrm{SO}_{2}$ molecule is actually quite close to 120 degrees. We will follow the general principle that a 120-degree angle provides lone pairs with enough space so that distortions do not occur. Angles less than 120 degrees are distorted when lone pairs are present.

FIGURE 8.22 The molecular structure of methanol. (a) The arrangement of electron pairs and atoms around the carbon atom. (b) The arrangement of bonding and lone pairs around the oxygen atom. (c) The molecular structure.

## Molecules Containing No Single Central Atom

So far we have considered molecules consisting of one central atom surrounded by other atoms. The VSEPR model can be readily extended to more complicated molecules, such as methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$. This molecule is represented by the following Lewis structure:

The molecular structure can be predicted from the arrangement of pairs around the carbon and oxygen atoms. Note that there are four pairs of electrons around the carbon, which requires a tetrahedral arrangement [Fig. 8.22(a)]. The oxygen also has four pairs, which requires a tetrahedral arrangement. However, in this case the tetrahedron will be slightly distorted by the space requirements of the lone pairs [Fig. 8.22(b)]. The overall geometric arrangement for the molecule is shown in Fig. 8.22(c).

## LET'S REVIEW Summary of the VSEPR Model

The rules for using the VSEPR model to predict molecular structure are as follows:
\# Determine the Lewis structure(s) for the molecule.
" For molecules with resonance structures, use any of the structures to predict the molecular structure.
" Sum the electron pairs around the central atom.
" In counting pairs, count each multiple bond as a single effective pair.
\# The arrangement of the pairs is determined by minimizing electron-pair repulsions. These arrangements are shown in Table 8.7.
" Lone pairs require more space than bonding pairs do. Choose an arrangement that gives the lone pairs as much room as possible. Recognize that the lone pairs may produce a slight distortion of the structure at angles less than 120 degrees.

## The VSEPR Model—How Well Does It Work?

The VSEPR model is very simple. There are only a few rules to remember, yet the model correctly predicts the molecular structures of most molecules formed from nonmetallic elements. Molecules of any size can be treated by applying the VSEPR model to each appropriate atom (those bonded to at least two other atoms) in the molecule. Thus we can use this model to predict the structures of molecules with hundreds of atoms. It does, however, fail in a few instances. For example, phosphine $\left(\mathrm{PH}_{3}\right)$, which has a Lewis structure analogous to that of ammonia,

would be predicted to have a molecular structure similar to that for $\mathrm{NH}_{3}$, with bond angles of approximately 107 degrees. However, the bond angles of phosphine are actually 94 degrees. There are ways of explaining this structure, but more rules have to be added to the model.

This again illustrates the point that simple models are bound to have exceptions. In introductory chemistry we want to use simple models that fit the majority of cases; we are willing to accept a few failures rather than complicate the model. The amazing thing about the VSEPR model is that such a simple model predicts correctly the structures of so many molecules.

## Bond energy

> The energy necessary to break a covalent bond
) Increases as the number of shared pairs increases
> Can be used to estimate the enthalpy change for a chemical reaction

## Lewis structures

) Show how the valence electron pairs are arranged among the atoms in a molecule or polyatomic ion
> Stable molecules usually contain atoms that have their valence orbitals filled
> Leads to a duet rule for hydrogen
) Leads to an octet rule for second-row elements
> The atoms of elements in the third row and beyond can exceed the octet rule
> Several equivalent Lewis structures can be drawn for some molecules, a concept called resonance
> When several nonequivalent Lewis structures can be drawn for a molecule, formal charge is often used to choose the most appropriate structure(s)

## VSEPR model

> Based on the idea that electron pairs will be arranged around a central atom in a way that minimizes the electron repulsions
> Can be used to predict the geometric structure of most molecules

## Review Questions Answers to the Review Buestions can be found on the Student website (accessible from www.cengagebirain.com).

1. Distinguish between the terms electronegativity versus electron affinity, covalent bond versus ionic bond, and pure covalent bond versus polar covalent bond. Characterize the types of bonds in terms of electronegativity difference. Energetically, why do ionic and covalent bonds form?
2. When an element forms an anion, what happens to the radius? When an element forms a cation, what happens to the radius? Why? Define the term isoelectronic. When comparing sizes of ions, which ion has the largest radius and which ion has the smallest radius in an isoelectronic series? Why?
3. Define the term lattice energy. Why, energetically, do ionic compounds form? Figure 8.11 illustrates the energy changes involved in the formation of $\mathrm{MgO}(s)$ and $\operatorname{NaF}(s)$. Why is the lattice energy of $\mathrm{MgO}(s)$ so different from that of $\mathrm{NaF}(s)$ ? Magnesium oxide is composed of $\mathrm{Mg}^{2+}$ and $\mathrm{O}^{2-}$ ions. Energetically, why does $\mathrm{Mg}^{2+} \mathrm{O}^{2-}$ form and not $\mathrm{Mg}^{+} \mathrm{O}^{-}$? Why doesn't $\mathrm{Mg}^{3+} \mathrm{O}^{3-}$ form?
4. Explain how bond energies can be used to estimate $\Delta H$ for a reaction. Why is this an estimate of $\Delta H$ ? How do the product bond strengths compare to the reactant bond strengths for an exothermic reaction? For an endothermic reaction? What is the relationship between the number of bonds between two atoms and bond strength? Bond length?
5. Give a rationale for the octet rule and the duet rule for H in terms of orbitals. Give the steps for drawing a Lewis structure for a molecule or ion. In general, molecules and ions always follow the octet rule unless it is impossible. The three types of exceptions are molecules/ions with too few electrons, molecules/ions with an odd number of electrons, and molecules/ions with too many electrons. Which atoms sometimes have fewer than 8 electrons around them? Give an example. Which atoms sometimes have more than 8 electrons around them? Give some examples. Why are oddelectron species generally very reactive and uncommon? Give an example of an odd-electron molecule.
6. Explain the terms resonance and delocalized electrons. When a substance exhibits resonance, we say that none of the individual Lewis structures accurately portrays the bonding in the substance. Why do we draw resonance structures?
7. Define formal charge and explain how to calculate it. What is the purpose of the formal charge? Organic compounds are composed mostly of carbon and hydrogen, but also may have oxygen, nitrogen, and/or halogens in the formula. Formal charge arguments work very well for organic compounds when drawing the best Lewis structure. How do C, H, N, O, and Cl satisfy the octet rule in organic compounds so as to have a formula charge of zero?
8. Explain the main postulate of the VSEPR model. List the five base geometries (along with bond angles) that most molecules or ions adopt to minimize electron-pair repulsions. Why are bond angles sometimes slightly less than predicted in actual molecules as compared to what is predicted by the VSEPR model?
9. Give two requirements that should be satisfied for a molecule to be polar. Explain why $\mathrm{CF}_{4}$ and $\mathrm{XeF}_{4}$ are nonpolar compounds (have no net dipole moments) while $\mathrm{SF}_{4}$ is polar (has a net dipole moment). Is $\mathrm{CO}_{2}$ polar? What about COS? Explain.

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. Explain the electronegativity trends across a row and down a column of the periodic table. Compare these trends with those of ionization energies and atomic radii. How are they related?
2. The ionic compound $A B$ is formed. The charges on the ions may be $+1,-1 ;+2,-2 ;+3,-3$; or even larger. What are the factors that determine the charge for an ion in an ionic compound?
3. Using only the periodic table, predict the most stable ion for $\mathrm{Na}, \mathrm{Mg}, \mathrm{Al}, \mathrm{S}, \mathrm{Cl}, \mathrm{K}, \mathrm{Ca}$, and Ga . Arrange these from largest to smallest radius, and explain why the radius varies as it does. Compare your predictions with Fig. 8.8.
4. The bond energy for a $\mathrm{C}-\mathrm{H}$ bond is about $413 \mathrm{~kJ} / \mathrm{mol}$ in $\mathrm{CH}_{4}$ but $380 \mathrm{~kJ} / \mathrm{mol}$ in $\mathrm{CHBr}_{3}$. Although these values are relatively close in magnitude, they are different. Explain why they are different. Does the fact that the bond energy is lower in $\mathrm{CHBr}_{3}$ make any sense? Why?
5. Consider the following statement: "Because oxygen wants to have a negative-two charge, the second electron affinity is more negative than the first." Indicate everything that is correct in this statement. Indicate everything that is incorrect. Correct the incorrect statements and explain.
6. Which has the greater bond lengths: $\mathrm{NO}_{2}^{-}$or $\mathrm{NO}_{3}{ }^{-}$? Explain.
7. The following ions are best described with resonance structures. Draw the resonance structures, and using formal charge arguments, predict the best Lewis structure for each ion.
a. $\mathrm{NCO}^{-}$
b. $\mathrm{CNO}^{-}$
8. Would you expect the electronegativity of titanium to be the same in the species $\mathrm{Ti}, \mathrm{Ti}^{2+}, \mathrm{Ti}^{3+}$, and $\mathrm{Ti}^{4+}$ ? Explain.
9. The second electron affinity values for both oxygen and sulfur are unfavorable (endothermic). Explain.
10. What is meant by a chemical bond? Why do atoms form bonds with each other? Why do some elements exist as molecules in nature instead of as free atoms?
11. Why are some bonds ionic and some covalent?
12. How does a bond between Na and Cl differ from a bond between C and O ? What about a bond between N and N ?
13. Consider the following compounds: $\mathrm{CO}_{2}, \mathrm{SO}_{2}, \mathrm{KrF}_{2}$, $\mathrm{SO}_{3}, \mathrm{NF}_{3}, \mathrm{IF}_{3}, \mathrm{CF}_{4}, \mathrm{SF}_{4}, \mathrm{XeF}_{4}, \mathrm{PF}_{5}, \mathrm{IF}_{5}$, and $\mathrm{SCl}_{6}$. These 12 compounds are all examples of different molecular structures. Draw the Lewis structures for each and predict the molecular structure. Predict the bond angles and the polarity of each. (A polar molecule has a net dipole moment, while a nonpolar molecule does not.)
See Exercises 115 and 116 for the molecular structures based on the trigonal bipyramid and the octahedral geometries.
14. Arrange the following molecules from most to least polar and explain your order: $\mathrm{CH}_{4}, \mathrm{CF}_{2} \mathrm{Cl}_{2}, \mathrm{CF}_{2} \mathrm{H}_{2}, \mathrm{CCl}_{4}$, and $\mathrm{CCl}_{2} \mathrm{H}_{2}$.
15. Does a Lewis structure tell which electrons come from which atoms? Explain.
16. True or false? In general, a large atom has a smaller electronegativity. Explain.
17. What is the central idea of the VSEPR model?
18. In Section 8.13 of the text, the term effective pair is used. What does this term mean?

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Resources Site.

## Questions

18. Most atoms in nature are found bonded together to form compounds instead of existing as individual atoms. Why is this true?
19. The following electrostatic potential diagrams represent $\mathrm{H}_{2}$, HCl , or NaCl . Label each and explain your choices.

-a

c
20. Describe the type of bonding that exists in the $\mathrm{F}_{2}(g)$ molecule. How does this type of bonding differ from that found in the $\mathrm{HF}(\mathrm{g})$ molecule? How is it similar?
21. Some plant fertilizer compounds are $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}, \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, $\mathrm{K}_{2} \mathrm{O}, \mathrm{P}_{2} \mathrm{O}_{5}$, and KCl . Which of these compounds contain both ionic and covalent bonds?
22. Some of the important properties of ionic compounds are as follows:
i. low electrical conductivity as solids and high conductivity in solution or when molten
ii. relatively high melting and boiling points
iii. brittleness
iv. solubility in polar solvents

How does the concept of ionic bonding discussed in this chapter account for these properties?
23. What is the electronegativity trend? Where does hydrogen fit into the electronegativity trend for the other elements in the periodic table?
24. Give one example of a compound having a linear molecular structure that has an overall dipole moment (is polar) and one example that does not have an overall dipole moment (is nonpolar). Do the same for molecules that have trigonal planar and tetrahedral molecular structures.
25. When comparing the size of different ions, the general radii trend discussed in Chapter 7 is usually not very useful. What do you concentrate on when comparing sizes of ions to each other or when comparing the size of an ion to its neutral atom?
26. In general, the higher the charge on the ions in an ionic compound, the more favorable the lattice energy. Why do some stable ionic compounds have +1 charged ions even though $+4,+5$, and +6 charged ions would have a more favorable lattice energy?
27. Combustion reactions of fossil fuels provide most of the energy needs of the world. Why are combustion reactions of fossil fuels so exothermic?
28. Which of the following statements is(are) true? Correct the false statements.
a. It is impossible to satisfy the octet rule for all atoms in $\mathrm{XeF}_{2}$.
b. Because $\mathrm{SF}_{4}$ exists, $\mathrm{OF}_{4}$ should also exist because oxygen is in the same family as sulfur.
c. The bond in $\mathrm{NO}^{+}$should be stronger than the bond in $\mathrm{NO}^{-}$.
d. As predicted from the two Lewis structures for ozone, one oxygen-oxygen bond is stronger than the other oxygenoxygen bond.
29. Use formal charge arguments to explain why CO has a much smaller dipole moment than would be expected on the basis of electronegativity.
30. The molecules $\mathrm{BF}_{3}, \mathrm{CF}_{4}, \mathrm{CO}_{2}, \mathrm{PF}_{5}$, and $\mathrm{SF}_{6}$ are all nonpolar, even though they contain polar bonds. Why?

## Exercises

In this section similar exercises are paired.

## Chemical Bonds and Electronegativity

${ }^{31}$. Without using Fig. 8.3, predict the order of increasing electronegativity in each of the following groups of elements.
a. $\mathrm{C}, \mathrm{N}, \mathrm{O}$
b. $\mathrm{S}, \mathrm{Se}, \mathrm{Cl}$
c. $\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn}$
d. $\mathrm{Tl}, \mathrm{S}, \mathrm{Ge}$
32. Without using Fig. 8.3, predict the order of increasing electronegativity in each of the following groups of elements.
a. $\mathrm{Na}, \mathrm{K}, \mathrm{Rb}$
b. $\mathrm{B}, \mathrm{O}, \mathrm{Ga}$
c. $\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$
d. $\mathrm{S}, \mathrm{O}, \mathrm{F}$
-33. Without using Fig. 8.3, predict which bond in each of the following groups will be the most polar.
a. $\mathrm{C}-\mathrm{F}, \mathrm{Si}-\mathrm{F}, \mathrm{Ge}-\mathrm{F}$
b. $\mathrm{P}-\mathrm{Cl}$ or $\mathrm{S}-\mathrm{Cl}$
c. $\mathrm{S}-\mathrm{F}, \mathrm{S}-\mathrm{Cl}, \mathrm{S}-\mathrm{Br}$
d. $\mathrm{Ti}-\mathrm{Cl}, \mathrm{Si}-\mathrm{Cl}, \mathrm{Ge}-\mathrm{Cl}$
34. Without using Fig. 8.3, predict which bond in each of the following groups will be the most polar.
a. $\mathrm{C}-\mathrm{H}, \mathrm{Si}-\mathrm{H}, \mathrm{Sn}-\mathrm{H}$
b. $\mathrm{Al}-\mathrm{Br}, \mathrm{Ga}-\mathrm{Br}$, $\mathrm{In}-\mathrm{Br}, \mathrm{Tl}-\mathrm{Br}$
c. $\mathrm{C}-\mathrm{O}$ or $\mathrm{Si}-\mathrm{O}$
d. $\mathrm{O}-\mathrm{F}$ or $\mathrm{O}-\mathrm{Cl}$
-35. Repeat Exercises 31 and 33, this time using the values for the electronegativities of the elements given in Fig. 8.3. Are there differences in your answers?
36. Repeat Exercises 32 and 34, this time using the values for the electronegativities of the elements given in Fig. 8.3. Are there differences in your answers?
-37 . Which of the following incorrectly shows the bond polarity? Show the correct bond polarity for those that are incorrect.
a. ${ }^{\delta+} \mathrm{H}-\mathrm{F}^{\delta-}$
b. ${ }^{\delta+} \mathrm{Cl}-\mathrm{I}^{\delta-}$
c. ${ }^{\delta+} \mathrm{Si}-\mathrm{S}^{\delta-}$
d. ${ }^{\delta+} \mathrm{Br}-\mathrm{Br}^{\delta-}$
e. ${ }^{\delta+} \mathrm{O}-\mathrm{P}^{\delta-}$
38. Indicate the bond polarity (show the partial positive and partial negative ends) in the following bonds.
a. $\mathrm{C}-\mathrm{O}$
b. $\mathrm{P}-\mathrm{H}$
c. $\mathrm{H}-\mathrm{Cl}$
d. $\mathrm{Br}-\mathrm{Te}$
e. $\mathrm{Se}-\mathrm{S}$
-39. Predict the type of bond (ionic, covalent, or polar covalent) one would expect to form between the following pairs of elements.
a. Rb and Cl
b. S and S
c. C and F
d. Ba and S
e. N and P
f. B and H
-40. List all the possible bonds that can occur between the elements P, Cs, O, and H. Predict the type of bond (ionic, covalent, or polar covalent) one would expect to form for each bond.
41. Hydrogen has an electronegativity value between boron and carbon and identical to phosphorus. With this in mind, rank the following bonds in order of decreasing polarity: $\mathrm{P}-\mathrm{H}$, $\mathrm{O}-\mathrm{H}, \mathrm{N}-\mathrm{H}, \mathrm{F}-\mathrm{H}, \mathrm{C}-\mathrm{H}$.
42. Rank the following bonds in order of increasing ionic character: $\mathrm{N}-\mathrm{O}, \mathrm{Ca}-\mathrm{O}, \mathrm{C}-\mathrm{F}, \mathrm{Br}-\mathrm{Br}, \mathrm{K}-\mathrm{F}$.
3. State whether or not each of the following has a permanent dipole moment.
a.

b.

c.

d.

e.

f.

44. The following electrostatic potential diagrams represent $\mathrm{CH}_{4}$, $\mathrm{NH}_{3}$, or $\mathrm{H}_{2} \mathrm{O}$. Label each and explain your choices.
a.

b.

c.

## Ions and Ionic Compounds

45. Write electron configurations for the most stable ion formed by each of the elements $\mathrm{Al}, \mathrm{Ba}, \mathrm{Se}$, and I (when in stable ionic compounds).
46. Write electron configurations for the most stable ion formed by each of the elements $\mathrm{Te}, \mathrm{Cl}, \mathrm{Sr}$, and Li (when in stable ionic compounds).
47. Predict the empirical formulas of the ionic compounds formed from the following pairs of elements. Name each compound.
a. Li and N
c. Rb and Cl
b. Ga and O
d. Ba and S
48. Predict the empirical formulas of the ionic compounds formed from the following pairs of elements. Name each compound.
a. Al and Cl
b. Na and O
c. Sr and F
d. Ca and Se
-49. Write electron configurations for
a. the cations $\mathrm{Mg}^{2+}, \mathrm{K}^{+}$, and $\mathrm{Al}^{3+}$.
b. the anions $\mathrm{N}^{3-}, \mathrm{O}^{2-}, \mathrm{F}^{-}$, and $\mathrm{Te}^{2-}$.
49. Write electron configurations for
a. the cations $\mathrm{Sr}^{2+}, \mathrm{Cs}^{+}, \mathrm{In}^{+}$, and $\mathrm{Pb}^{2+}$.
b. the anions $\mathrm{P}^{3-}, \mathrm{S}^{2-}$, and $\mathrm{Br}^{-}$.
[51. Which of the following ions have noble gas electron configurations?
a. $\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Sc}^{3+}, \mathrm{Co}^{3+}$
b. $\mathrm{Tl}^{+}, \mathrm{Te}^{2-}, \mathrm{Cr}^{3+}$
c. $\mathrm{Pu}^{4+}, \mathrm{Ce}^{4+}, \mathrm{Ti}^{4+}$
d. $\mathrm{Ba}^{2+}, \mathrm{Pt}^{2+}, \mathrm{Mn}^{2+}$
50. What noble gas has the same election configuration as each of the ions in the following compounds?
a. cesium sulfide
c. calcium nitride
b. strontium fluoride
d. aluminum bromide
-53. Give the formula of a negative ion that would have the same number of electrons as each of the following positive ions.
a. $\mathrm{Na}^{+}$
b. $\mathrm{Ca}^{2+}$
c. $\mathrm{Al}^{3+}$
d. $\mathrm{Rb}^{+}$
51. Give an example of an ionic compound where both the anion and the cation are isoelectronic with each of the following noble gases.
a. Ne
b. Ar
c. Kr
d. Xe
52. Give three ions that are isoelectronic with krypton. Place these ions in order of increasing size.
53. Consider the ions $\mathrm{Sc}^{3+}, \mathrm{Cl}^{-}, \mathrm{K}^{+}, \mathrm{Ca}^{2+}$, and $\mathrm{S}^{2-}$. Match these ions to the following pictures that represent the relative sizes of the ions.

-57. For each of the following groups, place the atoms and/or ions in order of decreasing size.
a. $\mathrm{Cu}, \mathrm{Cu}^{+}, \mathrm{Cu}^{2+}$
b. $\mathrm{Ni}^{2+}, \mathrm{Pd}^{2+}, \mathrm{Pt}^{2+}$
c. $\mathrm{O}, \mathrm{O}^{-}, \mathrm{O}^{2-}$
d. $\mathrm{La}^{3+}, \mathrm{Eu}^{3+}, \mathrm{Gd}^{3+}, \mathrm{Yb}^{3+}$
e. $\mathrm{Te}^{2-}, \mathrm{I}^{-}, \mathrm{Cs}^{+}, \mathrm{Ba}^{2+}, \mathrm{La}^{3+}$
54. For each of the following groups, place the atoms and/or ions in order of decreasing size.
a. $\mathrm{V}, \mathrm{V}^{2+}, \mathrm{V}^{3+}, \mathrm{V}^{5+}$
b. $\mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{Rb}^{+}, \mathrm{Cs}^{+}$
c. $\mathrm{Te}^{2-}, \mathrm{I}^{-}, \mathrm{Cs}^{+}, \mathrm{Ba}^{2+}$
d. $\mathrm{P}, \mathrm{P}^{-}, \mathrm{P}^{2-}, \mathrm{P}^{3-}$
e. $\mathrm{O}^{2-}, \mathrm{S}^{2-}, \mathrm{Se}^{2-}, \mathrm{Te}^{2-}$
${ }^{59}$. Which compound in each of the following pairs of ionic substances has the most exothermic lattice energy? Justify your answers.
a. $\mathrm{NaCl}, \mathrm{KCl}$
b. $\mathrm{LiF}, \mathrm{LiCl}$
c. $\mathrm{Mg}(\mathrm{OH})_{2}, \mathrm{MgO}$
d. $\mathrm{Fe}(\mathrm{OH})_{2}, \mathrm{Fe}(\mathrm{OH})_{3}$
e. $\mathrm{NaCl}, \mathrm{Na}_{2} \mathrm{O}$
f. $\mathrm{MgO}, \mathrm{BaS}$
55. Which compound in each of the following pairs of ionic substances has the most exothermic lattice energy? Justify your answers.
a. LiF, CsF
d. $\mathrm{Na}_{2} \mathrm{SO}_{4}, \mathrm{CaSO}_{4}$
b. $\mathrm{NaBr}, \mathrm{NaI}$
e. $\mathrm{KF}, \mathrm{K}_{2} \mathrm{O}$
c. $\mathrm{BaCl}_{2}, \mathrm{BaO}$
f. $\mathrm{Li}_{2} \mathrm{O}, \mathrm{Na}_{2} \mathrm{~S}$
-61. Use the following data to estimate $\Delta H_{\mathrm{f}}^{\circ}$ for potassium chloride.

$$
\mathrm{K}(s)+\frac{1}{2} \mathrm{Cl}_{2}(g) \longrightarrow \mathrm{KCl}(s)
$$

| Lattice energy | $-690 . \mathrm{kJ} / \mathrm{mol}$ |
| :--- | ---: |
| Ionization energy for K | $419 \mathrm{~kJ} / \mathrm{mol}$ |
| Electron affinity of Cl | $-349 \mathrm{~kJ} / \mathrm{mol}$ |
| Bond energy of $\mathrm{Cl}_{2}$ | $239 \mathrm{~kJ} / \mathrm{mol}$ |
| Enthalpy of sublimation for K | $90 . \mathrm{kJ} / \mathrm{mol}$ |

62. Use the following data to estimate $\Delta H_{\mathrm{f}}^{\circ}$ for magnesium fluoride.

$$
\mathrm{Mg}(s)+\mathrm{F}_{2}(g) \longrightarrow \mathrm{MgF}_{2}(s)
$$

Lattice energy
$-2913 \mathrm{~kJ} / \mathrm{mol}$
First ionization energy of Mg $735 \mathrm{~kJ} / \mathrm{mol}$
Second ionization energy of Mg $1445 \mathrm{~kJ} / \mathrm{mol}$
Electron affinity of F
$-328 \mathrm{~kJ} / \mathrm{mol}$
Bond energy of $\mathrm{F}_{2}$ $154 \mathrm{~kJ} / \mathrm{mol}$
Enthalpy of sublimation for Mg
150. $\mathrm{kJ} / \mathrm{mol}$
-63. Consider the following energy changes:

Magnesium oxide exists as $\mathrm{Mg}^{2+} \mathrm{O}^{2-}$ and not as $\mathrm{Mg}^{+} \mathrm{O}^{-}$. Explain.
64. Compare the electron affinity of fluorine to the ionization energy of sodium. Is the process of an electron being "pulled" from the sodium atom to the fluorine atom exothermic or endothermic? Why is NaF a stable compound? Is the overall formation of NaF endothermic or exothermic? How can this be?
-65. Consider the following: $\operatorname{Li}(s)+\frac{1}{2} \mathrm{I}_{2}(g) \rightarrow \operatorname{LiI}(s) \Delta H=$ -292 kJ . $\mathrm{LiI}(s)$ has a lattice energy of $-753 \mathrm{~kJ} / \mathrm{mol}$. The ionization energy of $\operatorname{Li}(g)$ is $520 . \mathrm{kJ} / \mathrm{mol}$, the bond energy of $\mathrm{I}_{2}(g)$ is $151 \mathrm{~kJ} / \mathrm{mol}$, and the electron affinity of $\mathrm{I}(g)$ is $-295 \mathrm{~kJ} / \mathrm{mol}$. Use these data to determine the heat of sublimation of $\operatorname{Li}(s)$.
66. Use the following data (in $\mathrm{kJ} / \mathrm{mol}$ ) to estimate $\Delta H$ for the reaction $\mathrm{S}^{-}(g)+\mathrm{e}^{-} \rightarrow \mathrm{S}^{2-}(g)$. Include an estimate of uncertainty.

|  | $\Delta H_{\text {f }}$ | Lattice <br> Energy | Ionization Energy of M | $\begin{gathered} \Delta H_{\text {sub }} \\ \text { of } \mathrm{M} \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{Na}_{2} \mathrm{~S}$ | -365 | -2203 | 495 | 109 |
| $\mathrm{K}_{2} \mathrm{~S}$ | -381 | -2052 | 419 | 90 |
| $\mathrm{Rb}_{2} \mathrm{~S}$ | -361 | -1949 | 409 | 82 |
| $\mathrm{Cs}_{2} \mathrm{~S}$ | -360 | -1850 | 382 | 78 |
|  | $\begin{gathered} \mathrm{S}(s) \\ +\mathrm{e}^{-} \end{gathered}$ | $\begin{aligned} & \rightarrow \mathrm{S}(g) \\ & \rightarrow \mathrm{S}^{-}(g) \end{aligned}$ | $\begin{aligned} \Delta H & =277 \mathrm{~kJ} / \mathrm{mol} \\ \Delta H & =-200 \mathrm{~kJ} / \mathrm{mol} \end{aligned}$ |  |

Assume that all values are known to $\pm 1 \mathrm{~kJ} / \mathrm{mol}$.
67. Rationalize the following lattice energy values:

| Compound | Lattice Energy <br> $(\mathrm{kJ} / \mathrm{mol})$ |
| :---: | :---: |
| CaSe | -2862 |
| $\mathrm{Na}_{2} \mathrm{Se}$ | -2130 |
| CaTe | -2721 |
| $\mathrm{Na}_{2} \mathrm{Te}$ | -2095 |

68. The lattice energies of $\mathrm{FeCl}_{3}, \mathrm{FeCl}_{2}$, and $\mathrm{Fe}_{2} \mathrm{O}_{3}$ are (in no particular order) $-2631,-5359$, and $-14,774 \mathrm{~kJ} / \mathrm{mol}$. Match the appropriate formula to each lattice energy. Explain.

## Bond Energies

69. Use bond energy values (Table 8.5) to estimate $\Delta H$ for each of the following reactions in the gas phase.
a. $\mathrm{H}_{2}+\mathrm{Cl}_{2} \rightarrow 2 \mathrm{HCl}$
b. $\mathrm{N} \equiv \mathrm{N}+3 \mathrm{H}_{2} \rightarrow 2 \mathrm{NH}_{3}$
70. Use bond energy values (Table 8.5) to estimate $\Delta H$ for each of the following reactions.

b.

-71. Use bond energies (Table 8.5) to predict $\Delta H$ for the isomerization of methyl isocyanide to acetonitrile:

$$
\mathrm{CH}_{3} \mathrm{~N} \equiv \mathrm{C}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{C} \equiv \mathrm{~N}(g)
$$

72. Acetic acid is responsible for the sour taste of vinegar. It can be manufactured using the following reaction:

Use tabulated values of bond energies (Table 8.5) to estimate $\Delta H$ for this reaction.
-73. Use bond energies to predict $\Delta H$ for the following reaction:

$$
\mathrm{H}_{2} \mathrm{~S}(g)+3 \mathrm{~F}_{2}(g) \longrightarrow \mathrm{SF}_{4}(g)+2 \mathrm{HF}(g)
$$

74. The major industrial source of hydrogen gas is by the following reaction:

$$
\mathrm{CH}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{CO}(g)+3 \mathrm{H}_{2}(g)
$$

Use bond energies to predict $\Delta H$ for this reaction.

Use bond energies to estimate $\Delta H$ for the combustion of one mole of acetylene:

$$
\mathrm{C}_{2} \mathrm{H}_{2}(g)+\frac{5}{2} \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

76. Use data from Table 8.5 to estimate $\Delta H$ for the combustion of methane $\left(\mathrm{CH}_{4}\right)$, as shown below:

77. Consider the following reaction:

Estimate the carbon-fluorine bond energy given that the $\mathrm{C}-\mathrm{C}$ bond energy is $347 \mathrm{~kJ} / \mathrm{mol}$, the $\mathrm{C}=\mathrm{C}$ bond energy is $614 \mathrm{~kJ} / \mathrm{mol}$, and the $\mathrm{F}-\mathrm{F}$ bond energy is $154 \mathrm{~kJ} / \mathrm{mol}$.
78. Consider the following reaction:

$$
\mathrm{A}_{2}+\mathrm{B}_{2} \longrightarrow 2 \mathrm{AB} \quad \Delta H=-285 \mathrm{~kJ}
$$

The bond energy for $\mathrm{A}_{2}$ is one-half the amount of the AB bond energy. The bond energy of $\mathrm{B}_{2}=432 \mathrm{~kJ} / \mathrm{mol}$. What is the bond energy of $\mathrm{A}_{2}$ ?
-79. Compare your answers from parts a and b of Exercise 69 with $\Delta H$ values calculated for each reaction using standard enthalpies of formation in Appendix 4. Do enthalpy changes calculated from bond energies give a reasonable estimate of the actual values?
80. Compare your answer from Exercise 72 to the $\Delta H$ value calculated from standard enthalpies of formation in Appendix 4. Explain any discrepancies.
81. The standard enthalpies of formation for $\mathrm{S}(g), \mathrm{F}(g), \mathrm{SF}_{4}(g)$, and $\mathrm{SF}_{6}(\mathrm{~g})$ are $+278.8,+79.0,-775$, and $-1209 \mathrm{~kJ} / \mathrm{mol}$, respectively.
a. Use these data to estimate the energy of an $\mathrm{S}-\mathrm{F}$ bond.
b. Compare your calculated value to the value given in Table 8.5. What conclusions can you draw?
c. Why are the $\Delta H_{\mathrm{f}}^{\circ}$ values for $\mathrm{S}(g)$ and $\mathrm{F}(g)$ not equal to zero, since sulfur and fluorine are elements?
82. Use the following standard enthalpies of formation to estimate the $\mathrm{N}-\mathrm{H}$ bond energy in ammonia: $\mathrm{N}(\mathrm{g}), 472.7 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{H}(g)$, $216.0 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{NH}_{3}(g),-46.1 \mathrm{~kJ} / \mathrm{mol}$. Compare your value to the one in Table 8.5.
83. The standard enthalpy of formation for $\mathrm{N}_{2} \mathrm{H}_{4}(g)$ is $95.4 \mathrm{~kJ} /$ mol . Use this and the data in Exercise 82 to estimate the $\mathrm{N}-\mathrm{N}$ single bond energy. Compare this with the value in Table 8.5.
84. The standard enthalpy of formation for $\mathrm{NO}(g)$ is $90 . \mathrm{kJ} / \mathrm{mol}$. Use this and the values for the $\mathrm{O}=\mathrm{O}$ and $\mathrm{N} \equiv \mathrm{N}$ bond energies to estimate the bond strength in NO.

## Lewis Structures and Resonance

85. Write Lewis structures that obey the octet rule (duet rule for $\mathrm{H})$ for each of the following molecules. Carbon is the central atom in $\mathrm{CH}_{4}$, nitrogen is the central atom in $\mathrm{NH}_{3}$, and oxygen is the central atom in $\mathrm{H}_{2} \mathrm{O}$.
a. $\mathrm{F}_{2}$
b. $\mathrm{O}_{2}$
c. CO
d. $\mathrm{CH}_{4}$
e. $\mathrm{NH}_{3}$
f. $\mathrm{H}_{2} \mathrm{O}$
g. HF
86. Write Lewis structures that obey the octet rule (duet rule for H ) for each of the following molecules.
a. $\mathrm{H}_{2} \mathrm{CO}$
b. $\mathrm{CO}_{2}$
c. HCN

Carbon is the central atom in all of these molecules.
87. Write Lewis structures that obey the octet rule for each of the following molecules.
a. $\mathrm{CCl}_{4}$
b. $\mathrm{NCl}_{3}$
c. $\mathrm{SeCl}_{2}$
d. ICl

In each case, the atom listed first is the central atom.
88. Write Lewis structures that obey the octet rule for each of the following molecules and ions. (In each case the first atom listed is the central atom.)
a. $\mathrm{POCl}_{3}, \mathrm{SO}_{4}{ }^{2-}, \mathrm{XeO}_{4}, \mathrm{PO}_{4}{ }^{3-}, \mathrm{ClO}_{4}^{-}$
b. $\mathrm{NF}_{3}, \mathrm{SO}_{3}{ }^{2-}, \mathrm{PO}_{3}{ }^{3-}, \mathrm{ClO}_{3}{ }^{-}$
c. $\mathrm{ClO}_{2}^{-}, \mathrm{SCl}_{2}, \mathrm{PCl}_{2}^{-}$
d. Considering your answers to parts $a, b$, and $c$, what conclusions can you draw concerning the structures of species containing the same number of atoms and the same number of valence electrons?
89. One type of exception to the octet rule are compounds with central atoms having fewer than eight electrons around them. $\mathrm{BeH}_{2}$ and $\mathrm{BH}_{3}$ are examples of this type of exception. Draw the Lewis structures for $\mathrm{BeH}_{2}$ and $\mathrm{BH}_{3}$.
90. Lewis structures can be used to understand why some molecules react in certain ways. Write the Lewis structures for the reactants and products in the reactions described below.
a. Nitrogen dioxide dimerizes to produce dinitrogen tetroxide.
b. Boron trihydride accepts a pair of electrons from ammonia, forming $\mathrm{BH}_{3} \mathrm{NH}_{3}$.
Give a possible explanation for why these two reactions occur.
-91. The most common type of exception to the octet rule are compounds or ions with central atoms having more than eight electrons around them. $\mathrm{PF}_{5}, \mathrm{SF}_{4}, \mathrm{ClF}_{3}$ and $\mathrm{Br}_{3}{ }^{-}$are examples of this type of exception. Draw the Lewis structure for these compounds or ions. Which elements, when they have to, can have more than eight electrons around them? How is this rationalized?
92. $\mathrm{SF}_{6}, \mathrm{ClF}_{5}$, and $\mathrm{XeF}_{4}$ are three compounds whose central atoms do not follow the octet rule. Draw Lewis structures for these compounds.
-93. Write Lewis structures for the following. Show all resonance structures where applicable.
a. $\mathrm{NO}_{2}{ }^{-}, \mathrm{NO}_{3}{ }^{-}, \mathrm{N}_{2} \mathrm{O}_{4}\left(\mathrm{~N}_{2} \mathrm{O}_{4}\right.$ exists as $\mathrm{O}_{2} \mathrm{~N}-\mathrm{NO}_{2}$. $)$
b. $\mathrm{OCN}^{-}, \mathrm{SCN}^{-}, \mathrm{N}_{3}^{-}$(Carbon is the central atom in $\mathrm{OCN}^{-}$ and $\mathrm{SCN}^{-}$.)
94. Some of the important pollutants in the atmosphere are ozone $\left(\mathrm{O}_{3}\right)$, sulfur dioxide, and sulfur trioxide. Write Lewis structures for these three molecules. Show all resonance structures where applicable.
-95. Benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ consists of a six-membered ring of carbon atoms with one hydrogen bonded to each carbon. Write Lewis structures for benzene, including resonance structures.
96. Borazine $\left(\mathrm{B}_{3} \mathrm{~N}_{3} \mathrm{H}_{6}\right)$ has often been called "inorganic" benzene. Write Lewis structures for borazine. Borazine contains a sixmembered ring of alternating boron and nitrogen atoms with one hydrogen bonded to each boron and nitrogen.
-97. An important observation supporting the concept of resonance in the localized electron model was that there are only three different structures of dichlorobenzene $\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Cl}_{2}\right)$. How does this fact support the concept of resonance? (See Exercise 95.)
98. Consider the following bond lengths:

$$
\mathrm{C}-\mathrm{O} \quad 143 \mathrm{pm} \quad \mathrm{C}=\mathrm{O} \quad 123 \mathrm{pm} \quad \mathrm{C} \equiv \mathrm{O} \quad 109 \mathrm{pm}
$$

In the $\mathrm{CO}_{3}{ }^{2-}$ ion, all three $\mathrm{C}-\mathrm{O}$ bonds have identical bond lengths of 136 pm . Why?
99. A toxic cloud covered Bhopal, India, in December 1984 when water leaked into a tank of methyl isocyanate, and the product escaped into the atmosphere. Methyl isocyanate is used in the production of many pesticides. Draw the Lewis structure for methyl isocyanate, $\mathrm{CH}_{3} \mathrm{NCO}$, including resonance forms. The skeletal structure is

100. Ampyra is a drug used to improve mobility in patients with multiple sclerosis (MS). The skeletal structure of Ampyra is

Draw the Lewis structure (including resonance forms) for Ampyra.
-101. Order the following species with respect to carbon-oxygen bond length (longest to shortest).

$$
\mathrm{CO}, \quad \mathrm{CO}_{2}, \quad \mathrm{CO}_{3}^{2-}, \quad \mathrm{CH}_{3} \mathrm{OH}
$$

What is the order from the weakest to the strongest carbonoxygen bond? $\left(\mathrm{CH}_{3} \mathrm{OH}\right.$ exists as $\mathrm{H}_{3} \mathrm{C}-\mathrm{OH}$.)
102. Place the species below in order of the shortest to the longest nitrogen-oxygen bond.

$$
\begin{aligned}
& \quad \mathrm{H}_{2} \mathrm{NOH}, \quad \mathrm{~N}_{2} \mathrm{O}, \quad \mathrm{NO}^{+}, \\
& \left(\mathrm{H}_{2} \mathrm{NOH} \text { exists as } \mathrm{H}_{2} \mathrm{~N}-\mathrm{OH} .\right)
\end{aligned}
$$

## Formal Charge

-103. Use the formal charge arguments to rationalize why $\mathrm{BF}_{3}$ would not follow the octet rule.
104. Three resonance structures can be drawn for $\mathrm{CO}_{2}$. Which resonance structure is best from a formal charge standpoint?
-105. Write Lewis structures that obey the octet rule for the following species. Assign the formal charge for each central atom.
a. $\mathrm{POCl}_{3}$
b. $\mathrm{SO}_{4}{ }^{2-}$
c. $\mathrm{ClO}_{4}^{-}$
d. $\mathrm{PO}_{4}{ }^{3-}$
e. $\mathrm{SO}_{2} \mathrm{Cl}_{2}$
f. $\mathrm{XeO}_{4}$
g. $\mathrm{ClO}_{3}{ }^{-}$
h. $\mathrm{NO}_{4}{ }^{3-}$
106. Write Lewis structures for the species in Exercise 105 that involve minimum formal charges.
107. Write the Lewis structure for $\mathrm{O}_{2} \mathrm{~F}_{2}\left(\mathrm{O}_{2} \mathrm{~F}_{2}\right.$ exists as $\mathrm{F}-\mathrm{O}-\mathrm{O}-\mathrm{F})$. Assign oxidation states and formal charges to the atoms in $\mathrm{O}_{2} \mathrm{~F}_{2}$. This compound is a vigorous and potent oxidizing and fluorinating agent. Are oxidation states or formal charges more useful in accounting for these properties of $\mathrm{O}_{2} \mathrm{~F}_{2}$ ?
108. Oxidation of the cyanide ion produces the stable cyanate ion, $\mathrm{OCN}^{-}$. The fulminate ion, $\mathrm{CNO}^{-}$, on the other hand, is very unstable. Fulminate salts explode when struck; $\mathrm{Hg}(\mathrm{CNO})_{2}$ is used in blasting caps. Write the Lewis structures and assign formal charges for the cyanate and fulminate ions. Why is the fulminate ion so unstable? ( C is the central atom in $\mathrm{OCN}^{-}$and N is the central atom in $\mathrm{CNO}^{-}$.)
-109. When molten sulfur reacts with chlorine gas, a vile-smelling orange liquid forms that has an empirical formula of SCl . The structure of this compound has a formal charge of zero on all elements in the compound. Draw the Lewis structure for the vile-smelling orange liquid.
110. Carbon and sulfur form compounds with each other with the formulas $\mathrm{CS}_{2}$ and $\mathrm{C}_{3} \mathrm{~S}_{2}$. Draw a Lewis structure for each compound that has a formal charge of zero for all atoms in the structure.
-111. A common trait of simple organic compounds is to have Lewis structures where all atoms have a formal charge of zero. Consider the following incomplete Lewis structure for an organic compound called methyl cyanoacrylate, the main ingredient in Super Glue.

Draw a complete Lewis structure for methyl cyanoacrylate in which all atoms have a formal charge of zero.
112. Benzoic acid is a food preservative. The space-filling model for benzoic acid is shown below.

Draw the Lewis structure for benzoic acid, including all resonance structures in which all atoms have a formal charge of zero.

## Molecular Structure and Polarity

113. Predict the molecular structure and bond angles for each molecule or ion in Exercises 87 and 93.
114. Predict the molecular structure and bond angles for each molecule or ion in Exercises 88 and 94.
-115. There are several molecular structures based on the trigonal bipyramid geometry (see Table 8.9). Three such structures are

| A | A | $\mathrm{A}^{90^{\circ}} \mathrm{A}$ |
| :---: | :---: | :---: |
| . | . $170^{\circ}$ | A |
| $180^{\circ}$ : B | $\mathrm{B}-\mathrm{A}$ | $120^{\circ}$ (B: |
| - | 90 |  |
| A | A | ${ }_{90}{ }^{\circ} \mathrm{A}$ |
| Linear | T-shaped | See-saw |

Which of the compounds in Exercises 91 and 92 have these molecular structures?
116. Two variations of the octahedral geometry (see Table 8.7) are illustrated below.

Square planar

Which of the compounds in Exercises 91 and 92 have these molecular structures?
117. Write the name of each of the following molecular structures.
a.

d.

e.
118. Consider the molecular structures illustrated in the previous exercise. For each structure, give an example compound that has that arrangement of atoms.
-119. Predict the molecular structure (including bond angles) for each of the following.
a. $\mathrm{SeO}_{3}$
b. $\mathrm{SeO}_{2}$
120. Predict the molecular structure (including bond angles) for each of the following.
a. $\mathrm{PCl}_{3}$
b. $\mathrm{SCl}_{2}$
c. $\mathrm{SiF}_{4}$
-121. Predict the molecular structure (including bond angles) for each of the following. (See Exercises 115 and 116.)
a. $\mathrm{XeCl}_{2}$
b. $\mathrm{ICl}_{3}$
c. $\mathrm{TeF}_{4}$
d. $\mathrm{PCl}_{5}$
122. Predict the molecular structure (including bond angles) for each of the following. (See Exercises 115 and 116.)
a. $\mathrm{ICl}_{5}$
b. $\mathrm{XeCl}_{4}$
c. $\mathrm{SeCl}_{6}$
-123. Which of the molecules in Exercise 119 have net dipole moments (are polar)?
124. Which of the molecules in Exercise 120 have net dipole moments (are polar)?
-125. Which of the molecules in Exercise 121 have net dipole moments (are polar)?
126. Which of the molecules in Exercise 122 have net dipole moments (are polar)?
-127. Write Lewis structures and predict the molecular structures of the following. (See Exercises 115 and 116.)
a. $\mathrm{OCl}_{2}, \mathrm{KrF}_{2}, \mathrm{BeH}_{2}, \mathrm{SO}_{2}$
b. $\mathrm{SO}_{3}, \mathrm{NF}_{3}, \mathrm{IF}_{3}$
c. $\mathrm{CF}_{4}, \mathrm{SeF}_{4}, \mathrm{KrF}_{4}$
d. $\mathrm{IF}_{5}, \mathrm{AsF}_{5}$

Which of these compounds are polar?
128. Write Lewis structures and predict whether each of the following is polar or nonpolar.
a. HOCN (exists as $\mathrm{HO}-\mathrm{CN}$ )
b. COS
c. $\mathrm{XeF}_{2}$
d. $\mathrm{CF}_{2} \mathrm{Cl}_{2}$
e. $\mathrm{SeF}_{6}$
f. $\mathrm{H}_{2} \mathrm{CO}$ (C is the central atom)
-129. Consider the following Lewis structure where E is an unknown element:

What are some possible identities for element E? Predict the molecular structure (including bond angles) for this ion.
130. Consider the following Lewis structure where $E$ is an unknown element:

What are some possible identities for element E? Predict the molecular structure (including bond angles) for this ion. (See Exercises 115 and 116.)
-131. Two different compounds exist having the formula $\mathrm{N}_{2} \mathrm{~F}_{2}$. One compound is polar whereas the other is nonpolar. Draw Lewis structures for $\mathrm{N}_{2} \mathrm{~F}_{2}$ consistent with these observations.
132. Two different compounds have the formula $\mathrm{XeF}_{2} \mathrm{Cl}_{2}$. Write Lewis structures for these two compounds, and describe how measurement of dipole moments might be used to distinguish between them.

## Additional Exercises

133. Arrange the following in order of increasing radius and increasing ionization energy.
a. $\mathrm{N}^{+}, \mathrm{N}, \mathrm{N}^{-}$
b. $\mathrm{Se}, \mathrm{Se}^{-}, \mathrm{Cl}, \mathrm{Cl}^{+}$
c. $\mathrm{Br}^{-}, \mathrm{Rb}^{+}, \mathrm{Sr}^{2+}$
134. For each of the following, write an equation that corresponds to the energy given.
a. lattice energy of NaCl
b. lattice energy of $\mathrm{NH}_{4} \mathrm{Br}$
c. lattice energy of MgS
d. $\mathrm{O}=\mathrm{O}$ double bond energy beginning with $\mathrm{O}_{2}(g)$ as a reactant
135. Use bond energies (Table 8.5), values of electron affinities (Table 7.7), and the ionization energy of hydrogen ( $1312 \mathrm{~kJ} / \mathrm{mol}$ ) to estimate $\Delta H$ for each of the following reactions.
a. $\mathrm{HF}(g) \rightarrow \mathrm{H}^{+}(g)+\mathrm{F}^{-}(g)$
b. $\mathrm{HCl}(\mathrm{g}) \rightarrow \mathrm{H}^{+}(\mathrm{g})+\mathrm{Cl}^{-}(\mathrm{g})$
c. $\mathrm{HI}(g) \rightarrow \mathrm{H}^{+}(g)+\mathrm{I}^{-}(g)$
d. $\mathrm{H}_{2} \mathrm{O}(\mathrm{g}) \rightarrow \mathrm{H}^{+}(\mathrm{g})+\mathrm{OH}^{-}(\mathrm{g})$
(Electron affinity of $\mathrm{OH}(\mathrm{g})=-180 . \mathrm{kJ} / \mathrm{mol}$.)
136. Calcium carbonate $\left(\mathrm{CaCO}_{3}\right)$ shells are used by mollusks, corals, and snails to form protective coverings. Draw the Lewis structure for $\mathrm{CaCO}_{3}$. Be sure to include any resonance structures.
137. Which member of the following pairs would you expect to be more energetically stable? Justify each choice.
a. NaBr or $\mathrm{NaBr}_{2}$
b. $\mathrm{ClO}_{4}$ or $\mathrm{ClO}_{4}^{-}$
c. $\mathrm{SO}_{4}$ or $\mathrm{XeO}_{4}$
d. $\mathrm{OF}_{4}$ or $\mathrm{SeF}_{4}$
138. What do each of the following sets of compounds/ions have in common with each other?
a. $\mathrm{SO}_{3}, \mathrm{NO}_{3}^{-}, \mathrm{CO}_{3}{ }^{2-}$
b. $\mathrm{O}_{3}, \mathrm{SO}_{2}, \mathrm{NO}_{2}^{-}$
139. What do each of the following sets of compounds/ions have in common with each other? See your Lewis structures for Exercises 119 through 122.
a. $\mathrm{XeCl}_{4}, \mathrm{XeCl}_{2}$
b. $\mathrm{ICl}_{5}, \mathrm{TeF}_{4}, \mathrm{ICl}_{3}, \mathrm{PCl}_{3}, \mathrm{SCl}_{2}, \mathrm{SeO}_{2}$
140. Although both $\mathrm{Br}_{3}{ }^{-}$and $\mathrm{I}_{3}{ }^{-}$ions are known, the $\mathrm{F}_{3}{ }^{-}$ion has not been observed. Explain.
141. The space shuttle Orbiter uses the oxidation of methyl hydrazine by dinitrogen tetroxide for propulsion:

$$
\begin{aligned}
5 \mathrm{~N}_{2} \mathrm{O}_{4}(g)+4 \mathrm{~N}_{2} \mathrm{H}_{3} \mathrm{CH}_{3}(g) \rightarrow & \\
& 12 \mathrm{H}_{2} \mathrm{O}(g)+9 \mathrm{~N}_{2}(g)+4 \mathrm{CO}_{2}(g)
\end{aligned}
$$

Use bond energies to estimate $\Delta H$ for this reaction. The structures for the reactants are

142. Nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$ has three possible Lewis structures:

$$
\dot{\mathrm{N}}=\mathrm{N}=\dot{\mathrm{O}}: \longleftrightarrow: \mathrm{N} \equiv \mathrm{~N}-\ddot{\mathrm{O}}: \longleftrightarrow: \dot{\mathrm{N}}-\mathrm{N} \equiv \mathrm{O}
$$

Given the following bond lengths,

$$
\begin{array}{llll}
\mathrm{N}-\mathrm{N} & 167 \mathrm{pm} & \mathrm{~N}=\mathrm{O} & 115 \mathrm{pm} \\
\mathrm{~N}=\mathrm{N} & 120 \mathrm{pm} & \mathrm{~N}-\mathrm{O} & 147 \mathrm{pm} \\
\mathrm{~N} \equiv \mathrm{~N} & 110 \mathrm{pm} & &
\end{array}
$$

rationalize the observations that the $\mathrm{N}-\mathrm{N}$ bond length in $\mathrm{N}_{2} \mathrm{O}$ is 112 pm and that the $\mathrm{N}-\mathrm{O}$ bond length is 119 pm . Assign formal charges to the resonance structures for $\mathrm{N}_{2} \mathrm{O}$. Can you eliminate any of the resonance structures on the basis of formal charges? Is this consistent with observation?
143. Refer back to Exercises 105 and 106. Would you make the same prediction for the molecular structure for each case using the Lewis structure obtained in Exercise 105 as compared with the one obtained in Exercise 106?
144. Which of the following molecules have net dipole moments? For the molecules that are polar, indicate the polarity of each bond and the direction of the net dipole moment of the molecule.
a. $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{CHCl}_{3}, \mathrm{CCl}_{4}$
b. $\mathrm{CO}_{2}, \mathrm{~N}_{2} \mathrm{O}$
c. $\mathrm{PH}_{3}, \mathrm{NH}_{3}$
145. The structure of $\mathrm{TeF}_{5}{ }^{-}$is

Draw a complete Lewis structure for $\mathrm{TeF}_{5}{ }^{-}$, and explain the distortion from the ideal square pyramidal structure. (See Exercise 116.)
146. Look up the energies for the bonds in CO and $\mathrm{N}_{2}$. Although the bond in CO is stronger, CO is considerably more reactive than $\mathrm{N}_{2}$. Give a possible explanation.

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
147. Classify the bonding in each of the following molecules as ionic, polar covalent, or nonpolar covalent.
a. $\mathrm{H}_{2}$
b. $\mathrm{K}_{3} \mathrm{P}$
c. NaI
d. $\mathrm{SO}_{2}$
e. HF
f. $\mathrm{CCl}_{4}$
g. $\mathrm{CF}_{4}$
h. $\mathrm{K}_{2} \mathrm{~S}$
148. List the bonds $\mathrm{P}-\mathrm{Cl}, \mathrm{P}-\mathrm{F}, \mathrm{O}-\mathrm{F}$, and $\mathrm{Si}-\mathrm{F}$ from least polar to most polar.
149. Arrange the atoms and/or ions in the following groups in order of decreasing size.
a. $\mathrm{O}, \mathrm{O}^{-}, \mathrm{O}^{2-}$
b. $\mathrm{Fe}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Zn}^{2+}$
c. $\mathrm{Ca}^{2+}, \mathrm{K}^{+}, \mathrm{Cl}^{-}$
150. Use the following data to estimate $\Delta H_{\mathrm{f}}^{\circ}$ for barium bromide.

$$
\mathrm{Ba}(s)+\mathrm{Br}_{2}(g) \longrightarrow \mathrm{BaBr}_{2}(s)
$$

Lattice energy
$-1985 \mathrm{~kJ} / \mathrm{mol}$
First ionization energy of Ba $503 \mathrm{~kJ} / \mathrm{mol}$
Second ionization energy of Ba $965 \mathrm{~kJ} / \mathrm{mol}$
Electron affinity of Br
$-325 \mathrm{~kJ} / \mathrm{mol}$
Bond energy of $\mathrm{Br}_{2}$
$193 \mathrm{~kJ} / \mathrm{mol}$
Enthalpy of sublimation of Ba $178 \mathrm{~kJ} / \mathrm{mol}$
151. Use bond energy values to estimate $\Delta H$ for the following gas phase reaction:

$$
\mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{H}_{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CH}_{2} \mathrm{OHCH}_{2} \mathrm{OH}(g)
$$

152. Which of the following compounds or ions exhibit resonance?
a. $\mathrm{O}_{3}$
b. $\mathrm{CNO}^{-}$
c. $\mathrm{AsI}_{3}$
d. $\mathrm{CO}_{3}{ }^{2-}$
e. $\mathrm{AsF}_{3}$
153. The formulas of several chemical substances are given in the table below. For each substance in the table, give its chemical name and predict its molecular structure.

| Formula | Name |
| :--- | :--- |
| $\mathrm{CO}_{2}$ |  |
| $\mathrm{NH}_{3}$ |  |
| $\mathrm{SO}_{3}$ |  |
| $\mathrm{H}_{2} \mathrm{O}$ |  |
| $\mathrm{ClO}_{4}^{-}$ |  |

154. Predict the molecular structure, bond angles, and polarity (has a net dipole moment or has no net dipole moment) for each of the following compounds.
a. $\mathrm{SeCl}_{4}$
b. $\mathrm{SO}_{2}$
c. $\mathrm{KrF}_{4}$
d. $\mathrm{CBr}_{4}$
e. $\mathrm{IF}_{3}$
f. $\mathrm{ClF}_{5}$

## Challenge Problems

155. Use Coulomb's law,

$$
V=\frac{Q_{1} Q_{2}}{4 \pi \epsilon_{0} r}=2.31 \times 10^{-19} \mathrm{~J} \cdot \mathrm{~nm}\left(\frac{Q_{1} Q_{2}}{r}\right)
$$

to calculate the energy of interaction for the following two arrangements of charges, each having a magnitude equal to the electron charge.

b. $1 \times 10^{-10} \mathrm{~m}$
156. An alternative definition of electronegativity is

$$
\text { Electronegativity }=\text { constant (I.E. }- \text { E.A.) }
$$

where I.E. is the ionization energy and E.A. is the electron affinity using the sign conventions of this book. Use data in Chapter 7 to calculate the (I.E. - E.A.) term for F, Cl, Br, and I. Do these values show the same trend as the electronegativity values given in this chapter? The first ionization energies of the halogens are $1678,1255,1138$, and $1007 \mathrm{~kJ} / \mathrm{mol}$, respectively. (Hint: Choose a constant so that the electronegativity of fluorine equals 4.0. Using this constant, calculate relative electronegativities for the other halogens and compare to values given in the text.)
157. Calculate the standard heat of formation of the compound $\mathrm{ICl}(g)$ at $25^{\circ} \mathrm{C}$. (Hint: Use Table 8.5 and Appendix 4 data.)
158. Given the following information:

Heat of sublimation of $\operatorname{Li}(s)=166 \mathrm{~kJ} / \mathrm{mol}$
Bond energy of $\mathrm{HCl}=427 \mathrm{~kJ} / \mathrm{mol}$
Ionization energy of $\operatorname{Li}(g)=520 . \mathrm{kJ} / \mathrm{mol}$
Electron affinity of $\mathrm{Cl}(\mathrm{g})=-349 \mathrm{~kJ} / \mathrm{mol}$
Lattice energy of $\mathrm{LiCl}(s)=-829 \mathrm{~kJ} / \mathrm{mol}$
Bond energy of $\mathrm{H}_{2}=432 \mathrm{~kJ} / \mathrm{mol}$
Calculate the net change in energy for the following reaction:

$$
2 \mathrm{Li}(s)+2 \mathrm{HCl}(g) \longrightarrow 2 \mathrm{LiCl}(s)+\mathrm{H}_{2}(g)
$$

159. Use data in this chapter (and Chapter 7) to discuss why MgO is an ionic compound but CO is not an ionic compound.
160. Think of forming an ionic compound as three steps (this is a simplification, as with all models): (1) removing an electron from the metal; (2) adding an electron to the nonmetal; and (3) allowing the metal cation and nonmetal anion to come together.
a. What is the sign of the energy change for each of these three processes?
b. In general, what is the sign of the sum of the first two processes? Use examples to support your answer.
c. What must be the sign of the sum of the three processes?
d. Given your answer to part c , why do ionic bonds occur?
e. Given your above explanations, why is NaCl stable but not $\mathrm{Na}_{2} \mathrm{Cl}$ ? $\mathrm{NaCl}_{2}$ ? What about MgO compared to $\mathrm{MgO}_{2}$ ? $\mathrm{Mg}_{2} \mathrm{O}$ ?
161. The compound $\mathrm{NF}_{3}$ is quite stable, but $\mathrm{NCl}_{3}$ is very unstable ( $\mathrm{NCl}_{3}$ was first synthesized in 1811 by P. L. Dulong, who lost three fingers and an eye studying its properties). The compounds $\mathrm{NBr}_{3}$ and $\mathrm{NI}_{3}$ are unknown, although the explosive compound $\mathrm{NI}_{3} \cdot \mathrm{NH}_{3}$ is known. Account for the instability of these halides of nitrogen.
162. Three processes that have been used for the industrial manufacture of acrylonitrile $\left(\mathrm{CH}_{2} \mathrm{CHCN}\right)$, an important chemical used in the manufacture of plastics, synthetic rubber, and fibers, are shown below. Use bond energy values (Table 8.5) to estimate $\Delta H$ for each of the reactions.

b. $4 \mathrm{CH}_{2}=\mathrm{CHCH}_{3}+6 \mathrm{NO} \xrightarrow[\mathrm{Ag}]{700^{\circ} \mathrm{C}}$

$$
4 \mathrm{CH}_{2}=\mathrm{CHCN}+6 \mathrm{H}_{2} \mathrm{O}+\mathrm{N}_{2}
$$

The nitrogen-oxygen bond energy in nitric oxide (NO) is $630 . \mathrm{kJ} / \mathrm{mol}$.
c. $2 \mathrm{CH}_{2}=\mathrm{CHCH}_{3}+2 \mathrm{NH}_{3}+3 \mathrm{O}_{2} \xrightarrow{\text { Catalyst }} \mathrm{C} \begin{aligned} & 425-510^{\circ} \mathrm{C} \\ & 2 \mathrm{CH}_{2}=\mathrm{CHCN}+6 \mathrm{H}_{2} \mathrm{O}\end{aligned}$
d. Is the elevated temperature noted in parts b and c needed to provide energy to endothermic reactions?
163. The compound hexaazaisowurtzitane is one of the highestenergy explosives known ( $C$ \& E News, Jan. 17, 1994, p. 26). The compound, also known as CL-20, was first synthesized in 1987. The method of synthesis and detailed performance data are still classified because of CL-20's potential military application in rocket boosters and in warheads of "smart" weapons. The structure of CL-20 is

In such shorthand structures, each point where lines meet represents a carbon atom. In addition, the hydrogens attached to the carbon atoms are omitted; each of the six carbon atoms has one hydrogen atom attached. Finally, assume that the two O atoms in the $\mathrm{NO}_{2}$ groups are attached to N with one single bond and one double bond.

Three possible reactions for the explosive decomposition of CL-20 are
i. $\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{~N}_{12} \mathrm{O}_{12}(\mathrm{~s}) \rightarrow 6 \mathrm{CO}(g)+6 \mathrm{~N}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(g)+\frac{3}{2} \mathrm{O}_{2}(g)$
ii. $\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{~N}_{12} \mathrm{O}_{12}(s) \rightarrow 3 \mathrm{CO}(g)+3 \mathrm{CO}_{2}(g)+6 \mathrm{~N}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(g)$
iii. $\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{~N}_{12} \mathrm{O}_{12}(s) \rightarrow 6 \mathrm{CO}_{2}(g)+6 \mathrm{~N}_{2}(g)+3 \mathrm{H}_{2}(g)$
a. Use bond energies to estimate $\Delta H$ for these three reactions.
b. Which of the above reactions releases the largest amount of energy per kilogram of CL-20?
164. Many times extra stability is characteristic of a molecule or ion in which resonance is possible. How could this be used to explain the acidities of the following compounds? (The acidic hydrogen is marked by an asterisk.) Part c shows resonance in the $\mathrm{C}_{6} \mathrm{H}_{5}$ ring.
a.

b.

c.

165. The study of carbon-containing compounds and their properties is called organic chemistry. Besides carbon atoms, organic compounds also can contain hydrogen, oxygen, and nitrogen atoms (as well as other types of atoms). A common trait of simple organic compounds is to have Lewis structures where all atoms have a formal charge of zero. Consider the following incomplete Lewis structure for an organic compound called histidine (an amino acid), which is one of the building blocks of proteins found in our bodies:

Draw a complete Lewis structure for histidine in which all atoms have a formal charge of zero. What should be the approximate bond angles about the carbon atom labeled 1 and the nitrogen atom labeled 2 ?
166. Draw a Lewis structure for the $N, N$-dimethylformamide molecule. The skeletal structure is

Various types of evidence lead to the conclusion that there is some double bond character to the $\mathrm{C}-\mathrm{N}$ bond. Draw one or more resonance structures that support this observation.
167. Predict the molecular structure for each of the following. (See Exercises 115 and 116.)
a. $\mathrm{BrFI}_{2}$
b. $\mathrm{XeO}_{2} \mathrm{~F}_{2}$
c. $\mathrm{TeF}_{2} \mathrm{Cl}_{3}{ }^{-}$

For each formula there are at least two different structures that can be drawn using the same central atom. Draw all possible structures for each formula.
168. Consider the following computer-generated model of caffeine.

Draw a Lewis structure for caffeine in which all atoms have a formal charge of zero.
169. Cholesterol $\left(\mathrm{C}_{27} \mathrm{H}_{46} \mathrm{O}\right)$ has the following structure:

In such shorthand structures, each point where lines meet represents a carbon atom, and most H atoms are not shown. Draw the complete structure showing all carbon and hydrogen atoms. (There will be four bonds to each carbon atom.) What are the predicted bond angles exhibited in cholesterol? Is cholesterol a planar molecule as indicated in the structure above?

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
170. Most cars in the United States use gasohol for fuel. Gasohol is a mixture consisting of about $10 \%$ ethanol and $90 \%$ gasoline. The enthalpy of combustion per gram of gasoline is $-47.8 \mathrm{~kJ} / \mathrm{g}$. Using bond energies in Table 8.5 , estimate the enthalpy of combustion per gram of ethanol. How do the two enthalpies of combustion compare with each other? Assume the combustion reaction for ethanol is

$$
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(g)+3 \mathrm{O}_{2}(g) \rightarrow 2 \mathrm{CO}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(g)
$$

171. A compound, $\mathrm{XF}_{5}$, is $42.81 \%$ fluorine by mass. Identify the element X . What is the molecular structure of $\mathrm{XF}_{5}$ ?
172. A polyatomic ion is composed of $C, N$, and an unknown element $X$. The skeletal Lewis structure of this polyatomic ion is $[\mathrm{X}-\mathrm{C}-\mathrm{N}]^{-}$. The ion $\mathrm{X}^{2-}$ has an electron configuration of $[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{6}$. What is element X ? Knowing the identity of X , complete the Lewis structure of the polyatomic ion, including all important resonance structures.
173. Identify the following elements based on their electron configurations and rank them in order of increasing electronegativity: $[\mathrm{Ar}] 4 s^{1} 3 d^{5} ;[\mathrm{Ne}] 3 s^{2} 3 p^{3} ;[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{3} ;[\mathrm{Ne}] 3 s^{2} 3 p^{5}$.

## Marathon Problems

## These problems are designed to incorporate several concepts and

 techniques into one situation.174. Identify the five compounds of $\mathrm{H}, \mathrm{N}$, and O described as follows. For each compound, write a Lewis structure that is consistent with the information given.
a. All the compounds are electrolytes, although not all of them are strong electrolytes. Compounds C and D are ionic and compound $B$ is covalent.
b. Nitrogen occurs in its highest possible oxidation state in compounds A and C ; nitrogen occurs in its lowest possible oxidation state in compounds $\mathrm{C}, \mathrm{D}$, and E . The formal charge on both nitrogens in compound C is +1 ; the formal charge on the only nitrogen in compound $B$ is 0 .
c. Compounds A and E exist in solution. Both solutions give off gases. Commercially available concentrated solutions of compound A are normally 16 M . The commercial, concentrated solution of compound E is 15 M .
d. Commercial solutions of compound E are labeled with a misnomer that implies that a binary, gaseous compound of nitrogen and hydrogen has reacted with water to produce ammonium ions and hydroxide ions. Actually, this reaction occurs to only a slight extent.
e. Compound D is $43.7 \% \mathrm{~N}$ and $50.0 \% \mathrm{O}$ by mass. If compound D were a gas at STP , it would have a density of $2.86 \mathrm{~g} / \mathrm{L}$.
f. A formula unit of compound C has one more oxygen than a formula unit of compound $D$. Compounds C and A have one ion in common when compound A is acting as a strong electrolyte.
g. Solutions of compound C are weakly acidic; solutions of compound A are strongly acidic; solutions of compounds $B$ and $E$ are basic. The titration of 0.726 g compound $B$ requires 21.98 mL of 1.000 M HCl for complete neutralization.
175. An ionic compound made from the metal $M$ and the diatomic gas $\mathrm{X}_{2}$ has the formula $\mathrm{M}_{a} \mathrm{X}_{b}$, in which $a=1$ or 2 and $b=1$ or 2 . Use the data provided to determine the most likely values for $a$ and $b$, along with the most likely charges for each of the ions in the ionic compound.
Data (in units of $\mathrm{kJ} / \mathrm{mol}$ )
Successive ionization energies of M: 480., 4750.
Successive electron affinity values for X: $-175,920$.
Enthalpy of sublimation for $\mathrm{M}(s) \rightarrow \mathrm{M}(g): 110$.
Bond energy of $\mathrm{X}_{2}: 250$.
Lattice energy for MX $\left(\mathrm{M}^{+}\right.$and $\left.\mathrm{X}^{-}\right):-1200$.
Lattice energy for $\mathrm{MX}_{2}\left(\mathrm{M}^{2+}\right.$ and $\left.\mathrm{X}^{-}\right):-3500$.
Lattice energy for $\mathrm{M}_{2} \mathrm{X}\left(\mathrm{M}^{+}\right.$and $\left.\mathrm{X}^{2-}\right):-3600$.
Lattice energy for MX $\left(\mathrm{M}^{2+}\right.$ and $\left.\mathrm{X}^{2-}\right):-4800$.

Chili peppers taste hot because of capsaicin, a complex molecule containing atoms with many different hybridizations. (Image Source)

9.5 Combining the Localized Electron and Molecular Orbital Models
n Chapter 8 we discussed the fundamental concepts of bonding and introduced the most widely used simple model for covalent bonding: the localized electron model. We saw the usefulness of a bonding model as a means for systematizing chemistry by allowing us to look at molecules in terms of individual bonds. We also saw that molecular structure can be predicted by minimizing electron-pair repulsions. In this chapter we will examine bonding models in more detail, particularly focusing on the role of orbitals.

## 9.1

The valence orbitals are the orbitals associated with the highest principal quantum level that contains electrons on a given atom.

## Hybridization and the Localized Electron Model

As we saw in Chapter 8, the localized electron model views a molecule as a collection of atoms bound together by sharing electrons between their atomic orbitals. The arrangement of valence electrons is represented by the Lewis structure (or structures, where resonance occurs), and the molecular geometry can be predicted from the VSEPR model. In this section we will describe the atomic orbitals used to share electrons and hence to form the bonds.

## $s p^{3}$ Hybridization

Let us reconsider the bonding in methane, which has the Lewis structure and molecular geometry shown in Fig. 9.1. In general, we assume that bonding involves only the valence orbitals. This means that the hydrogen atoms in methane use $1 s$ orbitals. The valence orbitals of a carbon atom are the $2 s$ and $2 p$ orbitals shown in Fig. 9.2. In thinking about how carbon can use these orbitals to bond to the hydrogen atoms, we can see two related problems:

1. Using the $2 p$ and $2 s$ atomic orbitals will lead to two different types of $\mathrm{C}-\mathrm{H}$ bonds: (a) those from the overlap of a $2 p$ orbital of carbon and a $1 s$ orbital of hydrogen (there will be three of these) and (b) those from the overlap of a $2 s$ orbital of carbon and a $1 s$ orbital of hydrogen (there will be one of these). This is a problem because methane is known to have four identical $\mathrm{C}-\mathrm{H}$ bonds.

b
FIGURE 9.1 (a) The Lewis structure of the methane molecule. (b) The tetrahedral molecular geometry of the methane molecule.

FIGURE 9.2 The valence orbitals on a free carbon atom: $2 s, 2 p_{x}, 2 p_{y}$, and $2 p_{z}$.

FIGURE 9.3 The "native" $2 s$ and three $2 p$ atomic orbitals characteristic of a free carbon atom are combined to form a new set of four $s p^{3}$ orbitals. The small lobes of the orbitals are usually omitted from diagrams for clarity.

FIGURE 9.4 Cross section of an $s p^{3}$ orbital. This shows a "slice" of the electron density of the $s p^{3}$ orbitals illustrated in the center diagram of Fig. 9.3.
(Generated from a program by Robert Allendoerfer on Project SERAPHIM disk PC2402; printed with permission.)

Hybridization is a modification of the localized electron model to account for the observation that atoms often seem to use special atomic orbitals in forming molecules.

Note that the shapes of the hybrid orbitals shown in Figure 9.3 are "mushroom-like," calculated from wave functions.
2. Since the carbon $2 p$ orbitals are mutually perpendicular, we might expect the three $\mathrm{C}-\mathrm{H}$ bonds formed with these orbitals to be oriented at 90-degree angles:

However, the methane molecule is known by experiment to be tetrahedral with bond angles of 109.5 degrees.

This analysis leads to one of two conclusions: Either the simple localized electron model is wrong or carbon adopts a set of atomic orbitals other than its "native" $2 s$ and $2 p$ orbitals to bond to the hydrogen atoms in forming the methane molecule. The second conclusion seems more reasonable. The $2 s$ and $2 p$ orbitals present on an isolated carbon atom may not be the best set of orbitals for bonding; a new set of atomic orbitals might better serve the carbon atom in forming molecules. To account for the known structure of methane, it makes sense to assume that the carbon atom has four equivalent atomic orbitals, arranged tetrahedrally. In fact such a set of orbitals can be obtained quite readily by combining the carbon $2 s$ and $2 p$ orbitals, as shown schematically in Fig. 9.3. This mixing of the native atomic orbitals to form special orbitals for bonding is called hybridization., The four new orbitals are called $s p^{3}$ orbitals because they are formed from one $2 s$ and three $2 p$ orbitals. We say that the carbon atom undergoes $\boldsymbol{s} \boldsymbol{p}^{\mathbf{3}}$ hybridization or is $\boldsymbol{s} \boldsymbol{p}^{\mathbf{3}}$ hybridized. The four $s p^{3}$ orbitals are identical in shape, each one having a large lobe and a small lobe (Fig. 9.4). The four orbitals are oriented in space so that the large lobes form a tetrahedral arrangement, as shown in Fig. 9.3.

The hybridization of the carbon $2 s$ and $2 p$ orbitals also can be represented by an orbital energy-level diagram (Fig. 9.5). Note that electrons have been omitted because

the $\mathrm{CH}_{4}$ molecule

FIGURE 9.5 An energy-level diagram showing the formation of four $s p^{3}$ orbitals.

FIGURE 9.6 The tetrahedral set of four $s p^{3}$ orbitals of the carbon atom are used to share electron pairs with the four 1s orbitals of the hydrogen atoms to form the four equivalent $\mathrm{C}-\mathrm{H}$ bonds. This accounts for the known tetrahedral structure of the $\mathrm{CH}_{4}$ molecule.

## EXAMPLE 9.1

FIGURE 9.7 The nitrogen atom in ammonia is $s p^{3}$ hybridized.

we do not need to be concerned with the electron arrangements on the individual atoms-it is the total number of electrons and the arrangement of these electrons in the molecule that are important. We are assuming that carbon's atomic orbitals are rearranged to accommodate the best electron arrangement for the molecule as a whole. The new $s p^{3}$ atomic orbitals on carbon are used to share electron pairs with the $1 s$ orbitals from the four hydrogen atoms (Fig. 9.6).

At this point let's summarize the bonding in the methane molecule. The experimentally known structure of this molecule can be explained if we assume that the carbon atom adopts a special set of atomic orbitals. These new orbitals are obtained by combining the $2 s$ and the three $2 p$ orbitals of the carbon atom to produce four identically shaped orbitals that are oriented toward the corners of a tetrahedron and are used to bond to the hydrogen atoms. Thus the four $s p^{3}$ orbitals on carbon in methane are postulated to account for its known structure.

Remember this principle: Whenever a set of equivalent tetrahedral atomic orbitals is required by an atom, this model assumes that the atom adopts a set of $s p^{3}$ orbitals; the atom becomes $s p^{3}$ hybridized.

It is really not surprising that an atom in a molecule might adopt a different set of atomic orbitals (called hybrid orbitals) from those it has in the free state. It does not seem unreasonable that to achieve minimum energy, an atom uses one set of atomic orbitals in the free state and a different set in a molecule. This is consistent with the idea that a molecule is more than simply a sum of its parts. What the atoms in a molecule were like before the molecule was formed is not as important as how the electrons are best arranged in the molecule. Therefore, this model assumes that the individual atoms respond as needed to achieve the minimum energy for the molecule.

여Tㅏㄴㄴ THINKINC What if the $s p^{3}$ hybrid orbitals were higher in energy than the $p$ orbitals in the free atom? How would this affect our model of bonding?

## The Localized Electron Model I

Describe the bonding in the ammonia molecule using the localized electron model.

## SOLUTION <br> A complete description of the bonding involves three steps:

1. writing the Lewis structure
2. determining the arrangement of electron pairs using the VSEPR model
3. determining the hybrid atomic orbitals needed to describe the bonding in the molecule

The Lewis structure for $\mathrm{NH}_{3}$ is

The four electron pairs around the nitrogen atom require a tetrahedral arrangement to minimize repulsions. We have seen that a tetrahedral set of $s p^{3}$ hybrid orbitals is obtained by combining the $2 s$ and three $2 p$ orbitals. In the $\mathrm{NH}_{3}$ molecule, three of the $s p^{3}$ orbitals are used to form bonds to the three hydrogen atoms, and the fourth $s p^{3}$ orbital holds the lone pair (Fig. 9.7).

FIGURE 9.8 The hybridization of the $s, p_{x}$, and $p_{y}$ atomic orbitals results in the formation of three $s p^{2}$ orbitals centered in the $x y$ plane. The large lobes of the orbitals lie in the plane at angles of 120 degrees and point toward the corners of a triangle.

A double bond acts as one effective electron pair.
$s p^{2}$ hybridization gives a trigonal planar arrangement of atomic orbitals.

Note in Fig. 9.10 and the figures that follow that the orbital lobes are artificially narrowed to more clearly show their relative orientations.

FIGURE 9.9 An orbital energy-level diagram for $s p^{2}$ hybridization. Note that one $p$ orbital remains unchanged.

## $s p^{2}$ Hybridization

Ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ is an important starting material in the manufacture of plastics. The $\mathrm{C}_{2} \mathrm{H}_{4}$ molecule has 12 valence electrons and the following Lewis structure:

We saw in Chapter 8 that a double bond acts as one effective pair, so in the ethylene molecule each carbon is surrounded by three effective pairs. This requires a trigonal planar arrangement with bond angles of 120 degrees. What orbitals do the carbon atoms in this molecule employ? The molecular geometry requires a set of orbitals in one plane at angles of 120 degrees. Since the $2 s$ and $2 p$ valence orbitals of carbon do not have the required arrangement, we need a set of hybrid orbitals.

The $s p^{3}$ orbitals we have just considered will not work because they are at angles of 109.5 degrees rather than the required 120 degrees. In ethylene the carbon atom must hybridize in a different manner. A set of three orbitals arranged at 120-degree angles in the same plane can be obtained by combining one $s$ orbital and two $p$ orbitals, as shown in Fig. 9.8. The orbital energy-level diagram for this arrangement is shown in Fig. 9.9. Since one $2 s$ and two $2 p$ orbitals are used to form these hybrid orbitals, this is called $s p^{2}$ hybridization. Note from Fig. 9.8 that the plane of the $s p^{2}$ hybridized orbitals is determined by which $p$ orbitals are used. Since in this case we have arbitrarily decided to use the $p_{x}$ and $p_{y}$ orbitals, the hybrid orbitals are centered in the $x y$ plane.

In forming the $s p^{2}$ orbitals, one $2 p$ orbital on carbon has not been used. This remaining $p$ orbital $\left(p_{z}\right)$ is oriented perpendicular to the plane of the $s p^{2}$ orbitals, as shown in Fig. 9.10.

Now we will see how these orbitals can be used to account for the bonds in ethylene. The three $s p^{2}$ orbitals on each carbon can be used to share electrons (Fig. 9.11). In each of these bonds, the electron pair is shared in an area centered on a line running between the atoms. This type of covalent bond is called a sigma ( $\boldsymbol{\sigma}$ ) bond. In the

FIGURE 9.10 When an s and two $p$ orbitals are mixed to form a set of three $s p^{2}$ orbitals, one $p$ orbital remains unchanged and is perpendicular to the plane of the hybrid orbitals. Note that in this figure and those that follow, the orbitals are drawn with narrowed lobes to show their orientations more clearly.

FIGURE 9.13 (a) The orbitals used to form the bonds in ethylene. (b) The Lewis structure for ethylene.

FIGURE 9.11 The $\sigma$ bonds in ethylene. Note that for each bond the shared electron pair occupies the region directly between the atoms.

FIGURE 9.12 A carbon-carbon double bond consists of a $\sigma$ bond and a $\pi$ bond. In the $\sigma$ bond the shared electrons occupy the space directly between the atoms. The $\pi$ bond is formed from the unhybridized $p$ orbitals on the two carbon atoms. In a $\pi$ bond the shared electron pair occupies the space above and below a line joining the atoms.
ethylene molecule, the $\sigma$ bonds are formed using $s p^{2}$ orbitals on each carbon atom and the $1 s$ orbital on each hydrogen atom.

How can we explain the double bond between the carbon atoms? In the $\sigma$ bond the electron pair occupies the space between the carbon atoms. The second bond must therefore result from sharing an electron pair in the space above and below the $\sigma$ bond. This type of bond can be formed using the $2 p$ orbital perpendicular to the $s p^{2}$ hybrid orbitals on each carbon atom (see Fig. 9.10). These parallel $p$ orbitals can share an electron pair, which occupies the space above and below a line joining the atoms, to form a pi ( $\pi$ ) bond (Fig. 9.12).

Note that $\sigma$ bonds are formed from orbitals whose lobes point toward each other, but $\pi$ bonds result from parallel orbitals. A double bond always consists of one $\sigma$ bond, where the electron pair is located directly between the atoms, and one $\pi$ bond, where the shared pair occupies the space above and below the $\sigma$ bond.

We can now completely specify the orbitals that this model assumes are used to form the bonds in the ethylene molecule. As shown in Fig. 9.13, the carbon atoms use $s p^{2}$ hybrid orbitals to form the $\sigma$ bonds to the hydrogen atoms and to each other, and they use $p$ orbitals to form the $\pi$ bond with each other. Note that we have accounted fully for the Lewis structure of ethylene with its carbon-carbon double bond and carbon-hydrogen single bonds.

This example illustrates an important general principle of this model: Whenever an atom is surrounded by three effective pairs, a set of $s p^{2}$ hybrid orbitals is required.

a

b

FIGURE 9.14 When one $s$ orbital and one $p$ orbital are hybridized, a set of two $s p$ orbitals oriented at 180 degrees results.

FIGURE 9.15 The hybrid orbitals in the $\mathrm{CO}_{2}$ molecule.

FIGURE 9.16 The orbital energy-level diagram for the formation of $s p$ hybrid orbitals on carbon.

More rigorous theoretical models of $\mathrm{CO}_{2}$ indicate that each of the oxygen atoms uses two p orbitals simultaneously to form the pi bonds to the carbon atom, thus leading to unusually strong $\mathrm{C}=\mathrm{O}$ bonds.

FIGURE 9.17 The orbitals of an $s p$ hybridized carbon atom.

## sp Hybridization

Another type of hybridization occurs in carbon dioxide, which has the following Lewis structure:

$$
\dot{\mathrm{O}}=\mathrm{C}=\dot{\mathrm{O}}
$$

In the $\mathrm{CO}_{2}$ molecule, the carbon atom has two effective pairs that will be arranged at an angle of 180 degrees. We therefore need a pair of atomic orbitals oriented in opposite directions. This requires a new type of hybridization, since neither $s p^{3}$ nor $s p^{2}$ hybrid orbitals will fit this case. To obtain two hybrid orbitals arranged at 180 degrees requires $s p$ hybridization, involving one $s$ orbital and one $p$ orbital (Fig. 9.14).

In terms of this model, two effective pairs around an atom will always require $s p$ hybridization of that atom. The $s p$ orbitals of carbon in carbon dioxide can be seen in Fig. 9.15, and the corresponding orbital energy-level diagram for their formation is given in Fig. 9.16. These $s p$ hybrid orbitals are used to form the $\sigma$ bonds between the carbon and the oxygen atoms. Note that two $2 p$ orbitals remain unchanged on the $s p$ hybridized carbon. These are used to form the $\pi$ bonds with the oxygen atoms.

In the $\mathrm{CO}_{2}$ molecule, each oxygen atom* has three effective pairs around it, requiring a trigonal planar arrangement of the pairs. Since a trigonal set of hybrid orbitals requires $s p^{2}$ hybridization, each oxygen atom is $s p^{2}$ hybridized. One $p$ orbital on each oxygen is unchanged and is used for the $\pi$ bond with the carbon atom.

Now we are ready to use our model to describe the bonding in carbon dioxide. The $s p$ orbitals on carbon form $\sigma$ bonds with the $s p^{2}$ orbitals on the two oxygen atoms (see Fig. 9.15). The remaining $s p^{2}$ orbitals on the oxygen atoms hold lone pairs. The $\pi$ bonds between the carbon atom and each oxygen atom are formed by the overlap of parallel $2 p$ orbitals. The $s p$ hybridized carbon atom has two unhybridized $p$ orbitals (Fig. 9.17). Each of these $p$ orbitals is used to form a $\pi$ bond with an oxygen atom

[^15]

FIGURE 9.18 The orbital arrangement for an $s p^{2}$ hybridized oxygen atom.

FIGURE 9.19 (a) The orbitals used to form the bonds in carbon dioxide. Note that the carbon-oxygen double bonds each consist of one $\sigma$ bond and one $\pi$ bond. (b) The Lewis structure for carbon dioxide.
(Fig. 9.18). The total bonding picture for the $\mathrm{CO}_{2}$ molecule is shown in Fig. 9.19. Note that this picture of the bonding neatly explains the arrangement of electrons predicted by the Lewis structure.

Another molecule whose bonding can be described by $s p$ hybridization is acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$, which has the systematic name ethyne. The Lewis structure for acetylene is

$$
\mathrm{H}-\mathrm{C} \equiv \mathrm{C}-\mathrm{H}
$$

Because the triple bond counts as one effective repulsive unit, each carbon has two effective pairs, which requires a linear arrangement. Thus each carbon atom requires $s p$ hybridization, leaving two unchanged $p$ orbitals (see Fig. 9.16). One of the oppositely oriented (see Fig. 9.14) $s p$ orbitals is used to form a bond to the hydrogen atom; the other $s p$ orbital overlaps with the similar $s p$ orbital on the other carbon to form the sigma bond. The two pi bonds are formed from the overlap of the two $p$ orbitals on each carbon. This accounts for the triple bond (one sigma and two pi bonds) in acetylene.

## EXAMPLE 9.2 The Localized Electron Model II

Describe the bonding in the $\mathrm{N}_{2}$ molecule.

## SOLUTION The Lewis structure for the nitrogen molecule is

$$
: \mathrm{N} \equiv \mathrm{~N}:
$$

where each nitrogen atom is surrounded by two effective pairs. (Remember that a multiple bond counts as one effective pair.) This gives a linear arrangement (180 degrees) requiring a pair of oppositely directed orbitals. This situation requires $s p$ hybridization. Each nitrogen atom in the nitrogen molecule has two $s p$ hybrid orbitals and two unchanged $p$ orbitals [Fig. 9.20(a)]. The $s p$ orbitals are used to form the $\sigma$ bond between the nitrogen atoms and to hold lone pairs [Fig. 9.20(b)]. The $p$ orbitals are used to form the two $\pi$ bonds [Fig. 9.20(c)]; each pair of overlapping parallel $p$ orbitals holds one electron pair. Such bonding accounts for the electron arrangement given by the Lewis structure. The triple bond consists of a $\sigma$ bond (overlap of two $s p$ orbitals) and two $\pi$ bonds (each one from an overlap of two $p$ orbitals). In addition, a lone pair occupies an $s p$ orbital on each nitrogen atom.

FIGURE 9.20
(a) An $s p$ hybridized nitrogen atom. There are two $s p$ hybrid orbitals and two unhybridized $p$ orbitals. (b) The $\sigma$ bond in the $\mathrm{N}_{2}$ molecule. (c) The two $\pi$ bonds in $\mathrm{N}_{2}$ are formed when electron pairs are shared between two sets of parallel $p$ orbitals. (d) The total bonding picture for $\mathrm{N}_{2}$.

FIGURE 9.21 A set of $d s p^{3}$ hybrid orbitals on a phosphorus atom. Note that the set of five $d s p^{3}$ orbitals has a trigonal bipyramidal arrangement. (Each $d s p^{3}$ orbital also has a small lobe that is not shown in this diagram.)

Although this simple model can be used to account for the bonding in these molecules, it now seems clear that it mistakenly invokes the use of the $d$ orbitals in the actual bonding of the molecule.

FIGURE 9.22 The structure of the $\mathrm{PCl}_{5}$ molecule.

## dsp ${ }^{3}$ Hybridization

To illustrate the treatment of a molecule in which the central atom exceeds the octet rule, consider the bonding in the phosphorus pentachloride molecule $\left(\mathrm{PCl}_{5}\right)$. The Lewis structure

shows that the phosphorus atom is surrounded by five electron pairs. Since five pairs require a trigonal bipyramidal arrangement, we need a trigonal bipyramidal set of atomic orbitals on phosphorus. Such a set of orbitals is formed by $d s p^{3}$ hybridization of one $d$ orbital, one $s$ orbital, and three $p$ orbitals (Fig. 9.21). Although this model is convenient, its use of the $d$ orbitals does not give an accurate picture of the actual bonding in this molecule. Recent research shows that a more complex model for the bonding in molecules that exceed the octet rule is needed. This new model does not employ $d$ orbitals for describing the bonding in these molecules. (A description of this model is beyond the scope of this text.) This problem reminds us once again that the simple models we use often contain oversimplifications. We will continue to employ this simple model even with its problems because of its convenience and widespread use.

In this model we assume that the phosphorus atom in the $\mathrm{PCl}_{5}$ molecule uses its five $d s p^{3}$ orbitals to share electrons with the five chlorine atoms. Note that a set of five effective pairs around a given atom always requires a trigonal bipyramidal arrangement, which in turn implies $d s p^{3}$ hybridization of that atom.

The Lewis structure for $\mathrm{PCl}_{5}$ shows that each chlorine atom is surrounded by four electron pairs. This requires a tetrahedral arrangement, which in turn requires a set of four $s p^{3}$ orbitals on each chlorine atom.

Now we can describe the bonding in the $\mathrm{PCl}_{5}$ molecule shown in Fig. 9.22. The five $\mathrm{P}-\mathrm{Cl} \sigma$ bonds are formed by sharing electrons between a $d s p^{3}$ orbital on the phosphorus atom and an orbital on each chlorine.

## EXAMPLE 9.3 The Localized Electron Model III

SOLUTION
$d^{2} s p^{3}$ hybridization gives six orbitals arranged octahedrally.

FIGURE 9.23 An octahedral set of $d^{2} s p^{3}$ orbitals on a sulfur atom. The small lobe of each hybrid orbital has been omitted for clarity.

Describe the bonding in the triiodide ion $\left(\mathrm{I}_{3}{ }^{-}\right)$.
The Lewis structure for $\mathrm{I}_{3}{ }^{-}$

$$
[\because \ddot{\mathrm{I}}-\ddot{\mathrm{I}}-\ddot{\mathrm{I}}]^{-}
$$

shows that the central iodine atom has five pairs of electrons (see Section 8.11). A set of five pairs requires a trigonal bipyramidal arrangement, which in turn requires a set of $d s p^{3}$ orbitals. The outer iodine atoms have four pairs of electrons, which calls for a tetrahedral arrangement and $s p^{3}$ hybridization.

Thus the central iodine is $d s p^{3}$ hybridized. Three of these hybrid orbitals hold lone pairs, and two of them overlap with $s p^{3}$ orbitals of the other two iodine atoms to form $\sigma$ bonds.

See Exercise 9.29

## $d^{2} s p^{3}$ Hybridization

Some molecules have six pairs of electrons around a central atom; an example is sulfur hexafluoride $\left(\mathrm{SF}_{6}\right)$, which has the Lewis structure

This requires an octahedral arrangement of pairs and in turn this model implies an octahedral set of six hybrid orbitals, or $\boldsymbol{d}^{2} \boldsymbol{s} \boldsymbol{p}^{3}$ hybridization, in which two $d$ orbitals, one $s$ orbital, and three $p$ orbitals are combined (Fig. 9.23). Six electron pairs around an atom are always arranged octahedrally and imply $d^{2} s p^{3}$ hybridization of the atom. Each of the $d^{2} s p^{3}$ orbitals on the sulfur atom is used to bond to a fluorine atom. Since there are four pairs on each fluorine atom, the fluorine atoms are assumed to be $s p^{3}$ hybridized.

## INTERACTIVE EXAMPLE 9.4 The Localized Electron Model IV

How is the xenon atom in $\mathrm{XeF}_{4}$ hybridized?

## SOLUTION

As seen in Example 8.13, $\mathrm{XeF}_{4}$ has six pairs of electrons around xenon that are arranged octahedrally to minimize repulsions. An octahedral set of six atomic orbitals is required by this model to hold these electrons, and the xenon atom is $d^{2} s p^{3}$ hybridized.

Xenon uses six $d^{2} s p^{3}$ hybrid atomic orbitals to bond to the four fluorine atoms and to hold the two lone pairs.

## The Localized Electron Model: A Summary

The description of a molecule using the localized electron model involves three distinct steps.

## PROBLEM-SOLVING STRATEGY

## Using the Localized Electron Model

1. Draw the Lewis structure(s).
2. Determine the arrangement of electron pairs using the VSEPR model.
3. Specify the hybrid orbitals needed to accommodate the electron pairs.

It is important to do the steps in this order. For a model to be successful, it must follow nature's priorities. In the case of bonding, it seems clear that the tendency for a molecule to minimize its energy is more important than the maintenance of the characteristics of atoms as they exist in the free state. The atoms adjust to meet the "needs" of the molecule. When considering the bonding in a particular molecule, therefore, we always start with the molecule rather than the component atoms. In the molecule the electrons will be arranged to give each atom a noble gas configuration, where possible, and to minimize electron-pair repulsions. We then assume that the atoms adjust their orbitals by hybridization to allow the molecule to adopt the structure that gives the minimum energy.

In applying the localized electron model, we must remember not to overemphasize the characteristics of the separate atoms. It is not where the valence electrons originate that is important; it is where they are needed in the molecule to achieve stability. In the same vein, it is not the orbitals in the isolated atom that matter, but which orbitals the molecule requires for minimum energy.

The requirements for the various types of hybridization are summarized in Fig. 9.24 on the following page.

## The Localized Electron Model V

For each of the following molecules or ions, predict the hybridization of each atom, and describe the molecular structure.
a. CO
b. $\mathrm{BF}_{4}^{-}$
c. $\mathrm{XeF}_{2}$

SOLUTION
a. The CO molecule has 10 valence electrons, and its Lewis structure is

$$
: \mathrm{C} \equiv \mathrm{O}:
$$

Each atom has two effective pairs, which means that both are $s p$ hybridized. The triple bond consists of a $\sigma$ bond produced by overlap of an $s p$ orbital from each atom and two $\pi$ bonds produced by overlap of $2 p$ orbitals from each atom. The lone pairs are in $s p$ orbitals. Since the CO molecule has only two atoms, it must be linear.

FIGURE 9.24 The relationship of the number of effective pairs, their spatial arrangement, and the hybrid orbital set required.

| Number of <br> Effective Pairs | Arrangement of Pairs | Hybridization Required |
| :---: | :---: | :---: |
| 2 | Linear | $s p$ |
| 3 |  | Trigonal <br> planar |
| 4 |  |  |
|  |  |  |

b. The $\mathrm{BF}_{4}{ }^{-}$ion has 32 valence electrons. The Lewis structure shows four pairs of electrons around the boron atom, which means a tetrahedral arrangement:

This requires $s p^{3}$ hybridization of the boron atom. Each fluorine atom also has four electron pairs and can be assumed to be $s p^{3}$ hybridized (only one
$s p^{3}$ orbital is shown for each fluorine atom). The $\mathrm{BF}_{4}{ }^{-}$ion's molecular structure is tetrahedral.

c. The $\mathrm{XeF}_{2}$ molecule has 22 valence electrons. The Lewis structure shows five electron pairs on the xenon atom, which requires a trigonal bipyramidal arrangement:

Note that the lone pairs are placed in the plane where they are 120 degrees apart. To accommodate five pairs at the vertices of a trigonal bipyramid requires that the xenon atom adopt a set of five $d s p^{3}$ orbitals. Each fluorine atom has four electron pairs and can be assumed to be $s p^{3}$ hybridized. The $\mathrm{XeF}_{2}$ molecule has a linear arrangement of atoms.

### 9.2 The Molecular Orbital Model

We have seen that the localized electron model is of great value in interpreting the structure and bonding of molecules. However, there are some problems with this model. For example, it incorrectly assumes that electrons are localized, and so the concept of resonance must be added. Also, the model does not deal effectively with molecules containing unpaired electrons. And finally, the model gives no direct information about bond energies.

Molecular orbital theory parallels the atomic theory discussed in Chapter 7.

FIGURE 9.25 The combination of hydrogen 1 s atomic orbitals to form MOs. The phases of the orbitals are shown by signs inside the boundary surfaces. When the orbitals are added, the matching phases produce constructive interference, which gives enhanced electron probability between the nuclei. This results in a bonding molecular orbital. When one orbital is subtracted from the other, destructive interference occurs between the opposite phases, leading to a node between the nuclei. This is an antibonding MO.

FIGURE 9.26 (a) The MO energylevel diagram for the $\mathrm{H}_{2}$ molecule.
(b) The shapes of the MOs are obtained by squaring the wave functions for $\mathrm{MO}_{1}$ and $\mathrm{MO}_{2}$. The positions of the nuclei are indicated by .

Another model often used to describe bonding is the molecular orbital model. To introduce the assumptions, methods, and results of this model, we will consider the simplest of all molecules, $\mathrm{H}_{2}$, which consists of two protons and two electrons. A very stable molecule, $\mathrm{H}_{2}$ is lower in energy than the separated hydrogen atoms by $432 \mathrm{~kJ} / \mathrm{mol}$.

Since the hydrogen molecule consists of protons and electrons, the same components found in separated hydrogen atoms, it seems reasonable to use a theory similar to the atomic theory discussed in Chapter 7, which assumes that the electrons in an atom exist in orbitals of a given energy. Can we apply this same type of model to the hydrogen molecule? Yes. In fact, describing the $\mathrm{H}_{2}$ molecule in terms of quantum mechanics is quite straightforward.

However, even though it is formulated rather easily, this problem cannot be solved exactly. The difficulty is the same as that in dealing with polyelectronic atoms-the electron correlation problem. Since we do not know the details of the electron movements, we cannot deal with the electron-electron interactions in a specific way. We need to make approximations that allow a solution of the problem but do not destroy the model's physical integrity. The success of these approximations can be measured only by comparing predictions based on theory with experimental observations. In this case we will see that the simplified model works very well.

Just as atomic orbitals are solutions to the quantum mechanical treatment of atoms, molecular orbitals (MOs) are solutions to the molecular problem. Molecular orbitals have many of the same characteristics as atomic orbitals. Two of the most important are that they can hold two electrons with opposite spins and that the square of the molecular orbital wave function indicates electron probability.

We will now describe the bonding in the hydrogen molecule using this model. The first step is to obtain the hydrogen molecule's orbitals, a process that is greatly simplified if we assume that the molecular orbitals can be constructed from the hydrogen $1 s$ atomic orbitals.

When the quantum mechanical equations for the hydrogen molecule are solved, two molecular orbitals result, which can be represented as

$$
\begin{aligned}
& \mathrm{MO}_{1}=1 s_{\mathrm{A}}+1 s_{\mathrm{B}} \\
& \mathrm{MO}_{2}=1 s_{\mathrm{A}}-1 s_{\mathrm{B}}
\end{aligned}
$$

where $1 s_{\mathrm{A}}$ and $1 s_{\mathrm{B}}$ represent the $1 s$ orbitals from the two separated hydrogen atoms. This process is shown schematically in Fig. 9.25.

The orbital properties of most interest are size, shape (described by the electron probability distribution), and energy. These properties for the hydrogen molecular orbitals are represented in Fig. 9.26. From Fig. 9.26 we can note several important points:

1. The electron probability of both molecular orbitals is centered along the line passing through the two nuclei. For $\mathrm{MO}_{1}$ the greatest electron probability is between the nuclei, and for $\mathrm{MO}_{2}$ it is on either side of the nuclei. This type of electron distribution is described as $\operatorname{sigma}(\sigma)$, as in the localized electron model. Accordingly, we refer to $\mathrm{MO}_{1}$ and $\mathrm{MO}_{2}$ as sigma ( $\boldsymbol{\sigma}$ ) molecular orbitals.

-b
Electron probability distribution

FIGURE 9.27 Bonding and antibonding molecular orbitals (MOs).

Bonding will result if the molecule has lower energy than the separated atoms.

FIGURE 9.28 A molecular orbital energy-level diagram for the $\mathrm{H}_{2}$ molecule.
2. In the molecule only the molecular orbitals are available for occupation by electrons. The $1 s$ atomic orbitals of the hydrogen atoms no longer exist, because the $\mathrm{H}_{2}$ molecule-a new entity-has its own set of new orbitals.
3. $\mathrm{MO}_{1}$ is lower in energy than the $1 s$ orbitals of free hydrogen atoms, while $\mathrm{MO}_{2}$ is higher in energy than the $1 s$ orbitals. This fact has very important implications for the stability of the $\mathrm{H}_{2}$ molecule, since if the two electrons (one from each hydrogen atom) occupy the lower-energy $\mathrm{MO}_{1}$, they will have lower energy than they do in the two separate hydrogen atoms. This situation favors molecule formation, because nature tends to seek the lowest energy state. That is, the driving force for molecule formation is that the molecular orbital available to the two electrons has lower energy than the atomic orbitals these electrons occupy in the separated atoms. This situation is favorable to bonding, or probonding.

On the other hand, if the two electrons were forced to occupy the higherenergy $\mathrm{MO}_{2}$, they would be definitely antibonding. In this case, these electrons would have lower energy in the separated atoms than in the molecule, and the separated state would be favored. Of course, since the lower-energy $\mathrm{MO}_{1}$ is available, the two electrons occupy that MO and the molecule is stable.

We have seen that the molecular orbitals of the hydrogen molecule fall into two classes: bonding and antibonding. A bonding molecular orbital is lower in energy than the atomic orbitals of which it is composed. Electrons in this type of orbital will favor the molecule; that is, they will favor bonding. An antibonding molecular orbital is higher in energy than the atomic orbitals of which it is composed. Electrons in this type of orbital will favor the separated atoms (they are antibonding). Figure 9.27 illustrates these ideas.
4. Figure 9.26 shows that for the bonding molecular orbital in the $\mathrm{H}_{2}$ molecule the electrons have the greatest probability of being between the nuclei. This is exactly what we would expect, since the electrons can lower their energies by being simultaneously attracted by both nuclei. On the other hand, the electron distribution for the antibonding molecular orbital is such that the electrons are mainly outside the space between the nuclei. This type of distribution is not expected to provide any bonding force. In fact, it causes the electrons to be higher in energy than in the separated atoms. Thus the molecular orbital model produces electron distributions and energies that agree with our basic ideas of bonding. This fact reassures us that the model is physically reasonable.
5. The labels on molecular orbitals indicate their symmetry (shape), the parent atomic orbitals, and whether they are bonding or antibonding. Antibonding character is indicated by an asterisk. For the $\mathrm{H}_{2}$ molecule, both MOs have $\sigma$ symmetry, and both are constructed from hydrogen $1 s$ atomic orbitals. The molecular orbitals for $\mathrm{H}_{2}$ are therefore labeled as follows:

$$
\begin{aligned}
& \mathrm{MO}_{1}=\sigma_{1 s} \\
& \mathrm{MO}_{2}=\sigma_{1 s} *
\end{aligned}
$$

6. Molecular electron configurations can be written in much the same way as atomic (electron) configurations. Since the $\mathrm{H}_{2}$ molecule has two electrons in the $\sigma_{1 s}$ molecular orbital, the electron configuration is $\sigma_{1 s}{ }^{2}$.
7. Each molecular orbital can hold two electrons, but the spins must be opposite.
8. Orbitals are conserved. The number of molecular orbitals will always be the same as the number of atomic orbitals used to construct them.

Many of the above points are summarized in Fig. 9.28.
Now suppose we could form the $\mathrm{H}_{2}^{-}$ion from a hydride ion $\left(\mathrm{H}^{-}\right)$and a hydrogen atom. Would this species be stable? Since the $\mathrm{H}^{-}$ion has the configuration $1 s^{2}$ and the H atom has a $1 s^{1}$ configuration, we will use $1 s$ atomic orbitals to construct

FIGURE 9.29 The molecular orbital energy-level diagram for the $\mathrm{H}_{2}{ }^{-}$ion.

Although the model predicts that $\mathrm{H}_{2}{ }^{-}$ should be stable, this ion has never been observed, again emphasizing the perils of simple models.

FIGURE 9.30 The molecular orbital energy-level diagram for the $\mathrm{He}_{2}$ molecule.
the MO diagram for the $\mathrm{H}_{2}{ }^{-}$ion (Fig. 9.29). The electron configuration for $\mathrm{H}_{2}{ }^{-}$is $\left(\sigma_{1 s}\right)^{2}\left(\sigma_{1 s}\right)^{1}$.

The key idea is that the $\mathrm{H}_{2}{ }^{-}$ion will be stable if it has a lower energy than its separated parts. From Fig. 9.29 we see that in going from the separated $\mathrm{H}^{-}$ion and H atom to the $\mathrm{H}_{2}{ }^{-}$ion, the model predicts that two electrons are lowered in energy and one electron is raised in energy. In other words, two electrons are bonding and one electron is antibonding. Since more electrons favor bonding, $\mathrm{H}_{2}{ }^{-}$is predicted to be a stable entity-a bond has formed. But how would we expect the bond strengths in the molecules of $\mathrm{H}_{2}$ and $\mathrm{H}_{2}{ }^{-}$to compare?

In the formation of the $\mathrm{H}_{2}$ molecule, two electrons are lowered in energy and no electrons are raised in energy compared with the parent atoms. When $\mathrm{H}_{2}{ }^{-}$is formed, two electrons are lowered in energy and one is raised, producing a net lowering of the energy of only one electron. Thus the model predicts that $\mathrm{H}_{2}$ is twice as stable as $\mathrm{H}_{2}{ }^{-}$ with respect to their separated components. In other words, the bond in the $\mathrm{H}_{2}$ molecule is predicted to be about twice as strong as the bond in the $\mathrm{H}_{2}{ }^{-}$ion.

## Bond Order

To indicate bond strength, we use the concept of bond order. Bond order is the difference between the number of bonding electrons and the number of antibonding electrons divided by 2.

$$
\text { Bond order }=\frac{\text { number of bonding electrons }- \text { number of antibonding electrons }}{2}
$$

We divide by 2 because, from the localized electron model, we are used to thinking of bonds in terms of pairs of electrons.

Since the $\mathrm{H}_{2}$ molecule has two bonding electrons and no antibonding electrons, the bond order is

$$
\text { Bond order }=\frac{2-0}{2}=1
$$

The $\mathrm{H}_{2}{ }^{-}$ion has two bonding electrons and one antibonding electron; the bond order is

$$
\text { Bond order }=\frac{2-1}{2}=\frac{1}{2}
$$

Bond order is an indication of bond strength because it reflects the difference between the number of bonding electrons and the number of antibonding electrons. Larger bond order means greater bond strength.

We will now apply the molecular orbital model to the helium molecule $\left(\mathrm{He}_{2}\right)$. Does this model predict that this molecule will be stable? Since the He atom has a $1 s^{2}$ configuration, $1 s$ orbitals are used to construct the molecular orbitals, and the molecule will have four electrons. From the diagram shown in Fig. 9.30, it is apparent that two electrons are raised in energy and two are lowered in energy. Thus the bond order is zero:

$$
\frac{2-2}{2}=0
$$

This implies that the $\mathrm{He}_{2}$ molecule is not stable with respect to the two free He atoms, which agrees with the observation that helium gas consists of individual He atoms.

### 9.3 Bonding in Homonuclear Diatomic Molecules

In this section we consider homonuclear diatomic molecules (those composed of two identical atoms) of elements in Period 2 of the periodic table. Since the lithium atom has a $1 s^{2} 2 s^{1}$ electron configuration, it would seem that we should use the $\mathrm{Li} 1 s$ and $2 s$ orbitals to form the molecular orbitals of the $\mathrm{Li}_{2}$ molecule. However, the $1 s$ orbitals on

FIGURE 9.31 The relative sizes of the lithium $1 s$ and $2 s$ atomic orbitals in $\mathrm{Li}_{2}$.

A
Beryllium metal.
orbitals can overlap, as shown in (b) and (c), and the third pair can overlap headon, as shown in (d).
FIGURE 9.33 (a) The three mutually perpendicular $2 p$ orbitals on two adjacent boron atoms. The signs indicate the orbital phases. Two pairs of parallel $p$

FIGURE 9.32 The molecular orbital energy-level diagram for the $\mathrm{Li}_{2}$ molecule.
the lithium atoms are much smaller than the $2 s$ orbitals and therefore do not overlap in space to any appreciable extent (Fig. 9.31). Thus the two electrons in each $1 s$ orbital can be assumed to be localized and not to participate in the bonding. To participate in molecular orbitals, atomic orbitals must overlap in space. This means that only the valence orbitals of the atoms contribute significantly to the molecular orbitals of a particular molecule.

The molecular orbital diagram of the $\mathrm{Li}_{2}$ molecule and the shapes of its bonding and antibonding MOs are shown in Fig. 9.32. The electron configuration for $\mathrm{Li}_{2}$ (valence electrons only) is $\sigma_{2 s}{ }^{2}$, and the bond order is

$$
\frac{2-0}{2}=1
$$

$\mathrm{Li}_{2}$ is a stable molecule (has lower energy than two separated lithium atoms). However, this does not mean that $\mathrm{Li}_{2}$ is the most stable form of elemental lithium. In fact, at normal temperature and pressure, lithium exists as a solid containing many lithium atoms bound to each other.

For the beryllium molecule $\left(\mathrm{Be}_{2}\right)$, the bonding and antibonding orbitals both contain two electrons. In this case the bond order is $(2-2) / 2=0$, and since $\mathrm{Be}_{2}$ is not more stable than two separated Be atoms, no molecule forms. However, beryllium metal contains many beryllium atoms bonded to each other and is stable for reasons we will discuss in Chapter 10.

Since the boron atom has a $1 s^{2} 2 s^{2} 2 p^{1}$ configuration, we describe the $\mathrm{B}_{2}$ molecule by considering how $p$ atomic orbitals combine to form molecular orbitals. Recall that $p$ orbitals have two lobes and that they occur in sets of three mutually perpendicular orbitals [Fig. 9.33(a)]. When two B atoms approach each other, two pairs of $p$ orbitals

can overlap in a parallel fashion [Fig. 9.33(b) and (c)] and one pair can overlap headon [Fig. 9.33(d)].

First, let's consider the molecular orbitals from the head-on overlap. The bonding orbital is formed by reversing the sign of the right orbital so the positive phases of both orbitals match between the nuclei to produce constructive interference. This leads to enhanced electron probability between the nuclei. The antibonding orbital is formed by the direct combination of the orbitals, which gives destructive interference of the positive phase of one orbital with the negative phase of the second orbital. This produces a node between the nuclei, which gives decreased electron probability. Note that the electrons in the bonding MO are, as expected, concentrated between the nuclei, and the electrons in the antibonding MO are concentrated outside the area between the two nuclei. Also, both these MOs are $\sigma$ molecular orbitals.

When the parallel $p$ orbitals are combined with the positive and negative phases matched, constructive interference occurs, giving a bonding $\pi$ orbital. When the orbitals have opposite phases (the signs of one orbital are reversed), destructive interference occurs, resulting in an antibonding $\pi$ orbital.

Since the electron probability lies above and below the line between the nuclei, both the orbitals are pi $(\boldsymbol{\pi})$ molecular orbitals. They are designated as $\pi_{2 p}$ for the bonding MO and $\pi_{2 p}{ }^{*}$ for the antibonding MO. A similar set of $\pi$ molecular orbitals is formed from overlap of the parallel $p_{z}$ atomic orbitals.

Let's try to make an educated guess about the relative energies of the $\sigma$ and $\pi$ molecular orbitals formed from the $2 p$ atomic orbitals. Would we expect the electrons to prefer the $\sigma$ bonding orbital (where the electron probability is concentrated in the area between the nuclei) or the $\pi$ bonding orbital? The $\sigma$ orbital would seem to have the lower energy, since the electrons are closest to the two nuclei. This agrees with the observation that $\sigma$ interactions are stronger than $\pi$ interactions.

FIGURE 9.34 The expected molecular orbital energy-level diagram resulting from the combination of the $2 p$ orbitals on two boron atoms.

FIGURE 9.35 The expected molecular orbital energy-level diagram for the $\mathrm{B}_{2}$ molecule.

FIGURE 9.36 Diagram of the kind of apparatus used to measure the paramagnetism of a sample. A paramagnetic sample will appear heavier when the electromagnet is turned on because the sample is attracted into the inducing magnetic field.

Figure 9.34 gives the molecular orbital energy-level diagram expected when the two sets of $2 p$ orbitals on the boron atoms combine to form molecular orbitals. Note that there are two $\pi$ bonding orbitals at the same energy (degenerate orbitals) formed from the two pairs of parallel $p$ orbitals, and there are two degenerate $\pi$ antibonding orbitals. The energy of the $\pi_{2 p}$ orbitals is expected to be higher than that of the $\sigma_{2 p}$ orbital because $\sigma$ interactions are generally stronger than $\pi$ interactions.

To construct the total molecular orbital diagram for the $\mathrm{B}_{2}$ molecule, we make the assumption that the $2 s$ and $2 p$ orbitals combine separately (in other words, there is no $2 s-2 p$ mixing). The resulting diagram is shown in Fig. 9.35. Note that $\mathrm{B}_{2}$ has six valence electrons. (Remember the $1 s$ orbitals and electrons are assumed not to participate in the bonding.) This diagram predicts the bond order:

$$
\frac{4-2}{2}=1
$$

Therefore, $\mathrm{B}_{2}$ should be a stable molecule.

## Paramagnetism

At this point we need to discuss an additional molecular property-magnetism. Most materials have no magnetism until they are placed in a magnetic field. However, in the presence of such a field, magnetism of two types can be induced. Paramagnetism causes the substance to be attracted into the inducing magnetic field. Diamagnetism causes the substance to be repelled from the inducing magnetic field. Figure 9.36 illustrates how paramagnetism is measured. The sample is weighed with the electromagnet turned off and then weighed again with the electromagnet turned on. An increase in weight when the field is turned on indicates the sample is paramagnetic. Studies have shown that paramagnetism is associated with unpaired electrons and diamagnetism is associated with paired electrons. Any substance that has both paired and unpaired electrons will exhibit a net paramagnetism, since the effect of paramagnetism is much stronger than that of diamagnetism.

The molecular orbital energy-level diagram represented in Fig. 9.35 predicts that the $B_{2}$ molecule will be diamagnetic, since the MOs contain only paired electrons. However, experiments show that $B_{2}$ is actually paramagnetic with two unpaired electrons. Why does the model yield the wrong prediction? This is yet another illustration of how models are developed and used. In general, we try to use the simplest possible model that accounts for all the important observations. In this case, although the simplest model successfully describes the diatomic molecules up to $B_{2}$, it certainly is suspect if it cannot describe the $\mathrm{B}_{2}$ molecule correctly. This means we must either discard the model or find a way to modify it.

Let's consider one assumption that we made. In our treatment of $B_{2}$, we have assumed that the $s$ and $p$ orbitals combine separately to form molecular orbitals. Calculations show that when the $s$ and $p$ orbitals are allowed to mix in the same molecular orbital, a different energy-level diagram results for $\mathrm{B}_{2}$ (Fig. 9.37). Note that even though the $s$ and $p$ contributions to the MOs are no longer separate, we retain the simple orbital designations. The energies of $\pi_{2 p}$ and $\sigma_{2 p}$ orbitals are reversed by $p-s$ mixing, and the $\sigma_{2 s}$ and the $\sigma_{2 s} *$ orbitals are no longer equally spaced relative to the energy of the free $2 s$ orbital.

When the six valence electrons for the $B_{2}$ molecule are placed in the modified energy-level diagram, each of the last two electrons goes into one of the degenerate $\pi_{2 p}$ orbitals. This produces a paramagnetic molecule in agreement with experimental results. Thus when the model is extended to allow $p-s$ mixing in molecular orbitals, it predicts the correct magnetism. Note that the bond order is $(4-2) / 2=1$, as before.

The remaining diatomic molecules of the elements in Period 2 can be described using similar ideas. For example, the $\mathrm{C}_{2}$ and $\mathrm{N}_{2}$ molecules use the same set of orbitals as for $\mathrm{B}_{2}$ (see Fig. 9.37). Because the importance of $2 s-2 p$ mixing decreases across the

FIGURE 9.37 The correct molecular orbital energy-level diagram for the $\mathrm{B}_{2}$ molecule. When $p-s$ mixing is allowed, the energies of the $\sigma_{2 p}$ and $\pi_{2 p}$ orbitals are reversed. The two electrons from the B $2 p$ orbitals now occupy separate, degenerate $\pi_{2 p}$ molecular orbitals and thus have parallel spins. Therefore, this diagram explains the observed paramagnetism of $B_{2}$.
period, the $\sigma_{2 p}$ and $\pi_{2 p}$ orbitals revert to the order expected in the absence of $2 s-2 p$ mixing for the molecules $\mathrm{O}_{2}$ and $\mathrm{F}_{2}$ (Fig. 9.38).
 than $\sigma_{2 p}$ orbitals? What would you expect the $\mathrm{B}_{2}$ molecular orbital energy-level diagram to look like (without considering $p-s$ mixing)? Compare your expected diagram to Figs. 9.34 and 9.35, and state the differences from each.

Several significant points arise from the orbital diagrams, bond strengths, and bond lengths summarized in Fig. 9.38 for the Period 2 diatomics:

1. There are definite correlations between bond order, bond energy, and bond length. As the bond order predicted by the molecular orbital model increases, the bond energy increases and the bond length decreases. This is a clear indication that the bond order predicted by the model accurately reflects bond strength, and it strongly supports the reasonableness of the MO model.
2. Comparison of the bond energies of the $B_{2}$ and $F_{2}$ molecules indicates that bond order cannot automatically be associated with a particular bond energy. Although both molecules have a bond order of 1 , the bond in $\mathrm{B}_{2}$ appears to be about twice as strong as the bond in $\mathrm{F}_{2}$. As we will see in our later discussion of the halogens, $\mathrm{F}_{2}$ has an unusually weak single bond due to larger than usual electron-electron repulsions (there are 14 valence electrons on the small $\mathrm{F}_{2}$ molecule).
3. Note the very large bond energy associated with the $\mathrm{N}_{2}$ molecule, which the molecular orbital model predicts will have a bond order of 3 , a triple bond. The very strong bond in $\mathrm{N}_{2}$ is the principal reason that many nitrogen-containing compounds are used as high explosives. The reactions involving these explosives

|  | $\mathrm{B}_{2}$ | $\mathrm{C}_{2}$ | $\mathrm{N}_{2}$ |
| :---: | :---: | :---: | :---: |

FIGURE 9.38 The molecular orbital energy-level diagrams, bond orders, bond energies, and bond lengths for the diatomic molecules $\mathrm{B}_{2}$ through $\mathrm{F}_{2}$. Note that for $\mathrm{O}_{2}$ and $\mathrm{F}_{2}$ the $\sigma_{2 p}$ orbital is lower in energy than the $\pi_{2 p}$ orbitals.

FIGURE 9.39 When liquid oxygen is poured into the space between the poles of a strong magnet, it remains there until it boils away. This attraction of liquid oxygen for the magnetic field demonstrates the paramagnetism of the $\mathrm{O}_{2}$ molecule.
give the very stable $\mathrm{N}_{2}$ molecule as a product, thus releasing large quantities of energy.
4. The $\mathrm{O}_{2}$ molecule is known to be paramagnetic. This can be very convincingly demonstrated by pouring liquid oxygen between the poles of a strong magnet (Fig. 9.39). The oxygen remains there until it evaporates. Significantly, the molecular orbital model correctly predicts oxygen's paramagnetism, while the localized electron model predicts a diamagnetic molecule.

## Photoelectron Spectroscopy (PES) for Molecules

We introduced photoelectron spectroscopy (PES) in Section 7.12 when discussing ionization energies of atoms. The PES spectrum of a molecule provides valuable information about the energy levels in that molecule. For example, the PES spectrum of $\mathrm{N}_{2}$ shows how the technique works. The actual PES spectrum itself is complex because of the coupling of the ionization energies of the electrons with the energies resulting from vibrations of the two nitrogen atoms. However, the results show three main areas of energy absorption at $15.6,16.7$, and 18.6 eV . We can interpret these results by looking at the molecular orbital diagram or $\mathrm{N}_{2}$ (see Fig. 9.38). Note from this diagram that $\mathrm{N}_{2}$ has five filled molecular orbitals: $\sigma_{2 s}, \sigma_{2 s}{ }^{*}$, two $\pi_{2 p}$, and $\sigma_{2 p}$. We can represent the energies required to remove these electrons in the diagram represented in Fig. 9.40.

Note from Fig. 9.40 that the energies of the bound electrons are negative and that zero corresponds to electrons that are free of the influence of the two N nuclei-they are free electrons. Also note that no transition is represented for the $\sigma_{2 s}$ electrons. These electrons have such low energy that they require more than the 21.2 eV that can be furnished by the helium source.

As we can see from this example, PES furnishes valuable information about the energies of electrons in molecules. As a result, it is a very useful tool for characterizing and testing our theories of bonding in molecules.

FIGURE 9.40 Representation of the removal of various electrons from $\mathrm{N}_{2}$. The diagram is not drawn to scale.

## INTERACTIVE EXAMPLE 9.6 The Molecular Orbital Model I

For the species $\mathrm{O}_{2}, \mathrm{O}_{2}^{+}$, and $\mathrm{O}_{2}^{-}$, give the electron configuration and the bond order for each. Which has the strongest bond?

## SOLUTION

The $\mathrm{O}_{2}$ molecule has 12 valence electrons $(6+6) ; \mathrm{O}_{2}{ }^{+}$has 11 valence electrons $(6+6-1)$; and $\mathrm{O}_{2}^{-}$has 13 valence electrons $(6+6+1)$. We will assume that the ions can be treated using the same molecular orbital diagram as for the neutral diatomic molecule:

|  | $\mathbf{O}_{\mathbf{2}}$ | $\mathbf{O}_{\mathbf{2}}{ }^{+}$ | $\mathbf{O}_{\mathbf{2}}{ }^{-}$ |
| :--- | :---: | :---: | :---: |
| $\sigma_{2 p}{ }^{*}$ | - | - | - |
| $\pi_{2 p}{ }^{*}$ | $\uparrow \uparrow \uparrow$ | $\uparrow \uparrow-$ | $\uparrow \downarrow \uparrow$ |
| $\pi_{2 p}$ | $\uparrow \downarrow \uparrow \downarrow$ | $\uparrow \downarrow \uparrow \downarrow$ | $\uparrow \downarrow \uparrow \downarrow$ |
| $\sigma_{2 p}$ | $\uparrow \downarrow$ | $\uparrow \downarrow$ | $\uparrow \downarrow$ |
| $\sigma_{2 s}{ }^{*}$ | $\uparrow \downarrow$ | $\uparrow \downarrow$ | $\uparrow \downarrow$ |
| $\sigma_{2 s}$ | $\uparrow \downarrow$ | $\uparrow \downarrow$ | $\uparrow \downarrow$ |

The electron configuration for each species can then be taken from the diagram:

$$
\begin{array}{ll}
\mathrm{O}_{2}: & \left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s} *\right)^{2}\left(\sigma_{2 p}\right)^{2}\left(\pi_{2 p}\right)^{4}\left(\pi_{2 p} *\right)^{2} \\
\mathrm{O}_{2}^{+}: & \left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s} *\right)^{2}\left(\sigma_{2 p}\right)^{2}\left(\pi_{2 p}\right)^{4}\left(\pi_{2 p} *\right)^{1} \\
\mathrm{O}_{2}^{-}: & \left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s} *\right)^{2}\left(\sigma_{2 p}\right)^{2}\left(\pi_{2 p}\right)^{4}\left(\pi_{2 p} *\right)^{3}
\end{array}
$$

The bond orders are:

$$
\begin{aligned}
& \text { For } \mathrm{O}_{2}: \quad \frac{8-4}{2}=2 \\
& \text { For } \mathrm{O}_{2}^{+}: \quad \frac{8-3}{2}=2.5 \\
& \text { For } \mathrm{O}_{2}^{-}: \quad \frac{8-5}{2}=1.5
\end{aligned}
$$

Thus $\mathrm{O}_{2}{ }^{+}$is expected to have the strongest bond of the three species.

## INTERACTIVE EXAMPLE 9.7 The Molecular Orbital Model II

Use the molecular orbital model to predict the bond order and magnetism of each of the following molecules.
a. $\mathrm{Ne}_{2}$
b. $\mathrm{P}_{2}$

SOLUTION
a. The valence orbitals for Ne are $2 s$ and $2 p$. Thus we can use the molecular orbitals we have already constructed for the diatomic molecules of the Period 2 elements. The $\mathrm{Ne}_{2}$ molecule has 16 valence electrons (8 from each atom). Placing
these electrons in the appropriate molecular orbitals produces the following diagram:

The bond order is $(8-8) / 2=0$, and $\mathrm{Ne}_{2}$ does not exist.
b. The $\mathrm{P}_{2}$ molecule contains phosphorus atoms from the third row of the periodic table. We will assume that the diatomic molecules of the Period 3 elements can be treated in a way very similar to that which we have used so far. Thus we will draw the MO diagram for $\mathrm{P}_{2}$ analogous to that for $\mathrm{N}_{2}$. The only change will be that the molecular orbitals will be formed from $3 s$ and $3 p$ atomic orbitals. The $P_{2}$ model has 10 valence electrons ( 5 from each phosphorus atom). The resulting molecular orbital diagram is

The molecule has a bond order of 3 and is expected to be diamagnetic.

### 9.4 Bonding in Heteronuclear Diatomic Molecules

In this section we will deal with selected examples of heteronuclear (different atoms)

FIGURE 9.41 The molecular orbital energy-level diagram for the NO molecule. We assume that orbital order is the same as that for $\mathrm{N}_{2}$. The bond order is 2.5 .
diatomic molecules. A special case involves molecules containing atoms adjacent to each other in the periodic table. Since the atoms involved in such a molecule are so similar, we can use the molecular orbital diagram for homonuclear molecules. For example, we can predict the bond order and magnetism of nitric oxide (NO) by placing its 11 valence electrons ( 5 from nitrogen and 6 from oxygen) in the molecular orbital energy-level diagram shown in Fig. 9.41. The molecule should be paramagnetic and has a bond order of

$$
\frac{8-3}{2}=2.5
$$

Experimentally, nitric oxide is indeed found to be paramagnetic. Notice that this oddelectron molecule is described very naturally by the MO model. In contrast, the localized electron model, in the simple form used in this text, cannot be used readily to treat such molecules.

## INTERACTIVE EXAMPLE 9.8 The Molecular Orbital Model III

SOLUTION

FIGURE 9.42 The molecular orbital energy-level diagram for both the $\mathrm{NO}^{+}$ and $\mathrm{CN}^{-}$ions.

FIGURE 9.43 A partial molecular orbital energy-level diagram for the HF molecule.

Use the molecular orbital model to predict the magnetism and bond order of the $\mathrm{NO}^{+}$ and $\mathrm{CN}^{-}$ions.

The $\mathrm{NO}^{+}$ion has 10 valence electrons $(5+6-1)$. The $\mathrm{CN}^{-}$ion also has 10 valence electrons $(4+5+1)$. Both ions are therefore diamagnetic and have a bond order derived from the equation

$$
\frac{8-2}{2}=3
$$

The molecular orbital diagram for these two ions is the same (Fig. 9.42).

## See Exercises 9.55 and 9.56

When the two atoms of a diatomic molecule are very different, the energy-level diagram for homonuclear molecules can no longer be used. A new diagram must be devised for each molecule. We will illustrate this case by considering the hydrogen fluoride (HF) molecule. The electron configurations of the hydrogen and fluorine atoms are $1 s^{1}$ and $1 s^{2} 2 s^{2} 2 p^{5}$, respectively. To keep things as simple as possible, we will assume that fluorine uses only one of its $2 p$ orbitals to bond to hydrogen. Thus the molecular orbitals for HF will be composed of fluorine $2 p$ and hydrogen $1 s$ orbitals. Figure 9.43 gives the partial molecular orbital energy-level diagram for HF, focusing only on the orbitals involved in the bonding. We are assuming that fluorine's other valence electrons remain localized on the fluorine. The $2 p$ orbital of fluorine is shown at a lower energy than the $1 s$ orbital of hydrogen on the diagram because fluorine binds its valence electrons more tightly. Thus the $2 p$ electron on a free fluorine atom is at lower energy than the $1 s$ electron on a free hydrogen atom. The diagram predicts that the HF molecule should be stable because both electrons are lowered in energy relative to their energy in the free hydrogen and fluorine atoms, which is the driving force for bond formation.

Because the fluorine $2 p$ orbital is lower in energy than the hydrogen $1 s$ orbital, the electrons prefer to be closer to the fluorine atom. That is, the $\sigma$ molecular orbital containing the bonding electron pair shows greater electron probability close to the fluorine (Fig. 9.44). The electron pair is not shared equally. This causes the fluorine atom to have a slight excess of negative charge and leaves the hydrogen atom partially positive. This is exactly the bond polarity observed for HF. Thus the molecular orbital model accounts in a straightforward way for the different electronegativities of hydrogen and fluorine and the resulting unequal charge distribution.

## 9.5

FIGURE 9.44 The electron probability distribution in the bonding molecular orbital of the HF molecule. Note the greater electron density close to the fluorine atom.

## Combining the Localized Electron and Molecular Orbital Models

One of the main difficulties with the localized electron model is its assumption that electrons are localized. This problem is most apparent with molecules for which several valid Lewis structures can be drawn. It is clear that none of these structures taken alone adequately describes the electronic structure of the molecule. The concept of resonance was invented to solve this problem. However, even with resonance included, the localized electron model does not describe molecules and ions such as $\mathrm{O}_{3}$ and $\mathrm{NO}_{3}{ }^{-}$in a very satisfying way.

It would seem that the ideal bonding model would be one with the simplicity of the localized electron model but with the delocalization characteristic of the molecular orbital model. We can achieve this by combining the two models to describe molecules that require resonance. Note that for species such as $\mathrm{O}_{3}$ and $\mathrm{NO}_{3}{ }^{-}$the double bond

## CHEMICAL CONNECTIONS

## What's Hot?

O
ne of the best things about New Mexico is the food. Authentic New Mexican cuisine uses liberal amounts of green and red chilies—often called chili peppers. Chilies apparently originated in parts of South America and were spread north by birds. When Columbus came to North America, which he originally thought was India, he observed the natives using chilies for spicing foods. When he took chilies back to Europe, Columbus mistakenly called them peppers and the name stuck.

The spicy payload of chilies is delivered mainly by the chemical capsaicin, which has the following structure:

Capsaicin was isolated as a pure substance by L. T. Thresh in 1846 . Since then substituted capsaicins have also been found in chilies. The spicy power of chilies derives mostly from capsaicin and dihydrocapsaicin.

The man best known for explaining the "heat" of chilies is Wilbur Scoville, who defined the Scoville unit for measuring chili power. He arbitrarily established the hotness of pure capsaicin as 16 million. On this scale a typical green or red chili has a rating of about 2500

Scoville units. You may have had an encounter with habanero chilies that left you looking for a firehose to put out the blaze in your mouth-habaneros have a Scoville rating of about 500,000!

Capsaicin has found many uses outside of cooking. It is used in pepper sprays and repellant sprays for many garden pests, although birds are unaffected by capsaicin. Capsaicin also stimulates the body's circulation and causes pain receptors to release endorphins, similar to the effect produced by intense exercise. Instead of jogging you may want to sit on the couch eating chilies. Either way you are going to sweat.

In molecules that require resonance, it is the $\pi$ bonding that is most clearly delocalized. decalized.

FIGURE 9.45 The resonance structures for $\mathrm{O}_{3}$ and $\mathrm{NO}_{3}{ }^{-}$. Note that it is the double bond that occupies various positions in the resonance structures.
changes position in the resonance structures (Fig. 9.45). Since a double bond involves one $\sigma$ and one $\pi$ bond, there is a $\sigma$ bond between all bound atoms in each resonance structure. It is really the $\pi$ bond that has different locations in the various resonance structures.

Therefore, we conclude that the $\sigma$ bonds in a molecule can be described as being localized with no apparent problems. It is the $\pi$ bonding that must be treated as being delocalized. Thus for molecules that require resonance, we will use the localized electron model to describe the $\sigma$ bonding and the molecular orbital model to describe the $\pi$ bonding. This allows us to keep the bonding model as simple as possible and yet give a more physically accurate description of such molecules.

We will illustrate the general method by considering the bonding in benzene, an important industrial chemical that must be handled carefully because it is a known carcinogen. The benzene molecule $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ consists of a planar hexagon of carbon atoms with one hydrogen atom bound to each carbon atom [Fig. 9.46(a)]. In the

FIGURE 9.46 (a) The benzene molecule consists of a ring of six carbon atoms with one hydrogen atom bound to each carbon; all atoms are in the same plane. All the C-C bonds are known to be equivalent. (b) Two of the resonance structures for the benzene molecule. The localized electron model must invoke resonance to account for the six equal C-C bonds.

-a

b
molecule all six $\mathrm{C}-\mathrm{C}$ bonds are known to be equivalent. To explain this fact, the localized electron model must invoke resonance [Fig. 9.46(b)].

A better description of the bonding in benzene results when we use a combination of the models, as described above. In this description it is assumed that the $\sigma$ bonds of carbon involve $s p^{2}$ orbitals (Fig. 9.47). These $\sigma$ bonds are all centered in the plane of the molecule.

Since each carbon atom is $s p^{2}$ hybridized, a $p$ orbital perpendicular to the plane of the ring remains on each carbon atom. These six $p$ orbitals can be used to form $\pi$ molecular orbitals [Fig. 9.48(a)]. The electrons in the resulting $\pi$ molecular orbitals are delocalized above and below the plane of the ring [Fig. 9.48(b)]. This gives six equivalent $\mathrm{C}-\mathrm{C}$ bonds, as required by the known structure of the benzene molecule. The benzene structure is often written as

to indicate the delocalized $\pi$ bonding in the molecule.
Very similar treatments can be applied to other planar molecules for which resonance is required by the localized electron model. For example, the $\mathrm{NO}_{3}{ }^{-}$ion can be described using the $\pi$ molecular orbital system shown in Fig. 9.49. In this molecule each atom is assumed to be $s p^{2}$ hybridized, which leaves one $p$ orbital on each atom perpendicular to the plane of the ion. These $p$ orbitals can combine to form the $\pi$ molecular orbital system.

FIGURE 9.47 The $\sigma$ bonding system in the benzene molecule.

FIGURE 9.48 (a) The $\pi$ molecular orbital system in benzene is formed by combining the six $p$ orbitals from the six $s p^{2}$ hybridized carbon atoms. (b) The electrons in the resulting $\pi$ molecular orbitals are delocalized over the entire ring of carbon atoms, giving six equivalent bonds. A composite of these orbitals is represented here.

FIGURE 9.49 (a) The $p$ orbitals used to form the $\pi$ bonding system in the $\mathrm{NO}_{3}{ }^{-}$ion. (b) A representation of the delocalization of the electrons in the $\pi$ molecular orbital system of the $\mathrm{NO}_{3}{ }^{-}$ ion.

## Two widely used bonding models

> Localized electron model
> Molecular orbital model

## Localized electron model

> Molecule is pictured as a group of atoms sharing electron pairs between atomic orbitals
> Hybrid orbitals, which are combinations of the "native" atomic orbitals, are often required to account for the molecular structure
) Six electron pairs (octahedral arrangement) require $d^{2} s p^{3}$ orbitals
, Five electron pairs (trigonal bipyramidal arrangement) require $d s p^{3}$ orbitals
> Four electron pairs (tetrahedral arrangement) require $s p^{3}$ orbitals
> Three electron pairs (trigonal planar arrangement) require $s p^{2}$ orbitals
> Two electron pairs (linear arrangement) require $s p$ orbitals

## Two types of bonds

> Sigma $(\sigma)$ : electrons are shared in the area centered on a line joining the atoms
> $\mathrm{Pi}(\pi)$ : a shared electron pair occupies the space above and below the line joining the atoms

## Molecular orbital model

> A molecule is assumed to be a new entity consisting of positively charged nuclei and electrons
) The electrons in the molecule are contained in molecular orbitals, which in the simplest form of the model are constructed from the atomic orbitals of the constituent atoms
> The model correctly predicts relative bond strength, magnetism, and bond polarity
> It correctly portrays electrons as being delocalized in polyatomic molecules
> The main disadvantage of the model is that it is difficult to apply qualitatively to polyatomic molecules

## Molecular orbitals are classified in two ways: energy and shape

## > Energy

) A bonding MO is lower in energy than the atomic orbitals from which it is constructed. Electrons in this type of MO are lower in energy in the molecule than in the separated atoms and thus favor molecule formation.
> An antibonding MO is higher in energy than the atomic orbitals from which it is constructed. Electrons in this type of MO are higher in energy in the molecule than in the separated atoms and thus do not favor molecule formation.
> Shape (symmetry)
> Sigma $(\sigma)$ MOs have their electron probability centered on a line passing through the nuclei
, $\operatorname{Pi}(\pi)$ MOs have their electron probability concentrated above and below the line connecting the nuclei

## Bond order is an index of bond strength <br> $$
\text { Bond order }=\frac{\text { number of bonding electrons }- \text { number of antibonding electrons }}{2}
$$ <br> Molecules that require the concept of resonance in the localized electron model can be more accurately described by combining the localized electron and molecular orbital models

> The $\sigma$ bonds are localized
) The $\pi$ bonds are delocalized

## Review Questions Answers to the Review Questions can be found on the Student website (accessible from wwww.cengagebrain.com)

1. Why do we hybridize atomic orbitals to explain the bonding in covalent compounds? What type of bonds form from hybrid orbitals, $\sigma$ or $\pi$ ? Explain.
2. What hybridization is required for central atoms that have a tetrahedral arrangement of electron pairs? A trigonal planar arrangement of electron pairs? A linear arrangement of electron pairs? How many unhybridized $p$ atomic orbitals are present when a central atom exhibits tetrahedral geometry? Trigonal planar geometry? Linear geometry? What are the unhybridized $p$ atomic orbitals used for?
3. Describe the bonding in $\mathrm{H}_{2} \mathrm{~S}, \mathrm{CH}_{4}, \mathrm{H}_{2} \mathrm{CO}$, and HCN using the localized electron model.
4. What hybridization is required for central atoms exhibiting trigonal bipyramidal geometry? Octahedral geometry? Describe the bonding of $\mathrm{PF}_{5}, \mathrm{SF}_{4}, \mathrm{SF}_{6}$, and $\mathrm{IF}_{5}$ using the localized electron model.
5. Electrons in $\sigma$ bonding molecular orbitals are most likely to be found in the region between the two bonded atoms. Why does this arrangement favor bonding? In a $\sigma$ antibonding orbital, where are the electrons most likely to be found in relation to the nuclei in a bond?
6. Show how $2 s$ orbitals combine to form $\sigma$ bonding and $\sigma$ antibonding molecular orbitals. Show how $2 p$ orbitals overlap to form $\sigma$ bonding, $\pi$ bonding, $\pi$ antibonding, and $\sigma$ antibonding molecular orbitals.
7. What are the relationships among bond order, bond energy, and bond length? Which of these can be measured? Distinguish between the terms paramagnetic and diamagnetic. What type of experiment can be done to determine if a material is paramagnetic?
8. How does molecular orbital theory explain the following observations?
a. $\mathrm{H}_{2}$ is stable, while $\mathrm{He}_{2}$ is unstable.
b. $\mathrm{B}_{2}$ and $\mathrm{O}_{2}$ are paramagnetic, while $\mathrm{C}_{2}, \mathrm{~N}_{2}$, and $\mathrm{F}_{2}$ are diamagnetic.
c. $\mathrm{N}_{2}$ has a very large bond energy associated with it.
d. $\mathrm{NO}^{+}$is more stable than $\mathrm{NO}^{-}$.
9. Consider the heteronuclear diatomic molecule HF. Explain in detail how molecular orbital theory is applied to describe the bonding in HF.
10. What is delocalized $\pi$ bonding, and what does it explain? Explain the delocalized $\pi$ bonding system in $\mathrm{C}_{6} \mathrm{H}_{6}$ (benzene) and $\mathrm{O}_{3}$ (ozone).

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. What are molecular orbitals? How do they compare with atomic orbitals? Can you tell by the shape of the bonding and antibonding orbitals which is lower in energy? Explain.
2. Explain the difference between the $\sigma$ and $\pi$ MOs for homonuclear diatomic molecules. How are bonding and antibonding orbitals different? Why are there two $\pi$ MOs and one $\sigma$ MO? Why are the $\pi$ MOs degenerate?
3. Compare Figs. 9.35 and 9.37 . Why are they different? Because $\mathrm{B}_{2}$ is known to be paramagnetic, the $\pi_{2 p}$ and $\sigma_{2 p}$ molecular orbitals must be switched from the first prediction. What is the rationale for this? Why might one expect the $\sigma_{2 p}$ to be lower in energy than the $\pi_{2 p}$ ? Why can't we use diatomic oxygen to help us decide whether the $\sigma_{2 p}$ or $\pi_{2 p}$ is lower in energy?
4. Which of the following would you expect to be more favorable energetically? Explain.
a. an $\mathrm{H}_{2}$ molecule in which enough energy is added to excite one electron from the bonding to the antibonding MO
b. two separate H atoms
5. Draw the Lewis structure for HCN . Indicate the hybrid orbitals, and draw a picture showing all the bonds between the atoms, labeling each bond as $\sigma$ or $\pi$.
6. Which is the more correct statement: "The methane molecule $\left(\mathrm{CH}_{4}\right)$ is a tetrahedral molecule because it is $s p^{3}$ hybridized" or "The methane molecule $\left(\mathrm{CH}_{4}\right)$ is $s p^{3}$ hybridized because it is a tetrahedral molecule"? What, if anything, is the difference between these two statements?
7. Compare and contrast the MO model with the LE model. When is each useful?
8. What are the relationships among bond order, bond energy, and bond length? Which of these quantities can be measured?
9. The molecules $\mathrm{N}_{2}$ and CO are isoelectronic but their properties are quite different. Although as a first approximation we often use the same MO diagram for both, suggest how the MOs in $\mathrm{N}_{2}$ and CO might be different.
10. Do lone pairs about a central atom affect the hybridization of the central atom? If so, how?

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

11. In the hybrid orbital model, compare and contrast $\sigma$ bonds with $\pi$ bonds. What orbitals form the $\sigma$ bonds and what orbitals form the $\pi$ bonds? Assume the $z$-axis is the internuclear axis.
12. In the molecular orbital model, compare and contrast $\sigma$ bonds with $\pi$ bonds. What orbitals form the $\sigma$ bonds and what orbitals form the $\pi$ bonds? Assume the $z$-axis is the internuclear axis.
13. Why are $d$ orbitals sometimes used to form hybrid orbitals? Which period of elements does not use $d$ orbitals for hybridization? If necessary, which $d$ orbitals ( $3 d, 4 d, 5 d$, or $6 d$ ) would sulfur use to form hybrid orbitals requiring $d$ atomic orbitals? Answer the same question for arsenic and for iodine.
14. The atoms in a single bond can rotate about the internuclear axis without breaking the bond. The atoms in a double and triple bond cannot rotate about the internuclear axis unless the bond is broken. Why?
15. The following illustration shows the orbitals used to form the bonds in carbon dioxide.

Each color represents a different orbital. Label each orbital, draw the Lewis structure for carbon dioxide, and explain how the localized electron model describes the bonding in $\mathrm{CO}_{2}$.
16. As compared with CO and $\mathrm{O}_{2}, \mathrm{CS}$ and $\mathrm{S}_{2}$ are very unstable molecules. Give an explanation based on the relative abilities of the sulfur and oxygen atoms to form $\pi$ bonds.
17. Compare and contrast bonding molecular orbitals with antibonding molecular orbitals.
18. What modification to the molecular orbital model was made from the experimental evidence that $B_{2}$ is paramagnetic?
19. Why does the molecular orbital model do a better job in explaining the bonding in $\mathrm{NO}^{-}$and NO than the hybrid orbital model?
20. The three NO bonds in $\mathrm{NO}_{3}{ }^{-}$are all equivalent in length and strength. How is this explained even though any valid Lewis structure for $\mathrm{NO}_{3}{ }^{-}$has one double bond and two single bonds to nitrogen?

## Exercises

## In this section similar exercises are paired.

## The Localized Electron Model and Hybrid Orbitals

21. Use the localized electron model to describe the bonding in $\mathrm{H}_{2} \mathrm{O}$.
22. Use the localized electron model to describe the bonding in $\mathrm{CCl}_{4}$.
23. Use the localized electron model to describe the bonding in $\mathrm{H}_{2} \mathrm{CO}$ (carbon is the central atom).
24. Use the localized electron model to describe the bonding in $\mathrm{C}_{2} \mathrm{H}_{2}$ (exists as HCCH ).
25. The space-filling models of ethane and ethanol are shown below.

|  | C |
| :---: | :---: |
| Ethane | C |
| $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ | Ethanol |
| $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ | $O$ |

Use the localized electron model to describe the bonding in ethane and ethanol.
26. The space-filling models of hydrogen cyanide and phosgene are shown below.

Use the localized electron model to describe the bonding in hydrogen cyanide and phosgene.
-27. Give the expected hybridization of the central atom for the molecules or ions in Exercises 87 and 93 from Chapter 8.
28. Give the expected hybridization of the central atom for the molecules or ions in Exercises 88 and 94 from Chapter 8.
29. Give the expected hybridization of the central atom for the molecules or ions in Exercise 91 from Chapter 8.
30. Give the expected hybridization of the central atom for the molecules in Exercise 92 from Chapter 8.
-31. Give the expected hybridization of the central atom for the molecules in Exercises 119 and 120 from Chapter 8.
32. Give the expected hybridization of the central atom for the molecules in Exercises 121 and 122 from Chapter 8.
-33. For each of the following molecules, write the Lewis structure(s), predict the molecular structure (including bond angles), give the expected hybrid orbitals on the central atom, and predict the overall polarity.
a. $\mathrm{CF}_{4}$
b. $\mathrm{NF}_{3}$
c. $\mathrm{OF}_{2}$
d. $\mathrm{BF}_{3}$
e. $\mathrm{BeH}_{2}$
f. $\mathrm{TeF}_{4}$
g. $\mathrm{AsF}_{5}$
h. $\mathrm{KrF}_{2}$
i. $\mathrm{KrF}_{4}$
j. $\mathrm{SeF}_{6}$
k. $\mathrm{IF}_{5}$
l. $\mathrm{IF}_{3}$
34. For each of the following molecules or ions that contain sulfur, write the Lewis structure(s), predict the molecular structure (including bond angles), and give the expected hybrid orbitals for sulfur.
a. $\mathrm{SO}_{2}$
b. $\mathrm{SO}_{3}$
c.

d.

e. $\mathrm{SO}_{3}{ }^{2-}$
f. $\mathrm{SO}_{4}{ }^{2-}$
g. $\mathrm{SF}_{2}$
h. $\mathrm{SF}_{4}$
i. $\mathrm{SF}_{6}$
j. $\mathrm{F}_{3} \mathrm{~S}-\mathrm{SF}$
k. $\mathrm{SF}_{5}{ }^{+}$
-35. Why must all six atoms in $\mathrm{C}_{2} \mathrm{H}_{4}$ lie in the same plane?
36. The allene molecule has the following Lewis structure:

Must all hydrogen atoms lie the same plane? If not, what is their spatial relationship? Explain.
-37. Indigo is the dye used in coloring blue jeans. The term navy blue is derived from the use of indigo to dye British naval uniforms in the eighteenth century. The structure of the indigo molecule is

a. How many $\sigma$ bonds and $\pi$ bonds exist in the molecule?
b. What hybrid orbitals are used by the carbon atoms in the indigo molecule?
38. Urea, a compound formed in the liver, is one of the ways humans excrete nitrogen. The Lewis structure for urea is

Using hybrid orbitals for carbon, nitrogen, and oxygen, determine which orbitals overlap to form the various bonds in urea.
-39. Biacetyl and acetoin are added to margarine to make it taste more like butter.

Biacetyl

Acetoin

Complete the Lewis structures, predict values for all $\mathrm{C}-\mathrm{C}-\mathrm{O}$ bond angles, and give the hybridization of the carbon atoms in these two compounds. Must the four carbon atoms and two oxygen atoms in biacetyl lie the same plane? How many $\sigma$ bonds and how many $\pi$ bonds are there in biacetyl and acetoin?
40. Many important compounds in the chemical industry are derivatives of ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$. Two of them are acrylonitrile and methyl methacrylate.

Acrylonitrile

Methyl methacrylate

Complete the Lewis structures, showing all lone pairs. Give approximate values for bond angles $a$ through $f$. Give the hybridization of all carbon atoms. In acrylonitrile, how many of the atoms in the molecule must lie in the same plane? How many $\sigma$ bonds and how many $\pi$ bonds are there in methyl methacrylate and acrylonitrile?
-41. Two molecules used in the polymer industry are azodicarbonamide and methyl cyanoacrylate. Their structures are

Azodicarbonamide

Methyl cyanoacrylate

Azodicarbonamide is used in forming polystyrene. When added to the molten plastic, it decomposes to nitrogen, carbon monoxide, and ammonia gases, which are captured as bubbles in the molten polymer. Methyl cyanoacrylate is the main ingredient in super glue. As the glue sets, methyl cyanoacrylate polymerizes across the carbon-carbon double bond. (See Chapter 22.)
a. Complete the Lewis structures showing all lone pairs of electrons.
b. Which hybrid orbitals are used by the carbon atoms in each molecule and the nitrogen atom in azodicarbonamide?
c. How many $\pi$ bonds are present in each molecule?
d. Give approximate values for the bond angles marked $a$ through $h$ in the above structures.
42. Hot and spicy foods contain molecules that stimulate paindetecting nerve endings. Two such molecules are piperine and capsaicin:

Piperine

Capsaicin

Piperine is the active compound in white and black pepper, and capsaicin is the active compound in chili peppers. The ring structures in piperine and capsaicin are shorthand notation. Each point where lines meet represents a carbon atom.
a. Complete the Lewis structure for piperine and capsaicin showing all lone pairs of electrons.
b. How many carbon atoms are $s p, s p^{2}$, and $s p^{3}$ hybridized in each molecule?
c. Which hybrid orbitals are used by the nitrogen atoms in each molecule?
d. Give approximate values for the bond angles marked $a$ through $l$ in the above structures.
-43. One of the first drugs to be approved for use in treatment of acquired immune deficiency syndrome (AIDS) was azidothymidine (AZT). Complete the Lewis structure for AZT.

a. How many carbon atoms are $s p^{3}$ hybridized?
b. How many carbon atoms are $s p^{2}$ hybridized?
c. Which atom is $s p$ hybridized?
d. How many $\sigma$ bonds are in the molecule?
e. How many $\pi$ bonds are in the molecule?
f. What is the $\mathrm{N}=\mathrm{N}=\mathrm{N}$ bond angle in the azide $\left(-\mathrm{N}_{3}\right)$ group?
g. What is the $\mathrm{H}-\mathrm{O}-\mathrm{C}$ bond angle in the side group attached to the five-membered ring?
h. What is the hybridization of the oxygen atom in the $-\mathrm{CH}_{2} \mathrm{OH}$ group?
44. Minoxidil $\left(\mathrm{C}_{9} \mathrm{H}_{15} \mathrm{~N}_{5} \mathrm{O}\right)$ is a compound produced by the Pharmacia \& Upjohn Company that has been approved as a treatment for some types of male pattern baldness.

Note that in such shorthand ring structures, each point where lines meet is a carbon atom and that the hydrogen atoms bonded to the carbon atoms in the rings have been omitted. There will be four bonds to each carbon atom.
a. Give the hybridization of the five nitrogen atoms in minoxidil.
b. Give the hybridization of each of the nine carbon atoms in minoxidil.
c. Give the approximate values for the bond angles marked $a, b, c, d, e$, and $f$.
d. Including all the hydrogen atoms, how many $\sigma$ bonds exist in minoxidil?
e. How many $\pi$ bonds exist in minoxidil?

## The Molecular Orbital Model

45. Consider the following molecular orbitals formed from the combination of two hydrogen $1 s$ orbitals:

a. Which is the bonding molecular orbital and which is the antibonding molecular orbital? Explain how you can tell by looking at their shapes.
b. Which of the two molecular orbitals is lower in energy? Why is this true?
46. Sketch the molecular orbital and label its type ( $\sigma$ or $\pi$; bonding or antibonding) that would be formed when the following atomic orbitals overlap. Explain your labels.
a.

b.

d.

-47. Which of the following are predicted by the molecular orbital model to be stable diatomic species?
a. $\mathrm{H}_{2}{ }^{+}, \mathrm{H}_{2}, \mathrm{H}_{2}^{-}, \mathrm{H}_{2}^{2-}$
b. $\mathrm{He}_{2}{ }^{2+}, \mathrm{He}_{2}{ }^{+}, \mathrm{He}_{2}$
47. Which of the following are predicted by the molecular orbital model to be stable diatomic species?
a. $\mathrm{N}_{2}{ }^{2-}, \mathrm{O}_{2}{ }^{2-}, \mathrm{F}_{2}{ }^{2-}$
b. $\mathrm{Be}_{2}, \mathrm{~B}_{2}, \mathrm{Ne}_{2}$
48. Using the molecular orbital model, write electron configurations for the following diatomic species and calculate the bond orders. Which ones are paramagnetic?
a. $\mathrm{Li}_{2}$
b. $\mathrm{C}_{2}$
c. $\mathrm{S}_{2}$
49. Consider the following electron configuration:

$$
\left(\sigma_{3 s}\right)^{2}\left(\sigma_{3 s}^{*}\right)^{2}\left(\sigma_{3 p}\right)^{2}\left(\pi_{3 p}\right)^{4}\left(\pi_{3 p} *\right)^{4}
$$

Give four species that, in theory, would have this electron configuration.
51. Which charge(s) for the $\mathrm{N}_{2}$ molecule would give a bond order of 2.5 ?
52. Using the molecular orbital model to describe the bonding in $\mathrm{F}_{2}{ }^{+}, \mathrm{F}_{2}$, and $\mathrm{F}_{2}^{-}$, predict the bond orders and the relative bond lengths for these three species. How many unpaired electrons are present in each species?
-53. Sodium can react with oxygen to form sodium peroxide $\left(\mathrm{Na}_{2} \mathrm{O}_{2}\right)$, which is composed of $\mathrm{Na}^{+}$and $\mathrm{O}_{2}{ }^{2-}$ ions. Potassium can react with oxygen to form potassium superoxide $\left(\mathrm{KO}_{2}\right)$, which is composed of $\mathrm{K}^{+}$and $\mathrm{O}_{2}{ }^{-}$ions. Does the peroxide ion or the superoxide ion have the shorter bond length? Explain.
54. A Lewis structure obeying the octet rule can be drawn for $\mathrm{O}_{2}$ as follows:

$$
: \dot{\mathrm{O}}=\dot{\mathrm{O}}
$$

Use the molecular orbital energy-level diagram for $\mathrm{O}_{2}$ to show that the above Lewis structure corresponds to an excited state.
-55. Using the molecular orbital model, write electron configurations for the following diatomic species and calculate the bond orders. Which ones are paramagnetic? Place the species in order of increasing bond length and bond energy.
a. CO
b. $\mathrm{CO}^{+}$
c. $\mathrm{CO}^{2+}$
56. Using the molecular orbital model, write electron configurations for the following diatomic species and calculate the bond orders. Which ones are paramagnetic? Place the species in order of increasing bond length and bond energy.
a. $\mathrm{CN}^{+}$
b. CN
c. $\mathrm{CN}^{-}$
-57. In which of the following diatomic molecules would the bond strength be expected to weaken as an electron is removed?
a. $\mathrm{H}_{2}$
b. $\mathrm{B}_{2}$
c. $\mathrm{C}_{2}{ }^{2-}$
d. OF
58. In terms of the molecular orbital model, which species in each of the following two pairs will most likely be the one to gain an electron? Explain.
a. CN or NO
b. $\mathrm{O}_{2}{ }^{2+}$ or $\mathrm{N}_{2}{ }^{2+}$
59. Show how two $2 p$ atomic orbitals can combine to form a $\sigma$ or a $\pi$ molecular orbital.
60. Show how a hydrogen $1 s$ atomic orbital and a fluorine $2 p$ atomic orbital overlap to form bonding and antibonding molecular orbitals in the hydrogen fluoride molecule. Are these molecular orbitals $\sigma$ or $\pi$ molecular orbitals?
61. Use Figs. 9.43 and 9.44 to answer the following questions.
a. Would the bonding molecular orbital in HF place greater electron density near the H or the F atom? Why?
b. Would the bonding molecular orbital have greater fluorine $2 p$ character, greater hydrogen $1 s$ character, or an equal contribution from both? Why?
c. Answer the previous two questions for the antibonding molecular orbital in HF.
62. The diatomic molecule OH exists in the gas phase. OH plays an important part in combustion reactions and is a reactive oxidizing agent in polluted air. The bond length and bond energy have been measured to be 97.06 pm and $424.7 \mathrm{~kJ} / \mathrm{mol}$, respectively. Assume that the OH molecule is analogous to the HF molecule discussed in the chapter and that the MOs result from the overlap of a $p_{z}$ orbital from oxygen and the $1 s$ orbital of hydrogen (the $\mathrm{O}-\mathrm{H}$ bond lies along the $z$ axis).
a. Draw pictures of the sigma bonding and antibonding molecular orbitals in OH .
b. Which of the two MOs has the greater hydrogen $1 s$ character?
c. Can the $2 p_{x}$ orbital of oxygen form MOs with the $1 s$ orbital of hydrogen? Explain.
d. Knowing that only the $2 p$ orbitals of oxygen interact significantly with the $1 s$ orbital of hydrogen, complete the MO energy-level diagram for OH. Place the correct number of electrons in the energy levels.
e. Estimate the bond order for OH .
f. Predict whether the bond order of $\mathrm{OH}^{+}$is greater than, less than, or the same as that of OH . Explain.
$\Gamma$ 63. Acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ can be produced from the reaction of calcium carbide $\left(\mathrm{CaC}_{2}\right)$ with water. Use both the localized electron and molecular orbital models to describe the bonding in the acetylide anion $\left(\mathrm{C}_{2}{ }^{2-}\right)$.
64. Describe the bonding in $\mathrm{NO}^{+}, \mathrm{NO}^{-}$, and NO using both the localized electron and molecular orbital models. Account for any discrepancies between the two models.
-65. Describe the bonding in the $\mathrm{O}_{3}$ molecule and the $\mathrm{NO}_{2}{ }^{-}$ion using the localized electron model. How would the molecular orbital model describe the $\pi$ bonding in these two species?
66. Describe the bonding in the $\mathrm{CO}_{3}{ }^{2-}$ ion using the localized electron model. How would the molecular orbital model describe the $\pi$ bonding in this species?

## Additional Exercises

67. Draw the Lewis structures, predict the molecular structures, and describe the bonding (in terms of the hybrid orbitals for the central atom) for the following.
a. $\mathrm{XeO}_{3}$
b. $\mathrm{XeO}_{4}$
c. $\mathrm{XeOF}_{4}$
d. $\mathrm{XeOF}_{2}$
e. $\mathrm{XeO}_{3} \mathrm{~F}_{2}$
68. The antibiotic thiarubin-A was discovered by studying the feeding habits of wild chimpanzees in Tanzania. The structure for thiarubin-A is

a. Complete the Lewis structure showing all lone pairs of electrons.
b. Indicate the hybrid orbitals used by the carbon and sulfur atoms in thiarubin-A.
c. How many $\sigma$ and $\pi$ bonds are present in this molecule?
69. Two structures can be drawn for cyanuric acid:

a. Are these two structures the same molecule? Explain.
b. Give the hybridization of the carbon and nitrogen atoms in each structure.
c. Use bond energies (Table 8.5) to predict which form is more stable; that is, which contains the strongest bonds?
70. Give the expected hybridization for the molecular structures illustrated below.
a.

b.

c.

71. Vitamin $B_{6}$ is an organic compound whose deficiency in the human body can cause apathy, irritability, and an increased susceptibility to infections. An incomplete Lewis structure for vitamin $\mathrm{B}_{6}$ is shown below. Complete the Lewis structure and answer the following questions. Hint: Vitamin $\mathrm{B}_{6}$ can be classified as an organic compound (a compound based on carbon atoms). The majority of Lewis structures for simple organic compounds have all atoms with a formal charge of zero. Therefore, add lone pairs and multiple bonds to the structure below to give each atom a formal charge of zero.

a. How many $\sigma$ bonds and $\pi$ bonds exist in vitamin $\mathrm{B}_{6}$ ?
b. Give approximate values for the bond angles marked $a$ through $g$ in the structure.
c. How many carbon atoms are $s p^{2}$ hybridized?
d. How many carbon, oxygen, and nitrogen atoms are $s p^{3}$ hybridized?
e. Does vitamin $B_{6}$ exhibit delocalized $\pi$ bonding? Explain.
72. Aspartame is an artificial sweetener marketed under the name NutraSweet. A partial Lewis structure for aspartame is shown below.

Aspartame can be classified as an organic compound (a compound based on carbon atoms). The majority of Lewis structures for simple organic compounds have all atoms with a formal charge of zero. Therefore, add lone pairs and multiple bonds to the structure above to give each atom a formal charge of zero when drawing the Lewis structure. Also note that the six-sided ring is shorthand notation for a benzene ring $\left(-\mathrm{C}_{6} \mathrm{H}_{5}\right)$. Benzene is discussed in Section 9.5. Complete the Lewis structure for aspartame. How many C and N atoms exhibit $s p^{2}$ hybridization? How many C and O atoms exhibit $s p^{3}$ hybridization? How many $\sigma$ and $\pi$ bonds are in aspartame?
73. Using bond energies from Table 8.5, estimate the barrier to rotation about a carbon-carbon double bond. To do this, consider what must happen to go from

to

in terms of making and breaking chemical bonds; that is, what must happen in terms of the $\pi$ bond?
74. The three most stable oxides of carbon are carbon monoxide $(\mathrm{CO})$, carbon dioxide $\left(\mathrm{CO}_{2}\right)$, and carbon suboxide $\left(\mathrm{C}_{3} \mathrm{O}_{2}\right)$. The space-filling models for these three compounds are

For each oxide, draw the Lewis structure, predict the molecular structure, and describe the bonding (in terms of the hybrid orbitals for the carbon atoms).
75. Complete the Lewis structures of the following molecules. Predict the molecular structure, polarity, bond angles, and hybrid orbitals used by the atoms marked by asterisks for each molecule.
a. $\mathrm{BH}_{3}$

b. $\mathrm{N}_{2} \mathrm{~F}_{2}$

$$
\mathrm{F}-\mathrm{N}^{*}-\mathrm{N}^{*}-\mathrm{F}
$$

c. $\mathrm{C}_{4} \mathrm{H}_{6}$

76. Complete the following resonance structures for $\mathrm{POCl}_{3}$.

a. Would you predict the same molecular structure from each resonance structure?
b. What is the hybridization of P in each structure?
c. What orbitals can the P atom use to form the $\pi$ bond in structure B?
d. Which resonance structure would be favored on the basis of formal charges?
77. The $\mathrm{N}_{2} \mathrm{O}$ molecule is linear and polar.
a. On the basis of this experimental evidence, which arrangement, NNO or NON, is correct? Explain your answer.
b. On the basis of your answer to part a, write the Lewis structure of $\mathrm{N}_{2} \mathrm{O}$ (including resonance forms). Give the formal charge on each atom and the hybridization of the central atom.
c. How would the multiple bonding in $: \mathrm{N} \equiv \mathrm{N}-\ddot{\mathrm{O}}:$ be described in terms of orbitals?
78. The transport of $\mathrm{O}_{2}$ in the blood is carried out by hemoglobin. Carbon monoxide (CO) can interfere with $\mathrm{O}_{2}$ transport because hemoglobin has a stronger affinity for CO than for $\mathrm{O}_{2}$. If CO is present, normal uptake of $\mathrm{O}_{2}$ is prevented, depriving the body of needed $\mathrm{O}_{2}$. Using the molecular orbital model, write the electron configurations for CO and for $\mathrm{O}_{2}$. From your configurations, give two property differences between CO and $\mathrm{O}_{2}$.
79. Using molecular orbital theory, explain why the removal of an electron from $\mathrm{O}_{2}$ strengthens bonding, whereas the removal of an electron from $\mathrm{N}_{2}$ weakens bonding.
80. Describe the bonding in the first excited state of $\mathrm{N}_{2}$ (the one closest in energy to the ground state) using the molecular orbital model. What differences do you expect in the properties of the molecule in the ground state as compared to the first excited state? (An excited state of a molecule corresponds to an electron arrangement other than that giving the lowest possible energy.)
81. Using an MO energy-level diagram, would you expect $\mathrm{F}_{2}$ to have a lower or higher first ionization energy than atomic fluorine? Why?
82. Show how a $d_{x z}$ atomic orbital and a $p_{z}$ atomic orbital combine to form a bonding molecular orbital. Assume the $x$-axis is the internuclear axis. Is a $\sigma$ or a $\pi$ molecular orbital formed? Explain.
83. What type of molecular orbital would result from the in-phase combination of two $d_{x z}$ atomic orbitals shown below? Assume the $x$-axis is the internuclear axis.

84. Consider three molecules: A, B, and C. Molecule A has a hybridization of $s p^{3}$. Molecule B has two more effective pairs (electron pairs around the central atom) than molecule A. Molecule C consists of two $\sigma$ bonds and two $\pi$ bonds. Give the molecular structure, hybridization, bond angles, and an example for each molecule.

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
85. Draw the Lewis structures for $\mathrm{SeO}_{2}, \mathrm{PCl}_{3}, \mathrm{NNO}, \mathrm{COS}$, and $\mathrm{PF}_{3}$. Which of the compounds are polar? Which of the compounds exhibit at least one bond angle that is approximately $120^{\circ}$ ? Which of the compounds exhibit $s p^{3}$ hybridization by the central atom? Which of the compounds have a linear molecular structure?
86. Draw the Lewis structures for $\mathrm{TeCl}_{4}, \mathrm{ICl}_{5}, \mathrm{PCl}_{5}, \mathrm{KrCl}_{4}$, and $\mathrm{XeCl}_{2}$. Which of the compounds exhibit at least one bond angle that is approximately $120^{\circ}$ ? Which of the compounds exhibit $d^{2} s p^{3}$ hybridization? Which of the compounds have a square planar molecular structure? Which of the compounds are polar?
87. A variety of chlorine oxide fluorides and related cations and anions are known. They tend to be powerful oxidizing and fluorinating agents. $\mathrm{FClO}_{3}$ is the most stable of this group of compounds and has been studied as an oxidizing component in rocket propellants. Draw a Lewis structure for $\mathrm{F}_{3} \mathrm{ClO}$, $\mathrm{F}_{2} \mathrm{ClO}_{2}{ }^{+}$, and $\mathrm{F}_{3} \mathrm{ClO}_{2}$. What is the molecular structure for each species, and what is the expected hybridization of the central chlorine atom in each compound or ion?
88. Pelargondin is the molecule responsible for the red color of the geranium flower. It also contributes to the color of ripe strawberries and raspberries. The structure of pelargondin is:

How many $\sigma$ and $\pi$ bonds exist in pelargondin? What is the hybridization of the carbon atoms marked 1-4?
89. Complete a Lewis structure for the compound shown below, then answer the following questions. How many carbon atoms are $s p^{2}$ hybridized? How many $\mathrm{C}-\mathrm{N}$ bonds are formed by the overlap of an $s p^{3}$ hybridized carbon with an $s p^{3}$ hybridized nitrogen? How many lone pairs of electrons are in the Lewis structure of your molecule? How many $\pi$ bonds are present?

90. Which of the following statements concerning $\mathrm{SO}_{2}$ is(are) true?
a. The central sulfur atom is $s p^{2}$ hybridized.
b. One of the sulfur-oxygen bonds is longer than the other(s).
c. The bond angles about the central sulfur atom are about $120^{\circ}$.
d. There are two $\sigma$ bonds in $\mathrm{SO}_{2}$.
e. There are no resonance structures for $\mathrm{SO}_{2}$.
91. Consider the molecular orbital electron configurations for $\mathrm{N}_{2}$, $\mathrm{N}_{2}{ }^{+}$, and $\mathrm{N}_{2}{ }^{-}$. For each compound or ion, fill in the table below with the correct number of electrons in each molecular orbital.

92. Place the species $\mathrm{B}_{2}{ }^{+}, \mathrm{B}_{2}$, and $\mathrm{B}_{2}{ }^{-}$in order of increasing bond length and increasing bond energy.

## Challenge Problems

93. Consider the following computer-generated model of caffeine:

Complete a Lewis structure for caffeine in which all atoms have a formal charge of zero (as is typical with most organic compounds). How many central C and N atoms exhibit approximate $120^{\circ}$ bond angles? How many C and N atoms are $s p^{3}$ hybridized? $s p$ hybridized? How many $\sigma$ and $\pi$ bonds are there?
94. Cholesterol $\left(\mathrm{C}_{27} \mathrm{H}_{46} \mathrm{O}\right)$ has the following structure:

In such shorthand structures, each point where lines meet represents a carbon atom and most H atoms are not shown. Draw the complete structure showing all carbon and hydrogen atoms. (There will be four bonds to each carbon atom.) Indicate which carbon atoms use $s p^{2}$ or $s p^{3}$ hybrid orbitals.
95. Cyanamide ( $\mathrm{H}_{2} \mathrm{NCN}$ ), an important industrial chemical, is produced by the following steps:

$$
\begin{gathered}
\mathrm{CaC}_{2}+\mathrm{N}_{2} \longrightarrow \mathrm{CaNCN}+\mathrm{C} \\
\mathrm{CaNCN} \xrightarrow{\text { Acid }} \mathrm{H}_{2} \mathrm{NCN}
\end{gathered}
$$

Calcium cyanamide (CaNCN) is used as a direct-application fertilizer, weed killer, and cotton defoliant. It is also used to make cyanamide, dicyandiamide, and melamine plastics:

a. Write Lewis structures for $\mathrm{NCN}^{2-}, \mathrm{H}_{2} \mathrm{NCN}$, dicyandiamide, and melamine, including resonance structures where appropriate.
b. Give the hybridization of the C and N atoms in each species.
c. How many $\sigma$ bonds and how many $\pi$ bonds are in each species?
d. Is the ring in melamine planar?
e. There are three different $\mathrm{C}-\mathrm{N}$ bond distances in dicyandiamide, $\mathrm{NCNC}\left(\mathrm{NH}_{2}\right)_{2}$, and the molecule is nonlinear. Of all the resonance structures you drew for this molecule, predict which should be the most important.
96. In Exercise 95 in Chapter 8, the Lewis structures for benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ were drawn. Using one of the Lewis structures, estimate $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{C}_{6} \mathrm{H}_{6}(\mathrm{~g})$ using bond energies and given that the standard enthalpy of formation of $\mathrm{C}(g)$ is $717 \mathrm{~kJ} / \mathrm{mol}$. The experimental $\Delta H_{\mathrm{f}}^{\mathrm{o}}$ value of $\mathrm{C}_{6} \mathrm{H}_{6}(\mathrm{~g})$ is $83 \mathrm{~kJ} / \mathrm{mol}$. Explain the discrepancy between the experimental value and the calculated $\Delta H_{\mathrm{f}}^{\circ}$ value for $\mathrm{C}_{6} \mathrm{H}_{6}(\mathrm{~g})$.
97. A flask containing gaseous $\mathrm{N}_{2}$ is irradiated with $25-\mathrm{nm}$ light.
a. Using the following information, indicate what species can form in the flask during irradiation.

$$
\begin{array}{ll}
\mathrm{N}_{2}(g) \longrightarrow 2 \mathrm{~N}(g) & \Delta H=941 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{~N}_{2}(g) \longrightarrow \mathrm{N}_{2}^{+}(g)+\mathrm{e}^{-} & \Delta H=1501 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{~N}(g) \longrightarrow \mathrm{N}^{+}(g)+\mathrm{e}^{-} & \Delta H=1402 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

b. What range of wavelengths will produce atomic nitrogen in the flask but will not produce any ions?
c. Explain why the first ionization energy of $\mathrm{N}_{2}(1501 \mathrm{~kJ} /$ mol) is greater than the first ionization energy of atomic nitrogen ( $1402 \mathrm{~kJ} / \mathrm{mol}$ ).
98. The oxyanion of nitrogen in which it has the highest oxidation state is the nitrate ion $\left(\mathrm{NO}_{3}^{-}\right)$. The corresponding oxyanion of phosphorus is $\mathrm{PO}_{4}{ }^{3-}$. The $\mathrm{NO}_{4}{ }^{3-}$ ion is known but is not very stable. The $\mathrm{PO}_{3}{ }^{-}$ion is not known. Account for these differences in terms of the bonding in the four anions.
99. Values of measured bond energies may vary greatly depending on the molecule studied. Consider the following reactions:

$$
\begin{array}{ll}
\mathrm{NCl}_{3}(g) \longrightarrow \mathrm{NCl}_{2}(g)+\mathrm{Cl}(g) & \Delta H=375 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{ONCl}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{Cl}(g) & \Delta H=158 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

Rationalize the difference in the values of $\Delta H$ for these reactions, even though each reaction appears to involve only the breaking of one $\mathrm{N}-\mathrm{Cl}$ bond. (Hint: Consider the bond order of the NO bond in ONCl and in NO.)
100. Use the MO model to explain the bonding in $\mathrm{BeH}_{2}$. When constructing the MO energy-level diagram, assume that the Be's $1 s$ electrons are not involved in bond formation.
101. Bond energy has been defined in the text as the amount of energy required to break a chemical bond, so we have come to think of the addition of energy as breaking bonds. However, in some cases the addition of energy can cause the formation of bonds. For example, in a sample of helium gas subjected to a high-energy source, some $\mathrm{He}_{2}$ molecules exist momentarily and then dissociate. Use MO theory (and diagrams) to explain why $\mathrm{He}_{2}$ molecules can come to exist and why they dissociate.
102. Arrange the following from lowest to highest ionization energy: $\mathrm{O}, \mathrm{O}_{2}, \mathrm{O}_{2}{ }^{-}, \mathrm{O}_{2}{ }^{+}$. Explain your answer.
103. Use the MO model to determine which of the following has the smallest ionization energy: $\mathrm{N}_{2}, \mathrm{O}_{2}, \mathrm{~N}_{2}{ }^{2-}, \mathrm{N}_{2}{ }^{-}, \mathrm{O}_{2}{ }^{+}$. Explain your answer.
104. Given that the ionization energy of $\mathrm{F}_{2}{ }^{-}$is $290 \mathrm{~kJ} / \mathrm{mol}$, do the following:
a. Calculate the bond energy of $\mathrm{F}_{2}{ }^{-}$. You will need to look up the bond energy of $\mathrm{F}_{2}$ and ionization energy of $\mathrm{F}^{-}$.
b. Explain the difference in bond energy between $\mathrm{F}_{2}{ }^{-}$and $\mathrm{F}_{2}$ using MO theory.
105. Carbon monoxide (CO) forms bonds to a variety of metals and metal ions. Its ability to bond to iron in hemoglobin is the reason that CO is so toxic. The bond carbon monoxide forms to metals is through the carbon atom:

$$
\mathrm{M}-\mathrm{C} \equiv \mathrm{O}
$$

a. On the basis of electronegativities, would you expect the carbon atom or the oxygen atom to form bonds to metals?
b. Assign formal charges to the atoms in CO. Which atom would you expect to bond to a metal on this basis?
c. In the MO model, bonding MOs place more electron density near the more electronegative atom. (See the HF molecule in Figs. 9.43 and 9.44.) Antibonding MOs place more electron density near the less electronegative atom in the diatomic molecule. Use the MO model to predict which atom of carbon monoxide should form bonds to metals.
106. The space-filling model for benzoic acid, a food preservative, is shown below.

Benzoic acid
$\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2} \mathrm{H}\right)$
Describe the bonding in benzoic acid using the localized electron model combined with the molecular orbital model.

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
107. As the head engineer of your starship in charge of the warp drive, you notice that the supply of dilithium is critically low. While searching for a replacement fuel, you discover some diboron, $\mathrm{B}_{2}$.
a. What is the bond order in $\mathrm{Li}_{2}$ and $\mathrm{B}_{2}$ ?
b. How many electrons must be removed from $B_{2}$ to make it isoelectronic with $\mathrm{Li}_{2}$ so that it might be used in the warp drive?
c. The reaction to make $\mathrm{B}_{2}$ isoelectronic with $\mathrm{Li}_{2}$ is generalized (where $n=$ number of electrons determined in part b) as follows:

$$
\mathrm{B}_{2} \longrightarrow \mathrm{~B}_{2}{ }^{n+}+n \mathrm{e}^{-} \quad \Delta H=6455 \mathrm{~kJ} / \mathrm{mol}
$$

How much energy is needed to ionize $1.5 \mathrm{~kg} \mathrm{~B}_{2}$ to the desired isoelectronic species?
108. An unusual category of acids known as superacids, which are defined as any acid stronger than $100 \%$ sulfuric acid, can be prepared by seemingly simple reactions similar to the one below. In this example, the reaction of anhydrous HF with $\mathrm{SbF}_{5}$ produces the superacid $\left[\mathrm{H}_{2} \mathrm{~F}\right]^{+}\left[\mathrm{SbF}_{6}\right]^{-}$:

$$
2 \mathrm{HF}(l)+\mathrm{SbF}_{5}(l) \longrightarrow\left[\mathrm{H}_{2} \mathrm{~F}\right]^{+}\left[\mathrm{SbF}_{6}\right]^{-}(l)
$$

a. What are the molecular structures of all species in this reaction? What are the hybridizations of the central atoms in each species?
b. What mass of $\left[\mathrm{H}_{2} \mathrm{~F}\right]^{+}\left[\mathrm{SbF}_{6}\right]^{-}$can be prepared when 2.93 mL anhydrous HF (density $=0.975 \mathrm{~g} / \mathrm{mL}$ ) and $10.0 \mathrm{~mL} \mathrm{SbF}_{5}($ density $=3.10 \mathrm{~g} / \mathrm{mL})$ are allowed to react?
109. Determine the molecular structure and hybridization of the central atom X in the polyatomic ion $\mathrm{XY}_{3}{ }^{+}$given the following information: A neutral atom of X contains 36 electrons, and the element Y makes an anion with a 1 - charge, which has the electron configuration $1 s^{2} 2 s^{2} 2 p^{6}$.
110. Although nitrogen trifluoride $\left(\mathrm{NF}_{3}\right)$ is a thermally stable compound, nitrogen triiodide $\left(\mathrm{NI}_{3}\right)$ is known to be a highly explosive material. $\mathrm{NI}_{3}$ can be synthesized according to the equation

$$
\mathrm{BN}(s)+3 \mathrm{IF}(g) \longrightarrow \mathrm{BF}_{3}(g)+\mathrm{NI}_{3}(g)
$$

a. What is the enthalpy of formation for $\mathrm{NI}_{3}(s)$ given the enthalpy of reaction $(-307 \mathrm{~kJ})$ and the enthalpies of formation for $\mathrm{BN}(s)(-254 \mathrm{~kJ} / \mathrm{mol}), \operatorname{IF}(g)(-96 \mathrm{~kJ} / \mathrm{mol})$, and $\mathrm{BF}_{3}(\mathrm{~g})(-1136 \mathrm{~kJ} / \mathrm{mol})$ ?
b. It is reported that when the synthesis of $\mathrm{NI}_{3}$ is conducted using 4 moles of IF for every 1 mole of BN , one of the by-products isolated is $\left[\mathrm{IF}_{2}\right]^{+}\left[\mathrm{BF}_{4}\right]^{-}$. What are the molecular geometries of the species in this by-product? What are the hybridizations of the central atoms in each species in the by-product?

Huge crystals of calcium sulfate in The Cave of the Crystals in Mexico. (Carsten Peter/Speleoresearch Films/National Geographic Stock)

The Difference Between Real and Ideal Gases

TABLE 10.1 | Densities of the Three States of Water

| State | Density <br> $\left(\mathrm{g} / \mathrm{cm}^{3}\right)$ |
| :---: | :---: |
| Solid $\left(0^{\circ} \mathrm{C}, 1 \mathrm{~atm}\right)$ | 0.9168 |
| Liquid $\left(25^{\circ} \mathrm{C}, 1 \mathrm{~atm}\right)$ | 0.9971 |
| Gas $\left(400^{\circ} \mathrm{C}, 1 \mathrm{~atm}\right)$ | $3.26 \times 10^{-4}$ |

FIGURE 10.1 Schematic representations of the three states of matter.

You have only to think about water to appreciate how different the three states of matter are. Flying, swimming, and ice skating are all done in contact with water in its various forms. Clearly, the arrangements of the water molecules must be significantly different in its gas, liquid, and solid forms.

In Chapter 5 we saw that a gas can be pictured as a substance whose component particles are far apart, are in rapid random motion, and exert relatively small forces on each other. The kinetic molecular model was constructed to account for the ideal behavior that most gases approach at high temperatures and low pressures.

Solids are obviously very different from gases. A gas has low density and high compressibility and completely fills its container. Solids have much greater densities, are compressible only to a very slight extent, and are rigid-a solid maintains its shape irrespective of its container. These properties indicate that the components of a solid are close together and exert large attractive forces on each other.

The properties of liquids lie somewhere between those of solids and gases but not midway between, as can be seen from some of the properties of the three states of water. For example, compare the enthalpy change for the melting of ice at $0^{\circ} \mathrm{C}$ (the heat of fusion) with that for vaporizing liquid water at $100^{\circ} \mathrm{C}$ (the heat of vaporization):

$$
\begin{array}{ll}
\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) & \Delta H_{\text {fus }}^{\circ}=6.02 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g) & \Delta H^{\circ}{ }_{\text {vap }}=40.7 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

These values show a much greater change in structure in going from the liquid to the gaseous state than in going from the solid to the liquid state. This suggests that there are extensive attractive forces among the molecules in liquid water, similar to but not as strong as those in the solid state.

The relative similarity of the liquid and solid states also can be seen in the densities of the three states of water. As shown in Table 10.1, the densities for liquid and solid water are quite close.* Compressibilities also can be used to explore the relationship among water's states. At $25^{\circ} \mathrm{C}$, the density of liquid water changes from $0.9971 \mathrm{~g} / \mathrm{cm}^{3}$ at a pressure of 1 atm to $1.046 \mathrm{~g} / \mathrm{cm}^{3}$ at 1065 atm . Given the large change in pressure, this is a very small variation in the density. Ice also shows little variation in density with increased pressure. On the other hand, at $400^{\circ} \mathrm{C}$, the density of gaseous water changes from $3.26 \times 10^{-4} \mathrm{~g} / \mathrm{cm}^{3}$ at 1 atm pressure to $0.157 \mathrm{~g} / \mathrm{cm}^{3}$ at 242 atm -a huge variation.

The conclusion is clear. The liquid and solid states show many similarities and are strikingly different from the gaseous state, as shown schematically in Fig. 10.1. We must bear this in mind as we develop models for the structures of solids and liquids.

We will proceed in our study of liquids and solids by first considering the properties and structures of liquids and solids. Then we will consider the changes in state that occur between solid and liquid, liquid and gas, and solid and gas.
*Although the densities of solid and liquid water are quite similar, as is typical for most substances, water is quite unusual in that the density of its solid state is slightly less than that of its liquid state. For most substances, the density of the solid state is slightly greater than that of the liquid state.

Intermolecular forces were introduced in Chapter 5 to explain nonideal gas behavior.

Remember that temperature is a measure of the random motions of the particles in a substance.

Dipole-dipole forces are forces that act between polar molecules.

-a

Attraction---------
Repulsion -=- =- =- =-
-b
FIGURE 10.2 (a) The electrostatic interaction of two polar molecules.
(b) The interaction of many dipoles in a condensed state.

In Chapters 8 and 9 we saw that atoms can form stable units called molecules by sharing electrons. This is called intramolecular (within the molecule) bonding. In this chapter we consider the properties of the condensed states of matter (liquids and solids) and the forces that cause the aggregation of the components of a substance to form a liquid or a solid. These forces may involve covalent or ionic bonding, or they may involve weaker interactions usually called intermolecular forces (because they occur between, rather than within, molecules).

It is important to recognize that when a substance such as water changes from solid to liquid to gas, the molecules remain intact. The changes in states are due to changes in the forces among the molecules rather than in those within the molecules. In ice, as we will see later in this chapter, the molecules are virtually locked in place, although they can vibrate about their positions. If energy is added, the motions of the molecules increase, and they eventually achieve the greater movement and disorder characteristic of liquid water. The ice has melted. As more energy is added, the gaseous state is eventually reached, with the individual molecules far apart and interacting relatively little. However, the gas still consists of water molecules. It would take much energy to overcome the covalent bonds and decompose the water molecules into their component atoms. This can be seen by comparing the energy needed to vaporize 1 mole of liquid water ( 40.7 kJ ) with that needed to break the $\mathrm{O}-\mathrm{H}$ bonds in 1 mole of water molecules ( 934 kJ ).

## Dipole-Dipole Forces

As we saw in Section 8.3, molecules with polar bonds often behave in an electric field as if they had a center of positive charge and a center of negative charge. That is, they exhibit a dipole moment. Molecules with dipole moments can attract each other electrostatically by lining up so that the positive and negative ends are close to each other [Fig. 10.2(a)]. This is called a dipole-dipole attraction. In a condensed state such as a liquid, where many molecules are in close proximity, the dipoles find the best compromise between attraction and repulsion. That is, the molecules orient themselves to maximize the $\oplus---\ominus$ interactions and to minimize $\oplus---\oplus$ and $\Theta---\ominus$ interactions [Fig. 10.2(b)].

Dipole-dipole forces are typically only about $1 \%$ as strong as covalent or ionic bonds, and they rapidly become weaker as the distance between the dipoles increases. At low pressures in the gas phase, where the molecules are far apart, these forces are relatively unimportant.

Particularly strong dipole-dipole forces, however, are seen among molecules in which hydrogen is bound to a highly electronegative atom, such as nitrogen, oxygen, or fluorine. Two factors account for the strengths of these interactions: the great polarity of the bond and the close approach of the dipoles, allowed by the very small size of the hydrogen atom. Because dipole-dipole attractions of this type are so unusually strong, they are given a special name-hydrogen bonding. Figure 10.3 shows hydrogen bonding among water molecules, which occurs between the partially positive H atoms and the lone pairs on adjacent water molecules.

Hydrogen bonding has a very important effect on physical properties. For example, the boiling points for the covalent hydrides of the elements in Groups 4A, 5A, 6A, and 7A are given in Fig. 10.4. Note that the nonpolar tetrahedral hydrides of Group 4A show a steady increase in boiling point with molar mass (that is, in going down the group), whereas, for the other groups, the lightest member has an unexpectedly high boiling point. Why? The answer lies in the especially large hydrogen bonding interactions that exist among the smallest molecules with the most polar $\mathrm{X}-\mathrm{H}$ bonds. These unusually strong hydrogen bonding forces are due primarily to two factors. One factor

FIGURE 10.3 (a) The polar water molecule. (b) Hydrogen bonding ( $\circ \cdot \circ$ ) among water molecules. Note that the small size of the hydrogen atom allows for close interactions.

It is customary to show intermolecular interactions using dashes or dots and covalent bonds using solid lines.

Boiling point will be defined precisely in Section 10.8.

FIGURE 10.4 The boiling points of the covalent hydrides of the elements in Groups 4A, 5A, 6A, and 7A. The dashed line shows the expected boiling point of water if it had no hydrogen bonding.

is the relatively large electronegativity values of the lightest elements in each group, which leads to especially polar X-H bonds. The second factor is the small size of the first element of each group, which allows for the close approach of the dipoles, further strengthening the intermolecular forces. Because the interactions among the molecules containing the lightest elements in Groups 5A and 6A are so strong, an unusually large quantity of energy must be supplied to overcome these interactions and separate the molecules to produce the gaseous state. These molecules will remain together in the liquid state even at high temperatures-hence the very high boiling points.

Hydrogen bonding is also important in organic molecules (molecules with a carbon chain backbone). For example, the alcohols methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ and ethanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)$ have much higher boiling points than would be expected from their molar masses because of the polar $\mathrm{O}-\mathrm{H}$ bonds in these molecules, which produce hydrogen bonding.

TABLE 10.2 | The Freezing Points of the Group 8A Elements

| Element | Freering Point <br> ( |
| :--- | :--- |
| Helium* | -269.7 |
| Neon | -248.6 |
| Argon | -189.4 |
| Krypton | -157.3 |
| Xenon | -111.9 |

*Helium is the only element that will not freeze by lowering its temperature at 1 atm. Pressure must be applied to freeze helium.

## London Dispersion Forces

Even molecules without dipole moments must exert forces on each other. We know this because all substances-even the noble gases-exist in the liquid and solid states under certain conditions. The forces that exist among noble gas atoms and nonpolar molecules are called London dispersion forces. To understand the origin of these forces, let's consider a pair of noble gas atoms. Although we usually assume that the electrons of an atom are uniformly distributed about the nucleus, this is apparently not true at every instant. As the electrons move about the nucleus, a momentary nonsymmetrical electron distribution can develop that produces a temporary dipolar arrangement of charge. The formation of this temporary dipole can, in turn, affect the electron distribution of a neighboring atom. That is, this instantaneous dipole that occurs accidentally in a given atom can then induce a similar dipole in a neighboring atom [Fig. 10.5(a)]. This phenomenon leads to an interatomic attraction that is relatively weak and short-lived but that can be very significant especially for large atoms (see below). For these interactions to become strong enough to produce a solid, the motions of the atoms must be greatly slowed down. This explains, for instance, why the noble gas elements have such low freezing points (Table 10.2).

Note from Table 10.2 that the freezing point rises going down the group. The principal cause for this trend is that as the atomic number increases, the number of electrons increases, and there is an increased chance of the occurrence of momentary dipole interactions. We describe this phenomenon using the term polarizability, which indicates the ease with which the electron "cloud" of an atom can be distorted to give a dipolar charge distribution. Thus we say that large atoms with many electrons exhibit a higher polarizability than small atoms. This means that the importance of London dispersion forces increases greatly as the number of electrons in the atom increases.

These same ideas also apply to nonpolar molecules such as $\mathrm{H}_{2}, \mathrm{CH}_{4}, \mathrm{CCl}_{4}$, and $\mathrm{CO}_{2}$ [Fig. 10.5(b)]. Since none of these molecules has a permanent dipole moment, their principal means of attracting each other is through London dispersion forces.

The dispersion forces in molecules with large atoms are quite significant and are often actually more important than dipole-dipole forces.

FIGURE 10.5 (a) An instantaneous polarization can occur on atom A , creating an instantaneous dipole. This dipole creates an induced dipole on neighboring atom B. (b) Nonpolar molecules such as $\mathrm{H}_{2}$ also can develop instantaneous and induced dipoles.

Although we usually think of dipole-dipole forces (DDF) as being very strong, sometimes London dispersion forces (LDF) can dominate for molecules with many electrons. An example of this situation is shown in Table 10.3 for the substances $\mathrm{BI}_{3}, \mathrm{PCl}_{3}$, and $\mathrm{NH}_{3}$. Note that $\mathrm{BI}_{3}$ has the highest boiling point because of the very strong London dispersion forces that occur among these large molecules. Also note that $\mathrm{PCl}_{3}$, which has both London dispersion forces and dipole-dipole forces, has a higher boiling point than $\mathrm{NH}_{3}$, which has very strong dipole-dipole (hydrogen bonding) forces and very weak London dispersion forces.

## TABLE 10.3 | Comparing Intermolecular Forces

| Molecule | Structure | Intermolecular <br> Forces | Boiling Point <br> $\left({ }^{\circ} \mathrm{C}\right)$ |
| :---: | :--- | :--- | :---: |
| $\mathrm{BI}_{3}$ | Trigonal planar | LDF | 209.5 |
| $\mathrm{PCl}_{3}$ | Pyramidal | LDF, DDF | 76.1 |
| $\mathrm{NH}_{3}$ | Pyramidal | LDF, DDF | -33.0 |

DDF, dipole-dipole forces; LDF, London dispersion forces.

## Distinguishing Between Chemical and Physical Changes at the Molecular Level

In Chapter 1 we defined physical and chemical changes mostly from a macroscopic perspective. A physical change was noted as a change in the form of the substance, but not in its chemical composition. A chemical change was defined as a change of substances into other substances with different properties and different composition. We can now look at these changes at the molecular level. Determining whether a process comes about because of disruption of intramolecular forces (chemical bonds) or intermolecular forces allows us to distinguish between chemical and physical changes.

A typical example of a physical change is a phase change, such as the boiling of water. In this process, energy as heat is transferred to liquid water and the intermolecular forces (hydrogen bonding in this case) are overcome, resulting in the formation of water vapor. We represent the equation for this process as:

$$
\mathrm{H}_{2} \mathrm{O}(l) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

Notice that the molecules do not change; that is, at the beginning and end of the physical change the chemical composition, $\mathrm{H}_{2} \mathrm{O}$, is the same. However, the molecules are held together by hydrogen bonding in the liquid but not in the vapor. Molecular level pictures of this process are shown below:

Ice

Water

Steam

So the change of water from the liquid to the gaseous phase is a physical process, because the $\mathrm{H}_{2} \mathrm{O}$ molecules remain intact during the process. If a process results by breaking and/or forming chemical bonds (or intramolecular forces), the process is a chemical change. For example, consider the combustion of methane $\left(\mathrm{CH}_{4}\right)$ to form carbon dioxide and water. The balanced equation is

$$
\mathrm{CH}_{4}+2 \mathrm{O}_{2} \rightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}
$$

For this reaction to occur, the chemical bonds between carbon and hydrogen in methane and between the oxygen atoms in diatomic oxygen must be broken, and chemical bonds between the carbon and oxygen in carbon dioxide and hydrogen and oxygen in water must be formed. Molecular level pictures of this process are shown below:

The distinction between physical and chemical changes is not always as clear as in the previous examples. For example, consider dissolving table salt, $\mathrm{NaCl}(s)$, in water. We can make an argument that this is a physical change by considering the equation for the process:

$$
\mathrm{NaCl}(s) \rightarrow \mathrm{NaCl}(a q)
$$

This equation is similar to the equation for the boiling of water in that the formula for the reactant and product is the same while only the form changes. It would appear, then, that the process of an ionic solid dissolving is a physical change. However, this conclusion is not as obvious if we look at a molecular view of the process, shown in Fig. 10.6.

For NaCl to go into solution, the ionic bonds holding the $\mathrm{Na}^{-}$and $\mathrm{Cl}^{-}$together must be broken. In addition, interactions are formed between the ions and the water molecules. The strength of these forces (especially the ionic bonds) can be similar to the strengths of covalent chemical bonds. From this perspective, we could argue that this process is a chemical change.

Thus, a molecular-level perspective can help us distinguish between chemical and physical changes by considering whether intramolecular or intermolecular forces are disrupted. However, we need to be careful to not oversimplify the issue, because some processes fall in a gray area between a purely chemical change and a purely physical change.

## Forces Between Polar and Nonpolar Molecules

Earlier in this chapter we discussed intermolecular forces between polar molecules (dipole-dipole interactions) and intermolecular forces between nonpolar molecules (London dispersion forces; these forces exist between polar molecules as well but are not as strong as the dipole-dipole interactions). While we have discussed the attraction between polar molecules and the attraction between nonpolar molecules, polar molecules and nonpolar molecules exhibit an attraction for one another as well. Recall that a nonpolar molecule can form an instantaneous dipole that can induce a similar dipole in a neighboring molecule. Similarly, a permanent dipole on a polar molecule can induce a dipole on a neighboring nonpolar molecule. This is termed a dipole-induced dipole interaction. The strength of this interaction depends on the natures of both the polar molecule and the nonpolar molecule. The larger the magnitude of the dipole in a polar molecule, the better able it is to induce a dipole in a neighboring molecule. Just as we discussed with London dispersion forces, nonpolar molecules with a greater number of electrons have an increased polarizability, therefore increasing the ease with which a dipole is induced.

탸ITICA․ ThINKINC You have learned the difference between intermolecular forces and intramolecular bonds. What if intermolecular forces were stronger than intramolecular bonds? What differences could you observe in the world?

### 10.2 The Liquid State

FIGURE 10.7 A molecule in the interior of a liquid is attracted by the molecules surrounding it, whereas a molecule at the surface of a liquid is attracted only by molecules below it and on each side. Remember that the molecules in a liquid are in constant motion.

For a given volume, a sphere has a smaller surface area than any other shape.

Surface tension: the resistance of a liquid to an increase in its surface area.

The composition of glass is discussed in Section 10.5.

Liquids and liquid solutions are vital to our lives. Of course, water is the most important liquid. Besides being essential to life, water provides a medium for food preparation, for transportation, for cooling in many types of machines and industrial processes, for recreation, for cleaning, and for a myriad of other uses.

Liquids exhibit many characteristics that help us understand their nature. We have already mentioned their low compressibility, lack of rigidity, and high density compared with gases. Many of the properties of liquids give us direct information about the forces that exist among the particles. For example, when a liquid is poured onto a solid surface, it tends to bead as droplets, a phenomenon that depends on the intermolecular forces. Although molecules in the interior of the liquid are completely surrounded by other molecules, those at the liquid surface are subject to attractions only from the side and from below (Fig. 10.7). The effect of this uneven pull on the surface molecules tends to draw them into the body of the liquid and causes a droplet of liquid to assume the shape that has the minimum surface area-a sphere.

To increase a liquid's surface area, molecules must move from the interior of the liquid to the surface. This requires energy, since some intermolecular forces must be overcome. The resistance of a liquid to an increase in its surface area is called the surface tension of the liquid. As we would expect, liquids with relatively large intermolecular forces, such as those with polar molecules, tend to have relatively high surface tensions.

Polar liquids typically exhibit capillary action, the spontaneous rising of a liquid in a narrow tube. Two different types of forces are responsible for this property: cohesive forces, the intermolecular forces among the molecules of the liquid, and adhesive forces, the forces between the liquid molecules and their container. We have already seen how cohesive forces operate among polar molecules. Adhesive forces occur when a container is made of a substance that has polar bonds. For example, a glass surface contains many oxygen atoms with partial negative charges that are attractive to the

FIGURE 10.8 Polar water forms a concave meniscus in a glass tube, whereas nonpolar liquid mercury forms a convex meniscus.

Viscosity: a measure of a liquid's resistance to flow.

positive end of a polar molecule such as water. This ability of water to "wet" glass makes it creep up the walls of the tube where the water surface touches the glass. This, however, tends to increase the surface area of the water, which is opposed by the cohesive forces that try to minimize the surface. Thus because water has both strong cohesive (intermolecular) forces and strong adhesive forces to glass, it "pulls itself" up a glass capillary tube (a tube with a small diameter) to a height where the weight of the column of water just balances the water's tendency to be attracted to the glass surface. The concave shape of the meniscus (Fig. 10.8) shows that water's adhesive forces toward the glass are stronger than its cohesive forces. A nonpolar liquid such as mercury (see Fig. 10.8) shows a convex meniscus. This behavior is characteristic of a liquid in which the cohesive forces are stronger than the adhesive forces toward glass.

Another property of liquids strongly dependent on intermolecular forces is viscosity, a measure of a liquid's resistance to flow. As might be expected, liquids with large intermolecular forces tend to be highly viscous. For example, glycerol, whose structure is

has an unusually high viscosity due mainly to its high capacity to form hydrogen bonds using its $\mathrm{O}-\mathrm{H}$ groups (see margin).

Molecular complexity also leads to higher viscosity because very large molecules can become entangled with each other. For example, gasoline, a nonviscous liquid, contains hydrocarbon molecules of the type $\mathrm{CH}_{3}-\left(\mathrm{CH}_{2}\right)_{n}-\mathrm{CH}_{3}$, where $n$ varies from about 3 to 8 . However, grease, which is very viscous, contains much larger hydrocarbon molecules in which $n$ varies from 20 to 25 .

## Structural Model for Liquids

In many respects, the development of a structural model for liquids presents greater challenges than the development of such a model for the other two states of matter. In the gaseous state, the particles are so far apart and are moving so rapidly that intermolecular forces are negligible under most circumstances. This means that we can use a relatively simple model for gases. In the solid state, although the intermolecular forces are large, the molecular motions are minimal, and fairly simple models are again possible. The liquid state, however, has both strong intermolecular forces and significant molecular motions. Such a situation precludes the use of really simple models for

## CHEMICAL CONNECTIDNS

## Smart Fluids

Matter seems to be getting smarter these days. Increasingly, we have discovered materials that can remember their initial shape after being deformed or can sense and respond to their environment. In particular, valuable new materials have been formulated whose properties can be changed instantly by applying a magnetic or electric field.

One example of such a substance is a fluid whose flow characteristics (rheology) can be changed from free flowing to almost solid in about 0.01 second by the application of an electromagnetic field. This "magnetorheological" (MR) fluid was developed by Lord Corporation. Working in

Magnetic field off Magnetic particles flow randomly
collaboration with Delphi Corporation, the company is applying the fluid in suspension control of General Motors automobiles such as Cadillacs and Corvettes. The so-called Magneride system has sensors that monitor the road surface and provide information about what suspension damping is needed. In response, a message is instantly sent to an electromagnetic

This Corvette ZR1 uses magnetorheological fluid in its suspension system.

Magnetic field on
Applied field ( $H$ ) creates structure that increases viscosity
coil in the shock absorbers, which adjusts the viscosity of the MR fluid to provide continuously variable damping. The result: an amazingly smooth ride and unerring road-holding ability.

The MR fluid is composed of a synthetic oil in which particles of an ironcontaining compound are suspended. When the magnetic field is turned off, these particles flow freely in all directions (see the figure above). When the field is turned on, the particles aggregate into chains that line up perpendicular to the flow of the fluid, thereby increasing its viscosity in proportion to the strength of the applied field.

Many other applications of MR fluids besides auto suspensions are under development. One very large-scale application is in Japan's National Museum of Emerging Science and Innovation, where an MR fluid is being used in dampers to protect the building against earthquake damage. Large MR-fluid dampers are also being used for stabilizing bridges such as the Dong Ting Lake Bridge in China's Hunan province to steady it in high winds.
liquids. Recent advances in spectroscopy, the study of the manner in which substances interact with electromagnetic radiation, make it possible to follow the very rapid changes that occur in liquids. As a result, our models of liquids are becoming more accurate. As a starting point, a typical liquid might best be viewed as containing a large number of regions where the arrangements of the components are similar to those found in the solid, but with more disorder, and a smaller number of regions where holes are present. The situation is highly dynamic, with rapid fluctuations occurring in both types of regions.

### 10.3 An Introduction to Structures and Types of Solids

There are many ways to classify solids, but the broadest categories are crystalline solids, those with a highly regular arrangement of their components, and amorphous solids, those with considerable disorder in their structures.

The regular arrangement of the components of a crystalline solid at the microscopic level produces the beautiful, characteristic shapes of crystals, such as those shown in Fig. 10.9. The positions of the components in a crystalline solid are usually represented by a lattice, a three-dimensional system of points designating the positions of the components (atoms, ions, or molecules) that make up the substance. The smallest repeating unit of the lattice is called the unit cell. Thus a particular lattice can be generated by repeating the unit cell in all three dimensions to form the extended structure. Three common unit cells and their lattices are shown in Fig. 10.10. Note from Fig. 10.10 that the extended structure in each case can be viewed as a series of repeating unit cells that share common faces in the interior of the solid.

Although we will concentrate on crystalline solids in this book, there are many important noncrystalline (amorphous) materials. An example is common glass, which is best pictured as a solution in which the components are "frozen in place" before they can achieve an ordered arrangement. Although glass is a solid (it has a rigid shape), a great deal of disorder exists in its structure.

## X-Ray Analysis of Solids

The structures of crystalline solids are most commonly determined by X-ray diffraction. Diffraction occurs when beams of light are scattered from a regular array of points in which the spacings between the components are comparable with the wavelength of the light. Diffraction is due to constructive interference when the waves of parallel beams are in phase and to destructive interference when the waves are out of phase.

When X rays of a single wavelength are directed at a crystal, a diffraction pattern is obtained, as we saw in Fig. 7.6. The light and dark areas on the photographic plate occur because the waves scattered from various atoms may reinforce or cancel each other (Fig. 10.11). The key to whether the waves reinforce or cancel is the difference in distance traveled by the waves after they strike the atoms. The waves are in phase before they are reflected, so if the difference in distance traveled is an integral number of wavelengths, the waves will still be in phase.

Since the distance traveled depends on the distance between the atoms, the diffraction pattern can be used to determine the interatomic spacings. The exact relationship can be worked out using the diagram in Fig. 10.12, which shows two in-phase waves being reflected by atoms in two different layers in a crystal. The extra distance traveled

FIGURE 10.9 Crystals of iron pyrite.

by the lower wave is the sum of the distances $x y$ and $y z$, and the waves will be in phase after reflection if

$$
\begin{equation*}
x y+y z=n \lambda \tag{10.1}
\end{equation*}
$$

where $n$ is an integer and $\lambda$ is the wavelength of the $X$ rays. Using trigonometry (see Fig. 10.12), we can show that

$$
\begin{equation*}
x y+y z=2 d \sin \theta \tag{10.2}
\end{equation*}
$$

where $d$ is the distance between the atoms and $\theta$ is the angle of incidence and reflection. Combining Equation (10.1) and Equation (10.2) gives

$$
\begin{equation*}
n \lambda=2 d \sin \theta \tag{10.3}
\end{equation*}
$$

a
FIGURE 10.11 X rays scattered from two different atoms may reinforce (constructive interference) or cancel (destructive interference) one another. (a) Both the incident rays and the reflected rays are also in phase. In this case, $d_{1}$ is such that the difference in the distances traveled by the two rays is a whole number of wavelengths. (b) The incident rays are in phase but the reflected rays are exactly out of phase. In this case $d_{2}$ is such that the difference in distances traveled by the two rays is an odd number of half wavelengths.

$\Delta$
Student operating an X-ray diffractometer at Colgate University.

Equation (10.3) is called the Bragg equation after William Henry Bragg (1862-1942) and his son William Lawrence Bragg (1890-1972), who shared the Nobel Prize in physics in 1915 for their pioneering work in X-ray crystallography.

A diffractometer is a computer-controlled instrument used for carrying out the X-ray analysis of crystals. It rotates the crystal with respect to the X-ray beam and collects the data produced by the scattering of the X rays from the various planes of atoms in the crystal. The results are then analyzed by computer.

The techniques for crystal structure analysis have reached a level of sophistication that allows the determination of very complex structures, such as those important in biological systems. For example, the structures of several enzymes have been determined, thus enabling biochemists to understand how they perform their functions. We will explore this topic further in Chapter 12. Using X-ray diffraction, we can gather data on bond lengths and angles and in so doing can test the predictions of our models of molecular geometry.

FIGURE 10.12 Reflection of $X$ rays of wavelength $\lambda$ from a pair of atoms in two different layers of a crystal. The lower wave travels an extra distance equal to the sum of $x y$ and $y z$. If this distance is an integral number of wavelengths ( $n=1,2,3, \ldots$ ), the waves will reinforce each other when they exit the crystal.

## INTERACTIVE EXAMPLE 10.1

## Using the Bragg Equation

X rays of wavelength $1.54 \AA$ were used to analyze an aluminum crystal. A reflection was produced at $\theta=19.3$ degrees. Assuming $n=1$, calculate the distance $d$ between the planes of atoms producing this reflection.

## SOLUTION

Buckminsterfullerene, $C_{60}$, is a particular member of the fullerene family.

The internal forces in a solid determine the properties of the solid.

To determine the distance between the planes, we use Equation (10.3) with $n=1$, $\lambda=1.54 \AA$, and $\theta=19.3$ degrees. Since $2 d \sin \theta=n \lambda$,

$$
d=\frac{n \lambda}{2 \sin \theta}=\frac{(1)(1.54 \AA)}{(2)(0.3305)}=2.33 \AA=233 \mathrm{pm}
$$

## See Exercises 10.49 through 10.52

## Types of Crystalline Solids

There are many different types of crystalline solids. For example, although both sugar and salt dissolve readily in water, the properties of the resulting solutions are quite different. The salt solution readily conducts an electric current, whereas the sugar solution does not. This behavior arises from the nature of the components in these two solids. Common salt $(\mathrm{NaCl})$ is an ionic solid; it contains $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions. When solid sodium chloride dissolves in the polar water, sodium and chloride ions are distributed throughout the resulting solution and are free to conduct electric current. Table sugar (sucrose), on the other hand, is composed of neutral molecules that are dispersed throughout the water when the solid dissolves. No ions are present, and the resulting solution does not conduct electricity. These examples illustrate two important types of solids: ionic solids, represented by sodium chloride, and molecular solids, represented by sucrose. Ionic solids have ions at the points of the lattice that describes the structure of the solid. A molecular solid, on the other hand, has discrete covalently bonded molecules at each of its lattice points. Ice is a molecular solid that has an $\mathrm{H}_{2} \mathrm{O}$ molecule at each point (Fig. 10.13).

A third type of solid is represented by elements such as carbon (which exists in the forms graphite, diamond, and the fullerenes), boron, silicon, and all metals. These substances all have atoms at the lattice points that describe the structure of the solid. Therefore, we call solids of this type atomic solids. Examples of these three types of solids are shown in Fig. 10.13.

To summarize, we find it convenient to classify solids according to what type of component occupies the lattice points. This leads to the classifications atomic solids (atoms at the lattice points), molecular solids (discrete, relatively small molecules at the lattice points), and ionic solids (ions at the lattice points). In addition, atomic solids are placed into the following subgroups based on the bonding that exists among the atoms in the solid: metallic solids, network solids, and Group $8 A$ solids. In metallic solids, a special type of delocalized nondirectional covalent bonding occurs. In network solids, the atoms bond to each other with strong directional covalent bonds that lead to giant molecules, or networks, of atoms. In the Group 8A solids, the noble gas elements are attracted to each other with London dispersion forces. The classification of solids is summarized in Table 10.4.

The markedly different bonding present in the various atomic solids leads to dramatically different properties for the resulting solids. For example, although argon,

## TABLE 10.4 | Classification of Solids

|  | Atomic Solids |  |  | Molecular Solids | Ionic Solids |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Metallic | Network | Group 8A |  |  |
| Components That Occupy the Lattice Points | Metal atoms | Nonmetal atoms | Group 8A atoms | Discrete molecules | Ions |
| Bonding | Delocalized covalent | Directional covalent (leading to giant molecules) | London dispersion forces | Dipole-dipole and/or London dispersion forces | Ionic |

FIGURE 10.13 Examples of three types of crystalline solids. Only part of the structure is shown in each case. (a) An atomic solid. (b) An ionic solid. (c) A molecular solid. The dotted lines show the hydrogen bonding interactions among the polar water molecules.
copper, and diamond all are atomic solids, they have strikingly different properties. Argon (a Group 8A solid) has a very low melting point $\left(-189^{\circ} \mathrm{C}\right)$, whereas diamond (a network solid) and copper (a metallic solid) melt at high temperatures (about 3500 and $1083^{\circ} \mathrm{C}$, respectively). Copper is an excellent conductor of electricity, whereas argon and diamond are both insulators. Copper can be easily changed in shape; it is both malleable (can be formed into thin sheets) and ductile (can be pulled into a wire). Diamond, on the other hand, is the hardest natural substance known. We will explore the structure and bonding of atomic solids in the next two sections.

### 10.4 Structure and Bonding in Metals

Metals are characterized by high thermal and electrical conductivity, malleability, and ductility. As we will see, these properties can be traced to the nondirectional covalent bonding found in metallic crystals.

A metallic crystal can be pictured as containing spherical atoms packed together and bonded to each other equally in all directions. We can model such a structure by packing uniform, hard spheres in a manner that most efficiently uses the available space. Such an arrangement is called closest packing. The spheres are packed in layers (Fig. 10.14), in which each sphere is surrounded by six others. In the second layer, the spheres do not lie directly over those in the first layer. Instead, each one occupies an indentation (or dimple) formed by three spheres in the first layer. In the

The closest packing model for metallic crystals assumes that metal atoms are uniform, hard spheres.

FIGURE 10.14 The closest packing arrangement of uniform spheres. In each layer a given sphere is surrounded by six others, creating six dimples, only three of which can be occupied in the next layer. (a) aba packing: The second layer is like the first, but it is displaced so that each sphere in the second layer occupies a dimple in the first layer. The spheres in the third layer occupy dimples in the second layer so that the spheres in the third layer lie directly over those in the first layer ( $a b a$ ). (b) abc packing: The spheres in the third layer occupy dimples in the second layer so that no spheres in the third layer lie above any in the first layer ( $a b c$ ). The fourth layer is like the first.

FIGURE 10.15 When spheres are closest packed so that the spheres in the third layer are directly over those in the first layer ( $a b a$ ), the unit cell is the hexagonal prism illustrated here in red.

-b
third layer, the spheres can occupy the dimples of the second layer in two possible ways: They can occupy positions so that each sphere in the third layer lies directly over a sphere in the first layer [the $a b a$ arrangement; Fig. 10.14(a)], or they can occupy positions so that no sphere in the third layer lies over one in the first layer [the $a b c$ arrangement; Fig. 10.14(b)].

The $a b a$ arrangement has the hexagonal unit cell shown in Fig. 10.15, and the resulting structure is called the hexagonal closest packed (hcp) structure. The $a b c$ arrangement has a face-centered cubic unit cell (Fig. 10.16), and the resulting structure is called the cubic closest packed (ccp) structure. Note that in the hcp structure the spheres in every other layer occupy the same vertical position (ababab • . ), whereas in the ccp structure the spheres in every fourth layer occupy the same vertical position $(a b c a b c a \cdots)$. A characteristic of both structures is that each sphere has 12 equivalent nearest neighbors: 6 in the same layer, 3 in the layer above, and 3 in the layer below (that form the dimples). This is illustrated for the hep structure in Fig. 10.17.

Knowing the net number of spheres (atoms) in a particular unit cell is important for many applications involving solids. To illustrate how to find the net number of spheres in a unit cell, we will consider a face-centered cubic unit cell (Fig. 10.18). Note that this unit first layer.

FIGURE 10.16 When spheres are packed in the $a b c$ arrangement, the unit cell is face-centered cubic. To make the cubic arrangement easier to see, the vertical axis has been tilted as shown.

FIGURE 10.17 The indicated sphere has 12 nearest neighbors.

FIGURE 10.18 The net number of spheres in a face-centered cubic unit cell. (a) Note that the sphere on a corner of the colored cell is shared with 7 other unit cells (a total of 8). Thus $\frac{1}{8}$ of such a sphere lies within a given unit cell. Since there are 8 corners in a cube, there are 8 of these $\frac{1}{8}$ pieces, or 1 net sphere. (b) The sphere on the center of each face is shared by 2 unit cells, and thus each unit cell has $\frac{1}{2}$ of each of these types of spheres. There are 6 of these $\frac{1}{2}$ spheres to give 3 net spheres. (c) Thus the face-centered cubic unit cell contains 4 net spheres (all of the pieces can be assembled to give 4 spheres).
cell is defined by the centers of the spheres on the cube's corners. Thus 8 cubes share a given sphere, so $\frac{1}{8}$ of this sphere lies inside each unit cell. Since a cube has 8 corners, there are $8 \times \frac{1}{8}$ pieces, or enough to put together 1 whole sphere. The spheres at the center of each face are shared by 2 unit cells, so $\frac{1}{2}$ of each lies inside a particular unit cell. Since the cube has 6 faces, we have $6 \times \frac{1}{2}$ pieces, or enough to construct 3 whole spheres. Thus the net number of spheres in a face-centered cubic unit cell is

$$
\left(8 \times \frac{1}{8}\right)+\left(6 \times \frac{1}{2}\right)=4
$$

## INTERACTIVE EXAMPLE 10.2 Calculating the Density of a Closest Packed Solid

Silver crystallizes in a cubic closest packed structure. The radius of a silver atom is 144 pm . Calculate the density of solid silver.

SOLUTION Density is mass per unit volume. Thus we need to know how many silver atoms occupy a given volume in the crystal. The structure is cubic closest packed, which means the unit cell is face-centered cubic, as shown in the accompanying figure.

Crystalline silver contains cubic closest packed silver atoms.

[^16]Ductile: can be drawn to form a wire.

We must find the volume of this unit cell for silver and the net number of atoms it contains. Note that in this structure the atoms touch along the diagonals for each face and not along the edges of the cube. Thus the length of the diagonal is $r+2 r+r$, or $4 r$. We use this fact to find the length of the edge of the cube by the Pythagorean theorem:

$$
\begin{aligned}
d^{2}+d^{2} & =(4 r)^{2} \\
2 d^{2} & =16 r^{2} \\
d^{2} & =8 r^{2} \\
d & =\sqrt{8 r^{2}}=r \sqrt{8}
\end{aligned}
$$

Since $r=144 \mathrm{pm}$ for a silver atom,

$$
d=(144 \mathrm{pm})(\sqrt{8})=407 \mathrm{pm}
$$

The volume of the unit cell is $d^{3}$, which is $(407 \mathrm{pm})^{3}$, or $6.74 \times 10^{7} \mathrm{pm}^{3}$. We convert this to cubic centimeters as follows:

$$
6.74 \times 10^{7} \mathrm{pm}^{3} \times\left(\frac{1.00 \times 10^{-10} \mathrm{~cm}}{\mathrm{pm}}\right)^{3}=6.74 \times 10^{-23} \mathrm{~cm}^{3}
$$

Since we know that the net number of atoms in the face-centered cubic unit cell is 4 , we have 4 silver atoms contained in a volume of $6.74 \times 10^{-23} \mathrm{~cm}^{3}$. The density is therefore

$$
\begin{aligned}
\text { Density } & =\frac{\text { mass }}{\text { volume }}=\frac{(4 \text { atoms })(107.9 \mathrm{~g} / \mathrm{mol})\left(1 \mathrm{~mol} / 6.022 \times 10^{23} \text { atoms }\right)}{6.74 \times 10^{-23} \mathrm{~cm}^{3}} \\
& =10.6 \mathrm{~g} / \mathrm{cm}^{3}
\end{aligned}
$$

See Exercises 10.53 through 10.55

Examples of metals that form cubic closest packed solids are aluminum, iron, copper, cobalt, and nickel. Magnesium and zinc are hexagonal closest packed. Calcium and certain other metals can crystallize in either of these structures. Some metals, however, assume structures that are not closest packed. For example, the alkali metals have structures characterized by a body-centered cubic (bcc) unit cell (see Fig. 10.10), where the spheres touch along the body diagonal of the cube. In this structure, each sphere has 8 nearest neighbors (count the number of atoms around the atom at the center of the unit cell), as compared with 12 in the closest packed structures. Why a particular metal adopts the structure it does is not well understood.

## Bonding Models for Metals

Any successful bonding model for metals must account for the typical physical properties of metals: malleability, ductility, and the efficient and uniform conduction of heat and electricity in all directions. Although the shapes of most pure metals can be changed relatively easily, most metals are durable and have high melting points. These facts indicate that the bonding in most metals is both strong and nondirectional. That is, although it is difficult to separate metal atoms, it is relatively easy to move them, provided the atoms stay in contact with each other.

The simplest picture that explains these observations is the electron sea model, which envisions a regular array of metal cations in a "sea" of valence electrons (Fig. 10.19). The mobile electrons can conduct heat and electricity, and the metal ions can be easily moved around as the metal is hammered into a sheet or pulled into a wire.

FIGURE 10.19 The electron sea model for metals postulates a regular array of cations in a "sea" of valence electrons. (a) Representation of an alkali metal (Group 1A) with one valence electron. (b) Representation of an alkaline earth metal (Group 2A) with two valence electrons.

## Number of interacting atomic orbitals

## 

FIGURE 10.20 The molecular orbital energy levels produced when various numbers of atomic orbitals interact. Note that for two atomic orbitals two rather widely spaced energy levels result. (Recall the description of $\mathrm{H}_{2}$ in Section 9.2.) As more atomic orbitals are available to form molecular orbitals, the resulting energy levels are more closely spaced, finally producing a band of very closely spaced orbitals.

A related model that gives a more detailed view of the electron energies and motions is the band model, or molecular orbital (MO) model, for metals. In this model, the electrons are assumed to travel around the metal crystal in molecular orbitals formed from the valence atomic orbitals of the metal atoms (Fig. 10.20).

Recall that in the MO model for the gaseous $\mathrm{Li}_{2}$ molecule (Section 9.3), two widely spaced molecular orbital energy levels (bonding and antibonding) result when two identical atomic orbitals interact. However, when many metal atoms interact, as in a metal crystal, the large number of resulting molecular orbitals become more closely spaced and finally form a virtual continuum of levels, called bands (see Fig. 10.20).

As an illustration, picture a magnesium metal crystal, which has an hcp structure. Since each magnesium atom has one $3 s$ and three $3 p$ valence atomic orbitals, a crystal with $n$ magnesium atoms has available $n(3 s)$ and $3 n(3 p)$ orbitals to form the molecular orbitals (Fig. 10.21). Note that the core electrons are localized, as shown by their presence in the energy "well" around each magnesium atom. However, the valence electrons occupy closely spaced molecular orbitals, which are only partially filled.

The existence of empty molecular orbitals close in energy to filled molecular orbitals explains the thermal and electrical conductivity of metal crystals. Metals conduct electricity and heat very efficiently because of the availability of highly mobile electrons. For example, when an electric potential is placed across a strip of metal, for current to flow, electrons must be free to move. In the band model for metals, the electrons in partially filled bonds are mobile. These conduction electrons are free to travel throughout the metal crystal as dictated by the potential imposed on the metal. The molecular orbitals occupied by these conducting electrons are called conduction bands. These mobile electrons also account for the efficiency of the conduction of heat through metals. When one end of a metal rod is heated, the mobile electrons can rapidly transmit the thermal energy to the other end.

## Metal Alloys

Because of the nature of the structure and bonding of metals, other elements can be introduced into a metallic crystal relatively easily to produce substances called alloys. An alloy is best defined as a substance that contains a mixture of elements and has metallic properties. Alloys can be conveniently classified into two types.

In a substitutional alloy some of the host metal atoms are replaced by other metal atoms of similar size. For example, in brass, approximately one-third of the atoms in the host copper metal have been replaced by zinc atoms [Fig. 10.22(a)]. Sterling silver ( $93 \%$ silver and $7 \%$ copper), pewter ( $85 \%$ tin, $7 \%$ copper, $6 \%$ bismuth, and $2 \%$ antimony), and plumber's solder ( $95 \%$ tin and $5 \%$ antimony) are other examples of substitutional alloys.

## CHEMICAL CDNNECTIDNS

## Closest Packing of M \& Ms

AIthough we usually think of scientists as dealing with esoteric and often toxic materials, sometimes they surprise us. For example, scientists at several prestigious universities have lately shown a lot of interest in M \& M candies.

To appreciate the scientists' interest in M \& Ms, we must consider the importance of packing atoms, molecules, or microcrystals in understanding the structures of solids. The most efficient use of space is the closest packing of uniform spheres, where $74 \%$ of the space is occupied by the spheres and $26 \%$ of space is left unoccupied. Although the structures of most pure metals can be explained in terms of closest packing, most other substances-such as many alloys and ceramics-consist of random arrays of microscopic particles. For this reason, it is of interest to study how such objects pack in a random way.

When uniform spheres, such as marbles, are poured into a large container, the resulting random packing of the spheres results in only $64 \%$ of the space being occupied by the spheres. Thus it was very surprising when Princeton University chemist Salvatore Torquato and his colleagues at Cornell and North Carolina Central Universities discovered that, when the ellipsoidalshaped $M \& M s$ are poured into a large container, the candies occupy $73.5 \%$ of the available space. In other words, the randomly packed M \& Ms occupy space with almost the same efficiency as closest packed spheres do.

Why do randomly packed ellipsoids occupy space so much more efficiently than randomly packed spheres? The scientists speculate that because the ellipsoids can tip and rotate in ways that spheres cannot, they can pack more closely to their neighbors.

According to Torquato, these results are important because they will help us
better understand the properties of disordered materials ranging from powders to glassy solids. He also says that $M$ \& Ms make ideal test objects because they are inexpensive and uniform and "you can eat the experiment afterward."

FIGURE 10.21 (left) A representation of the energy levels (bands) in a magnesium crystal. The electrons in the $1 s, 2 s$, and $2 p$ orbitals are close to the nuclei and thus are localized on each magnesium atom as shown. However, the $3 s$ and $3 p$ valence orbitals overlap and mix to form molecular orbitals. Electrons in these energy levels can travel throughout the crystal. (right) Crystals of magnesium grown from a vapor.

Brass

Steel
FIGURE 10.22 Two types of alloys.

TABLE 10.5 | The Composition of the Two Brands of Steel Tubing Commonly

| Reynolds | 0.25 | 0.25 | 1.3 | 0.20 | - |
| Columbus | 0.25 | 0.30 | 0.65 | 0.20 | 1.0 |

An interstitial alloy is formed when some of the interstices (holes) in the closest packed metal structure are occupied by small atoms [Fig. 10.22(b)]. Steel, the bestknown interstitial alloy, contains carbon atoms in the holes of an iron crystal. The presence of the interstitial atoms changes the properties of the host metal. Pure iron is relatively soft, ductile, and malleable due to the absence of directional bonding. The spherical metal atoms can be rather easily moved with respect to each other. However, when carbon, which forms strong directional bonds, is introduced into an iron crystal, the presence of the directional carbon-iron bonds makes the resulting alloy harder, stronger, and less ductile than pure iron. The amount of carbon directly affects the properties of steel. Mild steels, containing less than $0.2 \%$ carbon, are ductile and malleable and are used for nails, cables, and chains. Medium steels, containing 0.2 to $0.6 \%$ carbon, are harder than mild steels and are used in rails and structural steel beams. High-carbon steels, containing 0.6 to $1.5 \%$ carbon, are tough and hard and are used for springs, tools, and cutlery.

Many types of steel also contain elements in addition to iron and carbon. Such steels are often called alloy steels, and they can be viewed as being mixed interstitial (carbon) and substitutional (other metals) alloys. Bicycle frames, for example, are constructed from a wide variety of alloy steels. The compositions of the two brands of steel tubing most commonly used in expensive racing bicycles are given in Table 10.5.

## 10.5

Carbon and Silicon: Network Atomic Solids

Many atomic solids contain strong directional covalent bonds to form a solid that might best be viewed as a "giant molecule." We call these substances network solids. In contrast to metals, these materials are typically brittle and do not efficiently conduct heat or electricity. To illustrate network solids, in this section we will discuss two very important elements, carbon and silicon, and some of their compounds.

The two most common forms of carbon, diamond and graphite, are typical network solids. In diamond, the hardest naturally occurring substance, each carbon atom is surrounded by a tetrahedral arrangement of other carbon atoms to form a huge molecule [Fig. 10.23(a)]. This structure is stabilized by covalent bonds, which, in terms of the

-a
Diamond

-b
Graphite

FIGURE 10.24 Partial representation of the molecular orbital energies in (a) diamond and (b) a typical metal.

localized electron model, are formed by the overlap of $s p^{3}$ hybridized carbon atomic orbitals.

It is also useful to consider the bonding among the carbon atoms in diamond in terms of the molecular orbital model. Energy-level diagrams for diamond and a typical metal are given in Fig. 10.24. Recall that the conductivity of metals can be explained by postulating that electrons are excited from filled levels into the very near empty levels, or conduction bands. However, note that in the energy-level diagram for diamond there is a large gap between the filled and the empty levels. This means that electrons cannot be transferred easily to the empty conduction bands. As a result, diamond is not expected to be a good electrical conductor. In fact, this prediction of the model agrees exactly with the observed behavior of diamond, which is known to be an electrical insulator-it does not conduct an electric current.

Graphite is very different from diamond. While diamond is hard, basically colorless, and an insulator, graphite is slippery, black, and a conductor. These differences, of course, arise from the differences in bonding in the two types of solids. In contrast to the tetrahedral arrangement of carbon atoms in diamond, the structure of graphite is based on layers of carbon atoms arranged in fused six-membered rings [Fig. 10.23(b)]. Each carbon atom in a particular layer of graphite is surrounded by the three other carbon atoms in a trigonal planar arrangement with 120-degree bond angles. The localized electron model predicts $s p^{2}$ hybridization in this case. The three $s p^{2}$ orbitals on each carbon are used to form $\sigma$ bonds with three other carbon atoms. One $2 p$ orbital remains unhybridized on each carbon and is perpendicular to the plane of carbon atoms, as shown in Fig. 10.25. These orbitals combine to form a group of closely spaced $\pi$ molecular orbitals that are important in two ways. First, they contribute

## CHEMICAL CDNNECTIDNS

## Graphene-Miracle Substance?

Graphite is a fascinating substance consisting of "chicken-wire" layers of carbon atoms. Due to the strong carbon-carbon bonds in each of its layers, graphite is even more thermodynamically stable than diamond. Because of the unusual stability of graphite, scientists have long wondered whether graphene (the individual chicken-wire layers) could exist independently. This question was answered by Andre Gein and Konstantin Novoselov, two scientists working at the University of Manchester in the United Kingdom, when they were able to pull layers a single atom thick from graphite using Scotch tape. This work was deemed so important that Gein and Novoselov were awarded the Nobel Prize in physics in 2010.

Since the isolation of sheets of graphene by Gein and Novoselov, research in the properties and possible uses of this material has virtually exploded. Graphene has truly amazing properties. For example, it is believed to be the strongest material known,
more than 100 times stronger than steel. Also, it is stiffer than diamond, yet it can be stretched like rubber.

Much of the interest in graphene centers on the fact that it is the best conductor of heat and electricity known. Electrons travel through graphene at ultrafast speeds. In fact, electrons in graphene exhibit the fractional quantum Hall effect: The electrons act collectively as if they are particles with only a fraction of the charge of an electron. Because of its exceptional thermal and electrical conductivities, graphene appears to be an ideal candidate for future electronic devices. Scientists at IBM have already built graphene-based transistors that can switch on and off 26 billion times per second, far faster than conventional silicon-based devices.

One problem that has hampered the development of graphene-based devices is the difficulty in producing large sheets of graphene. Byung Hee Hong and his team, from South Korea, have recently reported making rectangular sheets of
graphene measuring 30 inches along the diagonal. It appears that we are very close to making commercial electronic devices based on the amazing properties of graphene.

A flexible electrode made of graphene.
significantly to the stability of the graphite layers because of the $\pi$ bond formation. Second, the $\pi$ molecular orbitals with their delocalized electrons account for the electrical conductivity of graphite. These closely spaced orbitals are exactly analogous to the conduction bands found in metal crystals.

Graphite is often used as a lubricant in locks (where oil is undesirable because it collects dirt). The slipperiness that is characteristic of graphite can be explained by noting that graphite has very strong bonding within the layers of carbon atoms but little bonding between the layers (the valence electrons are all used to form $\sigma$ and $\pi$ bonds among carbons within the layers). This arrangement allows the layers to slide past one another quite readily. Graphite's layered structure is shown in Fig. 10.26. This is in contrast to diamond, which has uniform bonding in all directions in the crystal.

Because of their extreme hardness, diamonds are used extensively in industrial cutting implements. Thus it is desirable to convert cheaper graphite to diamond. As we might expect from the higher density of diamond $\left(3.5 \mathrm{~g} / \mathrm{cm}^{3}\right)$ compared with that of graphite ( $2.2 \mathrm{~g} / \mathrm{cm}^{3}$ ), this transformation can be accomplished by applying very high pressures to graphite. The application of $150,000 \mathrm{~atm}$ of pressure at $2800^{\circ} \mathrm{C}$ converts graphite virtually completely to diamond. The high temperature is required to break the strong bonds in graphite so the rearrangement can occur.

FIGURE 10.27 (top) The structure of quartz (empirical formula $\mathrm{SiO}_{2}$ ). Quartz contains chains of $\mathrm{SiO}_{4}$ tetrahedra (bottom) that share oxygen atoms.

[^17]

FIGURE 10.26 Graphite consists of layers of carbon atoms.

Silicon is an important constituent of the compounds that make up the earth's crust. In fact, silicon is to geology as carbon is to biology. Just as carbon compounds are the basis for most biologically significant systems, silicon compounds are fundamental to most of the rocks, sands, and soils found in the earth's crust. However, although carbon and silicon are next to each other in Group 4A of the periodic table, the carbon-based compounds of biology and the silicon-based compounds of geology have markedly different structures. Carbon compounds typically contain long strings of carbon-carbon bonds, whereas the most stable silicon compounds involve chains with silicon-oxygen bonds.

The fundamental silicon-oxygen compound is silica, which has the empirical formula $\mathrm{SiO}_{2}$. Knowing the properties of the similar compound carbon dioxide, one might expect silica to be a gas that contains discrete $\mathrm{SiO}_{2}$ molecules. In fact, nothing could be further from the truth-quartz and some types of sand are typical of the materials composed of silica. What accounts for this difference? The answer lies in the bonding.

Recall that the Lewis structure of $\mathrm{CO}_{2}$ is

$$
\mathrm{O}=\mathrm{C}=\mathrm{O}
$$

and that each $\mathrm{C}=\mathrm{O}$ bond can be viewed as a combination of a $\sigma$ bond involving a carbon $s p$ hybrid orbital and a $\pi$ bond involving a carbon $2 p$ orbital. On the contrary, silicon cannot use its valence $3 p$ orbitals to form strong $\pi$ bonds with oxygen, mainly because of the larger size of the silicon atom and its orbitals, which results in less effective overlap with the smaller oxygen orbitals. Therefore, instead of forming $\pi$ bonds, the silicon atom satisfies the octet rule by forming single bonds with four oxygen atoms, as shown in the representation of the structure of quartz in Fig. 10.27. Note that each silicon atom is at the center of a tetrahedral arrangement of oxygen atoms, which are shared with other silicon atoms. Although the empirical formula for quartz is $\mathrm{SiO}_{2}$, the structure is based on a network of $\mathrm{SiO}_{4}$ tetrahedra with shared oxygen atoms rather than discrete $\mathrm{SiO}_{2}$ molecules. It is obvious that the differing abilities of carbon and silicon to form $\pi$ bonds with oxygen have profound effects on the structures and properties of $\mathrm{CO}_{2}$ and $\mathrm{SiO}_{2}$.

Compounds closely related to silica and found in most rocks, soils, and clays are the silicates. Like silica, the silicates are based on interconnected $\mathrm{SiO}_{4}$ tetrahedra. However, in contrast to silica, where the $\mathrm{O} / \mathrm{Si}$ ratio is $2: 1$, silicates have $\mathrm{O} / \mathrm{Si}$ ratios greater than 2:1 and contain silicon-oxygen anions. This means that to form the neutral solid silicates, cations are needed to balance the excess negative charge. In other words, silicates are salts containing metal cations and polyatomic silicon-oxygen anions. Examples of important silicate anions are shown in Fig. 10.28.

When silica is heated above its melting point (about $1600^{\circ} \mathrm{C}$ ) and cooled rapidly, an amorphous solid called a glass results (Fig. 10.29). Note that a glass contains a good deal of disorder, in contrast to the crystalline nature of quartz. Glass more closely resembles a very viscous solution than it does a crystalline solid. Common glass results

Silicon

- Oxygen
when substances such as $\mathrm{Na}_{2} \mathrm{CO}_{3}$ are added to the silica melt, which is then cooled. The properties of glass can be varied greatly by varying the additives. For example, addition of $\mathrm{B}_{2} \mathrm{O}_{3}$ produces a glass (called borosilicate glass) that expands and contracts little under large temperature changes. Thus it is useful for labware and cooking utensils. The most common brand name for this glass is Pyrex. The addition of $\mathrm{K}_{2} \mathrm{O}$ produces an especially hard glass that can be ground to the precise shapes needed for eyeglass and contact lenses. The compositions of several types of glass are shown in Table 10.6.

TABLE 10.6 | Compositions of Some Common Types of Glass

| Type of Class | Percentages of Various Components |  |  |  |  |  |  |

## Ceramics

Ceramics are typically made from clays (which contain silicates) and hardened by firing at high temperatures. Ceramics are nonmetallic materials that are strong, brittle, and resistant to heat and attack by chemicals.

Like glass, ceramics are based on silicates, but with that the resemblance ends. Glass can be melted and remelted as often as desired, but once a ceramic has been hardened, it is resistant to extremely high temperatures. This behavior results from the very different structures of glasses and ceramics. A glass is a homogeneous, noncrystalline "frozen solution," and a ceramic is heterogeneous. A ceramic contains two phases: minute crystals of silicates that are suspended in a glassy cement.

To understand how ceramics harden, it is necessary to know something about the structure of clays. Clays are formed by the weathering action of water and carbon dioxide on the mineral feldspar, which is a mixture of silicates with empirical formulas such as $\mathrm{K}_{2} \mathrm{O} \cdot \mathrm{Al}_{2} \mathrm{O}_{3} \cdot 6 \mathrm{SiO}_{2}$ and $\mathrm{Na}_{2} \mathrm{O} \cdot \mathrm{Al}_{2} \mathrm{O}_{3} \cdot 6 \mathrm{SiO}_{2}$. Feldspar is really an aluminosilicate in which aluminum as well as silicon atoms are part of the oxygen-bridged polyanion. The weathering of feldspar produces kaolinite, consisting of tiny thin platelets with the empirical formula $\mathrm{Al}_{2} \mathrm{Si}_{2} \mathrm{O}_{5}(\mathrm{OH})_{4}$. When dry, the platelets cling together; when water is present, they can slide over one another, giving clay its plasticity. As clay dries, the platelets begin to interlock again. When the remaining water is driven off during firing, the silicates and cations form a glass that binds the tiny crystals of kaolinite.

Ceramics have a very long history. Rocks, which are natural ceramic materials, served as the earliest tools. Later, clay vessels dried in the sun or baked in fires served as containers for food and water. These early vessels were no doubt crude and quite porous. With the discovery of glazing, which probably occurred about 3000 b.c. in Egypt, pottery became more serviceable as well as more beautiful. Prized porcelain is essentially the same material as crude earthenware, but specially selected clays and glazings are used for porcelain and the clay object is fired at a very high temperature.

Although ceramics have been known since antiquity, they are not obsolete materials. On the contrary, ceramics constitute one of the most important classes of "hightech" materials. Because of their stability at high temperatures and resistance to corrosion, ceramics seem an obvious choice for constructing jet and automobile engines in which the greatest fuel efficiencies are possible at very high temperatures. But ceramics are brittle-they break rather than bend-which limits their usefulness. However, more flexible ceramics can be obtained by adding small amounts of organic polymers. Taking their cue from natural "organoceramics" such as teeth and shells of sea creatures that contain small amounts of organic polymers, materials scientists have found that incorporating tiny amounts of long organic molecules into ceramics as they form produces materials that are much less subject to fracture. These materials should be useful for lighter, more durable engine parts, as well as for flexible superconducting wire and microelectronic devices. In addition, these organoceramics hold great promise for prosthetic devices such as artificial bones.

## Semiconductors

Elemental silicon has the same structure as diamond, as might be expected from its position in the periodic table (in Group 4A directly under carbon). Recall that in diamond there is a large energy gap between the filled and empty molecular orbitals (see Fig. 10.24). This gap prevents excitation of electrons to the empty molecular orbitals (conduction bands) and makes diamond an insulator. In silicon the situation is similar, but the energy gap is smaller. A few electrons can cross the gap at $25^{\circ} \mathrm{C}$, making silicon a semiconducting element, or semiconductor. In addition, at higher temperatures, where more energy is available to excite electrons into the conduction bands, the conductivity of silicon increases. This is typical behavior for a semiconducting element and is in contrast to that of metals, whose conductivity decreases with increasing temperature.

FIGURE 10.30 (a) A silicon crystal doped with arsenic, which has one more valence electron than silicon.
(b) A silicon crystal doped with boron, which has one fewer electron than silicon.

Electrons must be in singly occupied molecular orbitals to conduct a current.

FIGURE 10.31 Energy-level diagrams for (a) an n-type semiconductor and (b) a p-type semiconductor.

The small conductivity of silicon can be enhanced at normal temperatures if the silicon crystal is doped with certain other elements. For example, when a small fraction of silicon atoms is replaced by arsenic atoms, each having one more valence electron than silicon, extra electrons become available for conduction [Fig. 10.30(a)]. This produces an n-type semiconductor, a substance whose conductivity is increased by doping it with atoms having more valence electrons than the atoms in the host crystal. These extra electrons lie close in energy to the conduction bands and can be easily excited into these levels, where they can conduct an electric current [Fig. 10.31(a)].

We also can enhance the conductivity of silicon by doping the crystal with an element such as boron, which has only three valence electrons, one fewer than silicon. Because boron has one less electron than is required to form the bonds with the surrounding silicon atoms, an electron vacancy, or hole, is created [Fig. 10.30(b)]. As an electron fills this hole, it leaves a new hole, and this process can be repeated. Thus the hole advances through the crystal in a direction opposite to the movement of the electrons jumping to fill the hole. Another way of thinking about this phenomenon is that in pure silicon each atom has four valence electrons and the low-energy molecular orbitals are exactly filled. Replacing silicon atoms with boron atoms leaves vacancies in these molecular orbitals [see Fig. 10.31(b)]. This means that there is only one electron in some of the molecular orbitals, and these unpaired electrons can function as conducting electrons. Thus the substance becomes a better conductor. When semiconductors are doped with atoms having fewer valence electrons than the atoms of the host crystal, they are called p-type semiconductors, so named because the positive holes can be viewed as the charge carriers.

Most important applications of semiconductors involve connection of a p-type and an n-type to form a $\mathbf{p}-\mathbf{n}$ junction. Figure 10.32(a) shows a typical junction; the red dots represent excess electrons in the n-type semiconductor, and the white circles represent holes (electron vacancies) in the p-type semiconductor. At the junction, a small number of electrons migrate from the n-type region into the p-type region, where there are vacancies in the low-energy molecular orbitals. The effect of these migrations is to place a negative charge on the p-type region (since it now has a surplus of electrons) and a positive charge on the n-type region (since it has lost electrons, leaving holes in its low-energy molecular orbitals). This charge buildup, called the contact potential, or junction potential, prevents further migration of electrons.

Now suppose an external electric potential is applied by connecting the negative terminal of a battery to the p-type region and the positive terminal to the n-type region. The situation represented in Fig. 10.32(b) results. Electrons are drawn toward the positive terminal, and the resulting holes move toward the negative terminal-exactly opposite to the natural flow of electrons at the $\mathrm{p}-\mathrm{n}$ junction. The junction resists the imposed current flow in this direction and is said to be under reverse bias. No current flows through the system.

On the other hand, if the battery is connected so that the negative terminal is connected to the n-type region and the positive terminal is connected to the p-type region

FIGURE 10.32 The p-n junction involves the contact of a $p$-type and an n-type semiconductor. (a) The charge carriers of the p-type region are holes ( $)$. In the n-type region, the charge carriers are electrons ( $Q$ ).
(b) No current flows (reverse bias). (c) Current readily flows (forward bias). Note that each electron that crosses the boundary leaves a hole behind. Thus the electrons and the holes move in opposite directions.

[^18]
[Fig. 10.32(c)], the movement of electrons (and holes) is in the favored direction. The junction has low resistance, and a current flows easily. The junction is said to be under forward bias.

A p-n junction makes an excellent rectifier, a device that produces a pulsating direct current (flows in one direction) from alternating current (flows in both directions alternately). When placed in a circuit where the potential is constantly reversing, a $\mathrm{p}-\mathrm{n}$ junction transmits current only under forward bias, thus converting the alternating current to direct current. Radios, computers, and other electronic devices formerly used bulky, unreliable vacuum tubes as rectifiers. The $\mathrm{p}-\mathrm{n}$ junction has revolutionized electronics; modern solid-state components contain p-n junctions in printed circuits.

### 10.6 Molecular Solids

So far we have considered solids in which atoms occupy the lattice positions. In some of these substances (network solids), the solid can be considered to be one giant molecule. In addition, there are many types of solids that contain discrete molecular units at each lattice position. A common example is ice, where the lattice positions are occupied by water molecules [see Fig. 10.13(c)]. Other examples are dry ice (solid carbon dioxide), some forms of sulfur that contain $\mathrm{S}_{8}$ molecules [Fig. 10.33(a)], and certain forms of phosphorus that contain $\mathrm{P}_{4}$ molecules [Fig. 10.33(b)]. These substances are characterized by strong covalent bonding within the molecules but relatively weak forces between the molecules. For example, it takes only 6 kJ of energy to melt 1 mole of solid water (ice) because only intermolecular $\left(\mathrm{H}_{2} \mathrm{O}-\mathrm{H}_{2} \mathrm{O}\right)$ interactions must be overcome. However, 470 kJ of energy is required to break 1 mole of covalent $\mathrm{O}-\mathrm{H}$ bonds. The differences between the covalent bonds within the molecules and

FIGURE 10.33 (a) Sulfur crystals (yellow) contain $\mathrm{S}_{8}$ molecules. (b) White phosphorus (containing $\mathrm{P}_{4}$ molecules) is so reactive with the oxygen in air that it must be stored under water.

a

b
the forces between the molecules are apparent from the comparison of the interatomic and intermolecular distances in solids shown in Table 10.7.

The forces that exist among the molecules in a molecular solid depend on the nature of the molecules. Many molecules such as $\mathrm{CO}_{2}, \mathrm{I}_{2}, \mathrm{P}_{4}$, and $\mathrm{S}_{8}$ have no dipole moment, and the intermolecular forces are London dispersion forces. Because these forces are often relatively small, we might expect all these substances to be gaseous at $25^{\circ} \mathrm{C}$, as is the case for carbon dioxide. However, as the size of the molecules increases, the London forces become quite large, causing many of these substances to be solids at $25^{\circ} \mathrm{C}$.

When molecules do have dipole moments, their intermolecular forces are significantly greater, especially when hydrogen bonding is possible. Water molecules are particularly well suited to interact with each other because each molecule has two polar $\mathrm{O}-\mathrm{H}$ bonds and two lone pairs on the oxygen atom. This can lead to the association of four hydrogen atoms with each oxygen: two by covalent bonds and two by dipole forces:

Note the two relatively short covalent oxygen-hydrogen bonds and the two longer oxygen-hydrogen dipole interactions that can be seen in the ice structure in Fig. 10.13(c).

TABLE 10.7 | Comparison of Atomic Separations Within Molecules (Covalent Bonds) and Between Molecules (Intermolecular Interactions)

| Solid | Distance Between <br> Atoms in Molecule* | Closest Distance Between <br> Molecules in the Solid |
| :---: | :---: | :---: |
| $\mathrm{P}_{4}$ | 220 pm | 380 pm |
| $\mathrm{S}_{8}$ | 206 pm | 370 pm |
| $\mathrm{Cl}_{2}$ | 199 pm | 360 pm |

*The shorter distances within the molecules indicate stronger bonding.

### 10.7 Ionic Solids

FIGURE 10.34 The holes that exist among closest packed uniform spheres. (a) The trigonal hole formed by three spheres in a given plane. (b) The tetrahedral hole formed when a sphere occupies a dimple formed by three spheres in an adjacent layer. (c) The octahedral hole formed by six spheres in two adjacent layers.

[^19]Ionic solids are stable, high-melting substances held together by the strong electrostatic forces that exist between oppositely charged ions. The principles governing the structures of ionic solids were introduced in Section 8.5. In this section we will review and extend these principles.

The structures of most binary ionic solids, such as sodium chloride, can be explained by the closest packing of spheres. Typically, the larger ions, usually the anions, are packed in one of the closest packing arrangements (hcp or ccp), and the smaller cations fit into holes among the closest packed anions. The packing is done in a way that maximizes the electrostatic attractions among oppositely charged ions and minimizes the repulsions among ions with like charges.

There are three types of holes in closest packed structures:

1. Trigonal holes are formed by three spheres in the same layer [Fig. 10.34(a)].
2. Tetrahedral holes are formed when a sphere sits in the dimple of three spheres in an adjacent layer [Fig. 10.34(b)].
3. Octahedral holes are formed between two sets of three spheres in adjoining layers of the closest packed structures [Fig. 10.34(c)].

For spheres of a given diameter, the holes increase in size in the order

$$
\text { trigonal }<\text { tetrahedral }<\text { octahedral }
$$

In fact, trigonal holes are so small that they are never occupied in binary ionic compounds. Whether the tetrahedral or octahedral holes in a given binary ionic solid are occupied depends mainly on the relative sizes of the anion and cation. For example, in zinc sulfide the $\mathrm{S}^{2-}$ ions (ionic radius $=180 \mathrm{pm}$ ) are arranged in a cubic closest packed structure with the smaller $\mathrm{Zn}^{2+}$ ions (ionic radius $=70 \mathrm{pm}$ ) in the tetrahedral holes. The locations of the tetrahedral holes in the face-centered cubic unit cell of the ccp structure are shown in Fig. 10.35(a). Note from this figure that there are eight tetrahedral holes in the unit cell. Also recall from the discussion in Section 10.4 that there are four net spheres in the face-centered cubic unit cell. Thus there are twice as many tetrahedral holes as packed anions in the closest packed structure. Zinc sulfide must have the same number of $\mathrm{S}^{2-}$ ions and $\mathrm{Zn}^{2+}$ ions to achieve electrical neutrality. Thus in the zinc sulfide structure only half the tetrahedral holes contain $\mathrm{Zn}^{2+}$ ions, as shown in Fig. 10.35(c).

The structure of sodium chloride can be described in terms of a cubic closest packed array of $\mathrm{Cl}^{-}$ions with $\mathrm{Na}^{+}$ions in all the octahedral holes. The locations of the octahedral holes in the face-centered cubic unit cell are shown in Fig. 10.36(a). The easiest octahedral hole to find in this structure is the one at the center of the cube. Note that this hole is surrounded by six spheres, as is required to form an octahedron. The remaining octahedral holes are shared with other unit cells and are more difficult to visualize. However, it can be shown that the number of octahedral holes in the ccp structure is the same as the number of packed anions. Figure 10.36 (b) shows the

FIGURE 10.35 (a) The location (red X) of a tetrahedral hole in the face-centered cubic unit cell. (b) One of the tetrahedral holes. (c) The unit cell for ZnS where the $\mathrm{S}^{2-}$ ions (yellow) are closest packed with the $\mathrm{Zn}^{2+}$ ions (red) in alternating tetrahedral holes.
structure for sodium chloride that results from $\mathrm{Na}^{+}$ions filling all the octahedral holes in a ccp array of $\mathrm{Cl}^{-}$ions.

A great variety of ionic solids exists. Our purpose in this section is not to give an exhaustive treatment of ionic solids, but to emphasize the fundamental principles governing their structures. As we have seen, the most useful model for explaining the structures of these solids regards the ions as hard spheres that are packed to maximize attractions and minimize repulsions.

## EXAMPLE 10.3

## Determining the Number of lons in a Unit Cell

Determine the net number of $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions in the sodium chloride unit cell.

## SOLUTION

Note from Fig. 10.36(b) that the $\mathrm{Cl}^{-}$ions are cubic closest packed and thus form a facecentered cubic unit cell. There is a $\mathrm{Cl}^{-}$ion on each corner and one at the center of each face of the cube. Thus the net number of $\mathrm{Cl}^{-}$ions present in a unit cell is

$$
8\left(\frac{1}{8}\right)+6\left(\frac{1}{2}\right)=4
$$

The $\mathrm{Na}^{+}$ions occupy the octahedral holes located in the center of the cube and midway along each edge. The $\mathrm{Na}^{+}$ion in the center of the cube is contained entirely in the unit cell, whereas those on the edges are shared by four unit cells (four cubes share a common edge). Since the number of edges in a cube is 12 , the net number of $\mathrm{Na}^{+}$ions present is

$$
1(1)+12\left(\frac{1}{4}\right)=4
$$

FIGURE 10.36 (a) The locations (gray $X$ ) of the octahedral holes in the face-centered cubic unit cell. (b) Representation of the unit cell for solid NaCl . The $\mathrm{Cl}^{-}$ions (green spheres) have a ccp arrangement with $\mathrm{Na}^{+}$ions (gray spheres) in all the octahedral holes. Note that this representation shows the idealized closest packed structure of NaCl . In the actual structure, the $\mathrm{Cl}^{-}$ions do not quite touch.

## TABLE 10.8 | Types and Properties of Solids

| Type of Solid | Atomic |  |  | Molecular | Ionic |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Network | Metallic | Group 8A |  |  |
| Structural Unit | Atom | Atom | Atom | Molecule | Ion |
| Type of Bonding | Directional covalent bonds | Nondirectional covalent bonds involving electrons that are delocalized throughout the crystal | London dispersion forces | Polar molecules: dipoledipole interactions Nonpolar molecules: London dispersion forces | Ionic |
| Typical Properties | Hard | Wide range of hardness |  | Soft | Hard |
|  | High melting point | Wide range of melting points | Very low melting point | Low melting point | High melting point |
|  | Insulator | Conductor |  | Insulator | Insulator |
| Examples | Diamond | Silver | Argon(s) | Ice (solid $\mathrm{H}_{2} \mathrm{O}$ ) | Sodium chloride |
|  |  | Iron |  | Dry ice (solid $\mathrm{CO}_{2}$ ) | Calcium fluoride |
|  |  | Brass |  |  |  |

We have shown that the net number of ions in a unit cell is $4 \mathrm{Na}^{+}$ions and $4 \mathrm{Cl}^{-}$ions, which agrees with the $1: 1$ stoichiometry of sodium chloride.

See Exergises 10.71 through 10.78

In this chapter we have considered various types of solids. Table 10.8 summarizes these types of solids and some of their properties.

## INTERACTVE EXAMPLE 10.4 Types of Solids

Using Table 10.8 , classify each of the following substances according to the type of solid it forms.
a. Gold
b. Carbon dioxide
c. Lithium fluoride
d. Krypton

SOLUTION a. Solid gold is an atomic solid with metallic properties.
b. Solid carbon dioxide contains nonpolar carbon dioxide molecules and is a molecular solid.
c. Solid lithium fluoride contains $\mathrm{Li}^{+}$and $\mathrm{F}^{-}$ions and is a binary ionic solid.
d. Solid krypton contains krypton atoms that can interact only through London dispersion forces. It is an atomic solid but has properties characteristic of a molecular solid with nonpolar molecules.

## 10.8

## Vapor Pressure and Changes of State

Vapor is the usual term for the gas phase of a substance that exists as a solid or liquid at $25^{\circ} \mathrm{C}$ and 1 atm .
$\Delta H_{\text {vap }}$ for water at $100^{\circ} \mathrm{C}$ is $40.7 \mathrm{~kJ} / \mathrm{mol}$.

FIGURE 10.37 Behavior of a liquid in a closed container. (a) Initially, net evaporation occurs as molecules are transferred from the liquid to the vapor phase, so the amount of liquid decreases. (b) As the number of vapor molecules increases, the rate of return to the liquid (condensation) increases, until finally the rate of condensation equals the rate of evaporation. The system is at equilibrium, and no further changes occur in the amounts of vapor or liquid.

FIGURE 10.38 The rates of condensation and evaporation over time for a liquid sealed in a closed container. The rate of evaporation remains constant and the rate of condensation increases as the number of molecules in the vapor phase increases, until the two rates become equal. At this point, the equilibrium vapor pressure is attained.

Now that we have considered the general properties of the three states of matter, we can explore the processes by which matter changes state. One very familiar example of a change in state occurs when a liquid evaporates from an open container. This is clear evidence that the molecules of a liquid can escape the liquid's surface and form a gas, a process called vaporization, or evaporation. Vaporization is endothermic because energy is required to overcome the relatively strong intermolecular forces in the liquid. The energy required to vaporize 1 mole of a liquid at a pressure of 1 atm is called the heat of vaporization, or the enthalpy of vaporization, and is usually symbolized as $\Delta \boldsymbol{H}_{\text {vap }}$.

The endothermic nature of vaporization has great practical significance; in fact, one of the most important roles that water plays in our world is to act as a coolant. Because of the strong hydrogen bonding among its molecules in the liquid state, water has an unusually large heat of vaporization ( $40.7 \mathrm{~kJ} / \mathrm{mol}$ ). A significant portion of the sun's energy that reaches earth is spent evaporating water from the oceans, lakes, and rivers rather than warming the earth. The vaporization of water is also crucial to the body's temperature-control system through evaporation of perspiration.

## Vapor Pressure

When a liquid is placed in a closed container, the amount of liquid at first decreases but eventually becomes constant. The decrease occurs because there is an initial net transfer of molecules from the liquid to the vapor phase (Fig. 10.37). This evaporation process occurs at a constant rate at a given temperature (Fig. 10.38). However, the reverse process is different. Initially, as the number of vapor molecules increases, so does the rate of return of these molecules to the liquid. The process by which vapor molecules reform a liquid is called condensation. Eventually, enough vapor molecules are present above the liquid so that the rate of condensation equals the rate of evaporation (see

A system at equilibrium is dynamic on the molecular level but shows no macroscopic changes.

FIGURE 10.39 (a) The vapor pressure of a liquid can be measured easily using a simple barometer of the type shown here. (b) The three liquids, water, ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$, and diethyl ether $\left[\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{2} \mathrm{O}\right]$, have quite different vapor pressures. Ether is by far the most volatile of the three. Note that in each case a little liquid remains (floating on the mercury).

Fig. 10.38). At this point no further net change occurs in the amount of liquid or vapor because the two opposite processes exactly balance each other; the system is at equilibrium. Note that this system is highly dynamic on the molecular level-molecules are constantly escaping from and entering the liquid at a high rate. However, there is no net change because the two opposite processes just balance each other.

The pressure of the vapor present at equilibrium is called the equilibrium vapor pressure, or more commonly, the vapor pressure of the liquid. A simple barometer can measure the vapor pressure of a liquid [Fig. 10.39(a)]. The liquid is injected at the bottom of the tube of mercury and floats to the surface because the mercury is so dense. A portion of the liquid evaporates at the top of the column, producing a vapor whose pressure pushes some mercury out of the tube. When the system reaches equilibrium, the vapor pressure can be determined from the change in the height of the mercury column since

Thus

$$
\begin{aligned}
P_{\mathrm{atmosphere}} & =P_{\mathrm{vapor}}+P_{\mathrm{Hg} \text { column }} \\
P_{\mathrm{vapor}} & =P_{\mathrm{atmosphere}}-P_{\mathrm{Hg} \text { column }}
\end{aligned}
$$

 a bent shape and therefore is a polar molecule. This accounts for many of water's interesting properties. What if the water molecule was linear? How would this affect the properties of water, such as its surface tension, heat of vaporization, and vapor pressure? How would life be different?

The vapor pressures of liquids vary widely [Fig. 10.39(b)]. Liquids with high vapor pressures are said to be volatile-they evaporate rapidly from an open dish. The vapor pressure of a liquid is principally determined by the size of the intermolecular forces in the liquid. Liquids in which the intermolecular forces are large have relatively low vapor pressures because the molecules need high energies to escape to the vapor phase. For example, although water has a much lower molar mass than diethyl ether, the strong hydrogen-bonding forces that exist among water molecules in the liquid state cause water's vapor pressure to be much lower than that of diethyl ether [Fig. 10.39(b)]. In general, substances with large molar masses have relatively low vapor pressures, mainly because of the large dispersion forces. The more electrons a substance has, the more polarizable it is, and the greater the dispersion forces are.

## a

FIGURE 10.40 The number of molecules in a liquid with a given energy versus kinetic energy at two temperatures. Part (a) shows a lower temperature than that in part (b). Note that the proportion of molecules with enough energy to escape the liquid to the vapor phase (indicated by shaded areas) increases dramatically with temperature. This causes vapor pressure to increase markedly with temperature.

Measurements of the vapor pressure for a given liquid at several temperatures show that vapor pressure increases significantly with temperature. Figure 10.40 illustrates the distribution of molecular kinetic energy present in a liquid at two different temperatures. To overcome the intermolecular forces in a liquid, a molecule must have sufficient kinetic energy. As the temperature of the liquid is increased, the fraction of molecules having the minimum energy needed to overcome these forces and escape to the vapor phase increases markedly. Thus the vapor pressure of a liquid increases dramatically with temperature. Values for water at several temperatures are given in Table 10.9.

The quantitative nature of the temperature dependence of vapor pressure can be represented graphically. Plots of vapor pressure versus temperature for water, ethanol, and diethyl ether are shown in Fig. 10.41(a). Note the nonlinear increase in vapor

FIGURE 10.41 (a) The vapor pressure of water, ethanol, and diethyl ether as a function of temperature.
(b) Plots of $\ln \left(P_{\text {vap }}\right)$ versus $1 / T$ (Kelvin temperature) for water, ethanol, and diethyl ether.

Natural logarithms are reviewed in Appendix 1.2.
pressure for all the liquids as the temperature is increased. We find that a straight line can be obtained by plotting $\ln \left(P_{\text {vap }}\right)$ versus $1 / T$, where $T$ is the Kelvin temperature [Fig. 10.41(b)]. We can represent this behavior by the equation

$$
\begin{equation*}
\ln \left(P_{\text {vap }}\right)=-\frac{\Delta H_{\text {vap }}}{R}\left(\frac{1}{T}\right)+C \tag{10.4}
\end{equation*}
$$

where $\Delta H_{\text {vap }}$ is the enthalpy of vaporization, $R$ is the universal gas constant, and $C$ is a constant characteristic of a given liquid. The symbol $l n$ means that the natural logarithm of the vapor pressure is taken.

Equation (10.4) is the equation for a straight line of the form $y=m x+b$, where

$$
\begin{aligned}
y & =\ln \left(P_{\text {vap }}\right) \\
x & =\frac{1}{T} \\
m & =\text { slope }=-\frac{\Delta H_{\text {vap }}}{R} \\
b & =\text { intercept }=C
\end{aligned}
$$

## EXAMPLE 10.5 Determining Enthalpies of Vaporization

Equation (10.5) is called the ClausiusClapeyron equation.

SOLUTION When $\ln \left(P_{\text {vap }}\right)$ is plotted versus $1 / T$, the slope of the resulting straight line is

$$
-\frac{\Delta H_{\text {vap }}}{R}
$$

Note from Fig. 10.41(b) that the slopes of the lines for water and diethyl ether are both negative, as expected, and that the line for ether has the smaller slope. Thus ether has the smaller value of $\Delta H_{\text {vap }}$. This makes sense because the hydrogen bonding in water causes it to have a relatively large enthalpy of vaporization.

See Exercise 10.91

Equation (10.4) is important for several reasons. For example, we can determine the heat of vaporization for a liquid by measuring $P_{\text {vap }}$ at several temperatures and then evaluating the slope of a plot of $\ln \left(P_{\text {vap }}\right)$ versus $1 / T$. On the other hand, if we know the values of $\Delta H_{\text {vap }}$ and $P_{\text {vap }}$ at one temperature, we can use Equation (10.4) to calculate $P_{\text {vap }}$ at another temperature. This can be done by recognizing that the constant $C$ does not depend on temperature. Thus at two temperatures $T_{1}$ and $T_{2}$ we can solve Equation (10.4) for $C$ and then write the equality

$$
\ln \left(P_{\text {vap }, T_{1}}\right)+\frac{\Delta H_{\text {vap }}}{R T_{1}}=C=\ln \left(P_{\text {vap }, T_{2}}\right)+\frac{\Delta H_{\text {vap }}}{R T_{2}}
$$

This can be rearranged to
Using the plots in Fig. 10.41(b), determine whether water or diethyl ether has the larger enthalpy of vaporization.
(10.4) for $C$ and then wite the equality
or

$$
\begin{gather*}
\ln \left(P_{\text {vap }, T_{1}}\right)-\ln \left(P_{\text {vap }, T_{2}}\right)=\frac{\Delta H_{\text {vap }}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right) \\
\ln \left(\frac{P_{\text {vap }, T_{1}}}{P_{\text {vap }, T_{2}}}\right)=\frac{\Delta H_{\text {vap }}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right) \tag{10.5}
\end{gather*}
$$

## INTERACTIVE EXAMPLE 10.6

In solving this problem, we ignore the fact that $\Delta H_{\text {vap }}$ is slightly temperature dependent.

FIGURE 10.42 lodine being heated, causing it to sublime, forming crystals of $l_{2}(s)$ on the bottom of a test tube cooled by ice.

## SOLUTION

[^20]
## Calculating Vapor Pressure

The vapor pressure of water at $25^{\circ} \mathrm{C}$ is 23.8 torr, and the heat of vaporization of water at $25^{\circ} \mathrm{C}$ is $43.9 \mathrm{~kJ} / \mathrm{mol}$. Calculate the vapor pressure of water at $50 .{ }^{\circ} \mathrm{C}$.

Thus

$$
\begin{gathered}
P_{\text {vap }, T_{1}}=23.8 \text { torr } \\
T_{1}=25+273=298 \mathrm{~K} \\
T_{2}=50 .+273=323 \mathrm{~K} \\
\Delta H_{\text {vap }}=43.9 \mathrm{~kJ} / \mathrm{mol}=43,900 \mathrm{~J} / \mathrm{mol} \\
R=8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \\
\ln \left(\frac{23.8 \text { torr }}{P_{\text {vap }, T_{2}}(\text { torr })}\right)=\frac{43,900 \mathrm{~J} / \mathrm{mol}}{8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}}\left(\frac{1}{323 \mathrm{~K}}-\frac{1}{298 \mathrm{~K}}\right) \\
\ln \left(\frac{23.8}{P_{\text {vap } T_{2}}}\right)=-1.37
\end{gathered}
$$

Taking the antilog (see Appendix 1.2) of both sides gives

$$
\begin{aligned}
& \frac{23.8}{P_{\mathrm{vap}, T_{2}}}=0.254 \\
& P_{\mathrm{vap}, T_{2}}=93.7 \mathrm{torr}
\end{aligned}
$$

## See Exercises 10.93 through 10.96

Like liquids, solids have vapor pressures. Figure 10.42 shows iodine vapor forming solid iodine on the bottom of a cooled dish. Under normal conditions iodine sublimes; that is, it goes directly from the solid to the gaseous state without passing through the liquid state. Sublimation also occurs with dry ice (solid carbon dioxide).

## Changes of State

What happens when a solid is heated? Typically, it will melt to form a liquid. If the heating continues, the liquid will at some point boil and form the vapor phase. This process can be represented by a heating curve: a plot of temperature versus time for a process where energy is added at a constant rate.

The heating curve for water is given in Fig. 10.43. As energy flows into the ice, the random vibrations of the water molecules increase as the temperature rises. Eventually, the molecules become so energetic that they break loose from their lattice positions, and the change from solid to liquid occurs. This is indicated by a plateau at $0^{\circ} \mathrm{C}$ on the heating curve. At this temperature, called the melting point, all the added energy is used to disrupt the ice structure by breaking the hydrogen bonds, thus increasing the potential energy of the water molecules. The enthalpy change that occurs at the melting point when a solid melts is called the heat of fusion, or more accurately, the enthalpy of fusion, $\Delta \boldsymbol{H}_{\text {fus }}$. The melting points and enthalpies of fusion for several representative solids are listed in Table 10.10.

TABLE 10.10 |
Melting Points and Enthalpies of Fusion for Several Representative Solids

| Compound | Melting <br> Point <br> $\left({ }^{\circ} \mathrm{C}\right)$ | Enthalpy <br> of Fusion <br> (kJ/mol) |
| :---: | :---: | :---: |
| $\mathrm{O}_{2}$ | -218 | 0.45 |
| HCl | -114 | 1.99 |
| HI | -51 | 2.87 |
| $\mathrm{CCl}_{4}$ | -23 | 2.51 |
| $\mathrm{CHCl}_{3}$ | -64 | 9.20 |
| $\mathrm{H}_{2} \mathrm{O}$ | 0 | 6.02 |
| NaF | 992 | 29.3 |
| NaCl | 801 | 30.2 |

The melting and boiling points will be defined more precisely later in this section.

FIGURE 10.43 The heating curve (not drawn to scale) for a given quantity of water where energy is added at a constant rate. The plateau at the boiling point is longer than the plateau at the melting point because it takes almost seven times more energy (and thus seven times the heating time) to vaporize liquid water than to melt ice. The slopes of the other lines are different because the different states of water have different molar heat capacities (the energy required to raise the temperature of 1 mole of a substance by $1^{\circ} \mathrm{C}$ ).

The temperature remains constant until the solid has completely changed to liquid; then it begins to increase again. At $100^{\circ} \mathrm{C}$ the liquid water reaches its boiling point, and the temperature then remains constant as the added energy is used to vaporize the liquid. When the liquid is completely changed to vapor, the temperature again begins to rise. Note that changes of state are physical changes; although intermolecular forces have been overcome, no chemical bonds have been broken. If the water vapor were heated to much higher temperatures, the water molecules would break down into the individual atoms. This would be a chemical change, since covalent bonds are broken. We no longer have water after this occurs.

The melting and boiling points for a substance are determined by the vapor pressures of the solid and liquid states. Figure 10.44 shows the vapor pressures of solid and liquid water as functions of temperature near $0^{\circ} \mathrm{C}$. Note that below $0^{\circ} \mathrm{C}$ the vapor pressure of ice is less than the vapor pressure of liquid water. Also note that the vapor pressure of ice has a larger temperature dependence than that of the liquid. That is, the vapor pressure of ice increases more rapidly for a given rise in temperature than does the vapor pressure of water. Thus as the temperature of the solid is increased, a point is eventually reached where the liquid and solid have identical vapor pressures. This is the melting point.

These concepts can be demonstrated experimentally using the apparatus illustrated in Fig. 10.45, where ice occupies one compartment and liquid water the other. Consider the following cases.

## Case 1

A temperature at which the vapor pressure of the solid is greater than that of the liquid. At this temperature the solid requires a higher pressure than the liquid does to be in equilibrium with the vapor. Thus as vapor is released from the solid to try to achieve equilibrium, the liquid will absorb vapor in an attempt to reduce the vapor pressure to its equilibrium value. The net effect is a conversion from solid to liquid through the vapor phase. In fact, no solid can exist under these conditions. The amount of solid will steadily decrease and the volume of liquid will increase. Finally,

FIGURE 10.44 The vapor pressures of solid and liquid water as a function of temperature. The data for liquid water below $0^{\circ} \mathrm{C}$ are obtained from supercooled water. The data for solid water above $0^{\circ} \mathrm{C}$ are estimated by extrapolation of vapor pressure from below $0^{\circ} \mathrm{C}$.

FIGURE 10.45 An apparatus that allows solid and liquid water to interact only through the vapor state.

FIGURE 10.46 Water in a closed system with a pressure of 1 atm exerted on the piston. No bubbles can form within the liquid as long as the vapor pressure is less than 1 atm .

there will be only liquid in the right compartment, which will come to equilibrium with the water vapor, and no further changes will occur in the system. This temperature must be above the melting point of ice, since only the liquid state can exist.

## Case 2

A temperature at which the vapor pressure of the solid is less than that of the liquid. This is the opposite of the situation in case 1. In this case, the liquid requires a higher pressure than the solid does to be in equilibrium with the vapor, so the liquid will gradually disappear, and the amount of ice will increase. Finally, only the solid will remain, which will achieve equilibrium with the vapor. This temperature must be below the melting point of ice, since only the solid state can exist.

## Case 3

A temperature at which the vapor pressures of the solid and liquid are identical. In this case, the solid and liquid states have the same vapor pressure, so they can coexist in the apparatus at equilibrium simultaneously with the vapor. This temperature represents the freezing point where both the solid and liquid states can exist.

We can now describe the melting point of a substance more precisely. The normal melting point is defined as the temperature at which the solid and liquid states have the same vapor pressure under conditions where the total pressure is 1 atmosphere.

Boiling occurs when the vapor pressure of a liquid becomes equal to the pressure of its environment. The normal boiling point of a liquid is the temperature at which the vapor pressure of the liquid is exactly 1 atmosphere. This concept is illustrated in Fig. 10.46. At temperatures where the vapor pressure of the liquid is less than 1 atmosphere, no bubbles of vapor can form because the pressure on the surface of the liquid is greater than the pressure in any spaces in the liquid where the bubbles are trying to form. Only when the liquid reaches a temperature at which the pressure of vapor in the spaces in the liquid is 1 atmosphere can bubbles form and boiling occur.

However, changes of state do not always occur exactly at the boiling point or melting point. For example, water can be readily supercooled; that is, it can be cooled below $0^{\circ} \mathrm{C}$ at 1 atm pressure and remain in the liquid state. Supercooling occurs because, as it is cooled, the water may not achieve the degree of organization necessary to form ice at $0^{\circ} \mathrm{C}$, and thus it continues to exist as the liquid. At some point the correct ordering occurs and ice rapidly forms, releasing energy in the exothermic process and bringing the temperature back up to the melting point, where the remainder of the water freezes (Fig. 10.47).

A liquid also can be superheated, or raised to temperatures above its boiling point, especially if it is heated rapidly. Superheating can occur because bubble formation in

FIGURE 10.47 The supercooling of water. The extent of supercooling is given by $S$.

the interior of the liquid requires that many high-energy molecules gather in the same vicinity, and this may not happen at the boiling point, especially if the liquid is heated rapidly. If the liquid becomes superheated, the vapor pressure in the liquid is greater than the atmospheric pressure. Once a bubble does form, since its internal pressure is greater than that of the atmosphere, it can burst before rising to the surface, blowing the surrounding liquid out of the container. This is called bumping and has ruined many experiments. It can be avoided by adding boiling chips to the flask containing the liquid. Boiling chips are bits of porous ceramic material containing trapped air that escapes on heating, forming tiny bubbles that act as "starters" for vapor bubble formation. This allows a smooth onset of boiling as the boiling point is reached.

### 10.9 Phase Diagrams

A phase diagram is a convenient way of representing the phases of a substance as a function of temperature and pressure. For example, the phase diagram for water (Fig. 10.48) shows which state exists at a given temperature and pressure. It is important to recognize that a phase diagram describes conditions and events in a closed system of the type represented in Fig. 10.46, where no material can escape into the surroundings and no air is present. Notice that the diagram is not drawn to scale (neither axis is linear). This is done to emphasize certain features of the diagram that will be discussed below.

Temperature ( ${ }^{\circ} \mathrm{C}$ )

FIGURE 10.48 The phase diagram for water. $T_{\mathrm{m}}$ represents the normal melting point; $T_{3}$ and $P_{3}$ denote the triple point; $T_{\mathrm{b}}$ represents the normal boiling point; $T_{c}$ represents the critical temperature; $P_{c}$ represents the critical pressure. The negative slope of the solid/liquid line reflects the fact that the density of ice is less than that of liquid water. (Note that this line extends indefinitely, as indicated by the arrow.)

FIGURE 10.49 Diagrams of various heating experiments on samples of water in a closed system.

To show how to interpret the phase diagram for water, we will consider heating experiments at several pressures, shown by the dashed lines in Fig. 10.49.

## Experiment 1

Pressure is 1 atm. This experiment begins with the cylinder shown in Fig. 10.46 completely filled with ice at a temperature of $-20^{\circ} \mathrm{C}$ and the piston exerting a pressure of 1 atm directly on the ice (there is no air space). Since at temperatures below $0^{\circ} \mathrm{C}$ the vapor pressure of ice is less than 1 atm - which is the constant external pressure on the piston-no vapor is present in the cylinder. As the cylinder is heated, ice is the only component until the temperature reaches $0^{\circ} \mathrm{C}$, where the ice changes to liquid water as energy is added. This is the normal melting point of water. Note that under these conditions no vapor exists in the system. The vapor pressures of the solid and liquid are equal, but this vapor pressure is less than 1 atm , so no water vapor can exist. This is true on the solid/liquid line everywhere except at the triple point (see Experiment 3). When the solid has completely changed to liquid, the temperature again rises. At this point, the cylinder contains only liquid water. No vapor is present because the vapor pressure of liquid water under these conditions is less than 1 atm , the constant external pressure on the piston. Heating continues until the temperature of the liquid water reaches $100^{\circ} \mathrm{C}$. At this point, the vapor pressure of liquid water is 1 atm , and boiling occurs, with the liquid changing to vapor. This is the normal boiling point of water. After the liquid has been completely converted to steam, the temperature again rises as the heating continues. The cylinder now contains only water vapor.

## Experiment 2

Pressure is 2.0 torr. Again, we start with ice as the only component in the cylinder at $-20^{\circ} \mathrm{C}$. The pressure exerted by the piston in this case is only 2.0 torr. As heating proceeds, the temperature rises to $-10^{\circ} \mathrm{C}$, where the ice changes directly to vapor, a process known as sublimation. Sublimation occurs when the vapor pressure of ice is equal to the external pressure, which in this case is only 2.0 torr. No liquid water appears under these conditions because the vapor pressure of liquid water is always greater than 2.0 torr, and thus it cannot exist at this pressure. If liquid water were placed in a cylinder under such a low pressure, it would vaporize immediately at temperatures above $-10^{\circ} \mathrm{C}$ or freeze at temperatures below $-10^{\circ} \mathrm{C}$.

## Experiment 3

Pressure is 4.58 torr. Again, we start with ice as the only component in the cylinder at $-20^{\circ} \mathrm{C}$. In this case the pressure exerted on the ice by the piston is 4.58 torr. As the cylinder is heated, no new phase appears until the temperature reaches $0.01^{\circ} \mathrm{C}$ (273.16 K). At this point, called the triple point, solid and liquid water have identical

FIGURE 10.50 The phase diagram for water. At point $X$ on the phase diagram, water is a solid. However, as the external pressure is increased while the temperature remains constant (indicated by the vertical dotted line), the solid/ liquid line is crossed and the ice melts.
vapor pressures of 4.58 torr. Thus at $0.01^{\circ} \mathrm{C}(273.16 \mathrm{~K})$ and 4.58 torr all three states of water are present. In fact, only under these conditions can all three states of water coexist in a closed system.

## Experiment 4

Pressure is 225 atm . In this experiment we start with liquid water in the cylinder at $300^{\circ} \mathrm{C}$; the pressure exerted by the piston on the water is 225 atm . Liquid water can be present at this temperature because of the high external pressure. As the temperature increases, something happens that we did not see in the first three experiments: The liquid gradually changes into a vapor but goes through an intermediate "fluid" region, which is neither true liquid nor vapor. This is quite unlike the behavior at lower temperatures and pressures, say at $100^{\circ} \mathrm{C}$ and 1 atm , where the temperature remains constant while a definite phase change from liquid to vapor occurs. This unusual behavior occurs because the conditions are beyond the critical point for water. The critical temperature can be defined as the temperature above which the vapor cannot be liquefied no matter what pressure is applied. The critical pressure is the pressure required to produce liquefaction at the critical temperature. Together, the critical temperature and the critical pressure define the critical point. For water the critical point is $374^{\circ} \mathrm{C}$ and 218 atm . Note that the liquid/vapor line on the phase diagram for water ends at the critical point. Beyond this point the transition from one state to another involves the intermediate "fluid" region just described.

## Applications of the Phase Diagram for Water

There are several additional interesting features of the phase diagram for water. Note that the solid/liquid boundary line has a negative slope. This means that the melting point of ice decreases as the external pressure increases. This behavior, which is opposite to that observed for most substances, occurs because the density of ice is less than that of liquid water at the melting point. The maximum density of water occurs at $4^{\circ} \mathrm{C}$; when liquid water freezes, its volume increases.

We can account for the effect of pressure on the melting point of water using the following reasoning. At the melting point, liquid and solid water coexist-they are in dynamic equilibrium, since the rate at which ice is melting is just balanced by the rate at which the water is freezing. What happens if we apply pressure to this system? When subjected to increased pressure, matter reduces its volume. This behavior is most dramatic for gases but also occurs for condensed states. Since a given mass of ice at $0^{\circ} \mathrm{C}$ has a larger volume than the same mass of liquid water, the system can reduce its volume in response to the increased pressure by changing to liquid. Thus at $0^{\circ} \mathrm{C}$ and an external pressure greater than 1 atm , water is liquid. In other words, the freezing point of water is less than $0^{\circ} \mathrm{C}$ when the pressure is greater than 1 atm .

Figure 10.50 illustrates the effect of pressure on ice. At the point $X$ on the phase diagram, ice is subjected to increased pressure at constant temperature. Note that as the pressure is increased, the solid/liquid line is crossed, indicating that the ice melts. This phenomenon may be important in ice skating. The narrow blade of the skate exerts a large pressure, since the skater's weight is supported by the small area of the blade. Also, the frictional heating due to the moving skate contributes to the melting of the ice.* After the blade passes, the liquid refreezes as normal pressure and temperature return. Without this lubrication effect due to the thawing ice, ice skating would not be the smooth, graceful activity that many people enjoy.

Ice's lower density has other implications. When water freezes in a pipe or an engine block, it will expand and break the container. This is why water pipes are insulated in cold climates and antifreeze is used in water-cooled engines. The lower

[^21]

FIGURE 10.51 The phase diagram for carbon dioxide. The liquid state does not exist at a pressure of 1 atm . The solid/ liquid line has a positive slope, since the density of solid carbon dioxide is greater than that of liquid carbon dioxide.

TABLE 10.11 | Boiling Point of Water at Various Locations

| Death Valley, Calif. | -282 | 770 | 100.3 |

density of ice also means that ice formed on rivers and lakes will float, providing a layer of insulation that helps prevent bodies of water from freezing solid in the winter. Aquatic life can therefore continue to live through periods of freezing temperatures.

A liquid boils at the temperature where the vapor pressure of the liquid equals the external pressure. Thus the boiling point of a substance, like the melting point, depends on the external pressure. This is why water boils at different temperatures at different elevations (Table 10.11), and any cooking carried out in boiling water will be affected by this variation. For example, it takes longer to hard-boil an egg in Leadville, Colorado (elevation: $10,150 \mathrm{ft}$ ), than in San Diego, California (sea level), since water boils at a lower temperature in Leadville.

> Ice is less dense than liquid water, as evidenced by the fact that ice floats in a glass of water. What if ice was more dense than liquid water? How would this affect the phase diagram for water?

As we mentioned earlier, the phase diagram for water describes a closed system. Therefore, we must be very cautious in using the phase diagram to explain the behavior of water in a natural setting, such as on the earth's surface. For example, in dry climates (low humidity), snow and ice seem to sublime-a minimum amount of slush is produced. Wet clothes put on an outside line at temperatures below $0^{\circ} \mathrm{C}$ freeze and then dry while frozen. However, the phase diagram (Fig. 10.46) shows that ice should not be able to sublime at normal atmospheric pressures. What is happening in these cases? Ice in the natural environment is not in a closed system. The pressure is provided by the atmosphere rather than by a solid piston. This means that the vapor produced over the ice can escape from the immediate region as soon as it is formed. The vapor does not come to equilibrium with the solid, and the ice slowly disappears. Sublimation, which seems forbidden by the phase diagram, does in fact occur under these conditions, although it is not the sublimation under equilibrium conditions described by the phase diagram.

## The Phase Diagram for Carbon Dioxide

The phase diagram for carbon dioxide (Fig. 10.51) differs from that for water. The solid/liquid line has a positive slope, since solid carbon dioxide is more dense than liquid carbon dioxide. The triple point for carbon dioxide occurs at 5.1 atm and $-56.6^{\circ} \mathrm{C}$, and the critical point occurs at 72.8 atm and $31^{\circ} \mathrm{C}$. At a pressure of 1 atm , solid carbon dioxide sublimes at $-78^{\circ} \mathrm{C}$, a property that leads to its common name, $d r y$

## CHEMICAL CONNECTIONS

## Making Diamonds at Low Pressures: Fooling Mother Nature

| n 1955 Robert H. Wentorf, Jr., accomplished something that borders on alchemy-he turned peanut butter into diamonds. He and his coworkers at the General Electric Research and Development Center also changed roofing pitch, wood, coal, and many other carbon-containing materials into diamonds, using a process involving temperatures of $\approx 2000^{\circ} \mathrm{C}$ and pressures of $\approx 10^{5} \mathrm{~atm}$. Although the first diamonds made by this process looked like black sand because of the impurities present, the process has now been developed to a point such that beautiful, clear, gem-quality diamonds can be produced. General Electric now has the capacity to produce 150 million carats ( $30,000 \mathrm{~kg}$ ) of diamonds annually (virtually all of which is "diamond grit" used for industrial purposes such as abrasive coatings on cutting tools). The production of large, gem-quality diamonds by this process is still too expensive to compete with the natural sources of these stones. However, this may change as methods are developed for making diamonds at low pressures.

The high temperatures and pressures used in the GE process for making diamonds make sense if one looks at the accompanying phase diagram for carbon. Note that graphite-not diamond-is the most stable form of carbon under ordinary conditions of temperature and pressure. However, diamond becomes more stable than graphite at very high pressures (as one would expect from the greater density of diamond). The high temperature used in the GE process is necessary to disrupt the bonds in graphite so that diamond (the most stable form of carbon at the high pressures used in the process) can form. Once the diamond is produced, the elemental
carbon is "trapped" in this form at normal conditions $\left(25^{\circ} \mathrm{C}, 1 \mathrm{~atm}\right)$ because the reaction back to the graphite form is so slow. That is, even though graphite is more stable than diamond at $25^{\circ} \mathrm{C}$ and 1 atm, diamond can exist almost indefinitely because the conversion to graphite is a very slow reaction. As a result, diamonds formed at the high pressures found deep in the earth's crust can be brought to the earth's surface by natural geologic processes and continue to exist for millions of years.*

We have seen that diamond formed in the laboratory at high pressures is "trapped" in this form, but this process is very expensive. Can diamond be formed at low pressures? The phase diagram for carbon says no. However, researchers have found that under the right conditions diamonds can be "grown" at low pressures. The process used is called chemical vapor deposition (CVD). CVD uses an energy source to release carbon atoms from a compound such as methane into a steady flow of hydrogen gas (some of which is dissociated to produce hydrogen atoms). The carbon atoms then deposit as a diamond film on a surface maintained at a temperature between 600 and $900^{\circ} \mathrm{C}$. Why does diamond form on this surface rather than the favored graphite? Nobody is sure, but it has

[^22]
been suggested that at these relatively high temperatures the diamond structure grows faster than the graphite structure, so diamond is favored under these conditions. It also has been suggested that the hydrogen atoms present react much faster with graphite fragments than with diamond fragments, effectively removing any graphite from the growing film. Once it forms, of course, diamond is trapped. The major advantage of CVD is that there is no need for the extraordinarily high pressures used in the traditional process for synthesizing diamonds.

The first products with diamond films are already on the market. Audiophiles can buy tweeters that have diaphragms coated with a thin diamond film that limits sound distortion. Watches with diamond-coated crystals are planned, as are diamond-coated windows in infrared scanning devices used in analytical instruments and missile-guidance systems. These applications represent only the beginning for diamond-coated products.

ice. No liquid phase occurs under normal atmospheric conditions, making dry ice a convenient refrigerant.

Carbon dioxide is often used in fire extinguishers, where it exists as a liquid at $25^{\circ} \mathrm{C}$ under high pressures. Liquid carbon dioxide released from the extinguisher into the environment at 1 atm immediately changes to a vapor. Being heavier than air, this vapor smothers the fire by keeping oxygen away from the flame. The liquid/vapor transition is highly endothermic, so cooling also results, which helps to put out the fire.

## The Difference Between Real and Ideal Gases

In Chapter 5 we discussed that no real gas exactly follows the ideal gas law, although many gases come very close at low pressure and/or high temperature. The van der Waals equation was developed to correct for the assumptions made in the kinetic molecular theory.

One assumption is that the particles of a gas are assumed to exert no forces on each other. We know that all gas particles exhibit attractive forces, termed intermolecular forces, and that the strength of these varies depending on the nature of the particles.

For example, consider $\mathrm{He}(g)$ and $\mathrm{H}_{2} \mathrm{O}(g)$. The helium atoms exhibit the relatively weak London dispersion forces, whereas water molecules exhibit the much stronger hydrogen bonding. We would expect, then, that helium gas would behave much more ideally than water vapor. This is supported by van der Waals constants. Recall that to account for the interparticle attractions of a gas, van der Waals added a correction factor to the observed pressure as follows:

$$
P_{\mathrm{ideal}}=P_{\mathrm{obs}}+a\left(\frac{n}{V}\right)^{2}
$$

Because gas particles attract one another, the particles will collide with the walls of the container slightly less often than they would ideally, so we need to add a correction factor to make up for this. Although the constant $a$ in the correction factor was empirically determined by van der Waals, it turns out that the values of this constant generally serve as indexes of the strength of the intermolecular forces exhibited by the gas particles. For example, the value for the constant $a$ for helium is 0.034 , whereas that of water is 5.46 . Thus, the correction factor for water, which exhibits hydrogen bonding, is much greater than that of helium, which exhibits the much weaker London dispersion forces.

Because the particles attract each other, we can surmise that at sufficiently low temperatures (or high pressures) the gas will condense. This behavior is demonstrated by considering a plot of pressure versus volume for a real gas at various temperatures.

A plot of $P$ versus $V$ for a gas behaving ideally is a hyperbola, as shown in Fig. 5.5. The shape of this plot will not change at different temperatures. But for a real gas, this is not the case.

Recall that the critical temperature $\left(T_{\mathrm{c}}\right)$ of a substance is the temperature above which the vapor cannot be liquefied no matter what pressure is applied. Let's look at how the $P$ versus $V$ plot changes for a real gas at temperatures above, at, and below the critical temperature.

Note that at temperatures above the critical temperature, the plots looks similar to that of an ideal gas, although the shape changes as the temperature is lowered. At the critical temperature there is an inflection point, called the critical point (labeled $C_{\mathrm{p}}$ in Fig. 10.52). Below the critical temperature we can see that there is a region where the pressure decreases with decreasing volume. This is because the gas is condensing. In the region between points 1 and 2, the substance is in liquid/vapor equilibrium. At volumes below 1 , only liquid remains and the pressure increases as the liquid is compressed.

## For Review

## Key terms

Section 10.1
condensed states intermolecular forces dipole-dipole attraction hydrogen bonding London dispersion forces

Section 10.2
surface tension
capillary action
viscosity
Section 10.3
crystalline solid
amorphous solid
lattice
unit cell
X-ray diffraction ionic solid
molecular solid
atomic solid

## Condensed states of matter: liquids and solids

) Held together by forces among the component molecules, atoms, or ions
) Liquids exhibit properties such as surface tension, capillary action, and viscosity that depend on the forces among the components

## Dipole-dipole forces

) Attractions among molecules with dipole moments
) Hydrogen bonding is a particularly strong form of dipole-dipole attraction
> Occurs in molecules containing hydrogen bonded to a highly electronegative element such as nitrogen, oxygen, or fluorine
) Produces unusually high boiling points

## London dispersion forces

) Caused by instantaneous dipoles that form in atoms or nonpolar molecules

## Crystalline solids

> Have a regular arrangement of components often represented as a lattice; the smallest repeating unit of the lattice is called the unit cell
> Classified by the types of components:
> Atomic solids (atoms)
> Ionic solids (ions)
> Molecular solids (molecules)
) Arrangement of the components can be determined by X-ray analysis

## Key terms

Section 10.4
closest packing
hexagonal closest packed
(hcp) structure
cubic closest packed (ccp) structure
band model
molecular orbital (MO) model
alloy
substitutional alloy
interstitial alloy
Section 10.5

critical point

## Metals

> Structure is modeled by assuming atoms to be uniform spheres
> Closest packing
) Hexagonal
> Cubic
) Metallic bonding can be described in terms of two models
) Electron sea model: valence electrons circulate freely among the metal cations
) Band model: electrons are assumed to occupy molecular orbitals
> Conduction bands: closely spaced molecular orbitals with empty electron spaces
> Alloys: mixtures with metallic properties
) Substitutional
> Interstitial

## Network solids

) Contain giant networks of atoms covalently bound together
) Examples are diamond and graphite
> Silicates are network solids containing $\mathrm{Si}-\mathrm{O}-\mathrm{Si}$ bridges that form the basis for many rocks, clays, and ceramics

## Semiconductors

> Very pure silicon is "doped" with other elements
> n-type: doping atoms typically contain five valence electrons (one more than silicon)
> p-type: doping elements typically contain three valence electrons
> Modern electronics are based on devices with p-n junctions

## Molecular solids

> Components are discrete molecules
> Intermolecular forces are typically weak, leading to relatively low boiling and melting points

## Ionic solids

> Components are ions
> Interionic forces are relatively strong, leading to solids with high melting and boiling points
> Many structures consist of closest packing of the larger ions with the smaller ions in tetrahedral or octahedral holes

## Phase changes

) The change from liquid to gas (vapor) is called vaporization or evaporation
) Condensation is the reverse of vaporization
) Equilibrium vapor pressure: the pressure that occurs over a liquid or solid in a closed system when the rate of evaporation equals the rate of condensation
> Liquids whose components have high intermolecular forces have relatively low vapor pressures
> Normal boiling point: the temperature at which the vapor pressure of a liquid equals one atmosphere
> Normal melting point: the temperature at which a solid and its liquid have the same vapor pressure (at 1 atm external pressure)
) Phase diagram
) Shows what state exists at a given temperature and pressure in a closed system
) Triple point: temperature at which all three phases exist simultaneously
) Critical point: defined by the critical temperature and pressure
> Critical temperature: the temperature above which the vapor cannot be liquefied no matter the applied pressure

## Review Questions Answers to the Review Questions can be found on the Student website (accessible from www.cengagebrain.com).

1. What are intermolecular forces? How do they differ from intramolecular forces? What are dipole-dipole forces? How do typical dipole-dipole forces differ from hydrogen bonding interactions? In what ways are they similar? What are London dispersion forces? How do typical London dispersion forces differ from dipoledipole forces? In what ways are they similar? Describe the relationship between molecular size and strength of London dispersion forces. Place the major types of intermolecular forces in order of increasing strength. Is there some overlap? That is, can the strongest London dispersion forces be greater than some dipole-dipole forces? Give an example of such an instance.
2. Define the following terms, and describe how each depends on the strength of the intermolecular forces.
a. surface tension
b. viscosity
c. melting point
d. boiling point
e. vapor pressure
3. Compare and contrast solids, liquids, and gases.
4. Distinguish between the items in the following pairs.
a. crystalline solid; amorphous solid
b. ionic solid; molecular solid
c. molecular solid; network solid
d. metallic solid; network solid
5. What is a lattice? What is a unit cell? Describe a simple cubic unit cell. How many net atoms are contained in a simple cubic unit cell? How is the radius of the atom related to the cube edge length for a simple cubic unit cell? Answer the same questions for the body-centered cubic unit cell and for the face-centered unit cell.
6. What is closest packing? What is the difference between hexagonal closest packing and cubic closest packing? What is the unit cell for each closest packing?
7. Use the band model to describe differences among insulators, conductors, and semiconductors. Also use the band model to explain why each of the following increases the conductivity of a semiconductor.
a. increasing the temperature
b. irradiating with light
c. adding an impurity

How do conductors and semiconductors differ as to the effect of temperature on electrical conductivity? How can an n-type semiconductor be produced from pure germanium? How can a p-type semiconductor be produced from pure germanium?
8. Describe, in general, the structures of ionic solids. Compare and contrast the structure of sodium chloride and zinc sulfide. How many tetrahedral holes and octahedral holes are there per closest packed anion? In zinc sulfide, why are only one-half of the tetrahedral holes filled with cations?
9. Define each of the following.
a. evaporation
b. condensation
c. sublimation
d. boiling
e. melting
f. enthalpy of vaporization
g. enthalpy of fusion
h. heating curve
10. Why is the enthalpy of vaporization for water much greater than its enthalpy of fusion? What does this say about the changes in intermolecular forces in going from solid to liquid to vapor? What do we mean when we say that a liquid is volatile? Do volatile liquids have large or small vapor pressures at room temperature? What strengths of intermolecular forces occur in highly volatile liquids?
11. Compare and contrast the phase diagrams of water and carbon dioxide. Why doesn't $\mathrm{CO}_{2}$ have a normal melting point and a normal boiling point, whereas water does? The slopes of the solid-liquid lines in the phase diagrams of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ are different. What do the slopes of the solid-liquid lines indicate in terms of the relative densities of the solid and liquid states for each substance? How do the melting points of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ depend on pressure? How do the boiling points of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ depend on pressure? Rationalize why the critical temperature for $\mathrm{H}_{2} \mathrm{O}$ is greater than that for $\mathrm{CO}_{2}$.

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. It is possible to balance a paper clip on the surface of water in a beaker. If you add a bit of soap to the water, however, the paper clip sinks. Explain how the paper clip can float and why it sinks when soap is added.
2. Consider a sealed container half-filled with water. Which statement best describes what occurs in the container?
a. Water evaporates until the air is saturated with water vapor; at this point, no more water evaporates.
b. Water evaporates until the air is overly saturated (supersaturated) with water, and most of this water recondenses; this cycle continues until a certain amount of water vapor is present, and then the cycle ceases.
c. Water does not evaporate because the container is sealed.
d. Water evaporates, and then water evaporates and recondenses simultaneously and continuously.
e. Water evaporates until it is eventually all in vapor form.

Explain each choice. Justify your choice, and for choices you did not pick, explain what is wrong with them.
3. Explain the following: You add 100 mL water to a $500-\mathrm{mL}$ round-bottom flask and heat the water until it is boiling. You remove the heat and stopper the flask, and the boiling stops. You then run cool water over the neck of the flask, and the boiling begins again. It seems as though you are boiling water by cooling it.
4. Is it possible for the dispersion forces in a particular substance to be stronger than the hydrogen bonding forces in another substance? Explain your answer.
5. Does the nature of intermolecular forces change when a substance goes from a solid to a liquid, or from a liquid to a gas? What causes a substance to undergo a phase change?
6. Why do liquids have a vapor pressure? Do all liquids have vapor pressures? Explain. Do solids exhibit vapor pressure? Explain. How does vapor pressure change with changing temperature? Explain.
7. Water in an open beaker evaporates over time. As the water is evaporating, is the vapor pressure increasing, decreasing, or staying the same? Why?
8. What is the vapor pressure of water at $100^{\circ} \mathrm{C}$ ? How do you know?
9. Refer to Fig. 10.43. Why doesn't temperature increase continuously over time? That is, why does the temperature stay constant for periods of time?
10. Which are stronger, intermolecular or intramolecular forces for a given molecule? What observation(s) have you made that support this? Explain.
11. Why does water evaporate?
12. Why is $\mathrm{N}_{2}$ a gas at room temperature? Explain why lowering the temperature allows for liquid $\mathrm{N}_{2}$ to form.
13. White phosphorus and sulfur are both labeled molecular solids even though each is made of only phosphorus and sulfur, respectively. Why are they molecular solids? Why isn't diamond (which is made up of only carbon) a molecular solid?

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

14. The nonpolar hydrocarbon $\mathrm{C}_{25} \mathrm{H}_{52}$ is a solid at room temperature. Its boiling point is greater than $400^{\circ} \mathrm{C}$. Which has the stronger intermolecular forces, $\mathrm{C}_{25} \mathrm{H}_{52}$ or $\mathrm{H}_{2} \mathrm{O}$ ? Explain.
15. In the diagram below, which lines represent the hydrogen bonding?

a. the dotted lines between the hydrogen atoms of one water molecule and the oxygen atoms of a different water molecule
b. the solid lines between a hydrogen atom and oxygen atom in the same water molecule
c. Both the solid lines and dotted lines represent hydrogen bonding.
d. There are no hydrogen bonds represented in the diagram.
16. Hydrogen bonding is a special case of very strong dipoledipole interactions possible among only certain atoms. What atoms in addition to hydrogen are necessary for hydrogen bonding? How does the small size of the hydrogen atom contribute to the unusual strength of the dipole-dipole forces involved in hydrogen bonding?
17. Which gas, CO or $\mathrm{N}_{2}$, is expected to behave more ideally at 10 atm and $-50^{\circ} \mathrm{C}$ ?
18. The conductivity of silicon is enhanced by doping. What is doping?
19. Atoms are assumed to touch in closest packed structures, yet every closest packed unit cell contains a significant amount of empty space. Why?
20. Define critical temperature and critical pressure. In terms of the kinetic molecular theory, why is it impossible for a substance to exist as a liquid above its critical temperature?
21. What is an alloy? Explain the differences in structure between substitutional and interstitial alloys. Give an example of each type.
22. Describe what is meant by a dynamic equilibrium in terms of the vapor pressure of a liquid.
23. How does each of the following affect the rate of evaporation of a liquid in an open dish?
a. intermolecular forces
b. temperature
c. surface area
24. A common response to hearing that the temperature in New Mexico is $105^{\circ} \mathrm{F}$ is, "It's not that bad; it's a dry heat," whereas at the same time the summers in Atlanta, Georgia, are characterized as "dreadful," even though the air temperature is typically lower. What role does humidity play in how our bodies regulate temperature?
25. When a person has a severe fever, one therapy used to reduce the fever is an "alcohol rub." Explain how the evaporation of alcohol from a person's skin removes heat energy from the body.
26. Why is a burn from steam typically much more severe than a burn from boiling water?
27. When wet laundry is hung on a clothesline on a cold winter day, it will freeze but eventually dry. Explain.
28. Packaged foods that require cooking in boiling water often contain special directions for use at high elevations. Typically these directions indicate that the food should be cooked longer above 5000 ft . Explain why it takes longer to cook something at higher elevations.
29. You have three covalent compounds with three very different boiling points. All of the compounds have similar molar mass and relative shape. Explain how these three compounds could have very different boiling points.
30. Compare and contrast the structures of the following solids.
a. diamond versus graphite
b. silica versus silicates versus glass
31. Compare and contrast the structures of the following solids.
a. $\mathrm{CO}_{2}(s)$ versus $\mathrm{H}_{2} \mathrm{O}(s)$
b. $\mathrm{NaCl}(s)$ versus $\mathrm{CsCl}(s)$; see Exercise 71 for the structures.
32. Silicon carbide $(\mathrm{SiC})$ is an extremely hard substance that acts as an electrical insulator. Propose a structure for SiC .
33. Rationalize why chalk (calcium carbonate) has a higher melting point than motor oil (composed of large compounds containing only carbon and hydrogen), which has a higher melting point than water (a compound that exhibits hydrogen bonding).
34. A common prank on college campuses is to switch the salt and sugar on dining hall tables, which is usually easy because the substances look so much alike. Yet, despite the similarity in their appearance, these two substances differ greatly in their properties, since one is a molecular solid and the other is an ionic solid. How do the properties differ and why?
35. A plot of $\ln \left(P_{\text {vap }}\right)$ versus $1 / T(\mathrm{~K})$ is linear with a negative slope. Why is this the case?
36. Iodine, like most substances, exhibits only three phases: solid, liquid, and vapor. The triple point of iodine is at 90 torr and $115^{\circ} \mathrm{C}$. Which of the following statements concerning liquid $\mathrm{I}_{2}$ must be true? Explain your answer.
a. $\mathrm{I}_{2}(l)$ is more dense than $\mathrm{I}_{2}(g)$.
b. $\mathrm{I}_{2}(l)$ cannot exist above $115^{\circ} \mathrm{C}$.
c. $\mathrm{I}_{2}(l)$ cannot exist at 1 atmosphere pressure.
d. $\mathrm{I}_{2}(l)$ cannot have a vapor pressure greater than 90 torr.
e. $\mathrm{I}_{2}(l)$ cannot exist at a pressure of 10 torr.

## Exercises

In this section similar exercises are paired.

## Intermolecular Forces and Physical Properties

Identify the most important types of interparticle forces present in the solids of each of the following substances.
a. Ar
b. HCl
c. HF
d. $\mathrm{CaCl}_{2}$
e. $\mathrm{CH}_{4}$
f. CO
g. $\mathrm{NaNO}_{3}$
38. Identify the most important types of interparticle forces present in the solids of each of the following substances.
a. $\mathrm{BaSO}_{4}$
e. CsI
b. $\mathrm{H}_{2} \mathrm{~S}$
f. $\mathrm{P}_{4}$
c. Xe
g. $\mathrm{NH}_{3}$
d. $\mathrm{C}_{2} \mathrm{H}_{6}$
-39. Predict which substance in each of the following pairs would have the greater intermolecular forces.
a. $\mathrm{CO}_{2}$ or OCS
b. $\mathrm{SeO}_{2}$ or $\mathrm{SO}_{2}$
c. $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$ or $\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$
d. $\mathrm{CH}_{3} \mathrm{CH}_{3}$ or $\mathrm{H}_{2} \mathrm{CO}$
e. $\mathrm{CH}_{3} \mathrm{OH}$ or $\mathrm{H}_{2} \mathrm{CO}$
40. Consider the compounds $\mathrm{Cl}_{2}, \mathrm{HCl}, \mathrm{F}_{2}, \mathrm{NaF}$, and HF. Which compound has a boiling point closest to that of argon? Explain.
41. Rationalize the difference in boiling points for each of the following pairs of substances:
a. $\mathrm{Ar} \quad-186^{\circ} \mathrm{C}$
$\mathrm{HCl} \quad-85^{\circ} \mathrm{C}$
b. $\mathrm{HF} \quad 20^{\circ} \mathrm{C}$
$\mathrm{HCl} \quad-85^{\circ} \mathrm{C}$
c. $\mathrm{HCl} \quad-85^{\circ} \mathrm{C}$
$\mathrm{LiCl} \quad 1360^{\circ} \mathrm{C}$
d. n-pentane $\quad \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3} \quad 36.2^{\circ} \mathrm{C}$ $n$-hexane $\quad \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3} \quad 69^{\circ} \mathrm{C}$
42. Consider the following electrostatic potential diagrams:

Rank the compounds from lowest to highest boiling point and explain your answer.
43. In each of the following groups of substances, pick the one that has the given property. Justify your answer.
a. highest boiling point: $\mathrm{HBr}, \mathrm{Kr}$, or $\mathrm{Cl}_{2}$
b. highest freezing point: $\mathrm{H}_{2} \mathrm{O}, \mathrm{NaCl}$, or HF
c. lowest vapor pressure at $25^{\circ} \mathrm{C}: \mathrm{Cl}_{2}, \mathrm{Br}_{2}$, or $\mathrm{I}_{2}$
d. lowest freezing point: $\mathrm{N}_{2}, \mathrm{CO}$, or $\mathrm{CO}_{2}$
e. lowest boiling point: $\mathrm{CH}_{4}, \mathrm{CH}_{3} \mathrm{CH}_{3}$, or $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}$
f. highest boiling point: $\mathrm{HF}, \mathrm{HCl}$, or HBr
g. lowest vapor pressure at $25^{\circ} \mathrm{C}: \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}, \mathrm{CH}_{3} \mathrm{CCH}_{3}$,
44. In each of the following groups of substances, pick the one that has the given property. Justify each answer.
a. highest boiling point: $\mathrm{CCl}_{4}, \mathrm{CF}_{4}, \mathrm{CBr}_{4}$
b. lowest freezing point: $\mathrm{LiF}, \mathrm{F}_{2}, \mathrm{HCl}$
c. smallest vapor pressure at $25^{\circ} \mathrm{C}: \mathrm{CH}_{3} \mathrm{OCH}_{3}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}$
d. greatest viscosity: $\mathrm{H}_{2} \mathrm{~S}, \mathrm{HF}, \mathrm{H}_{2} \mathrm{O}_{2}$
e. greatest heat of vaporization: $\mathrm{H}_{2} \mathrm{CO}, \mathrm{CH}_{3} \mathrm{CH}_{3}, \mathrm{CH}_{4}$
f. smallest enthalpy of fusion: $\mathrm{I}_{2}, \mathrm{CsBr}, \mathrm{CaO}$

## Properties of Liquids

-45. The shape of the meniscus of water in a glass tube is different from that of mercury in a glass tube. Why?

Hg in glass
46. Explain why water forms into beads on a waxed car finish.
47. Hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$ is a syrupy liquid with a relatively low vapor pressure and a normal boiling point of $152.2^{\circ} \mathrm{C}$. Rationalize the differences of these physical properties from those of water.
48. Carbon diselenide $\left(\mathrm{CSe}_{2}\right)$ is a liquid at room temperature. The normal boiling point is $125^{\circ} \mathrm{C}$, and the melting point is $-45.5^{\circ} \mathrm{C}$. Carbon disulfide $\left(\mathrm{CS}_{2}\right)$ is also a liquid at room temperature with normal boiling and melting points of $46.5^{\circ} \mathrm{C}$ and $-111.6^{\circ} \mathrm{C}$, respectively. How do the strengths of the intermolecular forces vary from $\mathrm{CO}_{2}$ to $\mathrm{CS}_{2}$ to $\mathrm{CSe}_{2}$ ? Explain.

## Structures and Properties of Solids

49. X rays from a copper X-ray tube ( $\lambda=154 \mathrm{pm}$ ) were diffracted at an angle of 14.22 degrees by a crystal of silicon. Assuming first-order diffraction ( $n=1$ in the Bragg equation), what is the interplanar spacing in silicon?
50. The second-order diffraction $(n=2)$ for a gold crystal is at an angle of $22.20^{\circ}$ for $X$ rays of 154 pm . What is the spacing between these crystal planes?
-51. A topaz crystal has an interplanar spacing $(d)$ of $1.36 \AA$ $\left(1 \AA=1 \times 10^{-10} \mathrm{~m}\right)$. Calculate the wavelength of the X ray that should be used if $\theta=15.0^{\circ}$ (assume $n=1$ ).
51. $X$ rays of wavelength $2.63 \AA$ were used to analyze a crystal. The angle of first-order diffraction ( $n=1$ in the Bragg equation) was 15.55 degrees. What is the spacing between crystal planes, and what would be the angle for second-order diffraction $(n=2)$ ?
-53. Calcium has a cubic closest packed structure as a solid. Assuming that calcium has an atomic radius of 197 pm , calculate the density of solid calcium.
52. Nickel has a face-centered cubic unit cell. The density of nickel is $6.84 \mathrm{~g} / \mathrm{cm}^{3}$. Calculate a value for the atomic radius of nickel.
-55. A certain form of lead has a cubic closest packed structure with an edge length of 492 pm . Calculate the value of the atomic radius and the density of lead.
53. The density of polonium metal is $9.2 \mathrm{~g} / \mathrm{cm}^{3}$. If the extended lattice of polonium exhibits a simple cubic unit cell, estimate the atomic radius of polonium.
-57. You are given a small bar of an unknown metal X. You find the density of the metal to be $10.5 \mathrm{~g} / \mathrm{cm}^{3}$. An X-ray diffraction experiment measures the edge of the face-centered cubic unit cell as $4.09 \AA\left(1 \AA=10^{-10} \mathrm{~m}\right)$. Identify X .
54. A metallic solid with atoms in a face-centered cubic unit cell with an edge length of 392 pm has a density of $21.45 \mathrm{~g} / \mathrm{cm}^{3}$. Calculate the atomic mass and the atomic radius of the metal. Identify the metal.
55. Titanium metal has a body-centered cubic unit cell. The density of titanium is $4.50 \mathrm{~g} / \mathrm{cm}^{3}$. Calculate the edge length of the unit cell and a value for the atomic radius of titanium. (Hint: In a body-centered arrangement of spheres, the spheres touch across the body diagonal.)
56. Barium has a body-centered cubic structure. If the atomic radius of barium is 222 pm , calculate the density of solid barium.
-61. The radius of gold is 144 pm , and the density is $19.32 \mathrm{~g} / \mathrm{cm}^{3}$. Does elemental gold have a face-centered cubic structure or a body-centered cubic structure?
57. The radius of tungsten is 137 pm and the density is $19.3 \mathrm{~g} / \mathrm{cm}^{3}$. Does elemental tungsten have a face-centered cubic structure or a body-centered cubic structure?
-63. What fraction of the total volume of a cubic closest packed structure is occupied by atoms? (Hint: $V_{\text {sphere }}=\frac{4}{3} \pi r^{3}$.) What fraction of the total volume of a simple cubic structure is occupied by atoms? Compare the answers.
58. Iron has a density of $7.86 \mathrm{~g} / \mathrm{cm}^{3}$ and crystallizes in a bodycentered cubic lattice. Show that only $68 \%$ of a body-centered lattice is actually occupied by atoms, and determine the atomic radius of iron.
59. Explain how doping silicon with either phosphorus or gallium increases the electrical conductivity over that of pure silicon.
60. Explain how a p-n junction makes an excellent rectifier.
61. Selenium is a semiconductor used in photocopying machines. What type of semiconductor would be formed if a small amount of indium impurity is added to pure selenium?
62. The Group 3A/Group 5A semiconductors are composed of equal amounts of atoms from Group 3A and Group 5A-for example, InP and GaAs. These types of semiconductors are used in light-emitting diodes and solid-state lasers. What would you add to make a p-type semiconductor from pure GaAs? How would you dope pure GaAs to make an n-type semiconductor?
63. The band gap in aluminum phosphide (AlP) is 2.5 electronvolts ( $\left.1 \mathrm{eV}=1.6 \times 10^{-19} \mathrm{~J}\right)$. What wavelength of light is emitted by an AlP diode?
64. An aluminum antimonide solid-state laser emits light with a wavelength of $730 . \mathrm{nm}$. Calculate the band gap in joules.
-71. The structures of some common crystalline substances are shown below. Show that the net composition of each unit cell corresponds to the correct formula of each substance.

$\mathrm{Cl} \bigcirc \mathrm{Na}$

S ○ Zn

72. The unit cell for nickel arsenide is shown below. What is the formula of this compound?

-73. Cobalt fluoride crystallizes in a closest packed array of fluoride ions with the cobalt ions filling one-half of the octahedral holes. What is the formula of this compound?
74. The compounds $\mathrm{Na}_{2} \mathrm{O}, \mathrm{CdS}$, and $\mathrm{ZrI}_{4}$ all can be described as cubic closest packed anions with the cations in tetrahedral holes. What fraction of the tetrahedral holes is occupied for each case?

- 75. What is the formula for the compound that crystallizes with a cubic closest packed array of sulfur ions, and that contains zinc ions in $\frac{1}{8}$ of the tetrahedral holes and aluminum ions in $\frac{1}{2}$ of the octahedral holes?

76. Assume the two-dimensional structure of an ionic compound, $\mathrm{M}_{x} \mathrm{~A}_{y}$, is

What is the empirical formula of this ionic compound?
[77. A certain metal fluoride crystallizes in such a way that the fluoride ions occupy simple cubic lattice sites, while the metal ions occupy the body centers of half the cubes. What is the formula of the metal fluoride?
78. The structure of rhenium oxide can best be described as a simple cubic array of rhenium ions with the oxide ions at the center of each edge of the cubic unit cell. What is the charge of the rhenium ion in this compound?
[79. The unit cell of MgO is shown below.

Does MgO have a structure like that of NaCl or ZnS ? If the density of MgO is $3.58 \mathrm{~g} / \mathrm{cm}^{3}$, estimate the radius (in centimeters) of the $\mathrm{O}^{2-}$ anions and the $\mathrm{Mg}^{2+}$ cations.
80. In solid KCl the smallest distance between the centers of a potassium ion and a chloride ion is 314 pm . Calculate the length of the edge of the unit cell and the density of KCl , assuming it has the same structure as sodium chloride.
-81. The CsCl structure is a simple cubic array of chloride ions with a cesium ion at the center of each cubic array (see Exercise 71 ). Given that the density of cesium chloride is $3.97 \mathrm{~g} /$ $\mathrm{cm}^{3}$, and assuming that the chloride and cesium ions touch along the body diagonal of the cubic unit cell, calculate the distance between the centers of adjacent $\mathrm{Cs}^{+}$and $\mathrm{Cl}^{-}$ions in the solid. Compare this value with the expected distance based on the sizes of the ions. The ionic radius of $\mathrm{Cs}^{+}$is 169 pm , and the ionic radius of $\mathrm{Cl}^{-}$is 181 pm .
82. MnO has either the NaCl type structure or the CsCl type structure (see Exercise 71). The edge length of the MnO unit cell is $4.47 \times 10^{-8} \mathrm{~cm}$ and the density of MnO is $5.28 \mathrm{~g} / \mathrm{cm}^{3}$.
a. Does MnO crystallize in the NaCl or the CsCl type structure?
b. Assuming that the ionic radius of oxygen is 140 . pm, estimate the ionic radius of manganese.
-83. What type of solid will each of the following substances form?
a. $\mathrm{CO}_{2}$
g. KBr
b. $\mathrm{SiO}_{2}$
h. $\mathrm{H}_{2} \mathrm{O}$
c. Si
i. NaOH
d. $\mathrm{CH}_{4}$
j. U
e. Ru
k. $\mathrm{CaCO}_{3}$
f. $\mathrm{I}_{2}$
l. $\mathrm{PH}_{3}$
84. What type of solid will each of the following substances form?
a. diamond
g. $\mathrm{NH}_{4} \mathrm{NO}_{3}$
b. $\mathrm{PH}_{3}$
h. $\mathrm{SF}_{2}$
c. $\mathrm{H}_{2}$
i. Ar
d. Mg
j. Cu
e. KCl
k. $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$
f. quartz
-85. The memory metal, nitinol, is an alloy of nickel and titanium. It is called a memory metal because after being deformed, a piece of nitinol wire will return to its original shape. The structure of nitinol consists of a simple cubic array of Ni atoms and an inner penetrating simple cubic array of Ti atoms. In the extended lattice, a Ti atom is found at the center of a cube of Ni atoms; the reverse is also true.
a. Describe the unit cell for nitinol.
b. What is the empirical formula of nitinol?
c. What are the coordination numbers (number of nearest neighbors) of Ni and Ti in nitinol?
86. Superalloys have been made of nickel and aluminum. The alloy owes its strength to the formation of an ordered phase, called the gamma-prime phase, in which Al atoms are at the corners of a cubic unit cell and Ni atoms are at the face centers. What is the composition (relative numbers of atoms) for this phase of the nickel-aluminum superalloy?
87. Perovskite is a mineral containing calcium, titanium, and oxygen. Two different representations of the unit cell are shown below. Show that both these representations give the same formula and the same number of oxygen atoms around each titanium atom.

88. A mineral crystallizes in a cubic closest packed array of oxygen ions with aluminum ions in some of the octahedral holes and magnesium ions in some of the tetrahedral holes. Deduce the formula of this mineral and predict the fraction of octahedral holes and tetrahedral holes that are filled by the various cations.
89. Materials containing the elements $\mathrm{Y}, \mathrm{Ba}, \mathrm{Cu}$, and O that are superconductors (electrical resistance equals zero) at temperatures above that of liquid nitrogen were recently discovered. The structures of these materials are based on the perovskite structure. Were they to have the ideal perovskite structure, the superconductor would have the structure shown in part (a) of the following figure.

(a) Ideal perovskite structure
(b) Actual structure of superconductor
a. What is the formula of this ideal perovskite material?
b. How is this structure related to the perovskite structure shown in Exercise 87?
These materials, however, do not act as superconductors unless they are deficient in oxygen. The structure of the actual superconducting phase appears to be that shown in part (b) of the figure.
c. What is the formula of this material?
90. The structures of another class of ceramic, high-temperature superconductors are shown in the following figure.
a. Determine the formula of each of these four superconductors.
b. One of the structural features that appears to be essential for high-temperature superconductivity is the presence of planar sheets of copper and oxygen atoms. As the number of sheets in each unit cell increases, the temperature for the onset of superconductivity increases. Order the four structures from lowest to the highest superconducting temperature.
c. Assign oxidation states to Cu in each structure assuming Tl exists as $\mathrm{Tl}^{3+}$. The oxidation states of $\mathrm{Ca}, \mathrm{Ba}$, and O are assumed to be $+2,+2$, and -2 , respectively.
d. It also appears that copper must display a mixture of oxidation states for a material to exhibit superconductivity. Explain how this occurs in these materials as well as in the superconductor in Exercise 89.

## Phase Changes and Phase Diagrams

91. Plot the following data and determine $\Delta H_{\text {vap }}$ for magnesium and lithium. In which metal is the bonding stronger?

| Vapor Pressure <br> $(\mathrm{mm} \mathrm{Hg})$ | Temperature $\left({ }^{\circ} \mathrm{C}\right)$ |  |
| :---: | :---: | :---: |
|  | Li | $\mathbf{M g}$ |
| 1. | 750. | 620. |
| 10. | 890. | 740. |
| 100. | 1080. | 900. |
| 400. | 1240. | 1040. |
| 760. | 1310. | 1110. |
|  |  |  |

92. From the following data for liquid nitric acid, determine its heat of vaporization and normal boiling point.

| Temperature <br> $\left({ }^{\circ} \mathrm{C}\right)$ | Vapor Pressure <br> $(\mathrm{mm} \mathrm{Hg})$ |
| :---: | :---: |
| 0. | 14.4 |
| 10. | 26.6 |
| 20. | 47.9 |
| 30. | 81.3 |
| 40. | 133 |
| 50. | 208 |
| 80. | 670. |

-93. In Breckenridge, Colorado, the typical atmospheric pressure is 520 . torr. What is the boiling point of water $\left(\Delta H_{\text {vap }}=\right.$ $40.7 \mathrm{~kJ} / \mathrm{mol}$ ) in Breckenridge?
94. The temperature inside a pressure cooker is $115^{\circ} \mathrm{C}$. Calculate the vapor pressure of water inside the pressure cooker. What would be the temperature inside the pressure cooker if the vapor pressure of water was 3.50 atm ?
95. Diethyl ether $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{3}\right)$ was one of the first chemicals used as an anesthetic. At $34.6^{\circ} \mathrm{C}$, diethyl ether has a vapor pressure of 760 . torr, and at $17.9^{\circ} \mathrm{C}$, it has a vapor pressure of 400. torr. What is the $\Delta H$ of vaporization for diethyl ether?
96. Mercury is the only metal that is a liquid at room temperature. When mercury vapor is inhaled, it is readily absorbed by the lungs, causing significant health risks. The enthalpy of vaporization of mercury is $59.1 \mathrm{~kJ} / \mathrm{mol}$. The normal boiling point of mercury is $357^{\circ} \mathrm{C}$. What is the vapor pressure of mercury at $25^{\circ} \mathrm{C}$ ?
-97. A substance, X, has the following properties:

Sketch a heating curve for substance X starting at $-50 .{ }^{\circ} \mathrm{C}$.
98. Use the heating-cooling curve below to answer the following questions.

a. What is the freezing point of the liquid?
b. What is the boiling point of the liquid?
c. Which is greater, the heat of fusion or the heat of vaporization? Explain each term and explain how the heatingcooling curve above helps you to answer the question.
99. The molar heat of fusion of sodium metal is $2.60 \mathrm{~kJ} / \mathrm{mol}$, whereas its heat of vaporization is $97.0 \mathrm{~kJ} / \mathrm{mol}$.
a. Why is the heat of vaporization so much larger than the heat of fusion?
b. What quantity of heat would be needed to melt 1.00 g sodium at its normal melting point?
c. What quantity of heat would be needed to vaporize 1.00 g sodium at its normal boiling point?
d. What quantity of heat would be evolved if 1.00 g sodium vapor condensed at its normal boiling point?
100. The molar heat of fusion of benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ is $9.92 \mathrm{~kJ} / \mathrm{mol}$. Its molar heat of vaporization is $30.7 \mathrm{~kJ} / \mathrm{mol}$. Calculate the heat required to melt 8.25 g benzene at its normal melting point. Calculate the heat required to vaporize 8.25 g benzene at its normal boiling point. Why is the heat of vaporization more than three times the heat of fusion?
-101. What quantity of energy does it take to convert 0.500 kg ice at $-20.0^{\circ} \mathrm{C}$ to steam at $250.0^{\circ} \mathrm{C}$ ? Specific heat capacities: ice, $2.03 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$; liquid, $4.18 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$; steam, $2.02 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$; $\Delta H_{\text {vap }}=40.7 \mathrm{~kJ} / \mathrm{mol} ; \Delta H_{\text {fus }}=6.02 \mathrm{~kJ} / \mathrm{mol}$.
102. What quantity of energy is needed to heat a 1.00 -mole sample of $\mathrm{H}_{2} \mathrm{O}$ from $-30.0^{\circ} \mathrm{C}$ to $140.0^{\circ} \mathrm{C}$ ? (see Exercise 101)
-103. An ice cube tray contains enough water at $22.0^{\circ} \mathrm{C}$ to make 18 ice cubes that each has a mass of 30.0 g . The tray is placed in a freezer that uses $\mathrm{CF}_{2} \mathrm{Cl}_{2}$ as a refrigerant. The heat of vaporization of $\mathrm{CF}_{2} \mathrm{Cl}_{2}$ is $158 \mathrm{~J} / \mathrm{g}$. What mass of $\mathrm{CF}_{2} \mathrm{Cl}_{2}$ must be vaporized in the refrigeration cycle to convert all the water at $22.0^{\circ} \mathrm{C}$ to ice at $-5.0^{\circ} \mathrm{C}$ ? The heat capacities for $\mathrm{H}_{2} \mathrm{O}(s)$ and $\mathrm{H}_{2} \mathrm{O}(l)$ are $2.03 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$ and $4.18 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$, respectively, and the enthalpy of fusion for ice is $6.02 \mathrm{~kJ} / \mathrm{mol}$.
104. A $0.250-\mathrm{g}$ chunk of sodium metal is cautiously dropped into a mixture of 50.0 g water and 50.0 g ice, both at $0^{\circ} \mathrm{C}$. The reaction is
$2 \mathrm{Na}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q)+\mathrm{H}_{2}(g) \quad \Delta H=-368 \mathrm{~kJ}$
Assuming no heat loss to the surroundings, will the ice melt? Assuming the final mixture has a specific heat capacity of $4.18 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$, calculate the final temperature. The enthalpy of fusion for ice is $6.02 \mathrm{~kJ} / \mathrm{mol}$.
-105. Consider the phase diagram given below. What phases are present at points $A$ through $H$ ? Identify the triple point, normal boiling point, normal freezing point, and critical point. Which phase is denser, solid or liquid?

106. Sulfur exhibits two solid phases, rhombic and monoclinic. Use the accompanying phase diagram for sulfur to answer the following questions. (The phase diagram is not to scale.)

a. How many triple points are in the phase diagram?
b. What phases are in equilibrium at each of the triple points?
c. What is the stable phase at 1 atm and $100 .{ }^{\circ} \mathrm{C}$ ?
d. What are the normal melting point and the normal boiling point of sulfur?
e. Which is the densest phase?
f. At a pressure of $1.0 \times 10^{-5} \mathrm{~atm}$, can rhombic sulfur sublime?
g. What phase changes occur when the pressure on a sample of sulfur at $100 .{ }^{\circ} \mathrm{C}$ is increased from $1.0 \times 10^{-8} \mathrm{~atm}$ to 1500 atm?
107. Use the accompanying phase diagram for carbon to answer the following questions.
a. How many triple points are in the phase diagram?
b. What phases can coexist at each triple point?
c. What happens if graphite is subjected to very high pressures at room temperature?
d. If we assume that the density increases with an increase in pressure, which is more dense, graphite or diamond?

108. Like most substances, bromine exists in one of the three typical phases. $\mathrm{Br}_{2}$ has a normal melting point of $-7.2^{\circ} \mathrm{C}$ and a normal boiling point of $59^{\circ} \mathrm{C}$. The triple point for $\mathrm{Br}_{2}$ is $-7.3^{\circ} \mathrm{C}$ and 40 torr, and the critical point is $320^{\circ} \mathrm{C}$ and 100 atm . Using this information, sketch a phase diagram for bromine indicating the points described above. Based on your phase diagram, order the three phases from least dense to most dense. What is the stable phase of $\mathrm{Br}_{2}$ at room temperature and 1 atm? Under what temperature conditions can liquid bromine never exist? What phase changes occur as the temperature of a sample of bromine at 0.10 atm is increased from $-50^{\circ} \mathrm{C}$ to $200^{\circ} \mathrm{C}$ ?
-109. The melting point of a fictional substance $X$ is $225^{\circ} \mathrm{C}$ at 10.0 atm . If the density of the solid phase of $X$ is $2.67 \mathrm{~g} / \mathrm{cm}^{3}$ and the density of the liquid phase is $2.78 \mathrm{~g} / \mathrm{cm}^{3}$ at 10.0 atm , predict whether the normal melting point of X will be less than, equal to, or greater than $225^{\circ} \mathrm{C}$. Explain.
110. Consider the following data for xenon:

| Triple point: | $-121^{\circ} \mathrm{C}, 280$ torr |
| :--- | :--- |
| Normal melting point: | $-112^{\circ} \mathrm{C}$ |
| Normal boiling point: | $-107^{\circ} \mathrm{C}$ |

Which is more dense, $\mathrm{Xe}(s)$ or $\mathrm{Xe}(l)$ ? How do the melting point and boiling point of xenon depend on pressure?

## Additional Exercises

111. Which is stronger, a dipole-dipole interaction between two molecules or a covalent bond between two atoms within the same molecule? Explain.
112. Consider the following formulas for $n$-pentane and neopentane:

Both compounds have the same overall formula $\left(\mathrm{C}_{5} \mathrm{H}_{12}\right.$, molar mass $=72.15 \mathrm{~g} / \mathrm{mol}$ ), yet $n$-pentane boils at $36.2^{\circ} \mathrm{C}$ whereas neopentane boils at $9.5^{\circ} \mathrm{C}$. Rationalize the differences in the boiling points between these two nonpolar compounds.
113. Some of the physical properties of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{D}_{2} \mathrm{O}$ are as follows:

| Property | $\mathbf{H}_{2} \mathrm{O}$ | $\mathbf{D}_{2} \mathrm{O}$ |
| :--- | :---: | :---: |
| Density at $20^{\circ} \mathrm{C}(\mathrm{g} / \mathrm{mL})$ | 0.997 | 1.108 |
| Boiling point $\left({ }^{\circ} \mathrm{C}\right)$ | 100.00 | 101.41 |
| Melting point $\left({ }^{\circ} \mathrm{C}\right)$ | 0.00 | 3.79 |
| $\Delta H^{\circ}$ vap $(\mathrm{kJ} / \mathrm{mol})$ | 40.7 | 41.61 |
| $\Delta H^{\circ}$ fus $(\mathrm{kJ} / \mathrm{mol})$ | 6.02 | 6.3 |

Account for the differences. (Note: D is a symbol often used for ${ }^{2} \mathrm{H}$, the deuterium isotope of hydrogen.)
114. Rationalize the following boiling points:

115. Consider the following vapor pressure versus temperature plot for three different substances: A, B, and C.

If the three substances are $\mathrm{CH}_{4}, \mathrm{SiH}_{4}$, and $\mathrm{NH}_{3}$, match each curve to the correct substance.
116. Consider the following enthalpy changes:

$$
\begin{aligned}
\mathrm{F}^{-}+\mathrm{HF} \longrightarrow \mathrm{FHF}^{-} \\
\\
\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{O}+\mathrm{HF} \longrightarrow\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{O}--\mathrm{HF} \\
\Delta H=-46 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+\mathrm{HOH}(\mathrm{~g}) \longrightarrow \mathrm{H}_{2} \mathrm{O}--\mathrm{HOH}(\text { in ice }) \\
\Delta H=-21 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

How do the strengths of hydrogen bonds vary with the electronegativity of the element to which hydrogen is bonded? Where in the preceding series would you expect hydrogen bonds of the following type to fall?

117. Consider the following data for an unknown substance X :
$\Delta H_{\text {vap }}=20.00 \mathrm{~kJ} / \mathrm{mol}$
$\Delta H_{\text {fus }}=5.00 \mathrm{~kJ} / \mathrm{mol}$
Specific heat capacity of solid $=3.00 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$
Specific heat capacity of liquid $=2.50 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$
Boiling point $=75.0^{\circ} \mathrm{C}$
Melting point $=-15.0^{\circ} \mathrm{C}$
Molar mass $=100.0 \mathrm{~g} / \mathrm{mol}$
In the heating of substance $X$, energy (heat) is added at a constant rate of $450.0 \mathrm{~J} / \mathrm{min}$. At this rate, how long will it take to heat 10.0 g of X from $-35.0^{\circ} \mathrm{C}$ to $25.0^{\circ} \mathrm{C}$ ?
118. Consider the data for substance $X$ given in Exercise 117. When the temperature of 1.000 mole of $\mathrm{X}(\mathrm{g})$ is lowered from $100.0^{\circ} \mathrm{C}$ to form $\mathrm{X}(l)$ at $50.0^{\circ} \mathrm{C}, 28.75 \mathrm{~kJ}$ of heat is released. Calculate the specific heat capacity of $\mathrm{X}(\mathrm{g})$.
119. The unit cell for a pure xenon fluoride compound is shown below. What is the formula of the compound?

120. Boron nitride ( BN ) exists in two forms. The first is a slippery solid formed from the reaction of $\mathrm{BCl}_{3}$ with $\mathrm{NH}_{3}$, followed by heating in an ammonia atmosphere at $750^{\circ} \mathrm{C}$. Subjecting the first form of BN to a pressure of $85,000 \mathrm{~atm}$ at $1800^{\circ} \mathrm{C}$ produces a second form that is the second hardest substance known. Both forms of BN remain solids to $3000^{\circ} \mathrm{C}$. Suggest structures for the two forms of BN.
121. Consider the following data concerning four different substances.

|  | Conducts <br> Electricity <br> as a Solid | Other Properties |
| :---: | :---: | :--- |
| Compound | No | Gas at $25^{\circ} \mathrm{C}$ |
| $\mathrm{B}_{2} \mathrm{H}_{6}$ | No | High mp |
| $\mathrm{SiO}_{2}$ | No | Aqueous solution <br> Conducts electricity |
| CsI | Yes | High mp |
| W |  |  |

Label the four substances as either ionic, network, metallic, or molecular solids.
122. Argon has a cubic closest packed structure as a solid. Assuming that argon has a radius of 190. pm, calculate the density of solid argon.
123. Dry nitrogen gas is bubbled through liquid benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ at $20.0^{\circ} \mathrm{C}$. From 100.0 L of the gaseous mixture of nitrogen and benzene, 24.7 g benzene is condensed by passing the mixture through a trap at a temperature where nitrogen is gaseous and the vapor pressure of benzene is negligible. What is the vapor pressure of benzene at $20.0^{\circ} \mathrm{C}$ ?
124. A $20.0-\mathrm{g}$ sample of ice at $-10.0^{\circ} \mathrm{C}$ is mixed with 100.0 g water at $80.0^{\circ} \mathrm{C}$. Calculate the final temperature of the mixture assuming no heat loss to the surroundings. The heat capacities of $\mathrm{H}_{2} \mathrm{O}(s)$ and $\mathrm{H}_{2} \mathrm{O}(l)$ are 2.03 and $4.18 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$, respectively, and the enthalpy of fusion for ice is $6.02 \mathrm{~kJ} / \mathrm{mol}$.
125. Consider a $75.0-\mathrm{g}$ sample of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ at $125^{\circ} \mathrm{C}$. What phase(s) is(are) present when 215 kJ of energy is removed from this sample? (See Exercise 101)
126. Carbon tetrachloride, $\mathrm{CCl}_{4}$, has a vapor pressure of 213 torr at $40 .{ }^{\circ} \mathrm{C}$ and 836 torr at $80 .{ }^{\circ} \mathrm{C}$. What is the normal boiling point of $\mathrm{CCl}_{4}$ ?
127. A special vessel (see Fig. 10.45) contains ice and supercooled water (both at $-10^{\circ} \mathrm{C}$ ) connected by vapor space. Describe what happens to the amounts of ice and water as time passes.
128. What pressure would have to be applied to steam at $350^{\circ} \mathrm{C}$ to condense the steam to liquid? Assume $\Delta H_{\text {vap }}=40.7 \mathrm{~kJ} / \mathrm{mol}$.
129. In regions with dry climates, evaporative coolers are used to cool air. A typical electric air conditioner is rated at $1.00 \times 10^{4}$ Btu/h (1 Btu, or British thermal unit = amount of energy to raise the temperature of 1 lb water by $1^{\circ} \mathrm{F}$ ). What quantity of water must be evaporated each hour to dissipate as much heat as a typical electric air conditioner?
130. The critical point of $\mathrm{NH}_{3}$ is $132^{\circ} \mathrm{C}$ and 111 atm , and the critical point of $\mathrm{N}_{2}$ is $-147^{\circ} \mathrm{C}$ and 34 atm . Which of these substances cannot be liquefied at room temperature no matter how much pressure is applied? Explain.

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
131. Which of the following compound(s) exhibit only London dispersion intermolecular forces? Which compound(s) exhibit hydrogen-bonding forces? Considering only the compounds without hydrogen-bonding interactions, which compounds have dipole-dipole intermolecular forces?
a. $\mathrm{SF}_{4}$
b. $\mathrm{CO}_{2}$
c. $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$
d. HF
e. $\mathrm{ICl}_{5}$
f. $\mathrm{XeF}_{4}$
132. Which of the following statements about intermolecular forces is(are) true?
a. London dispersion forces are the only type of intermolecular force that nonpolar molecules exhibit.
b. Molecules that have only London dispersion forces will always be gases at room temperature $\left(25^{\circ} \mathrm{C}\right)$.
c. The hydrogen-bonding forces in $\mathrm{NH}_{3}$ are stronger than those in $\mathrm{H}_{2} \mathrm{O}$.
d. The molecules in $\mathrm{SO}_{2}(\mathrm{~g})$ exhibit dipole-dipole intermolecular interactions.
e. $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}$ has stronger London dispersion forces than does $\mathrm{CH}_{4}$.
133. Which of the following statements is(are) true?
a. LiF will have a higher vapor pressure at $25^{\circ} \mathrm{C}$ than $\mathrm{H}_{2} \mathrm{~S}$.
b. HF will have a lower vapor pressure at $-50^{\circ} \mathrm{C}$ than HBr .
c. $\mathrm{Cl}_{2}$ will have a higher boiling point than Ar .
d. HCl is more soluble in water than in $\mathrm{CCl}_{4}$.
e. MgO will have a higher vapor pressure at $25^{\circ} \mathrm{C}$ than $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$.
134. Aluminum has an atomic radius of 143 pm and forms a solid with a cubic closest packed structure. Calculate the density of solid aluminum in $\mathrm{g} / \mathrm{cm}^{3}$.
135. Pyrolusite is a mineral containing manganese ions and oxide ions. Its structure can best be described as a body-centered cubic array of manganese ions with two oxide ions inside the unit cell and two oxide ions each on two faces of the cubic unit cell. What is the charge on the manganese ions in pyrolusite?
136. The structure of the compound $\mathrm{K}_{2} \mathrm{O}$ is best described as a cubic closest packed array of oxide ions with the potassium ions in tetrahedral holes. What percent of the tetrahedral holes are occupied in this solid?
137. What type of solid (network, metallic, Group 8A, ionic, or molecular) will each of the following substances form?
a. Kr
b. $\mathrm{SO}_{2}$
c. Ni
d. $\mathrm{SiO}_{2}$
e. $\mathrm{NH}_{3}$
f. Pt
138. Some ice cubes at $0^{\circ} \mathrm{C}$ with a total mass of 403 g are placed in a microwave oven and subjected to 750 . W ( $750 \mathrm{~J} / \mathrm{s}$ ) of energy for 5.00 minutes. What is the final temperature of the water? Assume all the energy of the microwave is absorbed by the water, and assume no heat loss by the water.
139. The enthalpy of vaporization for acetone is $32.0 \mathrm{~kJ} / \mathrm{mol}$. The normal boiling point for acetone is $56.5^{\circ} \mathrm{C}$. What is the vapor pressure of acetone at $23.5^{\circ} \mathrm{C}$ ?
140. Choose the statements that correctly describe the following phase diagram.

a. If the temperature is raised from 50 K to 400 K at a pressure of 1 atm , the substance boils at approximately 185 K .
b. The liquid phase of this substance cannot exist under conditions of 2 atm at any temperature.
c. The triple point occurs at approximately 165 K .
d. At a pressure of 1.5 atm , the melting point of the substance is approximately 370 K .
e. The critical point occurs at approximately 1.7 atm and 410 K.

## Challenge Problems

141. When 1 mole of benzene is vaporized at a constant pressure of 1.00 atm and at its boiling point of $353.0 \mathrm{~K}, 30.79 \mathrm{~kJ}$ of energy (heat) is absorbed and the volume change is +28.90 L . What are $\Delta E$ and $\Delta H$ for this process?
142. You and a friend each synthesize a compound with the formula $\mathrm{XeCl}_{2} \mathrm{~F}_{2}$. Your compound is a liquid and your friend's compound is a gas (at the same conditions of temperature and pressure). Explain how the two compounds with the same formulas can exist in different phases at the same conditions of pressure and temperature.
143. Using the heats of fusion and vaporization for water given in Exercise 101, calculate the change in enthalpy for the sublimation of water:

$$
\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g)
$$

Using the $\Delta H$ value given in Exercise 116 and the number of hydrogen bonds formed with each water molecule, estimate what portion of the intermolecular forces in ice can be accounted for by hydrogen bonding.
144. Consider a perfectly insulated and sealed container. Determine the minimum volume of a container such that a gallon of water at $25^{\circ} \mathrm{C}$ will evaporate completely. If the container is a cube, determine the dimensions in feet. Assume the density of water is $0.998 \mathrm{~g} / \mathrm{cm}^{3}$.
145. Consider two different organic compounds, each with the formula $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}$. One of these compounds is a liquid at room conditions and the other is a gas. Write Lewis structures consistent with this observation, and explain your answer. (Hint: The oxygen atom in both structures satisfies the octet rule with two bonds and two lone pairs.)
146. Rationalize the differences in physical properties in terms of intermolecular forces for the following organic compounds. Compare the first three substances with each other, compare the last three with each other, and then compare all six. Can you account for any anomalies?

|  | bp <br> $\left({ }^{\circ} \mathrm{C}\right)$ | mp <br> $\left({ }^{\circ} \mathrm{C}\right)$ | $\Delta H_{\text {vap }}$ <br> $(\mathrm{kJ} / \mathrm{mol})$ |
| :--- | ---: | ---: | :---: |
| Benzene, $\mathrm{C}_{6} \mathrm{H}_{6}$ | 80 | 6 | 33.9 |
| Naphthalene, $\mathrm{C}_{10} \mathrm{H}_{8}$ | 218 | 80 | 51.5 |
| Carbon tetrachloride | 76 | -23 | 31.8 |
| Acetone, $\mathrm{CH}_{3} \mathrm{COCH}_{3}$ | 56 | -95 | 31.8 |
| Acetic acid, $\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}$ | 118 | 17 | 39.7 |
| Benzoic acid, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2} \mathrm{H}$ | 249 | 122 | 68.2 |

147. Consider the following melting point data:

| Compound | NaCl | $\mathrm{MgCl}_{2}$ | $\mathrm{AlCl}_{3}$ | $\mathrm{SiCl}_{4}$ | $\mathrm{PCl}_{3}$ | $\mathrm{SCl}_{2}$ | $\mathrm{Cl}_{2}$ |
| :---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| mp $\left({ }^{\circ} \mathrm{C}\right)$ | 801 | 708 | 190 | -70 | -91 | -78 | -101 |
| Compound | NaF | $\mathrm{MgF}_{2}$ | $\mathrm{AlF}_{3}$ | $\mathrm{SiF}_{4}$ | $\mathrm{PF}_{5}$ | $\mathrm{SF}_{6}$ | $\mathrm{~F}_{2}$ |
| mp $\left({ }^{\circ} \mathrm{C}\right)$ | 997 | 1396 | 1040 | -90 | -94 | -56 | -220 |

Account for the trends in melting points in terms of interparticle forces.
148. Some ionic compounds contain a mixture of different charged cations. For example, wüstite is an oxide that contains both $\mathrm{Fe}^{2+}$ and $\mathrm{Fe}^{3+}$ cations and has a formula of $\mathrm{Fe}_{0.950} \mathrm{O}_{1.00}$. Calculate the fraction of iron ions present as $\mathrm{Fe}^{3+}$. What fraction of the sites normally occupied by $\mathrm{Fe}^{2+}$ must be vacant in this solid?
149. Some ionic compounds contain a mixture of different charged cations. For example, some titanium oxides contain a mixture of $\mathrm{Ti}^{2+}$ and $\mathrm{Ti}^{3+}$ ions. Consider a certain oxide of titanium that is $28.31 \%$ oxygen by mass and contains a mixture of $\mathrm{Ti}^{2+}$ and $\mathrm{Ti}^{3+}$ ions. Determine the formula of the compound and the relative numbers of $\mathrm{Ti}^{2+}$ and $\mathrm{Ti}^{3+}$ ions.
150. Spinel is a mineral that contains $37.9 \%$ aluminum, $17.1 \%$ magnesium, and $45.0 \%$ oxygen, by mass, and has a density of $3.57 \mathrm{~g} / \mathrm{cm}^{3}$. The edge of the cubic unit cell measures 809 pm . How many of each type of ion are present in the unit cell?
151. Mn crystallizes in the same type of cubic unit cell as Cu . Assuming that the radius of Mn is $5.6 \%$ larger than the radius of Cu and the density of copper is $8.96 \mathrm{~g} / \mathrm{cm}^{3}$, calculate the density of Mn.
152. You are asked to help set up a historical display in the park by stacking some cannonballs next to a Revolutionary War cannon. You are told to stack them by starting with a triangle in which each side is composed of four touching cannonballs. You are to continue stacking them until you have a single ball on the top centered over the middle of the triangular base.
a. How many cannonballs do you need?
b. What type of closest packing is displayed by the cannonballs?
c. The four corners of the pyramid of cannonballs form the corners of what type of regular geometric solid?
153. Some water is placed in a sealed glass container connected to a vacuum pump (a device used to pump gases from a container), and the pump is turned on. The water appears to boil and then freezes. Explain these changes using the phase diagram for water. What would happen to the ice if the vacuum pump was left on indefinitely?
154. The molar enthalpy of vaporization of water at 373 K and 1.00 atm is $40.7 \mathrm{~kJ} / \mathrm{mol}$. What fraction of this energy is used to change the internal energy of the water, and what fraction is used to do work against the atmosphere? (Hint: Assume that water vapor is an ideal gas.)
155. For a simple cubic array, solve for the volume of an interior sphere (cubic hole) in terms of the radius of a sphere in the array.
156. Rubidium chloride has the sodium chloride structure at normal pressures but assumes the cesium chloride structure at high pressures. (See Exercise 71.) What ratio of densities is expected for these two forms? Does this change in structure make sense on the basis of simple models? The ionic radius is 148 pm for $\mathrm{Rb}^{+}$and 181 pm for $\mathrm{Cl}^{-}$.

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
157. A 0.132 -mole sample of an unknown semiconducting material with the formula XY has a mass of 19.0 g . The element X has an electron configuration of $[\mathrm{Kr}] 5 s^{2} 4 d^{10}$. What is this semiconducting material? A small amount of the Y atoms in the semiconductor is replaced with an equivalent amount of atoms with an electron configuration of $[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{5}$. Does this correspond to n-type or p-type doping?
158. A metal burns in air at $600^{\circ} \mathrm{C}$ under high pressure to form an oxide with formula $\mathrm{MO}_{2}$. This compound is $23.72 \%$ oxygen by mass. The distance between touching atoms in a cubic closest packed crystal of this metal is 269.0 pm . What is this metal? What is its density?
159. One method of preparing elemental mercury involves roasting cinnabar $(\mathrm{HgS})$ in quicklime $(\mathrm{CaO})$ at $600 .{ }^{\circ} \mathrm{C}$ followed by condensation of the mercury vapor. Given the heat of vaporization of mercury ( $296 \mathrm{~J} / \mathrm{g}$ ) and the vapor pressure of mercury at $25.0^{\circ} \mathrm{C}\left(2.56 \times 10^{-3}\right.$ torr $)$, what is the vapor pressure of the condensed mercury at $300 .{ }^{\circ} \mathrm{C}$ ? How many atoms of mercury are present in the mercury vapor at $300 .{ }^{\circ} \mathrm{C}$ if the reaction is conducted in a closed $15.0-\mathrm{L}$ container?

## Marathon Problem

This problem is designed to incorporate several concepts and techniques into one situation.
160. General Zod has sold Lex Luthor what Zod claims to be a new copper-colored form of kryptonite, the only substance that can harm Superman. Lex, not believing in honor among thieves, decided to carry out some tests on the supposed kryptonite. From previous tests, Lex knew that kryptonite is a metal having a specific heat capacity of $0.082 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$ and a density of $9.2 \mathrm{~g} / \mathrm{cm}^{3}$.

Lex Luthor's first experiment was an attempt to find the specific heat capacity of kryptonite. He dropped a $10 \mathrm{~g} \pm 3 \mathrm{~g}$ sample of the metal into a boiling water bath at a temperature of $100.0^{\circ} \mathrm{C} \pm 0.2^{\circ} \mathrm{C}$. He waited until the metal had reached the bath temperature and then quickly transferred it to $100 \mathrm{~g} \pm$ 3 g of water that was contained in a calorimeter at an initial temperature of $25.0^{\circ} \mathrm{C} \pm 0.2^{\circ} \mathrm{C}$. The final temperature of the metal and water was $25.2^{\circ} \mathrm{C}$. Based on these results, is it possible to distinguish between copper and kryptonite? Explain.

When Lex found that his results from the first experiment were inconclusive, he decided to determine the density of the sample. He managed to steal a better balance and determined the mass of another portion of the purported kryptonite to be $4 \mathrm{~g} \pm 1 \mathrm{~g}$. He dropped this sample into water contained in a $25-\mathrm{mL}$ graduated cylinder and found that it displaced a volume of $0.42 \mathrm{~mL} \pm 0.02 \mathrm{~mL}$. Is the metal copper or kryptonite? Explain.

Lex was finally forced to determine the crystal structure of the metal General Zod had given him. He found that the cubic unit cell contained four atoms and had an edge length of 600. pm. Explain how this information enabled Lex to identify the metal as copper or kryptonite.

Will Lex be going after Superman with the kryptonite or seeking revenge on General Zod? What improvements could he have made in his experimental techniques to avoid performing the crystal structure determination?

Opals are formed from colloidal suspensions of silica when the liquid evaporates. (Horizon International/Alamy)

Most of the substances we encounter in daily life are mixtures: Wood, milk, gasoline, champagne, seawater, shampoo, steel, and air are common examples. When the components of a mixture are uniformly intermingled-that is, when a mixture is homogeneous-it is called a solution. Solutions can be gases, liquids, or solids, as shown in Table 11.1. However, we will be concerned in this chapter with the properties of liquid solutions, particularly those containing water. As we saw in Chapter 4, many essential chemical reactions occur in aqueous solutions because water is capable of dissolving so many substances.

### 11.1 Solution Composition

A solute is the substance being dissolved. The solvent is the dissolving medium.

Molarity $=\frac{\text { moles of solute }}{}$ liters of solution

When liquids are mixed, the liquid present in the largest amount is called the solvent.

In very dilute aqueous solutions, the magnitude of the molality and the molarity are almost the same.

Because a mixture, unlike a chemical compound, has a variable composition, the relative amounts of substances in a solution must be specified. The qualitative terms dilute (relatively little solute present) and concentrated (relatively large amount of solute) are often used to describe solution content, but we need to define solution composition more precisely to perform calculations. For example, in dealing with the stoichiometry of solution reactions in Chapter 4, we found it useful to describe solution composition in terms of molarity, or the number of moles of solute per liter of solution (symbolized by $M$ ).

Other ways of describing solution composition are also useful. Mass percent (sometimes called weight percent) is the percent by mass of the solute in the solution:

$$
\text { Mass percent }=\left(\frac{\text { mass of solute }}{\text { mass of solution }}\right) \times 100 \%
$$

Another way of describing solution composition is the mole fraction (symbolized by the lowercase Greek letter chi, $\chi$ ), the ratio of the number of moles of a given component to the total number of moles of solution. For a two-component solution, where $n_{\mathrm{A}}$ and $n_{\mathrm{B}}$ represent the number of moles of the two components,

$$
\text { Mole fraction of component } \mathrm{A}=\chi_{\mathrm{A}}=\frac{n_{\mathrm{A}}}{n_{\mathrm{A}}+n_{\mathrm{B}}}
$$

Still another way of describing solution composition is molality (symbolized by $m$ ), the number of moles of solute per kilogram of solvent:

$$
\text { Molality }=\frac{\text { moles of solute }}{\text { kilogram of solvent }}
$$

## TABLE 11.1 | Various Types of Solutions

| Example | State of Solution | State of Solute | State of Solvent |
| :--- | :--- | :--- | :--- | :--- |
| Air, natural gas | Gas | Gas | Gas |
| Vodka, antifreeze | Liquid | Liquid | Liquid |
| Brass | Solid | Solid | Solid |
| Carbonated water | Liquid | Gas | Liquid |
| Seawater, sugar solution | Liquid | Solid | Liquid |
| Hydrogen in platinum | Solid | Gas | Solid |

## INTERACTIVE EXAMPLE 11.1 Various Methods for Describing Solution Composition

A solution is prepared by mixing 1.00 g ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ with 100.0 g water to give a final volume of 101 mL . Calculate the molarity, mass percent, mole fraction, and molality of ethanol in this solution.

## SOLUTION

Since molarity depends on the volume of the solution, it changes slightly with temperature. Molality is independent of temperature because it depends only on mass.

## Molarity

The moles of ethanol can be obtained from its molar mass ( $46.07 \mathrm{~g} / \mathrm{mol}$ ):

$$
\begin{aligned}
& 1.00 \mathrm{~g} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH} \times \frac{1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}{46.07 \mathrm{~g} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}=2.17 \times 10^{-2} \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH} \\
& \text { Volume }
\end{aligned}=101 \mathrm{~mL} \times \frac{1 \mathrm{~L}}{1000 \mathrm{~mL}}=0.101 \mathrm{~L}, ~ \begin{aligned}
\text { Molarity of } \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH} & =\frac{\text { moles of } \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}{\text { liters of solution }}=\frac{2.17 \times 10^{-2} \mathrm{~mol}}{0.101 \mathrm{~L}} \\
& =0.215 \mathrm{M}
\end{aligned}
$$

## Mass Percent

- Mass percent $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}=\left(\frac{\text { mass of } \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}{\text { mass of solution }}\right) \times 100 \%$

$$
\begin{aligned}
& =\left(\frac{1.00 \mathrm{~g} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}{100.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}+1.00 \mathrm{~g} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}\right) \times 100 \% \\
& =0.990 \% \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}
\end{aligned}
$$

## Mole Fraction

$$
\begin{aligned}
& \text { Mole fraction of } \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}
\end{aligned}=\frac{n_{\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}}{n_{\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}+n_{\mathrm{H}_{2} \mathrm{O}}}, \begin{aligned}
n_{\mathrm{H}_{2} \mathrm{O}}=100.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} & \times \frac{1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}{18.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}=5.56 \mathrm{~mol} \\
\square \chi_{\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}} & =\frac{2.17 \times 10^{-2} \mathrm{~mol}}{2.17 \times 10^{-2} \mathrm{~mol}+5.56 \mathrm{~mol}} \\
& =\frac{2.17 \times 10^{-2}}{5.58}=0.00389
\end{aligned}
$$

## Molality

$$
\begin{aligned}
\text { Molality of } \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH} & =\frac{\text { moles of } \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}{\text { kilogram of } \mathrm{H}_{2} \mathrm{O}}=\frac{2.17 \times 10^{-2} \mathrm{~mol}}{100.0 \mathrm{~g} \times \frac{1 \mathrm{~kg}}{1000 \mathrm{~g}}} \\
& =\frac{2.17 \times 10^{-2} \mathrm{~mol}}{0.1000 \mathrm{~kg}} \\
& =0.217 \mathrm{~m}
\end{aligned}
$$

The definition of an equivalent depends on the reaction taking place in the solution.

The quantity we call equivalent mass here traditionally has been called equivalent weight.

Oxidation-reduction half-reactions were discussed in Section 4.10.

## TABLE 11.2 \| The Molar Mass, Equivalent Mass, and Relationship of Molarity and Normality for Several Acids and Bases

| Acid or Base | Molar <br> Mass | Equivalent <br> Mass | Relationship of <br> Molarity and Normality |
| :--- | :---: | :---: | :---: |
| HCl | 36.5 | 36.5 | $1 \mathrm{M}=1 \mathrm{~N}$ |
| $\mathrm{H}_{2} \mathrm{SO}_{4}$ | 98 | $\frac{98}{2}=49$ | $1 \mathrm{M}=2 \mathrm{~N}$ |
| NaOH | 40 | 40 | $1 \mathrm{M}=1 \mathrm{~N}$ |
| $\mathrm{Ca}(\mathrm{OH})_{2}$ | 74 | $\frac{74}{2}=37$ | $1 \mathrm{M}=2 \mathrm{~N}$ |

 different ionic solutes (Solution A and Solution B). What if you are told that Solution $A$ has a greater concentration than Solution $B$ by mass percent, but Solution B has a greater concentration than Solution A in terms of molality? Is this possible? If not, explain why not. If it is possible, provide example solutes for $A$ and $B$ and justify your answer with calculations.

Another concentration measure sometimes encountered is normality (symbolized by $N$ ). Normality is defined as the number of equivalents per liter of solution, where the definition of an equivalent depends on the reaction taking place in the solution. For an acid-base reaction, the equivalent is the mass of acid or base that can furnish or accept exactly 1 mole of protons ( $\mathrm{H}^{+}$ions). In Table 11.2, note, for example, that the equivalent mass of sulfuric acid is the molar mass divided by 2 , since each mole of $\mathrm{H}_{2} \mathrm{SO}_{4}$ can furnish 2 moles of protons. The equivalent mass of calcium hydroxide is also half the molar mass, since each mole of $\mathrm{Ca}(\mathrm{OH})_{2}$ contains 2 moles of $\mathrm{OH}^{-}$ions that can react with 2 moles of protons. The equivalent is defined so that 1 equivalent of acid will react with exactly 1 equivalent of base.

For oxidation-reduction reactions, the equivalent is defined as the quantity of oxidizing or reducing agent that can accept or furnish 1 mole of electrons. Thus 1 equivalent of reducing agent will react with exactly 1 equivalent of oxidizing agent. The equivalent mass of an oxidizing or reducing agent can be calculated from the number of electrons in its half-reaction. For example, $\mathrm{MnO}_{4}{ }^{-}$reacting in acidic solution absorbs five electrons to produce $\mathrm{Mn}^{2+}$ :

$$
\mathrm{MnO}_{4}^{-}+5 \mathrm{e}^{-}+8 \mathrm{H}^{+} \longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O}
$$

Since the $\mathrm{MnO}_{4}^{-}$ion present in 1 mole of $\mathrm{KMnO}_{4}$ consumes 5 moles of electrons, the equivalent mass is the molar mass divided by 5 :

$$
\text { Equivalent mass of } \mathrm{KMnO}_{4}=\frac{\text { molar mass }}{5}=\frac{158 \mathrm{~g}}{5}=31.6 \mathrm{~g}
$$

## INTERACTIVE EXAMPLE 11.2

## Calculating Various Methods of Solution Composition from the Molarity

The electrolyte in automobile lead storage batteries is a $3.75 M$ sulfuric acid solution that has a density of $1.230 \mathrm{~g} / \mathrm{mL}$. Calculate the mass percent, molality, and normality of the sulfuric acid.

SOLUTION

$\Delta$
A modern 12-volt lead storage battery of the type used in automobiles.

What is the density of the solution in grams per liter?

$$
1.230 \frac{\mathrm{~g}}{\mathrm{~mL}} \times \frac{1000 \mathrm{~mL}}{1 \mathrm{~L}}=1.230 \times 10^{3} \mathrm{~g} / \mathrm{L}
$$

What mass of $\mathrm{H}_{2} \mathrm{SO}_{4}$ is present in 1.00 L of solution?
We know 1 liter of this solution contains 1230. g of the mixture of sulfuric acid and water. Since the solution is 3.75 M , we know that 3.75 moles of $\mathrm{H}_{2} \mathrm{SO}_{4}$ is present per liter of solution. The number of grams of $\mathrm{H}_{2} \mathrm{SO}_{4}$ present is

$$
3.75 \mathrm{~mol} \times \frac{98.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{SO}_{4}}{1 \mathrm{~mol}}=368 \mathrm{~g} \mathrm{H}_{2} \mathrm{SO}_{4}
$$

How much water is present in 1.00 L of solution?
The amount of water present in 1 liter of solution is obtained from the difference

$$
\text { 1230. } \mathrm{g} \text { solution }-368 \mathrm{~g} \mathrm{H}_{2} \mathrm{SO}_{4}=862 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}
$$

What is the mass percent?
Since we now know the masses of the solute and solvent, we can calculate the mass percent.

$$
\begin{aligned}
\text { Mass percent } \mathrm{H}_{2} \mathrm{SO}_{4} & =\frac{\text { mass of } \mathrm{H}_{2} \mathrm{SO}_{4}}{\text { mass of solution }} \times 100 \%=\frac{368 \mathrm{~g}}{1230 . \mathrm{g}} \times 100 \% \\
& =29.9 \% \mathrm{H}_{2} \mathrm{SO}_{4}
\end{aligned}
$$

What is the molality?
From the moles of solute and the mass of solvent, we can calculate the molality.

$$
\begin{aligned}
\square \text { Molality of } \mathrm{H}_{2} \mathrm{SO}_{4} & =\frac{\text { moles } \mathrm{H}_{2} \mathrm{SO}_{4}}{\text { kilogram of } \mathrm{H}_{2} \mathrm{O}} \\
& =\frac{3.75 \mathrm{~mol} \mathrm{H}_{2} \mathrm{SO}_{4}}{862 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \times \frac{1 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O}}{1000 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}}=4.35 \mathrm{~m}
\end{aligned}
$$

What is the normality?
Since each sulfuric acid molecule can furnish two protons, 1 mole of $\mathrm{H}_{2} \mathrm{SO}_{4}$ represents 2 equivalents. Thus a solution with 3.75 moles of $\mathrm{H}_{2} \mathrm{SO}_{4}$ per liter contains $2 \times 3.75=$ 7.50 equivalents per liter.

■ The normality is 7.50 N .

### 11.2 The Energies of Solution Formation

DDT

Dissolving solutes in liquids is very common. We dissolve salt in the water used to cook vegetables, sugar in iced tea, stains in cleaning fluid, gaseous carbon dioxide in water to make carbonated water, ethanol in gasoline to make gasohol, and so on.

Solubility is important in other ways. For example, because the pesticide DDT is fatsoluble, it is retained and concentrated in animal tissues, where it causes detrimental effects. This is why DDT, even though it is effective for killing mosquitos, has been banned in the United States. Also, the solubility of various vitamins is important in determining correct dosages. The insolubility of barium sulfate means it can be used safely to improve X rays of the gastrointestinal tract, even though $\mathrm{Ba}^{2+}$ ions are quite toxic.

FIGURE 11.1 The formation of a liquid solution can be divided into three steps: (1) expanding the solute, (2) expanding the solvent, and (3) combining the expanded solute and solvent to form the solution.

Polar solvents dissolve polar solutes; nonpolar solvents dissolve nonpolar solutes.

The enthalpy of solution is the sum of the energies used in expanding both solvent and solute and the energy of solventsolute interaction.

FIGURE 11.2 The heat of solution (a) $\Delta H_{\text {soln }}$ has a negative sign (the process is exothermic) if Step 3 releases more energy than that required by Steps 1 and 2 . (b) $\Delta H_{\text {soln }}$ has a positive sign (the process is endothermic) if Steps 1 and 2 require more energy than is released in Step 3. (If the energy changes for Steps 1 and 2 equal that for Step 3, then $\Delta H_{\text {soln }}$ is zero.)

What factors affect solubility? The cardinal rule of solubility is like dissolves like. We find that we must use a polar solvent to dissolve a polar or ionic solute and a nonpolar solvent to dissolve a nonpolar solute. Now we will try to understand why this behavior occurs. To simplify the discussion, we will assume that the formation of a liquid solution takes place in three distinct steps:

1. Separating the solute into its individual components (expanding the solute)
2. Overcoming intermolecular forces in the solvent to make room for the solute (expanding the solvent)
3. Allowing the solute and solvent to interact to form the solution

These steps are illustrated in Fig. 11.1. Steps 1 and 2 require energy, since forces must be overcome to expand the solute and solvent. Step 3 usually releases energy. In other words, Steps 1 and 2 are endothermic, and Step 3 is often exothermic. The enthalpy change associated with the formation of the solution, called the enthalpy (heat) of solution $\left(\Delta H_{\text {soln }}\right)$, is the sum of the $\Delta H$ values for the steps:

$$
\Delta H_{\mathrm{soln}}=\Delta H_{1}+\Delta H_{2}+\Delta H_{3}
$$

where $\Delta H_{\text {soln }}$ may have a positive sign (energy absorbed) or a negative sign (energy released) (Fig. 11.2).

$\Delta H_{1}$ is expected to be small for nonpolar solutes but can be large for large molecules with a great number of electrons.

## A

Gasoline floating on water. Since gasoline is nonpolar, it is immiscible with water, because water contains polar molecules.

FIGURE 11.3 (a) Orange and yellow spheres separated by a partition in a closed container. (b) The spheres after the partition is removed and the container has been shaken for some time.

To illustrate the importance of the various energy terms in the equation for $\Delta H_{\text {soln }}$, we will consider two specific cases. First, we know that oil is not soluble in water. When oil tankers leak, the petroleum forms an oil slick that floats on the water and is eventually carried onto the beaches. We can explain the immiscibility of oil and water by considering the energy terms involved. Oil is a mixture of nonpolar molecules that interact through London dispersion forces, which depend on molecule size and number of electrons. We expect $\Delta H_{1}$ to be small for a typical nonpolar solute, but it will be relatively large for the large oil molecules. However, $\Delta H_{2}$ will be large and positive because it takes considerable energy to overcome the hydrogen-bonding forces among the water molecules to expand the solvent. As stated, the term $\Delta H_{3}$ is often exothermic. This is true even for interactions between polar and nonpolar molecules. Recall from Chapter 10 that a polar molecule can induce a dipole on a neighboring nonpolar molecule (this is termed a dipole-induced dipole interaction). However, the magnitude of this interaction is not as great as the magnitude of a dipole-dipole interaction. In the case of oil and water, then, the magnitude of $\Delta H_{3}$ will be smaller than the sum of $\Delta H_{1}$ and $\Delta H_{2}$. Thus $\Delta H_{\text {soln }}$ will be large and positive because of the $\Delta H_{1}$ and $\Delta H_{2}$ terms. Since a large amount of energy would have to be expended to form an oil-water solution, this process does not occur to any appreciable extent. These same arguments hold true for any nonpolar solute and polar solvent-the combination of a nonpolar solute and a highly polar solvent is not expected to produce a solution.

As a second case, let's consider the solubility of an ionic solute, such as sodium chloride, in water. Here the term $\Delta H_{1}$ is large and positive because the strong ionic forces in the crystal must be overcome, and $\Delta H_{2}$ is large and positive because hydrogen bonds must be broken in the water. Finally, $\Delta H_{3}$ is large and negative because of the strong interactions between the ions and the water molecules. In fact, the exothermic and endothermic terms essentially cancel, as shown from the known values:

$$
\begin{array}{rlrl}
\mathrm{NaCl}(s) & \longrightarrow \mathrm{Na}^{+}(g)+\mathrm{Cl}^{-}(g) & \Delta H_{1} & =786 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Na}^{+}(g)+\mathrm{Cl}^{-}(g) \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{Cl}^{-}(a q) & \Delta H_{\mathrm{hyd}} & =\Delta H_{2}+\Delta H_{3} \\
& =-783 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

Here the enthalpy (heat) of hydration $\left(\Delta H_{\text {hyd }}\right)$ combines the terms $\Delta H_{2}$ (for expanding the solvent) and $\Delta H_{3}$ (for solvent-solute interactions). The heat of hydration represents the enthalpy change associated with the dispersal of a gaseous solute in water. Thus the heat of solution for dissolving sodium chloride is the sum of $\Delta H_{1}$ and $\Delta H_{\mathrm{hyd}}$ :

$$
\Delta H_{\mathrm{soln}}=786 \mathrm{~kJ} / \mathrm{mol}-783 \mathrm{~kJ} / \mathrm{mol}=3 \mathrm{~kJ} / \mathrm{mol}
$$

Note that $\Delta H_{\text {soln }}$ is small but positive; the dissolving process requires a small amount of energy. Then why is NaCl so soluble in water? The answer lies in nature's tendency toward higher probability of the mixed state. That is, processes naturally run in the direction that leads to the most probable state. For example, imagine equal numbers of orange and yellow spheres separated by a partition [Fig. 11.3(a)]. If we remove the partition and shake the container, the spheres will mix [Fig. 11.3(b)], and no amount of shaking will cause them to return to the state of separated orange and yellow. Why? The mixed state is simply much more likely to occur (more probable) than the original

The factors that act as driving forces for a process are discussed more fully in Chapter 17.

TABLE 11.3 | The Energy Terms for Various Types of Solutes and Solvents

|  | $\Delta H_{1}$ | $\Delta H_{2}$ | $\Delta H_{3}$ | $\Delta H_{\text {soln }}$ | Outcome |
| :---: | :--- | :--- | :--- | :--- | :--- |
| Polar solute, <br> polar solvent | Large | Large | Large, <br> negative | Small | Solution forms |
| Nonpolar solute, <br> polar solvent | Small | Large | Small | Large, <br> positive | No solution forms |
| Nonpolar solute, <br> nonpolar solvent | Small | Small | Small | Small | Solution forms |
| Polar solute, <br> nonpolar solvent | Large | Small | Small | Large, <br> positive | No solution forms |

separate state because there are many more ways of placing the spheres to give a mixed state than a separated state. This is a general principle. One factor that favors a process is an increase in probability.

But energy considerations are also important. Processes that require large amounts of energy tend not to occur. Since dissolving 1 mole of solid NaCl requires only a small amount of energy, the solution forms, presumably because of the large increase in the probability of the state when the solute and solvent are mixed.

The various possible cases for solution formation are summarized in Table 11.3. Note that in two cases, polar-polar and nonpolar-nonpolar, the heat of solution is expected to be small. In these cases, the solution forms because of the increase in the probability of the mixed state. In the other cases (polar-nonpolar and nonpolar-polar), the heat of solution is expected to be large and positive, and the large quantity of energy required acts to prevent the solution from forming. Although this discussion has greatly oversimplified the complex driving forces for solubility, these ideas are a useful starting point for understanding the observation that like dissolves like.

## You and a friend are studying for a

chemistry exam. What if your friend tells you, "Since exothermic processes are favored and the sign of the enthalpy change tells us whether or not a process is endothermic or exothermic, the sign of $\Delta H_{\text {soln }}$ tells us whether or not a solution will form"? How would you explain to your friend that this conclusion is not correct? What part, if any, of what your friend says is correct?

## INTERACTIVE EXAMPLE 11.3 Differentiating Solvent Properties

Decide whether liquid hexane $\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)$ or liquid methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ is the more appropriate solvent for the substances grease $\left(\mathrm{C}_{20} \mathrm{H}_{42}\right)$ and potassium iodide (KI).

## SOLUTION

Hexaneisanonpolarsolventbecauseitcontains $\mathrm{C}-\mathrm{H}$ bonds. Thus hexane will work best for the nonpolar solute grease. Methanol has an $\mathrm{O}-\mathrm{H}$ group that makes it significantly polar. Thus it will serve as the better solvent for the ionic solid KI.

Grease

FIGURE 11.4 Thin layer chromatography. (a) The plate is spotted and placed into the solvent. (b) After some time, the solvent (mobile phase) will travel up the plate. The less polar component travels farther than the more polar component.

## Chromatography

In Chapter 1 we introduced the technique of chromatography as a way of separating a mixture. Now that we have considered solution formation, we can better understand how chromatography works. There are many different methods of chromatography, but all include a system with two phases: a mobile phase and a stationary phase.

For the purposes of this discussion, we will consider thin layer chromatography (TLC), which uses a TLC plate as the stationary phase. This plate consists of a plastic sheet covered with a thin layer of silica gel. The silica gel is very polar and is capable of hydrogen bonding. The mixture to be analyzed is placed ("spotted") on the plate, and the plate is dipped into a solvent (the mobile phase). The solvent travels up the plate due to capillary action, which is why it is termed the mobile phase.

For example, suppose we have a mixture of two polar compounds, A and B, and A is more polar than B. Also assume that the solvent we have chosen is slightly polar. In this case, A (more polar) will have a greater affinity for the silica gel on the plate than for the mobile solvent. Compound B (less polar) will have more affinity for the mobile phase than for the silica gel. Thus, the less polar component (B) will travel farther with the solvent, and the mixture will be separated (Fig. 11.4). This example shows how TLC depends on the relative polarities of substances to be separated.

### 11.3 Factors Affecting Solubility

## Structure Effects

In the last section we saw that solubility is favored if the solute and solvent have similar polarities. Since it is the molecular structure that determines polarity, there should be a definite connection between structure and solubility. Vitamins provide an excellent example of the relationship among molecular structure, polarity, and solubility.

Recently, there has been considerable publicity about the pros and cons of consuming large quantities of vitamins. For example, large doses of vitamin $C$ have been advocated to combat various illnesses, including the common cold. Vitamin E has been extolled as a youth-preserving elixir and a protector against the carcinogenic (cancercausing) effects of certain chemicals. However, there are possible detrimental effects from taking large amounts of some vitamins, depending on their solubilities.

Vitamins can be divided into two classes: fat-soluble (vitamins A, D, E, and K) and water-soluble (vitamins B and C). The reason for the differing solubility characteristics

a

Vitamin A

Vitamin C

FIGURE 11.5 The molecular structures of (a) vitamin A (nonpolar, fat-soluble) and (b) vitamin C (polar, watersoluble). The highlighted areas in the structural formulas indicate polar bonds. Note that vitamin C contains far more polar bonds than vitamin A.
can be seen by comparing the structures of vitamins A and C (Fig. 11.5). Vitamin A, composed mostly of carbon and hydrogen atoms that have similar electronegativities, is virtually nonpolar. This causes it to be soluble in nonpolar materials such as body fat, which is also largely composed of carbon and hydrogen, but not soluble in polar solvents such as water. On the other hand, vitamin C has many polar $\mathrm{O}-\mathrm{H}$ and $\mathrm{C}-\mathrm{O}$ bonds, making the molecule polar and thus water-soluble. We often describe nonpolar materials such as vitamin A as hydrophobic (water-fearing) and polar substances such as vitamin C as hydrophilic (water-loving).

Because of their solubility characteristics, the fat-soluble vitamins can build up in the fatty tissues of the body. This has both positive and negative effects. Since these vitamins can be stored, the body can tolerate for a time a diet deficient in vitamin A, D, E, or K. Conversely, if excessive amounts of these vitamins are consumed, their buildup can lead to the illness hypervitaminosis.

In contrast, the water-soluble vitamins are excreted by the body and must be consumed regularly. This fact was first recognized when the British navy discovered that scurvy, a disease often suffered by sailors, could be prevented if the sailors regularly ate fresh limes (which are a good source of vitamin C) when aboard ship (hence the name "limey" for the British sailor).

## Pressure Effects

While pressure has little effect on the solubilities of solids or liquids, it does significantly increase the solubility of a gas. Carbonated beverages, for example, are always bottled at high pressures of carbon dioxide to ensure a high concentration of carbon dioxide in the liquid. The fizzing that occurs when you open a can of soda results from the escape of gaseous carbon dioxide because under these conditions the pressure of $\mathrm{CO}_{2}$ above the solution is now much lower than that used in the bottling process.

FIGURE 11.6 (a) A gaseous solute in equilibrium with a solution. (b) The piston is pushed in, which increases the pressure of the gas and the number of gas molecules per unit volume. This causes an increase in the rate at which the gas enters the solution, so the concentration of dissolved gas increases. (c) The greater gas concentration in the solution causes an increase in the rate of escape. A new equilibrium is reached.

William Henry (1774-1836), a close friend of John Dalton, formulated his law in 1801.

Henry's law holds only when there is no chemical reaction between the solute and solvent.

The increase in gas solubility with pressure can be understood from Fig. 11.6. Figure 11.6(a) shows a gas in equilibrium with a solution; that is, the gas molecules are entering and leaving the solution at the same rate. If the pressure is suddenly increased [Fig. 11.6(b)], the number of gas molecules per unit volume increases, and the gas enters the solution at a higher rate than it leaves. As the concentration of dissolved gas increases, the rate of the escape of the gas also increases until a new equilibrium is reached [Fig. 11.6(c)], where the solution contains more dissolved gas than before.

The relationship between gas pressure and the concentration of dissolved gas is given by Henry's law:

$$
C=k P
$$

where $C$ represents the concentration of the dissolved gas, $k$ is a constant characteristic of a particular solution, and $P$ represents the partial pressure of the gaseous solute above the solution. In words, Henry's law states that the amount of a gas dissolved in a solution is directly proportional to the pressure of the gas above the solution.

Henry's law is obeyed most accurately for dilute solutions of gases that do not dissociate in or react with the solvent. For example, Henry's law is obeyed by oxygen gas in water, but it does not correctly represent the behavior of gaseous hydrogen chloride in water because of the dissociation reaction

$$
\mathrm{HCl}(g) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

## INTERACTVE EXAMPLE 11.4 Calculations Using Henry's Law

A certain soft drink is bottled so that a bottle at $25^{\circ} \mathrm{C}$ contains $\mathrm{CO}_{2}$ gas at a pressure of 5.0 atm over the liquid. Assuming that the partial pressure of $\mathrm{CO}_{2}$ in the atmosphere is $4.0 \times 10^{-4} \mathrm{~atm}$, calculate the equilibrium concentrations of $\mathrm{CO}_{2}$ in the soda both before and after the bottle is opened. The Henry's law constant for $\mathrm{CO}_{2}$ in aqueous solution is $3.1 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot$ atm at $25^{\circ} \mathrm{C}$.

## SOLUTION

What is Henry's law for $\mathrm{CO}_{2}$ ?

$$
C_{\mathrm{CO}_{2}}=k_{\mathrm{CO}_{2}} P_{\mathrm{CO}_{2}}
$$

where $k_{\mathrm{CO}_{2}}=3.1 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$.

Carbonation in
a glass of soda.

FIGURE 11.7 The solubilities of several solids as a function of temperature. Note that while most substances become more soluble in water with increasing temperature, sodium sulfate and cerium sulfate become less soluble.
$\Delta H_{\text {soln }}^{\circ}$ refers to the formation of a $1.0-M$ ideal solution and is not necessarily relevant to the process of dissolving a solid in a saturated solution. Thus $\Delta H_{\text {soln }}^{\circ}$ is of limited use in predicting the variation of solubility with temperature.

FIGURE $\mathbf{1 1 . 8}$ The solubilities of several gases in water as a function of temperature at a constant pressure of 1 atm of gas above the solution.

What is the $C_{\mathrm{CO}_{2}}$ in the unopened bottle?
In the unopened bottle, $P_{\mathrm{CO}_{2}}=5.0 \mathrm{~atm}$ and
$\square C_{\mathrm{CO}_{2}}=k_{\mathrm{CO}_{2}} P_{\mathrm{CO}_{2}}=\left(3.1 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}\right)(5.0 \mathrm{~atm})=0.16 \mathrm{~mol} / \mathrm{L}$
What is the $C_{\mathrm{CO}_{2}}$ in the opened bottle?
In the opened bottle, the $\mathrm{CO}_{2}$ in the soda eventually reaches equilibrium with the atmospheric $\mathrm{CO}_{2}$, so $P_{\mathrm{CO}_{2}}=4.0 \times 10^{-4} \mathrm{~atm}$ and

$$
C_{\mathrm{CO}_{2}}=k_{\mathrm{CO}_{2}} P_{\mathrm{CO}_{2}}=\left(3.1 \times 10^{-2} \frac{\mathrm{~mol}}{\mathrm{~L} \cdot \mathrm{~atm}}\right)\left(4.0 \times 10^{-4} \mathrm{~atm}\right)=1.2 \times 10^{-5} \mathrm{~mol} / \mathrm{L}
$$

Note the large change in concentration of $\mathrm{CO}_{2}$. This is why soda goes "flat" after being open for a while.

## See Exercises 11.57 and 11.58

## Temperature Effects (for Aqueous Solutions)

Everyday experiences of dissolving substances such as sugar may lead you to think that solubility always increases with temperature. This is not the case. The dissolving of a solid occurs more rapidly at higher temperatures, but the amount of solid that can be dissolved may increase or decrease with increasing temperature. The effect of temperature on the solubility in water of several solids is shown in Fig. 11.7. Note that although the solubility of most solids in water increases with temperature, the solubilities of some substances (such as sodium sulfate and cerium sulfate) decrease with increasing temperature.

Predicting the temperature dependence of solubility is very difficult. For example, although there is some correlation between the sign of $\Delta H_{\text {soln }}^{\circ}$ and the variation of solubility with temperature, important exceptions exist.* The only sure way to determine the temperature dependence of a solid's solubility is by experiment.

The behavior of gases dissolving in water appears less complex. The solubility of a gas in water typically decreases with increasing temperature, ${ }^{\dagger}$ as is shown for several cases in Fig. 11.8. This temperature effect has important environmental implications because of the widespread use of water from lakes and rivers for industrial cooling. After being used, the water is returned to its natural source at a higher than ambient temperature (thermal pollution has occurred). Because it is warmer, this water contains less than the normal concentration of oxygen and is also less dense; it tends to "float" on the colder water below, thus blocking normal oxygen absorption. This effect can be especially important in deep lakes. The warm upper layer can seriously decrease the amount of oxygen available to aquatic life in the deeper layers of the lake.

The decreasing solubility of gases with increasing temperature is also responsible for the formation of boiler scale. As we will see in more detail in Chapter 14, the bicarbonate ion is formed when carbon dioxide is dissolved in water containing the carbonate ion:

$$
\mathrm{CO}_{3}^{2-}(a q)+\mathrm{CO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{HCO}_{3}^{-}(a q)
$$

When the water also contains $\mathrm{Ca}^{2+}$ ions, this reaction is especially importantcalcium bicarbonate is soluble in water, but calcium carbonate is insoluble. When the water is heated, the carbon dioxide is driven off. For the system to replace the lost carbon dioxide, the reverse reaction must occur:

$$
2 \mathrm{HCO}_{3}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(a q)+\mathrm{CO}_{3}^{2-}(a q)
$$

[^23]

## 11.4

A nonvolatile solute has no tendency to escape from solution into the vapor phase.

FIGURE 11.10 An aqueous solution and pure water in a closed environment. (a) Initial stage. (b) After a period of time, the water is transferred to the solution.

FIGURE 11.9 A pipe with accumulated mineral deposits. The cross section clearly indicates the reduction in pipe capacity.

This reaction, however, also increases the concentration of carbonate ions, causing solid calcium carbonate to form. This solid is the boiler scale that coats the walls of containers such as industrial boilers and tea kettles. Boiler scale reduces the efficiency of heat transfer and can lead to blockage of pipes (Fig. 11.9).

## The Vapor Pressures of Solutions

Liquid solutions have physical properties significantly different from those of the pure solvent, a fact that has great practical importance. For example, we add antifreeze to the water in a car's cooling system to prevent freezing in winter and boiling in summer. We also melt ice on sidewalks and streets by spreading salt. These preventive measures work because of the solute's effect on the solvent's properties.

To explore how a nonvolatile solute affects a solvent, we will consider the experiment represented in Fig. 11.10, in which a sealed container encloses a beaker containing an aqueous sulfuric acid solution and a beaker containing pure water. Gradually, the volume of the sulfuric acid solution increases and the volume of the pure water decreases. Why? We can explain this observation if the vapor pressure of the pure solvent is greater than that of the solution. Under these conditions, the pressure of vapor necessary to achieve equilibrium with the pure solvent is greater than that required to reach equilibrium with the aqueous acid solution. Thus as the pure solvent emits vapor to attempt to reach equilibrium, the aqueous sulfuric acid solution absorbs vapor to try to lower the vapor pressure toward its equilibrium value. This process results in a net transfer of water from the pure water through the vapor phase to the sulfuric acid solution. The system can reach an equilibrium vapor pressure only when all the water is transferred to the solution. This experiment is just one of many observations indicating that the presence of a nonvolatile solute lowers the vapor pressure of a solvent.

We can account for this behavior in terms of the simple model shown in Fig. 11.11. The dissolved nonvolatile solute decreases the number of solvent molecules per unit volume and it should proportionately lower the escaping tendency of the solvent molecules. For example, in a solution consisting of half nonvolatile solute molecules and half solvent molecules, we might expect the observed vapor pressure to be half

## CHEMICAL CONNECTIONS

## The Lake Nyos Tragedy

On August 21, 1986, a cloud of gas suddenly boiled from Lake Nyos in Cameroon, killing nearly 2000 people. Although at first it was speculated that the gas was hydrogen sulfide, it now seems clear it was carbon dioxide. What would cause Lake Nyos to emit this huge, suffocating cloud of $\mathrm{CO}_{2}$ ? Although the answer may never be known for certain, many scientists believe that the lake suddenly"turned over," bringing to the surface water that contained huge quantities of dissolved carbon dioxide. Lake Nyos is a deep lake
that is thermally stratified: Layers of warm, less dense water near the surface float on the colder, denser water layers near the lake's bottom. Under normal conditions the lake stays this way; there is little mixing among the different layers. Scientists believe that over hundreds or thousands of years, carbon dioxide gas had seeped into the cold water at the lake's bottom and dissolved in great amounts because of the large pressure of $\mathrm{CO}_{2}$ present (in accordance with Henry's law). For some reason on August 21, 1986, the lake

FIGURE 11.11 The presence of a nonvolatile solute inhibits the escape of solvent molecules from the liquid and so lowers the vapor pressure of the solvent.
that of the pure solvent, since only half as many molecules can escape. In fact, this is what is observed.

Detailed studies of the vapor pressures of solutions containing nonvolatile solutes were carried out by François M. Raoult (1830-1901). His results are described by the equation known as Raoult's law:

$$
P_{\text {soln }}=\chi_{\text {solvent }} P_{\text {solvent }}^{0}
$$

Pure solvent
apparently suffered an overturn, possibly due to wind or to unusual cooling of the lake's surface by monsoon clouds. This caused water that was greatly supersaturated with $\mathrm{CO}_{2}$ to reach the surface and release tremendous quantities of gaseous $\mathrm{CO}_{2}$ that suffocated thousands of humans and animals before they knew what hit them-a tragic, monumental illustration of Henry's law.

Since 1986 the scientists studying Lake Nyos and nearby Lake Monoun have observed a rapid recharging of the $\mathrm{CO}_{2}$ levels in the deep waters of these lakes, causing concern that another deadly gas release could occur at any time. Apparently the only way to prevent such a disaster is to pump away the $\mathrm{CO}_{2}$-charged deep water in the two lakes. Scientists at a conference to study this problem in 1994 recommended such a solution, but it has not yet been funded by Cameroon.

FIGURE 11.12 For a solution that obeys Raoult's law, a plot of $P_{\text {soln }}$ versus $\chi_{\text {solvent }}$ gives a straight line.
where $P_{\text {soln }}$ is the observed vapor pressure of the solution, $\chi_{\text {solvent }}$ is the mole fraction of solvent, and $P_{\text {solvent }}^{0}$ is the vapor pressure of the pure solvent. Note that for a solution of half solute and half solvent molecules, $\chi_{\text {solvent }}$ is 0.5 , so the vapor pressure of the solution is half that of the pure solvent. On the other hand, for a solution in which three-fourths of the solution molecules are solvent, $\chi_{\text {solvent }}=\frac{3}{4}=0.75$, and $P_{\text {soln }}=$ $0.75 P_{\text {solvent }}^{0}$. The idea is that the nonvolatile solute simply dilutes the solvent.

Raoult's law is a linear equation of the form $y=m x+b$, where $y=P_{\text {soln }}, x=$ $\chi_{\text {solvent }}, m=P_{\text {solvent }}^{0}$, and $b=0$. Thus a plot of $P_{\text {soln }}$ versus $\chi_{\text {solvent }}$ gives a straight line with a slope equal to $P_{\text {solvent }}^{0}$ (Fig. 11.12).

## INTERACTIVE EXAMPLE 11.5 Calculating the Vapor Pressure of a Solution

Calculate the expected vapor pressure at $25^{\circ} \mathrm{C}$ for a solution prepared by dissolving 158.0 g common table sugar (sucrose, molar mass $=342.3 \mathrm{~g} / \mathrm{mol}$ ) in $643.5 \mathrm{~cm}^{3}$ of water. At $25^{\circ} \mathrm{C}$, the density of water is $0.9971 \mathrm{~g} / \mathrm{cm}^{3}$ and the vapor pressure is 23.76 torr.

## SOLUTION

What is Raoult's law for this case?

$$
P_{\text {soln }}=\chi_{\mathrm{H}_{2} \mathrm{O}} P_{\mathrm{H}_{2} \mathrm{O}}^{0}
$$

To calculate the mole fraction of water in the solution, we must first determine the number of moles of sucrose and the moles of water present.
What are the moles of sucrose?

$$
\begin{aligned}
\text { Moles of sucrose } & =158.0 \mathrm{~g} \text { sucrose } \times \frac{1 \mathrm{~mol} \text { sucrose }}{342.3 \mathrm{~g} \text { sucrose }} \\
& =0.4616 \mathrm{~mol} \text { sucrose }
\end{aligned}
$$

What are the moles of water?
To determine the moles of water present, we first convert volume to mass using the density:

$$
643.5 \mathrm{~cm}^{3} \mathrm{H}_{2} \mathrm{O} \times \frac{0.9971 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}{\mathrm{~cm}^{3} \mathrm{H}_{2} \mathrm{O}}=641.6 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}
$$

The number of moles of water is therefore

$$
641.6 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}{18.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}=35.60 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}
$$

What is the mole fraction of water in the solution?

$$
\begin{aligned}
\chi_{\mathrm{H}_{2} \mathrm{O}} & =\frac{\mathrm{mol} \mathrm{H}_{2} \mathrm{O}}{\mathrm{~mol} \mathrm{H}_{2} \mathrm{O}+\text { mol sucrose }}=\frac{35.60 \mathrm{~mol}}{35.60 \mathrm{~mol}+0.4616 \mathrm{~mol}} \\
& =\frac{35.60 \mathrm{~mol}}{36.06 \mathrm{~mol}}=0.9873
\end{aligned}
$$

$\square$ The vapor pressure of the solution is: $P_{\text {soln }}=\chi_{\mathrm{H}_{2} \mathrm{O}} P_{\mathrm{H}_{2} \mathrm{O}}^{0}=(0.9872)(23.76$ torr $)$ $=23.46$ torr
Thus the vapor pressure of water has been lowered from 23.76 torr in the pure state to 23.46 torr in the solution. The vapor pressure has been lowered by 0.30 torr.

The lowering of vapor pressure depends on the number of solute particles present in the solution.

## INTERACTIVE EXAMPLE 11.6

## SOLUTION

FIGURE 11.13 When a solution contains two volatile components, both contribute to the total vapor pressure. Note that in this case the solution contains equal numbers of the components $O$ and $O$, but the vapor contains more othan . This means that component $O$ is more volatile (has a higher vapor pressure as a pure liquid) than component 0 .

The phenomenon of the lowering of the vapor pressure gives us a convenient way to "count" molecules and thus provides a means for experimentally determining molar masses. Suppose a certain mass of a compound is dissolved in a solvent and the vapor pressure of the resulting solution is measured. Using Raoult's law, we can determine the number of moles of solute present. Since the mass of this number of moles is known, we can calculate the molar mass.

We also can use vapor pressure measurements to characterize solutions. For example, 1 mole of sodium chloride dissolved in water lowers the vapor pressure approximately twice as much as expected because the solid has two ions per formula unit, which separate when it dissolves. Thus vapor pressure measurements can give valuable information about the nature of the solute after it dissolves.

## Calculating the Vapor Pressure of a Solution Containing lonic Solute

Predict the vapor pressure of a solution prepared by mixing 35.0 g solid $\mathrm{Na}_{2} \mathrm{SO}_{4}$ (molar mass $=142.05 \mathrm{~g} / \mathrm{mol}$ ) with 175 g water at $25^{\circ} \mathrm{C}$. The vapor pressure of pure water at $25^{\circ} \mathrm{C}$ is 23.76 torr.

First, we need to know the mole fraction of $\mathrm{H}_{2} \mathrm{O}$.

$$
\begin{gathered}
n_{\mathrm{H}_{2} \mathrm{O}}=175 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}{18.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}=9.71 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O} \\
n_{\mathrm{Na}_{2} \mathrm{SO}_{4}}=35.0 \mathrm{~g} \mathrm{Na}_{2} \mathrm{SO}_{4} \times \frac{1 \mathrm{~mol} \mathrm{Na}_{2} \mathrm{SO}_{4}}{142.05 \mathrm{~g} \mathrm{Na}_{2} \mathrm{SO}_{4}}=0.246 \mathrm{~mol} \mathrm{Na}_{2} \mathrm{SO}_{4}
\end{gathered}
$$

It is essential to recognize that when 1 mole of solid $\mathrm{Na}_{2} \mathrm{SO}_{4}$ dissolves, it produces 2 moles of $\mathrm{Na}^{+}$ions and 1 mole of $\mathrm{SO}_{4}{ }^{2-}$ ions. Thus the number of solute particles present in this solution is three times the number of moles of solute dissolved:

$$
\begin{aligned}
& n_{\text {solute }}=3(0.246)=0.738 \mathrm{~mol} \\
& \chi_{\mathrm{H}_{2} \mathrm{O}}=\frac{n_{\mathrm{H}_{2} \mathrm{O}}}{n_{\text {solute }}+n_{\mathrm{H}_{2} \mathrm{O}}}=\frac{9.71 \mathrm{~mol}}{0.738 \mathrm{~mol}+9.72 \mathrm{~mol}}=\frac{9.71}{10.458}=0.929
\end{aligned}
$$

Now we can use Raoult's law to predict the vapor pressure:

$$
\square P_{\text {soln }}=\chi_{\mathrm{H}_{2} \mathrm{O}} P_{\mathrm{H}_{2} \mathrm{O}}^{0}=(0.929)(23.76 \text { torr })=22.1 \text { torr }
$$

## Nonideal Solutions

So far we have assumed that the solute is nonvolatile and so does not contribute to the vapor pressure over the solution. However, for liquid-liquid solutions where both components are volatile, a modified form of Raoult's law applies:

$$
P_{\text {TOTAL }}=P_{\mathrm{A}}+P_{\mathrm{B}}=\chi_{\mathrm{A}} P_{\mathrm{A}}^{0}+\chi_{\mathrm{B}} P_{\mathrm{B}}^{0}
$$

where $P_{\text {TOTAL }}$ represents the total vapor pressure of a solution containing A and $\mathrm{B}, \chi_{\mathrm{A}}$ and $\chi_{\mathrm{B}}$ are the mole fractions of A and $\mathrm{B}, P_{\mathrm{A}}^{0}$ and $P_{\mathrm{B}}^{0}$ are the vapor pressures of pure A and pure B , and $P_{\mathrm{A}}$ and $P_{\mathrm{B}}$ are the partial pressures resulting from molecules of A and of B in the vapor above the solution (Fig. 11.13).

A liquid-liquid solution that obeys Raoult's law is called an ideal solution. Raoult's law is to solutions what the ideal gas law is to gases. As with gases, ideal behavior for solutions is never perfectly achieved but is sometimes closely approached.

Strong solute-solvent interaction gives a vapor pressure lower than that predicted by Raoult's law.

-
Strong solute-solvent interactions

FIGURE 11.14 Vapor pressure for a solution of two volatile liquids. (a) The behavior predicted for an ideal liquid-liquid solution by Raoult's law. (b) A solution for which $P_{\text {TOTAL }}$ is larger than the value calculated from Raoult's law. This solution shows a positive deviation from Raoult's law. (c) A solution for which $P_{\text {TOTAL }}$ is smaller than the value calculated from Raoult's law. This solution shows a negative deviation from Raoult's law.

Benzene

Toluene

TABLE 11.4 \| Summary of the Behavior of Various Types of Solutions

| Interactive Forces <br> Between Solute $(A)$ and <br> Solvent (B) Particles | (Hsoln | $\Delta T$ for <br> Solution <br> Formation | Deviation <br> from Raoult's <br> Law | Zero | None <br> (ideal solution) |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $A \leftrightarrow A, B \leftrightarrow B \equiv A \leftrightarrow B$ | Zero | Benzene- <br> toluene |  |  |  |
| $A \leftrightarrow A, B \leftrightarrow B<A \leftrightarrow B$ | Negative <br> (exothermic) | Positive | Negative | Acetone- <br> water |  |
| $A \leftrightarrow A, B \leftrightarrow B>A \leftrightarrow B$ | Positive <br> (endothermic) | Negative | Positive | Ethanol- <br> hexane |  |

Finally, for a solution of very similar liquids, such as benzene and toluene (shown in margin), the enthalpy of solution is very close to zero, and thus the solution closely obeys Raoult's law (ideal behavior).

A summary of the behavior of various types of solutions is given in Table 11.4.

## INTERACTIVE EXAMPLE 11.1

Acetone

Chloroform

In this case the usually nonpolar $\mathrm{C}-\mathrm{H}$ bond is strongly polarized by the three attached, highly electronegative chlorine atoms, thus producing hydrogen bonding.

## SOLUTION

## Calculating the Vapor Pressure of a Solution Containing Two Liquids

A solution is prepared by mixing 5.81 g acetone $\left(\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{O}\right.$, molar mass $\left.=58.1 \mathrm{~g} / \mathrm{mol}\right)$ and 11.9 g chloroform $\left(\mathrm{HCCl}_{3}\right.$, molar mass $\left.=119.4 \mathrm{~g} / \mathrm{mol}\right)$. At $35^{\circ} \mathrm{C}$, this solution has a total vapor pressure of 260 . torr. Is this an ideal solution? The vapor pressures of pure acetone and pure chloroform at $35^{\circ} \mathrm{C}$ are 345 and 293 torr, respectively.
To decide whether this solution behaves ideally, we first calculate the expected vapor pressure using Raoult's law:

$$
P_{\mathrm{TOTAL}}=\chi_{\mathrm{A}} P_{\mathrm{A}}^{0}+\chi_{\mathrm{C}} P_{\mathrm{C}}^{0}
$$

where A stands for acetone and C stands for chloroform. The calculated value can then be compared with the observed vapor pressure.

First, we must calculate the number of moles of acetone and chloroform:

$$
\begin{gathered}
5.81 \mathrm{~g} \text { acetone } \times \frac{1 \mathrm{~mol} \text { acetone }}{58.1 \mathrm{~g} \text { acetone }}=0.100 \mathrm{~mol} \text { acetone } \\
11.9 \mathrm{~g} \text { chloroform } \times \frac{1 \mathrm{~mol} \text { chloroform }}{119 \mathrm{~g} \text { chloroform }}=0.100 \mathrm{~mol} \text { chloroform }
\end{gathered}
$$

Since the solution contains equal numbers of moles of acetone and chloroform, that is,

$$
\chi_{\mathrm{A}}=0.500 \quad \text { and } \quad \chi_{\mathrm{C}}=0.500
$$

the expected vapor pressure is

$$
\square P_{\mathrm{TOTAL}}=(0.500)(345 \text { torr })+(0.500)(293 \text { torr })=319 \text { torr }
$$

Comparing this value with the observed pressure of 260 . torr shows that the solution does not behave ideally. The observed value is lower than that expected. This negative deviation from Raoult's law can be explained in terms of the hydrogen-bonding interaction

which lowers the tendency of these molecules to escape from the solution.
See Exercises 11.68, 11.64, 11.70, and 11.107

### 11.5 Boiling-Point Elevation and Freezing-Point Depression

In the preceding section we saw how a solute affects the vapor pressure of a liquid solvent. Because changes of state depend on vapor pressure, the presence of a solute also affects the freezing point and boiling point of a solvent. Freezing-point depression, boiling-point elevation, and osmotic pressure (discussed in Section 11.6) are called colligative properties. As we will see, they are grouped together because they depend only on the number, and not on the identity, of the solute particles in an ideal solution. Because of their direct relationship to the number of solute particles, the colligative properties are very useful for characterizing the nature of a solute after it is dissolved in a solvent and for determining molar masses of substances.

## Boiling-Point Elevation

Normal boiling point was defined in Section 10.8.

The normal boiling point of a liquid occurs at the temperature where the vapor pressure is equal to 1 atmosphere. We have seen that a nonvolatile solute lowers the vapor pressure of the solvent. Therefore, such a solution must be heated to a higher temperature than the boiling point of the pure solvent to reach a vapor pressure of 1 atmosphere. This means that a nonvolatile solute elevates the boiling point of the solvent. Figure 11.15 shows the phase diagram for an aqueous solution containing a nonvolatile solute. Note that the liquid/vapor line is shifted to higher temperatures than those for pure water.

As you might expect, the magnitude of the boiling-point elevation depends on the concentration of the solute. The change in boiling point can be represented by the equation

$$
\Delta T=K_{\mathrm{b}} m_{\text {solute }}
$$

where $\Delta T$ is the boiling-point elevation, or the difference between the boiling point of the solution and that of the pure solvent, $K_{\mathrm{b}}$ is a constant that is characteristic of the solvent and is called the molal boiling-point elevation constant, and $m_{\text {solute }}$ is the molality of the solute in the solution.

Values of $K_{\mathrm{b}}$ for some common solvents are given in Table 11.5. The molar mass of a solute can be determined from the observed boiling-point elevation, as shown in Example 11.8.

FIGURE 11.15 Phase diagrams for pure water (purple lines) and for an aqueous solution containing a nonvolatile solute (blue lines). Note that the boiling point of the solution is higher than that of pure water. Conversely, the freezing point of the solution is lower than that of pure water. The effect of a nonvolatile solute is to extend the liquid range of a solvent. These lines are not drawn to scale.

## Calculating the Molar Mass by Boiling-Point Elevation

A solution was prepared by dissolving 18.00 g glucose in 150.0 g water. The resulting solution was found to have a boiling point of $100.34^{\circ} \mathrm{C}$. Calculate the molar mass of glucose. Glucose is a molecular solid that is present as individual molecules in solution.
where

$$
\begin{aligned}
\Delta T & =K_{\mathrm{b}} m_{\text {solute }} \\
\Delta T & =100.34^{\circ} \mathrm{C}-100.00^{\circ} \mathrm{C}=0.34^{\circ} \mathrm{C}
\end{aligned}
$$

From Table 11.5, for water $K_{\mathrm{b}}=0.51$. The molality of this solution then can be calculated by rearranging the boiling-point elevation equation to give

$$
m_{\text {solute }}=\frac{\Delta T}{K_{\mathrm{b}}}=\frac{0.34^{\circ} \mathrm{C}}{0.51^{\circ} \mathrm{C} \cdot \mathrm{~kg} / \mathrm{mol}}=0.67 \mathrm{~mol} / \mathrm{kg}
$$

The solution was prepared using 0.1500 kg water. Using the definition of molality, we can find the number of moles of glucose in the solution.

$$
\begin{aligned}
& m_{\text {solute }}=0.67 \mathrm{~mol} / \mathrm{kg}=\frac{\text { mol solute }}{\mathrm{kg} \text { solvent }}=\frac{n_{\text {glucose }}}{0.1500 \mathrm{~kg}} \\
& n_{\text {glucose }}=(0.67 \mathrm{~mol} / \mathrm{kg})(0.1500 \mathrm{~kg})=0.10 \mathrm{~mol}
\end{aligned}
$$

Thus 0.10 mole of glucose has a mass of 18.00 g , and 1.0 mole of glucose has a mass of $180 \mathrm{~g}(10 \times 18.00 \mathrm{~g})$. The molar mass of glucose is $180 \mathrm{~g} / \mathrm{mol}$.

## See Exercise 11.72

## Freezing-Point Depression

When a solute is dissolved in a solvent, the freezing point of the solution is lower than that of the pure solvent. Why? Recall that the vapor pressures of ice and liquid water are the same at $0^{\circ} \mathrm{C}$. Suppose a solute is dissolved in water. The resulting solution will not freeze at $0^{\circ} \mathrm{C}$ because the water in the solution has a lower vapor pressure than that of pure ice. No ice will form under these conditions. However, the vapor pressure of ice decreases more rapidly than that of liquid water as the temperature decreases. Therefore, as the solution is cooled, the vapor pressure of the ice and that of the liquid

FIGURE 11.16 (a) Ice in equilibrium with liquid water. (b) Ice in equilibrium with liquid water containing a dissolved solute (shown in red).

Melting point and freezing point both refer to the temperature where the solid and liquid coexist.

-a

water in the solution will eventually become equal. The temperature at which this occurs is the new freezing point of the solution and is below $0^{\circ} \mathrm{C}$. The freezing point has been depressed.

We can account for this behavior in terms of the simple model shown in Fig. 11.16. The presence of the solute lowers the rate at which molecules in the liquid return to the solid state. Thus for an aqueous solution, only the liquid state is found at $0^{\circ} \mathrm{C}$. As the solution is cooled, the rate at which water molecules leave the solid ice decreases until this rate and the rate of formation of ice become equal and equilibrium is reached. This is the freezing point of the water in the solution.

Because a solute lowers the freezing point of water, compounds such as sodium chloride and calcium chloride are often spread on streets and sidewalks to prevent ice from forming in freezing weather. Of course, if the outside temperature is lower than the freezing point of the resulting salt solution, ice forms anyway. So this procedure is not effective at extremely cold temperatures.

The solid/liquid line for an aqueous solution is shown on the phase diagram for water in Fig. 11.15. Since the presence of a solute elevates the boiling point and depresses the freezing point of the solvent, adding a solute has the effect of extending the liquid range.

The equation for freezing-point depression is analogous to that for boiling-point elevation:

$$
\Delta T=K_{\mathrm{f}} m_{\text {solute }}
$$

where $\Delta T$ is the freezing-point depression, or the difference between the freezing point of the pure solvent and that of the solution, and $K_{\mathrm{f}}$ is a constant that is characteristic of a particular solvent and is called the molal freezing-point depression constant. Values of $K_{\mathrm{f}}$ for common solvents are listed in Table 11.5.

Like the boiling-point elevation, the observed freezing-point depression can be used to determine molar masses and to characterize solutions.

## INTERACTVE EXAMPLE 11.8 Freezing-Point Depression

What mass of ethylene glycol $\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}\right.$, molar mass $\left.=62.1 \mathrm{~g} / \mathrm{mol}\right)$, the main component of antifreeze, must be added to 10.0 L water to produce a solution for use in a car's radiator that freezes at $-10.0^{\circ} \mathrm{F}\left(-23.3^{\circ} \mathrm{C}\right)$ ? Assume the density of water is exactly $1 \mathrm{~g} / \mathrm{mL}$.

## SOLUTION

Ethylene glycol

The freezing point must be lowered from $0^{\circ} \mathrm{C}$ to $-23.3^{\circ} \mathrm{C}$. To determine the molality of ethylene glycol needed to accomplish this, we can use the equation

$$
\Delta T=K_{\mathrm{f}} m_{\text {solute }}
$$

where $\Delta T=23.3^{\circ}$ and $K_{\mathrm{f}}=1.86$ (from Table 11.5). Solving for the molality gives

$$
m_{\text {solute }}=\frac{\Delta T}{K_{\mathrm{f}}}=\frac{23.3^{\circ} \mathrm{C}}{1.86^{\circ} \mathrm{C} \cdot \mathrm{~kg} / \mathrm{mol}}=12.5 \mathrm{~mol} / \mathrm{kg}
$$

The addition of antifreeze lowers the freezing point of water in a car's radiator.

This means that 12.5 moles of ethylene glycol must be added per kilogram of water. We have 10.0 L , or 10.0 kg , of water. Therefore, the total number of moles of ethylene glycol needed is

$$
\frac{12.5 \mathrm{~mol}}{\mathrm{~kg}} \times 10.0 \mathrm{~kg}=1.25 \times 10^{2} \mathrm{~mol}
$$

The mass of ethylene glycol needed is

$$
1.25 \times 10^{2} \mathrm{~mol} \times \frac{62.1 \mathrm{~g}}{\mathrm{~mol}}=7.76 \times 10^{3} \mathrm{~g}(\text { or } 7.76 \mathrm{~kg})
$$

## INTERACTIVE EXAMPLE 11.10

## Determining Molar Mass by Freezing-Point Depression

A chemist is trying to identify a human hormone that controls metabolism by determining its molar mass. A sample weighing 0.546 g was dissolved in 15.0 g benzene, and the freezing-point depression was determined to be $0.240^{\circ} \mathrm{C}$. Calculate the molar mass of the hormone.

From Table $11.5, K_{\mathrm{f}}$ for benzene is $5.12^{\circ} \mathrm{C} \cdot \mathrm{kg} / \mathrm{mol}$, so the molality of the hormone is

$$
m_{\text {hormone }}=\frac{\Delta T}{K_{\mathrm{f}}}=\frac{0.240^{\circ} \mathrm{C}}{5.12^{\circ} \mathrm{C} \cdot \mathrm{~kg} / \mathrm{mol}}=4.69 \times 10^{-2} \mathrm{~mol} / \mathrm{kg}
$$

The moles of hormone can be obtained from the definition of molality:

$$
4.69 \times 10^{-2} \mathrm{~mol} / \mathrm{kg}=m_{\text {solute }}=\frac{\mathrm{mol} \text { hormone }}{0.0150 \mathrm{~kg} \text { benzene }}
$$

or

$$
\text { mol hormone }=\left(4.69 \times 10^{-2} \frac{\mathrm{~mol}}{\mathrm{~kg}}\right)(0.0150 \mathrm{~kg})=7.04 \times 10^{-4} \mathrm{~mol}
$$

Since 0.546 g hormone was dissolved, $7.04 \times 10^{-4}$ mole of hormone has a mass of 0.546 g , and

$$
\begin{gathered}
\frac{0.546 \mathrm{~g}}{7.04 \times 10^{-4} \mathrm{~mol}}=\frac{x}{1.00 \mathrm{~mol}} \\
x=776
\end{gathered}
$$

Thus the molar mass of the hormone is $776 \mathrm{~g} / \mathrm{mol}$.

### 11.6 Osmotic Pressure

Osmotic pressure, another of the colligative properties, can be understood from Fig. 11.17. A solution and pure solvent are separated by a semipermeable membrane, which allows solvent but not solute molecules to pass through. As time passes, the

Applied pressure, needed to stop osmosis

FIGURE 11.18 The normal flow of solvent into the solution (osmosis) can be prevented by applying an external pressure to the solution. The minimum pressure required to stop the osmosis is equal to the osmotic pressure of the solution.

FIGURE 11.19 (a) A pure solvent and its solution (containing a nonvolatile solute) are separated by a semipermeable membrane through which solvent molecules (blue) can pass but solute molecules (green) cannot. The rate of solvent transfer is greater from solvent to solution than from solution to solvent. (b) The system at equilibrium, where the rate of solvent transfer is the same in both directions.

FIGURE 11.17 A tube with a bulb on the end that is covered by a semipermeable membrane. The solution is inside the tube and is bathed in the pure solvent. There is a net transfer of solvent molecules into the solution until the hydrostatic pressure equalizes the solvent flow in both directions.
volume of the solution increases and that of the solvent decreases. This flow of solvent into the solution through the semipermeable membrane is called osmosis. Eventually the liquid levels stop changing, indicating that the system has reached equilibrium. Because the liquid levels are different at this point, there is a greater hydrostatic pressure on the solution than on the pure solvent. This excess pressure is called the osmotic pressure.

We can take another view of this phenomenon, as illustrated in Fig. 11.18. Osmosis can be prevented by applying a pressure to the solution. The minimum pressure that stops the osmosis is equal to the osmotic pressure of the solution. A simple model to explain osmotic pressure can be constructed as shown in Fig. 11.19. The membrane allows only solvent molecules to pass through. However, the initial rates of solvent transfer to and from the solution are not the same. The solute particles interfere with the passage of solvent, so the rate of transfer is slower from the solution to the solvent than in the reverse direction. Thus there is a net transfer of solvent molecules into the solution, which causes the solution volume to increase. As the solution level rises in the tube, the resulting pressure exerts an extra "push" on the solvent molecules in the solution, forcing them back through the membrane. Eventually, enough pressure develops so that the solvent transfer becomes equal in both directions. At this point, equilibrium is achieved and the levels stop changing.

Osmotic pressure can be used to characterize solutions and determine molar masses, as can the other colligative properties, but osmotic pressure is particularly useful because a small concentration of solute produces a relatively large osmotic pressure.

Experiments show that the dependence of the osmotic pressure on solution concentration is represented by the equation

$$
\Pi=M R T
$$

where $\Pi$ is the osmotic pressure in atmospheres, $M$ is the molarity of the solution, $R$ is the gas law constant, and $T$ is the Kelvin temperature.

A molar mass determination using osmotic pressure is illustrated in Example 11.11.

Consider the model of osmotic pressure as shown in Fig. 11.19. What if both sides contained a different pure solvent, each with a different vapor pressure? What would the system look like at equilibrium? Assume the different solvent molecules are able to pass through the membrane.

## INTERACTIVE EXAMPLE 11.11

SOLUTION

Measurements of osmotic pressure generally give much more accurate molar mass values than those from freezing-point or boiling-point changes.

We use the equation

$$
\Pi=M R T
$$

In this case we have

$$
\begin{aligned}
\Pi & =1.12 \mathrm{torr} \times \frac{1 \mathrm{~atm}}{760 \mathrm{torr}}=1.47 \times 10^{-3} \mathrm{~atm} \\
R & =0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol} \\
T & =25.0+273=298 \mathrm{~K}
\end{aligned}
$$

Note that the osmotic pressure must be converted to atmospheres because of the units of $R$.
Solving for $M$ gives

$$
M=\frac{1.47 \times 10^{-3} \mathrm{~atm}}{(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K})}=6.01 \times 10^{-5} \mathrm{~mol} / \mathrm{L}
$$

Since $1.00 \times 10^{-3} \mathrm{~g}$ protein was dissolved in 1 mL solution, the mass of protein per liter of solution is 1.00 g . The solution's concentration is $6.01 \times 10^{-5} \mathrm{~mol} / \mathrm{L}$. This concentration is produced from $1.00 \times 10^{-3} \mathrm{~g}$ protein per milliliter, or $1.00 \mathrm{~g} / \mathrm{L}$. Thus $6.01 \times 10^{-5} \mathrm{~mol}$ protein has a mass of 1.00 g and

$$
\begin{aligned}
\frac{1.00 \mathrm{~g}}{6.01 \times 10^{-5} \mathrm{~mol}} & =\frac{x}{1.00 \mathrm{~mol}} \\
x & =1.66 \times 10^{4} \mathrm{~g}
\end{aligned}
$$

The molar mass of the protein is $1.66 \times 10^{4} \mathrm{~g} / \mathrm{mol}$. This molar mass may seem very large, but it is relatively small for a protein.

## See Exercises 11.81 and 11.82

In osmosis, a semipermeable membrane prevents transfer of all solute particles. A similar phenomenon, called dialysis, occurs at the walls of most plant and animal cells. However, in this case the membrane allows transfer of both solvent molecules and small solute molecules and ions. One of the most important applications of

FIGURE 11.20 Representation of the functioning of an artificial kidney.

$\Delta$
Patient undergoing dialysis.

The brine used in pickling causes the cucumbers to shrivel.

dialysis is the use of artificial kidney machines to purify the blood. The blood is passed through a cellophane tube, which acts as the semipermeable membrane. The tube is immersed in a dialyzing solution (Fig. 11.20). This "washing" solution contains the same concentrations of ions and small molecules as blood but has none of the waste products normally removed by the kidneys. The resulting dialysis (movement of waste molecules into the washing solution) cleanses the blood.

Solutions that have identical osmotic pressures are said to be isotonic solutions. Fluids administered intravenously must be isotonic with body fluids. For example, if red blood cells are bathed in a hypertonic solution, which is a solution having an osmotic pressure higher than that of the cell fluids, the cells will shrivel because of a net transfer of water out of the cells. This phenomenon is called crenation. The opposite phenomenon, called hemolysis, occurs when cells are bathed in a hypotonic solution, a solution with an osmotic pressure lower than that of the cell fluids. In this case, the cells rupture because of the flow of water into the cells.

We can use the phenomenon of crenation to our advantage. Food can be preserved by treating its surface with a solute that gives a solution that is hypertonic to bacteria cells. Bacteria on the food then tend to shrivel and die. This is why salt can be used to protect meat and sugar can be used to protect fruit.

## INTERACTIVE EXAMPLE 11.12 Isotonic Solutions

What concentration of sodium chloride in water is needed to produce an aqueous solution isotonic with blood $\left(\Pi=7.70 \mathrm{~atm}\right.$ at $\left.25^{\circ} \mathrm{C}\right)$ ?

## SOLUTION

We can calculate the molarity of the solute from the equation

$$
\begin{aligned}
& \Pi=M R T \text { or } \quad M=\frac{\Pi}{R T} \\
& M=\frac{7.70 \mathrm{~atm}}{(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K})}=0.315 \mathrm{~mol} / \mathrm{L}
\end{aligned}
$$

This represents the total molarity of solute particles. But NaCl gives two ions per formula unit. Therefore, the concentration of NaCl needed is $\frac{0.315 M}{2}=0.1575 \mathrm{M}=$ 0.158 M . That is,

$$
\begin{aligned}
\mathrm{NaCl} & \longrightarrow \mathrm{Na}^{+}+\mathrm{Cl}^{-} \\
0.1575 M & \underbrace{0.1575 M 00.1575 M}_{0.315 M}
\end{aligned}
$$

Normal

## Reverse Osmosis

If a solution in contact with pure solvent across a semipermeable membrane is subjected to an external pressure larger than its osmotic pressure, reverse osmosis occurs. The pressure will cause a net flow of solvent from the solution to the solvent (Fig. 11.21). In reverse osmosis, the semipermeable membrane acts as a "molecular filter" to remove solute particles. This fact is applicable to the desalination (removal of dissolved salts) of seawater, which is highly hypertonic to body fluids and thus is not drinkable.

As the population of the Sun Belt areas of the United States increases, more demand will be placed on the limited supplies of fresh water there. One obvious source of fresh water is from the desalination of seawater. Various schemes have been suggested, including solar evaporation, reverse osmosis, and even a plan for towing icebergs from Antarctica. The problem, of course, is that all the available processes are expensive. However, as water shortages increase, desalination is becoming necessary. For example, the first full-time public desalination plant in the United States started operations on Catalina Island, just off the coast of California (Fig. 11.22). This plant, which can produce 132,000 gallons of drinkable water from the Pacific Ocean every day, operates by reverse osmosis. Powerful pumps, developing over $800 \mathrm{lb} / \mathrm{in}^{2}$ of pressure, are used to force seawater through synthetic semipermeable membranes.

Catalina Island's plant may be just the beginning. The city of Santa Barbara opened a $\$ 40$ million desalination plant in 1992 that can produce 8 million gallons of drinking water per day. The southern California city of Carlsbad opened a reverse osmosis desalination plant in 2012 that can produce 50 million gallons of drinking water daily from seawater. Desalination plants are also in the works for Huntington Beach, California, and Camp Pendleton, a military base just north of Carlsbad.

A small-scale, manually operated reverse osmosis desalinator has been developed by the U.S. Navy to provide fresh water on life rafts. Potable water can be supplied by this desalinator at the rate of 1.25 gallons of water per hour-enough to keep 25 people alive. This compact desalinator, which weighs only 10 pounds, can now replace the bulky cases of fresh water formerly stored in Navy life rafts.

FIGURE 11.21 Reverse osmosis. A pressure greater than the osmotic pressure of the solution is applied, which causes a net flow of solvent molecules (blue) from the solution to the pure solvent. The solute molecules (green) remain behind.

FIGURE 11.22 (a) Residents of Catalina Island off the coast of southern California are benefiting from a desalination plant that can supply 132,000 gallons a day, or one-third of the island's daily needs. (b) Machinery in the desalination plant for Catalina Island.

### 11.7 Colligative Properties of Electrolyte Solutions

Dutch chemist J. H. van't Hoff (1852-1911) received the first Nobel Prize in chemistry in 1901.

FIGURE 11.23 In an aqueous solution a few ions aggregate, forming ion pairs that behave as a unit.

As we have seen previously, the colligative properties of solutions depend on the total concentration of solute particles. For example, a $0.10-m$ glucose solution shows a freezing-point depression of $0.186^{\circ} \mathrm{C}$ :

$$
\Delta T=K_{\mathrm{f}} m=\left(1.86^{\circ} \mathrm{C} \cdot \mathrm{~kg} / \mathrm{mol}\right)(0.100 \mathrm{~mol} / \mathrm{kg})=0.186^{\circ} \mathrm{C}
$$

On the other hand, a $0.10-\mathrm{m}$ sodium chloride solution should show a freezing-point depression of $0.37^{\circ} \mathrm{C}$, since the solution is 0.10 m Na ions and $0.10 \mathrm{~m} \mathrm{Cl}{ }^{-}$ions. Therefore, the solution contains a total of 0.20 m solute particles, and $\Delta T=\left(1.86^{\circ} \mathrm{C} \cdot\right.$ $\mathrm{kg} / \mathrm{mol})(0.20 \mathrm{~mol} / \mathrm{kg})=0.37^{\circ} \mathrm{C}$.

The relationship between the moles of solute dissolved and the moles of particles in solution is usually expressed using the van't Hoff factor, $i$ :

$$
i=\frac{\text { moles of particles in solution }}{\text { moles of solute dissolved }}
$$

The expected value for $i$ can be calculated for a salt by noting the number of ions per formula unit. For example, for $\mathrm{NaCl}, i$ is 2 ; for $\mathrm{K}_{2} \mathrm{SO}_{4}, i$ is 3 ; and for $\mathrm{Fe}_{3}\left(\mathrm{PO}_{4}\right)_{2}, i$ is 5. These calculated values assume that when a salt dissolves, it completely dissociates into its component ions, which then move around independently. This assumption is not always true. For example, the freezing-point depression observed for 0.10 m NaCl is 1.87 times that for 0.10 m glucose rather than twice as great. That is, for a $0.10-\mathrm{m} \mathrm{NaCl}$ solution, the observed value for $i$ is 1.87 rather than 2 . Why? The best explanation is that ion pairing occurs in solution (Fig. 11.23). At a given instant a small percentage of the sodium and chloride ions are paired and thus count as a single particle. In general, ion pairing is most important in concentrated solutions. As the solution becomes more

TABLE 11.6 | Expected and Observed Values of the van't Hoff Factor for 0.05 m Solutions of Several Electrolytes

| Electrolyte | $\boldsymbol{i}$ (expected) | $\boldsymbol{i}$ (observed) |
| :--- | :---: | :---: |
| NaCl | 2.0 | 1.9 |
| $\mathrm{MgCl}_{2}$ | 3.0 | 2.7 |
| $\mathrm{MgSO}_{4}$ | 2.0 | 1.3 |
| $\mathrm{FeCl}_{3}$ | 4.0 | 3.4 |
| HCl | 2.0 | 1.9 |
| Glucose* | 1.0 | 1.0 |
|  |  |  |

*A nonelectrolyte shown for comparison.
dilute, the ions are farther apart and less ion pairing occurs. For example, in a 0.0010-m NaCl solution, the observed value of $i$ is 1.97 , which is very close to the expected value.

Ion pairing occurs to some extent in all electrolyte solutions. Table 11.6 shows expected and observed values of $i$ for a given concentration of various electrolytes. Note that the deviation of $i$ from the expected value tends to be greatest where the ions have multiple charges. This is expected because ion pairing ought to be most important for highly charged ions.

The colligative properties of electrolyte solutions are described by including the van't Hoff factor in the appropriate equation. For example, for changes in freezing and boiling points, the modified equation is

$$
\Delta T=i m K
$$

where $K$ represents the freezing-point depression or boiling-point elevation constant for the solvent.

For the osmotic pressure of electrolyte solutions, the equation is

$$
\Pi=i M R T
$$

## INTERACTIVE EXAMPLE 11.13 Osmotic Pressure

The observed osmotic pressure for a $0.10-M$ solution of $\mathrm{Fe}\left(\mathrm{NH}_{4}\right)_{2}\left(\mathrm{SO}_{4}\right)_{2}$ at $25^{\circ} \mathrm{C}$ is 10.8 atm . Compare the expected and experimental values for $i$.

SOLUTION The ionic solid $\mathrm{Fe}\left(\mathrm{NH}_{4}\right)_{2}\left(\mathrm{SO}_{4}\right)_{2}$ dissociates in water to produce 5 ions:

$$
\mathrm{Fe}\left(\mathrm{NH}_{4}\right)_{2}\left(\mathrm{SO}_{4}\right)_{2} \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Fe}^{2+}+2 \mathrm{NH}_{4}^{+}+2 \mathrm{SO}_{4}^{2-}
$$

Thus the expected value for $i$ is 5 . We can obtain the experimental value for $i$ by using the equation for osmotic pressure:

$$
\Pi=i M R T \quad \text { or } \quad i=\frac{\Pi}{M R T}
$$

where $\Pi=10.8 \mathrm{~atm}, M=0.10 \mathrm{~mol} / \mathrm{L}, R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$, and $T=25+273=$ 298 K. Substituting these values into the equation gives

$$
i=\frac{\Pi}{M R T}=\frac{10.8 \mathrm{~atm}}{(0.10 \mathrm{~mol} / \mathrm{L})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K})}=4.4
$$

The experimental value for $i$ is less than the expected value, presumably because of ion pairing.

## CHEMICAL CDNNECTIDNS

## The Drink of Champions—Water

|n 1965, the University of Florida football team, the Gators, participated in a research program to test a sports drink formula containing a mixture of carbohydrates and electrolytes. The drink was used to help prevent dehydration caused by extreme workouts in the hot Florida climate. The Gators' success that season was in part attributed to their use of the sports drink formula. In 1967, a modified form of this formula was marketed with the name Gatorade. Today, Gatorade leads sales in sports drinks, but many other brands have entered a market where annual sales exceed $\$ 700$ million!

During moderate- to high-intensity exercise, glycogen (a fuel reserve that helps maintain normal body processes) can be depleted within 60 to 90 minutes. Blood-sugar levels drop as the glycogen reserves are used up, and lactic acid (a by-product of glucose metabolism) builds up in muscle tissue, causing fatigue and muscle cramps. Muscles also generate a large amount of heat that must be dissipated. Water, which has a large specific heat capacity, is used to take heat away from these muscles. Sweating and evaporative cooling help the
body maintain a constant temperature, but at a huge cost. During a highintensity workout in hot weather, anywhere from 1 to 3 quarts of water can be lost from sweating per hour. Sweating away more than $2 \%$ of your body weight-a quart for every 100 poundscan put a large stress on the heart, increasing body temperature and decreasing performance. Excessive sweating also results in the loss of sodium and potassium ions-two very important electrolytes that are present in the fluids inside and outside cells.

All the major sports drinks contain three main ingredients-carbohydrates in the form of simple sugars such as sucrose, glucose, and fructose; electrolytes, including sodium and potassium ions; and water. Because these are the three major substances lost through sweating, good scientific reasoning suggests that drinking sports drinks should improve performance. But just how effectively do sports drinks deliver on their promises?

Recent studies have confirmed that athletes who eat a balanced diet and drink plenty of water are just as well off as those who consume sports drinks. A sports drink may have only one

For healthy athletes, drinking water during exercise may be as effective as drinking sports drinks.
advantage over drinking water-it tastes better than water to most athletes. And if a drink tastes better, it will encourage more consumption, thus keeping cells hydrated.

Since most of the leading sports drinks contain the same ingredients in similar concentrations, taste may be the single most important factor in choosing your drink. If you are not interested in any particular sports drink, drink plenty of water. The key to quality performance is to keep your cells hydrated.

### 11.8 Colloids

FIGURE 11.24 The Tyndall effect.

Mud can be suspended in water by vigorous stirring. When the stirring stops, most of the particles rapidly settle out, but even after several days some of the smallest particles remain suspended. Although undetected in normal lighting, their presence can be demonstrated by shining a beam of intense light through the suspension. The beam is visible from the side because the light is scattered by the suspended particles (Fig. 11.24). In a true solution, on the other hand, the beam is invisible from the side because the individual ions and molecules dispersed in the solution are too small to scatter visible light.

The scattering of light by particles is called the Tyndall effect and is often used to distinguish between a suspension and a true solution.

A suspension of tiny particles in some medium is called a colloidal dispersion, or a colloid. The suspended particles are single large molecules or aggregates of molecules

## CHEMICAL CONNECTIONS

## Organisms and Ice Formation

The ice-cold waters of the polar oceans are teeming with fish that seem immune to freezing. One might think that these fish have some kind of antifreeze in their blood. However, studies show that they are protected from freezing in a very different way from the way antifreeze protects our cars. As we have seen in this chapter, solutes such as sugar, salt, and ethylene glycol lower the temperature at which the solid and liquid phases of water can coexist. However, the fish could not tolerate high concentrations of solutes in their blood because of the osmotic pressure effects. Instead, they are protected by proteins in their blood. These proteins allow the water in the bloodstream to be supercooled-exist below $0^{\circ} \mathrm{C}$-without forming ice. They apparently coat the surface of each tiny ice crystal as soon as it begins to form, preventing it from growing to a size that would cause biologic damage.

Although it might at first seem surprising, this research on polar fish
has attracted the attention of ice cream manufacturers. Premium quality ice cream is smooth; it does not have large ice crystals in it. The makers of ice cream would like to incorporate these polar fish proteins, or molecules that behave similarly, into ice cream to prevent the growth of ice crystals during storage.

Fruit and vegetable growers have a similar interest: They also want to prevent ice formation that damages their crops during an unusual cold wave. However, this is a very different kind of problem than keeping polar fish from freezing. Many types of fruits and vegetables are colonized by bacteria that manufacture a protein that encourages freezing by acting as a nucleating agent to start an ice crystal. Chemists have identified the offending protein in the bacteria and the gene that is responsible for making it. They have learned to modify the genetic material of these bacteria in a way that removes their ability to make the protein that

Blackfin icefish, Chaenocephalus aceratus.
encourages ice crystal formation. If testing shows that these modified bacteria have no harmful effects on the crop or the environment, the original bacteria strain will be replaced with the new form so that ice crystals will not form so readily when a cold snap occurs.
or ions ranging in size from 1 to 1000 nm . Colloids are classified according to the states of the dispersed phase and the dispersing medium. Table 11.7 summarizes various types of colloids.

What stabilizes a colloid? Why do the particles remain suspended rather than forming larger aggregates and precipitating out? The answer is complicated, but the main factor seems to be electrostatic repulsion. A colloid, like all other macroscopic substances, is electrically neutral. However, when a colloid is placed in an electric field, the dispersed particles all migrate to the same electrode and thus must all have the same charge. How is this possible? The center of a colloidal particle (a tiny ionic crystal, a group of molecules, or a single large molecule) attracts from the medium a layer of ions, all of the same charge. This group of ions, in turn, attracts another layer of oppositely charged ions (Fig. 11.25). Because the colloidal particles all have an outer layer of ions with the same charge, they repel each other and do not easily aggregate to form particles that are large enough to precipitate.

The destruction of a colloid, called coagulation, usually can be accomplished either by heating or by adding an electrolyte. Heating increases the velocities of the colloidal particles, causing them to collide with enough energy that the ion barriers are penetrated and the particles can aggregate. Because this process is repeated many times, the particle grows to a point where it settles out. Adding an electrolyte neutralizes the adsorbed ion layers. This is why clay suspended in rivers is deposited where

FIGURE 11.26 The Cottrell precipitator installed in a smokestack. The charged plates attract the colloidal particles because of their ion layers and thus remove them from the smoke.

TABLE 11.7 | Types of Colloids

| Examples | Dispersing <br> Medium | Dispersed <br> Substance | Colloid Type |
| :--- | :--- | :--- | :--- | :--- |
| Fog, aerosol sprays | Gas | Liquid | Aerosol |
| Smoke, airborne bacteria | Gas | Solid | Aerosol |
| Whipped cream, soapsuds | Liquid | Gas | Foam |
| Milk, mayonnaise | Liquid | Liquid | Emulsion |
| Paint, clays, gelatin | Liquid | Solid | Sol |
| Marshmallow, polystyrene foam | Solid | Gas | Solid foam |
| Butter, cheese | Solid | Liquid | Solid emulsion |
| Ruby glass | Solid | Solid | Solid sol |

the river reaches the ocean, forming the deltas characteristic of large rivers like the Mississippi. The high salt content of the seawater causes the colloidal clay particles to coagulate.

The removal of soot from smoke is another example of the coagulation of a colloid. When smoke is passed through an electrostatic precipitator (Fig. 11.26), the suspended solids are removed. The use of precipitators has produced an immense improvement in the air quality of heavily industrialized cities.

## For Review

## Key terms

Section 11.1
molarity
mass percent
mole fraction
molality
normality
Section 11.2
enthalpy (heat) of solution enthalpy (heat) of hydration

Section 11.3
Henry's law
thermal pollution
Section 11.4
Raoult's law
ideal solution

## Solution composition

> Molarity $(M)$ : moles solute per liter of solution
) Mass percent: ratio of mass of solute to mass of solution times $100 \%$
> Mole fraction $(\chi)$ : ratio of moles of a given component to total moles of all components
> Molality ( $m$ ): moles solute per mass of solvent (in kg )
> Normality $(N)$ : number of equivalents per liter of solution

## Enthalpy of solution ( $\Delta H_{\text {soln }}$ )

> The enthalpy change accompanying solution formation
) Can be partitioned into
> The energy required to overcome the solute-solute interactions
> The energy required to "make holes" in the solvent
) The energy associated with solute-solvent interactions

## Factors that affect solubility

> Polarity of solute and solvent
> "Like dissolves like" is a useful generalization
> Pressure increases the solubility of gases in a solvent
) Henry's law: $C=k P$
> Temperature effects
) Increased temperature decreases the solubility of a gas in water
> Most solids are more soluble at higher temperatures, but important exceptions exist

## Vapor pressure of solutions

> A solution containing a nonvolatile solute has a lower vapor pressure than a solution of the pure solvent
> Raoult's law defines an ideal solution:

$$
P_{\text {vapor }}^{\text {soln }}=\chi_{\text {solvent }} P_{\text {vapor }}^{\text {solvent }}
$$

> Solutions in which the solute-solvent attractions differ from the solute-solute and solvent-solvent attractions violate Raoult's law

## Colligative properties

) Depend on the number of solute particles present
) Boiling-point elevation: $\Delta T=K_{\mathrm{b}} m_{\text {solute }}$
> Freezing-point lowering: $\Delta T=K_{\mathrm{f}} m_{\text {solute }}$
> Osmotic pressure: $\Pi=M R T$
> Osmosis occurs when a solution and pure solvent are separated by a semipermeable membrane that allows solvent molecules to pass but not solute particles
> Reverse osmosis occurs when the applied pressure is greater than the osmotic pressure of the solution
> Because colligative properties depend on the number of particles, solutes that break into several ions when they dissolve have an effect proportional to the number of ions produced
> The van't Hoff factor $i$ represents the number of ions produced by each formula unit of solute

## Colloids

> A suspension of tiny particles stabilized by electrostatic repulsion among the ion layers surrounding the individual particles
> Can be coagulated (destroyed) by heating or adding an electrolyte

## Review Questions Answers to the Review Questions can be found on the Student website (accessible from www.cengagehrain.com).

1. The four most common ways to describe solution composition are mass percent, mole fraction, molarity, and molality. Define each of these solution composition terms. Why is molarity temperature-dependent, whereas the other three solution composition terms are temperature-independent?
2. Using KF as an example, write equations that refer to $\Delta H_{\text {soln }}$ and $\Delta H_{\text {hyd }}$. Lattice energy was defined in Chapter 8 as $\Delta H$ for the reaction $\mathrm{K}^{+}(g)+\mathrm{F}^{-}(g) \longrightarrow \mathrm{KF}(s)$. Show how you would utilize Hess's law to calculate $\Delta H_{\text {soln }}$ from $\Delta H_{\mathrm{hyd}}$ and $\Delta H_{\mathrm{LE}}$ for KF , where $\Delta H_{\mathrm{LE}}=$ lattice energy. $\Delta H_{\text {soln }}$ for KF , as for other soluble ionic compounds, is a relatively small number. How can this be since $\Delta H_{\text {hyd }}$ and $\Delta H_{\mathrm{LE}}$ are relatively large negative numbers?
3. What does the axiom "like dissolves like" mean? There are four types of solute/solvent combinations: polar solutes in polar solvents, nonpolar solutes in polar solvents, and so on. For each type of solution, discuss the magnitude of $\Delta H_{\text {soln }}$.
4. Structure, pressure, and temperature all have an effect on solubility. Discuss each of their effects. What is Henry's law? Why does Henry's law not work for $\mathrm{HCl}(g)$ ? What do the terms hydrophobic and hydrophilic mean?
5. Define the terms in Raoult's law. Figure 11.10 illustrates the net transfer of water molecules from pure water to an aqueous solution of a nonvolatile solute. Explain why eventually all of the water from the beaker of pure water will transfer to the aqueous solution. If the experiment illustrated in Fig. 11.10 was performed using a volatile solute, what would happen? How do you calculate the total vapor pressure when both the solute and solvent are volatile?
6. In terms of Raoult's law, distinguish between an ideal liquid-liquid solution and a nonideal liquid-liquid solution. If a solution is ideal, what is true about $\Delta H_{\text {soln }}$, $\Delta T$ for the solution formation, and the interactive forces within the pure solute and pure solvent as compared to the interactive forces within the solution? Give an example of an ideal solution. Answer the previous two questions for solutions that exhibit either negative or positive deviations from Raoult's law.
7. Vapor-pressure lowering is a colligative property, as are freezing-point depression and boiling-point elevation. What is a colligative property? Why is the freezing point depressed for a solution as compared to the pure solvent? Why is the boiling point elevated for a solution as compared to the pure solvent? Explain how to
calculate $\Delta T$ for a freezing-point depression problem or a boiling-point elevation problem. Of the solvents listed in Table 11.5, which would have the largest freezing-point depression for a 0.50 molal solution? Which would have the smallest boiling-point elevation for a 0.50 molal solution?

A common application of freezing-point depression and boiling-point elevation experiments is to provide a means to calculate the molar mass of a nonvolatile solute. What data are needed to calculate the molar mass of a nonvolatile solute? Explain how you would manipulate these data to calculate the molar mass of the nonvolatile solute.
8. What is osmotic pressure? How is osmotic pressure calculated? Molarity units are used in the osmotic pressure equation. When does the molarity of a solution approximately equal the molality of the solution? Before refrigeration was common, many foods were

## Active Learning Questions

## These questions are designed to be used by groups of students in class.

1. Consider Fig. 11.10. According to the caption and picture, water seems to go from one beaker to another.
a. Explain why this occurs.
b. The explanation in the text uses terms such as vapor pressure and equilibrium. Explain what these have to do with the phenomenon. For example, what is coming to equilibrium?
c. Does all the water end up in the second beaker?
d. Is water evaporating from the beaker containing the solution? If so, is the rate of evaporation increasing, decreasing, or staying constant?
Draw pictures to illustrate your explanations.
2. Once again, consider Fig. 11.10. Suppose instead of having a nonvolatile solute in the solvent in one beaker, the two beakers contain different volatile liquids. That is, suppose one beaker contains liquid A ( $P_{\text {vap }}=50$ torr) and the other beaker contains liquid B ( $P_{\text {vap }}=100$ torr). Explain what happens as time passes. How is this similar to the first case (shown in the figure)? How is it different?
3. Assume that you place a freshwater plant into a saltwater solution and examine it under a microscope. What happens to the plant cells? What if you placed a saltwater plant in pure water? Explain. Draw pictures to illustrate your explanations.
4. How does $\Delta H_{\text {soln }}$ relate to deviations from Raoult's law? Explain.
5. You have read that adding a solute to a solvent can both increase the boiling point and decrease the freezing point. A friend of yours explains it to you like this: "The solute and solvent can be like salt in water. The salt gets in the way of freezing in that it blocks the water molecules from joining together. The salt acts like a strong bond holding the water molecules together so that it is harder to boil." What do you say to your friend?
preserved by salting them heavily, and many fruits were preserved by mixing them with a large amount of sugar (fruit preserves). How do salt and sugar act as preservatives? Two applications of osmotic pressure are dialysis and desalination. Explain these two processes.
6. Distinguish between a strong electrolyte, a weak electrolyte, and a nonelectrolyte. How can colligative properties be used to distinguish between them? What is the van't Hoff factor? Why is the observed freezing-point depression for electrolyte solutions sometimes less than the calculated value? Is the discrepancy greater for concentrated or dilute solutions?
7. What is a colloidal dispersion? Give some examples of colloids. The Tyndall effect is often used to distinguish between a colloidal suspension and a true solution. Explain. The destruction of a colloid is done through a process called coagulation. What is coagulation?
8. You drop an ice cube (made from pure water) into a saltwater solution at $0^{\circ} \mathrm{C}$. Explain what happens and why.
9. Using the phase diagram for water and Raoult's law, explain why salt is spread on the roads in winter (even when it is below freezing).
10. You and your friend are each drinking cola from separate 2-L bottles. Both colas are equally carbonated. You are able to drink 1 L of cola, but your friend can drink only about half a liter. You each close the bottles and place them in the refrigerator. The next day when you each go to get the colas, whose will be more carbonated and why?
11. Is molality or molarity dependent on temperature? Explain your answer. Why is molality, and not molarity, used in the equations describing freezing-point depression and boiling-point elevation?
12. Consider a beaker of salt water sitting open in a room. Over time, does the vapor pressure increase, decrease, or stay the same? Explain.
13. If a solution shows positive deviations from Raoult's law, would you expect the solution to have a higher or lower boiling point than if it were ideal? Explain.
14. A $0.10-\mathrm{m} \mathrm{NaCl}$ aqueous solution has a higher boiling point than a $0.10-m \mathrm{MgSO}_{4}$ aqueous solution. Explain why.
A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Solution Review

If you have trouble with these exercises, review Sections 4.1 to 4.3
in Chapter 4.
13. Rubbing alcohol contains 585 g isopropanol $\left(\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}\right)$ per liter (aqueous solution). Calculate the molarity.
14. What mass of sodium oxalate $\left(\mathrm{Na}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ is needed to prepare 0.250 L of a $0.100-M$ solution?
15. What volume of 0.25 M HCl solution must be diluted to prepare 1.00 L of 0.040 M HCl ?
16. What volume of a $0.580-M$ solution of $\mathrm{CaCl}_{2}$ contains 1.28 g solute?
17. Calculate the sodium ion concentration when 70.0 mL of 3.0 M sodium carbonate is added to 30.0 mL of 1.0 M sodium bicarbonate.
18. Write equations showing the ions present after the following strong electrolytes are dissolved in water.
a. $\mathrm{HNO}_{3}$
b. $\mathrm{Na}_{2} \mathrm{SO}_{4}$
c. $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$
d. $\mathrm{SrBr}_{2}$
e. $\mathrm{KClO}_{4}$
f. $\mathrm{NH}_{4} \mathrm{Br}$
g. $\mathrm{NH}_{4} \mathrm{NO}_{3}$
h. $\mathrm{CuSO}_{4}$
i. NaOH

## Questions

19. Rationalize the temperature dependence of the solubility of a gas in water in terms of the kinetic molecular theory.
20. The weak electrolyte $\mathrm{NH}_{3}(g)$ does not obey Henry's law. Why? $\mathrm{O}_{2}(g)$ obeys Henry's law in water but not in blood (an aqueous solution). Why?
21. The two beakers in the sealed container illustrated below contain pure water and an aqueous solution of a volatile solute.

If the solute is less volatile than water, explain what will happen to the volumes in the two containers as time passes.
22. The following plot shows the vapor pressure of various solutions of components A and B at some temperature.

Which of the following statements is false concerning solutions of A and B?
a. The solutions exhibit negative deviations from Raoult's law.
b. $\Delta H_{\text {soln }}$ for the solutions should be exothermic.
c. The intermolecular forces are stronger in solution than in either pure A or pure B .
d. Pure liquid $B$ is more volatile than pure liquid $A$.
e. The solution with $\chi_{\text {B }}=0.6$ will have a lower boiling point than either pure $A$ or pure $B$.
23. When pure methanol is mixed with water, the resulting solution feels warm. Would you expect this solution to be ideal? Explain.
24. Detergent molecules can stabilize the emulsion of oil in water as well as remove dirt from soiled clothes. A typical detergent is sodium dodecylsulfate, or SDS, and it has a formula of $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{10} \mathrm{CH}_{2} \mathrm{SO}_{4}{ }^{-} \mathrm{Na}^{+}$. In aqueous solution, SDS suspends oil or dirt by forming small aggregates of detergent anions called micelles. Propose a structure for micelles.
25. For an acid or a base, when is the normality of a solution equal to the molarity of the solution and when are the two concentration units different?
26. In order for sodium chloride to dissolve in water, a small amount of energy must be added during solution formation. This is not energetically favorable. Why is NaCl so soluble in water?
27. Which of the following statements is(are) true? Correct the false statements.
a. The vapor pressure of a solution is directly related to the mole fraction of solute.
b. When a solute is added to water, the water in solution has a lower vapor pressure than that of pure ice at $0^{\circ} \mathrm{C}$.
c. Colligative properties depend only on the identity of the solute and not on the number of solute particles present.
d. When sugar is added to water, the boiling point of the solution increases above $100^{\circ} \mathrm{C}$ because sugar has a higher boiling point than water.
28. Is the following statement true or false? Explain your answer. When determining the molar mass of a solute using boilingpoint or freezing-point data, camphor would be the best solvent choice of all of the solvents listed in Table 11.5.
29. Adding a solute to a solvent extends the liquid phase over a larger temperature range. Explain this statement.
30. Table sugar $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ or urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right]$ can be used by road crews to melt ice on roads, but solutions of $\mathrm{CaCl}_{2}$ are generally used instead. Assuming equal costs per pound of substance, why is $\mathrm{CaCl}_{2}$ used instead of table sugar or urea?
31. If two different aqueous solutions of proteins have the same boiling point, what other physical properties are the same between the two solutions? Assume dilute solutions.
32. An extremely important application of dialysis is the use of artificial kidney machines to purify blood. Explain how dialysis can be used to purify blood.
33. Explain the terms isotonic solution, crenation, and hemolysis.
34. What is ion pairing?

## Exercises

In this section similar exercises are paired.

## Solution Composition

-35. If 500. g of water is added to 75 g of a $2.5-\mathrm{m} \mathrm{NaCl}$ solution, what is the mass percent of NaCl in the diluted solution?
36. A typical IV used in hospitals is dextrose $5 \%$ in water (called D5W). This solution is injected into veins through an IV to replace lost fluids and to provide carbohydrates. Injectable medicines are also delivered to the body using the D5W IV. D5W contains 5.0 g dextrose monohydrate $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}\right)$ per 100.0 mL of solution. Assuming a density of $1.01 \mathrm{~g} / \mathrm{cm}^{3}$, calculate the molarity and molality of D5W.
[37. A solution of phosphoric acid was made by dissolving 10.0 g $\mathrm{H}_{3} \mathrm{PO}_{4}$ in 100.0 mL water. The resulting volume was 104 mL . Calculate the density, mole fraction, molarity, and molality of the solution. Assume water has a density of $1.00 \mathrm{~g} / \mathrm{cm}^{3}$.
38. An aqueous antifreeze solution is $40.0 \%$ ethylene glycol $\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}\right)$ by mass. The density of the solution is $1.05 \mathrm{~g} / \mathrm{cm}^{3}$. Calculate the molality, molarity, and mole fraction of the ethylene glycol.
-39. Common commercial acids and bases are aqueous solutions with the following properties:

|  | Density <br> $\left(\mathrm{c} / \mathrm{cm}^{3}\right)$ | Mass Percent <br> of Solute |
| :--- | :---: | :---: |
| Hydrochloric acid | 1.19 | 38 |
| Nitric acid | 1.42 | 70. |
| Sulfuric acid | 1.84 | 95 |
| Acetic acid | 1.05 | 99 |
| Ammonia | 0.90 | 28 |

Calculate the molarity, molality, and mole fraction of each of the preceding reagents.
-40. In lab you need to prepare at least 100 mL of each of the following solutions. Explain how you would proceed using the given information.
a. 2.0 m KCl in water (density of $\mathrm{H}_{2} \mathrm{O}=1.00 \mathrm{~g} / \mathrm{cm}^{3}$ )
b. $15 \% \mathrm{NaOH}$ by mass in water $\left(d=1.00 \mathrm{~g} / \mathrm{cm}^{3}\right)$
c. $25 \% \mathrm{NaOH}$ by mass in $\mathrm{CH}_{3} \mathrm{OH}\left(d=0.79 \mathrm{~g} / \mathrm{cm}^{3}\right)$
d. 0.10 mole fraction of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ in water $\left(d=1.00 \mathrm{~g} / \mathrm{cm}^{3}\right)$
41. A solution is prepared by mixing 25 mL pentane $\left(\mathrm{C}_{5} \mathrm{H}_{12}, d=\right.$ $0.63 \mathrm{~g} / \mathrm{cm}^{3}$ ) with 45 mL hexane ( $\left.\mathrm{C}_{6} \mathrm{H}_{14}, d=0.66 \mathrm{~g} / \mathrm{cm}^{3}\right)$. Assuming that the volumes add on mixing, calculate the mass percent, mole fraction, molality, and molarity of the pentane.
42. A solution is prepared by mixing 50.0 mL toluene $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}_{3}\right.$, $\left.d=0.867 \mathrm{~g} / \mathrm{cm}^{3}\right)$ with 125 mL benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}, d=0.874 \mathrm{~g} / \mathrm{cm}^{3}\right)$. Assuming that the volumes add on mixing, calculate the mass percent, mole fraction, molality, and molarity of the toluene.
43. A bottle of wine contains $12.5 \%$ ethanol by volume. The density of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ is $0.789 \mathrm{~g} / \mathrm{cm}^{3}$. Calculate the concentration of ethanol in wine in terms of mass percent and molality.
44. Calculate the molarity and mole fraction of acetone in a $1.00-m$ solution of acetone $\left(\mathrm{CH}_{3} \mathrm{COCH}_{3}\right)$ in ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$. (Density of acetone $=0.788 \mathrm{~g} / \mathrm{cm}^{3}$; density of ethanol $=$ $0.789 \mathrm{~g} / \mathrm{cm}^{3}$.) Assume that the volumes of acetone and ethanol add.
45. A 1.37-M solution of citric acid $\left(\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)$ in water has a density of $1.10 \mathrm{~g} / \mathrm{cm}^{3}$. Calculate the mass percent, molality, mole fraction, and normality of the citric acid. Citric acid has three acidic protons.
46. Calculate the normality of each of the following solutions.
a. 0.250 M HCl
b. $0.105 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$
c. $5.3 \times 10^{-2} \mathrm{M} \mathrm{H}_{3} \mathrm{PO}_{4}$
d. 0.134 M NaOH
e. $0.00521 \mathrm{M} \mathrm{Ca}(\mathrm{OH})_{2}$

What is the equivalent mass for each of the acids or bases listed above?

## Energetics of Solutions and Solubility

47. The lattice energy* of NaI is $-686 \mathrm{~kJ} / \mathrm{mol}$, and the enthalpy of hydration is $-694 \mathrm{~kJ} / \mathrm{mol}$. Calculate the enthalpy of solution per mole of solid NaI. Describe the process to which this enthalpy change applies.
48. a. Use the following data to calculate the enthalpy of hydration for calcium chloride and calcium iodide.

|  | Lattice Energy | $\Delta \boldsymbol{H}_{\text {soln }}$ |
| :--- | :---: | :---: |
| $\mathrm{CaCl}_{2}(\mathrm{~s})$ | $-2247 \mathrm{~kJ} / \mathrm{mol}$ | $-46 \mathrm{~kJ} / \mathrm{mol}$ |
| $\mathrm{Cal}_{2}(\mathrm{~s})$ | $-2059 \mathrm{~kJ} / \mathrm{mol}$ | $-104 \mathrm{~kJ} / \mathrm{mol}$ |

b. Based on your answers to part a, which ion, $\mathrm{Cl}^{-}$or $\mathrm{I}^{-}$, is more strongly attracted to water?
-49. Although $\mathrm{Al}(\mathrm{OH})_{3}$ is insoluble in water, NaOH is very soluble. Explain in terms of lattice energies.
50. The high melting points of ionic solids indicate that a lot of energy must be supplied to separate the ions from one another. How is it possible that the ions can separate from one another when soluble ionic compounds are dissolved in water, often with essentially no temperature change?
-51. Which solvent, water or carbon tetrachloride, would you choose to dissolve each of the following?
a. $\mathrm{KrF}_{2}$
b. $\mathrm{SF}_{2}$
c. $\mathrm{SO}_{2}$
d. $\mathrm{CO}_{2}$
e. $\mathrm{MgF}_{2}$
f. $\mathrm{CH}_{2} \mathrm{O}$
g. $\mathrm{CH}_{2}=\mathrm{CH}_{2}$
52. Which solvent, water or hexane $\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)$, would you choose to dissolve each of the following?
a. $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}$
b. $\mathrm{CS}_{2}$
c. $\mathrm{CH}_{3} \mathrm{OH}$
d. $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{16} \mathrm{CH}_{2} \mathrm{OH}$
e. HCl
f. $\mathrm{C}_{6} \mathrm{H}_{6}$

[^24]-53. For each of the following pairs, predict which substance would be more soluble in water.
a.

$\mathrm{NH}_{3}$ or

$\mathrm{PH}_{3}$
or

b. $\quad \mathrm{CH}_{3} \mathrm{CN}$
$\mathrm{CH}_{3} \mathrm{CH}_{3}$

or

54. Which ion in each of the following pairs would you expect to be more strongly hydrated? Why?
a. $\mathrm{Na}^{+}$or $\mathrm{Mg}^{2+}$
b. $\mathrm{Mg}^{2+}$ or $\mathrm{Be}^{2+}$
c. $\mathrm{Fe}^{2+}$ or $\mathrm{Fe}^{3+}$
d. $\mathrm{F}^{-}$or $\mathrm{Br}^{-}$
e. $\mathrm{Cl}^{-}$or $\mathrm{ClO}_{4}^{-}$
f. $\mathrm{ClO}_{4}{ }^{-}$or $\mathrm{SO}_{4}{ }^{2-}$

Rationalize the trend in water solubility for the following simple alcohols:

| Alcohol | $\begin{gathered} \text { Solubility } \\ \left(\mathrm{g} / 100 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \text { at } 20^{\circ} \mathrm{C}\right) \end{gathered}$ |
| :---: | :---: |
| Methanol, $\mathrm{CH}_{3} \mathrm{OH}$ | Soluble in all proportions |
| Ethanol, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ | Soluble in all proportions |
| Propanol, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | Soluble in all proportions |
| Butanol, $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 8.14 |
| Pentanol, $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{CH}_{2} \mathrm{OH}$ | 2.64 |
| Hexanol, $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{4} \mathrm{CH}_{2} \mathrm{OH}$ | 0.59 |
| Heptanol, $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{5} \mathrm{CH}_{2} \mathrm{OH}$ | 0.09 |

56. In flushing and cleaning columns used in liquid chromatography to remove adsorbed contaminants, a series of solvents is used. Hexane $\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)$, chloroform $\left(\mathrm{CHCl}_{3}\right)$, methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$, and water are passed through the column in that order. Rationalize the order in terms of intermolecular forces and the mutual solubility (miscibility) of the solvents.
-57. The solubility of nitrogen in water is $8.21 \times 10^{-4} \mathrm{~mol} / \mathrm{L}$ at $0^{\circ} \mathrm{C}$ when the $\mathrm{N}_{2}$ pressure above water is 0.790 atm . Calculate the Henry's law constant for $\mathrm{N}_{2}$ in units of $\mathrm{mol} / \mathrm{L} \cdot \mathrm{atm}$ for Henry's law in the form $C=k P$, where $C$ is the gas concentration in $\mathrm{mol} / \mathrm{L}$. Calculate the solubility of $\mathrm{N}_{2}$ in water when the partial pressure of nitrogen above water is 1.10 atm at $0^{\circ} \mathrm{C}$.
57. Calculate the solubility of $\mathrm{O}_{2}$ in water at a partial pressure of $\mathrm{O}_{2}$ of 120 torr at $25^{\circ} \mathrm{C}$. The Henry's law constant for $\mathrm{O}_{2}$ is $1.3 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$ for Henry's law in the form $C=k P$, where $C$ is the gas concentration ( $\mathrm{mol} / \mathrm{L}$ ).

## Vapor Pressures of Solutions

The vapor pressure of a solution containing 53.6 g glycerin $\left(\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{3}\right)$ in 133.7 g ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ is 113 torr at $40^{\circ} \mathrm{C}$. Calculate the vapor pressure of pure ethanol at $40^{\circ} \mathrm{C}$ assuming that glycerin is a nonvolatile, nonelectrolyte solute in ethanol.
60. An aqueous solution containing glucose has a vapor pressure of 19.6 torr at $25^{\circ} \mathrm{C}$. What would be the vapor pressure of this solution at $45^{\circ} \mathrm{C}$ ? The vapor pressure of pure water is 23.8 torr at $25^{\circ} \mathrm{C}$ and 71.9 torr at $45^{\circ} \mathrm{C}$. If the glucose in the solution were substituted with an equivalent amount (moles) of NaCl , what would be the vapor pressure at $45^{\circ} \mathrm{C}$ ?
$\sigma^{61}$. The normal boiling point of diethyl ether is $34.5^{\circ} \mathrm{C}$. A solution containing a nonvolatile solute dissolved in diethyl ether has a vapor pressure of 698 torr at $34.5^{\circ} \mathrm{C}$. What is the mole fraction of diethyl ether in this solution?
62. At a certain temperature, the vapor pressure of pure benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ is 0.930 atm . A solution was prepared by dissolving 10.0 g of a nondissociating, nonvolatile solute in 78.11 g of benzene at that temperature. The vapor pressure of the solution was found to be 0.900 atm . Assuming the solution behaves ideally, determine the molar mass of the solute.
663. Pentane $\left(\mathrm{C}_{5} \mathrm{H}_{12}\right)$ and hexane $\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)$ form an ideal solution. At $25^{\circ} \mathrm{C}$ the vapor pressures of pentane and hexane are 511 and 150 . torr, respectively. A solution is prepared by mixing 25 mL pentane (density, $0.63 \mathrm{~g} / \mathrm{mL}$ ) with 45 mL hexane (density, $0.66 \mathrm{~g} / \mathrm{mL}$ ).
a. What is the vapor pressure of the resulting solution?
b. What is the composition by mole fraction of pentane in the vapor that is in equilibrium with this solution?
64. A solution is prepared by mixing 0.0300 mole of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and 0.0500 mole of $\mathrm{CH}_{2} \mathrm{Br}_{2}$ at $25^{\circ} \mathrm{C}$. Assuming the solution is ideal, calculate the composition of the vapor (in terms of mole fractions) at $25^{\circ} \mathrm{C}$. At $25^{\circ} \mathrm{C}$, the vapor pressures of pure $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and pure $\mathrm{CH}_{2} \mathrm{Br}_{2}$ are 133 and 11.4 torr, respectively.
65. What is the composition of a methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$-propanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)$ solution that has a vapor pressure of 174 torr at $40^{\circ} \mathrm{C}$ ? At $40^{\circ} \mathrm{C}$, the vapor pressures of pure methanol and pure propanol are 303 and 44.6 torr, respectively. Assume the solution is ideal.
66. Benzene and toluene form an ideal solution. Consider a solution of benzene and toluene prepared at $25^{\circ} \mathrm{C}$. Assuming the mole fractions of benzene and toluene in the vapor phase are equal, calculate the composition of the solution. At $25^{\circ} \mathrm{C}$ the vapor pressures of benzene and toluene are 95 and 28 torr, respectively.
67. Which of the following will have the lowest total vapor pressure at $25^{\circ} \mathrm{C}$ ?
a. pure water (vapor pressure $=23.8$ torr at $25^{\circ} \mathrm{C}$ )
b. a solution of glucose in water with $\chi_{\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}}=0.01$
c. a solution of sodium chloride in water with $\chi_{\mathrm{NaCl}}=0.01$
d. a solution of methanol in water with $\chi_{\mathrm{CH}_{3} \mathrm{OH}}=0.2$ (Consider the vapor pressure of both methanol [143 torr at $\left.25^{\circ} \mathrm{C}\right]$ and water.)
68. Which of the choices in Exercise 67 has the highest vapor pressure?
69. Match the vapor pressure diagrams with the solute-solvent combinations and explain your answers.

70. The vapor pressures of several solutions of water-propanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)$ were determined at various compositions, with the following data collected at $45^{\circ} \mathrm{C}$ :

| $\chi_{\mathrm{H}_{2} \mathrm{O}}$ |
| :--- |
| 0 | Vapor Pressure (torr)

a. Are solutions of water and propanol ideal? Explain.
b. Predict the sign of $\Delta H_{\text {soln }}$ for water-propanol solutions.
c. Are the interactive forces between propanol and water molecules weaker than, stronger than, or equal to the interactive forces between the pure substances? Explain.
d. Which of the solutions in the data would have the lowest normal boiling point?

## Colligative Properties

-71. A solution is prepared by dissolving 27.0 g urea, $\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}$, in 150.0 g water. Calculate the boiling point of the solution. Urea is a nonelectrolyte.
72. A $2.00-\mathrm{g}$ sample of a large biomolecule was dissolved in 15.0 g carbon tetrachloride. The boiling point of this solution was determined to be $77.85^{\circ} \mathrm{C}$. Calculate the molar mass of the biomolecule. For carbon tetrachloride, the boiling-point constant is $5.03^{\circ} \mathrm{C} \cdot \mathrm{kg} / \mathrm{mol}$, and the boiling point of pure carbon tetrachloride is $76.50^{\circ} \mathrm{C}$.
-73. What mass of glycerin $\left(\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{3}\right)$, a nonelectrolyte, must be dissolved in 200.0 g water to give a solution with a freezing point of $-1.50^{\circ} \mathrm{C}$ ?
74. The freezing point of $t$-butanol is $25.50^{\circ} \mathrm{C}$ and $K_{\mathrm{f}}$ is $9.1^{\circ} \mathrm{C} \cdot \mathrm{kg} / \mathrm{mol}$. Usually $t$-butanol absorbs water on exposure to air. If the freezing point of a $10.0-\mathrm{g}$ sample of $t$-butanol is $24.59^{\circ} \mathrm{C}$, how many grams of water are present in the sample?
-75. Calculate the freezing point and boiling point of an antifreeze solution that is $50.0 \%$ by mass of ethylene glycol $\left(\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)$ in water. Ethylene glycol is a nonelectrolyte.
76. What volume of ethylene glycol $\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}\right)$, a nonelectrolyte, must be added to 15.0 L water to produce an antifreeze solution with a freezing point of $-25.0^{\circ} \mathrm{C}$ ? What is the boiling point of this solution? (The density of ethylene glycol is $1.11 \mathrm{~g} / \mathrm{cm}^{3}$, and the density of water is $1.00 \mathrm{~g} / \mathrm{cm}^{3}$.)
Reserpine is a natural product isolated from the roots of the shrub Rauwolfia serpentina. It was first synthesized in 1956 by Nobel Prize winner R. B. Woodward. It is used as a tranquilizer and sedative. When 1.00 g reserpine is dissolved in 25.0 g camphor, the freezing-point depression is $2.63^{\circ} \mathrm{C}\left(K_{\mathrm{f}}\right.$ for camphor is $40 .{ }^{\circ} \mathrm{C} \cdot \mathrm{kg} / \mathrm{mol}$ ). Calculate the molality of the solution and the molar mass of reserpine.
78. A solution contains 3.75 g of a nonvolatile pure hydrocarbon in 95 g acetone. The boiling points of pure acetone and the solution are $55.95^{\circ} \mathrm{C}$ and $56.50^{\circ} \mathrm{C}$, respectively. The molal boiling-point constant of acetone is $1.71^{\circ} \mathrm{C} \cdot \mathrm{kg} / \mathrm{mol}$. What is the molar mass of the hydrocarbon?
a. Calculate the freezing-point depression and osmotic pressure at $25^{\circ} \mathrm{C}$ of an aqueous solution containing $1.0 \mathrm{~g} / \mathrm{L}$ of a protein (molar mass $=9.0 \times 10^{4} \mathrm{~g} / \mathrm{mol}$ ) if the density of the solution is $1.0 \mathrm{~g} / \mathrm{cm}^{3}$.
b. Considering your answer to part a, which colligative property, freezing-point depression or osmotic pressure, would be better used to determine the molar masses of large molecules? Explain.
80. Erythrocytes are red blood cells containing hemoglobin. In a saline solution they shrivel when the salt concentration is high and swell when the salt concentration is low. In a $25^{\circ} \mathrm{C}$ aqueous solution of NaCl , whose freezing point is $-0.406^{\circ} \mathrm{C}$, erythrocytes neither swell nor shrink. If we want to calculate the osmotic pressure of the solution inside the erythrocytes under these conditions, what do we need to assume? Why? Estimate how good (or poor) of an assumption this is. Make this assumption and calculate the osmotic pressure of the solution inside the erythrocytes.
81. An aqueous solution of 10.00 g of catalase, an enzyme found in the liver, has a volume of 1.00 L at $27^{\circ} \mathrm{C}$. The solution's osmotic pressure at $27^{\circ} \mathrm{C}$ is found to be 0.745 torr. Calculate the molar mass of catalase.
82. A $0.15-\mathrm{g}$ sample of a purified protein is dissolved in water to give 2.0 mL of solution. The osmotic pressure is found to be 18.6 torr at $25^{\circ} \mathrm{C}$. Calculate the protein's molar mass.
-83. How would you prepare 1.0 L of an aqueous solution of sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ having an osmotic pressure of 15 atm at a temperature of $22^{\circ} \mathrm{C}$ ? Sucrose is a nonelectrolyte.
84. How would you prepare 1.0 L of an aqueous solution of sodium chloride having an osmotic pressure of 15 atm at $22^{\circ} \mathrm{C}$ ? Assume sodium chloride exists as $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions in solution.

## Properties of Electrolyte Solutions

85. Consider the following solutions:
$0.010 m \mathrm{Na}_{3} \mathrm{PO}_{4}$ in water
$0.020 m \mathrm{CaBr}_{2}$ in water
0.020 m KCl in water
0.020 m HF in water ( HF is a weak acid.)
a. Assuming complete dissociation of the soluble salts, which solution(s) would have the same boiling point as $0.040 m \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ in water? $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ is a nonelectrolyte.
b. Which solution would have the highest vapor pressure at $28^{\circ} \mathrm{C}$ ?
c. Which solution would have the largest freezing-point depression?
86. From the following: pure water solution of $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(m=0.01)$ in water solution of $\mathrm{NaCl}(m=0.01)$ in water solution of $\mathrm{CaCl}_{2}(m=0.01)$ in water Choose the one with the
a. highest freezing point.
d. lowest boiling point.
b. lowest freezing point.
c. highest boiling point.
e. highest osmotic pressure.
-87. Calculate the freezing point and the boiling point of each of the following solutions. (Assume complete dissociation.)
a. 5.0 g NaCl in $25 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$
b. $2.0 \mathrm{~g} \mathrm{Al}_{\left(\mathrm{NO}_{3}\right)_{3} \text { in } 15 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}, ~}^{\text {a }}$
87. A water desalination plant is set up near a salt marsh containing water that is 0.10 M NaCl . Calculate the minimum pressure that must be applied at $20 .{ }^{\circ} \mathrm{C}$ to purify the water by reverse osmosis. Assume NaCl is completely dissociated.
88. Determine the van't Hoff factor for the following ionic solute dissolved in water.

89. Consider the following representations of an ionic solute in water. Which flask contains $\mathrm{MgSO}_{4}$, and which flask contains NaCl ? How can you tell?

-91. Calculate the freezing point and the boiling point of each of the following aqueous solutions. (Assume complete dissociation.)
a. $0.050 \mathrm{~m} \mathrm{MgCl}{ }_{2}$
b. $0.050 m \mathrm{FeCl}_{3}$
90. Calculate the freezing point and the boiling point of each of the following solutions using the observed van't Hoff factors in Table 11.6.
a. $0.050 m \mathrm{MgCl}_{2}$
b. 0.050 m FeCl 3
-93. Use the following data for three aqueous solutions of $\mathrm{CaCl}_{2}$ to calculate the apparent value of the van't Hoff factor.

| Molality | Freezing-Point Depression $\left({ }^{\circ} \mathrm{C}\right)$ |
| :---: | :---: |
| 0.0225 | 0.110 |
| 0.0910 | 0.440 |
| 0.278 | 1.330 |

94. The freezing-point depression of a $0.091-m$ solution of CsCl is $0.320^{\circ} \mathrm{C}$. The freezing-point depression of a $0.091-m$ solution of $\mathrm{CaCl}_{2}$ is $0.440^{\circ} \mathrm{C}$. In which solution does ion association appear to be greater? Explain.
-95. In the winter of 1994, record low temperatures were registered throughout the United States. For example, in Champaign, Illinois, a record low of $-29^{\circ} \mathrm{F}$ was registered. At this temperature can salting icy roads with $\mathrm{CaCl}_{2}$ be effective in melting the ice?
a. Assume $i=3.00$ for $\mathrm{CaCl}_{2}$.
b. Assume the average value of $i$ from Exercise 93 .
(The solubility of $\mathrm{CaCl}_{2}$ in cold water is 74.5 g per 100.0 g water.)
95. A $0.500-\mathrm{g}$ sample of a compound is dissolved in enough water to form 100.0 mL of solution. This solution has an osmotic pressure of 2.50 atm at $25^{\circ} \mathrm{C}$. If each molecule of the solute dissociates into two particles (in this solvent), what is the molar mass of this solute?

## Additional Exercises

97. The solubility of benzoic acid,

is $0.34 \mathrm{~g} / 100 \mathrm{~mL}$ in water at $25^{\circ} \mathrm{C}$ and $10.0 \mathrm{~g} / 100 \mathrm{~mL}$ in benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ at $25^{\circ} \mathrm{C}$. Rationalize this solubility behavior. For a $1.0-\mathrm{m}$ solution of benzoic acid in benzene, would the measured freezing point depression be equal to, greater than, or less than $5.12^{\circ} \mathrm{C}$ ? ( $K_{\mathrm{f}}=5.12^{\circ} \mathrm{C} \cdot \mathrm{kg} / \mathrm{mol}$ for benzene. $)$
98. Would benzoic acid be more or less soluble in a $0.1-\mathrm{M} \mathrm{NaOH}$ solution than it is in water?
99. What stabilizes a colloidal suspension? Explain why adding heat or adding an electrolyte can cause the suspended particles to settle out.
100. Given the following electrostatic potential diagrams, comment on the expected solubility of $\mathrm{CH}_{4}$ in water and $\mathrm{NH}_{3}$ in water.

101. A $0.25-\mathrm{m}$ aqueous solution of $\mathrm{Na}_{3} \mathrm{PO}_{4}$ has a freezing point of $-1.6^{\circ} \mathrm{C}$. Is this solution behaving ideally?
102. In Exercise 104 in Chapter 5, the pressure of $\mathrm{CO}_{2}$ in a bottle of sparkling wine was calculated assuming that the $\mathrm{CO}_{2}$ was insoluble in water. This was a bad assumption. Redo this problem by assuming that $\mathrm{CO}_{2}$ obeys Henry's law. Use the data given in that problem to calculate the partial pressure of $\mathrm{CO}_{2}$ in the gas phase and the solubility of $\mathrm{CO}_{2}$ in the wine at $25^{\circ} \mathrm{C}$. The Henry's law constant for $\mathrm{CO}_{2}$ is $3.1 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$ at $25^{\circ} \mathrm{C}$ with Henry's law in the form $C=k P$, where $C$ is the concentration of the gas in $\mathrm{mol} / \mathrm{L}$.
103. Explain the following on the basis of the behavior of atoms and/or ions.
a. Cooking with water is faster in a pressure cooker than in an open pan.
b. Melted sea ice from the Arctic Ocean produces fresh water.
c. $\mathrm{CO}_{2}(s)$ (dry ice) does not have a normal boiling point under normal atmospheric conditions, even though $\mathrm{CO}_{2}$ is a liquid in fire extinguishers.
104. The term proof is defined as twice the percent by volume of pure ethanol in solution. Thus, a solution that is $95 \%$ (by volume) ethanol is 190 proof. What is the molarity of ethanol in a 92 proof ethanol-water solution? Assume the density of ethanol, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$, is $0.79 \mathrm{~g} / \mathrm{cm}^{3}$ and the density of water is $1.0 \mathrm{~g} / \mathrm{cm}^{3}$.
105. At $25^{\circ} \mathrm{C}$, the vapor in equilibrium with a solution containing carbon disulfide and acetonitrile has a total pressure of 263 torr and is 85.5 mole percent carbon disulfide. What is the mole fraction of carbon disulfide in the solution? At $25^{\circ} \mathrm{C}$, the vapor pressure of carbon disulfide is 375 torr. Assume the solution and vapor exhibit ideal behavior.
106. For each of the following solute-solvent combinations, state the sign and relative magnitudes for $\Delta H_{1}, \Delta H_{2}, \Delta H_{3}$, and $\Delta H_{\text {soln }}$ (as defined in Fig. 11.1 of the text). Explain your answers.

## and

a.

and
c.

107. A solution is made by mixing 50.0 g acetone $\left(\mathrm{CH}_{3} \mathrm{COCH}_{3}\right)$ and 50.0 g methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$. What is the vapor pressure of this solution at $25^{\circ} \mathrm{C}$ ? What is the composition of the vapor expressed as a mole fraction? Assume ideal solution and gas behavior. (At $25^{\circ} \mathrm{C}$ the vapor pressures of pure acetone and pure methanol are 271 and 143 torr, respectively.) The actual vapor pressure of this solution is 161 torr. Explain any discrepancies.
108. If the fluid inside a tree is about $0.1 M$ more concentrated in solute than the groundwater that bathes the roots, how high will a column of fluid rise in the tree at $25^{\circ} \mathrm{C}$ ? Assume that the density of the fluid is $1.0 \mathrm{~g} / \mathrm{cm}^{3}$. (The density of mercury is $13.6 \mathrm{~g} / \mathrm{cm}^{3}$.)
109. Thyroxine, an important hormone that controls the rate of metabolism in the body, can be isolated from the thyroid gland. When 0.455 g thyroxine is dissolved in 10.0 g benzene, the freezing point of the solution is depressed by $0.300^{\circ} \mathrm{C}$. What is the molar mass of thyroxine? See Table 11.5.
110. If the human eye has an osmotic pressure of 8.00 atm at $25^{\circ} \mathrm{C}$, what concentration of solute particles in water will provide an isotonic eyedrop solution (a solution with equal osmotic pressure)?
111. An unknown compound contains only carbon, hydrogen, and oxygen. Combustion analysis of the compound gives mass percents of $31.57 \% \mathrm{C}$ and $5.30 \% \mathrm{H}$. The molar mass is determined by measuring the freezing-point depression of an aqueous solution. A freezing point of $-5.20^{\circ} \mathrm{C}$ is recorded for a solution made by dissolving 10.56 g of the compound in 25.0 g water. Determine the empirical formula, molar mass, and molecular formula of the compound. Assume that the compound is a nonelectrolyte.
112. Consider the following:

What would happen to the level of liquid in the two arms if the semipermeable membrane separating the two liquids were permeable to
a. $\mathrm{H}_{2} \mathrm{O}$ (the solvent) only?
b. $\mathrm{H}_{2} \mathrm{O}$ and solute?
113. Consider an aqueous solution containing sodium chloride that has a density of $1.01 \mathrm{~g} / \mathrm{mL}$. Assume the solution behaves ideally. The freezing point of this solution at 1.0 atm is $-1.28^{\circ} \mathrm{C}$. Calculate the percent composition of this solution (by mass).
114. For each of the following, choose the pair of substances you would expect to give the most ideal solution. Explain your choices.
a. $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{6} \mathrm{CH}_{3}$ and $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{5} \mathrm{CH}_{3}$ or $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CH}_{3}-\mathrm{O}-\mathrm{CH}_{3}$
b. $\mathrm{CH}_{3} \mathrm{OH}$ and $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ or $\mathrm{CH}_{3} \mathrm{~F}$ and HF
115. The freezing point of an aqueous solution is $-2.79^{\circ} \mathrm{C}$.
a. Determine the boiling point of this solution.
b. Determine the vapor pressure (in mm Hg ) of this solution at $25^{\circ} \mathrm{C}$ (the vapor pressure of pure water at $25^{\circ} \mathrm{C}$ is 23.76 mm Hg ).
c. Explain any assumptions you make in solving parts a and b .
116. A solution at $50^{\circ} \mathrm{C}$ containing 2.0 mol of liquid A and 3.0 mol of liquid B has a total vapor pressure of 240 . torr. If pure $A$ has a vapor pressure of 150 . torr at $50^{\circ} \mathrm{C}$, what is the vapor pressure of pure B at $50^{\circ} \mathrm{C}$ ?
117. Patients undergoing an upper gastrointestinal tract laboratory test are typically given an X-ray contrast agent that aids with the radiologic imaging of the anatomy. One such contrast agent is sodium diatrizoate, a nonvolatile water-soluble compound. A $0.378-m$ solution is prepared by dissolving 38.4 g sodium diatrizoate $(\mathrm{NaDTZ})$ in $1.60 \times 10^{2} \mathrm{~mL}$ water at $31.2^{\circ} \mathrm{C}$ (the density of water at $31.2^{\circ} \mathrm{C}$ is $0.995 \mathrm{~g} / \mathrm{cm}^{3}$ ). What is the molar mass of sodium diatrizoate? What is the vapor pressure of this solution if the vapor pressure of pure water at $31.2^{\circ} \mathrm{C}$ is 34.1 torr?

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
118. A solution is prepared by dissolving 52.3 g cesium chloride in 60.0 g water. The volume of the solution is 63.3 mL . Calculate the mass percent, molarity, molality, and mole fraction of the CsCl solution.
119. The lattice energy of NaCl is $-786 \mathrm{~kJ} / \mathrm{mol}$, and the enthalpy of hydration of 1 mole of gaseous $\mathrm{Na}^{+}$and 1 mole of gaseous $\mathrm{Cl}^{-}$ions is $-783 \mathrm{~kJ} / \mathrm{mol}$. Calculate the enthalpy of solution per mole of solid NaCl .
120. For each of the following pairs, predict which substance is more soluble in water.
a. $\mathrm{CH}_{3} \mathrm{NH}_{2}$ or $\mathrm{NH}_{3}$
b. $\mathrm{CH}_{3} \mathrm{CN}$ or $\mathrm{CH}_{3} \mathrm{OCH}_{3}$
c. $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ or $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}$
d. $\mathrm{CH}_{3} \mathrm{OH}$ or $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$
e. $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CCH}_{2} \mathrm{OH}$ or $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{6} \mathrm{OH}$
f. $\mathrm{CH}_{3} \mathrm{OCH}_{3}$ or $\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}$
121. The normal boiling point of methanol is $64.7^{\circ} \mathrm{C}$. A solution containing a nonvolatile solute dissolved in methanol has a vapor pressure of 556 torr at $64.7^{\circ} \mathrm{C}$. What is the mole fraction of methanol in this solution?
122. A solution is prepared by mixing 1.000 mole of methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ and 3.18 moles of propanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)$. What is the composition of the vapor (in mole fractions) at $40^{\circ} \mathrm{C}$ ? $\mathrm{At} 40^{\circ} \mathrm{C}$, the vapor pressure of pure methanol is 303 torr, and the vapor pressure of pure propanol is 44.6 torr.
123. The molar mass of a nonelectrolyte is $58.0 \mathrm{~g} / \mathrm{mol}$. Determine the boiling point of a solution containing 35.0 g of this compound and 600.0 g of water. The barometric pressure during the experiment was such that the boiling point of pure water was $99.725^{\circ} \mathrm{C}$.
124. A $4.7 \times 10^{-2} \mathrm{mg}$ sample of a protein is dissolved in water to make 0.25 mL of solution. The osmotic pressure of the solution is 0.56 torr at $25^{\circ} \mathrm{C}$. What is the molar mass of the protein?
125. A solid consists of a mixture of $\mathrm{NaNO}_{3}$ and $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$. When 6.50 g of the solid is dissolved in 50.0 g of water, the freezing point of the solution is lowered by $5.23^{\circ} \mathrm{C}$. What is the composition by mass of the solid mixture?

## Challenge Problems

126. The vapor pressure of pure benzene is 750.0 torr and the vapor pressure of toluene is 300.0 torr at a certain temperature. You make a solution by pouring "some" benzene with "some" toluene. You then place this solution in a closed container and wait for the vapor to come into equilibrium with the solution. Next, you condense the vapor. You put this liquid (the condensed vapor) in a closed container and wait for the vapor to come into equilibrium with the solution. You then condense this vapor and find the mole fraction of benzene in this vapor to be 0.714 . Determine the mole fraction of benzene in the original solution assuming the solution behaves ideally.
127. Liquid A has vapor pressure $x$, and liquid $B$ has vapor pressure $y$. What is the mole fraction of the liquid mixture if the vapor above the solution is $30 . \%$ A by moles? $50 . \% \mathrm{~A}$ ? $80 . \% \mathrm{~A}$ ? (Calculate in terms of $x$ and $y$.)

Liquid A has vapor pressure $x$, liquid B has vapor pressure $y$. What is the mole fraction of the vapor above the solution if the liquid mixture is $30 . \% \mathrm{~A}$ by moles? $50 . \% \mathrm{~A}$ ? $80 . \% \mathrm{~A}$ ? (Calculate in terms of $x$ and $y$.)
128. Plants that thrive in salt water must have internal solutions (inside the plant cells) that are isotonic with (have the same osmotic pressure as) the surrounding solution. A leaf of a saltwater plant is able to thrive in an aqueous salt solution (at $25^{\circ} \mathrm{C}$ ) that has a freezing point equal to $-0.621^{\circ} \mathrm{C}$. You would like to use this information to calculate the osmotic pressure of the solution in the cell.
a. In order to use the freezing-point depression to calculate osmotic pressure, what assumption must you make (in addition to ideal behavior of the solutions, which we will assume)?
b. Under what conditions is the assumption (in part a) reasonable?
c. Solve for the osmotic pressure $\left(\right.$ at $\left.25^{\circ} \mathrm{C}\right)$ of the solution in the plant cell.
d. The plant leaf is placed in an aqueous salt solution (at $25^{\circ} \mathrm{C}$ ) that has a boiling point of $102.0^{\circ} \mathrm{C}$. What will happen to the plant cells in the leaf?
129. You make 20.0 g of a sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ and NaCl mixture and dissolve it in 1.00 kg water. The freezing point of this solution is found to be $-0.426^{\circ} \mathrm{C}$. Assuming ideal behavior, calculate the mass percent composition of the original mixture, and the mole fraction of sucrose in the original mixture.
130. An aqueous solution is $1.00 \% \mathrm{NaCl}$ by mass and has a density of $1.071 \mathrm{~g} / \mathrm{cm}^{3}$ at $25^{\circ} \mathrm{C}$. The observed osmotic pressure of this solution is 7.83 atm at $25^{\circ} \mathrm{C}$.
a. What fraction of the moles of NaCl in this solution exist as ion pairs?
b. Calculate the freezing point that would be observed for this solution.
131. The vapor in equilibrium with a pentane-hexane solution at $25^{\circ} \mathrm{C}$ has a mole fraction of pentane equal to 0.15 at $25^{\circ} \mathrm{C}$. What is the mole fraction of pentane in the solution? (See Exercise 63 for the vapor pressures of the pure liquids.)
132. A forensic chemist is given a white solid that is suspected of being pure cocaine $\left(\mathrm{C}_{17} \mathrm{H}_{21} \mathrm{NO}_{4}\right.$, molar mass $\left.=303.35 \mathrm{~g} / \mathrm{mol}\right)$. She dissolves $1.22 \pm 0.01 \mathrm{~g}$ of the solid in $15.60 \pm 0.01 \mathrm{~g}$ benzene. The freezing point is lowered by $1.32 \pm 0.04^{\circ} \mathrm{C}$.
a. What is the molar mass of the substance? Assuming that the percent uncertainty in the calculated molar mass is the same as the percent uncertainty in the temperature change, calculate the uncertainty in the molar mass.
b. Could the chemist unequivocally state that the substance is cocaine? For example, is the uncertainty small enough to distinguish cocaine from codeine $\left(\mathrm{C}_{18} \mathrm{H}_{21} \mathrm{NO}_{3}\right.$, molar mass $=299.36 \mathrm{~g} / \mathrm{mol})$ ?
c. Assuming that the absolute uncertainties in the measurements of temperature and mass remain unchanged, how could the chemist improve the precision of her results?
133. A $1.60-\mathrm{g}$ sample of a mixture of naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right)$ and anthracene $\left(\mathrm{C}_{14} \mathrm{H}_{10}\right)$ is dissolved in 20.0 g benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$. The freezing point of the solution is $2.81^{\circ} \mathrm{C}$. What is the composition as mass percent of the sample mixture? The freezing point of benzene is $5.51^{\circ} \mathrm{C}$ and $K_{\mathrm{f}}$ is $5.12^{\circ} \mathrm{C} \cdot \mathrm{kg} / \mathrm{mol}$.
134. A solid mixture contains $\mathrm{MgCl}_{2}$ and NaCl . When 0.5000 g of this solid is dissolved in enough water to form 1.000 L of solution, the osmotic pressure at $25.0^{\circ} \mathrm{C}$ is observed to be 0.3950 atm . What is the mass percent of $\mathrm{MgCl}_{2}$ in the solid? (Assume ideal behavior for the solution.)
135. Formic acid $\left(\mathrm{HCO}_{2} \mathrm{H}\right)$ is a monoprotic acid that ionizes only partially in aqueous solutions. A $0.10-M$ formic acid solution is $4.2 \%$ ionized. Assuming that the molarity and molality of the solution are the same, calculate the freezing point and the boiling point of 0.10 M formic acid.
136. You have a solution of two volatile liquids, $A$ and $B$ (assume ideal behavior). Pure liquid A has a vapor pressure of 350.0 torr and pure liquid B has a vapor pressure of 100.0 torr at the temperature of the solution. The vapor at equilibrium above the solution has double the mole fraction of substance A that the solution does. What is the mole fraction of liquid A in the solution?
137. In some regions of the southwest United States, the water is very hard. For example, in Las Cruces, New Mexico, the tap water contains about $560 \mu \mathrm{~g}$ of dissolved solids per milliliter. Reverse osmosis units are marketed in this area to soften water. A typical unit exerts a pressure of 8.0 atm and can produce 45 L water per day.
a. Assuming all of the dissolved solids are $\mathrm{MgCO}_{3}$ and assuming a temperature of $27^{\circ} \mathrm{C}$, what total volume of water must be processed to produce 45 L pure water?
b. Would the same system work for purifying seawater? (Assume seawater is 0.60 M NaCl .)
138. Specifications for lactated Ringer's solution, which is used for intravenous (IV) injections, are as follows to reach 100. mL of solution:
285-315 mg Na ${ }^{+}$
$14.1-17.3 \mathrm{mg} \mathrm{K}^{+}$
$4.9-6.0 \mathrm{mg} \mathrm{Ca}^{2+}$
$368-408 \mathrm{mg} \mathrm{Cl}^{-}$
231-261 mg lactate, $\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}{ }^{-}$
a. Specify the amount of $\mathrm{NaCl}, \mathrm{KCl}, \mathrm{CaCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{NaC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}$ needed to prepare 100. mL lactated Ringer's solution.
b. What is the range of the osmotic pressure of the solution at $37^{\circ} \mathrm{C}$, given the preceding specifications?

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
139. In a coffee-cup calorimeter, $1.60 \mathrm{~g} \mathrm{NH}_{4} \mathrm{NO}_{3}$ was mixed with 75.0 g water at an initial temperature $25.00^{\circ} \mathrm{C}$. After dissolution of the salt, the final temperature of the calorimeter contents was $23.34^{\circ} \mathrm{C}$.
a. Assuming the solution has a heat capacity of $4.18 \mathrm{~J} / \mathrm{g}$ ${ }^{\circ} \mathrm{C}$, and assuming no heat loss to the calorimeter, calculate the enthalpy of solution $\left(\Delta H_{\text {soln }}\right)$ for the dissolution of $\mathrm{NH}_{4} \mathrm{NO}_{3}$ in units of $\mathrm{kJ} / \mathrm{mol}$.
b. If the enthalpy of hydration for $\mathrm{NH}_{4} \mathrm{NO}_{3}$ is $-630 \mathrm{~kJ} / \mathrm{mol}$, calculate the lattice energy of $\mathrm{NH}_{4} \mathrm{NO}_{3}$.
140. Creatinine, $\mathrm{C}_{4} \mathrm{H}_{7} \mathrm{~N}_{3} \mathrm{O}$, is a by-product of muscle metabolism, and creatinine levels in the body are known to be a fairly reliable indicator of kidney function. The normal level of creatinine in the blood for adults is approximately 1.0 mg per deciliter (dL) of blood. If the density of blood is $1.025 \mathrm{~g} / \mathrm{mL}$, calculate the molality of a normal creatinine level in a $10.0-$ mL blood sample. What is the osmotic pressure of this solution at $25.0^{\circ} \mathrm{C}$ ?
141. An aqueous solution containing 0.250 mole of Q , a strong electrolyte, in $5.00 \times 10^{2} \mathrm{~g}$ water freezes at $-2.79^{\circ} \mathrm{C}$. What is the van't Hoff factor for Q ? The molal freezing-point depression constant for water is $1.86^{\circ} \mathrm{C} \cdot \mathrm{kg} / \mathrm{mol}$. What is the formula of Q if it is $38.68 \%$ chlorine by mass and there are twice as many anions as cations in one formula unit of Q ?
142. Anthraquinone contains only carbon, hydrogen, and oxygen. When 4.80 mg anthraquinone is burned, $14.2 \mathrm{mg} \mathrm{CO}_{2}$ and $1.65 \mathrm{mg} \mathrm{H}_{2} \mathrm{O}$ are produced. The freezing point of camphor is lowered by $22.3^{\circ} \mathrm{C}$ when 1.32 g anthraquinone is dissolved in 11.4 g camphor. Determine the empirical and molecular formulas of anthraquinone.

## chartea 12

These wheelchair athletes generate a great amount of kinetic energy as they race. (Simon Balson/Alamy)

### 12.5 Reaction Mechanisms

Mechanisms with Fast Forward and Reverse First Steps
12.6 A Model for Chemical Kinetics
12.7 Catalysis

Heterogeneous Catalysis Homogeneous Catalysis Acid Catalysis

The applications of chemistry focus largely on chemical reactions, and the commercial use of a reaction requires knowledge of several of its characteristics, including its stoichiometry, energetics, and rate. A reaction is defined by its reactants and products, whose identity must be learned by experiment. Once the reactants and products are known, the equation for the reaction can be written and balanced, and stoichiometric calculations can be carried out. Another very important characteristic of a reaction is its spontaneity. Spontaneity refers to the inherent tendency for the process to occur; however, it implies nothing about speed. Spontaneous does not mean fast. There are many spontaneous reactions that are so slow that no apparent reaction occurs over a period of weeks or years at normal temperatures. For example, there is a strong inherent tendency for gaseous hydrogen and oxygen to combine, that is,

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

but in fact the two gases can coexist indefinitely at $25^{\circ} \mathrm{C}$. Similarly, the gaseous reactions

$$
\begin{aligned}
\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) & \longrightarrow 2 \mathrm{HCl}(g) \\
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) & \longrightarrow 2 \mathrm{NH}_{3}(g)
\end{aligned}
$$

are both highly likely to occur from a thermodynamic standpoint, but we observe no reactions under normal conditions. In addition, the process of changing diamond to graphite is spontaneous but is so slow that it is not detectable.

To be useful, reactions must occur at a reasonable rate. To produce the 20 million tons of ammonia needed each year for fertilizer, we cannot simply mix nitrogen and hydrogen gases at $25^{\circ} \mathrm{C}$ and wait for them to react. It is not enough to understand the stoichiometry and thermodynamics of a reaction; we also must understand the factors that govern the rate of the reaction. The area of chemistry that concerns reaction rates is called chemical kinetics.

One of the main goals of chemical kinetics is to understand the steps by which a reaction takes place. This series of steps is called the reaction mechanism. Understanding the mechanism allows us to find ways to facilitate the reaction. For example, the Haber process for the production of ammonia requires high temperatures to achieve commercially feasible reaction rates. However, even higher temperatures (and more cost) would be required without the use of iron oxide, which speeds up the reaction.

In this chapter we will consider the main ideas of chemical kinetics. We will explore rate laws, reaction mechanisms, and simple models for chemical reactions.

### 12.1 Reaction Rates

To introduce the concept of the rate of a reaction, we will consider the decomposition of nitrogen dioxide, a gas that causes air pollution. Nitrogen dioxide decomposes to nitric oxide and oxygen as follows:

$$
2 \mathrm{NO}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

Suppose in a particular experiment we start with a flask of nitrogen dioxide at $300^{\circ} \mathrm{C}$ and measure the concentrations of nitrogen dioxide, nitric oxide, and oxygen as the nitrogen dioxide decomposes. The results of this experiment are summarized in Table 12.1, and the data are plotted in Fig. 12.1.

Note from these results that the concentration of the reactant $\left(\mathrm{NO}_{2}\right)$ decreases with time and the concentrations of the products ( NO and $\mathrm{O}_{2}$ ) increase with time (Fig. 12.2). Chemical kinetics deals with the speed at which these changes occur. The speed, or rate, of a process is defined as the change in a given quantity over a specific period of time. For chemical reactions, the quantity that changes is the amount or concentration

| TABLE 12.1 | Concentrations of Reactant and Products as a Function of Time for the Reaction $2 \mathrm{NO}_{2}(g) \rightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(\mathrm{~g})\left(\right.$ at $\left.300^{\circ} \mathrm{C}\right)$ |  |  |
| :---: | :---: | :---: | :---: |
|  |  | tration |  |
| Time ( $\pm 1$ s) | $\mathrm{NO}_{2}$ | NO | $\mathrm{O}_{2}$ |
| 0 | 0.0100 | 0 | 0 |
| 50 | 0.0079 | 0.0021 | 0.0011 |
| 100 | 0.0065 | 0.0035 | 0.0018 |
| 150 | 0.0055 | 0.0045 | 0.0023 |
| 200 | 0.0048 | 0.0052 | 0.0026 |
| 250 | 0.0043 | 0.0057 | 0.0029 |
| 300 | 0.0038 | 0.0062 | 0.0031 |
| 350 | 0.0034 | 0.0066 | 0.0033 |
| 400 | 0.0031 | 0.0069 | 0.0035 |

FIGURE 12.2 Representation of the reaction $2 \mathrm{NO}_{2}(g) \rightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(\mathrm{~g})$. (a) The reaction at the very beginning ( $t=0$ ). (b) and (c) As time passes, $\mathrm{NO}_{2}$ is converted to NO and $\mathrm{O}_{2}$.
[A] means concentration of $A$ in $\mathrm{mol} / \mathrm{L}$.

of a reactant or product. So the reaction rate of a chemical reaction is defined as the change in concentration of a reactant or product per unit time:

$$
\begin{aligned}
\text { Rate } & =\frac{\text { concentration of A at time } t_{2}-\text { concentration of A at time } t_{1}}{t_{2}-t_{1}} \\
& =\frac{\Delta[\mathrm{A}]}{\Delta t}
\end{aligned}
$$

where A is the reactant or product being considered, and the square brackets indicate concentration in mol/L. As usual, the symbol $\Delta$ indicates a change in a given quantity. Note that a change can be positive (increase) or negative (decrease), thus leading to a positive or negative reaction rate by this definition. However, for convenience, we will always define the rate as a positive quantity, as we will see.

Now let us calculate the average rate at which the concentration of $\mathrm{NO}_{2}$ changes over the first 50 seconds of the reaction using the data given in Table 12.1.

$$
\begin{aligned}
\frac{\text { Change in }\left[\mathrm{NO}_{2}\right]}{\text { Time elapsed }} & =\frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t} \\
& =\frac{\left[\mathrm{NO}_{2}\right]_{t=50}-\left[\mathrm{NO}_{2}\right]_{t=0}}{50 . \mathrm{s}-0 \mathrm{~s}} \\
& =\frac{0.0079 \mathrm{~mol} / \mathrm{L}-0.0100 \mathrm{~mol} / \mathrm{L}}{50 . \mathrm{s}} \\
& =-4.2 \times 10^{-5} \mathrm{~mol} /(\mathrm{L} \cdot \mathrm{~s})
\end{aligned}
$$

$\Delta$
The energy required for athletic exertion and the combustion of fuel in a race car both result from chemical reactions.

Appendix 1.3 reviews slopes of straight lines.

TABLE 12.2 | Average Rate (in $\mathrm{mol} /(\mathrm{L} \cdot \mathrm{s})$ ) of Decomposition of Nitrogen Dioxide as a Function of Time*

| $\frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}$ | Time Period <br> $(\mathbf{s})$ |
| :---: | :---: |
| $4.2 \times 10^{-5}$ | $0 \rightarrow 50$ |
| $2.8 \times 10^{-5}$ | $50 \rightarrow 100$ |
| $2.0 \times 10^{-5}$ | $100 \rightarrow 150$ |
| $1.4 \times 10^{-5}$ | $150 \rightarrow 200$ |
| $1.0 \times 10^{-5}$ | $200 \rightarrow 250$ |

*Note that the rate decreases with time.

Note that since the concentration of $\mathrm{NO}_{2}$ decreases with time, $\Delta\left[\mathrm{NO}_{2}\right]$ is a negative quantity. Because it is customary to work with positive reaction rates, we define the rate of this particular reaction as

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}
$$

Since the concentrations of reactants always decrease with time, any rate expression involving a reactant will include a negative sign. The average rate of this reaction from 0 to 50 seconds is then

$$
\begin{aligned}
\text { Rate } & =-\frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t} \\
= & -\left(-4.2 \times 10^{-5} \mathrm{~mol} /(\mathrm{L} \cdot \mathrm{~s})\right) \\
= & 4.2 \times 10^{-5} \mathrm{~mol} /(\mathrm{L} \cdot \mathrm{~s})
\end{aligned}
$$

The average rates for this reaction during several other time intervals are given in Table 12.2. Note that the rate is not constant but decreases with time. The rates given in Table 12.2 are average rates over 50 -second time intervals. The value of the rate at a particular time (the instantaneous rate) can be obtained by computing the slope of a line tangent to the curve at that point. Figure 12.1 shows a tangent drawn at $t=100$ seconds. The slope of this line gives the rate at $t=100$ seconds as follows:

$$
\begin{aligned}
\text { Slope of the tangent line } & =\frac{\text { change in } y}{\text { change in } x} \\
& =\frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t} \\
\text { Rate } & =-\frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
\text { Rate } & =-(\text { slope of the tangent line }) \\
& =-\left(\frac{-0.0026 \mathrm{~mol} / \mathrm{L}}{110 \mathrm{~s}}\right) \\
& =2.4 \times 10^{-5} \mathrm{~mol} /(\mathrm{L} \cdot \mathrm{~s})
\end{aligned}
$$

So far we have discussed the rate of this reaction only in terms of the reactant. The rate also can be defined in terms of the products. However, in doing so we must take

As we will see later, there is a certain type of rate that remains constant over time.
into account the coefficients in the balanced equation for the reaction, because the stoichiometry determines the relative rates of consumption of reactants and generation of products. For example, in the reaction we are considering,

$$
2 \mathrm{NO}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

both the reactant $\mathrm{NO}_{2}$ and the product NO have a coefficient of 2, so NO is produced at the same rate as $\mathrm{NO}_{2}$ is consumed. We can verify this from Fig. 12.1. Note that the curve for NO is the same shape as the curve for $\mathrm{NO}_{2}$, except that it is inverted, or flipped over. This means that, at any point in time, the slope of the tangent to the curve for NO will be the negative of the slope to the curve for $\mathrm{NO}_{2}$. (Verify this at the point $t=100$ seconds on both curves.) In the balanced equation, the product $\mathrm{O}_{2}$ has a coefficient of 1 , which means it is produced half as fast as NO, since NO has a coefficient of 2 . That is, the rate of NO production is twice the rate of $\mathrm{O}_{2}$ production.

We also can verify this fact from Fig. 12.1. For example, at $t=250$ seconds,

$$
\begin{aligned}
\text { Slope of the tangent to the NO curve } & =\frac{6.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L}}{70 . \mathrm{s}} \\
& =8.6 \times 10^{-6} \mathrm{~mol} /(\mathrm{L} \cdot \mathrm{~s}) \\
\text { Slope of the tangent to the } \mathrm{O}_{2} \text { curve } & =\frac{3.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L}}{70 . \mathrm{s}} \\
& =4.3 \times 10^{-6} \mathrm{~mol} /(\mathrm{L} \cdot \mathrm{~s})
\end{aligned}
$$

The slope at $t=250$ seconds on the NO curve is twice the slope of that point on the $\mathrm{O}_{2}$ curve, showing that the rate of production of NO is twice that of $\mathrm{O}_{2}$.

The rate information can be summarized as follows:

| Rate of consumption <br> of $\mathrm{NO}_{2}$ | $=$rate of production <br> of NO <br> $-\frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}$$=\frac{\Delta[\mathrm{NO}]}{\Delta t}$ |
| ---: | :--- |
| $=2\left(\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}\right)$ |  |

We have seen that the rate of a reaction is typically not constant. Most reaction rates change with time. This is so because the concentrations change with time (see Fig. 12.1).

Because the reaction rate changes with time, and because the rate is different (by factors that depend on the coefficients in the balanced equation) depending on which reactant or product is being studied, we must be very specific when we describe a rate for a chemical reaction.

### 12.2 Rate Laws: An Introduction

Chemical reactions are reversible. In our discussion of the decomposition of nitrogen dioxide, we have so far considered only the forward reaction, as shown here:

$$
2 \mathrm{NO}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

However, the reverse reaction also can occur. As NO and $\mathrm{O}_{2}$ accumulate, they can react to re-form $\mathrm{NO}_{2}$ :

$$
\mathrm{O}_{2}(g)+2 \mathrm{NO}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

When gaseous $\mathrm{NO}_{2}$ is placed in an otherwise empty container, initially the dominant reaction is

$$
2 \mathrm{NO}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

and the change in the concentration of $\mathrm{NO}_{2}\left(\Delta\left[\mathrm{NO}_{2}\right]\right)$ depends only on the forward reaction. However, after a period of time, enough products accumulate so that the

When forward and reverse reaction rates are equal, there will be no changes in the concentrations of reactants or products. This is called chemical equilibrium and is discussed fully in Chapter 13.
reverse reaction becomes important. Now $\Delta\left[\mathrm{NO}_{2}\right]$ depends on the difference in the rates of the forward and reverse reactions. This complication can be avoided if we study the rate of a reaction under conditions where the reverse reaction makes only a negligible contribution. Typically, this means that we must study a reaction at a point soon after the reactants are mixed, before the products have had time to build up to significant levels.

If we choose conditions where the reverse reaction can be neglected, the reaction rate will depend only on the concentrations of the reactants. For the decomposition of nitrogen dioxide, we can write

$$
\begin{equation*}
\text { Rate }=k\left[\mathrm{NO}_{2}\right]^{n} \tag{12.1}
\end{equation*}
$$

Such an expression, which shows how the rate depends on the concentrations of reactants, is called a rate law. The proportionality constant $k$, called the rate constant, and $n$, called the order of the reactant, must both be determined by experiment. The order of a reactant can be an integer (including zero) or a fraction. For the relatively simple reactions we will consider in this book, the orders will often be positive integers.

Note two important points about Equation (12.1):

1. The concentrations of the products do not appear in the rate law because the reaction rate is being studied under conditions where the reverse reaction does not contribute to the overall rate.
2. The value of the exponent $n$ must be determined by experiment; it cannot be written from the balanced equation.

Before we go further we must define exactly what we mean by the term rate in Equation (12.1). In Section 12.1 we saw that reaction rate means a change in concentration per unit time. However, which reactant or product concentration do we choose in defining the rate? For example, for the decomposition of $\mathrm{NO}_{2}$ to produce $\mathrm{O}_{2}$ and NO considered in Section 12.1, we could define the rate in terms of any of these three species. However, since $\mathrm{O}_{2}$ is produced only half as fast as NO , we must be careful to specify which species we are talking about in a given case. For instance, we might choose to define the reaction rate in terms of the consumption of $\mathrm{NO}_{2}$ :

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}=k\left[\mathrm{NO}_{2}\right]^{n}
$$

On the other hand, we could define the rate in terms of the production of $\mathrm{O}_{2}$ :

$$
\text { Rate }^{\prime}=\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=k^{\prime}\left[\mathrm{NO}_{2}\right]^{n}
$$

Note that because $2 \mathrm{NO}_{2}$ molecules are consumed for every $\mathrm{O}_{2}$ molecule produced,
or

$$
\begin{aligned}
\text { Rate } & =2 \times \text { rate }^{\prime} \\
k\left[\mathrm{NO}_{2}\right]^{n} & =2 k^{\prime}\left[\mathrm{NO}_{2}\right]^{n} \\
k & =2 \times k^{\prime}
\end{aligned}
$$

and
Thus the value of the rate constant depends on how the rate is defined.
In this text we will always be careful to define exactly what is meant by the rate for a given reaction so that there will be no confusion about which specific rate constant is being used.

## Types of Rate Laws

Notice that the rate law we have used to this point expresses rate as a function of concentration. For example, for the decomposition of $\mathrm{NO}_{2}$ we have defined

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}=k\left[\mathrm{NO}_{2}\right]^{n}
$$

The name differential rate law comes from a mathematical term. We will regard it simply as a label. The terms differential rate law and rate law will be used interchangeably in this text.
which tells us (once we have determined the value of $n$ ) exactly how the rate depends on the concentration of the reactant, $\mathrm{NO}_{2}$. A rate law that expresses how the rate depends on concentration is technically called the differential rate law, but it is often simply called the rate law. Thus when we use the term rate law in this text, we mean the expression that gives the rate as a function of concentration.

A second kind of rate law, the integrated rate law, also will be important in our study of kinetics. The integrated rate law expresses how the concentrations depend on time. Although we will not consider the details here, a given differential rate law is always related to a certain type of integrated rate law, and vice versa. That is, if we determine the differential rate law for a given reaction, we automatically know the form of the integrated rate law for the reaction. This means that once we determine experimentally either type of rate law for a reaction, we also know the other one.

Which rate law we choose to determine by experiment often depends on what types of data are easiest to collect. If we can conveniently measure how the rate changes as the concentrations are changed, we can readily determine the differential (rate/concentration) rate law. On the other hand, if it is more convenient to measure the concentration as a function of time, we can determine the form of the integrated (concentration/time) rate law. We will discuss how rate laws are actually determined in the next several sections.

Why are we interested in determining the rate law for a reaction? How does it help us? It helps us because we can work backward from the rate law to infer the steps by which the reaction occurs. Most chemical reactions do not take place in a single step but result from a series of sequential steps. To understand a chemical reaction, we must learn what these steps are. For example, a chemist who is designing an insecticide may study the reactions involved in the process of insect growth to see what type of molecule might interrupt this series of reactions. Or an industrial chemist may be trying to make a given reaction occur faster. To accomplish this, he or she must know which step is slowest, because it is that step that must be speeded up. Thus a chemist is usually not interested in a rate law for its own sake but because of what it reveals about the steps by which a reaction occurs. We will develop a process for finding the reaction steps in this chapter.

## LET'S REVIEW Rate Laws: A Summary

» There are two types of rate laws.

1. The differential rate law (often called simply the rate law) shows how the rate of a reaction depends on concentrations.
2. The integrated rate law shows how the concentrations of species in the reaction depend on time.
» Because we typically consider reactions only under conditions where the reverse reaction is unimportant, our rate laws will involve only concentrations of reactants.
" Because the differential and integrated rate laws for a given reaction are related in a welldefined way, the experimental determination of either of the rate laws is sufficient.
» Experimental convenience usually dictates which type of rate law is determined experimentally.
» Knowing the rate law for a reaction is important mainly because we can usually infer the individual steps involved in the reaction from the specific form of the rate law.

### 12.3 Determining the Form of the Rate Law

The first step in understanding how a given chemical reaction occurs is to determine the form of the rate law. That is, we need to determine experimentally the power to which each reactant concentration must be raised in the rate law. In this section we will

FIGURE 12.3 A plot of the concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ as a function of time for the reaction $2 \mathrm{~N}_{2} \mathrm{O}_{5}($ soln $) \rightarrow$ $4 \mathrm{NO}_{2}$ (soln) $+\mathrm{O}_{2}(\mathrm{~g})$ (at $45^{\circ} \mathrm{C}$ ). Note that the reaction rate at $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]=$ 0.90 M is twice that at $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]=$ 0.45 M .

TABLE 12.3 | Concentration/ Time Data for the Reaction $2 \mathrm{~N}_{2} \mathrm{O}_{5}($ soln $) \rightarrow 4 \mathrm{NO}_{2}($ soln $)+\mathrm{O}_{2}($ g $)$ (at $45^{\circ} \mathrm{C}$ )

| $\left[\mathrm{N}_{2} \mathbf{O}_{5}\right](\mathrm{mol} / \mathrm{L})$ | Time $(\mathbf{s})$ |
| :---: | ---: |
| 1.00 | 0 |
| 0.88 | 200 |
| 0.78 | 400 |
| 0.69 | 600 |
| 0.61 | 800 |
| 0.54 | 1000 |
| 0.48 | 1200 |
| 0.43 | 1400 |
| 0.38 | 1600 |
| 0.34 | 1800 |
| 0.30 | 2000 |

First order: rate $=k[\mathrm{~A}]$. Doubling the concentration of A doubles the reaction rate.

[^25]
explore ways to obtain the differential rate law for a reaction. First, we will consider the decomposition of dinitrogen pentoxide in carbon tetrachloride solution:
$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(\text { soln }) \longrightarrow 4 \mathrm{NO}_{2}(\text { soln })+\mathrm{O}_{2}(g)
$$

Data for this reaction at $45^{\circ} \mathrm{C}$ are listed in Table 12.3 and plotted in Fig. 12.3. In this reaction the oxygen gas escapes from the solution and thus does not react with the nitrogen dioxide, so we do not have to be concerned about the effects of the reverse reaction at any time over the life of the reaction. That is, the reverse reaction is negligible at all times over the course of this reaction.

Evaluation of the reaction rates at concentrations of $\mathrm{N}_{2} \mathrm{O}_{5}$ of 0.90 M and 0.45 M , by taking the slopes of the tangents to the curve at these points (see Fig. 12.3), yields the following data:

Note that when $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ is halved, the rate is also halved. This means that the rate of this reaction depends on the concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ to the first power. In other words, the (differential) rate law for this reaction is

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]}{\Delta t}=k\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]^{1}=k\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]
$$

Thus the reaction is first order in $\mathrm{N}_{2} \mathrm{O}_{5}$. Note that for this reaction the order is not the same as the coefficient of $\mathrm{N}_{2} \mathrm{O}_{5}$ in the balanced equation for the reaction. This reemphasizes the fact that the order of a particular reactant must be obtained by observing how the reaction rate depends on the concentration of that reactant.

We have seen that by determining the instantaneous rate at two different reactant concentrations, the rate law for the decomposition of $\mathrm{N}_{2} \mathrm{O}_{5}$ is shown to have the form

$$
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]
$$

where A represents $\mathrm{N}_{2} \mathrm{O}_{5}$.

## Method of Initial Rates

One common method for experimentally determining the form of the rate law for a reaction is the method of initial rates. The initial rate of a reaction is the instantaneous rate determined just after the reaction begins (just after $t=0$ ). The idea is to

| TABLE 12.4 | Initial Rates from Three Experiments for the Reaction$\mathrm{NH}_{4}^{+}(a q)+\mathrm{NO}_{2}^{-}(a q) \rightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$ |  |  |
| :---: | :---: | :---: | :---: |
| Experiment | Initial Concentration of $\mathrm{NH}_{4}{ }^{+}$ | Initial Concentration of $\mathrm{NO}_{2}^{-}$ | Initial Rate ( $\mathrm{mol} / \mathrm{L} \cdot \mathrm{s}$ ) |
| 1 | 0.100 M | 0.0050 M | $1.35 \times 10^{-7}$ |
| 2 | 0.100 M | 0.010 M | $2.70 \times 10^{-7}$ |
| 3 | 0.200 M | 0.010 M | $5.40 \times 10^{-7}$ |

determine the instantaneous rate before the initial concentrations of reactants have changed significantly. Several experiments are carried out using different initial concentrations, and the initial rate is determined for each run. The results are then compared to see how the initial rate depends on the initial concentrations. This allows the form of the rate law to be determined. We will illustrate the method of initial rates using the following equation:

$$
\mathrm{NH}_{4}^{+}(a q)+\mathrm{NO}_{2}^{-}(a q) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Table 12.4 gives initial rates obtained from three experiments involving different initial concentrations of reactants. The general form of the rate law for this reaction is

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{NH}_{4}^{+}\right]}{\Delta t}=k\left[\mathrm{NH}_{4}^{+}\right]^{n}\left[\mathrm{NO}_{2}^{-}\right]^{m}
$$

We can determine the values of $n$ and $m$ by observing how the initial rate depends on the initial concentrations of $\mathrm{NH}_{4}{ }^{+}$and $\mathrm{NO}_{2}{ }^{-}$. In Experiments 1 and 2, where the initial concentration of $\mathrm{NH}_{4}^{+}$remains the same but the initial concentration of $\mathrm{NO}_{2}{ }^{-}$doubles, the observed initial rate also doubles. Since

$$
\text { Rate }=k\left[\mathrm{NH}_{4}^{+}\right]^{n}\left[\mathrm{NO}_{2}^{-}\right]^{m}
$$

we have for Experiment 1

$$
\text { Rate }=1.35 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}=k(0.100 \mathrm{~mol} / \mathrm{L})^{n}(0.0050 \mathrm{~mol} / \mathrm{L})^{m}
$$

and for Experiment 2

$$
\text { Rate }=2.70 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}=k(0.100 \mathrm{~mol} / \mathrm{L})^{n}(0.010 \mathrm{~mol} / \mathrm{L})^{m}
$$

The ratio of these rates is

$$
\begin{aligned}
\frac{\text { Rate } 2}{\text { Rate } 1}= & \frac{2.70 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{1.35 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}=\frac{k(0.100 \mathrm{~mol} / \mathrm{L})^{n}(0.010 \mathrm{~mol} / \mathrm{L})^{m}}{k(0.100 \mathrm{~mol} / \mathrm{L})^{n}(0.0050 \mathrm{~mol} / \mathrm{L})^{m}} \\
= & \frac{(0.010 \mathrm{~mol} / \mathrm{L})^{m}}{(0.0050 \mathrm{~mol} / \mathrm{L})^{m}}=(2.0)^{m} \\
& \quad \frac{\text { Rate 2 }}{\text { Rate } 1}=2.00=(2.0)^{m}
\end{aligned}
$$

Thus
which means the value of $m$ is 1 . The rate law for this reaction is first order in the reactant $\mathrm{NO}_{2}{ }^{-}$.

A similar analysis of the results for Experiments 2 and 3 yields the ratio

$$
\begin{aligned}
\frac{\text { Rate } 3}{\text { Rate } 2} & =\frac{5.40 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{2.70 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}=\frac{(0.200 \mathrm{~mol} / \mathrm{L})^{n}}{(0.100 \mathrm{~mol} / \mathrm{L})^{n}} \\
& =2.00=\left(\frac{0.200}{0.100}\right)^{n}=(2.00)^{n}
\end{aligned}
$$

The value of $n$ is also 1 .

Overall reaction order is the sum of the orders for the various reactants.

We have shown that the values of $n$ and $m$ are both 1 and the rate law is

$$
\text { Rate }=k\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{NO}_{2}^{-}\right]
$$

This rate law is first order in both $\mathrm{NO}_{2}{ }^{-}$and $\mathrm{NH}_{4}{ }^{+}$. Note that it is merely a coincidence that $n$ and $m$ have the same values as the coefficients of $\mathrm{NH}_{4}{ }^{+}$and $\mathrm{NO}_{2}{ }^{-}$in the balanced equation for the reaction.

The overall reaction order is the sum of $n$ and $m$. For this reaction, $n+m=2$. The reaction is second order overall.

The value of the rate constant $k$ can now be calculated using the results of any of the three experiments shown in Table 12.4. From the data for Experiment 1, we know that

$$
\begin{aligned}
\text { Rate } & =k\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{NO}_{2}^{-}\right] \\
1.35 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s} & =k(0.100 \mathrm{~mol} / \mathrm{L})(0.0050 \mathrm{~mol} / \mathrm{L})
\end{aligned}
$$

Then

$$
k=\frac{1.35 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{(0.100 \mathrm{~mol} / \mathrm{L})(0.0050 \mathrm{~mol} / \mathrm{L})}=2.7 \times 10^{-4} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{~s}
$$

## EXAMPLE 12.1 Determining a Rate Law

The reaction between bromate ions and bromide ions in acidic aqueous solution is given by the equation

$$
\mathrm{BrO}_{3}^{-}(a q)+5 \mathrm{Br}^{-}(a q)+6 \mathrm{H}^{+}(a q) \longrightarrow 3 \mathrm{Br}_{2}(l)+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

Table 12.5 gives the results from four experiments. Using these data, determine the orders for all three reactants, the overall reaction order, and the value of the rate constant.

SOLUTION The general form of the rate law for this reaction is

$$
\text { Rate }=k\left[\mathrm{BrO}_{3}^{-}\right]^{n}\left[\mathrm{Br}^{-}\right]^{m}\left[\mathrm{H}^{+}\right]^{p}
$$

We can determine the values of $n, m$, and $p$ by comparing the rates from the various experiments. To determine the value of $n$, we use the results from Experiments 1 and 2 , in which only $\left[\mathrm{BrO}_{3}{ }^{-}\right]$changes:

$$
\left.\left.\begin{array}{l}
\frac{\text { Rate } 2}{\text { Rate } 1}=\frac{1.6 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{8.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}=\frac{k(0.20 \mathrm{~mol} / \mathrm{L})^{n}(0.10 \mathrm{~mol} / \mathrm{L})^{m}(0.10 \mathrm{~mol} / \mathrm{L})^{p}}{k(0.10 \mathrm{~mol} / \mathrm{L})^{n}(0.10 \mathrm{~mol} / \mathrm{L})^{m}(0.10 \mathrm{~mol} / \mathrm{L})^{p}} \\
\qquad 2.0
\end{array}\right)=\left(\frac{0.20 \mathrm{~mol} / \mathrm{L}}{0.10 \mathrm{~mol} / \mathrm{L}}\right)^{n}=(2.0)^{n}\right) \text { Thus } n \text { is equal to } 1 \text {. }
$$

TABLE 12.5 | The Results from Four Experiments to Study the Reaction $\mathrm{BrO}_{3}^{-}(a q)+5 \mathrm{Br}^{-}(a q)+6 \mathrm{H}^{+}(a q) \rightarrow 3 \mathrm{Br}_{2}(I)+3 \mathrm{H}_{2} \mathrm{O}(l)$

| Experiment | Initial <br> Concentration <br> of $\mathrm{BrO}_{\mathbf{3}^{-}}$ <br> $(\mathrm{mol} / \mathrm{L})$ | Initial <br> Concentration <br> of $\mathrm{Br}^{-}$ <br> $(\mathrm{mol} / \mathrm{L})$ | Initial <br> Concentration <br> of $\mathrm{H}^{+}$ <br> $(\mathrm{mol} / \mathrm{L})$ | Measured <br> Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 0.10 | 0.10 | 0.10 | $8.0 \times 10^{-4}$ |
| 2 | 0.20 | 0.10 | 0.10 | $1.6 \times 10^{-3}$ |
| 3 | 0.20 | 0.20 | 0.10 | $3.2 \times 10^{-3}$ |
| 4 | 0.10 | 0.10 | 0.20 | $3.2 \times 10^{-3}$ |

To determine the value of $m$, we use the results from Experiments 2 and 3, in which only $\left[\mathrm{Br}^{-}\right]$changes:

$$
\begin{aligned}
\frac{\text { Rate } 3}{\text { Rate } 2}=\frac{3.2 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{1.6 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}} & =\frac{k(0.20 \mathrm{~mol} / \mathrm{L})^{n}(0.20 \mathrm{~mol} / \mathrm{L})^{m}(0.10 \mathrm{~mol} / \mathrm{L})^{p}}{k(0.20 \mathrm{~mol} / \mathrm{L})^{n}(0.10 \mathrm{~mol} / \mathrm{L})^{m}(0.10 \mathrm{~mol} / \mathrm{L})^{p}} \\
2.0 & =\left(\frac{0.20 \mathrm{~mol} / \mathrm{L}}{0.10 \mathrm{~mol} / \mathrm{L}}\right)^{m}=(2.0)^{m}
\end{aligned}
$$

Thus $m$ is equal to 1 .
To determine the value of $p$, we use the results from Experiments 1 and 4, in which $\left[\mathrm{BrO}_{3}{ }^{-}\right]$and $\left[\mathrm{Br}^{-}\right]$are constant but $\left[\mathrm{H}^{+}\right]$differs:

$$
\begin{aligned}
\frac{\text { Rate } 4}{\text { Rate } 1}=\frac{3.2 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{8.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}} & =\frac{k(0.10 \mathrm{~mol} / \mathrm{L})^{n}(0.10 \mathrm{~mol} / \mathrm{L})^{m}(0.20 \mathrm{~mol} / \mathrm{L})^{p}}{k(0.10 \mathrm{~mol} / \mathrm{L})^{n}(0.10 \mathrm{~mol} / \mathrm{L})^{m}(0.10 \mathrm{~mol} / \mathrm{L})^{p}} \\
4.0 & =\left(\frac{0.20 \mathrm{~mol} / \mathrm{L}}{0.10 \mathrm{~mol} / \mathrm{L}}\right)^{p} \\
4.0 & =(2.0)^{p}=(2.0)^{2}
\end{aligned}
$$

Thus $p$ is equal to 2 .
The rate of this reaction is first order in $\mathrm{BrO}_{3}{ }^{-}$and $\mathrm{Br}^{-}$and second order in $\mathrm{H}^{+}$. The overall reaction order is $n+m+p=4$.

The rate law can now be written

$$
\text { Rate }=k\left[\mathrm{BrO}_{3}^{-}\right]\left[\mathrm{Br}^{-}\right]\left[\mathrm{H}^{+}\right]^{2}
$$

The value of the rate constant $k$ can be calculated from the results of any of the four experiments. For Experiment 1 , the initial rate is $8.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ and $\left[\mathrm{BrO}_{3}{ }^{-}\right]=$ $0.100 M,\left[\mathrm{Br}^{-}\right]=0.10 M$, and $\left[\mathrm{H}^{+}\right]=0.10 M$. Using these values in the rate law gives

$$
\begin{aligned}
8.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s} & =k(0.10 \mathrm{~mol} / \mathrm{L})(0.10 \mathrm{~mol} / \mathrm{L})(0.10 \mathrm{~mol} / \mathrm{L})^{2} \\
8.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s} & =k\left(1.0 \times 10^{-4} \mathrm{~mol}^{4} / \mathrm{L}^{4}\right) \\
\square k & =\frac{8.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{1.0 \times 10^{-4} \mathrm{~mol}^{4} / \mathrm{L}^{4}}=8.0 \mathrm{~L}^{3} / \mathrm{mol}^{3} \cdot \mathrm{~s}
\end{aligned}
$$

Reality Check Verify that the same value of $k$ can be obtained from the results of the other experiments.

## See Exercises 12.31 through 12.34

### 12.4 The Integrated Rate Law

The rate laws we have considered so far express the rate as a function of the reactant concentrations. It is also useful to be able to express the reactant concentrations as a function of time, given the (differential) rate law for the reaction. In this section we show how this is done.

We will proceed by first looking at reactions involving a single reactant:

$$
\mathrm{aA} \longrightarrow \text { products }
$$

all of which have a rate law of the form

$$
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]^{n}
$$

We will develop the integrated rate laws individually for the cases $n=1$ (first order), $n=2$ (second order), and $n=0$ (zero order).

Appendix 1.2 contains a review of logarithms.

An integrated rate law relates concentration to reaction time.

For a first-order reaction, a plot of $\ln [A]$ versus $t$ is always a straight line.

## First-Order Rate Laws

For the reaction

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(\text { soln }) \longrightarrow 4 \mathrm{NO}_{2}(\text { soln })+\mathrm{O}_{2}(g)
$$

we have found that the rate law is

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]}{\Delta t}=k\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]
$$

Since the rate of this reaction depends on the concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ to the first power, it is a first-order reaction. This means that if the concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ in a flask were suddenly doubled, the rate of production of $\mathrm{NO}_{2}$ and $\mathrm{O}_{2}$ also would double. This rate law can be put into a different form using a calculus operation known as integration, which yields the expression

$$
\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]=-k t+\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]_{0}
$$

where $\ln$ indicates the natural logarithm, $t$ is the time, $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ is the concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ at time $t$, and $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]_{0}$ is the initial concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ (at $t=0$, the start of the experiment). Note that such an equation, called the integrated rate law, expresses the concentration of the reactant as a function of time.

For a chemical reaction of the form

$$
\mathrm{aA} \longrightarrow \text { products }
$$

where the kinetics are first order in [A], the rate law is

$$
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]
$$

and the integrated first-order rate law is

$$
\begin{equation*}
\ln [\mathrm{A}]=-k t+\ln [\mathrm{A}]_{0} \tag{12.2}
\end{equation*}
$$

There are several important things to note about Equation (12.2):

1. The equation shows how the concentration of $A$ depends on time. If the initial concentration of A and the rate constant $k$ are known, the concentration of A at any time can be calculated.
2. Equation (12.2) is of the form $y=m x+b$, where a plot of $y$ versus $x$ is a straight line with slope $m$ and intercept $b$. In Equation

$$
y=\ln [\mathrm{A}] \quad x=t \quad m=-k \quad b=\ln [\mathrm{A}]_{0}
$$

Thus for a first-order reaction, plotting the natural logarithm of concentration versus time always gives a straight line. This fact is often used to test whether a reaction is first order. For the reaction

$$
\mathrm{aA} \longrightarrow \text { products }
$$

the reaction is first order in $A$ if a plot of $\ln [A]$ versus $t$ is a straight line. Conversely, if this plot is not a straight line, the reaction is not first order in A.
3. This integrated rate law for a first-order reaction also can be expressed in terms of a ratio of $[\mathrm{A}]$ and $[\mathrm{A}]_{0}$ as follows:

$$
\ln \left(\frac{[\mathrm{A}]_{0}}{[\mathrm{~A}]}\right)=k t
$$

## EXAMPLE 12.2 First-Order Rate Laws I

The decomposition of $\mathrm{N}_{2} \mathrm{O}_{5}$ in the gas phase was studied at constant temperature.

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

The following results were collected:

| $\begin{aligned} & {\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]} \\ & (\mathrm{mol} / \mathrm{L}) \end{aligned}$ | Time (s) |
| :---: | :---: |
| 0.1000 | 0 |
| 0.0707 | 50 |
| 0.0500 | 100 |
| 0.0250 | 200 |
| 0.0125 | 300 |
| 0.00625 | 400 |

Using these data, verify that the rate law is first order in $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$, and calculate the value of the rate constant, where the rate $=-\Delta\left[\mathrm{N}_{2} \mathrm{O}_{5}\right] / \Delta t$.

SOLUTION We can verify that the rate law is first order in $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ by constructing a plot of $\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ versus time.

| $\ln \left[\mathrm{N}_{2} \mathrm{O}_{\mathbf{5}}\right]$ | Time <br> $(\mathrm{s})$ |
| :---: | :---: |
| -2.303 | 0 |
| -2.649 | 50 |
| -2.996 | 100 |
| -3.689 | 200 |
| -4.382 | 300 |
| -5.075 | 400 |

The values of $\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ at various times are given in the table above and shown in the plot of $\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$. The fact that the plot is a straight line confirms that the reaction is first order in $\mathrm{N}_{2} \mathrm{O}_{5}$, since it follows the equation $\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]=-k t+\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]_{0}$.

Since the reaction is first order, the slope of the line equals $-k$, where

$$
\text { Slope }=\frac{\text { change in } y}{\text { change in } x}=\frac{\Delta y}{\Delta x}=\frac{\Delta\left(\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]\right)}{\Delta t}
$$

Since the first and last points are exactly on the line, we will use these points to calculate the slope:

$$
\begin{aligned}
\text { Slope } & =\frac{-5.075-(-2.303)}{400 . \mathrm{s}-0 \mathrm{~s}}=\frac{-2.772}{400 . \mathrm{s}}=-6.93 \times 10^{-3} \mathrm{~s}^{-1} \\
\square k & =-(\text { slope })=6.93 \times 10^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

## EXAMPLE 12.3 First-Order Rate Laws II

## SOLUTION

The antilog operation means to exponentiate (see Appendix 1.2).

Nuclear decay is a first-order process. We often use the mass of the sample or the number of atoms. We will discuss this more in Sections 19.2 and 19.5.

Using the data given in Example 12.2, calculate $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ at 150 s after the start of the reaction.

We know from Example 12.2 that $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]=0.0500 \mathrm{~mol} / \mathrm{L}$ at 100 s and $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]=$ $0.0250 \mathrm{~mol} / \mathrm{L}$ at 200 s . Since 150 s is halfway between 100 and 200 s , it is tempting to assume that we can simply use an arithmetic average to obtain $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ at that time. This is incorrect because it is $\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$, not $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$, that is directly proportional to $t$. To calculate $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ after 150 s , we use Equation (12.2):

$$
\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]=-k t+\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]_{0}
$$

where $t=150 . \mathrm{s}, k=6.93 \times 10^{-3} \mathrm{~s}^{-1}($ as determined in Example 12.2 $)$, and $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]_{0}=$ $0.1000 \mathrm{~mol} / \mathrm{L}$.

$$
\begin{aligned}
\ln \left(\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]_{t=150}\right) & =-\left(6.93 \times 10^{-3} \mathrm{~s}^{-1}\right)(150 . \mathrm{s})+\ln (0.100) \\
& =-1.040-2.303=-3.343 \\
\square\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]_{t=150} & =\operatorname{antilog}(-3.343)=0.0353 \mathrm{~mol} / \mathrm{L}
\end{aligned}
$$

Note that this value of $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ is not halfway between 0.0500 and $0.0250 \mathrm{~mol} / \mathrm{L}$.

See Exercise 12.39

## Half-Life of a First-Order Reaction

The time required for a reactant to reach half its original concentration is called the half-life of a reactant and is designated by the symbol $t_{1 / 2}$. For example, we can calculate the half-life of the decomposition reaction discussed in Example 12.2. The data plotted in Fig. 12.4 show that the half-life for this reaction is 100 seconds. We can see this by considering the following numbers:

Note that it always takes 100 seconds for $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ to be halved in this reaction.
A general formula for the half-life of a first-order reaction can be derived from the integrated rate law for the general reaction

$$
\mathrm{aA} \longrightarrow \text { products }
$$

If the reaction is first order in [A],

$$
\ln \left(\frac{[\mathrm{A}]_{0}}{[\mathrm{~A}]}\right)=k t
$$

FIGURE 12.4 A plot of $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ versus time for the decomposition reaction of $\mathrm{N}_{2} \mathrm{O}_{5}$.

For a first-order reaction, $t_{1 / 2}$ is independent of the initial concentration.

By definition, when $t=t_{1 / 2}$,

$$
[\mathrm{A}]=\frac{[\mathrm{A}]_{0}}{2}
$$

Then, for $t=t_{1 / 2}$, the integrated rate law becomes
or

$$
\begin{aligned}
\ln \left(\frac{[\mathrm{A}]_{0}}{[\mathrm{~A}]_{0} / 2}\right) & =k t_{1 / 2} \\
\ln (2) & =k t_{1 / 2}
\end{aligned}
$$

Substituting the value of $\ln (2)$ and solving for $t_{1 / 2}$ gives

$$
\begin{equation*}
t_{1 / 2}=\frac{0.693}{k} \tag{12.3}
\end{equation*}
$$

This is the general equation for the half-life of a first-order reaction. Equation (12.3) can be used to calculate $t_{1 / 2}$ if $k$ is known or $k$ if $t_{1 / 2}$ is known. Note that for a first-order reaction, the half-life does not depend on concentration. That is, the half-life for a firstorder reaction is constant. We will see this is not the case for second-order and zeroorder reactions.

## INTERACTIVE EXAMPLE 12.4

## Half-Life for a First-Order Reaction

A certain first-order reaction has a half-life of 20.0 minutes.
a. Calculate the rate constant for this reaction.
b. How much time is required for this reaction to be $75 \%$ complete?

SOLUTION a. Solving Equation (12.3) for $k$ gives

$$
k=\frac{0.693}{t_{1 / 2}}=\frac{0.693}{20.0 \mathrm{~min}}=3.47 \times 10^{-2} \mathrm{~min}^{-1}
$$

b. We use the integrated rate law in the form

$$
\ln \left(\frac{[\mathrm{A}]_{0}}{[\mathrm{~A}]}\right)=k t
$$

If the reaction is $75 \%$ complete, $75 \%$ of the reactant has been consumed, leaving $25 \%$ in the original form:

$$
\frac{[\mathrm{A}]}{[\mathrm{A}]_{0}} \times 100 \%=25 \%
$$

This means that

Then

$$
\begin{aligned}
\frac{[\mathrm{A}]}{[\mathrm{A}]_{0}} & =0.25 \text { or } \frac{[\mathrm{A}]_{0}}{[\mathrm{~A}]}=\frac{1}{0.25}=4.0 \\
\ln \left(\frac{[\mathrm{~A}]_{0}}{[\mathrm{~A}]}\right) & =\ln (4.0)=k t=\left(\frac{3.47 \times 10^{-2}}{\min }\right) t \\
t & =\frac{\ln (4.0)}{\frac{3.47 \times 10^{-2}}{\min }}=40 . \mathrm{min}
\end{aligned}
$$

and

■ Thus it takes 40. minutes for this particular reaction to reach $75 \%$ completion.
Let's consider another way of solving this problem using the definition of half-life. After one half-life the reaction has gone $50 \%$ to completion. If the initial concentration were $1.0 \mathrm{~mol} / \mathrm{L}$, after one half-life the concentration would be $0.50 \mathrm{~mol} / \mathrm{L}$. One more half-life would produce a concentration of $0.25 \mathrm{~mol} / \mathrm{L}$. Comparing $0.25 \mathrm{~mol} / \mathrm{L}$ with the original $1.0 \mathrm{~mol} / \mathrm{L}$ shows that $25 \%$ of the reactant is left after two half-lives. This is a general result. (What percentage of reactant remains after three half-lives?) Two halflives for this reaction is $2(20.0 \mathrm{~min})$, or 40.0 min , which agrees with the preceding answer.

## See Exergises 12.40 and 12.51 through 12.54

## Second-Order Rate Laws

For a general reaction involving a single reactant, that is,

$$
\mathrm{aA} \longrightarrow \text { products }
$$

that is second order in A , the rate law is

$$
\begin{equation*}
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]^{2} \tag{12.4}
\end{equation*}
$$

The integrated second-order rate law has the form

$$
\begin{equation*}
\frac{1}{[\mathrm{~A}]}=k t+\frac{1}{[\mathrm{~A}]_{0}} \tag{12.5}
\end{equation*}
$$

Note the following characteristics of Equation (12.5):

1. A plot of $1 /[\mathrm{A}]$ versus $t$ will produce a straight line with a slope equal to $k$.
2. Equation (12.5) shows how [A] depends on time and can be used to calculate [A] at any time $t$, provided $k$ and $[\mathrm{A}]_{0}$ are known.

When one half-life of the second-order reaction has elapsed $\left(t=t_{1 / 2}\right)$, by definition,

$$
[\mathrm{A}]=\frac{[\mathrm{A}]_{0}}{2}
$$

Equation (12.5) then becomes

$$
\begin{aligned}
\frac{1}{\frac{[\mathrm{~A}]_{0}}{2}} & =k t_{1 / 2}+\frac{1}{[\mathrm{~A}]_{0}} \\
\frac{2}{[\mathrm{~A}]_{0}}-\frac{1}{[\mathrm{~A}]_{0}} & =k t_{1 / 2} \\
\frac{1}{[\mathrm{~A}]_{0}} & =k t_{1 / 2}
\end{aligned}
$$

Solving for $t_{1 / 2}$ gives the expression for the half-life of a second-order reaction:

$$
\begin{equation*}
t_{1 / 2}=\frac{1}{k[\mathrm{~A}]_{0}} \tag{12.6}
\end{equation*}
$$

## EXAMPLE 12.5 Determining Rate Laws

Butadiene reacts to form its dimer according to the equation

$$
2 \mathrm{C}_{4} \mathrm{H}_{6}(\mathrm{~g}) \longrightarrow \mathrm{C}_{8} \mathrm{H}_{12}(\mathrm{~g})
$$

The following data were collected for this reaction at a given temperature:

Butadiene $\left(\mathrm{C}_{4} \mathrm{H}_{6}\right)$
$\left[\mathrm{C}_{4} \mathrm{H}_{6}\right](\mathrm{mol} / \mathrm{L}) \quad$ Time $( \pm 1 \mathrm{~s})$

| 0.01000 | 0 |
| ---: | ---: |
| 0.00625 | 1000 |
| 0.00476 | 1800 |
| 0.00370 | 2800 |
| 0.00313 | 3600 |
| 0.00270 | 4400 |
| 0.00241 | 5200 |
| 0.00208 | 6200 |

a. Is this reaction first order or second order?
b. What is the value of the rate constant for the reaction?
c. What is the half-life for the reaction under the initial conditions of this experiment?

## SOLUTION

a. To decide whether the rate law for this reaction is first order or second order, we must see whether the plot of $\ln \left[\mathrm{C}_{4} \mathrm{H}_{6}\right]$ versus time is a straight line (first order) or the plot of $1 /\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]$ versus time is a straight line (second order). The data necessary to make these plots are as follows:

| $\boldsymbol{t}(\mathrm{s})$ | $\frac{1}{\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]}$ | $\ln \left[\mathrm{C}_{4} \mathrm{H}_{6}\right]$ |
| ---: | :---: | :---: |
| 0 | 100 | -4.605 |
| 1000 | 160 | -5.075 |
| 1800 | 210 | -5.348 |
| 2800 | 270 | -5.599 |
| 3600 | 320 | -5.767 |
| 4400 | 370 | -5.915 |
| 5200 | 415 | -6.028 |
| 6200 | 481 | -6.175 |

FIGURE 12.5 (a) A plot of $\operatorname{In}\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]$ versust. (b) A plot of $1 /\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]$ versus $t$.

The resulting plots are shown in Fig. 12.5. Since the $\ln \left[\mathrm{C}_{4} \mathrm{H}_{6}\right]$ versus $t$ plot [Fig. 12.5(a)] is not a straight line, the reaction is not first order.

- The reaction is, however, second order, as shown by the linearity of the $1 /\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]$ versus $t$ plot [Fig. 12.5(b)]. Thus we can now write the rate law for this second-order reaction:

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]}{\Delta t}=k\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]^{2}
$$

b. For a second-order reaction, a plot of $1 /\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]$ versus $t$ produces a straight line of slope $k$. In terms of the standard equation for a straight line, $y=m x+b$, we have $y=1 /\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]$ and $x=t$. Thus the slope of the line can be expressed as follows:

$$
\text { Slope }=\frac{\Delta y}{\Delta x}=\frac{\Delta\left(\frac{1}{\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]}\right)}{\Delta t}
$$

Using the points at $t=0$ and $t=6200$, we can find the rate constant for the reaction:

$$
\square=\text { slope }=\frac{(481-100) \mathrm{L} / \mathrm{mol}}{(6200 .-0) \mathrm{s}}=\frac{381}{6200 .} \mathrm{L} / \mathrm{mol} \cdot \mathrm{~s}=6.14 \times 10^{-2} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{~s}
$$

c. The expression for the half-life of a second-order reaction is

$$
t_{1 / 2}=\frac{1}{k[\mathrm{~A}]_{0}}
$$

In this case $k=6.14 \times 10^{-2} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}\left(\right.$ from part b) and $[\mathrm{A}]_{0}=\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]_{0}=$ $0.01000 M$ (the concentration at $t=0$ ). Thus
$\square t_{1 / 2}=\frac{1}{\left(6.14 \times 10^{-2} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}\right)\left(1.000 \times 10^{-2} \mathrm{~mol} / \mathrm{L}\right)}=1.63 \times 10^{3} \mathrm{~s}$
The initial concentration of $\mathrm{C}_{4} \mathrm{H}_{6}$ is halved in 1630 s .

For a second-order reaction, $t_{1 / 2}$ is dependent on $[A]_{0}$. For a first-order reaction, $t_{1 / 2}$ is independent of $[A]_{0}$.

For each successive half-life, $[A]_{0}$ is halved. Since $t_{1 / 2}=1 / k[\mathrm{~A}]_{0}, t_{1 / 2}$ doubles.

A zero-order reaction has a constant rate.

FIGURE 12.6 A plot of $[A]$ versus $t$ for a zero-order reaction.

It is important to recognize the difference between the half-life for a first-order reaction and the half-life for a second-order reaction. For a second-order reaction, $t_{1 / 2}$ depends on both $k$ and $[\mathrm{A}]_{0}$; for a first-order reaction, $t_{1 / 2}$ depends only on $k$. For a first-order reaction, a constant time is required to reduce the concentration of the reactant by half, and then by half again, and so on, as the reaction proceeds. From Example 12.5 we can see that this is not true for a second-order reaction. For that second-order reaction, we found that the first half-life (the time required to go from $\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]=0.010 \mathrm{M}$ to $\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]=0.0050 \mathrm{M}$ ) is 1630 seconds. We can estimate the second half-life from the concentration data as a function of time. Note that to reach 0.0024 M $\mathrm{C}_{4} \mathrm{H}_{6}$ (approximately $0.0050 / 2$ ) requires 5200 seconds of reaction time. Thus to get from $0.0050 M \mathrm{C}_{4} \mathrm{H}_{6}$ to $0.0024 M \mathrm{C}_{4} \mathrm{H}_{6}$ takes 3570 seconds ( $5200-1630$ ). The second half-life is much longer than the first. This pattern is characteristic of second-order reactions. In fact, for a second-order reaction, each successive halflife is double the preceding one (provided the effects of the reverse reaction can be ignored, as we are assuming here). Prove this to yourself by examining the equation $t_{1 / 2}=1 /\left(k[\mathrm{~A}]_{0}\right)$.

## Zero-Order Rate Laws

Most reactions involving a single reactant show either first-order or second-order kinetics. However, sometimes such a reaction can be a zero-order reaction. The rate law for a zero-order reaction is

$$
\text { Rate }=k[\mathrm{~A}]^{0}=k(1)=k
$$

For a zero-order reaction, the rate is constant. It does not change with concentration as it does for first-order or second-order reactions.

The integrated rate law for a zero-order reaction is

$$
\begin{equation*}
[\mathrm{A}]=-k t+[\mathrm{A}]_{0} \tag{12.7}
\end{equation*}
$$

In this case a plot of [A] versus $t$ gives a straight line of slope $-k$ (Fig. 12.6).
The expression for the half-life of a zero-order reaction can be obtained from the integrated rate law. By definition, $[\mathrm{A}]=[\mathrm{A}]_{0} / 2$ when $t=t_{1 / 2}$, so
or

$$
\frac{[\mathrm{A}]_{0}}{2}=-k t_{1 / 2}+[\mathrm{A}]_{0}
$$

$$
k t_{1 / 2}=\frac{[\mathrm{A}]_{0}}{2}
$$

Solving for $t_{1 / 2}$ gives

$$
\begin{equation*}
t_{1 / 2}=\frac{[\mathrm{A}]_{0}}{2 k} \tag{12.8}
\end{equation*}
$$

Zero-order reactions are most often encountered when a substance such as a metal surface or an enzyme is required for the reaction to occur. For example, the decomposition reaction

$$
2 \mathrm{~N}_{2} \mathrm{O}(g) \longrightarrow 2 \mathrm{~N}_{2}(g)+\mathrm{O}_{2}(g)
$$

occurs on a hot platinum surface. When the platinum surface is completely covered with $\mathrm{N}_{2} \mathrm{O}$ molecules, an increase in the concentration of $\mathrm{N}_{2} \mathrm{O}$ has no effect on the rate, since only those $\mathrm{N}_{2} \mathrm{O}$ molecules on the surface can react. Under these conditions, the rate is a constant because it is controlled by what happens on the platinum surface rather than by the total concentration of $\mathrm{N}_{2} \mathrm{O}$ (Fig. 12.7). This reaction also can occur at high temperatures with no platinum surface present, but under these conditions, it is not zero order.

FIGURE 12.7 The decomposition reaction $2 \mathrm{~N}_{2} \mathrm{O}(\mathrm{g}) \rightarrow 2 \mathrm{~N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})$ takes place on a platinum surface. Although [ $\mathrm{N}_{2} \mathrm{O}$ ] is three times as great in (b) as in (a), the rate of decomposition of $\mathrm{N}_{2} \mathrm{O}$ is the same in both cases because the platinum surface can accommodate only a certain number of molecules. As a result, this reaction is zero order.

## 

 $\mathrm{aA} \rightarrow$ products. You run this reaction and wish to determine its order. What if you made a graph of reaction rate versus time? Could you use this to determine the order? Sketch three plots of rate versus time for the reaction if it is zero, first, or second order. Sketch these plots on the same graph and compare them. Defend your answer.
## Integrated Rate Laws for Reactions with More Than One Reactant

So far we have considered the integrated rate laws for simple reactions with only one reactant. Special techniques are required to deal with more complicated reactions. Let's consider the reaction

$$
\mathrm{BrO}_{3}^{-}(a q)+5 \mathrm{Br}^{-}(a q)+6 \mathrm{H}^{+}(a q) \longrightarrow 3 \mathrm{Br}_{2}(l)+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

From experimental evidence we know that the rate law is

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{BrO}_{3}^{-}\right]}{\Delta t}=k\left[\mathrm{BrO}_{3}^{-}\right]\left[\mathrm{Br}^{-}\right]\left[\mathrm{H}^{+}\right]^{2}
$$

Suppose we run this reaction under conditions where $\left[\mathrm{BrO}_{3}{ }^{-}\right]_{0}=1.0 \times 10^{-3} \mathrm{M}$, $\left[\mathrm{Br}^{-}\right]_{0}=1.0 \mathrm{M}$, and $\left[\mathrm{H}^{+}\right]_{0}=1.0 \mathrm{M}$. As the reaction proceeds, $\left[\mathrm{BrO}_{3}{ }^{-}\right]$decreases significantly, but because the $\mathrm{Br}^{-}$ion and $\mathrm{H}^{+}$ion concentrations are so large initially, relatively little of these two reactants is consumed. Thus $\left[\mathrm{Br}^{-}\right]$and $\left[\mathrm{H}^{+}\right]$remain approximately constant. In other words, under the conditions where the $\mathrm{Br}^{-}$ion and $\mathrm{H}^{+}$ion concentrations are much larger than the $\mathrm{BrO}_{3}{ }^{-}$ion concentration, we can assume that throughout the reaction

$$
\left[\mathrm{Br}^{-}\right]=\left[\mathrm{Br}^{-}\right]_{0} \quad \text { and } \quad\left[\mathrm{H}^{+}\right]=\left[\mathrm{H}^{+}\right]_{0}
$$

This means that the rate law can be written

$$
\text { Rate }=k\left[\mathrm{Br}^{-}\right]_{0}\left[\mathrm{H}^{+}\right]_{0}^{2}\left[\mathrm{BrO}_{3}^{-}\right]=k^{\prime}\left[\mathrm{BrO}_{3}^{-}\right]
$$

where, since $\left[\mathrm{Br}^{-}\right]_{0}$ and $\left[\mathrm{H}^{+}\right]_{0}$ are constant,

$$
k^{\prime}=k\left[\mathrm{Br}^{-}\right]_{0}\left[\mathrm{H}^{+}\right]_{0}^{2}
$$

The rate law

$$
\text { Rate }=k^{\prime}\left[\mathrm{BrO}_{3}^{-}\right]
$$

is first order. However, since this law was obtained by simplifying a more complicated one, it is called a pseudo-first-order rate law. Under the conditions of this experiment, a plot of $\ln \left[\mathrm{BrO}_{3}{ }^{-}\right]$versus $t$ will give a straight line where the slope is equal to $-k^{\prime}$. Since $\left[\mathrm{Br}^{-}\right]_{0}$ and $\left[\mathrm{H}^{+}\right]_{0}$ are known, the value of $k$ can be calculated from the equation

$$
k^{\prime}=k\left[\mathrm{Br}^{-}\right]_{0}\left[\mathrm{H}^{+}\right]_{0}^{2}
$$

which can be rearranged to give

$$
k=\frac{k^{\prime}}{\left[\mathrm{Br}^{-}\right]_{0}\left[\mathrm{H}^{+}\right]_{0}^{2}}
$$

Note that the kinetics of complicated reactions can be studied by observing the behavior of one reactant at a time. If the concentration of one reactant is much smaller than the concentrations of the others, then the amounts of those reactants present in large concentrations will not change significantly and can be regarded as constant. The change in concentration with time of the reactant present in a relatively small amount can then be used to determine the order of the reaction in that component. This technique allows us to determine rate laws for complex reactions.

## LET'S REVIEW Rate Laws: A Summary

1. To simplify the rate laws for reactions, we have always assumed that the rate is being studied under conditions where only the forward reaction is important. This produces rate laws that contain only reactant concentrations.
2. There are two types of rate laws.
a. The differential rate law (often called the rate law) shows how the rate depends on the concentrations. The forms of the rate laws for zero-order, first-order, and second-order kinetics of reactions with single reactants are shown in Table 12.6.
b. The integrated rate law shows how concentration depends on time. The integrated rate laws corresponding to zero-order, first-order, and second-order kinetics of one-reactant reactions are given in Table 12.6.
3. Whether we determine the differential rate law or the integrated rate law depends on the type of data that can be collected conveniently and accurately. Once we have experimentally determined either type of rate law, we can write the other for a given reaction.
4. The most common method for experimentally determining the differential rate law is the method of initial rates. In this method several experiments are run at different initial concentrations and the instantaneous rates are determined for each at the same value of $t$ (as close to $t=0$ as possible). The point is to evaluate the rate before the concentrations change significantly from the initial values. From a comparison of the initial rates and the initial concentrations, the dependence of the rate on the concentrations of various reactants can be obtained-that is, the order in each reactant can be determined.
5. To experimentally determine the integrated rate law for a reaction, concentrations are measured at various values of $t$ as the reaction proceeds. Then the job is to see which integrated rate law correctly fits the data. Typically this is done visually by ascertaining which type of plot gives a straight line. A summary for one-reactant reactions is given in Table 12.6. Once the correct straight-line plot is found, the correct integrated rate law can be chosen and the value of $k$ obtained from the slope. Also, the differential rate law for the reaction can then be written.
6. The integrated rate law for a reaction that involves several reactants can be treated by choosing conditions such that the concentration of only one reactant varies in a given experiment. This is done by having the concentration of one reactant remain small compared with the concentrations of all the others, causing a rate law such as

$$
\text { Rate }=k[\mathrm{~A}]^{n}[\mathrm{~B}]^{m}[\mathrm{C}]^{p}
$$

## LET'S REVIEW Rate Laws: A Summary (continued)

to reduce to

$$
\text { Rate }=k^{\prime}[\mathrm{A}]^{n}
$$

where $k^{\prime}=k[\mathrm{~B}]_{0}{ }^{m}[\mathrm{C}]_{0}{ }^{p}$ and $[\mathrm{B}]_{0} \geqslant[\mathrm{~A}]_{0}$ and $[\mathrm{C}]_{0} \geqslant[\mathrm{~A}]_{0}$. The value of $n$ is obtained by determining whether a plot of $[A]$ versus $t$ is linear $(n=0)$, a plot of $\ln [A]$ versus $t$ is linear $(n=1)$, or a plot of $1 /[A]$ versus $t$ is linear $(n=2)$. The value of $k^{\prime}$ is determined from the slope of the appropriate plot. The values of $m, p$, and $k$ can be found by determining the value of $k^{\prime}$ at several different concentrations of $B$ and $C$.

### 12.5 Reaction Mechanisms

A balanced equation does not tell us how the reactants become products.

An intermediate is formed in one step and used up in a subsequent step and so is never seen as a product.

Most chemical reactions occur by a series of steps called the reaction mechanism. To understand a reaction, we must know its mechanism, and one of the main purposes for studying kinetics is to learn as much as possible about the steps involved in a reaction. In this section we explore some of the fundamental characteristics of reaction mechanisms.

Consider the reaction between nitrogen dioxide and carbon monoxide:

$$
\mathrm{NO}_{2}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g)
$$

The rate law for this reaction is known from experiment to be

$$
\text { Rate }=k\left[\mathrm{NO}_{2}\right]^{2}
$$

As we will see, this reaction is more complicated than it appears from the balanced equation. This is quite typical; the balanced equation for a reaction tells us the reactants, the products, and the stoichiometry but gives no direct information about the reaction mechanism.

For the reaction between nitrogen dioxide and carbon monoxide, the mechanism is thought to involve the following steps:

$$
\begin{gathered}
\mathrm{NO}_{2}(g)+\mathrm{NO}_{2}(g) \xrightarrow{k_{1}} \mathrm{NO}_{3}(g)+\mathrm{NO}(g) \\
\mathrm{NO}_{3}(g)+\mathrm{CO}(g) \xrightarrow{k_{2}} \mathrm{NO}_{2}(g)+\mathrm{CO}_{2}(g)
\end{gathered}
$$

where $k_{1}$ and $k_{2}$ are the rate constants of the individual reactions. In this mechanism, gaseous $\mathrm{NO}_{3}$ is an intermediate, a species that is neither a reactant nor a product but that is formed and consumed during the reaction sequence. This reaction is illustrated in Fig. 12.8.

FIGURE 12.8 A molecular representation of the elementary steps in the reaction of $\mathrm{NO}_{2}$ and CO .

The prefix uni- means one, bi-means two, and ter- means three.
A unimolecular elementary step is always first order, a bimolecular step is always second order, and so on.

A reaction is only as fast as its slowest step.

Step 1

Step 2

Each of these two reactions is called an elementary step, a reaction whose rate law can be written from its molecularity. Molecularity is defined as the number of species that must collide to produce the reaction indicated by that step. A reaction involving one molecule is called a unimolecular step. Reactions involving the collision of two and three species are termed bimolecular and termolecular, respectively. Termolecular steps are quite rare, because the probability of three molecules colliding simultaneously is very small. Examples of these three types of elementary steps and the corresponding rate laws are shown in Table 12.7. Note from Table 12.7 that the rate law for an elementary step follows directly from the molecularity of that step. For example, for a bimolecular step the rate law is always second order, either of the form $k[A]^{2}$ for a step with a single reactant or of the form $k[\mathrm{~A}][\mathrm{B}]$ for a step involving two reactants.

We can now define a reaction mechanism more precisely. It is a series of elementary steps that must satisfy two requirements:

1. The sum of the elementary steps must give the overall balanced equation for the reaction.
2. The mechanism must agree with the experimentally determined rate law.

To see how these requirements are applied, we will consider the mechanism given above for the reaction of nitrogen dioxide and carbon monoxide. First, note that the sum of the two steps gives the overall balanced equation:

$$
\begin{aligned}
\mathrm{NO}_{2}(g)+\mathrm{NO}_{2}(g) & \longrightarrow \mathrm{NO}_{3}(g)+\mathrm{NO}(g) \\
\mathrm{NO}_{3}(g)+\mathrm{CO}(g) & \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{CO}_{2}(g) \\
\hline \mathrm{NO}_{2}(g)+\mathrm{NO}_{2}(g)+\mathrm{NO}_{3}(g)+\mathrm{CO}(g) & \longrightarrow \mathrm{NO}_{3}(g)+\mathrm{NO}(g)+\mathrm{NO}_{2}(g)+\mathrm{CO}_{2}(g) \\
\text { Overallr eaction: } \quad \mathrm{NO}_{2}(g)+\mathrm{CO}(g) & \longrightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g)
\end{aligned}
$$

The first requirement for a correct mechanism is met. To see whether the mechanism meets the second requirement, we need to introduce a new idea: the rate-determining step. Multistep reactions often have one step that is much slower than all the others. Reactants can become products only as fast as they can get through this slowest step. That is, the overall reaction can be no faster than the slowest, or rate-determining, step

## TABLE 12.7 | Examples of Elementary Steps

| Elementary Step | Molecularity | Rate Law |
| ---: | :--- | :--- |
| $\mathrm{A} \rightarrow$ products | Unimolecular | Rate $=k[\mathrm{~A}]$ |
| $\mathrm{A}+\mathrm{A} \rightarrow$ products <br> $(2 \mathrm{~A} \rightarrow$ products $)$ | Bimolecular | Rate $=k[\mathrm{~A}]^{2}$ |
| $\mathrm{~A}+\mathrm{B} \rightarrow$ products | Bimolecular | Rate $=k[\mathrm{~A}][\mathrm{B}]$ |
| $\mathrm{A}+\mathrm{A}+\mathrm{B} \rightarrow$ products <br> $(2 \mathrm{~A}+\mathrm{B} \rightarrow$ products $)$ | Termolecular | Rate $=k[\mathrm{~A}]^{2}[\mathrm{~B}]$ |
| $\mathrm{A}+\mathrm{B}+\mathrm{C} \rightarrow$ products | Termolecular | Rate $=k[\mathrm{~A}][\mathrm{B}][\mathrm{C}]$ |

$\Delta$
The rate at which this colored solution enters the flask is determined by the size of the funnel stem, not how fast the solution is poured.
in the sequence. An analogy for this situation is the pouring of water rapidly into a container through a funnel. The water collects in the container at a rate that is essentially determined by the size of the funnel opening and not by the rate of pouring.

Which is the rate-determining step in the reaction of nitrogen dioxide and carbon monoxide? Let's assume that the first step is rate-determining and the second step is relatively fast:

$$
\begin{aligned}
\mathrm{NO}_{2}(g)+\mathrm{NO}_{2}(g) & \longrightarrow \mathrm{NO}_{3}(g)+\mathrm{NO}(g) \\
\mathrm{NO}_{3}(g)+\mathrm{CO}(g) & \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{CO}_{2}(g)
\end{aligned} \quad \text { Slow (rate-determining) }
$$

What we have really assumed here is that the formation of $\mathrm{NO}_{3}$ occurs much more slowly than its reaction with CO . The rate of $\mathrm{CO}_{2}$ production is then controlled by the rate of formation of $\mathrm{NO}_{3}$ in the first step. Since this is an elementary step, we can write the rate law from the molecularity. The bimolecular first step has the rate law

$$
\text { Rate of formation of } \mathrm{NO}_{3}=\frac{\Delta\left[\mathrm{NO}_{3}\right]}{\Delta t}=k_{1}\left[\mathrm{NO}_{2}\right]^{2}
$$

Since the overall reaction rate can be no faster than the slowest step,

$$
\text { Overall rate }=k_{1}\left[\mathrm{NO}_{2}\right]^{2}
$$

Note that this rate law agrees with the experimentally determined rate law given earlier. The mechanism we assumed above satisfies the two requirements stated earlier and may be the correct mechanism for the reaction.

How does a chemist deduce the mechanism for a given reaction? The rate law is always determined first. Then, using chemical intuition and following the two rules given on the previous page, the chemist constructs possible mechanisms and tries, with further experiments, to eliminate those that are least likely. A mechanism can never be proved absolutely. We can say only that a mechanism that satisfies the two requirements is possibly correct. Deducing mechanisms for chemical reactions can be difficult and requires skill and experience. We will only touch on this process in this text.

## EXAMPLE 12.6 <br> Reaction Mechanisms

The balanced equation for the reaction of the gases nitrogen dioxide and fluorine is

$$
2 \mathrm{NO}_{2}(g)+\mathrm{F}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2} \mathrm{~F}(g)
$$

The experimentally determined rate law is

$$
\text { Rate }=k\left[\mathrm{NO}_{2}\right]\left[\mathrm{F}_{2}\right]
$$

A suggested mechanism for this reaction is

$$
\begin{aligned}
& \mathrm{NO}_{2}+\mathrm{F}_{2} \xrightarrow{k_{1}} \mathrm{NO}_{2} \mathrm{~F}+\mathrm{F} \\
& \mathrm{~F}+\mathrm{NO}_{2} \xrightarrow{k_{2}} \mathrm{NO}_{2} \mathrm{~F}
\end{aligned}
$$

Is this an acceptable mechanism? That is, does it satisfy the two requirements?
SOLUTION The first requirement for an acceptable mechanism is that the sum of the steps should give the balanced equation:

$$
\begin{aligned}
& \mathrm{NO}_{2}+\mathrm{F}_{2} \longrightarrow \mathrm{NO}_{2} \mathrm{~F}+\mathrm{F} \\
& \frac{\mathrm{~F}+\mathrm{NO}_{2}}{} \longrightarrow \mathrm{NO}_{2} \mathrm{~F} \\
& \hline 2 \mathrm{NO}_{2}+\mathrm{F}_{2}+\mathrm{F} \longrightarrow 2 \mathrm{NO}_{2} \mathrm{~F}+\mathrm{F} \\
& \text { Overallr eaction: } \quad 2 \mathrm{NO}_{2}+\mathrm{F}_{2} \longrightarrow 2 \mathrm{NO}_{2} \mathrm{~F}
\end{aligned}
$$

The first requirement is met.

The second requirement is that the mechanism must agree with the experimentally determined rate law. Since the proposed mechanism states that the first step is ratedetermining, the overall reaction rate must be that of the first step. The first step is bimolecular, so the rate law is

$$
\text { Rate }=k_{1}\left[\mathrm{NO}_{2}\right]\left[\mathrm{F}_{2}\right]
$$

This has the same form as the experimentally determined rate law. The proposed mechanism is acceptable because it satisfies both requirements. (Note that we have not proved that it is the correct mechanism.)

## See Exercises 12.63 and 12.64

Although the mechanism given in Example 12.6 has the correct stoichiometry and fits the observed rate law, other mechanisms may also satisfy these requirements. For example, the mechanism might be

$$
\begin{aligned}
& \mathrm{NO}_{2}+\mathrm{F}_{2} \longrightarrow \mathrm{NOF}_{2}+\mathrm{O} \\
& \mathrm{NO}_{2}+\mathrm{O} \longrightarrow \mathrm{NO}_{3} \\
& \mathrm{NOF}_{2}+\mathrm{NO}_{2} \longrightarrow \mathrm{NO}_{2} \mathrm{~F}+\mathrm{NOF} \\
& \mathrm{NO}_{3}+\mathrm{NOF} \text { Flow } \\
& \mathrm{NO}_{2} \mathrm{~F}+\mathrm{NO}_{2}
\end{aligned}
$$

To decide on the most probable mechanism for the reaction, the chemist doing the study would have to perform additional experiments.

## Mechanisms with Fast Forward and Reverse First Steps

A common type of reaction mechanism is one involving a first step in which both the forward and reverse reactions are very fast compared with the reactions in the second step. An example of this type of mechanism is that for the decomposition of ozone to oxygen. The balanced reaction is

$$
2 \mathrm{O}_{3}(\mathrm{~g}) \rightarrow 3 \mathrm{O}_{2}(\mathrm{~g})
$$

The observed rate law is

$$
\text { Rate }=k \frac{\left[\mathrm{O}_{3}\right]^{2}}{\left[\mathrm{O}_{2}\right]}
$$

Note that this rate law is unusual in that it contains the concentration of a product. The mechanism proposed for this process is

$$
\begin{aligned}
\mathrm{O}_{3} \xrightarrow[k_{1}]{k_{1}} & \mathrm{O}_{2}+\mathrm{O} \\
\mathrm{O}+\mathrm{O}_{3} \xrightarrow{k_{2}} & 2 \mathrm{O}_{2}
\end{aligned}
$$

The double arrows in the first step indicate that both the forward and reverse reactions are important. They have the rate constants $k_{1}$ and $k_{-1}$, respectively.

For this mechanism we will assume that both the forward and reverse reactions of the first step are very fast compared with the reaction in the second step. This means that the second step is rate determining. Therefore, the rate for the overall reaction is equal to the rate of the second step:

$$
\text { Rate }=k_{2}[\mathrm{O}]\left[\mathrm{O}_{3}\right]
$$

This rate law does not have the same form as the experimentally determined rate law. For one thing, it contains the concentration of the intermediate, an oxygen atom. We can remove [ O ] and obtain a rate law that agrees with the experiment results by making an additional assumption. We assume that the rates of the forward and reverse reactions in the first step are equal. That is, we assume that the initial reversible fast step is at equilibrium (We will discuss the concept of chemical equilibrium in more detail in Chapter 13.). This makes sense because the rates of both the forward and reverse reactions for the first step are so much faster than the rate of the second step. For the first step,

$$
\text { Rate of forward reaction }=k_{1}\left[\mathrm{O}_{3}\right]
$$

and

$$
\text { Rate of reverse reaction }=k_{-1}\left[\mathrm{O}_{2}\right][\mathrm{O}]
$$

Because the rates of the forward and reverse reactions in the first step are equal we have

$$
k_{1}\left[\mathrm{O}_{3}\right]=k_{-1}\left[\mathrm{O}_{2}\right][\mathrm{O}]
$$

We solve for [O]:

$$
[\mathrm{O}]=\frac{k_{1}\left[\mathrm{O}_{3}\right]}{k_{-1}\left[\mathrm{O}_{2}\right]}
$$

Now we substitute the expression for [O] into the rate law for the second step:

$$
\begin{aligned}
\text { Rate } & =k_{2}\left[\mathrm{O}_{2}\right]\left[\mathrm{O}_{3}\right]=k_{2}\left(\frac{k_{1}\left[\mathrm{O}_{3}\right]}{k_{-1}\left[\mathrm{O}_{2}\right]}\right)\left[\mathrm{O}_{3}\right]=\frac{k_{2} k_{1}\left[\mathrm{O}_{3}\right]^{2}}{k_{-1}\left[\mathrm{O}_{2}\right]} \\
& =k \frac{\left[\mathrm{O}_{3}\right]^{2}}{\left[\mathrm{O}_{2}\right]}
\end{aligned}
$$

where $k$ is a composite constant representing $k_{2} k_{1} / k_{-1}$.
This rate law, derived by postulating the two elementary steps and making assumptions about the relative rates of these steps, agrees with the experimental rate law. Since this mechanism (the elementary steps plus the assumptions) also gives the correct overall stoichiometry, it is an acceptable mechanism for the decomposition of ozone to oxygen.

## EXAMPLE 12.1 Reaction Mechanisms II

The gas-phase reaction of chlorine with chloroform is described by the equation

$$
\mathrm{Cl}_{2}(g)+\mathrm{CHCl}_{3}(g) \longrightarrow \mathrm{HCl}(g)+\mathrm{CCl}_{4}(g)
$$

The rate law determined from experiment has a noninteger order:

$$
\text { Rate }=k\left[\mathrm{Cl}_{2}\right]^{1 / 2}\left[\mathrm{CHCl}_{3}\right]
$$

A proposed mechanism for this reaction follows:

$$
\begin{array}{cl}
\mathrm{Cl}_{2}(g) \stackrel{k_{1}}{\rightleftharpoons} 2 \mathrm{Cl}(g) & \begin{array}{c}
\text { Both fast with equal rates } \\
\text { (fast equilibrium) }
\end{array} \\
\mathrm{Cl}(g)+\mathrm{CHCl}_{3}(g) \xrightarrow{k_{-1}} \mathrm{HCl}(g)+\mathrm{CCl}_{3}(g) & \text { Slow } \\
\mathrm{CCl}_{3}(g)+\mathrm{Cl}(g) \xrightarrow{k_{3}} \mathrm{CCl}_{4}(g) & \text { Fast }
\end{array}
$$

Is this an acceptable mechanism for the reaction?

## SOLUTION

Two questions must be answered. First, does the mechanism give the correct overall stoichiometry? Adding the three steps does yield the correct balanced equation:

$$
\begin{aligned}
\mathrm{Cl}_{2}(g) & \rightleftharpoons 2 \mathrm{Cl}(g) \\
\mathrm{Cl}^{(g)}+\mathrm{CHCl}_{3}(g) & \longrightarrow \mathrm{HCl}(g)+\mathrm{CCl}_{3}(g) \\
\mathrm{CCl}_{3}(g)+\mathrm{Cl}(g) & \longrightarrow \mathrm{CCl}_{4}(g) \\
\hline \mathrm{Cl}_{2}(g)+\mathrm{Cl}(g)+\mathrm{CHCl}_{3}(g)+\mathrm{CC}_{3}(g)+\mathrm{Cl}(g) & \longrightarrow 2 \mathrm{Cl}(g)+\mathrm{HCl}^{(g)}+\mathrm{CCl}_{3}(g)+\mathrm{CCl}_{4}(g) \\
\text { Overallr eaction: } \quad \mathrm{Cl}_{2}(g)+\mathrm{CHCl}_{3}(g) & \longrightarrow \mathrm{HCl}(g)+\mathrm{CCl}_{4}(g)
\end{aligned}
$$

Second, does the mechanism agree with the observed rate law? Since the overall reaction rate is determined by the rate of the slowest step,

$$
\text { Overall rate }=\text { rate of second step }=k_{2}[\mathrm{C} 1]\left[\mathrm{CHCl}_{3}\right]
$$

Since the chlorine atom is an intermediate, we must find a way to eliminate [ Cl$]$ in the rate law. This can be done by recognizing that since the first step is at equilibrium, its forward and reverse rates are equal:

$$
k_{1}\left[\mathrm{Cl}_{2}\right]=k_{-1}[\mathrm{Cl}]^{2}
$$

Solving for $[\mathrm{Cl}]^{2}$ gives

$$
[\mathrm{Cl}]^{2}=\frac{k_{1}\left[\mathrm{Cl}_{2}\right]}{k_{-1}}
$$

Taking the square root of both sides yields

$$
[\mathrm{Cl}]=\left(\frac{k_{1}}{k_{-1}}\right)^{1 / 2}\left[\mathrm{Cl}_{2}\right]^{1 / 2}
$$

and

$$
\begin{aligned}
& \text { Rate }=k_{2}[\mathrm{Cl}]\left[\mathrm{CHCl}_{3}\right]=k_{2}\left(\frac{k_{1}}{k_{-1}}\right)^{1 / 2}\left[\mathrm{Cl}_{2}\right]^{1 / 2}\left[\mathrm{CHCl}_{3}\right]=k\left[\mathrm{Cl}_{2}\right]^{1 / 2}\left[\mathrm{CHCl}_{3}\right] \\
& \mathrm{e} \\
& k=k_{2}\left(\frac{k_{1}}{k_{-1}}\right)^{1 / 2}
\end{aligned}
$$

where
The rate law derived from the mechanism agrees with the experimentally observed rate law. This mechanism satisfies the two requirements and thus is an acceptable mechanism.

## See Exercises 12.65 and 12.66

### 12.6 A Model for Chemical Kinetics

How do chemical reactions occur? We already have given some indications. For example, we have seen that the rates of chemical reactions depend on the concentrations of the reacting species. The initial rate for the reaction

$$
\mathrm{aA}+\mathrm{bB} \longrightarrow \text { products }
$$

can be described by the rate law

$$
\text { Rate }=k[\mathrm{~A}]^{n}[\mathrm{~B}]^{m}
$$

where the order of each reactant depends on the detailed reaction mechanism. This explains why reaction rates depend on concentration. But what about some of the other factors affecting reaction rates? For example, how does temperature affect the speed of a reaction?

We can answer this question qualitatively from our experience. We have refrigerators because food spoilage is retarded at low temperatures. The combustion of wood

$T(\mathbf{K})$
FIGURE 12.9 A plot showing the exponential dependence of the rate constant on absolute temperature. The exact temperature dependence of $k$ is different for each reaction. This plot represents the behavior of a rate constant that doubles for every increase in temperature of 10 K .
occurs at a measurable rate only at high temperatures. An egg cooks in boiling water much faster at sea level than in Leadville, Colorado (elevation $10,000 \mathrm{ft}$ ), where the boiling point of water is approximately $90^{\circ} \mathrm{C}$. These observations and others lead us to conclude that chemical reactions speed up when the temperature is increased. Experiments have shown that virtually all rate constants show an exponential increase with absolute temperature, as represented in Fig. 12.9.

In this section we discuss a model used to account for the observed characteristics of reaction rates. This model, called the collision model, is built around the central idea that molecules must collide to react. We have already seen how this assumption explains the concentration dependence of reaction rates. Now we need to consider whether this model can account for the observed temperature dependence of reaction rates.

The kinetic molecular theory of gases predicts that an increase in temperature raises molecular velocities and so increases the frequency of collisions between molecules. This idea agrees with the observation that reaction rates are greater at higher temperatures. Thus there is qualitative agreement between the collision model and experimental observations. However, it is found that the rate of reaction is much smaller than the calculated collision frequency in a collection of gas particles. This must mean that only a small fraction of the collisions produces a reaction. Why?

This question was first addressed in the 1880s by Svante Arrhenius. He proposed the existence of a threshold energy, called the activation energy, that must be overcome to produce a chemical reaction. Such a proposal makes sense, as we can see by considering the decomposition of BrNO in the gas phase:

$$
2 \mathrm{BrNO}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g)
$$

In this reaction two $\mathrm{Br}-\mathrm{N}$ bonds must be broken and one $\mathrm{Br}-\mathrm{Br}$ bond must be formed. Breaking a $\mathrm{Br}-\mathrm{N}$ bond requires considerable energy ( $243 \mathrm{~kJ} / \mathrm{mol}$ ), which must come from somewhere. The collision model postulates that the energy comes from the kinetic energies possessed by the reacting molecules before the collision. This kinetic energy is changed into potential energy as the molecules are distorted during a collision to break bonds and rearrange the atoms into the product molecules.

We can envision the reaction progress as shown in Fig. 12.10. The arrangement of atoms found at the top of the potential energy "hill," or barrier, is called the activated complex, or transition state. The conversion of BrNO to NO and $\mathrm{Br}_{2}$ is exothermic,

FIGURE 12.10 (a) The change in potential energy as a function of reaction progress for the reaction $2 \mathrm{BrNO} \rightarrow 2 \mathrm{NO}+\mathrm{Br}_{2}$. The activation energy $E_{\mathrm{a}}$ represents the energy needed to disrupt the BrNO molecules so that they can form products. The quantity $\Delta E$ represents the net change in energy in going from reactant to products. (b) A molecular representation of the reaction.

The higher the activation energy, the slower the reaction at a given temperature.

FIGURE 12.11 Plot showing the number of collisions with a particular energy at $T_{1}$ and $T_{2}$, where $T_{2}>T_{1}$.

A
A snowy tree cricket. The frequency of a cricket's chirps depends on the temperature of the cricket.
as indicated by the fact that the products have lower potential energy than the reactant. However, $\Delta E$ has no effect on the rate of the reaction. Rather, the rate depends on the size of the activation energy $E_{\mathrm{a}}$.

The main point here is that a certain minimum energy is required for two BrNO molecules to "get over the hill" so that products can form. This energy is furnished by the energy of the collision. A collision between two BrNO molecules with small kinetic energies will not have enough energy to get over the barrier. At a given temperature only a certain fraction of the collisions possesses enough energy to be effective (to result in product formation).

We can be more precise by recalling from Chapter 5 that a distribution of velocities exists in a sample of gas molecules. Therefore, a distribution of collision energies also exists, as shown in Fig. 12.11 for two different temperatures. Figure 12.11 also shows the activation energy for the reaction in question. Only collisions with energy greater than the activation energy are able to react (get over the barrier). At the lower temperature, $T_{1}$, the fraction of effective collisions is quite small. However, as the temperature is increased to $T_{2}$, the fraction of collisions with the required activation energy increases dramatically. When the temperature is doubled, the fraction of effective collisions much more than doubles. In fact, the fraction of effective collisions increases exponentially with temperature. This is encouraging for our theory; remember that rates of reactions are observed to increase exponentially with temperature. Arrhenius postulated that the number of collisions having an energy greater than or equal to the activation energy is given by the expression:
Number of collisions with the activation energy $=($ total number of collisions $) e^{-E_{2} / R T}$
where $E_{\mathrm{a}}$ is the activation energy, $R$ is the universal gas constant, and $T$ is the Kelvin temperature. The factor $e^{-E_{\mathrm{a}} / R T}$ represents the fraction of collisions with energy $E_{\mathrm{a}}$ or greater at temperature $T$.

We have seen that not all molecular collisions are effective in producing chemical reactions because a minimum energy is required for the reaction to occur. There is, however, another complication. Experiments show that the observed reaction rate is considerably smaller than the rate of collisions with enough energy to surmount the barrier. This means that many collisions, even though they have the required energy, still do not produce a reaction. Why not?

The answer lies in the molecular orientations during collisions. We can illustrate this using the reaction between two BrNO molecules (Fig. 12.12). Some collision orientations can lead to reaction, and others cannot. Therefore, we must include a correction factor to allow for collisions with nonproductive molecular orientations.

To summarize, two requirements must be satisfied for reactants to collide successfully (to rearrange to form products):

1. The collision must involve enough energy to produce the reaction; that is, the collision energy must equal or exceed the activation energy.
2. The relative orientation of the reactants must allow formation of any new bonds necessary to produce products.

Taking these factors into account, we can represent the rate constant as

$$
k=z p e^{-E_{\mathrm{a}} / R T}
$$

where $z$ is the collision frequency, $p$ is called the steric factor (always less than 1 ) and reflects the fraction of collisions with effective orientations, and $e^{-E_{\mathrm{a}} / R T}$ represents the fraction of collisions with sufficient energy to produce a reaction. This expression is most often written in form

$$
\begin{equation*}
k=A e^{-E_{\mathrm{a}} / R T} \tag{12.9}
\end{equation*}
$$

which is called the Arrhenius equation. In this equation, $A$ replaces $z p$ and is called the frequency factor for the reaction.

FIGURE 12.12 Several possible orientations for a collision between two BrNO molecules. Orientations (a) and (b) can lead to a reaction, but orientation (c) cannot.

Taking the natural logarithm of each side of the Arrhenius equation gives

$$
\begin{equation*}
\ln (k)=-\frac{E_{\mathrm{a}}}{R}\left(\frac{1}{T}\right)+\ln (A) \tag{12.10}
\end{equation*}
$$

Equation (12.10) is a linear equation of the type $y=m x+b$, where $y=\ln (k)$, $m=-E_{\mathrm{a}} / R=$ slope, $x=1 / T$, and $b=\ln (A)=$ intercept. Thus for a reaction where the rate constant obeys the Arrhenius equation, a plot of $\ln (k)$ versus $1 / T$ gives a straight line. The slope and intercept can be used to determine, respectively, the values of $E_{\mathrm{a}}$ and $A$ characteristic of that reaction. The fact that most rate constants obey the Arrhenius equation to a good approximation indicates that the collision model for chemical reactions is physically reasonable.
 be met to result in a chemical reaction between molecules. What if all collisions between molecules resulted in a chemical reaction? How would life be different?

## EXAMPLE 12.8 Determining Activation Energy I

The reaction

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

was studied at several temperatures, and the following values of $k$ were obtained:

| $k\left(\mathrm{~s}^{-1}\right)$ | $\boldsymbol{T}\left({ }^{\circ} \mathrm{C}\right)$ |
| :---: | :---: |
| $2.0 \times 10^{-5}$ | 20 |
| $7.3 \times 10^{-5}$ | 30 |
| $2.7 \times 10^{-4}$ | 40 |
| $9.1 \times 10^{-4}$ | 50 |
| $2.9 \times 10^{-3}$ | 60 |

Calculate the value of $E_{\mathrm{a}}$ for this reaction.

SOLUTION To obtain the value of $E_{\mathrm{a}}$, we need to construct a plot of $\ln (k)$ versus $1 / T$. First, we must calculate values of $\ln (k)$ and $1 / T$, as shown below:

| $\boldsymbol{T}\left({ }^{\circ} \mathbf{C}\right)$ | $\boldsymbol{T}(\mathbf{K})$ | $\mathbf{1 / T}\left(\mathbf{K}^{-1}\right)$ | $\boldsymbol{k}\left(\mathrm{s}^{-1}\right)$ | $\ln (\mathrm{k})$ |
| :---: | :---: | :---: | :---: | ---: |
| 20 | 293 | $3.41 \times 10^{-3}$ | $2.0 \times 10^{-5}$ | -10.82 |
| 30 | 303 | $3.30 \times 10^{-3}$ | $7.3 \times 10^{-5}$ | -9.53 |
| 40 | 313 | $3.19 \times 10^{-3}$ | $2.7 \times 10^{-4}$ | -8.22 |
| 50 | 323 | $3.10 \times 10^{-3}$ | $9.1 \times 10^{-4}$ | -7.00 |
| 60 | 333 | $3.00 \times 10^{-3}$ | $2.9 \times 10^{-3}$ | -5.84 |

The plot of $\ln (k)$ versus $1 / T$ is shown above, where the slope

$$
\frac{\Delta \ln (k)}{\Delta\left(\frac{1}{T}\right)}
$$

is found to be $-1.2 \times 10^{4} \mathrm{~K}$. The value of $E_{\mathrm{a}}$ can be determined by solving the following equation:

$$
\begin{aligned}
\text { Slope } & =-\frac{E_{\mathrm{a}}}{R} \\
\square E_{\mathrm{a}} & =-R(\text { slope })=-(8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})\left(-1.2 \times 10^{4} \mathrm{~K}\right) \\
& =1.0 \times 10^{5} \mathrm{~J} / \mathrm{mol}
\end{aligned}
$$

Thus the value of the activation energy for this reaction is $1.0 \times 10^{5} \mathrm{~J} / \mathrm{mol}$.
