The most common procedure for finding $E_{\mathrm{a}}$ for a reaction involves measuring the rate constant $k$ at several temperatures and then plotting $\ln (k)$ versus $1 / T$, as shown in Example 12.8. However, $E_{\mathrm{a}}$ also can be calculated from the values of $k$ at only two temperatures by using a formula that can be derived as follows from Equation (12.10).

At temperature $T_{1}$, where the rate constant is $k_{1}$,

$$
\ln \left(k_{1}\right)=-\frac{E_{\mathrm{a}}}{R T_{1}}+\ln (A)
$$

At temperature $T_{2}$, where the rate constant is $k_{2}$,

$$
\ln \left(k_{2}\right)=-\frac{E_{\mathrm{a}}}{R T_{2}}+\ln (A)
$$

Subtracting the first equation from the second gives

And

$$
\begin{align*}
\ln \left(k_{2}\right)-\ln \left(k_{1}\right) & =\left[-\frac{E_{\mathrm{a}}}{R T_{2}}+\ln (A)\right]-\left[-\frac{E_{\mathrm{a}}}{R T_{1}}+\ln (A)\right] \\
& =-\frac{E_{\mathrm{a}}}{R T_{2}}+\frac{E_{\mathrm{a}}}{R T_{1}} \\
\ln \left(\frac{k_{2}}{k_{1}}\right) & =\frac{E_{\mathrm{a}}}{R}\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right) \tag{12.11}
\end{align*}
$$

Therefore, the values of $k_{1}$ and $k_{2}$ measured at temperatures $T_{1}$ and $T_{2}$ can be used to calculate $E_{\mathrm{a}}$, as shown in Example 12.9.

> Most modern refrigerators have an internal temperature of $45^{\circ} \mathrm{F}$. What if refrigerators were set at $55^{\circ} \mathrm{F}$ in the factory? How would this affect our lives?

## INTERACTIVE EXAMPLE 12.9 Determining Activation Energy II

The gas-phase reaction between methane and diatomic sulfur is given by the equation

$$
\mathrm{CH}_{4}(g)+2 \mathrm{~S}_{2}(g) \longrightarrow \mathrm{CS}_{2}(g)+2 \mathrm{H}_{2} \mathrm{~S}(g)
$$

At $550^{\circ} \mathrm{C}$ the rate constant for this reaction is $1.1 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$, and at $625^{\circ} \mathrm{C}$ the rate constant is $6.4 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$. Using these values, calculate $E_{\mathrm{a}}$ for this reaction.
SOLUTION The relevant data are shown in the following table:

| $\boldsymbol{k}$ <br> $(\mathrm{L} / \mathrm{mol} \cdot \mathrm{s})$ | $\boldsymbol{T}$ <br> $\left({ }^{\circ} \mathrm{C}\right)$ | $\boldsymbol{T}$ |
| :---: | :---: | :---: |
| $(\mathrm{K})$ |  |  |
| $1.1=k_{1}$ | 550 | $823=T_{1}$ |
| $6.4=k_{2}$ | 625 | $898=T_{2}$ |

Substituting these values into Equation (12.11) gives

$$
\ln \left(\frac{6.4}{1.1}\right)=\frac{E_{\mathrm{a}}}{8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}}\left(\frac{1}{823 \mathrm{~K}}-\frac{1}{898 \mathrm{~K}}\right)
$$

Solving for $E_{\mathrm{a}}$ gives

$$
\begin{aligned}
E_{\mathrm{a}} & =\frac{(8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}) \ln \left(\frac{6.4}{1.1}\right)}{\left(\frac{1}{823 \mathrm{~K}}-\frac{1}{898 \mathrm{~K}}\right)} \\
& =1.4 \times 10^{5} \mathrm{~J} / \mathrm{mol}
\end{aligned}
$$

### 12.7 Catalysis

We have seen that the rate of a reaction increases dramatically with temperature. If a particular reaction does not occur fast enough at normal temperatures, we can speed it up by raising the temperature. However, sometimes this is not feasible. For example, living cells can survive only in a rather narrow temperature range, and the human body is designed to operate at an almost constant temperature of $98.6^{\circ} \mathrm{F}$. But many of the complicated biochemical reactions keeping us alive would be much too slow at this temperature without intervention. We exist only because the body contains many substances called enzymes, which increase the rates of these reactions. In fact, almost every biologically important reaction is assisted by a specific enzyme.

Although it is possible to use higher temperatures to speed up commercially important reactions, such as the Haber process for synthesizing ammonia, this is very expensive. In a chemical plant an increase in temperature means significantly increased costs for energy. The use of an appropriate catalyst allows a reaction to proceed rapidly at a relatively low temperature and can therefore hold down production costs.

A catalyst is a substance that speeds up a reaction without being consumed itself. Just as virtually all vital biologic reactions are assisted by enzymes (biologic catalysts), almost all industrial processes also involve the use of catalysts. For example, the production of sulfuric acid uses vanadium $(\mathrm{V})$ oxide, and the Haber process uses a mixture of iron and iron oxide.

How does a catalyst work? Remember that for each reaction a certain energy barrier must be surmounted. How can we make a reaction occur faster without raising the temperature to increase the molecular energies? The solution is to provide a new pathway for the reaction, one with a lower activation energy. This is what a catalyst does, as is shown in Fig. 12.13. Because the catalyst allows the reaction to occur with a lower activation energy, a much larger fraction of collisions is effective at a given temperature, and the reaction rate is increased. This effect is illustrated in Fig. 12.14. Note from this diagram that although a catalyst lowers the activation energy $E_{\mathrm{a}}$ for a reaction, it does not affect the energy difference $\Delta E$ between products and reactants.

Catalysts are classified as homogeneous or heterogeneous. A homogeneous catalyst is one that is present in the same phase as the reacting molecules. A heterogeneous catalyst exists in a different phase, usually as a solid.

FIGURE 12.14 Effect of a catalyst on the number of reaction-producing collisions. Because a catalyst provides a reaction pathway with a lower activation energy, a much greater fraction of the collisions is effective for the catalyzed pathway (b) than for the uncatalyzed pathway (a) (at a given temperature). This allows reactants to become products at a much higher rate, even though there is no temperature increase.

We have seen that we can increase the rate of a reaction by increasing the concentrations of one or more of the reactants and/or by increasing the temperature. Both of these observations can be explained by the collision model, which states that molecules must collide in order to react. It turns out that we can also increase the rate of a reaction involving a solid by increasing the surface area of one or more of the solid reactants. Thus, for example, wood chips burn more quickly in air than a large log does. This is also explained with the collision model because a larger surface area means that more of the reactant molecules are in contact with one another. Another way to speed up the rate of a reaction is by means of catalysis, which we will discuss in the next section.

FIGURE 12.13 Energy plots for a catalyzed and an uncatalyzed pathway for a given reaction.

-a

-b

FIGURE 12.15 Heterogeneous catalysis of the hydrogenation of ethylene. (a) The reactants above the metal surface. (b) Hydrogen is adsorbed onto the metal surface, forming metal-hydrogen bonds and breaking the $\mathrm{H}-\mathrm{H}$ bonds. The $\pi$ bond in ethylene is broken and metal-hydrogen bonds are formed during adsorption.
(c) The adsorbed molecules and atoms migrate toward each other on the metal surface, forming new $\mathrm{C}-\mathrm{H}$ bonds.
(d) The $C$ atoms in ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ have completely saturated bonding capacities and so cannot bind strongly to the metal surfaces. The $\mathrm{C}_{2} \mathrm{H}_{6}$ molecule thus escapes.

## Heterogeneous Catalysis

Heterogeneous catalysis most often involves gaseous reactants being adsorbed on the surface of a solid catalyst. Adsorption refers to the collection of one substance on the surface of another substance; absorption refers to the penetration of one substance into another. Water is absorbed by a sponge.

An important example of heterogeneous catalysis occurs in the hydrogenation of unsaturated hydrocarbons, compounds composed mainly of carbon and hydrogen with some carbon-carbon double bonds. Hydrogenation is an important industrial process used to change unsaturated fats, occurring as oils, to saturated fats (solid shortenings such as Crisco) in which the $\mathrm{C}=\mathrm{C}$ bonds have been converted to $\mathrm{C}-\mathrm{C}$ bonds through addition of hydrogen.

A simple example of hydrogenation involves ethylene:

This reaction is quite slow at normal temperatures, mainly because the strong bond in the hydrogen molecule results in a large activation energy for the reaction. However, the reaction rate can be greatly increased by using a solid catalyst of platinum, palladium, or nickel. The hydrogen and ethylene adsorb on the catalyst surface, where the reaction occurs. The main function of the catalyst apparently is to allow formation of metal-hydrogen interactions that weaken the $\mathrm{H}-\mathrm{H}$ bonds and facilitate the reaction. The mechanism is illustrated in Fig. 12.15.

## LETS REVIEW Heterogeneous Catalysis

Typically, heterogeneous catalysis involves four steps:

1. Adsorption and activation of the reactants
2. Migration of the adsorbed reactants on the surface
3. Reaction of the adsorbed substances
4. Escape, or desorption, of the products

Heterogeneous catalysis also occurs in the oxidation of gaseous sulfur dioxide to gaseous sulfur trioxide. This process is especially interesting because it illustrates both positive and negative consequences of chemical catalysis.

The negative side is the formation of damaging air pollutants. Recall that sulfur dioxide, a toxic gas with a choking odor, is formed whenever sulfur-containing fuels are burned. However, it is sulfur trioxide that causes most of the environmental damage, mainly through the production of acid rain. When sulfur trioxide combines with a droplet of water, sulfuric acid is formed:

$$
\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{SO}_{3}(g) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)
$$

This sulfuric acid can cause considerable damage to vegetation, buildings and statues, and fish populations.

Sulfur dioxide is not rapidly oxidized to sulfur trioxide in clean, dry air. Why, then, is there a problem? The answer is catalysis. Dust particles and water droplets catalyze the reaction between $\mathrm{SO}_{2}$ and $\mathrm{O}_{2}$ in the air.

On the positive side, the heterogeneous catalysis of the oxidation of $\mathrm{SO}_{2}$ is used to advantage in the manufacture of sulfuric acid, where the reaction of $\mathrm{O}_{2}$ and $\mathrm{SO}_{2}$ to form $\mathrm{SO}_{3}$ is catalyzed by a solid mixture of platinum and vanadium $(\mathrm{V})$ oxide.

Heterogeneous catalysis is also utilized in the catalytic converters in automobile exhaust systems. The exhaust gases, containing compounds such as nitric oxide, carbon

FIGURE 12.16 The exhaust gases (HC, hydrocarbons; $\mathrm{NO}_{x}$, nitrous oxides; and CO) from an automobile engine are passed through a catalytic converter to minimize environmental damage.

Although $\mathrm{O}_{2}$ is represented here as the oxidizing agent for NO , the actual oxidizing agent is probably some type of peroxide compound produced by reaction of oxygen with pollutants. The direct reaction of NO and $\mathrm{O}_{2}$ is very slow.

monoxide, and unburned hydrocarbons, are passed through a converter containing beads of solid catalyst (Fig. 12.16). The catalyst promotes the conversion of carbon monoxide to carbon dioxide, hydrocarbons to carbon dioxide and water, and nitric oxide to nitrogen gas to lessen the environmental impact of the exhaust gases. However, this beneficial catalysis can, unfortunately, be accompanied by the unwanted catalysis of the oxidation of $\mathrm{SO}_{2}$ to $\mathrm{SO}_{3}$, which reacts with the moisture present to form sulfuric acid.

Because of the complex nature of the reactions that take place in the converter, a mixture of catalysts is used. The most effective catalytic materials are transition metal oxides and noble metals such as palladium and platinum.

## Homogeneous Catalysis

A homogeneous catalyst exists in the same phase as the reacting molecules. There are many examples in both the gas and liquid phases. One such example is the unusual catalytic behavior of nitric oxide toward ozone. In the troposphere, that part of the atmosphere closest to earth, nitric oxide catalyzes ozone production. However, in the upper atmosphere it catalyzes the decomposition of ozone. Both these effects are unfortunate environmentally.

In the lower atmosphere, NO is produced in any high-temperature combustion process where $\mathrm{N}_{2}$ is present. The reaction

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)
$$

is very slow at normal temperatures because of the very strong $\mathrm{N} \equiv \mathrm{N}$ and $\mathrm{O}=\mathrm{O}$ bonds. However, at elevated temperatures, such as those found in the internal combustion engines of automobiles, significant quantities of NO form. Some of this NO is converted back to $\mathrm{N}_{2}$ in the catalytic converter, but significant amounts escape into the atmosphere to react with oxygen:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

In the atmosphere, $\mathrm{NO}_{2}$ can absorb light and decompose as follows:

$$
\mathrm{NO}_{2}(g) \xrightarrow{\text { Light }} \mathrm{NO}(g)+\mathrm{O}(g)
$$

The oxygen atom is very reactive and can combine with an oxygen molecule to form ozone:

$$
\mathrm{O}_{2}(g)+\mathrm{O}(g) \longrightarrow \mathrm{O}_{3}(g)
$$

Ozone is a powerful oxidizing agent that can react with other air pollutants to form substances irritating to the eyes and lungs, and is itself very toxic.

Total Ozone (Dobson Units)
$\begin{array}{lllll}110 & 220 & 330 & 440 & 550\end{array}$

## A

This graphic shows data from the Total Ozone Mapping Spectrometer (TOMS) Earth Probe.

In this series of reactions, nitric oxide is acting as a true catalyst because it assists the production of ozone without being consumed itself. This can be seen by summing the reactions:

$$
\begin{aligned}
\mathrm{NO}(g)+\frac{1}{2} \mathrm{O}_{2}(g) & \longrightarrow \mathrm{NO}_{2}(g) \\
\mathrm{NO}_{2}(g) & \xrightarrow{\text { Light }} \mathrm{NO}(g)+\mathrm{O}(g) \\
\mathrm{O}_{2}(g)+\mathrm{O}(g) & \longrightarrow \mathrm{O}_{3}(g) \\
\hline \frac{3}{2} \mathrm{O}_{2}(g) & \longrightarrow \mathrm{O}_{3}(g)
\end{aligned}
$$

In the upper atmosphere, the presence of nitric oxide has the opposite effect-the depletion of ozone. The series of reactions involved is

$$
\begin{aligned}
\mathrm{NO}(g)+\mathrm{O}_{3}(g) & \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g) \\
\mathrm{O}(g)+\mathrm{NO}_{2}(g) & \longrightarrow \mathrm{NO}(g)+\mathrm{O}_{2}(g) \\
\mathrm{O}(g)+\mathrm{O}_{3}(g) & \longrightarrow 2 \mathrm{O}_{2}(g)
\end{aligned}
$$

Nitric oxide is again catalytic, but here its effect is to change $\mathrm{O}_{3}$ to $\mathrm{O}_{2}$. This is a potential problem because $\mathrm{O}_{3}$, which absorbs ultraviolet light, is necessary to protect us from the harmful effects of this high-energy radiation. That is, we want $\mathrm{O}_{3}$ in the upper atmosphere to block ultraviolet radiation from the sun but not in the lower atmosphere, where we would have to breathe it and its oxidation products.

The ozone layer is also threatened by Freons, a group of stable, noncorrosive compounds, formerly used as refrigerants and as propellants in aerosol cans. The most commonly used substance of this type was Freon-12 $\left(\mathrm{CCl}_{2} \mathrm{~F}_{2}\right)$. The chemical inertness of Freons makes them valuable but also creates a problem, since they remain in the environment a long time. Eventually, they migrate into the upper atmosphere to be decomposed by high-energy light. Among the decomposition products are chlorine atoms:

$$
\mathrm{CCl}_{2} \mathrm{~F}_{2}(g) \xrightarrow{\text { Light }} \mathrm{CClF}_{2}(g)+\mathrm{Cl}(g)
$$

These chlorine atoms can catalyze the decomposition of ozone:

$$
\begin{aligned}
\mathrm{Cl}(g)+\mathrm{O}_{3}(g) & \longrightarrow \mathrm{ClO}(g)+\mathrm{O}_{2}(g) \\
\mathrm{O}(g)+\mathrm{ClO}(g) & \longrightarrow \mathrm{Cl}(g)+\mathrm{O}_{2}(g) \\
\mathrm{O}(g)+\mathrm{O}_{3}(g) & \longrightarrow 2 \mathrm{O}_{2}(g)
\end{aligned}
$$

The problem of Freons has been brought into strong focus by the discovery of a mysterious "hole" in the ozone layer in the stratosphere over Antarctica. Studies performed there to find the reason for the hole have found unusually high levels of chlorine monoxide ( ClO ). This strongly implicates the Freons in the atmosphere as being responsible for the ozone destruction.

Because they pose environmental problems, Freons have been banned by international agreement. Substitute compounds are now being used.

## Acid Catalysis

Acids and bases can serve as catalysts in chemical reactions. In acid-catalyzed reactions, for example, a reactant gains a proton $\left(\mathrm{H}^{+}\right)$. The $\mathrm{H}^{+}$ion, being positively charged, is attracted to the lone pairs on atoms such as $\mathrm{O}, \mathrm{N}$, or S in a molecule, or to $\pi$ bonds in an alkene or alkyne.

A common industrial method for the production of ethanol is the acid-catalyzed reaction of ethylene and water:

$$
\mathrm{CH}_{2}=\mathrm{CH}_{2}+\mathrm{H}_{2} \mathrm{O} \xrightarrow[\text { Catalyst }]{\text { Acid }} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}
$$

In this case, the $\mathrm{H}^{+}$is attracted to the double bond on ethylene to make a new intermediate that is very reactive. This provides for a new pathway for the reaction that has lower activation energy and therefore proceeds more quickly than without the addition of the acid catalyst.

## CHEMICAL CONNECTIONS

## Enzymes: Nature's Catalysts

The most impressive examples of homogeneous catalysis occur in nature, where the complex reactions necessary for plant and animal life are made possible by enzymes. Enzymes are large molecules specifically tailored to facilitate a given type of reaction. Usually enzymes are proteins, an important class of biomolecules constructed from $\alpha$-amino acids that have the general structure

where R represents any one of 20 different substituents. These amino acid molecules can be "hooked together" to form a polymer (a word meaning "many parts") called a protein. The general structure of a protein can be represented as follows:

Since specific proteins are needed by the human body, the proteins in food must be broken into their constituent amino acids, which are then used to construct new proteins in the body's cells. The reaction in which a protein is broken down one amino acid at a time is shown in Fig. 12.17. Note that in this reaction a water molecule reacts with a protein molecule to produce an

FIGURE 12.17 The removal of the end amino acid from a protein by reaction with a molecule of water. The products are an amino acid and a new, smaller protein.
amino acid and a new protein containing one less amino acid. Without the enzymes found in human cells, this reaction would be much too slow to be useful. One of these enzymes is carboxypeptidase-A, a zinc-containing protein (Fig. 12.18).

Carboxypeptidase-A captures the protein to be acted on (called the substrate) in a special groove and positions the substrate so that the end is in the active site, where the catalysis occurs (Fig. 12.19). Note that the $\mathrm{Zn}^{2+}$ ion bonds to the oxygen of the $\mathrm{C}=\mathrm{O}$ (carbonyl) group. This polarizes the electron density in the carbonyl group, allowing the neighboring $\mathrm{C}-\mathrm{N}$ bond to be broken much more easily. When the reaction is completed, the remaining portion of the substrate protein and the newly
formed amino acid are released by the enzyme.

The process just described for carboxypeptidase-A is characteristic of the behavior of other enzymes. Enzyme catalysis can be represented by the series of reactions shown below:

$$
\begin{aligned}
\mathrm{E}+\mathrm{S} & \longrightarrow \mathrm{E} \cdot \mathrm{~S} \\
\mathrm{E} \cdot \mathrm{~S} & \longrightarrow \mathrm{E}+\mathrm{P}
\end{aligned}
$$

where E represents the enzyme, S represents the substrate, $\mathrm{E} \cdot \mathrm{S}$ represents the enzyme-substrate complex, and P represents the products. The enzyme and substrate form a complex, where the reaction occurs. The enzyme then releases the product and is ready to repeat the process. The most amazing thing about enzymes is their efficiency. Because an enzyme plays its catalytic role over and over and very rapidly, only a tiny amount of enzyme is required. This makes the isolation of enzymes for study quite difficult.

-b
FIGURE 12.18 (a) The structure of the enzyme carboxypeptidase-A, which contains 307 amino acids. The zinc ion is shown above as a black sphere in the center. (b) Carboxypeptidase-A with a substrate (pink) in place.

FIGURE 12.19 Protein-substrate interaction. The substrate is shown in black and red, with the red representing the terminal amino acid. Blue indicates side chains from the enzyme that help bind the substrate.

The mechanism for this reaction can be represented as follows:

Because the carbon atom on the right side of the product written above does not have an octet of electrons, the product is more reactive with water than is ethylene. The reaction proceeds as follows:

Notice that $\mathrm{H}^{+}$is a product of the final reaction in the mechanism. Although it is not the same hydrogen ion that catalyzed the reaction, there is not a net consumption of $\mathrm{H}^{+}$ in the overall reaction.

## Chemical kinetics

) The study of the factors that control the rate (speed) of a chemical reaction
> Rate is defined in terms of the change in concentration of a given reaction component per unit time
> Kinetic measurements are often made under conditions where the reverse reaction is insignificant
> The kinetic and thermodynamic properties of a reaction are not fundamentally related

## Rate laws

> Differential rate law: describes the rate as a function of concentration

$$
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]^{n}
$$

) $k$ is the rate constant
> $n$ is the order; not related to the coefficients in the balanced equation
> Integrated rate law: describes the concentration as a function of time
> For a reaction of the type

$$
\begin{aligned}
& \mathrm{aA} \longrightarrow \text { products } \\
& \text { Rate }=k[\mathrm{~A}]^{n} \\
& {[\mathrm{~A}]=-k t+[\mathrm{A}]_{0}} \\
& t_{1 / 2}=\frac{[\mathrm{A}]_{0}}{2 k}
\end{aligned}
$$

& t_{1 / 2}=\frac{1}{k[\mathrm{~A}]_{0}}
\end{aligned}
$$

) The value of $k$ can be determined from the plot of the appropriate function of [A] versus $t$

## Reaction mechanism

) Series of elementary steps by which an overall reaction occurs
> Elementary step: rate law for the step can be written from the molecularity of the reaction
) Two requirements for an acceptable mechanism:
) The elementary steps sum to give the correct overall balanced equation
) The mechanism agrees with the experimentally determined rate law
> Simple reactions can have an elementary step that is slower than all of the other steps; this is called the rate-determining step.

## Kinetic models

) The simplest model to account for reaction kinetics is the collision model
) Molecules must collide to react
> The collision kinetic energy furnishes the potential energy needed to enable the reactants to rearrange to form products
) A certain threshold energy called the activation energy $\left(E_{\mathrm{a}}\right)$ is necessary for a reaction to occur
> The relative orientations of the colliding reactants are also a determining factor in the reaction rate
) This model leads to the Arrhenius equation:

$$
k=A e^{-E_{\mathrm{a}} / R T}
$$

> $A$ depends on the collision frequency and relative orientation of the molecules
) The value of $E_{\mathrm{a}}$ can be found by obtaining the values of $k$ at several temperatures

## Catalyst

> Speeds up a reaction without being consumed
) Works by providing a lower-energy pathway for the reaction
> Enzymes are biological catalysts
) Catalysts can be classified as homogeneous or heterogeneous
) Homogeneous: exist in the same phase as the reactants
> Heterogeneous: exist in a different phase than the reactants
) Acids and bases can serve as catalysts

## Review Questions Answers to the Review Questions can be found on the Student website (accessible from www.cengagebrain.com)

1. Define reaction rate. Distinguish between the initial rate, average rate, and instantaneous rate of a chemical reaction. Which of these rates is usually fastest? The initial rate is the rate used by convention. Give a possible explanation as to why.
2. Distinguish between the differential rate law and the integrated rate law. Which of these is often called just the "rate law"? What is $k$ in a rate law, and what are orders in a rate law? Explain.
3. One experimental procedure that can be used to determine the rate law of a reaction is the method of initial
rates. What data are gathered in the method of initial rates, and how are these data manipulated to determine $k$ and the orders of the species in the rate law? Are the units for $k$, the rate constant, the same for all rate laws? Explain. If a reaction is first order in A, what happens to the rate if [A] is tripled? If the initial rate for a reaction increases by a factor of 16 when [A] is quadrupled, what is the order of $n$ ? If a reaction is third order in A and [A] is doubled, what happens to the initial rate? If a reaction is zero order, what effect does [A] have on the initial rate of a reaction?
4. The initial rate for a reaction is equal to the slope of the tangent line at $t \approx 0$ in a plot of [A] versus time. From calculus, initial rate $=\frac{-d[\mathrm{~A}]}{d t}$. Therefore, the differential rate law for a reaction is Rate $=\frac{-d[\mathrm{~A}]}{d t}=k[\mathrm{~A}]^{n}$. Assuming you have some calculus in your background, derive the zero-, first-, and second-order integrated rate laws using the differential rate law.
5. Consider the zero-, first-, and second-order integrated rate laws. If you have concentration versus time data for some species in a reaction, what plots would you make to "prove" a reaction is either zero, first, or second order? How would the rate constant, $k$, be determined from such a plot? What does the $y$-intercept equal in each plot? When a rate law contains the concentration of two or more species, how can plots be used to determine $k$ and the orders of the species in the rate law?
6. Derive expressions for the half-life of zero-, first-, and second-order reactions using the integrated rate law for each order. How does each half-life depend on concentration? If the half-life for a reaction is 20. seconds, what would be the second half-life assuming the reaction is either zero, first, or second order?
7. Define each of the following.
a. elementary step
b. molecularity
c. reaction mechanism
d. intermediate
e. rate-determining step
8. What two requirements must be met to call a mechanism plausible? Why say a "plausible" mechanism instead of the "correct" mechanism? Is it true that most reactions occur by a one-step mechanism? Explain.
9. What is the premise underlying the collision model? How is the rate affected by each of the following?
a. activation energy
b. temperature
c. frequency of collisions
d. orientation of collisions

Sketch a potential energy versus reaction progress plot for an endothermic reaction and for an exothermic reaction. Show $\Delta E$ and $E_{\mathrm{a}}$ in both plots. When concentrations and temperatures are equal, would you expect the rate of the forward reaction to be equal to, greater than, or less than the rate of the reverse reaction if the reaction is exothermic? Endothermic?
10. Give the Arrhenius equation. Take the natural $\log$ of both sides and place this equation in the form of a straight-line equation $(y=m x+b)$. What data would you need and how would you graph those data to get a linear relationship using the Arrhenius equation? What does the slope of the straight line equal? What does the $y$-intercept equal? What are the units of $R$ in the Arrhenius equation? Explain how if you know the rate constant value at two different temperatures, you can determine the activation energy for the reaction.
11. Why does a catalyst increase the rate of a reaction? What is the difference between a homogeneous catalyst and a heterogeneous catalyst? Would a given reaction necessarily have the same rate law for both a catalyzed and an uncatalyzed pathway? Explain.
5. Consider the following statements: "In general, the rate of a chemical reaction increases a bit at first because it takes a while for the reaction to get 'warmed up.' After that, however, the rate of the reaction decreases because its rate is dependent on the concentrations of the reactants, and these are decreasing." Indicate everything that is correct in these statements, and indicate everything that is incorrect. Correct the incorrect statements and explain.
6. For the reaction $\mathrm{A}+\mathrm{B} \rightarrow \mathrm{C}$, explain at least two ways in which the rate law could be zero order in chemical A .
7. A friend of yours states, "A balanced equation tells us how chemicals interact. Therefore, we can determine the rate law directly from the balanced equation." What do you tell your friend?
8. Provide a conceptual rationale for the differences in the half-
lives of zero-, first-, and second-order reactions.

[^26]
## Active Learning Questions*

These questions are designed to be used by groups of students in class.

1. Define stability from both a kinetic and thermodynamic perspective. Give examples to show the differences in these concepts.
2. Describe at least two experiments you could perform to determine a rate law.
3. Make a graph of [A] versus time for zero-, first-, and secondorder reactions. From these graphs, compare successive halflives.
4. How does temperature affect $k$, the rate constant? Explain.
5. The rate constant ( $k$ ) depends on which of the following (there may be more than one answer)?
a. the concentration of the reactants
b. the nature of the reactants
c. the temperature
d. the order of the reaction

Explain.
A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

10. Table 12.2 illustrates how the average rate of a reaction decreases with time. Why does the average rate of a reaction generally decrease with time? How does the instantaneous rate of a reaction depend on time? Why are initial rates of a reaction primarily used by convention?
11. The rate law of a reaction can only be determined from experiment. Two experimental procedures for determining rate laws were outlined in Chapter 12. What are the two procedures and how are they used to determine the rate laws?
12. The plot below shows the number of collisions with a particular energy for two different temperatures.

a. Which is greater, $T_{2}$ or $T_{1}$ ? How can you tell?
b. What does this plot tell us about the temperature dependence of the rate of a chemical reaction? Explain your answer.
13. For the reaction

$$
\mathrm{O}_{2}(g)+2 \mathrm{NO}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

the observed rate law is

$$
\text { Rate }=k[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]
$$

Which of the changes listed below would affect the value of the rate constant $k$ ?
a. increasing the partial pressure of oxygen gas
b. changing the temperature
c. using an appropriate catalyst
14. Each of the statements given below is false. Explain why.
a. The activation energy of a reaction depends on the overall energy change ( $\Delta E$ ) for the reaction.
b. The rate law for a reaction can be deduced from examination of the overall balanced equation for the reaction.
c. Most reactions occur by one-step mechanisms.
15. Define what is meant by unimolecular and bimolecular steps. Why are termolecular steps infrequently seen in chemical reactions?
16. The type of rate law for a reaction, either the differential rate law or the integrated rate law, is usually determined by which data is easiest to collect. Explain.
17. The initial rate of a reaction doubles as the concentration of one of the reactants is quadrupled. What is the order of this reactant? If a reactant has a -1 order, what happens to the initial rate when the concentration of that reactant increases by a factor of two?
18. Hydrogen reacts explosively with oxygen. However, a mixture of $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ can exist indefinitely at room temperature. Explain why $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ do not react under these conditions.
19. The central idea of the collision model is that molecules must collide in order to react. Give two reasons why not all collisions of reactant molecules result in product formation.
20. Consider the following energy plots for a chemical reaction when answering the questions below.

a. Which plot (purple or blue) is the catalyzed pathway?

How do you know?
b. What does $\Delta E_{1}$ represent?
c. What does $\Delta E_{2}$ represent?
d. Is the reaction endothermic or exothermic?
21. Enzymes are kinetically important for many of the complex reactions necessary for plant and animal life to exist. However, only a tiny amount of any particular enzyme is required for these complex reactions to occur. Explain.
22. Individuals who suffer from lactose intolerance do not produce enough of the enzyme lactase. Explain why this is an issue.
23. The combustion of carbohydrates and the combustion of fats are both exothermic processes, yet the combustion of carbohydrates is a faster process. How can this be?
24. Would the slope of a $\ln (k)$ versus $1 / T$ plot (with temperature in kelvin) for a catalyzed reaction be more or less negative than the slope of the $\ln (k)$ versus $1 / T$ plot for the uncatalyzed reaction? Explain. Assume both rate laws are first-order overall.

## Exercises

In this section similar exercises are paired.

## Reaction Rates

25. Consider the reaction

$$
4 \mathrm{PH}_{3}(g) \longrightarrow \mathrm{P}_{4}(g)+6 \mathrm{H}_{2}(g)
$$

If, in a certain experiment, over a specific time period, 0.0048 mole of $\mathrm{PH}_{3}$ is consumed in a 2.0-L container each second of reaction, what are the rates of production of $\mathrm{P}_{4}$ and $\mathrm{H}_{2}$ in this experiment?
26. In the Haber process for the production of ammonia,

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
$$

what is the relationship between the rate of production of ammonia and the rate of consumption of hydrogen?
-27. At $40^{\circ} \mathrm{C}, \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})$ will decompose according to the following reaction:

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
$$

The following data were collected for the concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$ at various times.

a. Calculate the average rate of decomposition of $\mathrm{H}_{2} \mathrm{O}_{2}$ between 0 and $2.16 \times 10^{4} \mathrm{~s}$. Use this rate to calculate the average rate of production of $\mathrm{O}_{2}(\mathrm{~g})$ over the same time period.
b. What are these rates for the time period $2.16 \times 10^{4} \mathrm{~s}$ to $4.32 \times 10^{4} \mathrm{~s}$ ?
28. Consider the general reaction

$$
\mathrm{aA}+\mathrm{bB} \longrightarrow \mathrm{cC}
$$

and the following average rate data over some time period $\Delta t$ :

$$
\begin{aligned}
-\frac{\Delta \mathrm{A}}{\Delta t} & =0.0080 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s} \\
-\frac{\Delta \mathrm{B}}{\Delta t} & =0.0120 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s} \\
\frac{\Delta \mathrm{C}}{\Delta t} & =0.0160 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}
\end{aligned}
$$

Determine a set of possible coefficients to balance this general reaction.
-29. What are the units for each of the following if the concentrations are expressed in moles per liter and the time in seconds?
a. rate of a chemical reaction
b. rate constant for a zero-order rate law
c. rate constant for a first-order rate law
d. rate constant for a second-order rate law
e. rate constant for a third-order rate law
30. The rate law for the reaction

$$
\begin{gathered}
\mathrm{Cl}_{2}(g)+\mathrm{CHCl}_{3}(g) \longrightarrow \mathrm{HCl}(g)+\mathrm{CCl}_{4}(g) \\
\text { Rate }=k\left[\mathrm{Cl}_{2}\right]^{1 / 2}\left[\mathrm{CHCl}_{3}\right]
\end{gathered}
$$

is
What are the units for $k$, assuming time in seconds and concentration in $\mathrm{mol} / \mathrm{L}$ ?

## Rate Laws from Experimental Data: Initial Rates Method

-31. The reaction

$$
2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NOCl}(g)
$$

was studied at $-10^{\circ} \mathrm{C}$. The following results were obtained where

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{Cl}_{2}\right]}{\Delta t}
$$

| $[\mathrm{NO}]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | $\left[\mathrm{Cl}_{2}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{min})$ |
| :---: | :---: | :---: |
| 0.10 | 0.10 | 0.18 |
| 0.10 | 0.20 | 0.36 |
| 0.20 | 0.20 | 1.45 |

a. What is the rate law?
b. What is the value of the rate constant?
-32. The reaction

$$
2 \mathrm{I}^{-}(a q)+\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}(a q) \longrightarrow \mathrm{I}_{2}(a q)+2 \mathrm{SO}_{4}{ }^{2-}(a q)
$$

was studied at $25^{\circ} \mathrm{C}$. The following results were obtained where

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}\right]}{\Delta t}
$$

| $\left[I^{-}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | $\left[\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: |
| 0.080 | 0.040 | $12.5 \times 10^{-6}$ |
| 0.040 | 0.040 | $6.25 \times 10^{-6}$ |
| 0.080 | 0.020 | $6.25 \times 10^{-6}$ |
| 0.032 | 0.040 | $5.00 \times 10^{-6}$ |
| 0.060 | 0.030 | $7.00 \times 10^{-6}$ |

a. Determine the rate law.
b. Calculate a value for the rate constant for each experiment and an average value for the rate constant.
-33. The decomposition of nitrosyl chloride was studied:

$$
2 \mathrm{NOCl}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g)
$$

The following data were obtained where

$$
\text { Rate }=-\frac{\Delta[\mathrm{NOCl}]}{\Delta t}
$$

| $[\mathrm{NOCl}]_{0}$ <br> $\left(\right.$ molecules $\left./ \mathrm{cm}^{3}\right)$ | Initial Rate <br> $\left(\right.$ molecules $\left./ \mathrm{cm}^{3} \cdot \mathbf{s}\right)$ |
| :---: | :---: |
| $3.0 \times 10^{16}$ | $5.98 \times 10^{4}$ |
| $2.0 \times 10^{16}$ | $2.66 \times 10^{4}$ |
| $1.0 \times 10^{16}$ | $6.64 \times 10^{3}$ |
| $4.0 \times 10^{16}$ | $1.06 \times 10^{5}$ |

a. What is the rate law?
b. Calculate the value of the rate constant.
c. Calculate the value of the rate constant when concentrations are given in moles per liter.
34. The following data were obtained for the gas-phase decomposition of dinitrogen pentoxide,

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

| $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]_{0}$ |  |
| :---: | :---: |
| $(\mathrm{~mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| 0.0750 | $8.90 \times 10^{-4}$ |
| 0.190 | $2.26 \times 10^{-3}$ |
| 0.275 | $3.26 \times 10^{-3}$ |
| 0.410 | $4.85 \times 10^{-3}$ |

Defining the rate as $-\Delta\left[\mathrm{N}_{2} \mathrm{O}_{5}\right] / \Delta t$, write the rate law and calculate the value of the rate constant.
35. The reaction

$$
\mathrm{I}^{-}(a q)+\mathrm{OCl}^{-}(a q) \longrightarrow \mathrm{IO}^{-}(a q)+\mathrm{Cl}^{-}(a q)
$$

was studied, and the following data were obtained:

| $\left.\mathrm{II}^{-}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | $\left.[\mathrm{OCl}]_{0}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: |
| 0.12 | 0.18 | $7.91 \times 10^{-2}$ |
| 0.060 | 0.18 | $3.95 \times 10^{-2}$ |
| 0.030 | 0.090 | $9.88 \times 10^{-3}$ |
| 0.24 | 0.090 | $7.91 \times 10^{-2}$ |

a. What is the rate law?
b. Calculate the value of the rate constant.
c. Calculate the initial rate for an experiment where both $\mathrm{I}^{-}$ and $\mathrm{OCl}^{-}$are initially present at $0.15 \mathrm{~mol} / \mathrm{L}$.
36. The reaction

$$
2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

was studied, and the following data were obtained where

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}
$$

| $\left[\begin{array}{c}{[\mathrm{NO}]_{0}} \\ \left(\text { molecules } / \mathrm{cm}^{3}\right)\end{array}\right.$ | $\left[\mathrm{O}_{2}\right]_{0}$ <br> $\left(\right.$ molecules $\left./ \mathrm{cm}^{3}\right)$ | Initial Rate <br> $\left(\right.$ molecules $/ \mathrm{cm}^{3}$$\cdot$ s) |
| :---: | :---: | :---: |

What would be the initial rate for an experiment where $[\mathrm{NO}]_{0}=6.21 \times 10^{18}$ molecules $/ \mathrm{cm}^{3}$ and $\left[\mathrm{O}_{2}\right]_{0}=7.36 \times$ $10^{18}$ molecules $/ \mathrm{cm}^{3}$ ?
-37. The rate of the reaction between hemoglobin $(\mathrm{Hb})$ and carbon monoxide (CO) was studied at $20^{\circ} \mathrm{C}$. The following data were collected with all concentration units in $\mu \mathrm{mol} / \mathrm{L}$. (A hemoglobin concentration of $2.21 \mu \mathrm{~mol} / \mathrm{L}$ is equal to $2.21 \times 10^{-6} \mathrm{~mol} / \mathrm{L}$.)

| $[\mathrm{Hb}]_{0}$ <br> $(\mu \mathrm{~mol} / \mathrm{L})$ | $[\mathrm{CO}]_{0}$ <br> $(\mu \mathrm{~mol} / \mathrm{L})$ | Initial Rate <br> $(\mu \mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: |
| 2.21 | 1.00 | 0.619 |
| 4.42 | 1.00 | 1.24 |
| 4.42 | 3.00 | 3.71 |

a. Determine the orders of this reaction with respect to Hb and CO.
b. Determine the rate law.
c. Calculate the value of the rate constant.
d. What would be the initial rate for an experiment with $[\mathrm{Hb}]_{0}=3.36 \mu \mathrm{~mol} / \mathrm{L}$ and $[\mathrm{CO}]_{0}=2.40 \mu \mathrm{~mol} / \mathrm{L}$ ?
38. The following data were obtained for the reaction

$$
2 \mathrm{ClO}_{2}(a q)+2 \mathrm{OH}^{-}(a q) \xrightarrow[\mathrm{ClO}_{3}^{-}]{ } \quad(a q)+\mathrm{ClO}_{2}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

where
Rate $=-\frac{\Delta\left[\mathrm{ClO}_{2}\right]}{\Delta t}$

| $\left[\mathrm{ClO}_{2}\right]_{0}$ |  |  |
| :---: | :--- | :---: |
| $(\mathrm{~mol} / \mathrm{L})$ | $\left[\mathrm{OH}^{-}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| 0.0500 | 0.100 | $5.75 \times 10^{-2}$ |
| 0.100 | 0.100 | $2.30 \times 10^{-1}$ |
| 0.100 | 0.0500 | $1.15 \times 10^{-1}$ |

a. Determine the rate law and the value of the rate constant.
b. What would be the initial rate for an experiment with $\left[\mathrm{ClO}_{2}\right]_{0}=0.175 \mathrm{~mol} / \mathrm{L}$ and $\left[\mathrm{OH}^{-}\right]_{0}=0.0844 \mathrm{~mol} / \mathrm{L}$ ?

## Integrated Rate Laws

-39. The decomposition of hydrogen peroxide was studied, and the following data were obtained at a particular temperature:

| Time $(\mathrm{s})$ | $\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]$ <br> $(\mathrm{mol} / \mathrm{L})$ |
| :---: | :--- |
| 0 | 1.00 |
| $120 \pm 1$ | 0.91 |
| $300 \pm 1$ | 0.78 |
| $600 \pm 1$ | 0.59 |
| $1200 \pm 1$ | 0.37 |
| $1800 \pm 1$ | 0.22 |
| $2400 \pm 1$ | 0.13 |
| $3000 \pm 1$ | 0.082 |
| $3600 \pm 1$ | 0.050 |

Assuming that

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]}{\Delta t}
$$

determine the rate law, the integrated rate law, and the value of the rate constant. Calculate $\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]$ at 4000 . s after the start of the reaction.
40. A certain reaction has the following general form:

$$
\mathrm{aA} \longrightarrow \mathrm{bB}
$$

At a particular temperature and $[\mathrm{A}]_{0}=2.00 \times 10^{-2} M$, concentration versus time data were collected for this reaction, and a plot of $\ln [\mathrm{A}]$ versus time resulted in a straight line with a slope value of $-2.97 \times 10^{-2} \mathrm{~min}^{-1}$.
a. Determine the rate law, the integrated rate law, and the value of the rate constant for this reaction.
b. Calculate the half-life for this reaction.
c. How much time is required for the concentration of A to decrease to $2.50 \times 10^{-3} M$ ?
-41. The rate of the reaction

$$
\mathrm{NO}_{2}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g)
$$

depends only on the concentration of nitrogen dioxide below $225^{\circ} \mathrm{C}$. At a temperature below $225^{\circ} \mathrm{C}$, the following data were collected:

| Time $(\mathrm{s})$ | $\left[\mathrm{NO}_{2}\right](\mathrm{mol} / \mathrm{L})$ |
| :---: | :---: |
| 0 | 0.500 |
| $1.20 \times 10^{3}$ | 0.444 |
| $3.00 \times 10^{3}$ | 0.381 |
| $4.50 \times 10^{3}$ | 0.340 |
| $9.00 \times 10^{3}$ | 0.250 |
| $1.80 \times 10^{4}$ | 0.174 |

Determine the rate law, the integrated rate law, and the value of the rate constant. Calculate $\left[\mathrm{NO}_{2}\right]$ at $2.70 \times 10^{4} \mathrm{~s}$ after the start of the reaction.
42. A certain reaction has the following general form:

$$
\mathrm{aA} \longrightarrow \mathrm{bB}
$$

At a particular temperature and $[\mathrm{A}]_{0}=2.80 \times 10^{-3} \mathrm{M}$, concentration versus time data were collected for this reaction, and a plot of $1 /[\mathrm{A}]$ versus time resulted in a straight line with a slope value of $+3.60 \times 10^{-2} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$.
a. Determine the rate law, the integrated rate law, and the value of the rate constant for this reaction.
b. Calculate the half-life for this reaction.
c. How much time is required for the concentration of A to decrease to $7.00 \times 10^{-4} M$ ?
43. The decomposition of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ on an alumina $\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)$ surface

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(g) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

was studied at 600 K . Concentration versus time data were collected for this reaction, and a plot of [A] versus time resulted in a straight line with a slope of $-4.00 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$.
a. Determine the rate law, the integrated rate law, and the value of the rate constant for this reaction.
b. If the initial concentration of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ was $1.25 \times 10^{-2} M$, calculate the half-life for this reaction.
c. How much time is required for all the $1.25 \times 10^{-2} M$ $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ to decompose?
44. At 500 K in the presence of a copper surface, ethanol decomposes according to the equation

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{CHO}(g)+\mathrm{H}_{2}(g)
$$

The pressure of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ was measured as a function of time and the following data were obtained:

| Time $(\mathrm{s})$ | $P_{\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}$ (torr) |
| :---: | :---: |
| 0 | 250. |
| 100. | 237 |
| 200. | 224 |
| 300. | 211 |
| 400. | 198 |
| 500. | 185 |

Since the pressure of a gas is directly proportional to the concentration of gas, we can express the rate law for a gaseous reaction in terms of partial pressures. Using the above data, deduce the rate law, the integrated rate law, and the value of the rate constant, all in terms of pressure units in atm and time in seconds. Predict the pressure of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ after 900 . s from the start of the reaction. (Hint: To determine the order of the reaction with respect to $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$, compare how the pressure of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ decreases with each time listing.)
45. The dimerization of butadiene

$$
2 \mathrm{C}_{4} \mathrm{H}_{6}(\mathrm{~g}) \longrightarrow \mathrm{C}_{8} \mathrm{H}_{12}(\mathrm{~g})
$$

was studied at $500 . \mathrm{K}$, and the following data were obtained:

| Time <br> $(\mathrm{s})$ | $\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]$ <br> $(\mathrm{mol} / \mathrm{L})$ |
| :---: | :---: |
| 195 | $1.6 \times 10^{-2}$ |
| 604 | $1.5 \times 10^{-2}$ |
| 1246 | $1.3 \times 10^{-2}$ |
| 2180 | $1.1 \times 10^{-2}$ |
| 6210 | $0.68 \times 10^{-2}$ |

Assuming that

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{C}_{4} \mathrm{H}_{6}\right]}{\Delta t}
$$

determine the form of the rate law, the integrated rate law, and the value of the rate constant for this reaction.
46. The rate of the reaction

$$
\mathrm{O}(g)+\mathrm{NO}_{2}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

was studied at a certain temperature.
a. In one experiment, $\mathrm{NO}_{2}$ was in large excess, at a concentration of $1.0 \times 10^{13}$ molecules $/ \mathrm{cm}^{3}$ with the following data collected:

| Time $(\mathrm{s})$ | $[0]$ <br> $\left(\right.$ atoms $\left./ \mathrm{cm}^{3}\right)$ |
| :---: | :---: |
| 0 | $5.0 \times 10^{9}$ |
| $1.0 \times 10^{-2}$ | $1.9 \times 10^{9}$ |
| $2.0 \times 10^{-2}$ | $6.8 \times 10^{8}$ |
| $3.0 \times 10^{-2}$ | $2.5 \times 10^{8}$ |

What is the order of the reaction with respect to oxygen atoms?
b. The reaction is known to be first order with respect to $\mathrm{NO}_{2}$. Determine the overall rate law and the value of the rate constant.
-47. Experimental data for the reaction

$$
\mathrm{A} \longrightarrow 2 \mathrm{~B}+\mathrm{C}
$$

have been plotted in the following three different ways (with concentration units in $\mathrm{mol} / \mathrm{L}$ ):

What is the order of the reaction with respect to A , and what is the initial concentration of A?
48. Consider the data plotted in Exercise 47 when answering the following questions.
a. What is the concentration of A after 9 s ?
b. What are the first three half-lives for this experiment?
-49. The reaction

$$
\mathrm{A} \longrightarrow \mathrm{~B}+\mathrm{C}
$$

is known to be zero order in A and to have a rate constant of $5.0 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ at $25^{\circ} \mathrm{C}$. An experiment was run at $25^{\circ} \mathrm{C}$ where $[\mathrm{A}]_{0}=1.0 \times 10^{-3} \mathrm{M}$.
a. Write the integrated rate law for this reaction.
b. Calculate the half-life for the reaction.
c. Calculate the concentration of B after $5.0 \times 10^{-3} \mathrm{~s}$ has elapsed assuming $[B]_{0}=0$.
50. The decomposition of hydrogen iodide on finely divided gold at $150^{\circ} \mathrm{C}$ is zero order with respect to HI . The rate defined below is constant at $1.20 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$.

$$
\begin{gathered}
2 \mathrm{HI}(\mathrm{~g}) \xrightarrow{\mathrm{Au}} \mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \\
\text { Rate }=-\frac{\Delta[\mathrm{HI}]}{\Delta t}=k=1.20 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}
\end{gathered}
$$

a. If the initial HI concentration was $0.250 \mathrm{~mol} / \mathrm{L}$, calculate the concentration of HI at 25 minutes after the start of the reaction.
b. How long will it take for all of the 0.250 M HI to decompose?
-51. A certain first-order reaction is $45.0 \%$ complete in 65 s . What are the values of the rate constant and the half-life for this process?
52. A first-order reaction is $75.0 \%$ complete in 320 . s.
a. What are the first and second half-lives for this reaction?
b. How long does it take for $90.0 \%$ completion?
-53. The rate law for the decomposition of phosphine $\left(\mathrm{PH}_{3}\right)$ is

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{PH}_{3}\right]}{\Delta t}=k\left[\mathrm{PH}_{3}\right]
$$

It takes 120.s for $1.00 \mathrm{M}_{3}$ to decrease to 0.250 M . How much time is required for $2.00 \mathrm{M}_{3}$ to decrease to a concentration of 0.350 M ?
54. DDT (molar mass $=354.49 \mathrm{~g} / \mathrm{mol}$ ) was a widely used insecticide that was banned from use in the United States in 1973. This ban was brought about due to the persistence of DDT in many different ecosystems, leading to high accumulations of the substance in many birds of prey. The insecticide was shown to cause a thinning of egg shells, pushing many birds toward extinction. If a $20-\mathrm{L}$ drum of DDT was spilled into a pond, resulting in a DDT concentration of $8.75 \times 10^{-5} \mathrm{M}$, how long would it take for the levels of DDT to reach a concentration of $1.41 \times 10^{-7} M$ (a level that is generally assumed safe in mammals)? Assume the decomposition of DDT is a first-order process with a half-life of 56.0 days.
55. A certain substance, initially at 0.10 M in solution, decomposes by second-order kinetics. If the rate constant for this process is $0.40 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{min}$, how much time is required for the concentration to reach 0.020 M ?
56. The rate law for the reaction

$$
2 \mathrm{NOBr}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g)
$$

at some temperature is

$$
\text { Rate }=-\frac{\Delta[\mathrm{NOBr}]}{\Delta t}=k[\mathrm{NOBr}]^{2}
$$

a. If the half-life for this reaction is 2.00 s when $[\mathrm{NOBr}]_{0}=$ 0.900 M , calculate the value of $k$ for this reaction.
b. How much time is required for the concentration of NOBr to decrease to 0.100 M ?
57. For the reaction $\mathrm{A} \rightarrow$ products, successive half-lives are observed to be $10.0,20.0$, and 40.0 min for an experiment in which $[\mathrm{A}]_{0}=0.10 \mathrm{M}$. Calculate the concentration of A at the following times.
a. 80.0 min
b. 30.0 min
58. Theophylline is a pharmaceutical drug that is sometimes used to help with lung function. You observe a case where the initial lab results indicate that the concentration of theophylline in a patient's body decreased from $2.0 \times 10^{-3} M$ to $1.0 \times 10^{-3} M$ in 24 hours. In another 12 hours the drug concentration was found to be $5.0 \times 10^{-4} \mathrm{M}$. What is the value of the rate constant for the metabolism of this drug in the body?
59. You and a coworker have developed a molecule that has shown potential as cobra antivenin (AV). This antivenin works by binding to the venom (V), thereby rendering it nontoxic. This reaction can be described by the rate law

$$
\text { Rate }=k[\mathrm{AV}]^{1}[\mathrm{~V}]^{1}
$$

You have been given the following data from your coworker:

$$
\begin{aligned}
{[\mathrm{V}]_{0} } & =0.20 \mathrm{M} \\
{[\mathrm{AV}]_{0} } & =1.0 \times 10^{-4} \mathrm{M}
\end{aligned}
$$

A plot of $\ln [\mathrm{AV}]$ versus $t(\mathrm{~s})$ gives a straight line with a slope of $-0.32 \mathrm{~s}^{-1}$. What is the value of the rate constant $(k)$ for this reaction?
60. Consider the hypothetical reaction

$$
\mathrm{A}+\mathrm{B}+2 \mathrm{C} \longrightarrow 2 \mathrm{D}+3 \mathrm{E}
$$

where the rate law is

$$
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}][\mathrm{B}]^{2}
$$

An experiment is carried out where $[\mathrm{A}]_{0}=1.0 \times 10^{-2} \mathrm{M}$, $[\mathrm{B}]_{0}=3.0 \mathrm{M}$, and $[\mathrm{C}]_{0}=2.0 \mathrm{M}$. The reaction is started, and after 8.0 seconds, the concentration of A is $3.8 \times 10^{-3} \mathrm{M}$.
a. Calculate the value of $k$ for this reaction.
b. Calculate the half-life for this experiment.
c. Calculate the concentration of A after 13.0 seconds.
d. Calculate the concentration of C after 13.0 seconds.

## Reaction Mechanisms

61. Write the rate laws for the following elementary reactions.
a. $\mathrm{CH}_{3} \mathrm{NC}(\mathrm{g}) \rightarrow \mathrm{CH}_{3} \mathrm{CN}(\mathrm{g})$
b. $\mathrm{O}_{3}(g)+\mathrm{NO}(g) \rightarrow \mathrm{O}_{2}(g)+\mathrm{NO}_{2}(g)$
c. $\mathrm{O}_{3}(\mathrm{~g}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+\mathrm{O}(\mathrm{g})$
d. $\mathrm{O}_{3}(\mathrm{~g})+\mathrm{O}(\mathrm{g}) \rightarrow 2 \mathrm{O}_{2}(\mathrm{~g})$
62. A possible mechanism for the decomposition of hydrogen peroxide is

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{O}_{2} & \longrightarrow 2 \mathrm{OH} \\
\mathrm{H}_{2} \mathrm{O}_{2}+\mathrm{OH} & \longrightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{HO}_{2} \\
\mathrm{HO}_{2}+\mathrm{OH} & \longrightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{O}_{2}
\end{aligned}
$$

Using your results from Exercise 39, specify which step is the rate-determining step. What is the overall balanced equation for the reaction?
-63. A proposed mechanism for a reaction is

$$
\begin{aligned}
\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{Br} & \longrightarrow \mathrm{C}_{4} \mathrm{H}_{9}{ }^{+}+\mathrm{Br}^{-} \\
\mathrm{C}_{4} \mathrm{H}_{9}++\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}_{2}^{+} & \text {Slow } \\
\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}_{2}^{+}+\mathrm{H}_{2} \mathrm{O} & \mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}+\mathrm{H}_{3} \mathrm{O}^{+}
\end{aligned} \quad \text { Fast }
$$

Write the rate law expected for this mechanism. What is the overall balanced equation for the reaction? What are the intermediates in the proposed mechanism?
64. The mechanism for the gas-phase reaction of nitrogen dioxide with carbon monoxide to form nitric oxide and carbon dioxide is thought to be

$$
\begin{gathered}
\mathrm{NO}_{2}+\mathrm{NO}_{2} \longrightarrow \mathrm{NO}_{3}+\mathrm{NO} \\
\mathrm{NO}_{3}+\mathrm{CO} \longrightarrow \mathrm{NO}_{2}+\mathrm{CO}_{2}
\end{gathered}
$$

Write the rate law expected for this mechanism. What is the overall balanced equation for the reaction?
-65. Is the mechanism

$$
\begin{array}{r}
\mathrm{NO}+\mathrm{Cl}_{2} \xrightarrow{k_{1}} \mathrm{NOCl}_{2} \\
\mathrm{NOCl}_{2}+\mathrm{NO} \xrightarrow{k_{2}} 2 \mathrm{NOCl}
\end{array}
$$

consistent with the results obtained in Exercise 31? If so, which step is the rate-determining step?
66. The reaction

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

exhibits the rate law

$$
\text { Rate }=k[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]
$$

Which of the following mechanisms is consistent with this rate law?
a. $\mathrm{NO}+\mathrm{O}_{2} \longrightarrow \mathrm{NO}_{2}+\mathrm{O}$ Slow $\mathrm{O}+\mathrm{NO} \longrightarrow \mathrm{NO}_{2} \quad$ Fast
b. $\mathrm{NO}+\mathrm{O}_{2} \rightleftharpoons \mathrm{NO}_{3} \quad$ Fast equilibrium $\mathrm{NO}_{3}+\mathrm{NO} \longrightarrow 2 \mathrm{NO}_{2} \quad$ Slow
c. $2 \mathrm{NO} \longrightarrow \mathrm{N}_{2} \mathrm{O}_{2}$ Slow $\mathrm{N}_{2} \mathrm{O}_{2}+\mathrm{O}_{2} \longrightarrow \mathrm{~N}_{2} \mathrm{O}_{4} \quad$ Fast $\mathrm{N}_{2} \mathrm{O}_{4} \longrightarrow 2 \mathrm{NO}_{2} \quad$ Fast
d. $2 \mathrm{NO} \rightleftharpoons \mathrm{N}_{2} \mathrm{O}_{2} \quad$ Fast equilibrium
$\mathrm{N}_{2} \mathrm{O}_{2} \longrightarrow \mathrm{NO}_{2}+\mathrm{O} \quad$ Slow
$\mathrm{O}+\mathrm{NO} \longrightarrow \mathrm{NO}_{2}$
Fast

## Temperature Dependence of Rate Constants and the Collision Model

For the following reaction profile, indicate
a. the positions of reactants and products.
b. the activation energy.
c. $\Delta E$ for the reaction.

68. Draw a rough sketch of the energy profile for each of the following cases:
a. $\Delta E=+10 \mathrm{~kJ} / \mathrm{mol}, E_{\mathrm{a}}=25 \mathrm{~kJ} / \mathrm{mol}$
b. $\Delta E=-10 \mathrm{~kJ} / \mathrm{mol}, E_{\mathrm{a}}=50 \mathrm{~kJ} / \mathrm{mol}$
c. $\Delta E=-50 \mathrm{~kJ} / \mathrm{mol}, E_{\mathrm{a}}=50 \mathrm{~kJ} / \mathrm{mol}$
${ }^{69}$. The activation energy for the reaction

$$
\mathrm{NO}_{2}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g)
$$

is $125 \mathrm{~kJ} / \mathrm{mol}$, and $\Delta E$ for the reaction is $-216 \mathrm{~kJ} / \mathrm{mol}$. What is the activation energy for the reverse reaction

$$
\left[\mathrm{NO}(g)+\mathrm{CO}_{2}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{CO}(g)\right] ?
$$

70. The activation energy for some reaction

$$
\mathrm{X}_{2}(\mathrm{~g})+\mathrm{Y}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{XY}(\mathrm{~g})
$$

is $167 \mathrm{~kJ} / \mathrm{mol}$, and $\Delta E$ for the reaction is $+28 \mathrm{~kJ} / \mathrm{mol}$. What is the activation energy for the decomposition of XY?
-71. The rate constant for the gas-phase decomposition of $\mathrm{N}_{2} \mathrm{O}_{5}$,

$$
\mathrm{N}_{2} \mathrm{O}_{5}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(g)
$$

has the following temperature dependence:

| $\boldsymbol{T}(\mathbf{K})$ | $\boldsymbol{k}\left(\mathbf{s}^{-1}\right)$ |
| :---: | :---: |
| 338 | $4.9 \times 10^{-3}$ |
| 318 | $5.0 \times 10^{-4}$ |
| 298 | $3.5 \times 10^{-5}$ |

Make the appropriate graph using these data, and determine the activation energy for this reaction.
72. The reaction

$$
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}+\mathrm{OH}^{-} \longrightarrow\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}+\mathrm{Br}^{-}
$$

in a certain solvent is first order with respect to $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}$ and zero order with respect to $\mathrm{OH}^{-}$. In several experiments, the rate constant $k$ was determined at different temperatures. A plot of $\ln (k)$ versus $1 / T$ was constructed resulting in a straight line with a slope value of $-1.10 \times 10^{4} \mathrm{~K}$ and $y$-intercept of 33.5. Assume $k$ has units of $\mathrm{s}^{-1}$.
a. Determine the activation energy for this reaction.
b. Determine the value of the frequency factor $A$.
c. Calculate the value of $k$ at $25^{\circ} \mathrm{C}$.
-73. The activation energy for the decomposition of $\mathrm{HI}(g)$ to $\mathrm{H}_{2}(g)$ and $\mathrm{I}_{2}(\mathrm{~g})$ is $186 \mathrm{~kJ} / \mathrm{mol}$. The rate constant at 555 K is $3.52 \times$ $10^{-7} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$. What is the rate constant at 645 K ?
74. A first-order reaction has rate constants of $4.6 \times 10^{-2} \mathrm{~s}^{-1}$ and $8.1 \times 10^{-2} \mathrm{~s}^{-1}$ at $0^{\circ} \mathrm{C}$ and $20 .^{\circ} \mathrm{C}$, respectively. What is the value of the activation energy?
-75. A certain reaction has an activation energy of $54.0 \mathrm{~kJ} / \mathrm{mol}$. As the temperature is increased from $22^{\circ} \mathrm{C}$ to a higher temperature, the rate constant increases by a factor of 7.00. Calculate the higher temperature.
76. Chemists commonly use a rule of thumb that an increase of 10 K in temperature doubles the rate of a reaction. What must the activation energy be for this statement to be true for a temperature increase from 25 to $35^{\circ} \mathrm{C}$ ?
-77. Which of the following reactions would you expect to proceed at a faster rate at room temperature? Why? (Hint: Think about which reaction would have the lower activation energy.)

$$
\begin{aligned}
2 \mathrm{Ce}^{4+}(a q)+\mathrm{Hg}_{2}^{2+}(a q) & \longrightarrow 2 \mathrm{Ce}^{3+}(a q)+2 \mathrm{Hg}^{2+}(a q) \\
\mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{OH}^{-}(a q) & \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

78. One reason suggested for the instability of long chains of silicon atoms is that the decomposition involves the transition state shown below:

The activation energy for such a process is $210 \mathrm{~kJ} / \mathrm{mol}$, which is less than either the $\mathrm{Si}-\mathrm{Si}$ or the $\mathrm{Si}-\mathrm{H}$ bond energy. Why would a similar mechanism not be expected to play a very important role in the decomposition of long chains of carbon atoms as seen in organic compounds?

## Catalysts

-79. One mechanism for the destruction of ozone in the upper atmosphere is

$$
\begin{array}{lll}\mathrm{O}_{3}(g)+\mathrm{NO}(g) & \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g) & \text { Slow } \\ \mathrm{NO}_{2}(g)+\mathrm{O}(g) & \longrightarrow \mathrm{NO}(g)+\mathrm{O}_{2}(g) & \text { Fast } \\ \text { Overall reaction } \mathrm{O}_{3}(g)+\mathrm{O}(g) \longrightarrow 2 \mathrm{O}_{2}(g) & \end{array}
$$

a. Which species is a catalyst?
b. Which species is an intermediate?
c. $E_{\mathrm{a}}$ for the uncatalyzed reaction

$$
\mathrm{O}_{3}(g)+\mathrm{O}(g) \longrightarrow 2 \mathrm{O}_{2}(g)
$$

is 14.0 kJ . $E_{\mathrm{a}}$ for the same reaction when catalyzed is 11.9 kJ . What is the ratio of the rate constant for the catalyzed reaction to that for the uncatalyzed reaction at $25^{\circ} \mathrm{C}$ ? Assume that the frequency factor $A$ is the same for each reaction.
80. One of the concerns about the use of Freons is that they will migrate to the upper atmosphere, where chlorine atoms can be generated by the following reaction:

$$
\underset{\text { Freon-12 }}{\left.\mathrm{CCl}_{2} \mathrm{~F}_{2}(g) \xrightarrow{h v} \mathrm{CF}_{2} \mathrm{Cl}(g)+\mathrm{Cl}(g)\right)}
$$

Chlorine atoms can act as a catalyst for the destruction of ozone. The activation energy for the reaction

$$
\mathrm{Cl}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{ClO}(g)+\mathrm{O}_{2}(g)
$$

is $2.1 \mathrm{~kJ} / \mathrm{mol}$. Which is the more effective catalyst for the destruction of ozone, Cl or NO ? (See Exercise 79.)
81. Assuming that the mechanism for the hydrogenation of $\mathrm{C}_{2} \mathrm{H}_{4}$ given in Section 12.7 is correct, would you predict that the product of the reaction of $\mathrm{C}_{2} \mathrm{H}_{4}$ with $\mathrm{D}_{2}$ would be $\mathrm{CH}_{2} \mathrm{D}-\mathrm{CH}_{2} \mathrm{D}$ or $\mathrm{CHD}_{2}-\mathrm{CH}_{3}$ ? How could the reaction of $\mathrm{C}_{2} \mathrm{H}_{4}$ with $\mathrm{D}_{2}$ be used to confirm the mechanism for the hydrogenation of $\mathrm{C}_{2} \mathrm{H}_{4}$ given in Section 12.7?
82. The decomposition of $\mathrm{NH}_{3}$ to $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ was studied on two surfaces:

Without a catalyst, the activation energy is $335 \mathrm{~kJ} / \mathrm{mol}$.
a. Which surface is the better heterogeneous catalyst for the decomposition of $\mathrm{NH}_{3}$ ? Why?
b. How many times faster is the reaction at 298 K on the W surface compared with the reaction with no catalyst present? Assume that the frequency factor $A$ is the same for each reaction.
c. The decomposition reaction on the two surfaces obeys a rate law of the form

$$
\text { Rate }=k \frac{\left[\mathrm{NH}_{3}\right]}{\left[\mathrm{H}_{2}\right]}
$$

How can you explain the inverse dependence of the rate on the $\mathrm{H}_{2}$ concentration?

The decomposition of many substances on the surface of a heterogeneous catalyst shows the following behavior:

How do you account for the rate law changing from first order to zero order in the concentration of reactant?
84. For enzyme-catalyzed reactions that follow the mechanism

$$
\begin{aligned}
\mathrm{E}+\mathrm{S} & \rightleftharpoons \mathrm{E} \cdot \mathrm{~S} \\
\mathrm{E} \cdot \mathrm{~S} & \rightleftharpoons \mathrm{E}+\mathrm{P}
\end{aligned}
$$

a graph of the rate as a function of [S], the concentration of the substrate, has the following appearance:

Note that at higher substrate concentrations the rate no longer changes with [S]. Suggest a reason for this.
85. A popular chemical demonstration is the "magic genie" procedure, in which hydrogen peroxide decomposes to water and oxygen gas with the aid of a catalyst. The activation energy of this (uncatalyzed) reaction is $70.0 \mathrm{~kJ} / \mathrm{mol}$. When the catalyst is added, the activation energy (at $20 .{ }^{\circ} \mathrm{C}$ ) is $42.0 \mathrm{~kJ} / \mathrm{mol}$. Theoretically, to what temperature $\left({ }^{\circ} \mathrm{C}\right)$ would one have to heat the hydrogen peroxide solution so that the rate of the uncatalyzed reaction is equal to the rate of the catalyzed reaction at $20 .{ }^{\circ} \mathrm{C}$ ? Assume the frequency factor $A$ is constant, and assume the initial concentrations are the same.
86. The activation energy for a reaction is changed from $184 \mathrm{~kJ} /$ mol to $59.0 \mathrm{~kJ} / \mathrm{mol}$ at 600 . K by the introduction of a catalyst. If the uncatalyzed reaction takes about 2400 years to occur, about how long will the catalyzed reaction take? Assume the frequency factor $A$ is constant, and assume the initial concentrations are the same.

## Additional Exercises

87. Consider the following representation of the reaction $2 \mathrm{NO}_{2}(g) \rightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)$.

Determine the time for the final representation above if the reaction is
a. first order
b. second order
c. zero order
88. The reaction

$$
\mathrm{H}_{2} \mathrm{SeO}_{3}(a q)+6 \mathrm{I}^{-}(a q)+\underset{\longrightarrow}{4 \mathrm{H}^{+}(a q)} \mathrm{Se}(s)+2 \mathrm{I}_{3}^{-}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

was studied at $0^{\circ} \mathrm{C}$, and the following data were obtained:

| $\left[\mathrm{H}_{2} \mathrm{SeO}_{3}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | $\left[\mathrm{H}^{+}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | $\left[\mathrm{l}^{-}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: | :---: |
| $1.0 \times 10^{-4}$ | $2.0 \times 10^{-2}$ | $2.0 \times 10^{-2}$ | $1.66 \times 10^{-7}$ |
| $2.0 \times 10^{-4}$ | $2.0 \times 10^{-2}$ | $2.0 \times 10^{-2}$ | $3.33 \times 10^{-7}$ |
| $3.0 \times 10^{-4}$ | $2.0 \times 10^{-2}$ | $2.0 \times 10^{-2}$ | $4.99 \times 10^{-7}$ |
| $1.0 \times 10^{-4}$ | $4.0 \times 10^{-2}$ | $2.0 \times 10^{-2}$ | $6.66 \times 10^{-7}$ |
| $1.0 \times 10^{-4}$ | $1.0 \times 10^{-2}$ | $2.0 \times 10^{-2}$ | $0.42 \times 10^{-7}$ |
| $1.0 \times 10^{-4}$ | $2.0 \times 10^{-2}$ | $4.0 \times 10^{-2}$ | $13.2 \times 10^{-7}$ |
| $1.0 \times 10^{-4}$ | $1.0 \times 10^{-2}$ | $4.0 \times 10^{-2}$ | $3.36 \times 10^{-7}$ |

These relationships hold only if there is a very small amount of $\mathrm{I}_{3}{ }^{-}$present. What is the rate law and the value of the rate constant? (Assume that rate $=-\frac{\Delta\left[\mathrm{H}_{2} \mathrm{SeO}_{3}\right]}{\Delta t}$. $)$
89. Consider two reaction vessels, one containing A and the other containing B , with equal concentrations at $t=0$. If both substances decompose by first-order kinetics, where

$$
\begin{aligned}
& k_{\mathrm{A}}=4.50 \times 10^{-4} \mathrm{~s}^{-1} \\
& k_{\mathrm{B}}=3.70 \times 10^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

how much time must pass to reach a condition such that $[\mathrm{A}]=$ 4.00[B]?
90. Sulfuryl chloride $\left(\mathrm{SO}_{2} \mathrm{Cl}_{2}\right)$ decomposes to sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ and chlorine $\left(\mathrm{Cl}_{2}\right)$ by reaction in the gas phase. The following pressure data were obtained when a sample containing $5.00 \times 10^{-2} \mathrm{~mol}$ sulfuryl chloride was heated to $600 . \mathrm{K}$ in a $5.00 \times 10^{-1}$-L container.

| Time <br> (hours): | 0.00 | 1.00 | 2.00 | 4.00 | 8.00 | 16.00 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\boldsymbol{P}_{\mathrm{SO}_{2} \mathrm{Cl}_{2}}$ <br> (atm): | 4.93 | 4.26 | 3.52 | 2.53 | 1.30 | 0.34 |

Defining the rate as $-\frac{\Delta\left[\mathrm{SO}_{2} \mathrm{Cl}_{2}\right]}{\Delta t}$,
a. determine the value of the rate constant for the decomposition of sulfuryl chloride at 600 . K.
b. what is the half-life of the reaction?
c. what fraction of the sulfuryl chloride remains after 20.0 h ?
91. For the reaction

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

the following data were collected, where

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]}{\Delta t}
$$

| Time <br> (s) | $T=338 \mathrm{~K}$ <br> $\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]$ | $T=318 \mathrm{~K}$ <br> $\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]$ |
| ---: | :---: | :---: |
| 0 | $1.00 \times 10^{-1} \mathrm{M}$ | $1.00 \times 10^{-1} \mathrm{M}$ |
| 100. | $6.14 \times 10^{-2} \mathrm{M}$ | $9.54 \times 10^{-2} \mathrm{M}$ |
| 300. | $2.33 \times 10^{-2} \mathrm{M}$ | $8.63 \times 10^{-2} \mathrm{M}$ |
| 600. | $5.41 \times 10^{-3} \mathrm{M}$ | $7.43 \times 10^{-2} \mathrm{M}$ |
| 900. | $1.26 \times 10^{-3} \mathrm{M}$ | $6.39 \times 10^{-2} \mathrm{M}$ |

Calculate $E_{\mathrm{a}}$ for this reaction.
92. Experimental values for the temperature dependence of the rate constant for the gas-phase reaction

$$
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

are as follows:

| $\boldsymbol{T}$ | $\mathbf{k}$ |
| :---: | :---: |
| $\mathbf{( K )}$ | $(\mathrm{L} / \mathrm{mol} \cdot \mathrm{s})$ |
| 195 | $1.08 \times 10^{9}$ |
| 230. | $2.95 \times 10^{9}$ |
| 260. | $5.42 \times 10^{9}$ |
| 298 | $12.0 \times 10^{9}$ |
| 369 | $35.5 \times 10^{9}$ |

Make the appropriate graph using these data, and determine the activation energy for this reaction.
93. At $620 . \mathrm{K}$ butadiene dimerizes at a moderate rate. The following data were obtained in an experiment involving this reaction:

| $\boldsymbol{t}(\mathrm{s})$ | $\left[\mathbf{C}_{4} \mathrm{H}_{6}\right](\mathrm{mol} / \mathrm{L})$ |
| ---: | :---: |
| 0 | 0.01000 |
| 1000. | 0.00629 |
| 2000. | 0.00459 |
| 3000. | 0.00361 |

a. Determine the order of the reaction in butadiene.
b. In how many seconds is the dimerization $1.0 \%$ complete?
c. In how many seconds is the dimerization $10.0 \%$ complete?
d. What is the half-life for the reaction if the initial concentration of butadiene is 0.0200 M ?
e. Use the results from this problem and Exercise 45 to calculate the activation energy for the dimerization of butadiene.
94. For a first order gas phase reaction $\mathrm{A} \longrightarrow$ products, $k=$ $7.2 \times 10^{-4} \mathrm{~s}^{-1}$ at 660 . K and $k=1.7 \times 10^{-2} \mathrm{~s}^{-1}$ at 720 . K. If the initial pressure of A is 536 torr at $295^{\circ} \mathrm{C}$, how long will it take for the pressure of A to decrease to 268 torr?
95. Cobra venom helps the snake secure food by binding to acetylcholine receptors on the diaphragm of a bite victim, leading to the loss of function of the diaphragm muscle tissue and eventually death. In order to develop more potent antivenins, scientists have studied what happens to the toxin once it has bound the acetylcholine receptors. They have found that the toxin is released from the receptor in a process that can be described by the rate law

$$
\text { Rate }=k[\text { acetylcholine receptor-toxin complex }]
$$

If the activation energy of this reaction at $37.0^{\circ} \mathrm{C}$ is $26.2 \mathrm{~kJ} /$ mol and $A=0.850 \mathrm{~s}^{-1}$, what is the rate of reaction if you have a $0.200-M$ solution of receptor-toxin complex at $37.0^{\circ} \mathrm{C}$ ?
96. Iodomethane $\left(\mathrm{CH}_{3} \mathrm{I}\right)$ is a commonly used reagent in organic chemistry. When used properly, this reagent allows chemists to introduce methyl groups in many different useful applications. The chemical does pose a risk as a carcinogen, possibly owing to iodomethane's ability to react with portions of the DNA strand (if they were to come in contact). Consider the following hypothetical initial rates data:

| $\left[\begin{array}{ccc}{[\mathrm{DNA}]_{0}} \\ (\mu \mathrm{~mol} / \mathrm{L})\end{array}\right.$ | $\left[\mathrm{CH}_{3}\right]_{0}$ <br> $(\mu \mathrm{~mol} / \mathrm{L})$ | Initial Rate <br> $(\mu \mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: |
| 0.100 | 0.100 | $3.20 \times 10^{-4}$ |
| 0.100 | 0.200 | $6.40 \times 10^{-4}$ |
| 0.200 | 0.200 | $1.28 \times 10^{-3}$ |

Which of the following could be a possible mechanism to explain the initial rate data?
Mechanism I DNA $+\mathrm{CH}_{3} \mathrm{I} \longrightarrow$ DNA $-\mathrm{CH}_{3}^{+}+\mathrm{I}^{-}$
Mechanism II $\quad \mathrm{CH}_{3} \mathrm{I} \longrightarrow \mathrm{CH}_{3}{ }^{+}+\mathrm{I}^{-} \quad$ Slow

97. Experiments during a recent summer on a number of fireflies (small beetles, Lampyridaes photinus) showed that the average interval between flashes of individual insects was 16.3 s at $21.0^{\circ} \mathrm{C}$ and 13.0 s at $27.8^{\circ} \mathrm{C}$.
a. What is the apparent activation energy of the reaction that controls the flashing?
b. What would be the average interval between flashes of an individual firefly at $30.0^{\circ} \mathrm{C}$ ?
c. Compare the observed intervals and the one you calculated in part $b$ to the rule of thumb that the Celsius temperature is 54 minus twice the interval between flashes.
98. The activation energy of a certain uncatalyzed biochemical reaction is $50.0 \mathrm{~kJ} / \mathrm{mol}$. In the presence of a catalyst at $37^{\circ} \mathrm{C}$, the rate constant for the reaction increases by a factor of $2.50 \times 10^{3}$ as compared with the uncatalyzed reaction. Assuming the frequency factor $A$ is the same for both the catalyzed and uncatalyzed reactions, calculate the activation energy for the catalyzed reaction.
99. Consider the following initial rate data for the decomposition of compound $A B$ to give $A$ and $B$ :

| $[\mathrm{AB}]_{0}(\mathrm{~mol} / \mathrm{L})$ | Initial Rate $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: |
| 0.200 | $3.20 \times 10^{-3}$ |
| 0.400 | $1.28 \times 10^{-2}$ |
| 0.600 | $2.88 \times 10^{-2}$ |

Determine the half-life for the decomposition reaction initially having 1.00 M AB present.
100. Consider a hypothetical reaction between $A$ and $B$ :

$$
\mathrm{A}+\mathrm{B} \longrightarrow \text { products }
$$

Use the following initial rate data to calculate the rate constant for this reaction.

| $[\mathrm{A}]$ <br> $(\mathrm{mol} / \mathrm{L})$ | $[\mathrm{B}]$ <br> $(\mathrm{mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: |
| 0.20 | 1.0 | 3.0 |
| 0.50 | 1.0 | 11.8 |
| 2.0 | 2.0 | 189.5 |

101. Consider the reaction

$$
3 \mathrm{~A}+\mathrm{B}+\mathrm{C} \longrightarrow \mathrm{D}+\mathrm{E}
$$

where the rate law is defined as

$$
-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]^{2}[\mathrm{~B}][\mathrm{C}]
$$

An experiment is carried out where $[\mathrm{B}]_{0}=[\mathrm{C}]_{0}=1.00 \mathrm{M}$ and $[\mathrm{A}]_{0}=1.00 \times 10^{-4} \mathrm{M}$.
a. If after $3.00 \mathrm{~min},[\mathrm{~A}]=3.26 \times 10^{-5} \mathrm{M}$, calculate the value of $k$.
b. Calculate the half-life for this experiment.
c. Calculate the concentration of B and the concentration of A after 10.0 min .

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
102. The thiosulfate ion $\left(\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\right)$ is oxidized by iodine as follows:

$$
2 \mathrm{~S}_{2} \mathrm{O}_{3}^{2-}(a q)+\mathrm{I}_{2}(a q) \longrightarrow \mathrm{S}_{4} \mathrm{O}_{6}^{2-}(a q)+2 \mathrm{I}^{-}(a q)
$$

In a certain experiment, $7.05 \times 10^{-3} \mathrm{~mol} / \mathrm{L}^{2}$ of $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$ is consumed in the first 11.0 seconds of the reaction. Calculate the rate of consumption of $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$. Calculate the rate of production of iodide ion.
103. The reaction $\mathrm{A}(a q)+\mathrm{B}(a q) \longrightarrow$ products was studied, and the following data were obtained:

| $[\mathrm{A}]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | $[\mathrm{B}]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: |
| 0.12 | 0.18 | $3.46 \times 10^{-2}$ |
| 0.060 | 0.12 | $1.15 \times 10^{-2}$ |
| 0.030 | 0.090 | $4.32 \times 10^{-3}$ |
| 0.24 | 0.090 | $3.46 \times 10^{-2}$ |

What is the order of the reaction with respect to A ? What is the order of the reaction with respect to $B$ ? What is the value of the rate constant for the reaction?
104. A certain substance, initially present at 0.0800 M , decomposes by zero-order kinetics with a rate constant of $2.50 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$. Calculate the time (in seconds) required for the system to reach a concentration of 0.0210 M .
105. A reaction of the form

$$
\text { aA } \longrightarrow \text { Products }
$$

gives a plot of $\ln [\mathrm{A}]$ versus time (in seconds), which is a straight line with a slope of $-7.35 \times 10^{-3}$. Assuming $[\mathrm{A}]_{0}=$ $0.0100 M$, calculate the time (in seconds) required for the reaction to reach $22.9 \%$ completion.
106. A certain reaction has the form

$$
\mathrm{aA} \longrightarrow \text { Products }
$$

At a particular temperature, concentration versus time data were collected. A plot of $1 /[\mathrm{A}]$ versus time (in seconds) gave a straight line with a slope of $6.90 \times 10^{-2}$. What is the differential rate law for this reaction? What is the integrated rate law for this reaction? What is the value of the rate constant for this reaction? If $[\mathrm{A}]_{0}$ for this reaction is 0.100 M , what is the first half-life (in seconds)? If the original concentration (at $t=0$ ) is 0.100 M , what is the second half-life (in seconds)?
107. Which of the following statement(s) is(are) true?
a. The half-life for a zero-order reaction increases as the reaction proceeds.
b. A catalyst does not change the value of $\Delta \mathrm{E}$.
c. The half-life for a reaction, $\mathrm{aA} \longrightarrow$ products, that is first order in A increases with increasing $[\mathrm{A}]_{0}$.
d. The half-life for a second-order reaction increases as the reaction proceeds.
108. Consider the hypothetical reaction $\mathrm{A}_{2}(g)+\mathrm{B}_{2}(g) \longrightarrow$ $2 \mathrm{AB}(\mathrm{g})$, where the rate law is:

$$
-\frac{\Delta\left[\mathrm{A}_{2}\right]}{\Delta t}=k\left[\mathrm{~A}_{2}\right]\left[\mathrm{B}_{2}\right]
$$

The value of the rate constant at $302^{\circ} \mathrm{C}$ is $2.45 \times 10^{-4} \mathrm{~L} / \mathrm{mol}$ s , and at $508^{\circ} \mathrm{C}$ the rate constant is $0.891 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$. What is the activation energy for this reaction? What is the value of the rate constant for this reaction at $375^{\circ} \mathrm{C}$ ?
109. Experiments have shown that the average frequency of chirping by a snowy tree cricket (Oecanthus fultoni) depends on temperature as shown in the table.

| Chirping Rate (per min) | Temperature $\left({ }^{\circ} \mathrm{C}\right)$ |
| :---: | :---: |
| 178 | 25.0 |
| 126 | 20.3 |
| 100. | 17.3 |

What is the apparent activation energy of the process that controls the chirping? What is the rate of chirping expected at a temperature of $7.5^{\circ} \mathrm{C}$ ?

## Challenge Problems

110. Consider a reaction of the type $\mathrm{aA} \longrightarrow$ products, in which the rate law is found to be rate $=k[\mathrm{~A}]^{3}$ (termolecular reactions are improbable but possible). If the first half-life of the reaction is found to be 40 . s, what is the time for the second half-life? Hint: Using your calculus knowledge, derive the integrated rate law from the differential rate law for a termolecular reaction:

$$
\text { Rate }=\frac{-d[\mathrm{~A}]}{d t}=k[\mathrm{~A}]^{3}
$$

111. A study was made of the effect of the hydroxide concentration on the rate of the reaction

$$
\mathrm{I}^{-}(a q)+\mathrm{OCl}^{-}(a q) \longrightarrow \mathrm{IO}^{-}(a q)+\mathrm{Cl}^{-}(a q)
$$

The following data were obtained:

| []$\left.^{-}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | $\left.[\mathrm{OCl}]_{0}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | $\left[\mathrm{OH}^{-}\right]_{0}$ <br> $(\mathrm{~mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: | :---: |
| 0.0013 | 0.012 | 0.10 | $9.4 \times 10^{-3}$ |
| 0.0026 | 0.012 | 0.10 | $18.7 \times 10^{-3}$ |
| 0.0013 | 0.0060 | 0.10 | $4.7 \times 10^{-3}$ |
| 0.0013 | 0.018 | 0.10 | $14.0 \times 10^{-3}$ |
| 0.0013 | 0.012 | 0.050 | $18.7 \times 10^{-3}$ |
| 0.0013 | 0.012 | 0.20 | $4.7 \times 10^{-3}$ |
| 0.0013 | 0.018 | 0.20 | $7.0 \times 10^{-3}$ |

Determine the rate law and the value of the rate constant for this reaction.
112. Two isomers ( $A$ and $B$ ) of a given compound dimerize as follows:

$$
\begin{aligned}
& 2 \mathrm{~A} \xrightarrow{k_{1}} A_{2} \\
& 2 \mathrm{~B} \xrightarrow{k_{2}} \mathrm{~B}_{2}
\end{aligned}
$$

Both processes are known to be second order in reactant, and $k_{1}$ is known to be $0.250 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$ at $25^{\circ} \mathrm{C}$. In a particular experiment A and B were placed in separate containers at $25^{\circ} \mathrm{C}$, where $[\mathrm{A}]_{0}=1.00 \times 10^{-2} \mathrm{M}$ and $[\mathrm{B}]_{0}=2.50 \times 10^{-2} \mathrm{M}$. It was found that after each reaction had progressed for $3.00 \mathrm{~min},[\mathrm{~A}]=3.00[\mathrm{~B}]$. In this case the rate laws are defined as

$$
\begin{aligned}
& \text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=k_{1}[\mathrm{~A}]^{2} \\
& \text { Rate }=-\frac{\Delta[\mathrm{B}]}{\Delta t}=k_{2}[\mathrm{~B}]^{2}
\end{aligned}
$$

a. Calculate the concentration of $\mathrm{A}_{2}$ after 3.00 min .
b. Calculate the value of $k_{2}$.
c. Calculate the half-life for the experiment involving A.
113. The reaction

$$
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

was studied by performing two experiments. In the first experiment the rate of disappearance of NO was followed in the presence of a large excess of $\mathrm{O}_{3}$. The results were as follows $\left(\left[\mathrm{O}_{3}\right]\right.$ remains effectively constant at $1.0 \times 10^{14}$ molecules $/ \mathrm{cm}^{3}$ ):

| Time <br> $(\mathrm{ms})$ | [NO] <br> $\left(\right.$ molecules $\left./ \mathrm{cm}^{3}\right)$ |
| :---: | :---: |
| 0 | $6.0 \times 10^{8}$ |
| $100 \pm 1$ | $5.0 \times 10^{8}$ |
| $500 \pm 1$ | $2.4 \times 10^{8}$ |
| $700 \pm 1$ | $1.7 \times 10^{8}$ |
| $1000 \pm 1$ | $9.9 \times 10^{7}$ |

In the second experiment [NO] was held constant at $2.0 \times 10^{14}$ molecules $/ \mathrm{cm}^{3}$. The data for the disappearance of $\mathrm{O}_{3}$ are as follows:

| Time <br> $(\mathrm{ms})$ | $\left[\mathrm{O}_{3}\right]$ <br> $\left(\mathrm{molecules} / \mathrm{cm}^{3}\right)$ |
| :---: | :---: |
| 0 | $1.0 \times 10^{10}$ |
| $50 \pm 1$ | $8.4 \times 10^{9}$ |
| $100 \pm 1$ | $7.0 \times 10^{9}$ |
| $200 \pm 1$ | $4.9 \times 10^{9}$ |
| $300 \pm 1$ | $3.4 \times 10^{9}$ |

a. What is the order with respect to each reactant?
b. What is the overall rate law?
c. What is the value of the rate constant from each set of experiments?

$$
\text { Rate }=k^{\prime}[\mathrm{NO}]^{x} \quad \text { Rate }=k^{\prime \prime}\left[\mathrm{O}_{3}\right]^{y}
$$

d. What is the value of the rate constant for the overall rate law?

$$
\text { Rate }=k[\mathrm{NO}]^{x}\left[\mathrm{O}_{3}\right]^{y}
$$

114. The reaction
$5 \mathrm{Br}^{-}(a q)+\mathrm{BrO}_{3}^{-}(a q)+6 \mathrm{H}^{+}(a q) \longrightarrow 3 \mathrm{Br}_{2}(l)+3 \mathrm{H}_{2} \mathrm{O}(l)$ is expected to obey the mechanism
$\mathrm{BrO}_{3}^{-}(a q)+\mathrm{H}^{+}(a q) \stackrel{k_{1}}{\stackrel{k_{1}}{\rightleftharpoons}} \mathrm{HBrO}_{3}(a q)$

> Fast equilibrium
$\mathrm{HBrO}_{3}(a q)+\mathrm{H}^{+}(a q) \stackrel{k_{2}}{\rightleftharpoons} \mathrm{H}_{2} \mathrm{BrO}_{3}^{+}(a q)$
Fast equilibrium
$\mathrm{Br}^{-}(a q)+\mathrm{H}_{2} \mathrm{BrO}_{3}^{+}(a q) \xrightarrow{k_{3}}\left(\mathrm{Br}-\mathrm{BrO}_{2}\right)(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
Slow
$\left(\mathrm{Br}-\mathrm{BrO}_{2}\right)(a q)+4 \mathrm{H}^{+}(a q)+4 \mathrm{Br}^{-}(a q) \longrightarrow$ products
Fast
Write the rate law for this reaction.
115. In the gas phase, the production of phosgene from chlorine and carbon monoxide is assumed to proceed by the following mechanism:

Overall reaction: $\mathrm{CO}+\mathrm{Cl}_{2} \longrightarrow \mathrm{COCl}_{2}$
a. Write the rate law for this reaction.
b. Which species are intermediates?
116. Most reactions occur by a series of steps. The energy profile for a certain reaction that proceeds by a two-step mechanism is

On the energy profile, indicate
a. the positions of reactants and products.
b. the activation energy for the overall reaction.
c. $\Delta E$ for the reaction.
d. Which point on the plot represents the energy of the intermediate in the two-step reaction?
e. Which step in the mechanism for this reaction is rate determining, the first or the second step? Explain.
117. You are studying the kinetics of the reaction $\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \rightarrow$ $2 \mathrm{HF}(g)$ and you wish to determine a mechanism for the reaction. You run the reaction twice by keeping one reactant at a much higher pressure than the other reactant (this lowerpressure reactant begins at 1.000 atm ). Unfortunately, you neglect to record which reactant was at the higher pressure, and you forget which it was later. Your data for the first experiment are:

| Pressure of HF <br> (atm) | Time <br> (min) |
| :---: | :---: |
| 0 | 0 |
| 0.300 | 30.0 |
| 0.600 | 65.8 |
| 0.900 | 110.4 |
| 1.200 | 169.1 |
| 1.500 | 255.9 |

When you ran the second experiment (in which the higherpressure reactant was run at a much higher pressure), you determine the values of the apparent rate constants to be the same. It also turns out that you find data taken from another person in the lab. This individual found that the reaction proceeds 40.0 times faster at $55^{\circ} \mathrm{C}$ than at $35^{\circ} \mathrm{C}$. You also know, from the energy-level diagram, that there are three steps to the mechanism, and the first step has the highest activation energy. You look up the bond energies of the species involved and they are (in $\mathrm{kJ} / \mathrm{mol}$ ): $\mathrm{H}-\mathrm{H}(432), \mathrm{F}-\mathrm{F}(154)$, and $\mathrm{H}-\mathrm{F}$ (565).
a. Sketch an energy-level diagram (qualitative) that is consistent with the one described previously. Hint: See Exercise 116.
b. Develop a reasonable mechanism for the reaction.
c. Which reactant was limiting in the experiments?
118. The decomposition of $\mathrm{NO}_{2}(g)$ occurs by the following bimolecular elementary reaction:

$$
2 \mathrm{NO}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

The rate constant at 273 K is $2.3 \times 10^{-12} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$, and the activation energy is $111 \mathrm{~kJ} / \mathrm{mol}$. How long will it take for the concentration of $\mathrm{NO}_{2}(g)$ to decrease from an initial partial pressure of 2.5 atm to 1.5 atm at 500 . K? Assume ideal gas behavior.
119. The following data were collected in two studies of the reaction

$$
2 \mathrm{~A}+\mathrm{B} \longrightarrow \mathrm{C}+\mathrm{D}
$$

| Time <br> $(\mathrm{s})$ | Experiment 1 <br> $[\mathrm{A}](\mathrm{mol} / \mathrm{L}) \times \mathbf{1 0}^{\mathbf{- 2}}$ | Experiment 2 <br> [A] (mol/L) $\times \mathbf{1 0}^{\mathbf{- 2}}$ |
| :---: | :---: | :---: |
| 0 | 10.0 | 10.0 |
| 20. | 6.67 | 5.00 |
| 40. | 5.00 | 3.33 |
| 60. | 4.00 | 2.50 |
| 80. | 3.33 | 2.00 |
| 100. | 2.86 | 1.67 |
| 120. | 2.50 | 1.43 |

In Experiment $1,[\mathrm{~B}]_{0}=5.0 \mathrm{M}$.
In Experiment 2, $[\mathrm{B}]_{0}=10.0 \mathrm{M}$.

$$
\text { Rate }=\frac{-\Delta[\mathrm{A}]}{\Delta t}
$$

a. Why is $[\mathrm{B}]$ much greater than $[\mathrm{A}]$ ?
b. Give the rate law and value for $k$ for this reaction.
c. Which of the following mechanisms could be correct for this reaction? Justify your choice.
i. $\quad \mathrm{A}+\mathrm{B} \rightleftharpoons \mathrm{E}$ (fast equilibrium)
$\mathrm{E}+\mathrm{B} \longrightarrow \mathrm{C}+\mathrm{D}$ (slow)
ii. $\mathrm{A}+\mathrm{B} \rightleftharpoons \mathrm{E}$ (fast equilibrium)
$\mathrm{E}+\mathrm{A} \longrightarrow \mathrm{C}+\mathrm{D}$ (slow)
iii. $\mathrm{A}+\mathrm{A} \longrightarrow \mathrm{E}$ (slow)
$\mathrm{E}+\mathrm{B} \longrightarrow \mathrm{C}+\mathrm{D}$ (fast)
120. Consider the following hypothetical data collected in two studies of the reaction

$$
2 \mathrm{~A}+2 \mathrm{~B} \longrightarrow \mathrm{C}+2 \mathrm{D}
$$

| Time <br> $(\mathrm{s})$ | Experiment 1 <br> $[\mathrm{A}](\mathrm{mol} / \mathrm{L})$ | Experiment 2 <br> [A] (mol/L) |
| :---: | :---: | :---: |
| 0 | $1.0 \times 10^{-2}$ | $1.0 \times 10^{-2}$ |
| 10. | $8.4 \times 10^{-3}$ | $5.0 \times 10^{-3}$ |
| 20. | $7.1 \times 10^{-3}$ | $2.5 \times 10^{-3}$ |
| 30. | $?$ | $1.3 \times 10^{-3}$ |
| 40. | $5.0 \times 10^{-3}$ | $6.3 \times 10^{-4}$ |

In Experiment $1,[\mathrm{~B}]_{0}=10.0 \mathrm{M}$.
In Experiment 2, $[\mathrm{B}]_{0}=20.0 \mathrm{M}$.

$$
\text { Rate }=\frac{-\Delta[\mathrm{A}]}{\Delta t}
$$

a. Use the concentration versus time data to determine the rate law for the reaction.
b. Solve for the value of the rate constant $(k)$ for the reaction. Include units.
c. Calculate the concentration of A in Experiment 1 at $t=30$. s.
121. Consider the hypothetical reaction

$$
\mathrm{A}+\mathrm{B}+2 \mathrm{C} \longrightarrow 2 \mathrm{D}+3 \mathrm{E}
$$

In a study of this reaction three experiments were run at the same temperature. The rate is defined as $-\Delta[\mathrm{B}] / \Delta t$.
Experiment 1 :

$$
[\mathrm{A}]_{0}=2.0 \mathrm{M} \quad[\mathrm{~B}]_{0}=1.0 \times 10^{-3} \mathrm{M} \quad[\mathrm{C}]_{0}=1.0 \mathrm{M}
$$

| [B] (mol/L) | Time (s) |
| :---: | :---: |
| $2.7 \times 10^{-4}$ | $1.0 \times 10^{5}$ |
| $1.6 \times 10^{-4}$ | $2.0 \times 10^{5}$ |
| $1.1 \times 10^{-4}$ | $3.0 \times 10^{5}$ |
| $8.5 \times 10^{-5}$ | $4.0 \times 10^{5}$ |
| $6.9 \times 10^{-5}$ | $5.0 \times 10^{5}$ |
| $5.8 \times 10^{-5}$ | $6.0 \times 10^{5}$ |

## Experiment 2:

$$
[\mathrm{A}]_{0}=1.0 \times 10^{-2} \mathrm{M} \quad[\mathrm{~B}]_{0}=3.0 \mathrm{M} \quad[\mathrm{C}]_{0}=1.0 \mathrm{M}
$$

| $[\mathrm{A}](\mathrm{mol} / \mathrm{L})$ | Time $(\mathrm{s})$ |
| :---: | :---: |
| $8.9 \times 10^{-3}$ | 1.0 |
| $7.1 \times 10^{-3}$ | 3.0 |
| $5.5 \times 10^{-3}$ | 5.0 |
| $3.8 \times 10^{-3}$ | 8.0 |
| $2.9 \times 10^{-3}$ | 10.0 |
| $2.0 \times 10^{-3}$ | 13.0 |

## Experiment 3.

$$
[\mathrm{A}]_{0}=10.0 \mathrm{M} \quad[\mathrm{~B}]_{0}=5.0 \mathrm{M} \quad[\mathrm{C}]_{0}=5.0 \times 10^{-1} \mathrm{M}
$$

| $[\mathrm{C}](\mathrm{mol} / \mathrm{L})$ | Time $(\mathrm{s})$ |
| :---: | :---: |
| 0.43 | $1.0 \times 10^{-2}$ |
| 0.36 | $2.0 \times 10^{-2}$ |
| 0.29 | $3.0 \times 10^{-2}$ |
| 0.22 | $4.0 \times 10^{-2}$ |
| 0.15 | $5.0 \times 10^{-2}$ |
| 0.08 | $6.0 \times 10^{-2}$ |

Write the rate law for this reaction, and calculate the value of the rate constant.
122. Hydrogen peroxide and the iodide ion react in acidic solution as follows:

$$
\mathrm{H}_{2} \mathrm{O}_{2}(a q)+3 \mathrm{I}^{-}(a q)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{I}_{3}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

The kinetics of this reaction were studied by following the decay of the concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$ and constructing plots of $\ln \left[\mathrm{H}_{2} \mathrm{O}_{2}\right]$ versus time. All the plots were linear and all solutions had $\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]_{0}=8.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L}$. The slopes of these straight lines depended on the initial concentrations of $\mathrm{I}^{-}$and $\mathrm{H}^{+}$. The results follow:

| []$\left.^{-}\right]_{0}(\mathrm{~mol} / \mathrm{L})$ | $\left[\mathrm{H}^{+}\right]_{0}(\mathrm{~mol} / \mathrm{L})$ | Slope $\left(\mathrm{min}^{-1}\right)$ |
| :---: | :---: | :---: |
| 0.1000 | 0.0400 | -0.120 |
| 0.3000 | 0.0400 | -0.360 |
| 0.4000 | 0.0400 | -0.480 |
| 0.0750 | 0.0200 | -0.0760 |
| 0.0750 | 0.0800 | -0.118 |
| 0.0750 | 0.1600 | -0.174 |

The rate law for this reaction has the form

$$
\text { Rate }=\frac{-\Delta\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]}{\Delta t}=\left(k_{1}+k_{2}\left[\mathrm{H}^{+}\right]\right)\left[\mathrm{I}^{-}\right]^{m}\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]^{n}
$$

a. Specify the order of this reaction with respect to $\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]$ and $\left[I^{-}\right]$.
b. Calculate the values of the rate constants, $k_{1}$ and $k_{2}$.
c. What reason could there be for the two-term dependence of the rate on $\left[\mathrm{H}^{+}\right]$?

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
123. Sulfuryl chloride undergoes first-order decomposition at $320 .{ }^{\circ} \mathrm{C}$ with a half-life of 8.75 h .

$$
\mathrm{SO}_{2} \mathrm{Cl}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g)+\mathrm{Cl}_{2}(g)
$$

What is the value of the rate constant, $k$, in $\mathrm{s}^{-1}$ ? If the initial pressure of $\mathrm{SO}_{2} \mathrm{Cl}_{2}$ is 791 torr and the decomposition occurs in a $1.25-\mathrm{L}$ container, how many molecules of $\mathrm{SO}_{2} \mathrm{Cl}_{2}$ remain after 12.5 h ?
124. Upon dissolving $\operatorname{InCl}(s)$ in $\mathrm{HCl}, \mathrm{In}^{+}(a q)$ undergoes a disproportionation reaction according to the following unbalanced equation:

$$
\operatorname{In}^{+}(a q) \longrightarrow \operatorname{In}(s)+\operatorname{In}^{3+}(a q)
$$

This disproportionation follows first-order kinetics with a half-life of 667 s . What is the concentration of $\operatorname{In}^{+}(a q)$ after 1.25 h if the initial solution of $\mathrm{In}^{+}(a q)$ was prepared by dissolving $2.38 \mathrm{~g} \mathrm{InCl}(s)$ in dilute HCl to make $5.00 \times 10^{2} \mathrm{~mL}$ of solution? What mass of $\operatorname{In}(s)$ is formed after 1.25 h ?
125. The decomposition of iodoethane in the gas phase proceeds according to the following equation:

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{I}(g) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{HI}(g)
$$

At $660 . \mathrm{K}, k=7.2 \times 10^{-4} \mathrm{~s}^{-1}$; at $720 . \mathrm{K}, k=1.7 \times 10^{-2} \mathrm{~s}^{-1}$. What is the value of the rate constant for this first-order decomposition at $325^{\circ} \mathrm{C}$ ? If the initial pressure of iodoethane is 894 torr at $245^{\circ} \mathrm{C}$, what is the pressure of iodoethane after three half-lives?

## Marathon Problem

This problem is designed to incorporate several concepts and techniques into one situation.
126. Consider the following reaction:

$$
\mathrm{CH}_{3} \mathrm{X}+\mathrm{Y} \longrightarrow \mathrm{CH}_{3} \mathrm{Y}+\mathrm{X}
$$

At $25^{\circ} \mathrm{C}$, the following two experiments were run, yielding the following data:
Experiment 1: $[\mathrm{Y}]_{0}=3.0 \mathrm{M}$
$\left.\begin{array}{|c|c|}\hline\left[\mathrm{CH}_{3} \mathrm{X}\right] \\ (\mathrm{mol} / \mathrm{L})\end{array} \begin{array}{c}\text { Time } \\ (\mathrm{h})\end{array}\right]$

Experiment 2: $[\mathrm{Y}]_{0}=4.5 \mathrm{M}$

| $\left[\mathrm{CH}_{3} \mathrm{X}\right]$ <br> $(\mathrm{mol} / \mathrm{L})$ | Time <br> $(\mathrm{h})$ |
| :--- | :--- |
| $4.50 \times 10^{-3}$ | 0 |
| $1.70 \times 10^{-3}$ | 1.0 |
| $4.19 \times 10^{-4}$ | 2.5 |
| $1.11 \times 10^{-4}$ | 4.0 |
| $2.81 \times 10^{-5}$ | 5.5 |

Experiments also were run at $85^{\circ} \mathrm{C}$. The value of the rate constant at $85^{\circ} \mathrm{C}$ was found to be $7.88 \times 10^{8}$ (with the time in units of hours), where $\left[\mathrm{CH}_{3} \mathrm{X}\right]_{0}=1.0 \times 10^{-2} \mathrm{M}$ and $[\mathrm{Y}]_{0}=3.0 \mathrm{M}$.
a. Determine the rate law and the value of $k$ for this reaction at $25^{\circ} \mathrm{C}$.
b. Determine the half-life at $85^{\circ} \mathrm{C}$.
c. Determine $E_{\mathrm{a}}$ for the reaction.
d. Given that the $\mathrm{C}-\mathrm{X}$ bond energy is known to be about $325 \mathrm{~kJ} / \mathrm{mol}$, suggest a mechanism that explains the results in parts a and c.

The equilibrium in a saltwater aquarium must be carefully maintained to keep the sea life healthy. (Borissos/Dreamstime.com)

n doing stoichiometry calculations we assumed that reactions proceed to completion, that is, until one of the reactants runs out. Many reactions do proceed essentially to completion. For such reactions it can be assumed that the reactants are quantitatively converted to products and that the amount of limiting reactant that remains is negligible. On the other hand, there are many chemical reactions that stop far short of completion. An example is the dimerization of nitrogen dioxide:

$$
\mathrm{NO}_{2}(g)+\mathrm{NO}_{2}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}_{4}(g)
$$

The reactant, $\mathrm{NO}_{2}$, is a dark brown gas, and the product, $\mathrm{N}_{2} \mathrm{O}_{4}$, is a colorless gas. When $\mathrm{NO}_{2}$ is placed in an evacuated, sealed glass vessel at $25^{\circ} \mathrm{C}$, the initial dark brown color decreases in intensity as it is converted to colorless $\mathrm{N}_{2} \mathrm{O}_{4}$. However, even over a long period of time, the contents of the reaction vessel do not become colorless. Instead, the intensity of the brown color eventually becomes constant, which means that the concentration of $\mathrm{NO}_{2}$ is no longer changing. This is illustrated on the molecular level in Fig. 13.1. This observation is a clear indication that the reaction has stopped short of completion. In fact, the system has reached chemical equilibrium, the state where the concentrations of all reactants and products remain constant with time.

Any chemical reactions carried out in a closed vessel will reach equilibrium. For some reactions the equilibrium position so favors the products that the reaction appears to have gone to completion. We say that the equilibrium position for such reactions lies far to the right (in the direction of the products). For example, when gaseous hydrogen and oxygen are mixed in stoichiometric quantities and react to form water vapor, the reaction proceeds essentially to completion. The amounts of the reactants that remain when the system reaches equilibrium are so tiny as to be negligible. By contrast, some reactions occur only to a slight extent. For example, when solid CaO is placed in a closed vessel at $25^{\circ} \mathrm{C}$, the decomposition to solid Ca and gaseous $\mathrm{O}_{2}$ is virtually undetectable. In cases like this, the equilibrium position is said to lie far to the left (in the direction of the reactants).

In this chapter we will discuss how and why a chemical system comes to equilibrium and the characteristics of equilibrium. In particular, we will discuss how to calculate the concentrations of the reactants and products present for a given system at equilibrium.

### 13.1 The Equilibrium Condition

Since no changes occur in the concentrations of reactants or products in a reaction system at equilibrium, it may appear that everything has stopped. However, this is not the case. On the molecular level, there is frantic activity. Equilibrium is not static but is a highly dynamic situation. The concept of chemical equilibrium is analogous to the flow of cars across a bridge connecting two island cities. Suppose the traffic flow on the bridge is the same in both directions. It is obvious that there is motion, since one

FIGURE 13.1 A molecular representation of the reaction $2 \mathrm{NO}_{2}(g) \rightarrow \mathrm{N}_{2} \mathrm{O}_{4}(g)$ over time in a closed vessel. Note that the numbers of $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$ in the container become constant (c and d) after sufficient time has passed.

FIGURE 13.2 The changes in concentrations with time for the reaction $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})+\mathrm{CO}(\mathrm{g}) \rightleftharpoons \mathrm{H}_{2}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g})$ when equimolar quantities of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ and $\mathrm{CO}(g)$ are mixed.

can see the cars traveling back and forth across the bridge, but the number of cars in each city is not changing because equal numbers of cars are entering and leaving. The result is no net change in the car population.

To see how this concept applies to chemical reactions, consider the reaction between steam and carbon monoxide in a closed vessel at a high temperature where the reaction takes place rapidly:

$$
\mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g)
$$

Assume that the same number of moles of gaseous CO and gaseous $\mathrm{H}_{2} \mathrm{O}$ are placed in a closed vessel and allowed to react. The plots of the concentrations of reactants and products versus time are shown in Fig. 13.2. Note that since CO and $\mathrm{H}_{2} \mathrm{O}$ were originally present in equal molar quantities, and since they react in a $1: 1$ ratio, the concentrations of the two gases are always equal. Also, since $\mathrm{H}_{2}$ and $\mathrm{CO}_{2}$ are formed in equal amounts, they are always present in the same concentrations.

Figure 13.2 is a profile of the progress of the reaction. When CO and $\mathrm{H}_{2} \mathrm{O}$ are mixed, they immediately begin to react to form $\mathrm{H}_{2}$ and $\mathrm{CO}_{2}$. This leads to a decrease in the concentrations of the reactants, but the concentrations of the products, which were initially at zero, are increasing. Beyond a certain time, indicated by the dashed line in Fig. 13.2, the concentrations of reactants and products no longer changeequilibrium has been reached. Unless the system is somehow disturbed, no further changes in concentrations will occur. Note that although the equilibrium position lies far to the right, the concentrations of reactants never go to zero; the reactants will always be present in small but constant concentrations. This is shown on the microscopic level in Fig. 13.3.

What would happen to the gaseous equilibrium mixture of reactants and products represented in Fig. 13.3, parts (c) and (d), if we injected some $\mathrm{H}_{2} \mathrm{O}(g)$ into the box? To answer this question, we need to be sure we understand the equilibrium condition: The concentrations of reactants and products remain constant at equilibrium because the forward and reverse reaction rates are equal. If we inject some $\mathrm{H}_{2} \mathrm{O}$ molecules, what will happen to the forward reaction: $\mathrm{H}_{2} \mathrm{O}+\mathrm{CO} \rightarrow \mathrm{H}_{2}+\mathrm{CO}_{2}$ ? It will speed up

FIGURE 13.3 (a) $\mathrm{H}_{2} \mathrm{O}$ and CO are mixed in equal numbers and begin to react $(\mathbf{b})$ to form $\mathrm{CO}_{2}$ and $\mathrm{H}_{2}$. After time has passed, equilibrium is reached (c) and the numbers of reactant and product molecules then remain constant over time (d).

FIGURE 13.4 The changes with time in the rates of forward and reverse reactions for $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})+\mathrm{CO}(\mathrm{g}) \rightleftharpoons \mathrm{H}_{2}(\mathrm{~g})+$ $\mathrm{CO}_{2}(g)$ when equimolar quantities of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ and $\mathrm{CO}(\mathrm{g})$ are mixed. The rates do not change in the same way with time because the forward reaction has a much larger rate constant than the reverse reaction.

[^27]The relationship between equilibrium and thermodynamics is explored in Section 16.8.

## The United States produces about 20 million tons of ammonia annually.

[^28]
because more $\mathrm{H}_{2} \mathrm{O}$ molecules means more collisions between $\mathrm{H}_{2} \mathrm{O}$ and CO molecules. This in turn will form more products and will cause the reverse reaction $\mathrm{H}_{2} \mathrm{O}+\mathrm{CO} \leftarrow \mathrm{H}_{2}+\mathrm{CO}_{2}$ to speed up. Thus the system will change until the forward and reverse reaction rates again become equal. Will this new equilibrium position contain more or fewer product molecules than are shown in Fig. 13.3(c) and (d)? Think about this carefully. If you are not sure of the answer now, keep reading. We will consider this type of situation in more detail later in this chapter.

Why does equilibrium occur? We saw in Chapter 12 that molecules react by colliding with one another, and the more collisions, the faster the reaction. This is why reaction rates depend on concentrations. In this case the concentrations of $\mathrm{H}_{2} \mathrm{O}$ and CO are lowered by the forward reaction:

$$
\mathrm{H}_{2} \mathrm{O}+\mathrm{CO} \longrightarrow \mathrm{H}_{2}+\mathrm{CO}_{2}
$$

As the concentrations of the reactants decrease, the forward reaction slows down (Fig. 13.4). As in the bridge traffic analogy, there is also a reverse direction:

$$
\mathrm{H}_{2} \mathrm{O}+\mathrm{CO} \longleftarrow \mathrm{H}_{2}+\mathrm{CO}_{2}
$$

Initially in this experiment no $\mathrm{H}_{2}$ and $\mathrm{CO}_{2}$ were present, and this reverse reaction could not occur. However, as the forward reaction proceeds, the concentrations of $\mathrm{H}_{2}$ and $\mathrm{CO}_{2}$ build up, and the rate of the reverse reaction increases (Fig. 13.4) as the forward reaction slows down. Eventually, the concentrations reach levels where the rate of the forward reaction equals the rate of the reverse reaction. The system has reached equilibrium.

The equilibrium position of a reaction-left, right, or somewhere in between-is determined by many factors: the initial concentrations, the relative energies of the reactants and products, and the relative degree of "organization" of the reactants and products. Energy and organization come into play because nature tries to achieve minimum energy and maximum disorder, as we will show in detail in Chapter 16. For now, we will simply view the equilibrium phenomenon in terms of the rates of opposing reactions.

## The Characteristics of Chemical Equilibrium

To explore the important characteristics of chemical equilibrium, we will consider the synthesis of ammonia from elemental nitrogen and hydrogen:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

This process is of great commercial value because ammonia is an important fertilizer for the growth of corn and other crops. Ironically, this beneficial process was discovered in Germany just before World War I in a search for ways to produce nitrogenbased explosives. In the course of this work, German chemist Fritz Haber (1868-1934) pioneered the large-scale production of ammonia.

When gaseous nitrogen, hydrogen, and ammonia are mixed in a closed vessel at $25^{\circ} \mathrm{C}$, no apparent change in the concentrations occurs over time, regardless of the original amounts of the gases. Why? There are two possible reasons why the

FIGURE 13.5 A concentration profile for the reaction $\mathrm{N}_{2}(g)+$ $3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)$ when only $\mathrm{N}_{2}(g)$ and $\mathrm{H}_{2}(g)$ are mixed initially.
concentrations of the reactants and products of a given chemical reaction remain unchanged when mixed.

1. The system is at chemical equilibrium.
2. The forward and reverse reactions are so slow that the system moves toward equilibrium at a rate that cannot be detected.

The second reason applies to the nitrogen, hydrogen, and ammonia mixture at $25^{\circ} \mathrm{C}$. As we saw in Chapters 8 and 9 , the $\mathrm{N}_{2}$ molecule has a very strong triple bond ( $941 \mathrm{~kJ} / \mathrm{mol}$ ) and thus is very unreactive. Also, the $\mathrm{H}_{2}$ molecule has an unusually strong single bond ( $432 \mathrm{~kJ} / \mathrm{mol}$ ). Therefore, mixtures of $\mathrm{N}_{2}, \mathrm{H}_{2}$, and $\mathrm{NH}_{3}$ at $25^{\circ} \mathrm{C}$ can exist with no apparent change over long periods of time, unless a catalyst is introduced to speed up the forward and reverse reactions. Under appropriate conditions, the system does reach equilibrium, as shown in Fig. 13.5. Note that because of the reaction stoichiometry, $\mathrm{H}_{2}$ disappears three times as fast as $\mathrm{N}_{2}$ does and $\mathrm{NH}_{3}$ forms twice as fast as $\mathrm{N}_{2}$ disappears.

### 13.2 The Equilibrium Constant

Science is fundamentally empirical-it is based on experiment. The development of the equilibrium concept is typical. From their observations of many chemical reactions, two Norwegian chemists, Cato Maximilian Guldberg (1836-1902) and Peter Waage (1833-1900), proposed in 1864 the law of mass action as a general description of the equilibrium condition. Guldberg and Waage postulated that for a reaction of the type

$$
j \mathrm{~A}+k \mathrm{~B} \rightleftharpoons l \mathrm{C}+m \mathrm{D}
$$

where $\mathrm{A}, \mathrm{B}, \mathrm{C}$, and D represent chemical species and $j, k, l$, and $m$ are their coefficients in the balanced equation, the law of mass action is represented by the following equilibrium expression:

$$
K=\frac{[\mathrm{C}]^{[ }[\mathrm{D}]^{m}}{[\mathrm{~A}]^{j}[\mathrm{~B}]^{k}}
$$

The square brackets indicate the concentrations of the chemical species at equilibrium, and $K$ is a constant called the equilibrium constant.

## INTERACTIVE EXAMPLE 13.1 Writing Equilibrium Expressions

Write the equilibrium expression for the following reaction:

$$
4 \mathrm{NH}_{3}(g)+7 \mathrm{O}_{2}(g) \rightleftharpoons 4 \mathrm{NO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
$$

SOLUTION Applying the law of mass action gives

The square brackets indicate concentration in units of $\mathrm{mol} / \mathrm{L}$.

The value of the equilibrium constant at a given temperature can be calculated if we know the equilibrium concentrations of the reaction components, as illustrated in Example 13.2.

It is very important to note at this point that the equilibrium constants are customarily given without units. The reason for this is beyond the scope of this text, but it involves corrections for the nonideal behavior of the substances taking part in the reaction. When these corrections are made, the units cancel out and the corrected $K$ has no units. Thus we will not use units for $K$ in this text.

## INTERACTIVE EXAMPLE 13.2 Calculating the Values of $\boldsymbol{K}$

The following equilibrium concentrations were observed for the Haber process for synthesis of ammonia at $127^{\circ} \mathrm{C}$ :

$$
\begin{aligned}
{\left[\mathrm{NH}_{3}\right] } & =3.1 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \\
{\left[\mathrm{~N}_{2}\right] } & =8.5 \times 10^{-1} \mathrm{~mol} / \mathrm{L} \\
{\left[\mathrm{H}_{2}\right] } & =3.1 \times 10^{-3} \mathrm{~mol} / \mathrm{L}
\end{aligned}
$$

a. Calculate the value of $K$ at $127^{\circ} \mathrm{C}$ for this reaction.
b. Calculate the value of the equilibrium constant at $127^{\circ} \mathrm{C}$ for the reaction

$$
2 \mathrm{NH}_{3}(g) \rightleftharpoons \mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g)
$$

c. Calculate the value of the equilibrium constant at $127^{\circ} \mathrm{C}$ for the reaction given by the equation

$$
\frac{1}{2} \mathrm{~N}_{2}(g)+\frac{3}{2} \mathrm{H}_{2}(g) \rightleftharpoons \mathrm{NH}_{3}(g)
$$

SOLUTION a. What is the balanced equation for the Haber process?

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

Thus

$$
\begin{aligned}
K & =\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}=\frac{\left(3.1 \times 10^{-2}\right)^{2}}{\left(8.5 \times 10^{-1}\right)\left(3.1 \times 10^{-3}\right)^{3}} \\
& =3.8 \times 10^{4}
\end{aligned}
$$

Note that $K$ is written without units.
b. What is the equilibrium expression? This reaction is written in the reverse order from the equation given in part a. This leads to the equilibrium expression

$$
K^{\prime}=\frac{\left[\mathrm{N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}{\left[\mathrm{NH}_{3}\right]^{2}}
$$

which is the reciprocal of the expression used in part a. Therefore,

$$
K^{\prime}=\frac{\left[\mathrm{N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}{\left[\mathrm{NH}_{3}\right]^{2}}=\frac{1}{K}=\frac{1}{3.8 \times 10^{4}}=2.6 \times 10^{-5}
$$

c. What is the equilibrium constant? We use the law of mass action:

$$
K^{\prime \prime}=\frac{\left[\mathrm{NH}_{3}\right]}{\left[\mathrm{N}_{2}\right]^{1 / 2}\left[\mathrm{H}_{2}\right]^{3 / 2}}
$$

If we compare this expression to that obtained in part a, we see that since

$$
\begin{aligned}
\frac{\left[\mathrm{NH}_{3}\right]}{\left[\mathrm{N}_{2}\right]^{1 / 2}\left[\mathrm{H}_{2}\right]^{3 / 2}} & =\left(\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}\right)^{1 / 2} \\
K^{\prime \prime} & =K^{1 / 2}
\end{aligned}
$$

Thus

$$
K^{\prime \prime}=K^{1 / 2}=\left(3.8 \times 10^{4}\right)^{1 / 2}=1.9 \times 10^{2}
$$

| TABLE 13.1 | Results of Three Experiments for the Reaction$\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})$ |  |  |
| :---: | :---: | :---: | :---: |
| Experiment | Initial Concentrations | Equilibrium Concentrations | $\boldsymbol{K}=\frac{\left[\mathrm{NH}_{3}\right]^{2}}{[\mathrm{M}]_{3}[\mathrm{IN}]^{3}}$ |
| 1 | $\begin{aligned} & {\left[\mathrm{N}_{2}\right]_{0}=1.000 \mathrm{M}} \\ & {\left[\mathrm{H}_{2}\right]_{0}=1.000 \mathrm{M}} \\ & {\left[\mathrm{NH}_{3}\right]_{0}=0} \end{aligned}$ | $\begin{aligned} & {\left[\mathrm{N}_{2}\right]=0.921 \mathrm{M}} \\ & {\left[\mathrm{H}_{2}\right]=0.763 \mathrm{M}} \\ & {\left[\mathrm{NH}_{3}\right]=0.157 \mathrm{M}} \end{aligned}$ | $K=6.02 \times 10^{-2}$ |
| II | $\begin{aligned} & {\left[\mathrm{N}_{2}\right]_{0}=0} \\ & {\left[\mathrm{H}_{2}\right]_{0}=0} \\ & {\left[\mathrm{NH}_{3}\right]_{0}=1.000 \mathrm{M}} \end{aligned}$ | $\begin{aligned} & {\left[\mathrm{N}_{2}\right]=0.399 \mathrm{M}} \\ & {\left[\mathrm{H}_{2}\right]=1.197 \mathrm{M}} \\ & {\left[\mathrm{NH}_{3}\right]=0.203 \mathrm{M}} \end{aligned}$ | $K=6.02 \times 10^{-2}$ |
| III | $\begin{aligned} & {\left[\mathrm{N}_{2}\right]_{0}=2.00 \mathrm{M}} \\ & {\left[\mathrm{H}_{2}\right]_{0}=1.00 \mathrm{M}} \\ & {\left[\mathrm{NH}_{3}\right]_{0}=3.00 \mathrm{M}} \end{aligned}$ | $\begin{aligned} & {\left[\mathrm{N}_{2}\right]=2.59 \mathrm{M}} \\ & {\left[\mathrm{H}_{2}\right]=2.77 \mathrm{M}} \\ & {\left[\mathrm{NH}_{3}\right]=1.82 \mathrm{M}} \end{aligned}$ | $K=6.02 \times 10^{-2}$ |

positions. The specific equilibrium position adopted by a system depends on the initial concentrations, but the equilibrium constant does not.

## EXAMPLE 13.3 Equilibrium Positions

The following results were collected for two experiments involving the reaction at $600^{\circ} \mathrm{C}$ between gaseous sulfur dioxide and oxygen to form gaseous sulfur trioxide:

| Experiment 1 |  |  |  |  |  |  | Experiment 2 |  |
| :--- | :--- | :--- | :--- | :--- | :---: | :---: | :---: | :---: |
| Initial | Equilibrium | Initial | Equilibrium |  |  |  |  |  |
| $\left[\mathrm{SO}_{2}\right]_{0}=2.00 \mathrm{M}$ | $\left[\mathrm{SO}_{2}\right]=1.50 \mathrm{M}$ |  | $\left[\mathrm{SO}_{2}\right]_{0}=0.500 \mathrm{M}$ | $\left[\mathrm{SO}_{2}\right]=0.590 \mathrm{M}$ |  |  |  |  |
| $\left[\mathrm{O}_{2}\right]_{0}=1.50 \mathrm{M}$ | $\left[\mathrm{O}_{2}\right]=1.25 \mathrm{M}$ | $\left[\mathrm{O}_{2}\right]_{0}=0$ | $\left[\mathrm{O}_{2}\right]=0.0450 \mathrm{M}$ |  |  |  |  |  |
| $\left[\mathrm{SO}_{3}\right]_{0}=3.00 \mathrm{M}$ | $\left[\mathrm{SO}_{3}\right]=3.50 \mathrm{M}$ | $\left[\mathrm{SO}_{3}\right]_{0}=0.350 \mathrm{M}$ | $\left[\mathrm{SO}_{3}\right]=0.260 \mathrm{M}$ |  |  |  |  |  |

Show that the equilibrium constant is the same in both cases.

## SOLUTION The balanced equation for the reaction is

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{SO}_{3}(g)
$$

From the law of mass action,

$$
K=\frac{\left[\mathrm{SO}_{3}\right]^{2}}{\left[\mathrm{SO}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]}
$$

For Experiment 1,

$$
K_{1}=\frac{(3.50)^{2}}{(1.50)^{2}(1.25)}=4.36
$$

For Experiment 2,

$$
K_{2}=\frac{(0.260)^{2}}{(0.590)^{2}(0.0450)}=4.32
$$

$\square$ The value of $K$ is constant, within experimental error.

# 13.3 Equilibrium Expressions Involving Pressures 

The ideal gas equation was discussed in Section 5.3.
$K$ involves concentrations; $K_{p}$ involves pressures. In some books, the symbol $K_{C}$ is used instead of $K$.

So far we have been describing equilibria involving gases in terms of concentrations. Equilibria involving gases also can be described in terms of pressures. The relationship between the pressure and the concentration of a gas can be seen from the ideal gas equation:

$$
P V=n R T \quad \text { or } \quad P=\left(\frac{n}{V}\right) R T=C R T
$$

where $C$ equals $n / V$, or the number of moles $n$ of gas per unit volume $V$. Thus $C$ represents the molar concentration of the gas.

For the ammonia synthesis reaction, the equilibrium expression can be written in terms of concentrations, that is,

$$
K=\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}=\frac{\left(C_{\mathrm{NH}_{3}}\right)^{2}}{\left(C_{\mathrm{N}_{2}}\right)\left(C_{\mathrm{H}_{2}}\right)^{3}}=K_{\mathrm{c}}
$$

or in terms of the equilibrium partial pressures of the gases, that is,

$$
K_{\mathrm{p}}=\frac{\left(P_{\mathrm{NH}_{3}}\right)^{2}}{\left(P_{\mathrm{N}_{2}}\right)\left(P_{\mathrm{H}_{2}}\right)^{3}}
$$

Both the symbols $K$ and $K_{\mathrm{c}}$ are used commonly for an equilibrium constant in terms of concentrations. We will always use $K$ in this book. The symbol $K_{\mathrm{p}}$ represents an equilibrium constant in terms of partial pressures.

## INTERACTIVE EXAMPLE 13.4

## Calculating Values of $\boldsymbol{K}_{\mathrm{p}}$

The reaction for the formation of nitrosyl chloride

$$
2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons 2 \mathrm{NOCl}(g)
$$

was studied at $25^{\circ} \mathrm{C}$. The pressures at equilibrium were found to be

$$
\begin{aligned}
P_{\mathrm{NOCl}} & =1.2 \mathrm{~atm} \\
P_{\mathrm{NO}} & =5.0 \times 10^{-2} \mathrm{~atm} \\
P_{\mathrm{Cl}_{2}} & =3.0 \times 10^{-1} \mathrm{~atm}
\end{aligned}
$$

Calculate the value of $K_{\mathrm{p}}$ for this reaction at $25^{\circ} \mathrm{C}$.

SOLUTION For this reaction,

$$
\begin{aligned}
K_{\mathrm{p}} & =\frac{\left(P_{\mathrm{NOC1}}\right)^{2}}{\left(P_{\mathrm{NO}_{2}}\right)^{2}\left(P_{\mathrm{Cl}_{2}}\right)}=\frac{(1.2)^{2}}{\left(5.0 \times 10^{-2}\right)^{2}\left(3.0 \times 10^{-1}\right)} \\
& =1.9 \times 10^{3}
\end{aligned}
$$

The relationship between $K$ and $K_{\mathrm{p}}$ for a particular reaction follows from the fact that for an ideal gas, $C=P / R T$. For example, for the ammonia synthesis reaction,

$$
\begin{aligned}
K & =\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}=\frac{\left(C_{\mathrm{NH}_{H}}\right)^{2}}{\left(C_{\mathrm{N}_{2}}\right)\left(C_{\mathrm{H}_{2}}\right)^{3}} \\
& =\frac{\left(\frac{P_{\mathrm{NH}_{3}}}{R T}\right)^{2}}{\left(\frac{P_{\mathrm{N}_{2}}}{R T}\right)\left(\frac{P_{\mathrm{H}_{2}}}{R T}\right)^{3}}=\frac{\left(P_{\mathrm{NH}_{3}}\right)^{2}}{\left(P_{\mathrm{N}_{2}}\right)\left(P_{\mathrm{H}_{2}}\right)^{3}} \times \frac{\left(\frac{1}{R T}\right)^{2}}{\left(\frac{1}{R T}\right)^{4}} \\
& =\frac{\left(P_{\mathrm{NH}_{3}}\right)^{2}}{\left(P_{\mathrm{N}_{2}}\left(P_{\mathrm{H}_{2}}\right)^{3}\right.}(R T)^{2} \\
& =K_{\mathrm{p}}(R T)^{2}
\end{aligned}
$$

However, for the synthesis of hydrogen fluoride from its elements,

$$
\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \rightleftharpoons 2 \mathrm{HF}(g)
$$

the relationship between $K$ and $K_{\mathrm{p}}$ is given by

$$
\begin{aligned}
K & =\frac{[\mathrm{HF}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{F}_{2}\right]}=\frac{\left(C_{\mathrm{HF}}\right)^{2}}{\left(C_{\mathrm{H}_{2}}\right)\left(C_{\mathrm{F}_{2}}\right)} \\
& =\frac{\left(\frac{P_{\mathrm{HF}}}{R T}\right)^{2}}{\left(\frac{P_{\mathrm{H}_{2}}}{R T}\right)\left(\frac{P_{\mathrm{F}_{2}}}{R T}\right)}=\frac{\left(P_{\mathrm{HF}}\right)^{2}}{\left(P_{\mathrm{H}_{2}}\right)\left(P_{\mathrm{F}_{2}}\right)} \\
& =K_{\mathrm{p}}
\end{aligned}
$$

Thus for this reaction, $K$ is equal to $K_{\mathrm{p}}$. This equality occurs because the sum of the coefficients on either side of the balanced equation is identical, so the terms in $R T$ cancel out. In the equilibrium expression for the ammonia synthesis reaction, the sum of the powers in the numerator is different from that in the denominator, and $K$ does not equal $K_{\mathrm{p}}$.

For the general reaction

$$
j \mathrm{~A}+k \mathrm{~B} \rightleftharpoons l \mathrm{C}+m \mathrm{D}
$$

the relationship between $K$ and $K_{\mathrm{p}}$ is

$$
K_{\mathrm{p}}=K(R T)^{\Delta n}
$$

where $\Delta n$ is the sum of the coefficients of the gaseous products minus the sum of the coefficients of the gaseous reactants. This equation is quite easy to derive from the definitions of $K$ and $K_{\mathrm{p}}$ and the relationship between pressure and concentration. For the preceding general reaction,

$$
\begin{aligned}
K_{\mathrm{p}} & =\frac{\left(P_{\mathrm{C}}^{l}\right)\left({\left.P_{\mathrm{D}}{ }^{m}\right)}_{\left(P_{\mathrm{A}}^{j}\right)\left(P_{\mathrm{B}}^{k}\right)}^{k^{2}}=\frac{\left(C_{\mathrm{C}} \times R T\right)^{l}\left(C_{\mathrm{D}} \times R T\right)^{m}}{\left(C_{\mathrm{A}} \times R T\right)^{j}\left(C_{\mathrm{B}} \times R T\right)^{k}}\right.}{} \\
& =\frac{\left(C_{\mathrm{C}}^{l}\right)\left(C_{\mathrm{D}}{ }^{m}\right)}{\left(C_{\mathrm{A}}^{j}\right)\left(C_{\mathrm{B}}^{k}\right)} \times \frac{(R T)^{l+m}}{(R T)^{j+k}}=K(R T)^{(l+m)-(j+k)} \\
& =K(R T)^{\Delta n}
\end{aligned}
$$

where $\Delta n=(l+m)-(j+k)$, the difference in the sums of the coefficients for the gaseous products and reactants.
$\Delta n$ always involves products minus reactants.
 which $K=K_{p}$. The text states this is true "because the sum of the coefficients on either side of the balanced equation is identical. ..." What if you are told that for a reaction, $K=K_{p}$, and the sum of the coefficients on either side of the balanced equation is not equal? How is this possible?

## INTERACTIVE EXAMPLE 13.5 Calculating $\boldsymbol{K}$ from $\boldsymbol{K}_{\mathrm{p}}$

Using the value of $K_{\mathrm{p}}$ obtained in Example 13.4, calculate the value of $K$ at $25^{\circ} \mathrm{C}$ for the reaction

$$
2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons 2 \mathrm{NOCl}(g)
$$

SOLUTION From the value of $K_{\mathrm{p}}$, we can calculate $K$ using

$$
K_{\mathrm{p}}=K(R T)^{\Delta n}
$$

where $T=25+273=298 \mathrm{~K}$ and

Thus

$$
\begin{aligned}
& \Delta n=2-(2+1)=-1 \\
& \text { Sum of Sum of } \\
& \text { product reactant } \\
& \text { coefficients coefficients } \\
& \Delta n \\
& K_{\mathrm{p}}=K(R T)^{-1}=\frac{K}{R T}
\end{aligned}
$$

and

$$
\begin{aligned}
K & =K_{\mathrm{p}}(R T) \\
& =\left(1.9 \times 10^{3}\right)(0.08206)(298) \\
& =4.6 \times 10^{4}
\end{aligned}
$$

### 13.4 Heterogeneous Equilibria

So far we have discussed equilibria only for systems in the gas phase, where all reactants and products are gases. These are homogeneous equilibria. However, many equilibria involve more than one phase and are called heterogeneous equilibria. For example, the thermal decomposition of calcium carbonate in the commercial preparation of lime occurs by a reaction involving both solid and gas phases:

$$
\mathrm{CaCO}_{3}(s) \rightleftharpoons \underset{\substack{\uparrow \\ \text { Lime }}}{\mathrm{CaO}(s)+\mathrm{CO}_{2}(g)}
$$

Straightforward application of the law of mass action leads to the equilibrium expression

$$
K^{\prime}=\frac{\left[\mathrm{CO}_{2}\right][\mathrm{CaO}]}{\left[\mathrm{CaCO}_{3}\right]}
$$

Lime is among the top five chemicals manufactured in the United States in terms of the amount produced.

The concentrations of pure liquids and solids are constant.

## A

The Seven Sisters chalk cliffs in East Sussex, England. The chalk is made up of compressed calcium carbonate skeletons of microscopic algae from the late Cretaceous Period.

However, experimental results show that the position of a heterogeneous equilibrium does not depend on the amounts of pure solids or liquids present (Fig. 13.6). The fundamental reason for this behavior is that the concentrations of pure solids and liquids cannot change. Thus the equilibrium expression for the decomposition of solid calcium carbonate might be represented as

$$
K^{\prime}=\frac{\left[\mathrm{CO}_{2}\right] C_{1}}{C_{2}}
$$

where $C_{1}$ and $C_{2}$ are constants representing the concentrations of the solids CaO and $\mathrm{CaCO}_{3}$, respectively. This expression can be rearranged to give

$$
\frac{C_{2} K^{\prime}}{C_{1}}=K=\left[\mathrm{CO}_{2}\right]
$$

We can generalize from this result as follows: If pure solids or pure liquids are involved in a chemical reaction, their concentrations are not included in the equilibrium expression for the reaction. This simplification occurs only with pure solids or liquids, not with solutions or gases, since in these last two cases the concentrations can vary.

For example, in the decomposition of liquid water to gaseous hydrogen and oxygen,

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

where

$$
K=\left[\mathrm{H}_{2}\right]^{2}\left[\mathrm{O}_{2}\right] \quad \text { and } \quad K_{\mathrm{p}}=\left(P_{\mathrm{H}_{2}}\right)^{2}\left(P_{\mathrm{O}_{2}}\right)
$$

water is not included in either equilibrium expression because it is a pure liquid. However, if the reaction were carried out under conditions where the water is a gas rather than a liquid, that is,

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

then

$$
K=\frac{\left[\mathrm{H}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]}{\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}} \quad \text { and } \quad K_{\mathrm{p}}=\frac{\left(P_{\mathrm{H}_{2}}\right)^{2}\left(P_{\mathrm{O}_{\mathrm{O}}}\right)}{\left(P_{\mathrm{H}_{2} \mathrm{O}}\right)^{2}}
$$

because the concentration or pressure of water vapor can change.

FIGURE 13.6 The position of the equilibrium $\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+$ $\mathrm{CO}_{2}(g)$ does not depend on the amounts of $\mathrm{CaCO}_{3}(s)$ and $\mathrm{CaO}(s)$ present.

## INTERACTIVE EXAMPLE 13.i Equilibrium Expressions for Heterogeneous Equilibria

Write the expressions for $K$ and $K_{\mathrm{p}}$ for the following processes:
a. Solid phosphorus pentachloride decomposes to liquid phosphorus trichloride and chlorine gas.
b. Deep blue solid copper(II) sulfate pentahydrate is heated to drive off water vapor to form white solid copper(II) sulfate.

## SOLUTION

## A

Water applied to anhydrous copper(II) sulfate forms the dark blue hydrated compound.
a. What is the balanced equation for the reaction?

$$
\mathrm{PCl}_{5}(s) \rightleftharpoons \mathrm{PCl}_{3}(l)+\mathrm{Cl}_{2}(g)
$$

What are the equilibrium expressions?

$$
\square K=\left[\mathrm{Cl}_{2}\right] \quad \text { and } \quad K_{\mathrm{p}}=P_{\mathrm{Cl}_{2}}
$$

In this case neither the pure solid $\mathrm{PCl}_{5}$ nor the pure liquid $\mathrm{PCl}_{3}$ is included in the equilibrium expressions.
b. What is the balanced equation for the reaction?

$$
\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}(s) \rightleftharpoons \mathrm{CuSO}_{4}(s)+5 \mathrm{H}_{2} \mathrm{O}(g)
$$

What are the equilibrium expressions?

$$
K=\left[\mathrm{H}_{2} \mathrm{O}\right]^{5} \quad \text { and } \quad K_{\mathrm{p}}=\left(P_{\mathrm{H}_{2} \mathrm{O}}\right)^{5}
$$

The solids are not included.

## See Exercises 13.37 and 13.38

### 13.5 Applications of the Equilibrium Constant

Knowing the equilibrium constant for a reaction allows us to predict several important features of the reaction: the tendency of the reaction to occur (but not the speed of the reaction), whether a given set of concentrations represents an equilibrium condition, and the equilibrium position that will be achieved from a given set of initial concentrations.

To introduce some of these ideas, we will first consider the reaction
where and represent two different types of atoms. Assume that this reaction has an equilibrium constant equal to 16 .

In a given experiment, the two types of molecules are mixed together in the following amounts:

After the system reacts and comes to equilibrium, what will the system look like? We know that at equilibrium the ratio

$$
\frac{\left(N_{\infty}\right)\left(N_{\infty}\right)}{\left(N_{\infty}\right)\left(N_{\infty}\right)}=16
$$

must be satisfied, where each $N$ represents the number of molecules of each type. We originally have 9 molecules and 12 molecules. As a place to start, let's just assume that 5 molecules disappear for the system to reach equilibrium. Since equal numbers of the and molecules react, this means that molecules also will disappear. This also means that $5 \bigodot$ molecules and 5 molecules will be formed. We can summarize as follows:

## Initial Conditions

9

12 $\infty$ molecules | 9 | molecules |
| ---: | :--- |
| 0 | molecules |
| 0 | molecules |

## New Conditions

$$
\begin{array}{r}
9-5=4 \quad \bigcirc \text { molecules } \\
12-5=7 \quad @ \text { molecules } \\
0+5=5 \\
0+5=5
\end{array} \begin{aligned}
& \text { molecules } \\
& 0+0
\end{aligned}
$$

Do the new conditions represent equilibrium for this reaction system? We can find out by taking the ratio of the numbers of molecules:

$$
\frac{\left(N_{\infty}\right)\left(N_{\infty}\right)}{\left(N_{\infty}\right)\left(N_{\infty}\right)}=\frac{(5)(5)}{(4)(7)}=0.9
$$

Thus this is not an equilibrium position because the ratio is not 16 , as required for equilibrium. In which direction must the system move to achieve equilibrium? Since the observed ratio is smaller than 16 , we must increase the numerator and decrease the denominator: The system needs to move to the right (toward more products) to achieve equilibrium. That is, more than 5 of the original reactant molecules must disappear to reach equilibrium for this system. How can we find the correct number? Since we do not know the number of molecules that need to disappear to reach equilibrium, let's call this number $x$. Now we can set up a table similar to the one we used earlier:

Initial Conditions

| $9 \propto$ molecules | $x \propto$ disappear |
| ---: | :--- |
| $12 \propto$ molecules | $x \propto$ disappear |
| $0 \&$ molecules | $x \&$ form |
| $0 \propto$ molecules | $x \propto$ form |

## Equilibrium Conditions

| $9-x$ | molecules |  |
| ---: | ---: | :--- |
| $12-x$ | molecules |  |
| $x$ | $\&$ molecules |  |
| $x$ | $\propto$ | molecules |

For the system to be at equilibrium, we know that the following ratio must be satisfied:

$$
\frac{\left(N_{\infty}\right)\left(N_{\infty}\right)}{\left(N_{\infty}\right)\left(N_{\infty}\right)}=16=\frac{(x)(x)}{(9-x)(12-x)}
$$

The easiest way to solve for $x$ here is by trial and error. From our previous discussion, we know that $x$ is greater than 5 . Also, we know that it must be less than 9 because we have only 9 molecules to start. We can't use all of them or we will have a zero in the denominator, which causes the ratio to be infinitely large. By trial and error, we find that $x=8$ because

$$
\frac{(x)(x)}{(9-x)(12-x)}=\frac{(8)(8)}{(9-8)(12-8)}=\frac{64}{4}=16
$$

a

FIGURE 13.7 (a) A physical analogy illustrating the difference between thermodynamic and kinetic stabilities. The boulder is thermodynamically more stable (lower potential energy) in position $B$ than in position $A$ but cannot get over the hump $H$. (b) The reactants $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ have a strong tendency to form $\mathrm{H}_{2} \mathrm{O}$.That is, $\mathrm{H}_{2} \mathrm{O}$ has lower energy than $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$. However, the large activation energy $E_{\mathrm{a}}$ prevents the reaction at $25^{\circ} \mathrm{C}$. In other words, the magnitude of $K$ for the reaction depends on $\Delta E$, but the reaction rate depends on $E_{\mathrm{a}}$.

The equilibrium mixture can be pictured as follows:

Note that it contains $8 \propto$ molecules, $8 \infty$ molecules, $1 \bigcirc$ molecule, and $4 \infty$ molecules as required.

This pictorial example should help you understand the fundamental ideas of equilibrium. Now we will proceed to a more systematic, quantitative treatment of chemical equilibrium.

## The Extent of a Reaction

The inherent tendency for a reaction to occur is indicated by the magnitude of the equilibrium constant. A value of $K$ much larger than 1 means that at equilibrium the reaction system will consist of mostly products-the equilibrium lies to the right. Another way of saying this is that reactions with very large equilibrium constants go essentially to completion. On the other hand, a very small value of $K$ means that the system at equilibrium will consist of mostly reactants-the equilibrium position is far to the left. The given reaction does not occur to any significant extent.

It is important to understand that the size of $K$ and the time required to reach equilibrium are not directly related. The time required to achieve equilibrium depends on the reaction rate, which is determined by the size of the activation energy. The size of $K$ is determined by thermodynamic factors such as the difference in energy between products and reactants. This difference is represented in Fig. 13.7 and will be discussed in detail in Chapter 16.

## Reaction Quotient

When the reactants and products of a given chemical reaction are mixed, it is useful to know whether the mixture is at equilibrium or, if not, the direction in which the system must shift to reach equilibrium. If the concentration of one of the reactants or products is zero, the system will shift in the direction that produces the missing component. However, if all the initial concentrations are nonzero, it is more difficult to determine the direction of the move toward equilibrium. To determine the shift in such cases, we use the reaction quotient, $\boldsymbol{Q}$. The reaction quotient is obtained by applying the law of mass action using initial concentrations instead of equilibrium concentrations. For example, for the synthesis of ammonia

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

the expression for the reaction quotient is

$$
Q=\frac{\left[\mathrm{NH}_{3}\right]_{0}^{2}}{\left[\mathrm{~N}_{2}\right]_{0}\left[\mathrm{H}_{2}\right]_{0}^{3}}
$$

where the subscript zeros indicate initial concentrations.
To determine in which direction a system will shift to reach equilibrium, we compare the values of $Q$ and $K$. There are three possible cases (Fig. 13.8):

1. $Q$ is equal to $K$. The system is at equilibrium; no shift will occur.
2. $Q$ is greater than $K$. In this case, the ratio of initial concentrations of products to initial concentrations of reactants is too large. To reach equilibrium, a net change of products to reactants must occur. The system shifts to the left, consuming products and forming reactants, until equilibrium is achieved.

FIGURE 13.8 The relationship between reaction quotient $Q$ and the equilibrium constant $K$.

3. $Q$ is less than $K$. In this case, the ratio of initial concentrations of products to initial concentrations of reactants is too small. The system must shift to the right, consuming reactants and forming products, to attain equilibrium.

## INTERACTIVE EXAMPLE 13.7 Using the Reaction Quotient

For the synthesis of ammonia at $500^{\circ} \mathrm{C}$, the equilibrium constant is $6.0 \times 10^{-2}$. Predict the direction in which the system will shift to reach equilibrium in each of the following cases:
a. $\left[\mathrm{NH}_{3}\right]_{0}=1.0 \times 10^{-3} \mathrm{M} ;\left[\mathrm{N}_{2}\right]_{0}=1.0 \times 10^{-5} \mathrm{M} ;\left[\mathrm{H}_{2}\right]_{0}=2.0 \times 10^{-3} \mathrm{M}$
b. $\left[\mathrm{NH}_{3}\right]_{0}=2.00 \times 10^{-4} \mathrm{M} ;\left[\mathrm{N}_{2}\right]_{0}=1.50 \times 10^{-5} \mathrm{M} ;\left[\mathrm{H}_{2}\right]_{0}=3.54 \times 10^{-1} \mathrm{M}$
c. $\left[\mathrm{NH}_{3}\right]_{0}=1.0 \times 10^{-4} \mathrm{M} ;\left[\mathrm{N}_{2}\right]_{0}=5.0 \mathrm{M} ;\left[\mathrm{H}_{2}\right]_{0}=1.0 \times 10^{-2} \mathrm{M}$

SOLUTION a. What is the value of $Q$ ?

$$
\begin{aligned}
Q & =\frac{\left[\mathrm{NH}_{3}\right]_{0}^{2}}{\left[\mathrm{~N}_{2}\right]_{0}\left[\mathrm{H}_{2}\right]_{0}^{3}}=\frac{\left(1.0 \times 10^{-3}\right)^{2}}{\left(1.0 \times 10^{-5}\right)\left(2.0 \times 10^{-3}\right)^{3}} \\
& =1.3 \times 10^{7}
\end{aligned}
$$

Since $K=6.0 \times 10^{-2}, Q$ is much greater than $K$. To attain equilibrium, the concentrations of the products must be decreased and the concentrations of the reactants increased. The system will shift to the left:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longleftarrow 2 \mathrm{NH}_{3}(g)
$$

b. What is the value of $Q$ ?

$$
\begin{aligned}
Q & =\frac{\left[\mathrm{NH}_{3}\right]_{0}^{2}}{\left[\mathrm{~N}_{2}\right]_{0}\left[\mathrm{H}_{2}\right]_{0}^{3}}=\frac{\left(2.00 \times 10^{-4}\right)^{2}}{\left(1.50 \times 10^{-5}\right)\left(3.54 \times 10^{-1}\right)^{3}} \\
& =6.01 \times 10^{-2}
\end{aligned}
$$

$\square$ In this case $Q=K$, so the system is at equilibrium. No shift will occur.
c. What is the value of $Q$ ?

$$
\begin{aligned}
Q & =\frac{\left[\mathrm{NH}_{3}\right]_{0}^{2}}{\left[\mathrm{~N}_{2}\right]_{0}\left[\mathrm{H}_{2}\right]_{0}^{3}}=\frac{\left(1.0 \times 10^{-4}\right)^{2}}{(5.0)\left(1.0 \times 10^{-2}\right)^{3}} \\
& =2.0 \times 10^{-3}
\end{aligned}
$$

Here $Q$ is less than $K$, so the system will shift to the right to attain equilibrium by increasing the concentration of the product and decreasing the reactant concentrations:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
$$

## Calculating Equilibrium Pressures and Concentrations

A typical equilibrium problem involves finding the equilibrium concentrations (or pressures) of reactants and products, given the value of the equilibrium constant and the initial concentrations (or pressures). However, since such problems sometimes become complicated mathematically, we will develop useful strategies for solving them by considering cases for which we know one or more of the equilibrium concentrations (or pressures).

## INTERACTIVE EXAMPLE 13.8 Calculating Equilibrium Pressures I

Dinitrogen tetroxide in its liquid state was used as one of the fuels on the lunar lander for the NASA Apollo missions. In the gas phase, it decomposes to gaseous nitrogen dioxide:

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g)
$$

Consider an experiment in which gaseous $\mathrm{N}_{2} \mathrm{O}_{4}$ was placed in a flask and allowed to reach equilibrium at a temperature where $K_{\mathrm{p}}=0.133$. At equilibrium, the pressure of $\mathrm{N}_{2} \mathrm{O}_{4}$ was found to be 2.71 atm . Calculate the equilibrium pressure of $\mathrm{NO}_{2}(g)$.

SOLUTION

We know that the equilibrium pressures of the gases $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$ must satisfy the relationship

$$
K_{\mathrm{p}}=\frac{P_{\mathrm{NO}_{2}}^{2}}{P_{\mathrm{N}_{2} \mathrm{O}_{4}}}=0.133
$$

Since we know $P_{\mathrm{N}_{2} \mathrm{O}_{4}}$, we can simply solve for $P_{\mathrm{NO}_{2}}$ :

$$
P_{\mathrm{NO}_{2}}^{2}=K_{\mathrm{p}}\left(P_{\mathrm{N}_{2} \mathrm{O}_{4}}\right)=(0.133)(2.71)=0.360
$$

Therefore,

$$
\square P_{\mathrm{NO}_{2}}=\sqrt{0.360}=0.600
$$

Apollo II lunar landing module at Tranquility Base, 1969.

## INTERACTVE EXAMPLE 13.9 Calculating Equilibrium Pressures II

At a certain temperature, a 1.00 -L flask initially contained 0.298 mole of $\mathrm{PCl}_{3}(g)$ and $8.70 \times 10^{-3}$ mole of $\mathrm{PCl}_{5}(\mathrm{~g})$. After the system had reached equilibrium, $2.00 \times 10^{-3}$ mole of $\mathrm{Cl}_{2}(\mathrm{~g})$ was found in the flask. Gaseous $\mathrm{PCl}_{5}$ decomposes according to the reaction

$$
\begin{aligned}
& \mathrm{PCl}_{5}(g) \rightleftharpoons \mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \\
& \rightleftharpoons
\end{aligned}
$$

Calculate the equilibrium concentrations of all species and the value of $K$.

What is the equilibrium expression for this reaction?

$$
K=\frac{\left[\mathrm{Cl}_{2}\right]\left[\mathrm{PCl}_{3}\right]}{\left[\mathrm{PCl}_{5}\right]}
$$

To find the value of $K$, we must calculate the equilibrium concentrations of all species and then substitute these quantities into the equilibrium expression. The best method for finding the equilibrium concentrations is to begin with the initial concentrations, which we will define as the concentrations before any shift toward equilibrium has occurred. We will then modify these initial concentrations appropriately to find the equilibrium concentrations.

What are the initial concentrations?

$$
\begin{aligned}
{\left[\mathrm{Cl}_{2}\right]_{0} } & =0 \\
{\left[\mathrm{PCl}_{3}\right]_{0} } & =\frac{0.298 \mathrm{~mol}}{1.00 \mathrm{~L}}=0.298 \mathrm{M} \\
{\left[\mathrm{PCl}_{5}\right]_{0} } & =\frac{8.70 \times 10^{-3} \mathrm{~mol}}{1.00 \mathrm{~L}}=8.70 \times 10^{-3} \mathrm{M}
\end{aligned}
$$

What change is required to reach equilibrium?
Since no $\mathrm{Cl}_{2}$ was initially present but $2.00 \times 10^{-3} \mathrm{M} \mathrm{Cl}_{2}$ is present at equilibrium, $2.00 \times 10^{-3}$ mole of $\mathrm{PCl}_{5}$ must have decomposed to form $2.00 \times 10^{-3}$ mole of $\mathrm{Cl}_{2}$ and $2.00 \times 10^{-3}$ mole of $\mathrm{PCl}_{3}$. In other words, to reach equilibrium, the reaction shifted to the right:

$$
\begin{aligned}
& \mathrm{PCl}_{5}(g) \quad \longrightarrow \quad \mathrm{PCl}_{3}(g) \quad+\quad \mathrm{Cl}_{2}(g) \\
& 2.00 \times \underset{\substack{\uparrow \\
\text { Net amount of } \mathrm{PCl}_{5} \\
\text { decomposed }}}{10^{-3} \mathrm{~mol} \longrightarrow 2.00 \times 10^{-3} \mathrm{~mol}+\underset{\nearrow}{\text { Net amounts of }}} \underset{\begin{array}{c}
\text { Neducts formed }
\end{array}}{2.00} \times 10^{-3} \mathrm{~mol}
\end{aligned}
$$

Now we apply this change to the initial concentrations.
What are the equilibrium concentrations?

$$
\begin{aligned}
& \square\left[\mathrm{Cl}_{2}\right]=0+\frac{2.00 \times 10^{-3} \mathrm{~mol}}{1.00 \mathrm{~L}}=2.00 \times 10^{-3} \mathrm{M} \\
& \square\left[\mathrm{PCl}_{3}\right]=\underset{\substack{\uparrow \\
\left[\mathrm{PCl}_{3}\right]_{0}}}{0.298 \mathrm{M}+\frac{2.00 \times 10^{-3} \mathrm{~mol}}{1.00 \mathrm{~L}}=0.300 \mathrm{M}} \\
& \square\left[\mathrm{PCl}_{5}\right]=\underset{\substack{ \\
\left[\mathrm{PCl}_{5}\right]_{0}}}{8.70 \times 10^{-3} \mathrm{M}-\frac{2.00 \times 10^{-3} \mathrm{~mol}}{1.00 \mathrm{~L}}=6.70 \times 10^{-3} \mathrm{M}} \mathrm{C}
\end{aligned}
$$

What is the value of $K$ ?

- The equilibrium concentrations are substituted into the equilibrium expression:

$$
\begin{aligned}
K & =\frac{\left[\mathrm{Cl}_{2}\right]\left[\mathrm{PCl}_{3}\right]}{\left[\mathrm{PCl}_{5}\right]}=\frac{\left(2.00 \times 10^{-3}\right)(0.300)}{6.70 \times 10^{-3}} \\
& =8.96 \times 10^{-2}
\end{aligned}
$$

Sometimes we are not given any of the equilibrium concentrations (or pressures), only the initial values. Then we must use the stoichiometry of the reaction to express concentrations (or pressures) at equilibrium in terms of the initial values. This is illustrated in Example 13.10.

## INTERACTIVE EXAMPLE 13.10 Calculating Equilibrium Concentrations I

Carbon monoxide reacts with steam to produce carbon dioxide and hydrogen. At 700 K the equilibrium constant is 5.10 . Calculate the equilibrium concentrations of all species if 1.000 mol of each component is mixed in a $1.000-\mathrm{L}$ flask.

## SOLUTION

What is the balanced equation for the reaction?

$$
\mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g)
$$

What is the equilibrium expression?

$$
K=\frac{\left[\mathrm{CO}_{2}\right]\left[\mathrm{H}_{2}\right]}{[\mathrm{CO}]\left[\mathrm{H}_{2} \mathrm{O}\right]}=5.10
$$

What are the initial concentrations?

$$
[\mathrm{CO}]_{0}=\left[\mathrm{H}_{2} \mathrm{O}\right]_{0}=\left[\mathrm{CO}_{2}\right]_{0}=\left[\mathrm{H}_{2}\right]_{0}=\frac{1.000 \mathrm{~mol}}{1.000 \mathrm{~L}}=1.000 \mathrm{M}
$$

Is the system at equilibrium, and if not, which way will it shift to reach the equilibrium position? These questions can be answered by calculating $Q$ :

$$
Q=\frac{\left[\mathrm{CO}_{2}\right]_{0}\left[\mathrm{H}_{2}\right]_{0}}{[\mathrm{CO}]_{0}\left[\mathrm{H}_{2} \mathrm{O}\right]_{0}}=\frac{(1.000 \mathrm{~mol} / \mathrm{L})(1.000 \mathrm{~mol} / \mathrm{L})}{(1.000 \mathrm{~mol} / \mathrm{L})(1.000 \mathrm{~mol} / \mathrm{L})}=1.000
$$

Since $Q$ is less than $K$, the system is not at equilibrium initially but must shift to the right.

What are the equilibrium concentrations?
As before, we start with the initial concentrations and modify them to obtain the equilibrium concentrations. We must ask this question: How much will the system shift to the right to attain the equilibrium condition? In Example 13.9 the change needed for the system to reach equilibrium was given. However, in this case we do not have this information.

Since the required change in concentrations is unknown at this point, we will define it in terms of $x$. Let's assume that $x \mathrm{~mol} / \mathrm{L} \mathrm{CO}$ must react for the system to reach equilibrium. This means that the initial concentration of CO will decrease by $x \mathrm{~mol} / \mathrm{L}$ :

$$
\begin{gathered}
{[\mathrm{CO}]=[\mathrm{CO}]_{0}-x} \\
\uparrow \\
\text { Equilibrium } \\
\uparrow \begin{array}{c}
\uparrow \text { Initial } \\
\text { Change }
\end{array}
\end{gathered}
$$

Since each CO molecule reacts with one $\mathrm{H}_{2} \mathrm{O}$ molecule, the concentration of water vapor also must decrease by $x \mathrm{~mol} / \mathrm{L}$ :

$$
\left[\mathrm{H}_{2} \mathrm{O}\right]=\left[\mathrm{H}_{2} \mathrm{O}\right]_{0}-x
$$

As the reactant concentrations decrease, the product concentrations increase. Since all the coefficients are 1 in the balanced reaction, 1 mole of $\mathrm{CO}_{2}$ reacting with 1 mole of $\mathrm{H}_{2} \mathrm{O}$ will produce 1 mole of $\mathrm{CO}_{2}$ and 1 mole of $\mathrm{H}_{2}$. Or in the present case, to reach equilibrium, $x \mathrm{~mol} / \mathrm{L} \mathrm{CO}$ will react with $x \mathrm{~mol} / \mathrm{L}_{2} \mathrm{O}$ to give an additional $x \mathrm{~mol} / \mathrm{L}$ $\mathrm{CO}_{2}$ and $x \mathrm{~mol} / \mathrm{L} \mathrm{H}_{2}$ :

$$
x \mathrm{CO}+x \mathrm{H}_{2} \mathrm{O} \longrightarrow x \mathrm{CO}_{2}+x \mathrm{H}_{2}
$$

Thus the initial concentrations of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2}$ will increase by $x \mathrm{~mol} / \mathrm{L}$ :

$$
\begin{aligned}
{\left[\mathrm{CO}_{2}\right] } & =\left[\mathrm{CO}_{2}\right]_{0}+x \\
{\left[\mathrm{H}_{2}\right] } & =\left[\mathrm{H}_{2}\right]_{0}+x
\end{aligned}
$$

Now we have all the equilibrium concentrations defined in terms of the initial concentrations and the change $x$ :

| Initial <br> Concentration <br> $(\mathrm{mol} / \mathrm{L})$ | Change <br> (mol/L) | Equilibrium <br> Concentration <br> (mol/L) |
| :---: | :---: | :---: |
| $[\mathrm{CO}]_{0}=1.000$ | $-x$ | $1.000-x$ |
| $\left[\mathrm{H}_{2} \mathrm{O}\right]_{0}=1.000$ | $-x$ | $1.000-x$ |
| $\left[\mathrm{CO}_{2}\right]_{0}=1.000$ | $+x$ | $1.000+x$ |
| $\left[\mathrm{H}_{2}\right]_{0}=1.000$ | $+x$ | $1.000+x$ |

Note that the sign of $x$ is determined by the direction of the shift. In this example, the system shifts to the right, so the product concentrations increase and the reactant concentrations decrease. Also note that because the coefficients in the balanced equation are all 1 , the magnitude of the change is the same for all species.

Now since we know that the equilibrium concentrations must satisfy the equilibrium expression, we can find the value of $x$ by substituting these concentrations into the expression

$$
K=5.10=\frac{\left[\mathrm{CO}_{2}\right]\left[\mathrm{H}_{2}\right]}{[\mathrm{CO}]\left[\mathrm{H}_{2} \mathrm{O}\right]}=\frac{(1.000+x)(1.000+x)}{(1.000-x)(1.000-x)}=\frac{(1.000+x)^{2}}{(1.000-x)^{2}}
$$

Since the right side of the equation is a perfect square, the solution of the problem can be simplified by taking the square root of both sides:

$$
\sqrt{5.10}=2.26=\frac{1.000+x}{1.000-x}
$$

Multiplying and collecting terms gives

$$
x=0.387 \mathrm{~mol} / \mathrm{L}
$$

Thus the system shifts to the right, consuming $0.387 \mathrm{~mol} / \mathrm{L} \mathrm{CO}$ and $0.387 \mathrm{~mol} / \mathrm{L} \mathrm{H}_{2} \mathrm{O}$ and forming $0.387 \mathrm{~mol} / \mathrm{L} \mathrm{CO}_{2}$ and $0.387 \mathrm{~mol} / \mathrm{L} \mathrm{H}_{2}$.

Now the equilibrium concentrations can be calculated:

$$
\begin{aligned}
& {[\mathrm{CO}]=\left[\mathrm{H}_{2} \mathrm{O}\right]=1.000-x=1.000-0.387=0.613 \mathrm{M}} \\
& \square\left[\mathrm{CO}_{2}\right]=\left[\mathrm{H}_{2}\right]=1.000+x=1.000+0.387=1.387 \mathrm{M}
\end{aligned}
$$

Reality Check These values can be checked by substituting them back into the equilibrium expression to make sure they give the correct value for $K$ :

$$
K=\frac{\left[\mathrm{CO}_{2}\right]\left[\mathrm{H}_{2}\right]}{[\mathrm{CO}]\left[\mathrm{H}_{2} \mathrm{O}\right]}=\frac{(1.387)^{2}}{(0.613)^{2}}=5.12
$$

This result is the same as the given value of $K$ (5.10) within round-off error, so the answer must be correct.

## INTERACTIVE EXAMPLE 13.11

## SOLUTION

We often refer to this form as an ICE table (indicated by the first letters of Initial, Change, and Equilibrium).

## Calculating Equilibrium Concentrations II

Assume that the reaction for the formation of gaseous hydrogen fluoride from hydrogen and fluorine has an equilibrium constant of $1.15 \times 10^{2}$ at a certain temperature. In a particular experiment, 3.000 moles of each component were added to a $1.500-\mathrm{L}$ flask. Calculate the equilibrium concentrations of all species.
What is the balanced equation for the reaction?

$$
\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \rightleftharpoons 2 \mathrm{HF}(g)
$$

What is the equilibrium expression?

$$
K=1.15 \times 10^{2}=\frac{[\mathrm{HF}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{F}_{2}\right]}
$$

What are the initial concentrations?

$$
[\mathrm{HF}]_{0}=\left[\mathrm{H}_{2}\right]_{0}=\left[\mathrm{F}_{2}\right]_{0}=\frac{3.000 \mathrm{~mol}}{1.500 \mathrm{~L}}=2.000 \mathrm{M}
$$

What is the value of $Q$ ?

$$
Q=\frac{[\mathrm{HF}]_{0}^{2}}{\left[\mathrm{H}_{2}\right]_{0}\left[\mathrm{~F}_{2}\right]_{0}}=\frac{(2.000)^{2}}{(2.000)(2.000)}=1.000
$$

Since $Q$ is much less than $K$, the system must shift to the right to reach equilibrium.
What change in the concentrations is necessary?
Since this is presently unknown, we will define the change needed in terms of $x$. Let $x$ equal the number of moles per liter of $\mathrm{H}_{2}$ consumed to reach equilibrium. The stoichiometry of the reaction shows that $x \mathrm{~mol} / \mathrm{L} \mathrm{F}_{2}$ also will be consumed and $2 x \mathrm{~mol} / \mathrm{L} \mathrm{HF}$ will be formed:

$$
\begin{aligned}
\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) & \longrightarrow 2 \mathrm{HF}(g) \\
x \mathrm{~mol} / \mathrm{L}+x \mathrm{~mol} / \mathrm{L} & \longrightarrow 2 x \mathrm{~mol} / \mathrm{L}
\end{aligned}
$$

Now the equilibrium concentrations can be expressed in terms of $x$ :

| Initial <br> Concentration <br> $(\mathrm{mol} / \mathrm{L})$ | Change <br> $(\mathrm{mol} / \mathrm{L})$ | Equilibrium <br> Concentration <br> $(\mathrm{mol} / \mathrm{L})$ |
| :---: | :---: | :---: |
| $\left[\mathrm{H}_{2}\right]_{0}=2.000$ | $-x$ | $\left[\mathrm{H}_{2}\right]=2.000-x$ |
| $\left[\mathrm{~F}_{2}\right]_{0}=2.000$ | $-x$ | $\left[\mathrm{~F}_{2}\right]=2.000-x$ |
| $[\mathrm{HF}]_{0}=2.000$ | $+2 x$ | $[\mathrm{HF}]=2.000+2 x$ |

These concentrations can be represented in a shorthand table as follows:

|  | $\mathrm{H}_{2}(g)$ | + | $\mathrm{F}_{2}(g)$ | $\rightleftharpoons$ | $2 \mathrm{HF}(g)$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Initial | 2.000 |  | 2.000 |  | 2.000 |
| Change | $-x$ |  | $-x$ |  | $+2 x$ |
| Equilibrium | $2.000-x$ | $2.000-x$ |  | $2.000+2 x$ |  |

What is the value of $x$ ?
To solve for $x$, we substitute the equilibrium concentrations into the equilibrium expression:

$$
K=1.15 \times 10^{2}=\frac{[\mathrm{HF}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{F}_{2}\right]}=\frac{(2.000+2 x)^{2}}{(2.000-x)^{2}}
$$

The right side of this equation is a perfect square, so taking the square root of both sides gives

$$
\sqrt{1.15 \times 10^{2}}=\frac{2.000+2 x}{2.000-x}
$$

which yields $x=1.528$.
What are the equilibrium concentrations?

$$
\begin{aligned}
& {\left[\mathrm{H}_{2}\right]=\left[\mathrm{F}_{2}\right]=2.000 M-x=0.472 M} \\
& {[\mathrm{HF}]=2.000 M+2 x=5.056 \mathrm{M}}
\end{aligned}
$$

Reality Check Checking these values by substituting them into the equilibrium expression gives

$$
\frac{[\mathrm{HF}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{F}_{2}\right]}=\frac{(5.056)^{2}}{(0.472)^{2}}=1.15 \times 10^{2}
$$

which agrees with the given value of $K$.

### 13.6 Solving Equilibrium Problems

We have already considered most of the strategies needed to solve equilibrium problems. The typical procedure for analyzing a chemical equilibrium problem can be summarized as follows:

## PROBLEM-SOLVING STRATEGY

## Solving Equilibrium Problems

1. Write the balanced equation for the reaction.
2. Write the equilibrium expression using the law of mass action.
3. List the initial concentrations.
4. Calculate $Q$, and determine the direction of the shift to equilibrium.
5. Define the change needed to reach equilibrium, and define the equilibrium concentrations by applying the change to the initial concentrations.
6. Substitute the equilibrium concentrations into the equilibrium expression, and solve for the unknown.
7. Check your calculated equilibrium concentrations by making sure they give the correct value of $K$.

So far we have been careful to choose systems in which we can solve for the unknown by taking the square root of both sides of the equation. However, this type of system is not really very common, and we must now consider a more typical problem. Suppose for a synthesis of hydrogen fluoride from hydrogen and fluorine, 3.000 moles of $\mathrm{H}_{2}$ and 6.000 moles of $\mathrm{F}_{2}$ are mixed in a 3.000-L flask. Assume that the equilibrium constant for the synthesis reaction at this temperature is $1.15 \times 10^{2}$. We calculate the equilibrium concentration of each component as follows:

1. What is the balanced equation for the reaction?

$$
\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \rightleftharpoons 2 \mathrm{HF}(g)
$$

2. What is the equilibrium expression?

$$
K=1.15 \times 10^{2}=\frac{[\mathrm{HF}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{F}_{2}\right]}
$$

Use of the quadratic formula is explained in Appendix 1.4.
3. What are the initial concentrations?

$$
\begin{gathered}
{\left[\mathrm{H}_{2}\right]_{0}=\frac{3.000 \mathrm{~mol}}{3.000 \mathrm{~L}}=1.000 \mathrm{M}} \\
{\left[\mathrm{~F}_{2}\right]_{0}=\frac{6.000 \mathrm{~mol}}{3.000 \mathrm{~L}}=2.000 \mathrm{M}} \\
{[\mathrm{HF}]_{0}=0}
\end{gathered}
$$

4. What is $Q$ ?

There is no need to calculate $Q$ because no HF is present initially, and we know that the system must shift to the right to reach equilibrium.
5. What change is required to reach equilibrium?

If we let $x$ represent the number of moles per liter of $\mathrm{H}_{2}$ consumed to reach equilibrium, we can represent the equilibrium concentrations as follows:

|  | $\mathrm{H}_{2}(g)$ | + | $\mathrm{F}_{2}(g)$ | $\rightleftharpoons$ |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 1.000 |  | 2.000 |  |
| ChFange | $-x$ | $-x$ |  | $+2 x$ |
| Equilibrium | $1.000-x$ | $2.000-x$ | $2 x$ |  |

6. What is the value of $K$ ?

Substituting the equilibrium concentrations into the equilibrium expression gives

$$
K=1.15 \times 10^{2}=\frac{[\mathrm{HF}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{F}_{2}\right]}=\frac{(2 x)^{2}}{(1.000-x)(2.000-x)}
$$

Since the right side of this equation is not a perfect square, we cannot take the square root of both sides, but must use some other procedure.

First, do the indicated multiplication:

$$
\begin{gathered}
(1.000-x)(2.000-x)\left(1.15 \times 10^{2}\right)=(2 x)^{2} \\
\text { or } \quad\left(1.15 \times 10^{2}\right) x^{2}-3.000\left(1.15 \times 10^{2}\right) x+2.000\left(1.15 \times 10^{2}\right)=4 x^{2}
\end{gathered}
$$

and collect terms

$$
\left(1.11 \times 10^{2}\right) x^{2}-\left(3.45 \times 10^{2}\right) x+2.30 \times 10^{2}=0
$$

This is a quadratic equation of the general form

$$
a x^{2}+b x+c=0
$$

where the roots can be obtained from the quadratic formula:

$$
x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a}
$$

In this example, $a=1.11 \times 10^{2}, b=-3.45 \times 10^{2}$, and $c=2.30 \times 10^{2}$. Substituting these values into the quadratic formula gives two values for $x$ :

$$
x=2.14 \mathrm{~mol} / \mathrm{L} \quad \text { and } \quad x=0.968 \mathrm{~mol} / \mathrm{L}
$$

Both of these results cannot be valid (since a given set of initial concentrations leads to only one equilibrium position). How can we choose between them? Since the expression for the equilibrium concentration of $\mathrm{H}_{2}$ is

$$
\left[\mathrm{H}_{2}\right]=1.000 M-x
$$

the value of $x$ cannot be $2.14 \mathrm{~mol} / \mathrm{L}$ (because subtracting $2.14 M$ from 1.000 M gives a negative concentration of $\mathrm{H}_{2}$, which is physically impossible). Thus the correct value for $x$ is $0.968 \mathrm{~mol} / \mathrm{L}$, and the equilibrium concentrations are as follows:
■ $\left[\mathrm{H}_{2}\right]=1.000 M-0.968 M=3.2 \times 10^{-2} M$
■ $\left[\mathrm{F}_{2}\right]=2.000 M-0.968 M=1.032 M$
■ $[\mathrm{HF}]=2(0.968 M)=1.936 M$

## Reality Check

7. We can check these concentrations by substituting them into the equilibrium expression:

$$
\frac{[\mathrm{HF}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{F}_{2}\right]}=\frac{(1.936)^{2}}{\left(3.2 \times 10^{-2}\right)(1.032)}=1.13 \times 10^{2}
$$

This value is in close agreement with the given value for $K\left(1.15 \times 10^{2}\right)$, so the calculated equilibrium concentrations are correct.

This procedure is further illustrated for a problem involving pressures in Example 13.12.

## INTERACTVE EXAMPLE 13.12 Calculating Equilibrium Pressures

Assume that gaseous hydrogen iodide is synthesized from hydrogen gas and iodine vapor at a temperature where the equilibrium constant is $1.00 \times 10^{2}$. Suppose HI at $5.000 \times 10^{-1} \mathrm{~atm}, \mathrm{H}_{2}$ at $1.000 \times 10^{-2} \mathrm{~atm}$, and $\mathrm{I}_{2}$ at $5.000 \times 10^{-3} \mathrm{~atm}$ are mixed in a 5.000 -L flask. Calculate the equilibrium pressures of all species.

SOLUTION 1. What is the balanced equation for this process?

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftharpoons 2 \mathrm{HI}(g)
$$

2. What is the equilibrium expression in terms of pressure?

$$
K_{\mathrm{p}}=\frac{P_{\mathrm{HI}^{2}}^{2}}{\left(P_{\mathrm{H}_{2}}\right)\left(P_{\mathrm{I}_{2}}\right)}=1.00 \times 10^{2}
$$

3. What are the given initial pressures?

$$
\begin{aligned}
P_{\mathrm{HI}}^{0} & =5.000 \times 10^{-1} \mathrm{~atm} \\
P_{\mathrm{H}_{2}}^{0} & =1.000 \times 10^{-2} \mathrm{~atm} \\
P_{\mathrm{I}_{2}}^{0} & =5.000 \times 10^{-3} \mathrm{~atm}
\end{aligned}
$$

4. What is the value of $Q$ for this system?

$$
Q=\frac{\left(P_{\mathrm{HI}}^{0}\right)^{2}}{\left(P_{\mathrm{H}_{2}}^{0}\right)\left(P_{\mathrm{I}_{2}}^{0}\right)}=\frac{\left(5.000 \times 10^{-1} \mathrm{~atm}\right)^{2}}{\left(1.000 \times 10^{-2} \mathrm{~atm}\right)\left(5.000 \times 10^{-3} \mathrm{~atm}\right)}=5.000 \times 10^{3}
$$

Since $Q$ is greater than $K$, the system will shift to the left to reach equilibrium.
So far we have used moles or concentrations in stoichiometric calculations.
However, it is equally valid to use pressures for a gas-phase system at constant temperature and volume because in this case pressure is directly proportional to the number of moles:

$$
P=n\left(\frac{R T}{V}\right) \longleftarrow \text { Constant if constant } T \text { and } V
$$

Thus we can represent the change needed to achieve equilibrium in terms of pressures.
5. What change is required to reach equilibrium?

Let $x$ be the change in pressure (in atm) of $\mathrm{H}_{2}$ as the system shifts left toward equilibrium. This leads to the following equilibrium pressures:

|  | $\mathrm{H}_{2}(g)$ | + | $\mathrm{I}_{2}(\mathrm{~g})$ | $\rightleftharpoons$ |
| :--- | :---: | :---: | :---: | :---: |
| Initial | $1.000 \times 10^{-2}$ | $5.000 \times 10^{-3}$ |  | $2 \mathrm{HI}(\mathrm{g})$ |
| Change | $+x$ | $+x$ | $5.000 \times 10^{-1}$ |  |
| Equilibrium | $1.000 \times 10^{-2}+x$ | $5.000 \times 10^{-3}+x$ |  | $5.000 \times 10^{-1}-2 x$ |

6. What is the value of $K_{\mathrm{p}}$ ?

Substitution into the equilibrium expression gives

$$
K_{\mathrm{p}}=\frac{\left(P_{\mathrm{HI}}\right)^{2}}{\left(P_{\mathrm{H}_{2}}\right)\left(P_{\mathrm{I}_{2}}\right)}=\frac{\left(5.000 \times 10^{-1}-2 x\right)^{2}}{\left(1.000 \times 10^{-2}+x\right)\left(5.000 \times 10^{-3}+x\right)}
$$

Multiplying and collecting terms yield the quadratic equation where $a=9.60 \times 10^{1}, b=3.5$, and $c=-2.45 \times 10^{-1}$ :

$$
\left(9.60 \times 10^{1}\right) x^{2}+3.5 x-\left(2.45 \times 10^{-1}\right)=0
$$

From the quadratic formula, the correct value for $x$ is $x=3.55 \times 10^{-2} \mathrm{~atm}$.
What are the equilibrium pressures?
The equilibrium pressures can now be calculated from the expressions involving $x$ :

$$
\begin{aligned}
& P_{\mathrm{HI}}=5.000 \times 10^{-1} \mathrm{~atm}-2\left(3.55 \times 10^{-2}\right) \mathrm{atm}=4.29 \times 10^{-1} \mathrm{~atm} \\
& P_{\mathrm{H}_{2}}=1.000 \times 10^{-2} \mathrm{~atm}+3.55 \times 10^{-2} \mathrm{~atm}=4.55 \times 10^{-2} \mathrm{~atm} \\
& P_{\mathrm{I}_{2}}=5.000 \times 10^{-3} \mathrm{~atm}+3.55 \times 10^{-2} \mathrm{~atm}=4.05 \times 10^{-2} \mathrm{~atm}
\end{aligned}
$$

## Reality Check

7. $\frac{P_{\mathrm{HI}}^{2}}{P_{\mathrm{H}_{2}} \cdot P_{\mathrm{I}_{2}}}=\frac{\left(4.29 \times 10^{-1}\right)^{2}}{\left(4.55 \times 10^{-2}\right)\left(4.05 \times 10^{-2}\right)}=99.9$

This agrees with the given value of $K\left(1.00 \times 10^{2}\right)$, so the calculated equilibrium concentrations are correct.

## Treating Systems That Have Small Equilibrium Constants

We have seen that fairly complicated calculations are often necessary to solve equilibrium problems. However, under certain conditions, simplifications are possible that greatly reduce the mathematical difficulties. For example, gaseous NOCl decomposes to form the gases NO and $\mathrm{Cl}_{2}$. At $35^{\circ} \mathrm{C}$ the equilibrium constant is $1.6 \times 10^{-5}$. In an experiment in which 1.0 mole of NOCl is placed in a $2.0-\mathrm{L}$ flask, what are the equilibrium concentrations?

The balanced equation is

$$
2 \mathrm{NOCl}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g)
$$

and

$$
K=\frac{[\mathrm{NO}]^{2}\left[\mathrm{Cl}_{2}\right]}{[\mathrm{NOCl}]^{2}}=1.6 \times 10^{-5}
$$

The initial concentrations are

$$
[\mathrm{NOCl}]_{0}=\frac{1.0 \mathrm{~mol}}{2.0 \mathrm{~L}}=0.50 \mathrm{M} \quad[\mathrm{NO}]_{0}=0 \quad\left[\mathrm{Cl}_{2}\right]_{0}=0
$$

Since there are no products initially, the system will move to the right to reach equilibrium. We will define $x$ as the change in concentration of $\mathrm{Cl}_{2}$ needed to reach equilibrium. The changes in the concentrations of NOCl and NO can then be obtained from the balanced equation:

$$
\begin{aligned}
2 \mathrm{NOCl}(g) & \longrightarrow 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \\
2 x & \longrightarrow 2 x+x
\end{aligned}
$$

The concentrations can be summarized as follows:

|  | $2 \mathrm{NOCl}(g)$ | $\rightleftharpoons$ | $2 \mathrm{NO}(g)$ | + |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 0.50 |  | $\mathrm{Cl}_{2}(g)$ |  |
| Change | $-2 x$ |  | $+2 x$ | 0 |
| Equilibrium | $0.50-2 x$ | $2 x$ | $+x$ |  |

The equilibrium concentrations must satisfy the equilibrium expression

$$
K=1.6 \times 10^{-5}=\frac{[\mathrm{NO}]^{2}\left[\mathrm{Cl}_{2}\right]}{[\mathrm{NOCl}]^{2}}=\frac{(2 x)^{2}(x)}{(0.50-2 x)^{2}}
$$

Multiplying and collecting terms will give an equation with terms containing $x^{3}, x^{2}$, and $x$, which requires complicated methods to solve directly. However, we can avoid this situation by recognizing that since $K$ is so small $\left(1.6 \times 10^{-5}\right)$, the system will not proceed far to the right to reach equilibrium. That is, $x$ represents a relatively small number. The consequence of this fact is that the term $(0.50-2 x)$ can be approximated by 0.50 . That is, when $x$ is small,

$$
0.50-2 x \approx 0.50
$$

Making this approximation allows us to simplify the equilibrium expression:

$$
1.6 \times 10^{-5}=\frac{(2 x)^{2}(x)}{(0.50-2 x)^{2}} \approx \frac{(2 x)^{2}(x)}{(0.50)^{2}}=\frac{4 x^{3}}{(0.50)^{2}}
$$

Solving for $x^{3}$ gives

$$
x^{3}=\frac{\left(1.6 \times 10^{-5}\right)(0.50)^{2}}{4}=1.0 \times 10^{-6}
$$

and $x=1.0 \times 10^{-2}$.
How valid is this approximation? If $x=1.0 \times 10^{-2}$, then

$$
0.50-2 x=0.50-2\left(1.0 \times 10^{-2}\right)=0.48
$$

The difference between 0.50 and 0.48 is 0.02 , or $4 \%$ of the initial concentration of NOCl , a relatively small discrepancy that will have little effect on the outcome. That is, since $2 x$ is very small compared with 0.50 , the value of $x$ obtained in the approximate solution should be very close to the exact value. We use this approximate value of $x$ to calculate the equilibrium concentrations:

$$
\begin{aligned}
\square[\mathrm{NOCl}] & =0.50-2 x \approx 0.50 M \\
\quad[\mathrm{NO}] & =2 x=2\left(1.0 \times 10^{-2} M\right)=2.0 \times 10^{-2} M \\
{\left[\mathrm{Cl}_{2}\right] } & =x=1.0 \times 10^{-2} M
\end{aligned}
$$

## Reality Check

$$
\frac{[\mathrm{NO}]^{2}\left[\mathrm{Cl}_{2}\right]}{[\mathrm{NOCl}]^{2}}=\frac{\left(2.0 \times 10^{-2}\right)^{2}\left(1.0 \times 10^{-2}\right)}{(0.50)^{2}}=1.6 \times 10^{-5}
$$

Since the given value of $K$ is $1.6 \times 10^{-5}$, these calculated concentrations are correct.
This problem was much easier to solve than it appeared at first because the small value of $K$ and the resulting small shift to the right to reach equilibrium allowed simplification.

> that have small equilibrium constants by making approximations to simplify the math. What if the system has a very large equilibrium constant? What can you do to simplify the math for this case? Use the example from the text, but change the value of the equilibrium constant to $1.6 \times 10^{5}$ and rework the problem. Why can you not use approximations for the case in which $K=1.6$ ?

### 13.7 Le Châtelier's Principle

It is important to understand the factors that control the position of a chemical equilibrium. For example, when a chemical is manufactured, the chemists and chemical engineers in charge of production want to choose conditions that favor the desired product as much as possible. That is, they want the equilibrium to lie far to the right. When Fritz Haber was developing the process for the synthesis of ammonia, he did extensive studies on how temperature and pressure affect the equilibrium concentration of ammonia. Some of his results are given in Table 13.2. Note that the equilibrium amount of $\mathrm{NH}_{3}$ increases with an increase in pressure but decreases as the temperature is increased. Thus the amount of $\mathrm{NH}_{3}$ present at equilibrium is favored by conditions of low temperature and high pressure.

However, this is not the whole story. Carrying out the process at low temperatures is not feasible because then the reaction is too slow. Even though the equilibrium tends to shift to the right as the temperature is lowered, the attainment of equilibrium would be much too slow at low temperatures to be practical. This emphasizes once again that we must study both the thermodynamics and the kinetics of a reaction before we really understand the factors that control it.

We can qualitatively predict the effects of changes in concentration, pressure, and temperature on a system at equilibrium by using Le Châtelier's principle, which states that if a change is imposed on a system at equilibrium, the position of the equilibrium will shift in a direction that tends to reduce that change. Although this rule sometimes oversimplifies the situation, it works remarkably well.

## The Effect of a Change in Concentration

To see how we can predict the effect of change in concentration on a system at equilibrium, we will consider the ammonia synthesis reaction. Suppose there is an equilibrium position described by these concentrations:

$$
\left[\mathrm{N}_{2}\right]=0.399 \mathrm{M} \quad\left[\mathrm{H}_{2}\right]=1.197 \mathrm{M} \quad\left[\mathrm{NH}_{3}\right]=0.202 \mathrm{M}
$$

What will happen if $1.000 \mathrm{~mol} / \mathrm{L}_{2}$ is suddenly injected into the system? We can answer this question by calculating the value of $Q$. The concentrations before the system adjusts are

$$
\begin{gathered}
{\left[\mathrm{N}_{2}\right]_{0}=0.399 \mathrm{M}+\underset{\uparrow}{1.000} \mathrm{M}=1.399 \mathrm{M}} \\
\text { Added } \mathrm{N}_{2} \\
{\left[\mathrm{H}_{2}\right]_{0}=1.197 \mathrm{M}} \\
{\left[\mathrm{NH}_{3}\right]_{0}=0.202 \mathrm{M}}
\end{gathered}
$$

Note we are labeling these as "initial concentrations" because the system is no longer at equilibrium. Then

$$
Q=\frac{\left[\mathrm{NH}_{3}\right]_{0}^{2}}{\left[\mathrm{~N}_{2}\right]_{0}\left[\mathrm{H}_{2}\right]_{0}^{3}}=\frac{(0.202)^{2}}{(1.399)(1.197)^{3}}=1.70 \times 10^{-2}
$$

Since we are not given the value of $K$, we must calculate it from the first set of equilibrium concentrations:

$$
K=\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}=\frac{(0.202)^{2}}{(0.399)(1.197)^{3}}=5.96 \times 10^{-2}
$$

As expected, $Q$ is less than $K$ because the concentration of $\mathrm{N}_{2}$ was increased.
The system will shift to the right to come to the new equilibrium position. Rather than do the calculations, we simply summarize the results:

Note from these data that the equilibrium position does in fact shift to the right: The concentration of $\mathrm{H}_{2}$ decreases, the concentration of $\mathrm{NH}_{3}$ increases, and, of course, since nitrogen is added, the concentration of $\mathrm{N}_{2}$ shows an increase relative to the amount present in the original equilibrium position. (However, notice that the nitrogen showed a decrease relative to the amount present immediately after addition of the 1.000 mole of $\mathrm{N}_{2}$.)

We can understand this shift by thinking about reaction rates. When we add $\mathrm{N}_{2}$ molecules to the system, the number of collisions between $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ will increase, thus increasing the rate of the forward reaction and in turn increasing the rate of formation of $\mathrm{NH}_{3}$ molecules. More $\mathrm{NH}_{3}$ molecules will in turn lead to a higher rate for the reverse reaction. Eventually, the forward and reverse reaction rates will again become equal, and the system will reach its new equilibrium position.

We can predict this shift qualitatively by using Le Châtelier's principle. Since the change imposed is the addition of nitrogen, Le Châtelier's principle predicts that the system will shift in a direction that consumes nitrogen. This reduces the effect of the addition. Thus Le Châtelier's principle correctly predicts that adding nitrogen will cause the equilibrium to shift to the right (Fig. 13.9).

FIGURE 13.9 (a) The initial equilibrium mixture of $\mathrm{N}_{2}, \mathrm{H}_{2}$, and $\mathrm{NH}_{3}$. (b) Addition of $\mathrm{N}_{2}$. (c) The new equilibrium position for the system containing more $\mathrm{N}_{2}$ (due to addition of $\mathrm{N}_{2}$ ), less $\mathrm{H}_{2}$, and more $\mathrm{NH}_{3}$ than the mixture in (a).

The system shifts in the direction that compensates for the imposed change.

-

If ammonia had been added instead of nitrogen, the system would have shifted to the left to consume ammonia. So another way of stating Le Châtelier's principle is to say that if a component (reactant or product) is added to a reaction system at equilibrium (at constant $T$ and $P$ or constant $T$ and $V$ ), the equilibrium position will shift in the direction that lowers the concentration of that component. If a component is removed, the opposite effect occurs.

## INTERACTIVE EXAMPLE 13.13

SOLUTION

## Using Le Châtelier's Principle I

Arsenic can be extracted from its ores by first reacting the ore with oxygen (called roasting) to form solid $\mathrm{As}_{4} \mathrm{O}_{6}$, which is then reduced using carbon:

$$
\mathrm{As}_{4} \mathrm{O}_{6}(s)+6 \mathrm{C}(s) \rightleftharpoons \mathrm{As}_{4}(g)+6 \mathrm{CO}(g)
$$

Predict the direction of the shift of the equilibrium position in response to each of the following changes in conditions.
a. Addition of carbon monoxide
b. Addition or removal of carbon or tetraarsenic hexoxide $\left(\mathrm{As}_{4} \mathrm{O}_{6}\right)$
c. Removal of gaseous arsenic $\left(\mathrm{As}_{4}\right)$
a. Le Châtelier's principle predicts that the shift will be away from the substance whose concentration is increased. The equilibrium position will shift to the left when carbon monoxide is added.
b. Since the amount of a pure solid has no effect on the equilibrium position, changing the amount of carbon or tetraarsenic hexoxide will have no effect.
c. If gaseous arsenic is removed, the equilibrium position will shift to the right to form more products. In industrial processes, the desired product is often continuously removed from the reaction system to increase the yield.

## The Effect of a Change in Pressure

Basically, there are three ways to change the pressure of a reaction system involving gaseous components:

1. Add or remove a gaseous reactant or product.
2. Add an inert gas (one not involved in the reaction).
3. Change the volume of the container.

We have already considered the addition or removal of a reactant or product. When an inert gas is added, there is no effect on the equilibrium position. The addition of an inert gas increases the total pressure but has no effect on the concentrations or partial pressures of the reactants or products. That is, in this case the added molecules do not participate in the reaction in any way and thus cannot affect the equilibrium in any way. Thus the system remains at the original equilibrium position.

When the volume of the container is changed, the concentrations (and thus the partial pressures) of both reactants and products are changed. We could calculate $Q$ and predict the direction of the shift. However, for systems involving gaseous components, there is an easier way: We focus on the volume. The central idea is that when the volume of the container holding a gaseous system is reduced, the system responds by reducing its own volume. This is done by decreasing the total number of gaseous molecules in the system. This is illustrated by the $\mathrm{NO}_{2} / \mathrm{N}_{2} \mathrm{O}_{4}$ system shown in Fig. 13.10.

To see that this is true, we can rearrange the ideal gas law to give

$$
V=\left(\frac{R T}{P}\right) n
$$

or at constant $T$ and $P$,

$$
V \propto n
$$

That is, at constant temperature and pressure, the volume of a gas is directly proportional to the number of moles of gas present.

FIGURE 13.10 (a) Brown $\mathrm{NO}_{2}(g)$ and colorless $\mathrm{N}_{2} \mathrm{O}_{4}(g)$ in equilibrium in a syringe. (b) The volume is suddenly decreased, giving a greater concentration of both $\mathrm{N}_{2} \mathrm{O}_{4}$ and $\mathrm{NO}_{2}$ (indicated by the darker brown color). (c) A few seconds after the sudden volume decrease, the color is much lighter brown as the equilibrium shifts the brown $\mathrm{NO}_{2}(g)$ to colorless $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ as predicted by Le Châtelier's principle, since in the equilibrium

$$
2 \mathrm{NO}_{2}(\mathrm{~g}) \rightleftharpoons \mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})
$$

the product side has the smaller number of molecules.

FIGURE 13.11 (a) A mixture of $\mathrm{NH}_{3}(g), \mathrm{N}_{2}(g)$, and $\mathrm{H}_{2}(g)$ at equilibrium. (b) The volume is suddenly decreased.
(c) The new equilibrium position for the system containing more $\mathrm{NH}_{3}$ and less $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$. The reaction $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons$ $2 \mathrm{NH}_{3}(g)$ shifts to the right (toward the side with fewer molecules) when the container volume is decreased.

Suppose we have a mixture of the gases nitrogen, hydrogen, and ammonia at equilibrium (Fig. 13.11). If we suddenly reduce the volume, what will happen to the equilibrium position? The reaction system can reduce its volume by reducing the number of molecules present. This means that the reaction

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

will shift to the right, since in this direction four molecules (one of nitrogen and three of hydrogen) react to produce two molecules (of ammonia), thus reducing the total number of gaseous molecules present. The new equilibrium position will be farther to the right than the original one. That is, the equilibrium position will shift toward the side of the reaction involving the smaller number of gaseous molecules in the balanced equation.

The opposite is also true. When the container volume is increased, the system will shift so as to increase its volume. An increase in volume in the ammonia synthesis system will produce a shift to the left to increase the total number of gaseous molecules present.
estirleal Thlivkince You and a friend are studying for a chemistry exam. What if your friend says, "Adding an inert gas to a system of gaseous components at equilibrium never changes the equilibrium position"? How do you explain to your friend that this holds true for a system at constant volume but is not necessarily true for a system at constant pressure? When would it hold true for a system at constant pressure?

## INTERACTIVE EXAMPLE 13.14 Using Le Châtelier's Principle II

Predict the shift in equilibrium position that will occur for each of the following processes when the volume is reduced.
a. The preparation of liquid phosphorus trichloride by the reaction

$$
\mathrm{P}_{4}(s)+6 \mathrm{Cl}_{2}(g) \rightleftharpoons 4 \mathrm{PCl}_{3}(l)
$$

b. The preparation of gaseous phosphorus pentachloride according to the equation

$$
\mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{PCl}_{5}(g)
$$

c. The reaction of phosphorus trichloride with ammonia:

$$
\mathrm{PCl}_{3}(g)+3 \mathrm{NH}_{3}(g) \rightleftharpoons \mathrm{P}\left(\mathrm{NH}_{2}\right)_{3}(g)+3 \mathrm{HCl}(g)
$$

SOLUTION
a. Since $\mathrm{P}_{4}$ and $\mathrm{PCl}_{3}$ are a pure solid and a pure liquid, respectively, we need to consider only the effect of the change in volume on $\mathrm{Cl}_{2}$. The volume is decreased, so the position of the equilibrium will shift to the right, since the reactant side contains six gaseous molecules and the product side has none.
b. Decreasing the volume will shift the given reaction to the right, since the product side contains only one gaseous molecule while the reactant side has two.
c. Both sides of the balanced reaction equation have four gaseous molecules. A change in volume will have no effect on the equilibrium position. There is no shift in this case.

See Exercise 13.74

## The Effect of a Change in Temperature

It is important to realize that although the changes we have just discussed may alter the equilibrium position, they do not alter the equilibrium constant. For example, the addition of a reactant shifts the equilibrium position to the right but has no effect on the value of the equilibrium constant; the new equilibrium concentrations satisfy the original equilibrium constant.

The effect of temperature on equilibrium is different, however, because the value of $K$ changes with temperature. We can use Le Châtelier's principle to predict the direction of the change.

The synthesis of ammonia from nitrogen and hydrogen is exothermic. We can represent this by treating energy as a product:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)+92 \mathrm{~kJ}
$$

If energy is added to this system at equilibrium by heating it, Le Châtelier's principle predicts that the shift will be in the direction that consumes energy, that is, to the left. Note that this shift decreases the concentration of $\mathrm{NH}_{3}$ and increases the concentrations

Of course, energy is not a chemical product of this reaction, but thinking of it in this way makes it easy to apply Le Châtelier's principle.

b

## A

Shifting the $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})$ equilibrium by changing the temperature. (a) At $100^{\circ} \mathrm{C}$ the flask is definitely reddish brown due to a large amount of $\mathrm{NO}_{2}$ present. (b) At $\mathrm{O}^{\circ} \mathrm{C}$ the equilibrium is shifted toward colorless $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$.

TABLE 13.3 | Observed Value of $K$ for the Ammonia Synthesis Reaction as a Function of Temperature*

| Temperature (K) | $\boldsymbol{K}$ |
| :---: | :---: |
| 500 | 90 |
| 600 | 3 |
| 700 | 0.3 |
| 800 | 0.04 |

*For this exothermic reaction, the value of $K$ decreases as the temperature increases, as predicted by Le Châtelier's principle.
of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$, thus decreasing the value of $K$. The experimentally observed change in $K$ with temperature for this reaction is indicated in Table 13.3. The value of $K$ decreases with increased temperature, as predicted.

On the other hand, for an endothermic reaction, such as the decomposition of calcium carbonate,

$$
556 \mathrm{~kJ}+\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

an increase in temperature will cause the equilibrium to shift to the right and the value of $K$ to increase.

In summary, to use Le Châtelier's principle to describe the effect of a temperature change on a system at equilibrium, treat energy as a reactant (in an endothermic process) or as a product (in an exothermic process), and predict the direction of the shift in the same way as when an actual reactant or product is added or removed. Although Le Châtelier's principle cannot predict the size of the change in $K$, it does correctly predict the direction of the change.

## INTERACTIVE EXAMPLE 13.15 Using Le Châtelier's Principle III

For each of the following reactions, predict how the value of $K$ changes as the temperature is increased.
a. $\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g) \quad \Delta H^{\circ}=181 \mathrm{~kJ}$
b. $2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{SO}_{3}(g) \quad \Delta H^{\circ}=-198 \mathrm{~kJ}$

SOLUTION
a. This is an endothermic reaction, as indicated by the positive value for $\Delta H^{\circ}$. Energy can be viewed as a reactant, and $K$ increases (the equilibrium shifts to the right) as the temperature is increased.
b. This is an exothermic reaction (energy can be regarded as a product). As the temperature is increased, the value of $K$ decreases (the equilibrium shifts to the left).

See Exercises 13.79 and 13.80

We have seen how Le Châtelier's principle can be used to predict the effect of several types of changes on a system at equilibrium. To summarize these ideas, Table 13.4 shows how various changes affect the equilibrium position of the endothermic reaction

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g) \quad \Delta H^{\circ}=58 \mathrm{~kJ}
$$

TABLE 13.4 | Shifts in the Equilibrium Position for the Reaction $58 \mathrm{~kJ}+\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g})$

| Change | Shift |
| :--- | :--- |
| Addition of $\mathrm{N}_{2} \mathrm{O}_{4}(g)$ | Right |
| Addition of $\mathrm{NO}_{2}(g)$ | Left |
| Removal of $\mathrm{N}_{2} \mathrm{O}_{4}(g)$ | Left |
| Removal of $\mathrm{NO}_{2}(g)$ | Right |
| Addition of $\mathrm{He}(g)$ | None |
| Decrease container volume | Left |
| Increase container volume | Right |
| Increase temperature | Right |
| Decrease temperature | Left |

## Chemical equilibrium

) When a reaction takes place in a closed system, it reaches a condition where the concentrations of the reactants and products remain constant over time
> Dynamic state: reactants and products are interconverted continually
> Forward rate $=$ reverse rate
) The law of mass action: for the reaction

$$
\begin{aligned}
& j \mathrm{~A}+k \mathrm{~B} \rightleftharpoons m \mathrm{C}+n \mathrm{D} \\
& K=\frac{[\mathrm{C}]^{m}[\mathrm{D}]^{n}}{[\mathrm{~A}]^{j}[\mathrm{~B}]^{k}}=\text { equilibrium constant }
\end{aligned}
$$

) A pure liquid or solid is never included in the equilibrium expression
) For a gas-phase reaction, the reactants and products can be described in terms of their partial pressures and the equilibrium constant is called $K_{\mathrm{p}}$ :

$$
K_{\mathrm{p}}=K(R T)^{\Delta n}
$$

where $\Delta n$ is the sum of the coefficients of the gaseous products minus the sum of the coefficients of the gaseous reactants

## Equilibrium position

》 A set of reactant and product concentrations that satisfies the equilibrium constant expression
) There is one value of $K$ for a given system at a given temperature
> There are an infinite number of equilibrium positions at a given temperature depending on the initial concentrations
> A small value of $K$ means the equilibrium lies to the left; a large value of $K$ means the equilibrium lies to the right
> The size of $K$ has no relationship to the speed at which equilibrium is achieved
> $Q$, the reaction quotient, applies the law of mass action to initial concentrations rather than equilibrium concentrations
> If $Q>K$, the system will shift to the left to achieve equilibrium
> If $Q<K$, the system will shift to the right to achieve equilibrium
> Finding the concentrations that characterize a given equilibrium position:
) Start with the given initial concentrations (pressures)
) Define the change needed to reach equilibrium
) Apply the change to the initial concentrations (pressures) and solve for the equilibrium concentrations (pressures)

## Le Châtelier's principle

) Enables qualitative prediction of the effects of changes in concentration, pressure, and temperature on a system at equilibrium
> If a change in conditions is imposed on a system at equilibrium, the system will shift in a direction that compensates for the imposed change
> In other words, when a stress is placed on a system at equilibrium, the system shifts in the direction that relieves the stress

## Review Questions Answers to the Review Buestions can be found on the Student website (accessible from www.cengagedrain.com)

1. Characterize a system at chemical equilibrium with respect to each of the following:
a. the rates of the forward and reverse reactions
b. the overall composition of the reaction mixture

For a general reaction $3 \mathrm{~A}(g)+\mathrm{B}(g) \longrightarrow 2 \mathrm{C}(g)$, if one starts an experiment with only reactants present, show what the plot of concentrations of A, B, and C versus time would look like. Also sketch the plot illustrating the rate of the forward reaction and rate of the reverse reaction versus time.
2. What is the law of mass action? Is it true that the value of $K$ depends on the amounts of reactants and products mixed together initially? Explain. Is it true that reactions with large equilibrium constant values are very fast? Explain. There is only one value of the equilibrium constant for a particular system at a particular temperature, but there is an infinite number of equilibrium positions. Explain.
3. Consider the following reactions at some temperature:

$$
\begin{array}{rll}
2 \mathrm{NOCl}(g) & \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) & K=1.6 \times 10^{-5} \\
2 \mathrm{NO}(g) & \rightleftharpoons \mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) & K=1 \times 10^{31}
\end{array}
$$

For each reaction, assume some quantities of the reactants were placed in separate containers and allowed to come to equilibrium. Describe the relative amounts of reactants and products that would be present at equilibrium. At equilibrium, which is faster, the forward or reverse reaction in each case?
4. What is the difference between $K$ and $K_{\mathrm{p}}$ ? When does $K=K_{\mathrm{p}}$ for a reaction? When does $K \neq K_{\mathrm{p}}$ for a reaction? If the coefficients in a reaction equation are tripled, how is the new value of $K$ related to the initial value of $K$ ? If an equation for a reaction is reversed, how is the value of $K_{\mathrm{p}}$ for the reversed equation related to the value of $K_{\mathrm{p}}$ for the initial equation?
5. What are homogeneous equilibria? Heterogeneous equilibria? What is the difference in writing $K$ expressions for homogeneous versus heterogeneous reactions? Summarize which species are included in the $K$ expression and which species are not included.
6. Distinguish between the terms equilibrium constant and reaction quotient. When $Q=K$, what does this say about a reaction? When $Q<K$, what does this say about a reaction? When $Q>K$, what does this say about a reaction?
7. Summarize the steps for solving equilibrium problems (see the beginning of Section 13.6). In general, when
solving an equilibrium problem, you should always set up an ICE table. What is an ICE table?
8. A common type of reaction we will study is that having a very small $K$ value ( $K \ll 1$ ). Solving for equilibrium concentrations in an equilibrium problem usually requires many mathematical operations to be performed. However, the math involved when solving equilibrium problems for reactions having small $K$ values ( $K \ll 1$ ) is simplified. What assumption is made when solving the equilibrium concentrations for reactions with small $K$ values? Whenever assumptions are made, they must be checked for validity. In general, the " $5 \%$ rule" is used to check the validity of assuming $x$ (or $2 x, 3 x$, and so on) is very small compared to some number. When $x$ (or $2 x$, $3 x$, and so on) is less than $5 \%$ of the number the assumption was made against, then the assumption is said to be valid. If the $5 \%$ rule fails, what do you do to solve for the equilibrium concentrations?
9. What is Le Châtelier's principle? Consider the reaction $2 \mathrm{NOCl}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g)$. If this reaction is at equilibrium, what happens when the following changes occur?
a. $\operatorname{NOCl}(g)$ is added.
b. $\mathrm{NO}(g)$ is added.
c. $\mathrm{NOCl}(g)$ is removed.
d. $\mathrm{Cl}_{2}(g)$ is removed.
e. The container volume is decreased.

For each of these changes, what happens to the value of $K$ for the reaction as equilibrium is reached again? Give an example of a reaction for which the addition or removal of one of the reactants or products has no effect on the equilibrium position.

In general, how will the equilibrium position of a gas-phase reaction be affected if the volume of the reaction vessel changes? Are there reactions that will not have their equilibria shifted by a change in volume? Explain. Why does changing the pressure in a rigid container by adding an inert gas not shift the equilibrium position for a gas-phase reaction?
10. The only "stress" (change) that also changes the value of $K$ is a change in temperature. For an exothermic reaction, how does the equilibrium position change as temperature increases, and what happens to the value of $K$ ? Answer the same questions for an endothermic reaction. If the value of $K$ increases with a decrease in temperature, is the reaction exothermic or endothermic? Explain.

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. Consider an equilibrium mixture of four chemicals (A, B, C, and D , all gases) reacting in a closed flask according to the equation:

$$
\mathrm{A}(g)+\mathrm{B}(g) \rightleftharpoons \mathrm{C}(g)+\mathrm{D}(g)
$$

a. You add more A to the flask. How does the concentration of each chemical compare to its original concentration after equilibrium is reestablished? Justify your answer.
b. You have the original setup at equilibrium, and you add more D to the flask. How does the concentration of each chemical compare to its original concentration after equilibrium is reestablished? Justify your answer.
2. The boxes shown below represent a set of initial conditions for the reaction:

Draw a quantitative molecular picture that shows what this system looks like after the reactants are mixed in one of the boxes and the system reaches equilibrium. Support your answer with calculations.

3. For the reaction $\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftharpoons 2 \mathrm{HI}(g)$, consider two possibilities: (a) you mix 0.5 mole of each reactant, allow the system to come to equilibrium, and then add another mole of $\mathrm{H}_{2}$ and allow the system to reach equilibrium again, or (b) you mix 1.5 moles of $\mathrm{H}_{2}$ and 0.5 mole of $\mathrm{I}_{2}$ and allow the system to reach equilibrium. Will the final equilibrium mixture be different for the two procedures? Explain.
4. Given the reaction $\mathrm{A}(g)+\mathrm{B}(g) \rightleftharpoons \mathrm{C}(g)+\mathrm{D}(g)$, consider the following situations:
i. You have $1.3 M \mathrm{~A}$ and 0.8 MB initially.
ii. You have $1.3 \mathrm{MA}, 0.8 \mathrm{MB}$, and 0.2 M C initially.
iii. You have 2.0 MA and 0.8 MB initially.

Order the preceding situations in terms of increasing equilibrium concentration of D. Explain your order. Then give the order in terms of increasing equilibrium concentration of B and explain.
5. Consider the reaction $\mathrm{A}(g)+2 \mathrm{~B}(g) \rightleftharpoons \mathrm{C}(g)+\mathrm{D}(g)$ in a $1.0-\mathrm{L}$ rigid flask. Answer the following questions for each situation (a-d):
i. Estimate a range (as small as possible) for the requested substance. For example, [A] could be between $95 M$ and $100 M$.
ii. Explain how you decided on the limits for the estimated range.
iii. Indicate what other information would enable you to narrow your estimated range.
iv. Compare the estimated concentrations for a through d, and explain any differences.
a. If at equilibrium $[\mathrm{A}]=1 M$, and then 1 mole of C is added, estimate the value for $[\mathrm{A}]$ once equilibrium is reestablished.
b. If at equilibrium $[\mathrm{B}]=1 M$, and then 1 mole of C is added, estimate the value for $[\mathrm{B}]$ once equilibrium is reestablished.
c. If at equilibrium $[\mathrm{C}]=1 M$, and then 1 mole of C is added, estimate the value for [C] once equilibrium is reestablished.
d. If at equilibrium $[\mathrm{D}]=1 M$, and then 1 mole of C is added, estimate the value for [D] once equilibrium is reestablished.
6. Consider the reaction $\mathrm{A}(g)+\mathrm{B}(g) \rightleftharpoons \mathrm{C}(g)+\mathrm{D}(g)$. A friend asks the following: "I know we have been told that if a mixture of $\mathrm{A}, \mathrm{B}, \mathrm{C}$, and D is at equilibrium and more of A is added, more C and D will form. But how can more C and D form if we do not add more B?" What do you tell your friend?
7. Consider the following statements: "Consider the reaction $\mathrm{A}(g)+\mathrm{B}(g) \rightleftharpoons \mathrm{C}(g)$, for which at equilibrium $[\mathrm{A}]=2 M$, $[\mathrm{B}]=1 \mathrm{M}$, and $[\mathrm{C}]=4 \mathrm{M}$. To a 1-L container of the system at equilibrium, you add 3 moles of B . A possible equilibrium condition is $[\mathrm{A}]=1 \mathrm{M},[\mathrm{B}]=3 \mathrm{M}$, and $[\mathrm{C}]=6 \mathrm{M}$ because in both cases $K=2$." Indicate everything that is correct in these statements and everything that is incorrect. Correct the incorrect statements, and explain.
8. Le Châtelier's principle is stated (Section 13.7) as follows: "If a change is imposed on a system at equilibrium, the position of the equilibrium will shift in a direction that tends to reduce that change." The system $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)$ is used as an example in which the addition of nitrogen gas at equilibrium results in a decrease in $\mathrm{H}_{2}$ concentration and an increase in $\mathrm{NH}_{3}$ concentration. In the experiment the volume is assumed to be constant. On the other hand, if $\mathrm{N}_{2}$ is added to the reaction system in a container with a piston so that the pressure can be held constant, the amount of $\mathrm{NH}_{3}$ actually could decrease and the concentration of $\mathrm{H}_{2}$ would increase as equilibrium is reestablished. Explain how this can happen. Also, if you consider this same system at equilibrium, the addition of an inert gas, holding the pressure constant, does affect the equilibrium position. Explain why the addition of an inert gas to this system in a rigid container does not affect the equilibrium position.
9. The value of the equilibrium constant $K$ depends on which of the following (more than one answer may be correct)?
a. the initial concentrations of the reactants
b. the initial concentrations of the products
c. the temperature of the system
d. the nature of the reactants and products

Explain.
10. In Section 13.1 of your text, it is mentioned that equilibrium is reached in a "closed system." What is meant by the term "closed system," and why is it necessary to have a closed system in order for a system to reach equilibrium? Explain why equilibrium is not reached in an open system.
11. Explain why the development of a vapor pressure above a liquid in a closed container represents an equilibrium. What are the opposing processes? How do we recognize when the system has reached a state of equilibrium?

Evaporation

Condensation

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

12. Consider an initial mixture of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ gases that can be represented as follows:

The gases react to form ammonia gas $\left(\mathrm{NH}_{3}\right)$ as represented by the following concentration profile:

a. Label each plot on the graph as $\mathrm{N}_{2}, \mathrm{H}_{2}$, or $\mathrm{NH}_{3}$, and explain your answers.
b. Explain the relative shapes of the plots.
c. When is equilibrium reached? How do you know?
13. Consider the following reaction:

$$
\mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g)
$$

Amounts of $\mathrm{H}_{2} \mathrm{O}, \mathrm{CO}, \mathrm{H}_{2}$, and $\mathrm{CO}_{2}$ are put into a flask so that the composition corresponds to an equilibrium position. If the CO placed in the flask is labeled with radioactive ${ }^{14} \mathrm{C}$, will ${ }^{14} \mathrm{C}$ be found only in CO molecules for an indefinite period of time? Explain.
14. Consider the same reaction as in Question 13. In one experiment 1.0 mole of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ and 1.0 mole of $\mathrm{CO}(\mathrm{g})$ are put into a flask and heated to $350^{\circ} \mathrm{C}$. In a second experiment 1.0 mole of $\mathrm{H}_{2}(\mathrm{~g})$ and 1.0 mole of $\mathrm{CO}_{2}(\mathrm{~g})$ are put into another flask with the same volume as the first. This mixture is also heated to $350^{\circ} \mathrm{C}$. After equilibrium is reached, will there be any difference in the composition of the mixtures in the two flasks?
15. Suppose a reaction has the equilibrium constant $K=1.3 \times 10^{8}$. What does the magnitude of this constant tell you about the relative concentrations of products and reactants that will be present once equilibrium is reached? Is this reaction likely to be a good source of the products?
16. Suppose a reaction has the equilibrium constant $K=1.7 \times 10^{-8}$ at a particular temperature. Will there be a large or small amount of unreacted starting material present when this reaction reaches equilibrium? Is this reaction likely to be a good source of products at this temperature?
17. Consider the following reaction at some temperature:

$$
\mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g) \quad K=2.0
$$

Some molecules of $\mathrm{H}_{2} \mathrm{O}$ and CO are placed in a $1.0-\mathrm{L}$ container as shown below.

When equilibrium is reached, how many molecules of $\mathrm{H}_{2} \mathrm{O}$, $\mathrm{CO}, \mathrm{H}_{2}$, and $\mathrm{CO}_{2}$ are present? Do this problem by trial and error-that is, if two molecules of CO react, is this equilibrium; if three molecules of CO react, is this equilibrium; and so on.
18. Consider the following generic reaction:

$$
2 \mathrm{~A}_{2} \mathrm{~B}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{~A}_{2}(\mathrm{~g})+\mathrm{B}_{2}(\mathrm{~g})
$$

Some molecules of $\mathrm{A}_{2} \mathrm{~B}$ are placed in a $1.0-\mathrm{L}$ container. As time passes, several snapshots of the reaction mixture are taken as illustrated below.

Which illustration is the first to represent an equilibrium mixture? Explain. How many molecules of $\mathrm{A}_{2} \mathrm{~B}$ reacted initially?
19. Explain the difference between $K, K_{\mathrm{p}}$, and $Q$.
20. Consider the following reactions:
$\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftharpoons 2 \mathrm{HI}(g)$ and $\mathrm{H}_{2}(g)+\mathrm{I}_{2}(s) \rightleftharpoons 2 \mathrm{HI}(g)$
List two property differences between these two reactions that relate to equilibrium.
21. For a typical equilibrium problem, the value of $K$ and the initial reaction conditions are given for a specific reaction, and you are asked to calculate the equilibrium concentrations. Many of these calculations involve solving a quadratic or cubic equation. What can you do to avoid solving a quadratic or cubic equation and still come up with reasonable equilibrium concentrations?
22. Which of the following statements is(are) true? Correct the false statement(s).
a. When a reactant is added to a system at equilibrium at a given temperature, the reaction will shift right to reestablish equilibrium.
b. When a product is added to a system at equilibrium at a given temperature, the value of $K$ for the reaction will increase when equilibrium is reestablished.
c. When temperature is increased for a reaction at equilibrium, the value of $K$ for the reaction will increase.
d. When the volume of a reaction container is increased for a system at equilibrium at a given temperature, the reaction will shift left to reestablish equilibrium.
e. Addition of a catalyst (a substance that increases the speed of the reaction) has no effect on the equilibrium position.
23. Consider the reaction

$$
2 \mathrm{~N}_{2} \mathrm{O}(g)+\mathrm{O}_{2}(g) \leftrightharpoons 4 \mathrm{NO}(g)
$$

Suppose the system is at equilibrium, and then an additional mole of $\mathrm{N}_{2} \mathrm{O}(g)$ is injected into the system at constant temperature. Once the reaction reestablishes equilibrium, has the amount of $\mathrm{N}_{2} \mathrm{O}$ increased or decreased from its original equilibrium amount? Explain. What happens to the value of the equilibrium constant with this change?
24. The reaction to prepare methanol from carbon monoxide and hydrogen

$$
\mathrm{CO}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g}) \leftrightharpoons \mathrm{CH}_{3} \mathrm{OH}(\mathrm{~g})
$$

is exothermic. If you wanted to use this reaction to produce methanol commercially, would high or low temperatures favor a maximum yield? Explain.

## Exercises

In this section similar exercises are paired.

## The Equilibrium Constant

25. Write the equilibrium expression $(K)$ for each of the following gas-phase reactions.
a. $\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g)$
b. $\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g)$
c. $\mathrm{SiH}_{4}(g)+2 \mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{SiCl}_{4}(g)+2 \mathrm{H}_{2}(g)$
d. $2 \mathrm{PBr}_{3}(g)+3 \mathrm{Cl}_{2}(g) \rightleftharpoons 2 \mathrm{PCl}_{3}(g)+3 \mathrm{Br}_{2}(g)$
26. Write the equilibrium expression $\left(K_{\mathrm{p}}\right)$ for each reaction in Exercise 25.
-27. At a given temperature, $K=1.3 \times 10^{-2}$ for the reaction

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

Calculate values of $K$ for the following reactions at this temperature.
a. $\frac{1}{2} \mathrm{~N}_{2}(g)+\frac{3}{2} \mathrm{H}_{2}(g) \rightleftharpoons \mathrm{NH}_{3}(g)$
b. $2 \mathrm{NH}_{3}(g) \rightleftharpoons \mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g)$
c. $\mathrm{NH}_{3}(g) \rightleftharpoons \frac{1}{2} \mathrm{~N}_{2}(g)+\frac{3}{2} \mathrm{H}_{2}(g)$
d. $2 \mathrm{~N}_{2}(g)+6 \mathrm{H}_{2}(g) \rightleftharpoons 4 \mathrm{NH}_{3}(g)$
28. For the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{Br}_{2}(g) \rightleftharpoons 2 \mathrm{HBr}(g)
$$

$K_{\mathrm{p}}=3.5 \times 10^{4}$ at 1495 K . What is the value of $K_{\mathrm{p}}$ for the following reactions at 1495 K ?
a. $\operatorname{HBr}(g) \rightleftharpoons \frac{1}{2} \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{Br}_{2}(g)$
b. $2 \mathrm{HBr}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{Br}_{2}(g)$
c. $\frac{1}{2} \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{Br}_{2}(g) \rightleftharpoons \mathrm{HBr}(g)$
-29 . For the reaction

$$
2 \mathrm{NO}(g)+2 \mathrm{H}_{2}(g) \rightleftharpoons \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

it is determined that, at equilibrium at a particular temperature, the concentrations are as follows: $[\mathrm{NO}(\mathrm{g})]=8.1 \times 10^{-3} \mathrm{M}$, $\left[\mathrm{H}_{2}(g)\right]=4.1 \times 10^{-5} M,\left[\mathrm{~N}_{2}(g)\right]=5.3 \times 10^{-2} \mathrm{M}$, and $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right]=2.9 \times 10^{-3} \mathrm{M}$. Calculate the value of $K$ for the reaction at this temperature.
30. At high temperatures, elemental nitrogen and oxygen react with each other to form nitrogen monoxide:

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g)
$$

Suppose the system is analyzed at a particular temperature, and the equilibrium concentrations are found to be $\left[\mathrm{N}_{2}\right]=$ $0.041 M,\left[\mathrm{O}_{2}\right]=0.0078 \mathrm{M}$, and $[\mathrm{NO}]=4.7 \times 10^{-4} \mathrm{M}$. Calculate the value of $K$ for the reaction.
-31. At a particular temperature, a 3.0-L flask contains 2.4 moles of $\mathrm{Cl}_{2}, 1.0$ mole of NOCl , and $4.5 \times 10^{-3}$ mole of NO. Calculate $K$ at this temperature for the following reaction:

$$
2 \mathrm{NOCl}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g)
$$

32. At a particular temperature a 2.00 - L flask at equilibrium contains $2.80 \times 10^{-4}$ mole of $\mathrm{N}_{2}, 2.50 \times 10^{-5}$ mole of $\mathrm{O}_{2}$, and $2.00 \times 10^{-2}$ mole of $\mathrm{N}_{2} \mathrm{O}$. Calculate $K$ at this temperature for the reaction

$$
2 \mathrm{~N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{~N}_{2} \mathrm{O}(g)
$$

If $\left[\mathrm{N}_{2}\right]=2.00 \times 10^{-4} \mathrm{M},\left[\mathrm{N}_{2} \mathrm{O}\right]=0.200 \mathrm{M}$, and $\left[\mathrm{O}_{2}\right]=$ 0.00245 M , does this represent a system at equilibrium?
-33. The following equilibrium pressures at a certain temperature were observed for the reaction

$$
\begin{aligned}
2 \mathrm{NO}_{2}(g) & \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \\
P_{\mathrm{NO}_{2}} & =0.55 \mathrm{~atm} \\
P_{\mathrm{NO}} & =6.5 \times 10^{-5} \mathrm{~atm} \\
P_{\mathrm{O}_{2}} & =4.5 \times 10^{-5} \mathrm{~atm}
\end{aligned}
$$

Calculate the value for the equilibrium constant $K_{\mathrm{p}}$ at this temperature.
34. The following equilibrium pressures were observed at a certain temperature for the reaction

$$
\begin{gathered}
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g) \\
P_{\mathrm{NH}_{3}}=3.1 \times 10^{-2} \mathrm{~atm} \\
P_{\mathrm{N}_{2}}=8.5 \times 10^{-1} \mathrm{~atm} \\
P_{\mathrm{H}_{2}}=3.1 \times 10^{-3} \mathrm{~atm}
\end{gathered}
$$

Calculate the value for the equilibrium constant $K_{\mathrm{p}}$ at this temperature.
If $P_{\mathrm{N}_{2}}=0.525 \mathrm{~atm}, P_{\mathrm{NH}_{3}}=0.0167 \mathrm{~atm}$, and $P_{\mathrm{H}_{2}}=0.00761 \mathrm{~atm}$, does this represent a system at equilibrium?
-35. At $327^{\circ} \mathrm{C}$, the equilibrium concentrations are $\left[\mathrm{CH}_{3} \mathrm{OH}\right]=$ $0.15 M,[\mathrm{CO}]=0.24 M$, and $\left[\mathrm{H}_{2}\right]=1.1 M$ for the reaction

$$
\mathrm{CH}_{3} \mathrm{OH}(\mathrm{~g}) \rightleftharpoons \mathrm{CO}(\mathrm{~g})+2 \mathrm{H}_{2}(\mathrm{~g})
$$

Calculate $K_{\mathrm{p}}$ at this temperature.
36. At $1100 \mathrm{~K}, K_{\mathrm{p}}=0.25$ for the reaction

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{SO}_{3}(g)
$$

What is the value of $K$ at this temperature?
-37. Write expressions for $K$ and $K_{\mathrm{p}}$ for the following reactions.
a. $2 \mathrm{NH}_{3}(g)+\mathrm{CO}_{2}(g) \rightleftharpoons \mathrm{N}_{2} \mathrm{CH}_{4} \mathrm{O}(s)+\mathrm{H}_{2} \mathrm{O}(g)$
b. $2 \mathrm{NBr}_{3}(s) \rightleftharpoons \mathrm{N}_{2}(g)+3 \mathrm{Br}_{2}(g)$
c. $2 \mathrm{KClO}_{3}(s) \rightleftharpoons 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(\mathrm{~g})$
d. $\mathrm{CuO}(s)+\mathrm{H}_{2}(g) \rightleftharpoons \mathrm{Cu}(l)+\mathrm{H}_{2} \mathrm{O}(g)$
38. Write expressions for $K_{\mathrm{p}}$ for the following reactions.
a. $2 \mathrm{Fe}(s)+\frac{3}{2} \mathrm{O}_{2}(g) \rightleftharpoons \mathrm{Fe}_{2} \mathrm{O}_{3}(s)$
b. $\mathrm{CO}_{2}(g)+\mathrm{MgO}(s) \rightleftharpoons \mathrm{MgCO}_{3}(s)$
c. $\mathrm{C}(s)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}(g)+\mathrm{H}_{2}(g)$
d. $4 \mathrm{KO}_{2}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons 4 \mathrm{KOH}(\mathrm{s})+3 \mathrm{O}_{2}(\mathrm{~g})$
-39. For which reactions in Exercise 37 is $K_{\mathrm{p}}$ equal to $K$ ?
40. For which reactions in Exercise 38 is $K_{\mathrm{p}}$ equal to $K$ ?
-41. The formation of glucose from water and carbon dioxide is an extremely important reaction for life to exist. Plants perform this reaction through the process of photosynthesis, creating the base of the food chain. The unbalanced reaction is

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g}) \leftrightharpoons \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g})
$$

At a particular temperature, the following equilibrium concentrations were found: $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right]=7.9 \times 10^{-2} \mathrm{M},\left[\mathrm{CO}_{2}(\mathrm{~g})\right]=$ 0.93 M , and $\left[\mathrm{O}_{2}(\mathrm{~g})\right]=2.4 \times 10^{-3} \mathrm{M}$. Calculate the value of $K$ at this temperature for the reaction that produces 1 mol of glucose.
42. Consider the following reaction at a certain temperature:

$$
4 \mathrm{Fe}(s)+3 \mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)
$$

An equilibrium mixture contains 1.0 mole of Fe , $1.0 \times 10^{-3}$ mole of $\mathrm{O}_{2}$, and 2.0 moles of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ all in a $2.0-\mathrm{L}$ container. Calculate the value of $K$ for this reaction.
-43. In a study of the reaction

$$
3 \mathrm{Fe}(\mathrm{~s})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightleftharpoons \mathrm{Fe}_{3} \mathrm{O}_{4}(\mathrm{~s})+4 \mathrm{H}_{2}(\mathrm{~g})
$$

at 1200 K it was observed that when the equilibrium partial pressure of water vapor is 15.0 torr, the total pressure at equilibrium is 36.3 torr. Calculate the value of $K_{\mathrm{p}}$ for this reaction at 1200 K. (Hint: Apply Dalton's law of partial pressures.)
-44. Consider the following reaction at $725^{\circ} \mathrm{C}$ :

$$
\mathrm{C}(s)+\mathrm{CO}_{2}(g) \leftrightharpoons 2 \mathrm{CO}(g)
$$

At equilibrium, a $4.50-\mathrm{L}$ container has 2.6 g of carbon, $\mathrm{CO}_{2}$ at a partial pressure of 0.0020 atm , and a total pressure of 0.572 atm . Calculate $K_{\mathrm{p}}$ for this reaction at $725^{\circ} \mathrm{C}$.

## Equilibrium Calculations

45. The equilibrium constant is 0.0900 at $25^{\circ} \mathrm{C}$ for the reaction

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+\mathrm{Cl}_{2} \mathrm{O}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HOCl}(\mathrm{~g})
$$

For which of the following sets of conditions is the system at equilibrium? For those that are not at equilibrium, in which direction will the system shift?
a. A 1.0-L flask contains 1.0 mole of $\mathrm{HOCl}, 0.10$ mole of $\mathrm{Cl}_{2} \mathrm{O}$, and 0.10 mole of $\mathrm{H}_{2} \mathrm{O}$.
b. A 2.0-L flask contains 0.084 mole of $\mathrm{HOCl}, 0.080$ mole of $\mathrm{Cl}_{2} \mathrm{O}$, and 0.98 mole of $\mathrm{H}_{2} \mathrm{O}$.
c. A 3.0-L flask contains 0.25 mole of $\mathrm{HOCl}, 0.0010$ mole of $\mathrm{Cl}_{2} \mathrm{O}$, and 0.56 mole of $\mathrm{H}_{2} \mathrm{O}$.
46. The equilibrium constant $K_{\mathrm{p}}$ is $2.4 \times 10^{3}$ at a certain temperature for the reaction

$$
2 \mathrm{NO}(g) \leftrightharpoons \mathrm{N}_{2}(g)+\mathrm{O}_{2}(g)
$$

For which of the following sets of conditions is the system at equilibrium? For those not at equilibrium, in which direction will the system shift?
a. $P_{\mathrm{NO}}=0.012 \mathrm{~atm}, P_{\mathrm{N}_{2}}=0.11 \mathrm{~atm}, P_{\mathrm{O}_{2}}=2.0 \mathrm{~atm}$
b. $P_{\mathrm{NO}}=0.0078 \mathrm{~atm}, P_{\mathrm{N}_{2}}=0.36 \mathrm{~atm}, P_{\mathrm{O}_{2}}=0.67 \mathrm{~atm}$
c. $P_{\mathrm{NO}}=0.0062 \mathrm{~atm}, P_{\mathrm{N}_{2}}=0.51 \mathrm{~atm}, P_{\mathrm{O}_{2}}=0.18 \mathrm{~atm}$
-47. At $900^{\circ} \mathrm{C}, K_{\mathrm{p}}=1.04$ for the reaction

$$
\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

At a low temperature, dry ice (solid $\mathrm{CO}_{2}$ ), calcium oxide, and calcium carbonate are introduced into a $50.0-\mathrm{L}$ reaction chamber. The temperature is raised to $900^{\circ} \mathrm{C}$, resulting in the dry ice converting to gaseous $\mathrm{CO}_{2}$. For the following mixtures, will the initial amount of calcium oxide increase, decrease, or remain the same as the system moves toward equilibrium at $900^{\circ} \mathrm{C}$ ?
a. $655 \mathrm{~g} \mathrm{CaCO}_{3}, 95.0 \mathrm{~g} \mathrm{CaO}, P_{\mathrm{CO}_{2}}=2.55 \mathrm{~atm}$
b. $780 \mathrm{~g} \mathrm{CaCO}_{3}, 1.00 \mathrm{~g} \mathrm{CaO}, P_{\mathrm{CO}_{2}}=1.04 \mathrm{~atm}$
c. $0.14 \mathrm{~g} \mathrm{CaCO}_{3}, 5000 \mathrm{~g} \mathrm{CaO}, P_{\mathrm{CO}_{2}}=1.04 \mathrm{~atm}$
d. $715 \mathrm{~g} \mathrm{CaCO}_{3}, 813 \mathrm{~g} \mathrm{CaO}, P_{\mathrm{CO}_{2}}=0.211 \mathrm{~atm}$
48. Ethyl acetate is synthesized in a nonreacting solvent (not water) according to the following reaction:
$\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH} \rightleftharpoons \mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{C}_{2} \mathrm{H}_{5}+\mathrm{H}_{2} \mathrm{O} \quad K=2.2$ Acetic acid Ethanol Ethyl acetate
For the following mixtures (a-d), will the concentration of $\mathrm{H}_{2} \mathrm{O}$ increase, decrease, or remain the same as equilibrium is established?
a. $\left[\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{C}_{2} \mathrm{H}_{5}\right]=0.22 \mathrm{M},\left[\mathrm{H}_{2} \mathrm{O}\right]=0.10 \mathrm{M}$, $\left[\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}\right]=0.010 \mathrm{M},\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]=0.010 \mathrm{M}$
b. $\left[\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{C}_{2} \mathrm{H}_{5}\right]=0.22 \mathrm{M},\left[\mathrm{H}_{2} \mathrm{O}\right]=0.0020 \mathrm{M}$, $\left[\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}\right]=0.0020 \mathrm{M},\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]=0.10 \mathrm{M}$
c. $\left[\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{C}_{2} \mathrm{H}_{5}\right]=0.88 \mathrm{M},\left[\mathrm{H}_{2} \mathrm{O}\right]=0.12 \mathrm{M}$, $\left[\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}\right]=0.044 \mathrm{M},\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]=6.0 \mathrm{M}$
d. $\left[\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{C}_{2} \mathrm{H}_{5}\right]=4.4 \mathrm{M},\left[\mathrm{H}_{2} \mathrm{O}\right]=4.4 \mathrm{M}$, $\left[\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}\right]=0.88 \mathrm{M},\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]=10.0 \mathrm{M}$
e. What must the concentration of water be for a mixture with $\left[\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{C}_{2} \mathrm{H}_{5}\right]=2.0 \mathrm{M},\left[\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}\right]=0.10 \mathrm{M}$, and $\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]=5.0 \mathrm{M}$ to be at equilibrium?
f. Why is water included in the equilibrium expression for this reaction?
49. For the reaction

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

$K=2.4 \times 10^{-3}$ at a given temperature. At equilibrium in a 2.0-L container it is found that $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right]=1.1 \times 10^{-1} \mathrm{M}$ and $\left[\mathrm{H}_{2}(\mathrm{~g})\right]=1.9 \times 10^{-2} \mathrm{M}$. Calculate the moles of $\mathrm{O}_{2}(\mathrm{~g})$ present under these conditions.
50. The reaction

$$
2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g) \rightleftharpoons 2 \mathrm{NOBr}(g)
$$

has $K_{\mathrm{p}}=109$ at $25^{\circ} \mathrm{C}$. If the equilibrium partial pressure of $\mathrm{Br}_{2}$ is 0.0159 atm and the equilibrium partial pressure of NOBr is 0.0768 atm , calculate the partial pressure of NO at equilibrium.
[51. A 1.00-L flask was filled with 2.00 moles of gaseous $\mathrm{SO}_{2}$ and 2.00 moles of gaseous $\mathrm{NO}_{2}$ and heated. After equilibrium was reached, it was found that 1.30 moles of gaseous NO was present. Assume that the reaction

$$
\mathrm{SO}_{2}(g)+\mathrm{NO}_{2}(g) \rightleftharpoons \mathrm{SO}_{3}(g)+\mathrm{NO}(g)
$$

occurs under these conditions. Calculate the value of the equilibrium constant, $K$, for this reaction.
52. A sample of $S_{8}(g)$ is placed in an otherwise empty rigid container at 1325 K at an initial pressure of 1.00 atm , where it decomposes to $\mathrm{S}_{2}(g)$ by the reaction

$$
\mathrm{S}_{8}(\mathrm{~g}) \rightleftharpoons 4 \mathrm{~S}_{2}(\mathrm{~g})
$$

At equilibrium, the partial pressure of $\mathrm{S}_{8}$ is 0.25 atm . Calculate $K_{\mathrm{p}}$ for this reaction at 1325 K .
53. At a particular temperature, 12.0 moles of $\mathrm{SO}_{3}$ is placed into a 3.0-L rigid container, and the $\mathrm{SO}_{3}$ dissociates by the reaction

$$
2 \mathrm{SO}_{3}(g) \rightleftharpoons 2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g)
$$

At equilibrium, 3.0 moles of $\mathrm{SO}_{2}$ is present. Calculate $K$ for this reaction.
54. At a particular temperature, 8.0 moles of $\mathrm{NO}_{2}$ is placed into a 1.0-L container and the $\mathrm{NO}_{2}$ dissociates by the reaction

$$
2 \mathrm{NO}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

At equilibrium the concentration of $\mathrm{NO}(g)$ is 2.0 M . Calculate $K$ for this reaction.

An initial mixture of nitrogen gas and hydrogen gas is reacted in a rigid container at a certain temperature by the reaction

$$
3 \mathrm{H}_{2}(g)+\mathrm{N}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

At equilibrium, the concentrations are $\left[\mathrm{H}_{2}\right]=5.0 \mathrm{M},\left[\mathrm{N}_{2}\right]=$ 8.0 M , and $\left[\mathrm{NH}_{3}\right]=4.0 \mathrm{M}$. What were the concentrations of nitrogen gas and hydrogen gas that were reacted initially?
56. Nitrogen gas $\left(\mathrm{N}_{2}\right)$ reacts with hydrogen gas $\left(\mathrm{H}_{2}\right)$ to form ammonia $\left(\mathrm{NH}_{3}\right)$. At $200^{\circ} \mathrm{C}$ in a closed container, 1.00 atm of nitrogen gas is mixed with 2.00 atm of hydrogen gas. At equilibrium, the total pressure is 2.00 atm . Calculate the partial pressure of hydrogen gas at equilibrium, and calculate the $K_{\mathrm{p}}$ value for this reaction.
-57. At a particular temperature, $K=3.75$ for the reaction

$$
\mathrm{SO}_{2}(g)+\mathrm{NO}_{2}(g) \rightleftharpoons \mathrm{SO}_{3}(g)+\mathrm{NO}(g)
$$

If all four gases had initial concentrations of 0.800 M , calculate the equilibrium concentrations of the gases.
58. At a particular temperature, $K_{\mathrm{p}}=1.00 \times 10^{2}$ for the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \leftrightharpoons 2 \mathrm{HI}(g)
$$

If 2.00 atm of $\mathrm{H}_{2}(\mathrm{~g})$ and 2.00 atm of $\mathrm{I}_{2}(\mathrm{~g})$ are introduced into a $1.00-\mathrm{L}$ container, calculate the equilibrium partial pressures of all species.
-59. At $2200^{\circ} \mathrm{C}, K_{\mathrm{p}}=0.050$ for the reaction

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g)
$$

What is the partial pressure of NO in equilibrium with $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ that were placed in a flask at initial pressures of 0.80 and 0.20 atm , respectively?
60. At $25^{\circ} \mathrm{C}, K=0.090$ for the reaction

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+\mathrm{Cl}_{2} \mathrm{O}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HOCl}(\mathrm{~g})
$$

Calculate the concentrations of all species at equilibrium for each of the following cases.
a. $1.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$ and $2.0 \mathrm{~g} \mathrm{Cl}_{2} \mathrm{O}$ are mixed in a $1.0-\mathrm{L}$ flask.
b. 1.0 mole of pure HOCl is placed in a $2.0-\mathrm{L}$ flask.
-61. At $1100 \mathrm{~K}, K_{\mathrm{p}}=0.25$ for the reaction

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{SO}_{3}(\mathrm{~g})
$$

Calculate the equilibrium partial pressures of $\mathrm{SO}_{2}, \mathrm{O}_{2}$, and $\mathrm{SO}_{3}$ produced from an initial mixture in which $P_{\mathrm{SO}_{2}}=P_{\mathrm{O}_{2}}=$ 0.50 atm and $P_{\mathrm{SO}_{3}}=0$. (Hint: If you don't have a graphing calculator, then use the method of successive approximations to solve, as discussed in Appendix 1.4.)
62. At a particular temperature, $K_{\mathrm{p}}=0.25$ for the reaction

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g)
$$

a. A flask containing only $\mathrm{N}_{2} \mathrm{O}_{4}$ at an initial pressure of 4.5 atm is allowed to reach equilibrium. Calculate the equilibrium partial pressures of the gases.
b. A flask containing only $\mathrm{NO}_{2}$ at an initial pressure of 9.0 atm is allowed to reach equilibrium. Calculate the equilibrium partial pressures of the gases.
c. From your answers to parts $a$ and $b$, does it matter from which direction an equilibrium position is reached?
-63. At $35^{\circ} \mathrm{C}, K=1.6 \times 10^{-5}$ for the reaction

$$
2 \mathrm{NOCl}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g)
$$

Calculate the concentrations of all species at equilibrium for each of the following original mixtures.
a. 2.0 moles of pure NOCl in a $2.0-\mathrm{L}$ flask
b. 1.0 mole of NOCl and 1.0 mole of NO in a 1.0-L flask
c. 2.0 moles of NOCl and 1.0 mole of $\mathrm{Cl}_{2}$ in a $1.0-\mathrm{L}$ flask
64. At a particular temperature, $K=2.0 \times 10^{-6}$ for the reaction

$$
2 \mathrm{CO}_{2}(g) \rightleftharpoons 2 \mathrm{CO}(g)+\mathrm{O}_{2}(g)
$$

If 2.0 moles of $\mathrm{CO}_{2}$ is initially placed into a $5.0-\mathrm{L}$ vessel, calculate the equilibrium concentrations of all species.
65. Lexan is a plastic used to make compact discs, eyeglass lenses, and bullet-proof glass. One of the compounds used to make Lexan is phosgene $\left(\mathrm{COCl}_{2}\right)$, an extremely poisonous gas. Phosgene decomposes by the reaction

$$
\mathrm{COCl}_{2}(g) \rightleftharpoons \mathrm{CO}(g)+\mathrm{Cl}_{2}(g)
$$

for which $K_{\mathrm{p}}=6.8 \times 10^{-9}$ at $100^{\circ} \mathrm{C}$. If pure phosgene at an initial pressure of 1.0 atm decomposes, calculate the equilibrium pressures of all species.
66. The creation of shells by mollusk species is a fascinating process. By utilizing the $\mathrm{Ca}^{2+}$ in their food and aqueous environment, as well as some complex equilibrium processes, a hard calcium carbonate shell can be produced. One important equilibrium reaction in this complex process is

$$
\mathrm{HCO}_{3}^{-}(a q) \leftrightharpoons \mathrm{H}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q) K=5.6 \times 10^{-11}
$$

If 0.16 mole of $\mathrm{HCO}_{3}{ }^{-}$is placed into 1.00 L of solution, what will be the equilibrium concentration of $\mathrm{CO}_{3}{ }^{2-}$ ?
-67 . At $25^{\circ} \mathrm{C}, K_{\mathrm{p}}=2.9 \times 10^{-3}$ for the reaction

$$
\mathrm{NH}_{4} \mathrm{OCONH}_{2}(s) \rightleftharpoons 2 \mathrm{NH}_{3}(g)+\mathrm{CO}_{2}(g)
$$

In an experiment carried out at $25^{\circ} \mathrm{C}$, a certain amount of $\mathrm{NH}_{4} \mathrm{OCONH}_{2}$ is placed in an evacuated rigid container and allowed to come to equilibrium. Calculate the total pressure in the container at equilibrium.
68. A sample of solid ammonium chloride was placed in an evacuated container and then heated so that it decomposed to ammonia gas and hydrogen chloride gas. After heating, the total pressure in the container was found to be 4.4 atm . Calculate $K_{\mathrm{p}}$ at this temperature for the decomposition reaction

$$
\mathrm{NH}_{4} \mathrm{Cl}(s) \rightleftharpoons \mathrm{NH}_{3}(g)+\mathrm{HCl}(g)
$$

-69. For the reaction

$$
\mathrm{C}(s)+\mathrm{CO}_{2}(g) \leftrightharpoons 2 \mathrm{CO}(g)
$$

$K_{\mathrm{p}}=2.00$ at some temperature. If this reaction at equilibrium has a total pressure of 6.00 atm , determine the partial pressures of $\mathrm{CO}_{2}$ and CO in the reaction container.
70. The reaction

$$
\mathrm{NH}_{4} \mathrm{SH}(\mathrm{~s}) \leftrightharpoons \mathrm{NH}_{3}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})
$$

has $K_{\mathrm{p}}=0.10$ at $27^{\circ} \mathrm{C}$. What is the minimum amount of $\mathrm{NH}_{4} \mathrm{SH}$ that must be present for this reaction to be at equilibrium in a $10.0-\mathrm{L}$ container?

## Le Châtelier's Principle

-71. Suppose the reaction system

$$
\mathrm{UO}_{2}(s)+4 \mathrm{HF}(g) \rightleftharpoons \mathrm{UF}_{4}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

has already reached equilibrium. Predict the effect that each of the following changes will have on the equilibrium position. Tell whether the equilibrium will shift to the right, will shift to the left, or will not be affected.
a. Additional $\mathrm{UO}_{2}(s)$ is added to the system.
b. The reaction is performed in a glass reaction vessel; $\mathrm{HF}(g)$ attacks and reacts with glass.
c. Water vapor is removed.
72. Solid $\mathrm{NH}_{4} \mathrm{HS}$ decomposes by the following endothermic process:

$$
\mathrm{NH}_{4} \mathrm{HS}(\mathrm{~s}) \leftrightharpoons \mathrm{NH}_{3}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})
$$

a. What effect will adding more $\mathrm{NH}_{3}(g)$ have on the equilibrium?
b. What effect will adding more $\mathrm{NH}_{4} \mathrm{HS}(s)$ have on the equilibrium?
c. What effect will increasing the volume of the container have on the equilibrium?
d. What effect will decreasing the temperature have on the equilibrium?
73. For the following reactions, predict whether the mole fraction of the reactants or products increases or remains the same when the volume of the reaction vessel is increased.
a. $\mathrm{Br}_{2}(g)+\mathrm{H}_{2}(g) \leftrightharpoons 2 \mathrm{HBr}(g)$
b. $2 \mathrm{CH}_{4}(\mathrm{~g}) \leftrightharpoons \mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g})$
c. $2 \mathrm{HI}(g) \leftrightharpoons \mathrm{I}_{2}(s)+\mathrm{H}_{2}(g)$
74. Predict the shift in the equilibrium position that will occur for each of the following reactions when the volume of the reaction container is increased.
a. $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)$
b. $\mathrm{PCl}_{5}(g) \rightleftharpoons \mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g)$
c. $\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \rightleftharpoons 2 \mathrm{HF}(g)$
d. $\mathrm{COCl}_{2}(\mathrm{~g}) \rightleftharpoons \mathrm{CO}(\mathrm{g})+\mathrm{Cl}_{2}(\mathrm{~g})$
e. $\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$
75. An important reaction in the commercial production of hydrogen is

$$
\mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g)
$$

How will this system at equilibrium shift in each of the five following cases?
a. Gaseous carbon dioxide is removed.
b. Water vapor is added.
c. In a rigid reaction container, the pressure is increased by adding helium gas.
d. The temperature is increased (the reaction is exothermic).
e. The pressure is increased by decreasing the volume of the reaction container.
76. What will happen to the number of moles of $\mathrm{SO}_{3}$ in equilibrium with $\mathrm{SO}_{2}$ and $\mathrm{O}_{2}$ in the reaction

$$
2 \mathrm{SO}_{3}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

in each of the following cases?
a. Oxygen gas is added.
b. The pressure is increased by decreasing the volume of the reaction container.
c. In a rigid reaction container, the pressure is increased by adding argon gas.
d. The temperature is decreased (the reaction is endothermic).
e. Gaseous sulfur dioxide is removed.
777. In which direction will the position of the equilibrium

$$
2 \mathrm{HI}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{I}_{2}(g)
$$

be shifted for each of the following changes?
a. $\mathrm{H}_{2}(g)$ is added.
b. $\mathrm{I}_{2}(\mathrm{~g})$ is removed.
c. $\mathrm{HI}(g)$ is removed.
d. In a rigid reaction container, some $\operatorname{Ar}(g)$ is added.
e. The volume of the container is doubled.
f. The temperature is decreased (the reaction is exothermic).
78. Hydrogen for use in ammonia production is produced by the reaction

What will happen to a reaction mixture at equilibrium if
a. $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ is removed?
b. the temperature is increased (the reaction is endothermic)?
c. an inert gas is added to a rigid reaction container?
d. $\mathrm{CO}(g)$ is removed?
e. the volume of the container is tripled?
79. Old-fashioned "smelling salts" consist of ammonium carbonate, $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{CO}_{3}$. The reaction for the decomposition of ammonium carbonate

$$
\left(\mathrm{NH}_{4}\right)_{2} \mathrm{CO}_{3}(\mathrm{~s}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

is endothermic. Would the smell of ammonia increase or decrease as the temperature is increased?
80. Ammonia is produced by the Haber process, in which nitrogen and hydrogen are reacted directly using an iron mesh impregnated with oxides as a catalyst. For the reaction

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

equilibrium constants ( $K_{\mathrm{p}}$ values) as a function of temperature are
$300^{\circ} \mathrm{C}, \quad 4.34 \times 10^{-3}$
$500^{\circ} \mathrm{C}, \quad 1.45 \times 10^{-5}$
$600^{\circ} \mathrm{C}, \quad 2.25 \times 10^{-6}$
Is the reaction exothermic or endothermic?

## Additional Exercises

81. Calculate a value for the equilibrium constant for the reaction

$$
\mathrm{O}_{2}(\mathrm{~g})+\mathrm{O}(\mathrm{~g}) \rightleftharpoons \mathrm{O}_{3}(\mathrm{~g})
$$

given

$$
\begin{array}{cl}
\mathrm{NO}_{2}(g) \stackrel{h \nu}{\rightleftharpoons} \mathrm{NO}(g)+\mathrm{O}(g) & K=6.8 \times 10^{-49} \\
\mathrm{O}_{3}(g)+\mathrm{NO}(g) \rightleftharpoons \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g) & K=5.8 \times 10^{-34}
\end{array}
$$

(Hint: When reactions are added together, the equilibrium expressions are multiplied.)
82. Given the following equilibrium constants at $427^{\circ} \mathrm{C}$,

$$
\begin{array}{ll}
\mathrm{Na}_{2} \mathrm{O}(s) \rightleftharpoons 2 \mathrm{Na}(l)+\frac{1}{2} \mathrm{O}_{2}(g) & K_{1}=2 \times 10^{-25} \\
\mathrm{NaO}(g) \rightleftharpoons \mathrm{Na}(l)+\frac{1}{2} \mathrm{O}_{2}(g) & K_{2}=2 \times 10^{-5} \\
\mathrm{Na}_{2} \mathrm{O}_{2}(s) \rightleftharpoons 2 \mathrm{Na}(l)+\mathrm{O}_{2}(g) & K_{3}=5 \times 10^{-29} \\
\mathrm{NaO}_{2}(s) \rightleftharpoons \mathrm{Na}(l)+\mathrm{O}_{2}(g) & K_{4}=3 \times 10^{-14}
\end{array}
$$

determine the values for the equilibrium constants for the following reactions:
a. $\mathrm{Na}_{2} \mathrm{O}(s)+\frac{1}{2} \mathrm{O}_{2}(g) \rightleftharpoons \mathrm{Na}_{2} \mathrm{O}_{2}(s)$
b. $\mathrm{NaO}(g)+\mathrm{Na}_{2} \mathrm{O}(s) \rightleftharpoons \mathrm{Na}_{2} \mathrm{O}_{2}(s)+\mathrm{Na}(l)$
c. $2 \mathrm{NaO}(g) \rightleftharpoons \mathrm{Na}_{2} \mathrm{O}_{2}(s)$
(Hint: When reaction equations are added, the equilibrium expressions are multiplied.)
83. Consider the decomposition of the compound $\mathrm{C}_{5} \mathrm{H}_{6} \mathrm{O}_{3}$ as follows:

$$
\mathrm{C}_{5} \mathrm{H}_{6} \mathrm{O}_{3}(\mathrm{~g}) \rightleftharpoons \mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})+3 \mathrm{CO}(\mathrm{~g})
$$

When a 5.63 -g sample of pure $\mathrm{C}_{5} \mathrm{H}_{6} \mathrm{O}_{3}(g)$ was sealed into an otherwise empty $2.50-\mathrm{L}$ flask and heated to $200 .{ }^{\circ} \mathrm{C}$, the pressure in the flask gradually rose to 1.63 atm and remained at that value. Calculate $K$ for this reaction.
84. At $25^{\circ} \mathrm{C}, K_{\mathrm{p}} \approx 1 \times 10^{-31}$ for the reaction

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g)
$$

a. Calculate the concentration of NO, in molecules $/ \mathrm{cm}^{3}$, that can exist in equilibrium in air at $25^{\circ} \mathrm{C}$. In air, $P_{\mathrm{N}_{2}}=0.8 \mathrm{~atm}$ and $P_{\mathrm{O}_{2}}=0.2 \mathrm{~atm}$.
b. Typical concentrations of NO in relatively pristine environments range from $10^{8}$ to $10^{10}$ molecules $/ \mathrm{cm}^{3}$. Why is there a discrepancy between these values and your answer to part a?
85. The gas arsine, $\mathrm{AsH}_{3}$, decomposes as follows:

$$
2 \mathrm{AsH}_{3}(g) \rightleftharpoons 2 \mathrm{As}(s)+3 \mathrm{H}_{2}(g)
$$

In an experiment at a certain temperature, pure $\mathrm{AsH}_{3}(\mathrm{~g})$ was placed in an empty, rigid, sealed flask at a pressure of 392.0 torr. After 48 hours the pressure in the flask was observed to be constant at 488.0 torr.
a. Calculate the equilibrium pressure of $\mathrm{H}_{2}(g)$.
b. Calculate $K_{\mathrm{p}}$ for this reaction.
86. At a certain temperature, $K=9.1 \times 10^{-4}$ for the reaction

$$
\mathrm{FeSCN}^{2+}(a q) \rightleftharpoons \mathrm{Fe}^{3+}(a q)+\mathrm{SCN}^{-}(a q)
$$

Calculate the concentrations of $\mathrm{Fe}^{3+}, \mathrm{SCN}^{-}$, and $\mathrm{FeSCN}^{2+}$ in a solution that is initially $2.0 \mathrm{MFeSCN}{ }^{2+}$.
87. At a certain temperature, $K=1.1 \times 10^{3}$ for the reaction

$$
\mathrm{Fe}^{3+}(a q)+\mathrm{SCN}^{-}(a q) \rightleftharpoons \mathrm{FeSCN}^{2+}(a q)
$$

Calculate the concentrations of $\mathrm{Fe}^{3+}, \mathrm{SCN}^{-}$, and $\mathrm{FeSCN}^{2+}$ at equilibrium if 0.020 mole of $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$ is added to 1.0 L of 0.10 MKSCN . (Neglect any volume change.)
88. For the reaction

$$
\operatorname{PCl}_{5}(g) \rightleftharpoons \operatorname{PCl}_{3}(g)+\mathrm{Cl}_{2}(g)
$$

at $600 . \mathrm{K}$, the equilibrium constant, $K_{\mathrm{p}}$, is 11.5 . Suppose that $2.450 \mathrm{~g} \mathrm{PCl}_{5}$ is placed in an evacuated $500 .-\mathrm{mL}$ bulb, which is then heated to 600 . K.
a. What would be the pressure of $\mathrm{PCl}_{5}$ if it did not dissociate?
b. What is the partial pressure of $\mathrm{PCl}_{5}$ at equilibrium?
c. What is the total pressure in the bulb at equilibrium?
d. What is the percent dissociation of $\mathrm{PCl}_{5}$ at equilibrium?
89. At $25^{\circ} \mathrm{C}$, gaseous $\mathrm{SO}_{2} \mathrm{Cl}_{2}$ decomposes to $\mathrm{SO}_{2}(g)$ and $\mathrm{Cl}_{2}(g)$ to the extent that $12.5 \%$ of the original $\mathrm{SO}_{2} \mathrm{Cl}_{2}$ (by moles) has decomposed to reach equilibrium. The total pressure (at equilibrium) is 0.900 atm . Calculate the value of $K_{\mathrm{p}}$ for this system.
90. For the following reaction at a certain temperature

$$
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{F}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HF}(\mathrm{~g})
$$

it is found that the equilibrium concentrations in a $5.00-\mathrm{L}$ rigid container are $\left[\mathrm{H}_{2}\right]=0.0500 \mathrm{M},\left[\mathrm{F}_{2}\right]=0.0100 \mathrm{M}$, and $[\mathrm{HF}]=$ 0.400 M . If 0.200 mole of $\mathrm{F}_{2}$ is added to this equilibrium mixture, calculate the concentrations of all gases once equilibrium is reestablished.
91. Novelty devices for predicting rain contain cobalt(II) chloride and are based on the following equilibrium:

$$
\underset{\text { Purple }}{\mathrm{CoCl}_{2}(s)}+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightleftharpoons \underset{\text { Pink }}{\mathrm{CoCl}_{2}} \cdot 6 \mathrm{H}_{2} \mathrm{O}(s)
$$

What color will such an indicator be if rain is imminent?
92. Consider the reaction

$$
\mathrm{Fe}^{3+}(a q)+\mathrm{SCN}^{-}(a q) \rightleftharpoons \mathrm{FeSCN}^{2+}(a q)
$$

How will the equilibrium position shift if
a. water is added, doubling the volume?
b. $\mathrm{AgNO}_{3}(a q)$ is added? $(\mathrm{AgSCN}$ is insoluble.)
c. $\mathrm{NaOH}(a q)$ is added? $\left[\mathrm{Fe}(\mathrm{OH})_{3}\right.$ is insoluble.]
d. $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}(\mathrm{aq})$ is added?
93. Chromium(VI) forms two different oxyanions, the orange dichromate ion, $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}$, and the yellow chromate ion, $\mathrm{CrO}_{4}{ }^{2-}$. (See the following photos.) The equilibrium reaction between the two ions is

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons 2 \mathrm{CrO}_{4}{ }^{2-}(a q)+2 \mathrm{H}^{+}(a q)
$$

Explain why orange dichromate solutions turn yellow when sodium hydroxide is added.

94. The synthesis of ammonia gas from nitrogen gas and hydrogen gas represents a classic case in which a knowledge of kinetics and equilibrium was used to make a desired chemical reaction economically feasible. Explain how each of the following conditions helps to maximize the yield of ammonia.
a. running the reaction at an elevated temperature
b. removing the ammonia from the reaction mixture as it forms
c. using a catalyst
d. running the reaction at high pressure
95. Suppose $K=4.5 \times 10^{-3}$ at a certain temperature for the reaction

$$
\operatorname{PCl}_{5}(g) \rightleftharpoons \mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g)
$$

If it is found that the concentration of $\mathrm{PCl}_{5}$ is twice the concentration of $\mathrm{PCl}_{3}$, what must be the concentration of $\mathrm{Cl}_{2}$ under these conditions?
96. For the reaction below, $K_{\mathrm{p}}=1.16$ at $800 .{ }^{\circ} \mathrm{C}$.

$$
\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

If a $20.0-\mathrm{g}$ sample of $\mathrm{CaCO}_{3}$ is put into a $10.0-\mathrm{L}$ container and heated to $800 .{ }^{\circ} \mathrm{C}$, what percentage by mass of the $\mathrm{CaCO}_{3}$ will react to reach equilibrium?
97. Many sugars undergo a process called mutarotation, in which the sugar molecules interconvert between two isomeric forms, finally reaching an equilibrium between them. This is true for the simple sugar glucose, $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$, which exists in solution in isomeric forms called alpha-glucose and beta-glucose. If a solution of glucose at a certain temperature is analyzed, and it is found that the concentration of alpha-glucose is twice the concentration of beta-glucose, what is the value of $K$ for the interconversion reaction?
98. Peptide decomposition is one of the key processes of digestion, where a peptide bond is broken into an acid group and an amine group. We can describe this reaction as follows:
Peptide $(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons$ acid group $(a q)+$ amine group $(a q)$
If we place 1.0 mole of peptide into 1.0 L water, what will be the equilibrium concentrations of all species in this reaction? Assume the $K$ value for this reaction is $3.1 \times 10^{-5}$.
99. Methanol, a common laboratory solvent, poses a threat of blindness or death if consumed in sufficient amounts. Once in the body, the substance is oxidized to produce formaldehyde (embalming fluid) and eventually formic acid. Both of these substances are also toxic in varying levels. The equilibrium between methanol and formaldehyde can be described as follows:

$$
\mathrm{CH}_{3} \mathrm{OH}(a q) \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}(a q)+\mathrm{H}_{2}(a q)
$$

Assuming the value of $K$ for this reaction is $3.7 \times 10^{-10}$, what are the equilibrium concentrations of each species if you start with a 1.24 M solution of methanol? What will happen to the concentration of methanol as the formaldehyde is further converted to formic acid?
100. At a particular temperature, $K=1.00 \times 10^{2}$ for the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \leftrightharpoons 2 \mathrm{HI}(g)
$$

In an experiment, 1.00 mole of $\mathrm{H}_{2}, 1.00$ mole of $\mathrm{I}_{2}$, and 1.00 mole of HI are introduced into a $1.00-\mathrm{L}$ container. Calculate the concentrations of all species when equilibrium is reached.

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
101. For the reaction:

$$
3 \mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{O}_{3}(g)
$$

$K=1.8 \times 10^{-7}$ at a certain temperature. If at equilibrium $\left[\mathrm{O}_{2}\right]=0.062 \mathrm{M}$, calculate the equilibrium $\mathrm{O}_{3}$ concentration.
102. An equilibrium mixture contains 0.60 g solid carbon and the gases carbon dioxide and carbon monoxide at partial pressures of 2.60 atm and 2.89 atm , respectively. Calculate the value of $K_{\mathrm{p}}$ for the reaction $\mathrm{C}(s)+\mathrm{CO}_{2}(g) \rightleftharpoons 2 \mathrm{CO}(g)$.
103. At a particular temperature, 8.1 moles of $\mathrm{NO}_{2}$ gas are placed in a $3.0-\mathrm{L}$ container. Over time the $\mathrm{NO}_{2}$ decomposes to NO and $\mathrm{O}_{2}$ :

$$
2 \mathrm{NO}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

At equilibrium the concentration of $\mathrm{NO}(g)$ was found to be $1.4 \mathrm{~mol} / \mathrm{L}$. Calculate the value of $K$ for this reaction.
104. A sample of solid ammonium chloride was placed in an evacuated chamber and then heated, causing it to decompose according to the following reaction:

$$
\mathrm{NH}_{4} \mathrm{Cl}(s) \rightleftharpoons \mathrm{NH}_{3}(g)+\mathrm{HCl}(g)
$$

In a particular experiment, the equilibrium partial pressure of $\mathrm{NH}_{3}(g)$ in the container was 2.9 atm . Calculate the value of $K_{\mathrm{p}}$ for the decomposition of $\mathrm{NH}_{4} \mathrm{Cl}(s)$ at this temperature.
105. In a given experiment, 5.2 moles of pure NOCl were placed in an otherwise empty $2.0-\mathrm{L}$ container. Equilibrium was established by the following reaction:

$$
2 \mathrm{NOCl}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \quad K=1.6 \times 10^{-5}
$$

a. Using numerical values for the concentrations in the Initial row and expressions containing the variable $x$ in both the Change and Equilibrium rows, complete the following table summarizing what happens as this reaction reaches equilibrium. Let $x=$ the concentration of $\mathrm{Cl}_{2}$ that is present at equilibrium.

|  |  |  |
| :--- | :--- | :--- |
|  |  |  |
| Initial |  |  |
| ChaCl |  |  |
| Equilibrium | $2.6-2 x$ |  |

b. Calculate the equilibrium concentrations for all species.
106. For the reaction $\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g), K_{\mathrm{p}}=0.25$ at a certain temperature. If 0.040 atm of $\mathrm{N}_{2} \mathrm{O}_{4}$ is reacted initially, calculate the equilibrium partial pressures of $\mathrm{NO}_{2}(g)$ and $\mathrm{N}_{2} \mathrm{O}_{4}(g)$.
107. Consider the following exothermic reaction at equilibrium:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

Predict how the following changes affect the number of moles of each component of the system after equilibrium is reestablished by completing the table below. Complete the table with the terms increase, decrease, or no change.

|  |
| :--- |
| Add $\mathrm{N}_{2}(g)$ |
| Remove $\mathrm{H}_{2}(g)$ |
| Add $\mathrm{NH}_{3}(g)$ |
| Add $\mathrm{Ne}(g)$ |
| (constant $V$ ) |
| Increase the temperature |
| Decrease the volume <br> (constant $T$ ) <br> Add a catalyst |

108. For the following endothermic reaction at equilibrium:

$$
2 \mathrm{SO}_{3}(g) \rightleftharpoons 2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g)
$$

which of the following changes will increase the value of $K$ ?
a. increasing the temperature
b. decreasing the temperature
c. removing $\mathrm{SO}_{3}(g)$ (constant $T$ )
d. decreasing the volume (constant $T$ )
e. adding $\mathrm{Ne}(g)$ (constant $T$ )
f. adding $\mathrm{SO}_{2}(g)$ (constant $\left.T\right)$
g. adding a catalyst (constant $T$ )

## Challenge Problems

109. A 1.604-g sample of methane $\left(\mathrm{CH}_{4}\right)$ gas and 6.400 g oxygen gas are sealed into a $2.50-\mathrm{L}$ vessel at $411^{\circ} \mathrm{C}$ and are allowed to reach equilibrium. Methane can react with oxygen to form gaseous carbon dioxide and water vapor, or methane can react with oxygen to form gaseous carbon monoxide and water vapor. At equilibrium, the pressure of oxygen is 0.326 atm , and the pressure of water vapor is 4.45 atm . Calculate the pressures of carbon monoxide and carbon dioxide present at equilibrium.
110. A 4.72-g sample of methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ was placed in an otherwise empty $1.00-\mathrm{L}$ flask and heated to $250 .{ }^{\circ} \mathrm{C}$ to vaporize the methanol. Over time, the methanol vapor decomposed by the following reaction:

$$
\mathrm{CH}_{3} \mathrm{OH}(g) \rightleftharpoons \mathrm{CO}(g)+2 \mathrm{H}_{2}(g)
$$

After the system has reached equilibrium, a tiny hole is drilled in the side of the flask allowing gaseous compounds to effuse out of the flask. Measurements of the effusing gas show that it contains 33.0 times as much $\mathrm{H}_{2}(g)$ as $\mathrm{CH}_{3} \mathrm{OH}(g)$. Calculate $K$ for this reaction at $250 .{ }^{\circ} \mathrm{C}$.
111. At $35^{\circ} \mathrm{C}, K=1.6 \times 10^{-5}$ for the reaction

$$
2 \mathrm{NOCl}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g)
$$

If 2.0 moles of NO and 1.0 mole of $\mathrm{Cl}_{2}$ are placed into a $1.0-\mathrm{L}$ flask, calculate the equilibrium concentrations of all species.
112. Nitric oxide and bromine at initial partial pressures of 98.4 and 41.3 torr, respectively, were allowed to react at 300 . K. At equilibrium the total pressure was 110.5 torr. The reaction is

$$
2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g) \rightleftharpoons 2 \mathrm{NOBr}(g)
$$

a. Calculate the value of $K_{\mathrm{p}}$.
b. What would be the partial pressures of all species if NO and $\mathrm{Br}_{2}$, both at an initial partial pressure of 0.30 atm , were allowed to come to equilibrium at this temperature?
113. At $25^{\circ} \mathrm{C}, K_{\mathrm{p}}=5.3 \times 10^{5}$ for the reaction

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

When a certain partial pressure of $\mathrm{NH}_{3}(g)$ is put into an otherwise empty rigid vessel at $25^{\circ} \mathrm{C}$, equilibrium is reached when $50.0 \%$ of the original ammonia has decomposed. What was the original partial pressure of ammonia before any decomposition occurred?
114. Consider the reaction

$$
\mathrm{P}_{4}(g) \rightleftharpoons 2 \mathrm{P}_{2}(g)
$$

where $K_{\mathrm{p}}=1.00 \times 10^{-1}$ at 1325 K . In an experiment where $\mathrm{P}_{4}(g)$ is placed into a container at 1325 K , the equilibrium mixture of $\mathrm{P}_{4}(g)$ and $\mathrm{P}_{2}(g)$ has a total pressure of 1.00 atm. Calculate the equilibrium pressures of $\mathrm{P}_{4}(g)$ and $\mathrm{P}_{2}(g)$. Calculate the fraction (by moles) of $\mathrm{P}_{4}(g)$ that has dissociated to reach equilibrium.
115. The partial pressures of an equilibrium mixture of $\mathrm{N}_{2} \mathrm{O}_{4}(g)$ and $\mathrm{NO}_{2}(g)$ are $P_{\mathrm{N}_{2} \mathrm{O}_{4}}=0.34 \mathrm{~atm}$ and $P_{\mathrm{NO}_{2}}=1.20 \mathrm{~atm}$ at a certain temperature. The volume of the container is doubled. Calculate the partial pressures of the two gases when a new equilibrium is established.
116. At $125^{\circ} \mathrm{C}, K_{\mathrm{p}}=0.25$ for the reaction

$$
2 \mathrm{NaHCO}_{3}(s) \rightleftharpoons \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

A $1.00-\mathrm{L}$ flask containing $10.0 \mathrm{~g} \mathrm{NaHCO}_{3}$ is evacuated and heated to $125^{\circ} \mathrm{C}$.
a. Calculate the partial pressures of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ after equilibrium is established.
b. Calculate the masses of $\mathrm{NaHCO}_{3}$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}$ present at equilibrium.
c. Calculate the minimum container volume necessary for all of the $\mathrm{NaHCO}_{3}$ to decompose.
117. A mixture of $\mathrm{N}_{2}, \mathrm{H}_{2}$, and $\mathrm{NH}_{3}$ is at equilibrium [according to the equation $\left.\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)\right]$ as depicted below:

The volume is suddenly decreased (by increasing the external pressure) and a new equilibrium is established as depicted below:

a. If the volume of the final equilibrium mixture is 1.00 L , determine the value of the equilibrium constant, $K$, for the reaction. Assume temperature is constant.
b. Determine the volume of the initial equilibrium mixture assuming a final equilibrium volume of 1.00 L and assuming a constant temperature.
118. Consider the decomposition equilibrium for dinitrogen pentoxide:

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \rightleftharpoons 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

At a certain temperature and a total pressure of 1.00 atm , the $\mathrm{N}_{2} \mathrm{O}_{5}$ is $0.50 \%$ decomposed (by moles) at equilibrium.
a. If the volume is increased by a factor of 10.0 , will the mole percent of $\mathrm{N}_{2} \mathrm{O}_{5}$ decomposed at equilibrium be greater than, less than, or equal to $0.50 \%$ ? Explain your answer.
b. Calculate the mole percent of $\mathrm{N}_{2} \mathrm{O}_{5}$ that will be decomposed at equilibrium if the volume is increased by a factor of 10.0 .
119. An $8.00-\mathrm{g}$ sample of $\mathrm{SO}_{3}$ was placed in an evacuated container, where it decomposed at $600^{\circ} \mathrm{C}$ according to the following reaction:

$$
\mathrm{SO}_{3}(g) \rightleftharpoons \mathrm{SO}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g)
$$

At equilibrium the total pressure and the density of the gaseous mixture were 1.80 atm and $1.60 \mathrm{~g} / \mathrm{L}$, respectively. Calculate $K_{\mathrm{p}}$ for this reaction.
120. A sample of iron(II) sulfate was heated in an evacuated container to 920 K , where the following reactions occurred:

$$
\begin{gathered}
2 \mathrm{FeSO}_{4}(s) \rightleftharpoons \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+\mathrm{SO}_{3}(g)+\mathrm{SO}_{2}(g) \\
\mathrm{SO}_{3}(g) \rightleftharpoons \mathrm{SO}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g)
\end{gathered}
$$

After equilibrium was reached, the total pressure was 0.836 atm and the partial pressure of oxygen was 0.0275 atm . Calculate $K_{\mathrm{p}}$ for each of these reactions.
121. At 5000 K and $1.000 \mathrm{~atm}, 83.00 \%$ of the oxygen molecules in a sample have dissociated to atomic oxygen. At what pressure will $95.0 \%$ of the molecules dissociate at this temperature?
122. A sample of $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ is placed in an empty cylinder at $25^{\circ} \mathrm{C}$. After equilibrium is reached the total pressure is 1.5 atm and $16 \%$ (by moles) of the original $\mathrm{N}_{2} \mathrm{O}_{4}(g)$ has dissociated to $\mathrm{NO}_{2}(g)$.
a. Calculate the value of $K_{\mathrm{p}}$ for this dissociation reaction at $25^{\circ} \mathrm{C}$.
b. If the volume of the cylinder is increased until the total pressure is 1.0 atm (the temperature of the system remains constant), calculate the equilibrium pressure of $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ and $\mathrm{NO}_{2}(g)$.
c. What percentage (by moles) of the original $\mathrm{N}_{2} \mathrm{O}_{4}(g)$ is dissociated at the new equilibrium position (total pressure $=1.00 \mathrm{~atm})$ ?
123. A sample of gaseous nitrosyl bromide (NOBr) was placed in a container fitted with a frictionless, massless piston, where it decomposed at $25^{\circ} \mathrm{C}$ according to the following equation:

$$
2 \mathrm{NOBr}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g)
$$

The initial density of the system was recorded as $4.495 \mathrm{~g} / \mathrm{L}$. After equilibrium was reached, the density was noted to be $4.086 \mathrm{~g} / \mathrm{L}$.
a. Determine the value of the equilibrium constant $K$ for the reaction.
b. If $\operatorname{Ar}(g)$ is added to the system at equilibrium at constant temperature, what will happen to the equilibrium position? What happens to the value of $K$ ? Explain each answer.
124. The equilibrium constant $K_{\mathrm{p}}$ for the reaction

$$
\mathrm{CCl}_{4}(g) \rightleftharpoons \mathrm{C}(s)+2 \mathrm{Cl}_{2}(g)
$$

at $700^{\circ} \mathrm{C}$ is 0.76 . Determine the initial pressure of carbon tetrachloride that will produce a total equilibrium pressure of 1.20 atm at $700^{\circ} \mathrm{C}$.

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
125. For the reaction

$$
\mathrm{NH}_{3}(g)+\mathrm{H}_{2} \mathrm{~S}(g) \rightleftharpoons \mathrm{NH}_{4} \mathrm{HS}(s)
$$

$K=400$. at $35.0^{\circ} \mathrm{C}$. If 2.00 moles each of $\mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{~S}$, and $\mathrm{NH}_{4} \mathrm{HS}$ are placed in a $5.00-\mathrm{L}$ vessel, what mass of $\mathrm{NH}_{4} \mathrm{HS}$ will be present at equilibrium? What is the pressure of $\mathrm{H}_{2} \mathrm{~S}$ at equilibrium?
126. Given $K=3.50$ at $45^{\circ} \mathrm{C}$ for the reaction

$$
\mathrm{A}(g)+\mathrm{B}(g) \rightleftharpoons \mathrm{C}(g)
$$

and $K=7.10$ at $45^{\circ} \mathrm{C}$ for the reaction

$$
2 \mathrm{~A}(g)+\mathrm{D}(g) \rightleftharpoons \mathrm{C}(g)
$$

what is the value of $K$ at the same temperature for the reaction

$$
\mathrm{C}(\mathrm{~g})+\mathrm{D}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{~B}(\mathrm{~g})
$$

What is the value of $K_{\mathrm{p}}$ at $45^{\circ} \mathrm{C}$ for the reaction? Starting with 1.50 atm partial pressures of both C and D , what is the mole fraction of B once equilibrium is reached?
127. In a solution with carbon tetrachloride as the solvent, the compound $\mathrm{VCl}_{4}$ undergoes dimerization:

$$
2 \mathrm{VCl}_{4} \rightleftharpoons \mathrm{~V}_{2} \mathrm{Cl}_{8}
$$

When $6.6834 \mathrm{~g} \mathrm{VCl}_{4}$ is dissolved in 100.0 g carbon tetrachloride, the freezing point is lowered by $5.97^{\circ} \mathrm{C}$. Calculate the value of the equilibrium constant for the dimerization of $\mathrm{VCl}_{4}$ at this temperature. (The density of the equilibrium mixture is $1.696 \mathrm{~g} / \mathrm{cm}^{3}$, and $K_{\mathrm{f}}=29.8^{\circ} \mathrm{C} \mathrm{kg} / \mathrm{mol}$ for $\mathrm{CCl}_{4}$.)
128. The hydrocarbon naphthalene was frequently used in mothballs until recently, when it was discovered that human inhalation of naphthalene vapors can lead to hemolytic anemia. Naphthalene is $93.71 \%$ carbon by mass, and a 0.256 -mole sample of naphthalene has a mass of 32.8 g . What is the molecular formula of naphthalene? This compound works as a pesticide in mothballs by sublimation of the solid so that it fumigates enclosed spaces with its vapors according to the equation

$$
\begin{gathered}
\text { Naphthalene }(s) \rightleftharpoons \text { naphthalene }(g) \\
K=4.29 \times 10^{-6}(\text { at } 298 \mathrm{~K})
\end{gathered}
$$

If 3.00 g solid naphthalene is placed into an enclosed space with a volume of 5.00 L at $25^{\circ} \mathrm{C}$, what percentage of the naphthalene will have sublimed once equilibrium has been established?

## Marathon Problem

This problem is designed to incorporate several concepts and techniques into one situation.
129. A gaseous material $X Y(g)$ dissociates to some extent to produce $X(g)$ and $Y(g)$ :

$$
X Y(g) \rightleftharpoons X(g)+Y(g)
$$

A $2.00-\mathrm{g}$ sample of $X Y$ (molar mass $=165 \mathrm{~g} / \mathrm{mol}$ ) is placed in a container with a movable piston at $25^{\circ} \mathrm{C}$. The pressure is held constant at 0.967 atm . As XY begins to dissociate, the piston moves until 35.0 mole percent of the original XY has dissociated and then remains at a constant position. Assuming ideal behavior, calculate the density of the gas in the container after the piston has stopped moving, and determine the value of $K$ for this reaction of $25^{\circ} \mathrm{C}$.

The colors of hydrangea blossoms depend on the acidity of the soil. (Basie B/istockphoto.com)

14.12 Strategy for Solving Acid-Base Problems: A Summary
n this chapter we reencounter two very important classes of compounds, acids and bases. We will explore their interactions and apply the fundamentals of chemical equilibria discussed in Chapter 13 to systems involving proton-transfer reactions.

Acid-base chemistry is important in a wide variety of everyday applications. There are complex systems in our bodies that carefully control the acidity of our blood, since even small deviations may lead to serious illness and death. The same sensitivity exists in other life forms. If you have ever had tropical fish or goldfish, you know how important it is to monitor and control the acidity of the water in the aquarium.

Acids and bases are also important in industry. For example, the vast quantity of sulfuric acid manufactured in the United States each year is needed to produce fertilizers, polymers, steel, and many other materials.

The influence of acids on living things has assumed special importance in the United States, Canada, and Europe in recent years as a result of the phenomenon of acid rain. This problem is complex and has diplomatic and economic overtones that make it all the more difficult to solve.

### 14.1 The Nature of Acids and Bases

Acids and bases were first discussed in Section 4.2.

Acids were first recognized as a class of substances that taste sour. Vinegar tastes sour because it is a dilute solution of acetic acid; citric acid is responsible for the sour taste of a lemon. Bases, sometimes called alkalis, are characterized by their bitter taste and slippery feel. Commercial preparations for unclogging drains are highly basic.

The first person to recognize the essential nature of acids and bases was Svante Arrhenius. Based on his experiments with electrolytes, Arrhenius postulated that

$\Delta$
Liquids that contain acids and bases.

$\Delta$
Household products that contain acids and bases.

Recall that ( $a q$ ) means the substance is hydrated.

FIGURE 14.1 The reaction of HCl and $\mathrm{H}_{2} \mathrm{O}$.
acids produce hydrogen ions in aqueous solution, while bases produce hydroxide ions. At the time, the Arrhenius concept of acids and bases was a major step forward in quantifying acid-base chemistry, but this concept is limited because it applies only to aqueous solutions and allows for only one kind of base-the hydroxide ion. A more general definition of acids and bases was suggested by the Danish chemist Johannes Brønsted (1879-1947) and the English chemist Thomas Lowry (18741936). In terms of the Brønsted-Lowry model, an acid is a proton ( $\mathrm{H}^{+}$) donor, and a base is a proton acceptor. For example, when gaseous HCl dissolves in water, each HCl molecule donates a proton to a water molecule and so qualifies as a Brønsted-Lowry acid. The molecule that accepts the proton, in this case water, is a Brønsted-Lowry base.

To understand how water can act as a base, we need to remember that the oxygen of the water molecule has two unshared electron pairs, either of which can form a covalent bond with an $\mathrm{H}^{+}$ion. When gaseous HCl dissolves, the following reaction occurs:

Note that the proton is transferred from the HCl molecule to the water molecule to form $\mathrm{H}_{3} \mathrm{O}^{+}$, which is called the hydronium ion*. This reaction is represented in Fig. 14.1 using molecular models.

The general reaction that occurs when an acid is dissolved in water can best be represented as

$$
\begin{equation*}
\underset{\text { Acid }}{\mathrm{HA}(a q)}+\underset{\text { Base }}{\mathrm{H}_{2} \mathrm{O}(l)} \rightleftharpoons \underset{\substack{\text { Conjugate } \\ \text { acid }}}{\mathrm{H}_{3} \mathrm{O}^{+}(a q)}+\underset{\substack{\text { Conjugate } \\ \text { base }}}{\mathrm{A}^{-}(a q)} \tag{14.1}
\end{equation*}
$$

This representation emphasizes the significant role of the polar water molecule in pulling the proton from the acid. Note that the conjugate base is everything that remains of the acid molecule after a proton is lost. The conjugate acid is formed when the proton is transferred to the base. A conjugate acid-base pair consists of two substances related to each other by the donating and accepting of a single proton. In Equation (14.1) there are two conjugate acid-base pairs: HA and $\mathrm{A}^{-}$as well as $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{H}_{3} \mathrm{O}^{+}$. This reaction is represented by molecular models in Fig. 14.2.

It is important to note that Equation (14.1) really represents a competition for the proton between the two bases $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{A}^{-}$. If $\mathrm{H}_{2} \mathrm{O}$ is a much stronger base than $\mathrm{A}^{-}$, that is, if $\mathrm{H}_{2} \mathrm{O}$ has a much greater affinity for $\mathrm{H}^{+}$than does $\mathrm{A}^{-}$, the equilibrium position will be far to the right; most of the acid dissolved will be in the ionized form. Conversely, if $\mathrm{A}^{-}$is a much stronger base than $\mathrm{H}_{2} \mathrm{O}$, the equilibrium position will lie far to the left. In this case most of the acid dissolved will be present at equilibrium as HA.

[^30]In this chapter we will always represent an acid as simply dissociating. This does not mean we are using the Arrhenius model for acids. Since water does not affect the equilibrium position, it is simply easier to leave it out of the acid dissociation reaction.

The equilibrium expression for the reaction given in Equation (14.1) is

$$
\begin{equation*}
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]} \tag{14.2}
\end{equation*}
$$

where $K_{\mathrm{a}}$ is called the acid dissociation constant. Both $\mathrm{H}_{3} \mathrm{O}^{+}(a q)$ and $\mathrm{H}^{+}(a q)$ are commonly used to represent the hydrated proton. In this book we will often use simply $\mathrm{H}^{+}$, but you should remember that it is hydrated in aqueous solutions.

In Chapter 13 we saw that the concentration of a pure solid or a pure liquid is always omitted from the equilibrium expression. In a dilute solution we can assume that the concentration of liquid water remains essentially constant when an acid is dissolved. Thus the term $\left[\mathrm{H}_{2} \mathrm{O}\right]$ is not included in Equation (14.2), and the equilibrium expression for $K_{\mathrm{a}}$ has the same form as that for the simple dissociation into ions:

$$
\mathrm{HA}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{A}^{-}(a q)
$$

You should not forget, however, that water plays an important role in causing the acid to ionize.

Note that $K_{\mathrm{a}}$ is the equilibrium constant for the reaction in which a proton is removed from HA to form the conjugate base $\mathrm{A}^{-}$. We use $K_{\mathrm{a}}$ to represent only this type of reaction. Knowing this, you can write the $K_{\mathrm{a}}$ expression for any acid, even one that is totally unfamiliar to you. As you do Example 14.1, focus on the definition of the reaction corresponding to $K_{\mathrm{a}}$.

## INTERACTVE EXAMPLE 14.1 Acid Dissociation (Ionization) Reactions

Write the simple dissociation (ionization) reaction (omitting water) for each of the following acids.
a. hydrochloric acid $(\mathrm{HCl})$
b. acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$
c. the ammonium ion $\left(\mathrm{NH}_{4}^{+}\right)$
d. the anilinium ion $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}\right)$
e. the hydrated aluminum(III) ion $\left[\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$

SOLUTION a. $\mathrm{HCl}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q)$
b. $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)$
c. $\mathrm{NH}_{4}^{+}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{NH}_{3}(a q)$
d. $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}^{+}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}(a q)$
e. Although this formula looks complicated, writing the reaction is simple if you concentrate on the meaning of $K_{\mathrm{a}}$. Removing a proton, which can come only from one of the water molecules, leaves one $\mathrm{OH}^{-}$and five $\mathrm{H}_{2} \mathrm{O}$ molecules attached to the $\mathrm{Al}^{3+}$ ion. So the reaction is

$$
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}(a q)
$$

FIGURE 14.3 The reaction of $\mathrm{NH}_{3}$ with HCl to form $\mathrm{NH}_{4}{ }^{+}$and $\mathrm{Cl}^{-}$.

A
When $\mathrm{HCl}(\mathrm{g})$ and $\mathrm{NH}_{3}(\mathrm{~g})$ meet in a tube, a white ring of $\mathrm{NH}_{4} \mathrm{Cl}(\mathrm{s})$ forms.

The Brønsted-Lowry model is not limited to aqueous solutions; it can be extended to reactions in the gas phase. For example, we discussed the reaction between gaseous hydrogen chloride and ammonia when we studied diffusion (see Section 5.7):

$$
\mathrm{NH}_{3}(g)+\mathrm{HCl}(g) \rightleftharpoons \mathrm{NH}_{4} \mathrm{Cl}(s)
$$

In this reaction, a proton is donated by the hydrogen chloride to the ammonia, as shown by these Lewis structures:

Note that this is not considered an acid-base reaction according to the Arrhenius concept. Figure 14.3 shows a molecular representation of this reaction.

### 14.2 Acid Strength

The strength of an acid is defined by the equilibrium position of its dissociation (ionization) reaction:

$$
\mathrm{HA}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{A}^{-}(a q)
$$

A strong acid is one for which this equilibrium lies far to the right. This means that almost all the original HA is dissociated (ionized) at equilibrium [Fig. 14.4(a)]. There is an important connection between the strength of an acid and that of its conjugate base. A strong acid yields a weak conjugate base-one that has a low affinity for a proton. A strong acid also can be described as an acid whose conjugate base is a much weaker base than water (Fig. 14.5). In this case the water molecules win the competition for the $\mathrm{H}^{+}$ions.

Conversely, a weak acid is one for which the equilibrium lies far to the left. Most of the acid originally placed in the solution is still present as HA at equilibrium. That is, a weak acid dissociates only to a very small extent in aqueous solution [see Fig.

FIGURE 14.4 (a) A strong acid HA is completely ionized in water. This is represented in terms of both molecules and a bar graph. (b) A weak acid HB consists of mostly undissociated HB molecules in water.

FIGURE 14.5 The relationship of acid strength and conjugate base strength for the reaction

Perchloric acid can explode if handled improperly.

Sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$

Perchloric acid $\left(\mathrm{HClO}_{4}\right)$

Phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$

TABLE 14.1 | Various Ways to Describe Acid Strength
\(\left.$$
\begin{array}{|lll|}\hline \text { Property } & \text { Strong Acid } & \text { Weak Acid } \\
\hline K_{\mathrm{a}} \text { value } & K_{\mathrm{a}} \text { is large } & K_{\mathrm{a}} \text { is small } \\
\hline \text { Position of the dissociation (ionization) equilibrium } & \text { Far to the right } & \text { Far to the left } \\
\hline \begin{array}{l}\text { Equilibrium concentration of }\left[\mathrm{H}^{+}\right] \text {compared with } \\

\hline \begin{array}{l}\text { Strength of conjugate base compared with that of } \\
\text { water }\end{array} & \begin{array}{l}\mathrm{A}^{-} \text {much weaker } \\
\text { base than } \mathrm{H}_{2} \mathrm{O}\end{array}
$$ \& \mathrm{A}^{-} much stronger <br>

base than \mathrm{H}_{2} \mathrm{O}\end{array}\right]\)|  |
| :--- |

14.4(b)]. In contrast to a strong acid, a weak acid has a conjugate base that is a much stronger base than water. In this case a water molecule is not very successful in pulling an $\mathrm{H}^{+}$ion from the conjugate base. The weaker the acid, the stronger its conjugate base. The various ways of describing the strength of an acid are summarized in Table 14.1.

The common strong acids are sulfuric acid $\left[\mathrm{H}_{2} \mathrm{SO}_{4}(a q)\right]$, hydrochloric acid $[\mathrm{HCl}(a q)]$, nitric acid $\left[\mathrm{HNO}_{3}(a q)\right]$, and perchloric acid $\left[\mathrm{HClO}_{4}(a q)\right]$. Sulfuric acid is actually a diprotic acid, an acid having two acidic protons. The acid $\mathrm{H}_{2} \mathrm{SO}_{4}$ is a strong acid, virtually $100 \%$ dissociated (ionized) in water:

$$
\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q)
$$

The $\mathrm{HSO}_{4}{ }^{-}$ion, however, is a weak acid:

$$
\mathrm{HSO}_{4}^{-}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q)
$$

Most acids are oxyacids, in which the acidic proton is attached to an oxygen atom. The strong acids mentioned above, except hydrochloric acid, are typical examples. Many common weak acids, such as phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$, nitrous acid $\left(\mathrm{HNO}_{2}\right)$, and hypochlorous acid $(\mathrm{HOCl})$, are also oxyacids. Organic acids, those with a carbon atom backbone, commonly contain the carboxyl group:

Acids of this type are usually weak. Examples are acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$, often written $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$, and benzoic acid ( $\left.\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right)$. Note that the remainder of the hydrogens in these molecules are not acidic-they do not form $\mathrm{H}^{+}$in water.

There are some important acids in which the acidic proton is attached to an atom other than oxygen. The most significant of these are the hydrohalic acids HX , where X represents a halogen atom.

Table 14.2 contains a list of common monoprotic acids (those having one acidic proton) and their $K_{\mathrm{a}}$ values. Note that the strong acids are not listed. When a strong acid molecule such as HCl , for example, is placed in water, the position of the dissociation equilibrium

$$
\mathrm{HCl}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

lies so far to the right that $[\mathrm{HCl}]$ cannot be measured accurately. This prevents an accurate calculation of $K_{\mathrm{a}}$ :

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{Cl}^{-}\right]}{[\mathrm{HCl}]}
$$

Nitrous acid $\left(\mathrm{HNO}_{2}\right)$

Benzoic acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2} \mathrm{H}\right)$

TABLE 14.2 | Values of $K_{\mathrm{a}}$ for Some Common Monoprotic Acids

| Formula | Name | Value of $\mathrm{Ka}^{\text {* }}$ |
| :---: | :---: | :---: |
| $\mathrm{HSO}_{4}{ }^{-}$ | Hydrogen sulfate ion | $1.2 \times 10^{-2}$ |
| $\mathrm{HClO}_{2}$ | Chlorous acid | $1.2 \times 10^{-2}$ |
| $\mathrm{HC}_{2} \mathrm{H}_{2} \mathrm{ClO}_{2}$ | Monochloracetic acid | $1.35 \times 10^{-3}$ |
| HF | Hydrofluoric acid | $7.2 \times 10^{-4}$ |
| $\mathrm{HNO}_{2}$ | Nitrous acid | $4.0 \times 10^{-4}$ |
| $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ | Acetic acid | $1.8 \times 10^{-5}$ |
| $\left[\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ | Hydrated aluminum(III) ion | $1.4 \times 10^{-5}$ |
| HOCl | Hypochlorous acid | $3.5 \times 10^{-8}$ |
| HCN | Hydrocyanic acid | $6.2 \times 10^{-10}$ |
| $\mathrm{NH}_{4}^{+}$ | Ammonium ion | $5.6 \times 10^{-10}$ |
| $\mathrm{HOC}_{6} \mathrm{H}_{5}$ | Phenol | $1.6 \times 10^{-10}$ |

*The units of $K_{\mathrm{a}}$ are customarily omitted.
 in salad dressings. What if acetic acid was a strong acid instead of a weak acid? Would it be safe to use vinegar as a salad dressing?

## INTERACTIVE EXAMPLE 14.2 Relative Base Strength

Using Table 14.2, arrange the following species according to their strengths as bases: $\mathrm{H}_{2} \mathrm{O}, \mathrm{F}^{-}, \mathrm{Cl}^{-}, \mathrm{NO}_{2}^{-}$, and $\mathrm{CN}^{-}$.

SOLUTION Remember that water is a stronger base than the conjugate base of a strong acid but a weaker base than the conjugate base of a weak acid. This leads to the following order:

$$
\xrightarrow[{\text { Weakest bases } \xrightarrow{\mathrm{Cl}^{-}<\mathrm{H}_{2} \mathrm{O}<\text { conjugate bases of weak acids }} \text { Strongest bases }}]{ }
$$

We can order the remaining conjugate bases by recognizing that the strength of an acid is inversely related to the strength of its conjugate base. Since from Table 14.2 we have

$$
K_{\mathrm{a}} \text { for } \mathrm{HF}>K_{\mathrm{a}} \text { for } \mathrm{HNO}_{2}>K_{\mathrm{a}} \text { for } \mathrm{HCN}
$$

the base strengths increase as follows:

$$
\mathrm{F}^{-}<\mathrm{NO}_{2}^{-}<\mathrm{CN}^{-}
$$

The combined order of increasing base strength is

$$
\mathrm{Cl}^{-}<\mathrm{H}_{2} \mathrm{O}<\mathrm{F}^{-}<\mathrm{NO}_{2}^{-}<\mathrm{CN}^{-}
$$

## Water as an Acid and a Base

A substance is said to be amphoteric if it can behave either as an acid or as a base. Water is the most common amphoteric substance. We can see this clearly in the autoionization of water, which involves the transfer of a proton from one water molecule to another to produce a hydroxide ion and a hydronium ion:

In this reaction, one water molecule acts as an acid by furnishing a proton, and the other acts as a base by accepting the proton.

Autoionization can occur in other liquids besides water. For example, in liquid ammonia the autoionization reaction is

The autoionization reaction for water

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

leads to the equilibrium expression

$$
K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]
$$

where $K_{\mathrm{w}}$, called the ion-product constant (or the dissociation constant for water), always refers to the autoionization of water.

Experiment shows that at $25^{\circ} \mathrm{C}$ in pure water,

$$
\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-7} \mathrm{M}
$$

which means that at $25^{\circ} \mathrm{C}$

$$
\begin{aligned}
K_{\mathrm{w}} & =\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=\left(1.0 \times 10^{-7}\right)\left(1.0 \times 10^{-7}\right) \\
& =1.0 \times 10^{-14}
\end{aligned}
$$

## LET'S REVIEW Using $K_{w}$

It is important to recognize the meaning of $K_{\text {w }}$. In any aqueous solution at $25^{\circ} \mathrm{C}$, no matter what it contains, the product of $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$must always equal $1.0 \times 10^{-14}$. There are three possible situations:
" a neutral solution, where $\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]$
" an acidic solution, where $\left[\mathrm{H}^{+}\right]>\left[\mathrm{OH}^{-}\right]$
" a basic solution, where $\left[\mathrm{OH}^{-}\right]>\left[\mathrm{H}^{+}\right]$
In each case, however, at $25^{\circ} \mathrm{C}$,

$$
K_{\mathrm{w}}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}
$$

We normally consider the pH of solutions at $25^{\circ} \mathrm{C}$. However, it is important to realize that $K_{\mathrm{w}}$ is temperature dependent. For example, at $37^{\circ} \mathrm{C}$ (normal body temperature) the value of $K_{\mathrm{w}}=2.42 \times 10^{-14}$. This means for a neutral solution at $37^{\circ} \mathrm{C}$

$$
\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=2.42 \times 10^{-14}
$$

and

$$
\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]=1.55 \times 10^{-7}
$$

So the pH for a neutral solution at $37^{\circ} \mathrm{C}$ is 6.81 .

Calculate $\left[\mathrm{H}^{+}\right]$or $\left[\mathrm{OH}^{-}\right]$as required for each of the following solutions at $25^{\circ} \mathrm{C}$, and state whether the solution is neutral, acidic, or basic.
a. $1.0 \times 10^{-5} \mathrm{M} \mathrm{OH}^{-}$
b. $1.0 \times 10^{-7} \mathrm{M} \mathrm{OH}^{-}$
c. $10.0 \mathrm{M} \mathrm{H}^{+}$

## SOLUTION

a. $K_{\mathrm{w}}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}$. Since $\left[\mathrm{OH}^{-}\right]$is $1.0 \times 10^{-5} \mathrm{M}$, solving for $\left[\mathrm{H}^{+}\right]$ gives

$$
\left[\mathrm{H}^{+}\right]=\frac{1.0 \times 10^{-14}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{1.0 \times 10^{-5}}=1.0 \times 10^{-9} \mathrm{M}
$$

Since $\left[\mathrm{OH}^{-}\right]>\left[\mathrm{H}^{+}\right]$, the solution is basic.
b. As in part a, solving for $\left[\mathrm{H}^{+}\right]$gives

$$
\left[\mathrm{H}^{+}\right]=\frac{1.0 \times 10^{-14}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{1.0 \times 10^{-7}}=1.0 \times 10^{-7} \mathrm{M}
$$

Since $\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]$, the solution is neutral.
c. Solving for $\left[\mathrm{OH}^{-}\right]$gives

$$
\left[\mathrm{OH}^{-}\right]=\frac{1.0 \times 10^{-14}}{\left[\mathrm{H}^{+}\right]}=\frac{1.0 \times 10^{-14}}{10.0}=1.0 \times 10^{-15} \mathrm{M}
$$

Since $\left[\mathrm{H}^{+}\right]>\left[\mathrm{OH}^{-}\right]$, the solution is acidic.

See Exercises 14.49 and 14.50

Since $K_{\mathrm{w}}$ is an equilibrium constant, it varies with temperature. The effect of temperature is considered in Example 14.4.

## EXAMPLE 14.4 Autoionization of Water

At $60^{\circ} \mathrm{C}$, the value of $K_{\mathrm{w}}$ is $1 \times 10^{-13}$.
a. Using Le Châtelier's principle, predict whether the reaction

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

is exothermic or endothermic.
b. Calculate $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$in a neutral solution at $60^{\circ} \mathrm{C}$.

SOLUTION
a. $K_{\mathrm{w}}$ increases from $1 \times 10^{-14}$ at $25^{\circ} \mathrm{C}$ to $1 \times 10^{-13}$ at $60^{\circ} \mathrm{C}$. Le Châtelier's principle states that if a system at equilibrium is heated, it will adjust to consume energy.
■ Since the value of $K_{\mathrm{w}}$ increases with temperature, we must think of energy as a reactant, and so the process must be endothermic.
b. At $60^{\circ} \mathrm{C}$,

$$
\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=1 \times 10^{-13}
$$

For a neutral solution,

$$
\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]=\sqrt{1 \times 10^{-13}}=3 \times 10^{-7} \mathrm{M}
$$

See Exercise 14.51

### 14.3 The pH Scale

The pH scale is a compact
way to represent solution acidity.

Appendix 1.2 has a review of logs.

FIGURE 14.6 The pH scale and pH values of some common substances.

Because $\left[\mathrm{H}^{+}\right]$in an aqueous solution is typically quite small, the $\mathbf{p H}$ scale provides a convenient way to represent solution acidity. The pH is a $\log$ scale based on 10 , where

$$
\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]
$$

Thus for a solution where

$$
\begin{aligned}
{\left[\mathrm{H}^{+}\right] } & =1.0 \times 10^{-7} M \\
\mathrm{pH} & =-(-7.00)=7.00
\end{aligned}
$$

At this point we need to discuss significant figures for logarithms. The number of decimal places in the $\log$ is equal to the number of significant figures in the original number. Thus

$$
\begin{aligned}
{\left[\mathrm{H}^{+}\right] } & =1.0 \times 10^{-9} \mathrm{M} \text { significant figures } \\
\mathrm{pH} & =9.00
\end{aligned}
$$

Similar log scales are used for representing other quantities; for example,

$$
\begin{aligned}
\mathrm{pOH} & =-\log \left[\mathrm{OH}^{-}\right] \\
\mathrm{p} K & =-\log K
\end{aligned}
$$

Since pH is a $\log$ scale based on 10 , the pH changes by 1 for every power of 10 change in $\left[\mathrm{H}^{+}\right]$. For example, a solution of pH 3 has an $\mathrm{H}^{+}$concentration 10 times that of a solution of pH 4 and 100 times that of a solution of pH 5 . Also note that because pH is defined as $-\log \left[\mathrm{H}^{+}\right]$, the pH decreases as $\left[\mathrm{H}^{+}\right]$increases. The pH scale and the pH values for several common substances are shown in Fig. 14.6.

The pH of a solution is usually measured using a pH meter, an electronic device with a probe that can be inserted into a solution of unknown pH . The probe contains an acidic aqueous solution enclosed by a special glass membrane that allows migration of $\mathrm{H}^{+}$ions. If the unknown solution has a different pH from the solution in the probe, an electric potential results, which is registered on the meter (Fig. 14.7).

What if you lived on a planet identical to the earth but for which room temperature was $50^{\circ} \mathrm{C}$ ? How would the pH scale be different?

The pH meter is discussed more fully in Section 18.5 .

a

-b

FIGURE $\mathbf{1 4 . 7} \mathrm{pH}$ meters are used to measure acidity.

## INTERACTIVE EXAMPLE 14.5

## Calculating pH and pOH

Calculate pH and pOH for each of the following solutions at $25^{\circ} \mathrm{C}$.
a. $1.0 \times 10^{-3} \mathrm{M} \mathrm{OH}^{-}$
b. 1.0 M OH

SOLUTION
a. $\quad\left[\mathrm{H}^{+}\right]=\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{1.0 \times 10^{-3}}=1.0 \times 10^{-11} \mathrm{M}$

$$
\square \mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]=-\log \left(1.0 \times 10^{-11}\right)=11.00
$$

$$
\square \mathrm{pOH}=-\log \left[\mathrm{OH}^{-}\right]=-\log \left(1.0 \times 10^{-3}\right)=3.00
$$

b. $\quad\left[\mathrm{OH}^{-}\right]=\frac{K_{\mathrm{w}}}{\left[\mathrm{H}^{+}\right]}=\frac{1.0 \times 10^{-14}}{1.0}=1.0 \times 10^{-14} \mathrm{M}$
$\square \mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]=-\log (1.0)=0.00$
■ $\mathrm{pOH}=-\log \left[\mathrm{OH}^{-}\right]=-\log \left(1.0 \times 10^{-14}\right)=14.00$

## See Exercises 14.49 and 14.50

It is useful to consider the log form of the expression

$$
K_{\mathrm{w}}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]
$$

That is,
or

$$
\begin{gather*}
\log K_{\mathrm{w}}=\log \left[\mathrm{H}^{+}\right]+\log \left[\mathrm{OH}^{-}\right] \\
-\log K_{\mathrm{w}}=-\log \left[\mathrm{H}^{+}\right]-\log \left[\mathrm{OH}^{-}\right] \\
\mathrm{p} K_{\mathrm{w}}=\mathrm{pH}+\mathrm{pOH} \tag{14.3}
\end{gather*}
$$

Thus
Since $K_{\mathrm{w}}=1.0 \times 10^{-14}$,

$$
\mathrm{p} K_{\mathrm{w}}=-\log \left(1.0 \times 10^{-14}\right)=14.00
$$

Thus for any aqueous solution at $25^{\circ} \mathrm{C}, \mathrm{pH}$ and pOH add up to 14.00 :

$$
\begin{equation*}
\mathrm{pH}+\mathrm{pOH}=14.00 \tag{14.4}
\end{equation*}
$$

## CHEMICAL CDNNECTIDNS

## Arnold Beckman, Man of Science

A
rnold Beckman died at age 104 in May 2004. Beckman's leadership in science and business spans virtually the entire twentieth century. He was born in 1900 in Cullom, Illinois, a town of 500 people that had no electricity or telephones. Beckman says, "In Cullom we were forced to improvise. I think it was a good thing."

The son of a blacksmith, Beckman had his interest in science awakened at age nine. At that time, in the attic of his house he discovered J. Dorman Steele's Fourteen Weeks in Chemistry, a book containing instructions for doing chemistry experiments. Beckman became so fascinated with chemistry that his father built him a small "chemistry shed" in the backyard for his tenth birthday.

Beckman's interest in chemistry was fostered by his high school teachers, and he eventually attended the University of Illinois, Urbana-Champaign. He graduated with a bachelor's degree in chemical engineering in 1922 and stayed one more year to get a master's degree. He then went to Caltech, where he earned a Ph.D. and became a faculty member.

Beckman was always known for his inventiveness. As a youth he designed a pressurized fuel system for his Model T Ford to overcome problems with its
normal gravity feed fuel system-you had to back it up steep hills to keep it from starving for fuel. In 1927 he applied for his first patent: a buzzer to alert drivers that they were speeding.

In 1935 Beckman invented something that would cause a revolution in scientific instrumentation. A college friend who worked in a laboratory in the California citrus industry needed an accurate, convenient way to measure the acidity of orange juice. In response, Beckman invented the pH meter, which he initially called the acidimeter. This compact, sturdy device was an immediate hit. It signaled a new era in scientific instrumentation. In fact, business was so good that Beckman left Caltech to head his own company.

Over the years Beckman invented many other devices, including an improved potentiometer and an instrument for measuring the light absorbed by molecules. At age 65 he retired as president of Beckman Instruments (headquartered in Fullerton, California). After a merger the company became Beckman Coulter; it had sales of more than \$2 billion in 2003.

After stepping down as president of Beckman Instruments, Beckman began a new career-donating his wealth for the improvement of science. In 1984 he

$\Delta$
Arnold Beckman.
and Mabel, his wife of 58 years, donated $\$ 40$ million to his alma mater-the University of Illinois-to fund the Beckman Institute. The Beckmans have also funded many other research institutes, including one at Caltech, and formed a foundation that currently gives $\$ 20$ million each year to various scientific endeavors.

Arnold Beckman was a man known for his incredible creativity, but even more he was recognized as a man of absolute integrity. Beckman has important words for us: "Whatever you do, be enthusiastic about it."

Note: You can see Arnold Beckman's biography at the Chemical Heritage Foundation Web site (http://www.chemheritage.org).

## INTERACTIVE EXAMPLE 14.6 Calculations Using pH

The pH of a sample of human blood was measured to be 7.41 at $25^{\circ} \mathrm{C}$. Calculate pOH , $\left[\mathrm{H}^{+}\right]$, and $\left[\mathrm{OH}^{-}\right]$for the sample.

SOLUTION
Since $\mathrm{pH}+\mathrm{pOH}=14.00$,

$$
\mathrm{pOH}=14.00-\mathrm{pH}=14.00-7.41=6.59
$$

To find $\left[\mathrm{H}^{+}\right]$we must go back to the definition of pH :

$$
\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]
$$

Thus

$$
7.41=-\log \left[\mathrm{H}^{+}\right] \quad \text { or } \quad \log \left[\mathrm{H}^{+}\right]=-7.41
$$

We need to know the antilog of -7.41 . As shown in Appendix 1.2, taking the antilog is the same as exponentiation; that is,

$$
\operatorname{antilog}(n)=10^{n}
$$

Since $\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]$,

$$
-\mathrm{pH}=\log \left[\mathrm{H}^{+}\right]
$$

and $\left[\mathrm{H}^{+}\right]$can be calculated by taking the antilog of -pH :

$$
\left[\mathrm{H}^{+}\right]=\operatorname{antilog}(-\mathrm{pH})
$$

In the present case,

$$
\square\left[\mathrm{H}^{+}\right]=\operatorname{antilog}(-\mathrm{pH})=\operatorname{antilog}(-7.41)=10^{-7.41}=3.9 \times 10^{-8} \mathrm{M}
$$

Similarly, $\left[\mathrm{OH}^{-}\right]=\operatorname{antilog}(-\mathrm{pOH})$, and

$$
\left[\mathrm{OH}^{-}\right]=\operatorname{antilog}(-6.59)=10^{-6.59}=2.6 \times 10^{-7} \mathrm{M}
$$

## See Exercises 14.53 through 14.56

Now that we have considered all the fundamental definitions relevant to acid-base solutions, we can proceed to a quantitative description of the equilibria present in these solutions. The main reason that acid-base problems sometimes seem difficult is that a typical aqueous solution contains many components, so the problems tend to be complicated. However, you can deal with these problems successfully if you use the following general strategies:

## PROBLEM-SOLVING STRATEGY

## Solving Acid-Base Problems

» Think chemistry. Focus on the solution components and their reactions. It will almost always be possible to choose one reaction that is the most important.
" Be systematic. Acid-base problems require a step-by-step approach.
" Be flexible. Although all acid-base problems are similar in many ways, important differences do occur. Treat each problem as a separate entity. Do not try to force a given problem into matching any you have solved before. Look for both the similarities and the differences.
» Be patient. The complete solution to a complicated problem cannot be seen immediately in all its detail. Pick the problem apart into its workable steps.
" Be confident. Look within the problem for the solution, and let the problem guide you. Assume that you can think it out. Do not rely on memorizing solutions to problems. In fact, memorizing solutions is usually detrimental because you tend to try to force a new problem to be the same as one you have seen before. Understand and think; don't just memorize.

### 14.4 Calculating the pH of Strong Acid Solutions

When we deal with acid-base equilibria, we must focus on the solution components and their chemistry. For example, what species are present in a $1.0-M$ solution of HCl ? Since hydrochloric acid is a strong acid, we assume that it is completely dissociated. Thus although the label on the bottle says 1.0 MHCl , the solution contains virtually no HCl molecules. Typically, container labels indicate the substance(s) used to make up

Some Strong Acids
$\mathrm{HCl}(a q)$
$\mathrm{HNO}_{3}(\mathrm{aq})$
$\mathrm{H}_{2} \mathrm{SO}_{4}(a q)$
$\mathrm{HClO}_{4}(\mathrm{aq})$
$\mathrm{HBr}(\mathrm{aq})$
$\mathrm{HI}(\mathrm{aq})$

Always write the major species present in the solution.

The $\mathrm{H}^{+}$from the strong acid drives the equilibrium $\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}^{+}+\mathrm{OH}^{-}$to the left.

## INTERACTIVE EXAMPLE 14.7 pH of Strong Acids

b. Calculate the pH of $1.0 \times 10^{-10} \mathrm{M} \mathrm{HCl}$.

## SOLUTION

the solution but do not necessarily describe the solution components after dissolution. Thus a $1.0-M \mathrm{HCl}$ solution contains $\mathrm{H}^{+}$and $\mathrm{Cl}^{-}$ions rather than HCl molecules.

The next step in dealing with aqueous solutions is to determine which components are significant and which can be ignored. We need to focus on the major species, those solution components present in relatively large amounts. In 1.0 M HCl , for example, the major species are $\mathrm{H}^{+}, \mathrm{Cl}^{-}$, and $\mathrm{H}_{2} \mathrm{O}$. Since this is a very acidic solution, $\mathrm{OH}^{-}$is present only in tiny amounts and is classified as a minor species. In attacking acidbase problems, the importance of writing the major species in the solution as the first step cannot be overemphasized. This single step is the key to solving these problems successfully.

To illustrate the main ideas involved, let us calculate the pH of 1.0 MHCl . We first list the major species: $\mathrm{H}^{+}, \mathrm{Cl}^{-}$, and $\mathrm{H}_{2} \mathrm{O}$. Since we want to calculate the pH , we will focus on those major species that can furnish $\mathrm{H}^{+}$. Obviously, we must consider $\mathrm{H}^{+}$ from the dissociation of HCl . However, $\mathrm{H}_{2} \mathrm{O}$ also furnishes $\mathrm{H}^{+}$by autoionization, which is often represented by the simple dissociation reaction

$$
\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

However, is autoionization an important source of $\mathrm{H}^{+}$ions? In pure water at $25^{\circ} \mathrm{C}$, $\left[\mathrm{H}^{+}\right]$is $10^{-7} \mathrm{M}$. In 1.0 M HCl solution, the water will produce even less than $10^{-7} \mathrm{M}$ $\mathrm{H}^{+}$, since by Le Châtelier's principle the $\mathrm{H}^{+}$from the dissociated HCl will drive the position of the water equilibrium to the left. Thus the amount of $\mathrm{H}^{+}$contributed by water is negligible compared with the $1.0 \mathrm{M} \mathrm{H}^{+}$from the dissociation of HCl . Therefore, we can say that $\left[\mathrm{H}^{+}\right]$in the solution is 1.0 M . The pH is then

$$
\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]=-\log (1.0)=0
$$

a. Since $\mathrm{HNO}_{3}$ is a strong acid, the major species in solution are

$$
\mathrm{H}^{+}, \quad \mathrm{NO}_{3}^{-}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
$$

The concentration of $\mathrm{HNO}_{3}$ is virtually zero, since the acid completely dissociates in water. Also, $\left[\mathrm{OH}^{-}\right]$will be very small because the $\mathrm{H}^{+}$ions from the acid will drive the equilibrium

$$
\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

to the left. That is, this is an acidic solution where $\left[\mathrm{H}^{+}\right] \geqslant\left[\mathrm{OH}^{-}\right]$,
so $\left[\mathrm{OH}^{-}\right] \ll 10^{-7} M$. The sources of $\mathrm{H}^{+}$are

1. $\mathrm{H}^{+}$from $\mathrm{HNO}_{3}(0.10 \mathrm{M})$
2. $\mathrm{H}^{+}$from $\mathrm{H}_{2} \mathrm{O}$

The number of $\mathrm{H}^{+}$ions contributed by the autoionization of water will be very small compared with the 0.10 M contributed by the $\mathrm{HNO}_{3}$ and can be neglected.
Since the dissolved $\mathrm{HNO}_{3}$ is the only important source of $\mathrm{H}^{+}$ions in this solution,

$$
\square\left[\mathrm{H}^{+}\right]=0.10 M \quad \text { and } \quad \mathrm{pH}=-\log (0.10)=1.00
$$

b. Normally, in an aqueous solution of HCl the major species are $\mathrm{H}^{+}, \mathrm{Cl}^{-}$, and $\mathrm{H}_{2} \mathrm{O}$. However, in this case the amount of HCl in solution is so small that it has no effect; the only major species is $\mathrm{H}_{2} \mathrm{O}$.

- Thus the pH will be that of pure water, or $\mathrm{pH}=7.00$.

### 14.5 Calculating the pH of Weak Acid Solutions

First, always write the major species present in the solution.

Since a weak acid dissolved in water can be viewed as a prototype of almost any equilibrium occurring in aqueous solution, we will proceed carefully and systematically. Although some of the procedures we develop here may seem unnecessary, they will become essential as the problems become more complicated. We will develop the necessary strategies by calculating the pH of a $1.00-M$ solution of $\mathrm{HF}\left(K_{\mathrm{a}}=7.2 \times 10^{-4}\right)$.

The first step, as always, is to write the major species in the solution. From its small $K_{\mathrm{a}}$ value, we know that hydrofluoric acid is a weak acid and will be dissociated only to a slight extent. Thus when we write the major species, the hydrofluoric acid will be represented in its dominant form, as HF. The major species in solution are HF and $\mathrm{H}_{2} \mathrm{O}$.

The next step (since this is a pH problem) is to decide which of the major species can furnish $\mathrm{H}^{+}$ions. Actually, both major species can do so:

$$
\begin{array}{ll}
\mathrm{HF}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q) & K_{\mathrm{a}}=7.2 \times 10^{-4} \\
\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) & K_{\mathrm{w}}=1.0 \times 10^{-14}
\end{array}
$$

In aqueous solutions, however, typically one source of $\mathrm{H}^{+}$can be singled out as dominant. By comparing $K_{\mathrm{a}}$ for HF with $K_{\mathrm{w}}$ for $\mathrm{H}_{2} \mathrm{O}$, we see that hydrofluoric acid, although weak, is still a much stronger acid than water. Thus we will assume that hydrofluoric acid will be the dominant source of $\mathrm{H}^{+}$. We will ignore the tiny contribution by water.

Therefore, it is the dissociation of HF that will determine the equilibrium concentration of $\mathrm{H}^{+}$and hence the pH :

$$
\mathrm{HF}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

The equilibrium expression is

$$
K_{\mathrm{a}}=7.2 \times 10^{-4}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{F}^{-}\right]}{[\mathrm{HF}]}
$$

To solve the equilibrium problem, we follow the procedures developed in Chapter 13 for gas-phase equilibria. First, we list the initial concentrations, the concentrations before the reaction of interest has proceeded to equilibrium. Before any HF dissociates, the concentrations of the species in the equilibrium are

$$
[\mathrm{HF}]_{0}=1.00 \mathrm{M} \quad\left[\mathrm{~F}^{-}\right]_{0}=0 \quad\left[\mathrm{H}^{+}\right]_{0}=10^{-7} M \approx 0
$$

(Note that the zero value for $\left[\mathrm{H}^{+}\right]_{0}$ is an approximation, since we are neglecting the $\mathrm{H}^{+}$ ions from the autoionization of water.)

The next step is to determine the change required to reach equilibrium. Since some HF will dissociate to come to equilibrium (but this amount is presently unknown), we let $x$ be the change in the concentration of HF that is required to achieve equilibrium. That is, we assume that $x \mathrm{~mol} / \mathrm{L} \mathrm{HF}$ will dissociate to produce $x \mathrm{~mol} / \mathrm{L} \mathrm{H}^{+}$and $x \mathrm{~mol} / \mathrm{L}$ $\mathrm{F}^{-}$as the system adjusts to its equilibrium position. Now the equilibrium concentrations can be defined in terms of $x$ :

$$
\begin{aligned}
{[\mathrm{HF}] } & =[\mathrm{HF}]_{0}-x=1.00-x \\
{\left[\mathrm{~F}^{-}\right] } & =\left[\mathrm{F}^{-}\right]_{0}+x=0+x=x \\
{\left[\mathrm{H}^{+}\right] } & =\left[\mathrm{H}^{+}\right]_{0}+x \approx 0+x=x
\end{aligned}
$$

Substituting these equilibrium concentrations into the equilibrium expression gives

$$
K_{\mathrm{a}}=7.2 \times 10^{-4}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{F}^{-}\right]}{[\mathrm{HF}]}=\frac{(x)(x)}{1.00-x}
$$

This expression produces a quadratic equation that can be solved using the quadratic formula, as for the gas-phase systems in Chapter 13. However, since $K_{\mathrm{a}}$ for HF is so small, HF will dissociate only slightly, and $x$ is expected to be small. This will allow us to simplify the calculation. If $x$ is very small compared to 1.00 , the term in the denominator can be approximated as follows:

$$
1.00-x \approx 1.00
$$

The equilibrium expression then becomes

$$
7.2 \times 10^{-4}=\frac{(x)(x)}{1.00-x} \approx \frac{(x)(x)}{1.00}
$$

which yields

$$
\begin{aligned}
x^{2} & \approx\left(7.2 \times 10^{-4}\right)(1.00)=7.2 \times 10^{-4} \\
x & \approx \sqrt{7.2 \times 10^{-4}}=2.7 \times 10^{-2}
\end{aligned}
$$

How valid is the approximation that $[\mathrm{HF}]=1.00 M$ ? Because this question will arise often in connection with acid-base equilibrium calculations, we will consider it carefully. The validity of the approximation depends on how much accuracy we demand for the calculated value of $\left[H^{+}\right]$. Typically, the $K_{\mathrm{a}}$ values for acids are known to an accuracy of only about $\pm 5 \%$. It is reasonable therefore to apply this figure when determining the validity of the approximation

$$
[\mathrm{HA}]_{0}-x \approx[\mathrm{HA}]_{0}
$$

We will use the following test. First, we calculate the value of $x$ by making the approximation
where

$$
\begin{gathered}
K_{\mathrm{a}}=\frac{x^{2}}{[\mathrm{HA}]_{0}-x} \approx \frac{x^{2}}{[\mathrm{HA}]_{0}} \\
x^{2} \approx K_{\mathrm{a}}[\mathrm{HA}]_{0} \text { and } x \approx \sqrt{K_{\mathrm{a}}[\mathrm{HA}]_{0}}
\end{gathered}
$$

We then compare the sizes of $x$ and $[H A]_{0}$. If the expression

$$
\frac{x}{[\mathrm{HA}]_{0}} \times 100 \%
$$

is less than or equal to $5 \%$, the value of $x$ is small enough that the approximation

$$
[\mathrm{HA}]_{0}-x \approx[\mathrm{HA}]_{0}
$$

will be considered valid.
In our example,
and

$$
\begin{aligned}
x & =2.7 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \\
{[\mathrm{HA}]_{0} } & =[\mathrm{HF}]_{0}=1.00 \mathrm{~mol} / \mathrm{L} \\
\frac{x}{[\mathrm{HA}]_{0}} \times 100 & =\frac{2.7 \times 10^{-2}}{1.00} \times 100 \%=2.7 \%
\end{aligned}
$$

The approximation we made is considered valid, and the value of $x$ calculated using that approximation is acceptable. Thus

$$
x=\left[\mathrm{H}^{+}\right]=2.7 \times 10^{-2} M \quad \text { and } \quad \mathrm{pH}=-\log \left(2.7 \times 10^{-2}\right)=1.57
$$

This problem illustrates all the important steps for solving a typical equilibrium problem involving a weak acid. These steps are summarized as follows:

## PROBLEM-SOLVING STRATEGY

## Solving Weak Acid Equilibrium Problems

1. List the major species in the solution.
2. Choose the species that can produce $\mathrm{H}^{+}$, and write balanced equations for the reactions producing $\mathrm{H}^{+}$.
3. Using the values of the equilibrium constants for the reactions you have written, decide which equilibrium will dominate in producing $\mathrm{H}^{+}$.
4. Write the equilibrium expression for the dominant equilibrium.
5. List the initial concentrations of the species participating in the dominant equilibrium.
6. Define the change needed to achieve equilibrium; that is, define $x$.
7. Write the equilibrium concentrations in terms of $x$.
8. Substitute the equilibrium concentrations into the equilibrium expression.
9. Solve for $x$ the "easy" way, that is, by assuming that $[H A]_{0}-x \approx[H A]_{0}$.
10. Use the $5 \%$ rule to verify whether the approximation is valid.
11. Calculate $\left[\mathrm{H}^{+}\right]$and pH .

## INTERACTIVE EXAMPLE 14.8

## The pH of Weak Acids

The hypochlorite ion $\left(\mathrm{OCl}^{-}\right)$is a strong oxidizing agent often found in household
Major Species bleaches and disinfectants. It is also the active ingredient that forms when swimmingpool water is treated with chlorine. In addition to its oxidizing abilities, the hypochlorite ion has a relatively high affinity for protons (it is a much stronger base than $\mathrm{Cl}^{-}$, for example) and forms the weakly acidic hypochlorous acid ( HOCl , $K_{\mathrm{a}}=3.5 \times 10^{-8}$ ). Calculate the pH of a $0.100-\mathrm{M}$ aqueous solution of hypochlorous acid.

## SOLUTION

1. We list the major species. Since HOCl is a weak acid and remains mostly undissociated, the major species in a $0.100-M \mathrm{HOCl}$ solution are

$$
\mathrm{HOCl} \text { and } \mathrm{H}_{2} \mathrm{O}
$$

2. Both species can produce $\mathrm{H}^{+}$:

$$
\begin{aligned}
\mathrm{HOCl}(a q) & \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{OCl}^{-}(a q)
\end{aligned} \quad K_{\mathrm{a}}=3.5 \times 10^{-8}, ~=\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \quad \begin{aligned}
& \mathrm{w} \\
& \\
& \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons 1.0 \times 10^{-14}
\end{aligned}
$$

A
Swimming-pool water must be frequently tested for pH and chlorine content.
3. Since HOCl is a significantly stronger acid than $\mathrm{H}_{2} \mathrm{O}$, it will dominate in the production of $\mathrm{H}^{+}$.
4. We therefore use the following equilibrium expression:

$$
K_{\mathrm{a}}=3.5 \times 10^{-8}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{OCl}^{-}\right]}{[\mathrm{HOCl}]}
$$

5. The initial concentrations appropriate for this equilibrium are

$$
\begin{aligned}
{[\mathrm{HOCl}]_{0} } & =0.100 \mathrm{M} \\
{\left[\mathrm{OCl}^{-}\right]_{0} } & =0 \\
{\left[\mathrm{H}^{+}\right]_{0} } & \approx 0 \quad\left(\text { We neglect the contribution from } \mathrm{H}_{2} \mathrm{O} .\right)
\end{aligned}
$$

6. Since the system will reach equilibrium by the dissociation of HOCl , let $x$ be the amount of HOCl (in $\mathrm{mol} / \mathrm{L}$ ) that dissociates in reaching equilibrium.
7. The equilibrium concentrations in terms of $x$ are

$$
\begin{aligned}
{[\mathrm{HOCl}] } & =[\mathrm{HOCl}]_{0}-x=0.100-x \\
{\left[\mathrm{OCl}^{-}\right] } & =\left[\mathrm{OCl}^{-}\right]_{0}+x=0+x=x \\
{\left[\mathrm{H}^{+}\right] } & =\left[\mathrm{H}^{+}\right]_{0}+x \approx 0+x=x
\end{aligned}
$$

8. Substituting these concentrations into the equilibrium expression gives

$$
K_{\mathrm{a}}=3.5 \times 10^{-8}=\frac{(x)(x)}{0.100-x}
$$

9. Since $K_{\mathrm{a}}$ is so small, we can expect a small value for $x$. Thus we make the approximation $[\mathrm{HA}]_{0}-x \approx[\mathrm{HA}]_{0}$, or $0.100-x \approx 0.100$, which leads to the expression

$$
K_{\mathrm{a}}=3.5 \times 10^{-8}=\frac{x^{2}}{0.100-x} \approx \frac{x^{2}}{0.100}
$$

Solving for $x$ gives

$$
x=5.9 \times 10^{-5}
$$

10. The approximation $0.100-x \approx 0.100$ must be validated. To do this, we compare $x$ to $[\mathrm{HOCl}]_{0}$ :

$$
\frac{x}{[\mathrm{HA}]_{0}} \times 100=\frac{x}{[\mathrm{HOCl}]_{0}} \times 100=\frac{5.9 \times 10^{-5}}{0.100} \times 100=0.059 \%
$$

Since this value is much less than $5 \%$, the approximation is considered valid.
11. We calculate $\left[\mathrm{H}^{+}\right]$and pH :

$$
\left[\mathrm{H}^{+}\right]=x=5.9 \times 10^{-5} M \quad \text { and } \quad \mathrm{pH}=4.23
$$

See Exercises 14.65 and 14.66

## The pH of a Mixture of Weak Acids

Sometimes a solution contains two weak acids of very different strengths. This case is considered in Example 14.9. Note that the steps are again followed (though not labeled).

## INTERACTIVE EXAMPLE 14.9

## SOLUTION

Major Species

To avoid clutter we do not show the units of concentration in the ICE tables. All terms have units of $\mathrm{mol} / \mathrm{L}$.

## The pH of Weak Acid Mixtures

Calculate the pH of a solution that contains $1.00 \mathrm{MHCN}\left(K_{\mathrm{a}}=6.2 \times 10^{-10}\right)$ and $5.00 \mathrm{M} \mathrm{HNO}_{2}\left(K_{\mathrm{a}}=4.0 \times 10^{-4}\right)$. Also calculate the concentration of cyanide ion $\left(\mathrm{CN}^{-}\right)$in this solution at equilibrium.

Since HCN and $\mathrm{HNO}_{2}$ are both weak acids and are largely undissociated, the major species in the solution are

$$
\mathrm{HCN}, \quad \mathrm{HNO}_{2}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
$$

All three of these components produce $\mathrm{H}^{+}$:

$$
\begin{aligned}
& \mathrm{HCN}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{CN}^{-}(a q) \\
& \mathrm{HNO}_{2}(a q) K_{\mathrm{a}}=6.2 \times 10^{-10} \\
& \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{NO}_{2}^{-}(a q) \\
& \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \\
& K_{\mathrm{a}}=4.0 \times 10^{-4} \\
& K_{\mathrm{w}}=1.0 \times 10^{-14}
\end{aligned}
$$

A mixture of three acids might lead to a very complicated problem. However, the situation is greatly simplified by the fact that even though $\mathrm{HNO}_{2}$ is a weak acid, it is much stronger than the other two acids present (as revealed by the $K$ values). Thus $\mathrm{HNO}_{2}$ can be assumed to be the dominant producer of $\mathrm{H}^{+}$, and we will focus on the equilibrium expression

$$
K_{\mathrm{a}}=4.0 \times 10^{-4}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{NO}_{2}^{-}\right]}{\left[\mathrm{HNO}_{2}\right]}
$$

The initial concentrations, the definition of $x$, and the equilibrium concentrations are as follows:

It is convenient to represent these concentrations in the following shorthand form (called an ICE table):

|  | $\mathrm{HNO}_{2}(a q)$ | $\rightleftharpoons$ | $\mathrm{H}^{+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 5.00 |  | 0 | 0 |
| Change | $-x$ |  | $+x$ | $+x$ |
| Equilibrium | $5.00-x$ |  | $x$ | $x$ |

Substituting the equilibrium concentrations in the equilibrium expression and making the approximation that $5.00-x=5.00$ give

$$
K_{\mathrm{a}}=4.0 \times 10^{-4}=\frac{(x)(x)}{5.00-x} \approx \frac{x^{2}}{5.00}
$$

We solve for $x$ :

$$
x=4.5 \times 10^{-2}
$$

Using the $5 \%$ rule, we show that the approximation is valid:

$$
\frac{x}{\left[\mathrm{HNO}_{2}\right]_{0}} \times 100=\frac{4.5 \times 10^{-2}}{5.00} \times 100=0.90 \%
$$

Therefore,

$$
\left[\mathrm{H}^{+}\right]=x=4.5 \times 10^{-2} M \quad \text { and } \quad \mathrm{pH}=1.35
$$

We also want to calculate the equilibrium concentration of cyanide ion in this solution. The $\mathrm{CN}^{-}$ions in this solution come from the dissociation of HCN :

$$
\mathrm{HCN}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{CN}^{-}(a q)
$$

Although the position of this equilibrium lies far to the left and does not contribute significantly to $\left[\mathrm{H}^{+}\right], \mathrm{HCN}$ is the only source of $\mathrm{CN}^{-}$. Thus we must consider the extent of the dissociation of HCN to calculate [ $\mathrm{CN}^{-}$]. The equilibrium expression for the preceding reaction is

$$
K_{\mathrm{a}}=6.2 \times 10^{-10}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{CN}^{-}\right]}{[\mathrm{HCN}]}
$$

We know $\left[\mathrm{H}^{+}\right]$for this solution from the results of the first part of the problem. It is important to understand that there is only one kind of $\mathrm{H}^{+}$in this solution. It does not matter from which acid the $\mathrm{H}^{+}$ions originate. The equilibrium $\left[\mathrm{H}^{+}\right]$we need to insert into the HCN equilibrium expression is $4.5 \times 10^{-2} M$, even though the $\mathrm{H}^{+}$was contributed almost entirely from the dissociation of $\mathrm{HNO}_{2}$. What is [ HCN ] at equilibrium? We know $[\mathrm{HCN}]_{0}=1.00 M$, and since $K_{\mathrm{a}}$ for HCN is so small, a negligible amount of HCN will dissociate. Thus

$$
[\mathrm{HCN}]=[\mathrm{HCN}]_{0}-\text { amount of } \mathrm{HCN} \text { dissociated } \approx[\mathrm{HCN}]_{0}=1.00 \mathrm{M}
$$

Since $\left[\mathrm{H}^{+}\right]$and $[\mathrm{HCN}]$ are known, we can find $\left[\mathrm{CN}^{-}\right]$from the equilibrium expression:

$$
\begin{aligned}
& K_{\mathrm{a}}=6.2 \times 10^{-10}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{CN}^{-}\right]}{[\mathrm{HCN}]}=\frac{\left(4.5 \times 10^{-2}\right)\left[\mathrm{CN}^{-}\right]}{1.00} \\
& {\left[\mathrm{CN}^{-}\right]=\frac{\left(6.2 \times 10^{-10}\right)(1.00)}{4.5 \times 10^{-2}}=1.4 \times 10^{-8} M}
\end{aligned}
$$

Note the significance of this result. Since $\left[\mathrm{CN}^{-}\right]=1.4 \times 10^{-8} \mathrm{M}$ and HCN is the only source of $\mathrm{CN}^{-}$, this means that only $1.4 \times 10^{-8} \mathrm{~mol} / \mathrm{L}$ of HCN dissociated. This is a very small amount compared with the initial concentration of HCN, which is exactly what we would expect from its very small $K_{\mathrm{a}}$ value, and $[\mathrm{HCN}]=1.00 \mathrm{M}$ as assumed.

Percent dissociation is also known as percent ionization.

## Percent Dissociation

It is often useful to specify the amount of weak acid that has dissociated in achieving equilibrium in an aqueous solution. The percent dissociation is defined as follows:

$$
\begin{equation*}
\text { Percent dissociation }=\frac{\text { amount dissociated }(\mathrm{mol} / \mathrm{L})}{\text { initial concentration }(\mathrm{mol} / \mathrm{L})} \times 100 \% \tag{14.5}
\end{equation*}
$$

For example, we found earlier that in a $1.00-M$ solution of $\mathrm{HF},\left[\mathrm{H}^{+}\right]=2.7 \times 10^{-2} M$. To reach equilibrium, $2.7 \times 10^{-2} \mathrm{~mol} / \mathrm{L}$ of the original 1.00 MHF dissociates, so

$$
\text { Percent dissociation }=\frac{2.7 \times 10^{-2} \mathrm{~mol} / \mathrm{L}}{1.00 \mathrm{~mol} / \mathrm{L}} \times 100 \%=2.7 \%
$$

For a given weak acid, the percent dissociation increases as the acid becomes more dilute. For example, the percent dissociation of acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, K_{\mathrm{a}}=1.8 \times\right.$ $10^{-5}$ ) is significantly greater in a $0.10-M$ solution than in a $1.0-M$ solution, as demonstrated in Example 14.10.

## INTERACTIVE EXAMPLE 14.10

## SOLUTION

Major Species

$\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
$\mathrm{H}_{2} \mathrm{O}$

A
An acetic acid solution, which is a weak electrolyte, contains only a few ions and does not conduct as much current as a strong electrolyte. The bulb is only dimly lit.

## Calculating Percent Dissociation

Calculate the percent dissociation of acetic acid $\left(K_{\mathrm{a}}=1.8 \times 10^{-5}\right)$ in each of the following solutions:
a. $1.00 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
b. $0.100 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
a. Since acetic acid is a weak acid, the major species in this solution are $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$. Both species are weak acids, but acetic acid is a much stronger acid than water. Thus the dominant equilibrium will be

$$
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)
$$

and the equilibrium expression is

$$
K_{\mathrm{a}}=1.8 \times 10^{-5}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}
$$

The initial concentrations, definition of $x$, and equilibrium concentrations are:

|  | $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)$ | $\rightleftharpoons$ | $\mathrm{H}^{+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 1.00 | $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}(\mathrm{aq})$ |  |  |
| Change | $-x$ | 0 | 0 |  |
| Equilibrium | $1.00-x$ |  | $x$ | $x$ |
|  |  | $x$ | $x$ |  |

Inserting the equilibrium concentrations into the equilibrium expression and making the usual approximation that $x$ is small compared with $[\mathrm{HA}]_{0}$ give

$$
K_{\mathrm{a}}=1.8 \times 10^{-5}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}=\frac{(x)(x)}{1.00-x} \approx \frac{x^{2}}{1.00}
$$

Thus

$$
x^{2} \approx 1.8 \times 10^{-5} \quad \text { and } \quad x \approx 4.2 \times 10^{-3}
$$

The approximation $1.00-x \approx 1.00$ is valid by the $5 \%$ rule (check this yourself), so

$$
\left[\mathrm{H}^{+}\right]=x=4.2 \times 10^{-3} \mathrm{M}
$$

The percent dissociation is

$$
\frac{\left[\mathrm{H}^{+}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]_{0}} \times 100=\frac{4.2 \times 10^{-3}}{1.00} \times 100 \%=0.42 \%
$$

b. This is a similar problem, except that in this case $\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]=0.100 \mathrm{M}$. Analysis of the problem leads to the expression

$$
\begin{array}{ll} 
& K_{\mathrm{a}}=1.8 \times 10^{-5}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}=\frac{(x)(x)}{0.100-x} \approx \frac{x^{2}}{0.100} \\
\text { Thus } & x=\left[\mathrm{H}^{+}\right]=1.3 \times 10^{-3} M \\
\text { and } & \square \text { Percent dissociation }=\frac{1.3 \times 10^{-3}}{0.10} \times 100 \%=1.3 \%
\end{array}
$$

The more dilute the weak acid solution, the greater is the percent dissociation.

## More concentrated More dilute

FIGURE 14.8 The effect of dilution on the percent dissociation and $\left[\mathrm{H}^{+}\right]$of a weak acid solution.

The results in Example 14.10 show two important facts. The concentration of $\mathrm{H}^{+}$ion at equilibrium is smaller in the $0.10-M$ acetic acid solution than in the $1.0-M$ acetic acid solution, as we would expect. However, the percent dissociation is significantly greater in the $0.10-M$ solution than in the $1.0-M$ solution. This is a general result. For solutions of any weak acid $\mathrm{HA},\left[\mathrm{H}^{+}\right]$decreases as $[H A]_{0}$ decreases, but the percent dissociation increases as $[H A]_{0}$ decreases. This phenomenon can be explained as follows.

Consider the weak acid HA with the initial concentration $[\mathrm{HA}]_{0}$, where at equilibrium

Thus

$$
\begin{aligned}
{[\mathrm{HA}] } & =[\mathrm{HA}]_{0}-x \approx[\mathrm{HA}]_{0} \\
{\left[\mathrm{H}^{+}\right] } & =\left[\mathrm{A}^{-}\right]=x \\
K_{\mathrm{a}} & =\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]} \approx \frac{(x)(x)}{[\mathrm{HA}]_{0}}
\end{aligned}
$$

Now suppose enough water is added suddenly to dilute the solution by a factor of 10 . The new concentrations before any adjustment occurs are

$$
\begin{aligned}
& {\left[\mathrm{A}^{-}\right]_{\text {new }}=\left[\mathrm{H}^{+}\right]_{\text {new }}=\frac{x}{10}} \\
& {[\mathrm{HA}]_{\text {new }}=\frac{[\mathrm{HA}]_{0}}{10}}
\end{aligned}
$$

and $Q$, the reaction quotient, is

$$
Q=\frac{\left(\frac{x}{10}\right)\left(\frac{x}{10}\right)}{\frac{[\mathrm{HA}]_{0}}{10}}=\frac{1(x)(x)}{10[\mathrm{HA}]_{0}}=\frac{1}{10} K_{\mathrm{a}}
$$

Since $Q$ is less than $K_{\mathrm{a}}$, the system must adjust to the right to reach the new equilibrium position. Thus the percent dissociation increases when the acid is diluted. This behavior is summarized in Fig. 14.8. In Example 14.11 we see how the percent dissociation can be used to calculate the $K_{\mathrm{a}}$ value for a weak acid.

## INTERACTIVE EXAMPLE 14.11 Calculating $K_{\mathrm{a}}$ from Percent Dissociation

Lactic acid $\left(\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right)$ is a chemical that accumulates in muscle tissue during exertion. In a $0.100-M$ aqueous solution, lactic acid is $3.7 \%$ dissociated. Calculate the value of $K_{\mathrm{a}}$ for this acid.

SOLUTION From the small value for the percent dissociation, it is clear that $\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}$ is a weak acid. Thus the major species in the solution are the undissociated acid and water:

$$
\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3} \text { and } \mathrm{H}_{2} \mathrm{O}
$$

However, even though $\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}$ is a weak acid, it is a much stronger acid than water and will be the dominant source of $\mathrm{H}^{+}$in the solution. The dissociation reaction is

$$
\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}(a q)
$$

and the equilibrium expression is

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}\right]}{\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]}
$$

Strenuous exercise causes a buildup of lactic acid in muscle tissues.

The initial and equilibrium concentrations are as follows:

| Initial <br> Concentration (mol/L) |  | Equilibrium Concentration ( $\mathrm{mol} / \mathrm{L}$ ) |
| :---: | :---: | :---: |
| $\begin{aligned} & {\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]_{0}=0.10} \\ & {\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}^{-}-\right]_{0}=0} \\ & {\left[\mathrm{H}^{+}\right]_{0} \approx 0} \end{aligned}$ | $\xrightarrow[\substack{\mathrm{HC} C_{3} \mathrm{H}_{5} \mathrm{O}_{3} \\ \text { dissociates }}]{x \mathrm{~mol}}$ | $\begin{aligned} & {\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]=0.10-x} \\ & {\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}\right]=x} \\ & {\left[\mathrm{H}^{+}\right]=x} \end{aligned}$ |

The change needed to reach equilibrium can be obtained from the percent dissociation and Equation (14.5). For this acid,

$$
\text { Percent dissociation }=3.7 \%=\frac{x}{\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]_{0}} \times 100 \%=\frac{x}{0.10} \times 100 \%
$$

and

$$
x=\frac{3.7}{100}(0.10)=3.7 \times 10^{-3} \mathrm{~mol} / \mathrm{L}
$$

Now we can calculate the equilibrium concentrations:

$$
\begin{aligned}
{\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right] } & =0.10-x=0.10 \mathrm{M} \quad \text { (to the correct number of significant figures) } \\
{\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}\right] } & =\left[\mathrm{H}^{+}\right]=x=3.7 \times 10^{-3} \mathrm{M}
\end{aligned}
$$

These concentrations can now be used to calculate the value of $K_{\mathrm{a}}$ for lactic acid:

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}\right]}{\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]}=\frac{\left(3.7 \times 10^{-3}\right)\left(3.7 \times 10^{-3}\right)}{0.10}=1.4 \times 10^{-4}
$$

## See Exercises 14.77 and 14.78

## PROBLEM-SOLVING STRATEGY

## Solving Acid-Base Problems

1. List the major species in solution.
2. Look for reactions that can be assumed to go to completion-for example, a strong acid dissociating or $\mathrm{H}^{+}$reacting with $\mathrm{OH}^{-}$.
3. For a reaction that can be assumed to go to completion:
a. Determine the concentration of the products.
b. Write down the major species in solution after the reaction.
4. Look at each major component of the solution and decide if it is an acid or a base.
5. Pick the equilibrium that will control the pH . Use known values of the dissociation constants for the various species to help decide on the dominant equilibrium.
a. Write the equation for the reaction and the equilibrium expression.
b. Compute the initial concentrations (assuming the dominant equilibrium has not yet occurred, that is, no acid dissociation, and so on).
c. Define $x$.
d. Compute the equilibrium concentrations in terms of $x$.
e. Substitute the concentrations into the equilibrium expression, and solve for $x$.
f. Check the validity of the approximation.
g. Calculate the pH and other concentrations as required.

Although these steps may seem somewhat cumbersome, especially for simpler problems, they will become increasingly helpful as the aqueous solutions become more complicated. If you develop the habit of approaching acid-base problems systematically, the more complex cases will be much easier to manage.

```
In a basic solution at 25' C, pH > 7.
```

$\Delta$
An antacid containing aluminum and magnesium hydroxides.

Calcium carbonate is also used in scrubbing, as discussed in Section 5.10.

## Bases

According to the Arrhenius concept, a base is a substance that produces $\mathrm{OH}^{-}$ions in aqueous solution. According to the Brønsted-Lowry model, a base is a proton acceptor. The bases sodium hydroxide $(\mathrm{NaOH})$ and potassium hydroxide $(\mathrm{KOH})$ fulfill both criteria. They contain $\mathrm{OH}^{-}$ions in the solid lattice and, behaving as strong electrolytes, dissociate completely when dissolved in aqueous solution:

$$
\mathrm{NaOH}(s) \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

leaving virtually no undissociated NaOH . Thus a $1.0-\mathrm{M} \mathrm{NaOH}$ solution really contains $1.0 \mathrm{M} \mathrm{Na}^{+}$and $1.0 \mathrm{M} \mathrm{OH}^{-}$. Because of their complete dissociation, NaOH and KOH are called strong bases in the same sense as we defined strong acids.

All the hydroxides of the Group 1A elements ( $\mathrm{LiOH}, \mathrm{NaOH}, \mathrm{KOH}, \mathrm{RbOH}$, and CsOH ) are strong bases, but only NaOH and KOH are common laboratory reagents, because the lithium, rubidium, and cesium compounds are expensive. The alkaline earth (Group 2A) hydroxides- $\mathrm{Ca}(\mathrm{OH})_{2}, \mathrm{Ba}(\mathrm{OH})_{2}$, and $\mathrm{Sr}(\mathrm{OH})_{2}$-are also strong bases. For these compounds, 2 moles of hydroxide ion are produced for every mole of metal hydroxide dissolved in aqueous solution.

The alkaline earth hydroxides are not very soluble and are used only when the solubility factor is not important. In fact, the low solubility of these bases can sometimes be an advantage. For example, many antacids are suspensions of metal hydroxides, such as aluminum hydroxide and magnesium hydroxide. The low solubility of these compounds prevents a large hydroxide ion concentration that would harm the tissues of the mouth, esophagus, and stomach. Yet these suspensions furnish plenty of hydroxide ion to react with the stomach acid, since the salts dissolve as this reaction proceeds.

Calcium hydroxide, $\mathrm{Ca}(\mathrm{OH})_{2}$, often called slaked lime, is widely used in industry because it is inexpensive and plentiful. For example, slaked lime is used in scrubbing stack gases to remove sulfur dioxide from the exhaust of power plants and factories. In the scrubbing process a suspension of slaked lime is sprayed into the stack gases to react with sulfur dioxide gas according to the following steps:

$$
\begin{aligned}
\mathrm{SO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftharpoons \mathrm{H}_{2} \mathrm{SO}_{3}(a q) \\
\mathrm{Ca}(\mathrm{OH})_{2}(a q)+\mathrm{H}_{2} \mathrm{SO}_{3}(a q) & \rightleftharpoons \mathrm{CaSO}_{3}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

Slaked lime is also widely used in water treatment plants for softening hard water, which involves the removal of ions, such as $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$, that hamper the action of detergents. The softening method most often employed in water treatment plants is the lime-soda process, in which lime $(\mathrm{CaO})$ and soda ash $\left(\mathrm{Na}_{2} \mathrm{CO}_{3}\right)$ are added to the water. As we will see in more detail later in this chapter, the $\mathrm{CO}_{3}{ }^{2-}$ ion reacts with water to produce the $\mathrm{HCO}_{3}{ }^{-}$ion. When the lime is added to the water, it forms slaked lime, that is,

$$
\mathrm{CaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(a q)
$$

which then reacts with the $\mathrm{HCO}_{3}{ }^{-}$ion from the added soda ash and the $\mathrm{Ca}^{2+}$ ion in the hard water to produce calcium carbonate:

$$
\begin{gathered}
\mathrm{Ca}(\mathrm{OH})_{2}(a q)+\underset{\nearrow}{\mathrm{Ca}^{2+}}(a q)+2 \mathrm{HCO}_{3}^{-}(a q) \longrightarrow 2 \mathrm{CaCO}_{3}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \\
\text { From hard water }
\end{gathered}
$$

Thus, for every mole of $\mathrm{Ca}(\mathrm{OH})_{2}$ consumed, 1 mole of $\mathrm{Ca}^{2+}$ is removed from the hard water, thereby softening it. Some hard water naturally contains bicarbonate ions. In this case, no soda ash is needed-simply adding the lime produces the softening.

Calculating the pH of a strong base solution is relatively simple, as illustrated in Example 14.12.

## INTERACTIVE EXAMPLE 14.12 The pH of Strong Bases

Major Species
$\mathrm{Na}^{+}$
$\mathrm{OH}^{-}$

- $\mathrm{H}_{2} \mathrm{O}$

A base does not have to contain hydroxide ion.

## SOLUTION The major species in this solution are

$$
\underbrace{\mathrm{Na}^{+}, \quad \mathrm{OH}^{-}}_{\text {From } \mathrm{NaOH}}, \text { and } \mathrm{H}_{2} \mathrm{O}
$$

Although autoionization of water also produces $\mathrm{OH}^{-}$ions, the pH will be dominated by the $\mathrm{OH}^{-}$ions from the dissolved NaOH . Thus in the solution,

$$
\left[\mathrm{OH}^{-}\right]=5.0 \times 10^{-2} M
$$

and the concentration of $\mathrm{H}^{+}$can be calculated from $K_{\mathrm{w}}$ :

$$
\begin{aligned}
{\left[\mathrm{H}^{+}\right] } & =\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{5.0 \times 10^{-2}}=2.0 \times 10^{-13} \mathrm{M} \\
\square \mathrm{pH} & =12.70
\end{aligned}
$$

Note that this is a basic solution for which

$$
\left[\mathrm{OH}^{-}\right]>\left[\mathrm{H}^{+}\right] \text {and } \mathrm{pH}>7
$$

The added $\mathrm{OH}^{-}$from the salt has shifted the water autoionization equilibrium

$$
\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

to the left, significantly lowering $\left[\mathrm{H}^{+}\right]$compared with that in pure water.
Calculate the pH of a $5.0 \times 10^{-2}-M \mathrm{NaOH}$ solution.

Many types of proton acceptors (bases) do not contain the hydroxide ion. However, when dissolved in water, these substances increase the concentration of hydroxide ion because of their reaction with water. For example, ammonia reacts with water as follows:

$$
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

The ammonia molecule accepts a proton and thus functions as a base. Water is the acid in this reaction. Note that even though the base ammonia contains no hydroxide ion, it still increases the concentration of hydroxide ion to yield a basic solution.

Bases such as ammonia typically have at least one unshared pair of electrons that is capable of forming a bond with a proton. The reaction of an ammonia molecule with a water molecule can be represented as follows:

There are many bases like ammonia that produce hydroxide ion by reaction with water. In most of these bases, the lone pair is located on a nitrogen atom. Some examples are

Note that the first four bases can be thought of as substituted ammonia molecules with hydrogen atoms replaced by methyl $\left(\mathrm{CH}_{3}\right)$ or ethyl $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)$ groups. The pyridine molecule is like benzene

except that a nitrogen atom replaces one of the carbon atoms in the ring. The general reaction between a base B and water is given by

$$
\begin{equation*}
\underset{\text { Base }}{\mathrm{B}(a q)}+\underset{\text { Acid }}{\mathrm{H}_{2} \mathrm{O}(l)} \rightleftharpoons \underset{\substack{\text { Conjugate } \\ \text { acid }}}{\mathrm{BH}^{+}(a q)}+\underset{\substack{\text { Conjugate } \\ \text { base }}}{\mathrm{OH}^{-}(a q)} \tag{14.6}
\end{equation*}
$$

The equilibrium constant for this general reaction is

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{BH}^{+}\right]\left[\mathrm{OH}^{-}\right]}{[\mathrm{B}]}
$$

where $K_{\mathrm{b}}$ always refers to the reaction of a base with water to form the conjugate acid and the hydroxide ion.

Bases of the type represented by B in Equation (14.6) compete with $\mathrm{OH}^{-}$, a very strong base, for the $\mathrm{H}^{+}$ion. Thus their $K_{\mathrm{b}}$ values tend to be small (for example, for ammonia, $K_{\mathrm{b}}=1.8 \times 10^{-5}$ ), and they are called weak bases. The values of $K_{\mathrm{b}}$ for some common weak bases are listed in Table 14.3.

Typically, pH calculations for solutions of weak bases are very similar to those for weak acids, as illustrated by Examples 14.13 and 14.14.

TABLE 14.3 | Values of $K_{\mathrm{b}}$ for Some Common Weak Bases

| Name | Formula | Conjugate Acid | $\mathrm{K}_{\mathrm{b}}$ |
| :--- | :--- | :--- | :--- |
| Ammonia | $\mathrm{NH}_{3}$ | $\mathrm{NH}_{4}{ }^{+}$ | $1.8 \times 10^{-5}$ |
| Methylamine | $\mathrm{CH}_{3} \mathrm{NH}_{2}$ | $\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}$ | $4.38 \times 10^{-4}$ |
| Ethylamine | $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2}$ | $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}$ | $5.6 \times 10^{-4}$ |
| Aniline | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}$ | $3.8 \times 10^{-10}$ |
| Pyridine | $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$ | $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+}$ | $1.7 \times 10^{-9}$ |

## INTERACTIVE EXAMPLE 14.13

## SOLUTION

## The pH of Weak Bases I

Calculate the pH for a $15.0-\mathrm{M}$ solution of $\mathrm{NH}_{3}\left(K_{\mathrm{b}}=1.8 \times 10^{-5}\right)$.

Major Species solved $\mathrm{NH}_{3}$ will remain as $\mathrm{NH}_{3}$. Thus the major species in solution are

Both these substances can produce $\mathrm{OH}^{-}$according to the reactions

$$
\begin{array}{rll}
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q) & K_{\mathrm{b}}=1.8 \times 10^{-5} \\
\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) & K_{\mathrm{w}}=1.0 \times 10^{-14}
\end{array}
$$

However, the contribution from water can be neglected, since $K_{\mathrm{b}} \gg K_{\mathrm{w}}$. The equilibrium for $\mathrm{NH}_{3}$ will dominate, and the equilibrium expression to be used is

$$
K_{\mathrm{b}}=1.8 \times 10^{-5}=\frac{\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{3}\right]}
$$

The appropriate concentrations are

| Initial <br> Concentration ( $\mathrm{mol} / \mathrm{L}$ ) |  | Equilibrium Concentration ( $\mathrm{mol} / \mathrm{L}$ ) |
| :---: | :---: | :---: |
| $\begin{aligned} & {\left[\mathrm{NH}_{3}\right]_{0}=15.0} \\ & {\left[\mathrm{NH}_{4}^{+}\right]_{0}=0} \\ & {\left[\mathrm{OH}^{-}\right]_{0} \approx 0} \end{aligned}$ |  | $\begin{aligned} & {\left[\mathrm{NH}_{3}\right]=15.0-x} \\ & {\left[\mathrm{NH}_{4}^{+}\right]=x} \\ & {\left[\mathrm{OH}^{-}\right]=x} \end{aligned}$ |

In terms of an ICE table, these concentrations are

|  | $\mathrm{NH}_{3}(a q)$ | $\rightleftharpoons$ | $\mathrm{H}_{2} \mathrm{O}(l)$ | + | $\mathrm{NH}_{4}{ }^{+}(a q)$ | + | $\mathrm{OH}^{-}(a q)$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Initial | 15.0 |  | - | 0 |  | 0 |  |
| Change | $-x$ |  | - |  | $+x$ |  | $+x$ |
| Equilibrium | $15.0-x$ |  | - |  | $x$ |  | $x$ |

Substituting the equilibrium concentrations into the equilibrium expression and making the usual approximation gives

$$
\begin{gathered}
K_{\mathrm{b}}=1.8 \times 10^{-5}=\frac{\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{3}\right]}=\frac{(x)(x)}{15.0-x} \approx \frac{x^{2}}{15.0} \\
x \approx 1.6 \times 10^{-2}
\end{gathered}
$$

Thus
The $5 \%$ rule validates the approximation (check it yourself), so

$$
\left[\mathrm{OH}^{-}\right]=1.6 \times 10^{-2} \mathrm{M}
$$

Since we know that $K_{\mathrm{w}}$ must be satisfied for this solution, we can calculate $\left[\mathrm{H}^{+}\right]$as follows:

Therefore,

$$
\begin{gathered}
{\left[\mathrm{H}^{+}\right]=\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{1.6 \times 10^{-2}}=6.3 \times 10^{-13} \mathrm{M}} \\
\square \mathrm{pH}=-\log \left(6.3 \times 10^{-13}\right)=12.20
\end{gathered}
$$

## CHEMICAL CONNECTIDNS

## Amines

We have seen that many bases have nitrogen atoms with one lone pair and can be viewed as substituted ammonia molecules, with the general formula $\mathrm{R}_{x} \mathrm{NH}_{(3-x)}$. Compounds of this type are called amines. Amines are widely distributed in animals and plants, and complex amines often serve as messengers or regulators. For example, in the human nervous system, there are two amine stimulants, norepinephrine and adrenaline.

Adrenaline
Ephedrine, widely used as a decongestant, was a known drug in China over 2000 years ago. Indians in Mexico and the Southwest have used the hallucinogen mescaline, extracted from the peyote cactus, for centuries.

Ephedrine

Mescaline
Many other drugs, such as codeine and quinine, are amines, but they are usually not used in their pure amine forms. Instead, they are treated with an acid to become acid salts. An example of an acid salt is ammonium chloride, obtained by the reaction

$$
\mathrm{NH}_{3}+\mathrm{HCl} \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}
$$

Amines also can be protonated in this way. The resulting acid salt, written as AHCI (where A represents the amine), contains $\mathrm{AH}^{+}$and $\mathrm{Cl}^{-}$. In general, the acid salts are more stable and more soluble in water than the parent

Peyote cactus growing on a rock.
amines. For instance, the parent amine of the well-known local anesthetic novocaine is insoluble in water, whereas the acid salt is much more soluble.

[^31]Example 14.13 illustrates how a typical weak base equilibrium problem should be solved. Note two additional important points:

1. We calculated $\left[\mathrm{H}^{+}\right]$from $K_{\mathrm{w}}$ and then calculated the pH , but another method is available. The pOH could have been calculated from $\left[\mathrm{OH}^{-}\right]$and then used in Equation (14.3):

$$
\begin{aligned}
\mathrm{p} K_{\mathrm{w}} & =14.00=\mathrm{pH}+\mathrm{pOH} \\
\mathrm{pH} & =14.00-\mathrm{pOH}
\end{aligned}
$$

2. In a $15.0-M \mathrm{NH}_{3}$ solution, the equilibrium concentrations of $\mathrm{NH}_{4}^{+}$and $\mathrm{OH}^{-}$are each $1.6 \times 10^{-2} \mathrm{M}$. Only a small percentage,

$$
\frac{1.6 \times 10^{-2}}{15.0} \times 100 \%=0.11 \%
$$

of the ammonia reacts with water. Bottles containing $15.0 \mathrm{MH}_{3}$ solution are often labeled $15.0 \mathrm{M} \mathrm{NH}_{4} \mathrm{OH}$, but as you can see from these results, $15.0 \mathrm{MNH}_{3}$ is actually a much more accurate description of the solution contents.

## SOLUTION

Major Species

- $\mathrm{H}_{2} \mathrm{O}$

## The pH of Weak Bases II

Calculate the pH of a 1.0-M solution of methylamine $\left(K_{\mathrm{b}}=4.38 \times 10^{-4}\right)$.
Since methylamine $\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)$ is a weak base, the major species in solution are

$$
\mathrm{CH}_{3} \mathrm{NH}_{2} \text { and } \mathrm{H}_{2} \mathrm{O}
$$

Both are bases; however, water can be neglected as a source of $\mathrm{OH}^{-}$, so the dominant equilibrium is

$$
\begin{gathered}
\mathrm{CH}_{3} \mathrm{NH}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{CH}_{3} \mathrm{NH}_{3}^{+}(a q)+\mathrm{OH}^{-}(a q) \\
K_{\mathrm{b}}=4.38 \times 10^{-4}=\frac{\left[\mathrm{CH}_{3} \mathrm{NH}_{3}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{CH}_{3} \mathrm{NH}_{2}\right]}
\end{gathered}
$$

and
The ICE table is:

|  | $\mathrm{CH}_{3} \mathrm{NH}_{2}(a q)$ | + | $\mathrm{H}_{2} \mathrm{O}(l)$ | $\rightleftharpoons$ | $\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}(a q)$ | + | $\mathrm{OH}^{-}(a q)$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Initial | 1.0 | - |  | 0 | 0 |  |  |
| Change | $-x$ |  | - |  | $+x$ |  | $+x$ |
| Equilibrium | $1.0-x$ |  | - |  | $x$ | $x$ |  |

Substituting the equilibrium concentrations in the equilibrium expression and making the usual approximation give
and

$$
\begin{gathered}
K_{\mathrm{b}}=4.38 \times 10^{-4}=\frac{\left[\mathrm{CH}_{3} \mathrm{NH}_{3}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{CH}_{3} \mathrm{NH}_{2}\right]}=\frac{(x)(x)}{1.0-x} \approx \frac{x^{2}}{1.0} \\
x \approx 2.1 \times 10^{-2}
\end{gathered}
$$

The approximation is valid by the $5 \%$ rule, so

$$
\begin{aligned}
{\left[\mathrm{OH}^{-}\right] } & =x=2.1 \times 10^{-2} M \\
\mathrm{pOH} & =1.68 \\
\square \mathrm{pH} & =14.00-1.68=12.32
\end{aligned}
$$

## See Exercises 14.97 and 14.98

### 14.7 Polyprotic Acids

Some important acids, such as sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$ and phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$, can furnish more than one proton and are called polyprotic acids. A polyprotic acid always dissociates in a stepwise manner, one proton at a time. For example, the diprotic (twoproton) acid carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$, which is so important in maintaining a constant pH in human blood, dissociates in the following steps:

$$
\begin{array}{cc}
\mathrm{H}_{2} \mathrm{CO}_{3}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q) & K_{\mathrm{a}_{1}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{HCO}_{3}{ }^{-}\right]}{\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right]}=4.3 \times 10^{-7} \\
\mathrm{HCO}_{3}^{-}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q) & K_{\mathrm{a}_{2}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{CO}_{3}{ }^{2-}\right]}{\left[\mathrm{HCO}_{3}^{-}\right]}=5.6 \times 10^{-11}
\end{array}
$$

The successive $K_{\mathrm{a}}$ values for the dissociation equilibria are designated $K_{\mathrm{a}_{1}}$ and $K_{\mathrm{a}_{2}}$. Note that the conjugate base $\mathrm{HCO}_{3}{ }^{-}$of the first dissociation equilibrium becomes the acid in the second step.

Carbonic acid is formed when carbon dioxide gas is dissolved in water. In fact, the first dissociation step for carbonic acid is best represented by the reaction

$$
\mathrm{CO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q)
$$

A table of $K_{\mathrm{a}}$ values for polyprotic acids is also given in Appendix 5.2.

For a typical polyprotic acid in water, only the first dissociation step is important in determining the pH .
since relatively little $\mathrm{H}_{2} \mathrm{CO}_{3}$ actually exists in solution. However, it is convenient to consider $\mathrm{CO}_{2}$ in water as $\mathrm{H}_{2} \mathrm{CO}_{3}$ so that we can treat such solutions using the familiar dissociation reactions for weak acids.

Phosphoric acid is a triprotic acid (three protons) that dissociates in the following steps:

$$
\begin{gathered}
\mathrm{H}_{3} \mathrm{PO}_{4}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q) \\
K_{\mathrm{a}_{1}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]}{\left[\mathrm{H}_{3} \mathrm{PO}_{4}\right]}=7.5 \times 10^{-3} \\
\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{HPO}_{4}{ }^{2-}(a q) \\
K_{\mathrm{a}_{2}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{HPO}_{4}{ }^{2-}\right]}{\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]}=6.2 \times 10^{-8} \\
\mathrm{HPO}_{4}{ }^{2-}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{PO}_{4}^{3-}(a q) \\
K_{\mathrm{a}_{3}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{PO}_{4}^{3-}\right]}{\left[\mathrm{HPO}_{4}{ }^{2-}\right]}=4.8 \times 10^{-13}
\end{gathered}
$$

For a typical weak polyprotic acid,

$$
K_{\mathrm{a}_{1}}>K_{\mathrm{a}_{2}}>K_{\mathrm{a}_{3}}
$$

That is, the acid involved in each step of the dissociation is successively weaker, as shown by the stepwise dissociation constants given in Table 14.4. These values indicate that the loss of a second or third proton occurs less readily than loss of the first proton. This is not surprising; as the negative charge on the acid increases, it becomes more difficult to remove the positively charged proton.

Although we might expect the pH calculations for solutions of polyprotic acids to be complicated, the most common cases are surprisingly straightforward. To illustrate, we will consider a typical case, phosphoric acid, and a unique case, sulfuric acid.

## Phosphoric Acid

Phosphoric acid is typical of most polyprotic acids in that the successive $K_{\mathrm{a}}$ values are very different. For example, the ratios of successive $K_{\mathrm{a}}$ values (from Table 14.4) are

$$
\begin{aligned}
& \frac{K_{\mathrm{a}_{1}}}{K_{\mathrm{a}_{2}}}=\frac{7.5 \times 10^{-3}}{6.2 \times 10^{-8}}=1.2 \times 10^{5} \\
& \frac{K_{\mathrm{a}_{2}}}{K_{\mathrm{a}_{3}}}=\frac{6.2 \times 10^{-8}}{4.8 \times 10^{-13}}=1.3 \times 10^{5}
\end{aligned}
$$

Thus the relative acid strengths are

$$
\mathrm{H}_{3} \mathrm{PO}_{4} \gg \mathrm{H}_{2} \mathrm{PO}_{4}^{-} \gg \mathrm{HPO}_{4}{ }^{2-}
$$

This means that in a solution prepared by dissolving $\mathrm{H}_{3} \mathrm{PO}_{4}$ in water, only the first dissociation step makes an important contribution to $\left[\mathrm{H}^{+}\right]$. This greatly simplifies the pH calculations for phosphoric acid solutions, as is illustrated in Example 14.15.

TABLE 14.4 | Stepwise Dissociation Constants for Several Common Polyprotic Acids

| Name | Formula | $K_{a_{1}}$ | $K_{a_{2}}$ |
| :--- | :--- | :--- | :--- |
| Phosphoric acid | $\mathrm{H}_{3} \mathrm{PO}_{4}$ | $7.5 \times 10^{-3}$ | $6.2 \times 10^{-8}$ |
| Arsenic acid | $\mathrm{H}_{3} \mathrm{AsO}_{4}$ | $5.5 \times 10^{-3}$ | $1.7 \times 10^{-7}$ |
| Carbonic acid | $\mathrm{H}_{2} \mathrm{CO}_{3}$ | $4.3 \times 10^{-7}$ | $5.9 \times 10^{-13}$ |
| Sulfuric acid | $\mathrm{H}_{2} \mathrm{SO}_{4}$ | Large | $5.6 \times 10^{-11}$ |

[^32]
## INTERACTIVE EXAMPLE 14.15 The pH of a Polyprotic Acid

Calculate the pH of a $5.0-\mathrm{M}_{3} \mathrm{PO}_{4}$ solution and the equilibrium concentrations of the species $\mathrm{H}_{3} \mathrm{PO}_{4}, \mathrm{H}_{2} \mathrm{PO}_{4}^{-}, \mathrm{HPO}_{4}{ }^{2-}$, and $\mathrm{PO}_{4}{ }^{3-}$.

## SOLUTION

The major species in solution are

$$
\mathrm{H}_{3} \mathrm{PO}_{4} \text { and } \mathrm{H}_{2} \mathrm{O}
$$

None of the dissociation products of $\mathrm{H}_{3} \mathrm{PO}_{4}$ is written, since the $K_{\mathrm{a}}$ values are all so small that they will be minor species. The dominant equilibrium is the dissociation of $\mathrm{H}_{3} \mathrm{PO}_{4}$ :
where

$$
\begin{gathered}
\mathrm{H}_{3} \mathrm{PO}_{4}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q) \\
K_{\mathrm{a}_{1}}=7.5 \times 10^{-3}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]}{\left[\mathrm{H}_{3} \mathrm{PO}_{4}\right]}
\end{gathered}
$$

The ICE table is:

|  | $\mathrm{H}_{3} \mathrm{PO}_{4}(a q)$ | $\rightleftharpoons$ | $\mathrm{H}^{+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 5.0 |  | 0 | $\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}(a q)$ |
| Change | $-x$ |  | $+x$ | 0 |
| Equilibrium | $5.0-x$ |  | $x$ | $+x$ |
|  |  |  | $x$ |  |

Substituting the equilibrium concentrations into the expression for $K_{\mathrm{a}_{1}}$ and making the usual approximation give

Thus

$$
\begin{aligned}
K_{\mathrm{a}_{1}}=7.5 \times 10^{-3} & =\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]}{\left[\mathrm{H}_{3} \mathrm{PO}_{4}\right]}=\frac{(x)(x)}{5.0-x} \approx \frac{x^{2}}{5.0} \\
x & \approx 1.9 \times 10^{-1}
\end{aligned}
$$

Since $1.9 \times 10^{-1}$ is less than $5 \%$ of 5.0 , the approximation is acceptable, and

$$
\begin{aligned}
{\left[\mathrm{H}^{+}\right] } & =x=0.19 \mathrm{M} \\
\square \mathrm{pH} & =0.72
\end{aligned}
$$

So far we have determined that

$$
\left[\mathrm{H}^{+}\right]=\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]=0.19 \mathrm{M}
$$

and

$$
\square\left[\mathrm{H}_{3} \mathrm{PO}_{4}\right]=5.0-x=4.8 \mathrm{M}
$$

The concentration of $\mathrm{HPO}_{4}{ }^{2-}$ can be obtained by using the expression for $K_{\mathrm{a}_{2}}$ :
where

$$
K_{\mathrm{a}_{2}}=6.2 \times 10^{-8}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{HPO}_{4}{ }^{2-}\right]}{\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]}
$$

Thus

$$
\left[\mathrm{H}^{+}\right]=\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]=0.19 \mathrm{M}
$$

$\left[\mathrm{HO}_{4}^{2-}\right]=\mathrm{K}_{\mathrm{a}_{2}}=6.2 \times 10^{-8} \mathrm{M}$
To calculate $\left[\mathrm{PO}_{4}{ }^{3-}\right]$, we use the expression for $K_{\mathrm{a}_{3}}$ and the values of $\left[\mathrm{H}^{+}\right]$and [ $\mathrm{HPO}_{4}{ }^{2-}$ ] calculated previously:

$$
\begin{aligned}
K_{\mathrm{a}_{3}} & =\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{PO}_{4}^{3-}\right]}{\left[\mathrm{HPO}_{4}^{2-}\right]}=4.8 \times 10^{-13}=\frac{0.19\left[\mathrm{PO}_{4}^{3-}\right]}{\left(6.2 \times 10^{-8}\right)} \\
{\left[\mathrm{PO}_{4}^{3-}\right] } & =\frac{\left(4.8 \times 10^{-13}\right)\left(6.2 \times 10^{-8}\right)}{0.19}=1.6 \times 10^{-19} \mathrm{M}
\end{aligned}
$$

These results show that the second and third dissociation steps do not make an important contribution to $\left[\mathrm{H}^{+}\right]$. This is apparent from the fact that $\left[\mathrm{HPO}_{4}{ }^{2-}\right]$ is $6.2 \times 10^{-8} \mathrm{M}$, which means that only $6.2 \times 10^{-8} \mathrm{~mol} / \mathrm{L} \mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$has dissociated. The value of $\left[\mathrm{PO}_{4}{ }^{3-}\right]$ shows that the dissociation of $\mathrm{HPO}_{4}{ }^{2-}$ is even smaller. We must, however, use the second and third dissociation steps to calculate $\left[\mathrm{HPO}_{4}{ }^{2-}\right]$ and $\left[\mathrm{PO}_{4}{ }^{3-}\right]$, since these steps are the only sources of these ions.

## See Exercises 14.107 and 14. 108

## What if the three values of $K_{\mathrm{a}}$ for

 phosphoric acid were closer to each other in value? Why would this complicate the calculation of the pH for an aqueous solution of phosphoric acid?
## Sulfuric Acid

Sulfuric acid is unique among the common acids in that it is a strong acid in its first dissociation step and a weak acid in its second step:

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{HSO}_{4}{ }^{-}(a q) \quad K_{\mathrm{a}_{1}} \text { is very large } \\
& \mathrm{HSO}_{4}{ }^{-}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q) \quad K_{\mathrm{a}_{2}}=1.2 \times 10^{-2}
\end{aligned}
$$

Example 14.16 illustrates how to calculate the pH for sulfuric acid solutions.

## INTERACTIVE EXAMPLE 14.16 The pH of Sulfuric Acid

Calculate the pH of a $1.0-\mathrm{M}_{2} \mathrm{SO}_{4}$ solution.
SOLUTION The major species in the solution are

$$
\mathrm{H}^{+}, \mathrm{HSO}_{4}^{-}, \text {and } \mathrm{H}_{2} \mathrm{O}
$$

Major Species where the first two ions are produced by the complete first dissociation step of $\mathrm{H}_{2} \mathrm{SO}_{4}$.
 The concentration of $\mathrm{H}^{+}$in this solution will be at least 1.0 M , since this amount is produced by the first dissociation step of $\mathrm{H}_{2} \mathrm{SO}_{4}$. We must now answer this question: Does the $\mathrm{HSO}_{4}^{-}$ion dissociate enough to produce a significant contribution to the concentration of $\mathrm{H}^{+}$? This question can be answered by calculating the equilibrium concentrations for the dissociation reactions of $\mathrm{HSO}_{4}{ }^{-}$:
where

$$
\begin{gathered}
\mathrm{HSO}_{4}^{-}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q) \\
K_{\mathrm{a}_{2}}=1.2 \times 10^{-2}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{SO}_{4}^{2-}\right]}{\left[\mathrm{HSO}_{4}{ }^{2-}\right]}
\end{gathered}
$$

The ICE table is:

|  | $\mathrm{HSO}_{4}{ }^{-}(a q)$ | $\rightleftharpoons$ | $\mathrm{H}^{+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 1.0 |  | $\mathrm{SO}_{4}{ }^{2-}(a q)$ |  |
| Change | $-x$ |  | $+x$ | 0 |
| Equilibrium | $1.0-x$ |  | $1.0+x$ | $+x$ |
|  |  |  | $x$ |  |

Note that $\left[\mathrm{H}^{+}\right]_{0}$ is not equal to zero, as it usually is for a weak acid, because the first dissociation step has already occurred. Substituting the equilibrium concentrations into the expression for $K_{\mathrm{a}_{2}}$ and making the usual approximation give

Thus

$$
\begin{gathered}
K_{\mathrm{a}_{2}}=1.2 \times 10^{-2}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{SO}_{4}^{2-}\right]}{\left[\mathrm{HSO}_{4}^{-}\right]}=\frac{(1.0+x)(x)}{1.0-x} \approx \frac{(1.0)(x)}{(1.0)} \\
x \approx 1.2 \times 10^{-2}
\end{gathered}
$$

Since $1.2 \times 10^{-2}$ is $1.2 \%$ of 1.0 , the approximation is valid according to the $5 \%$ rule. Note that $x$ is not equal to $\left[\mathrm{H}^{+}\right]$in this case. Instead,

$$
\begin{aligned}
{\left[\mathrm{H}^{+}\right] } & =1.0 M+x=1.0 M+\left(1.2 \times 10^{-2}\right) M \\
& =1.0 M \quad \text { (to the correct number of significant figures) }
\end{aligned}
$$

Thus the dissociation of $\mathrm{HSO}_{4}^{-}$does not make a significant contribution to the concentration of $\mathrm{H}^{+}$, and

$$
\left[\mathrm{H}^{+}\right]=1.0 \mathrm{M} \quad \text { and } \quad \mathrm{pH}=0.00
$$

## See Exercise 14.111

Only in dilute $\mathrm{H}_{2} \mathrm{SO}_{4}$ solutions does the second dissociation step contribute significantly to $\left[\mathrm{H}^{+}\right]$.

Example 14.16 illustrates the most common case for sulfuric acid in which only the first dissociation makes an important contribution to the concentration of $\mathrm{H}^{+}$. In solutions more dilute than 1.0 M (for example, $0.10 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ ), the dissociation of $\mathrm{HSO}_{4}{ }^{-}$ is important, and solving the problem requires use of the quadratic formula, as shown in Example 14.17.

## EXAMPLE 14.17

SOLUTION

Substituting the equilibrium concentrations into the expression for $K_{\mathrm{a}_{2}}$ gives

$$
1.2 \times 10^{-2}=K_{\mathrm{a}_{2}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{SO}_{4}{ }^{2-}\right]}{\left[\mathrm{HSO}_{4}{ }^{-}\right]}=\frac{(0.0100+x)(x)}{(0.0100-x)}
$$

If we make the usual approximation, then $0.0100+x \approx 0.0100$ and $0.0100-x \approx$ 0.0100 , and we have

$$
1.2 \times 10^{-2}=\frac{(0.0100+x)(x)}{(0.0100-x)} \approx \frac{(0.0100) x}{(0.0100)}
$$

The calculated value of $x$ is

$$
x=1.2 \times 10^{-2}=0.012
$$

This value is larger than 0.010 , clearly a ridiculous result. Thus we cannot make the usual approximation and must instead solve the quadratic equation. The expression
leads to

$$
1.2 \times 10^{-2}=\frac{(0.0100+x)(x)}{(0.0100-x)}
$$

$$
\begin{aligned}
\left(1.2 \times 10^{-2}\right)(0.0100-x)= & (0.0100+x)(x) \\
\left(1.2 \times 10^{-4}\right)-\left(1.2 \times 10^{-2}\right) x & =\left(1.0 \times 10^{-2}\right) x+x^{2} \\
x^{2}+\left(2.2 \times 10^{-2}\right) x-\left(1.2 \times 10^{-4}\right) & =0
\end{aligned}
$$

This equation can be solved using the quadratic formula

$$
x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a}
$$

where $a=1, b=2.2 \times 10^{-2}$, and $c=-1.2 \times 10^{-4}$. Use of the quadratic formula gives one negative root (which cannot be correct) and one positive root,

Thus

$$
\left[\mathrm{H}^{+}\right]=0.0100+x=0.0100+0.0045=0.0145
$$

and
$\mathrm{pH}=1.84$
Note that in this case the second dissociation step produces about half as many $\mathrm{H}^{+}$ions as the initial step does.

This problem also can be solved by successive approximations, a method illustrated in Appendix 1.4.

## LET'S REVIEW Characteristics of Weak Polyprotic Acids

\# Typically, successive $K_{\mathrm{a}}$ values are so much smaller than the first value that only the first dissociation step makes a significant contribution to the equilibrium concentration of $\mathrm{H}^{+}$. This means that the calculation of the pH for a solution of a typical weak polyprotic acid is identical to that for a solution of a weak monoprotic acid.
") Sulfuric acid is unique in being a strong acid in its first dissociation step and a weak acid in its second step. For relatively concentrated solutions of sulfuric acid ( 1.0 M or higher), the large concentration of $\mathrm{H}^{+}$from the first dissociation step represses the second step, which can be neglected as a contributor of $\mathrm{H}^{+}$ions. For dilute solutions of sulfuric acid, the second step does make a significant contribution, and the quadratic equation must be used to obtain the total $\mathrm{H}^{+}$concentration.

### 14.8 Acid-Base Properties of Salts

Salt is simply another name for ionic compound. When a salt dissolves in water, we assume that it breaks up into its ions, which move about independently, at least in dilute solutions. Under certain conditions, these ions can behave as acids or bases. In this section we explore such reactions.

## Salts That Produce Neutral Solutions

Recall that the conjugate base of a strong acid has virtually no affinity for protons in water. This is why strong acids completely dissociate in aqueous solution. Thus, when anions such as $\mathrm{Cl}^{-}$and $\mathrm{NO}_{3}{ }^{-}$are placed in water, they do not combine with $\mathrm{H}^{+}$and have no effect on the pH . Cations such as $\mathrm{K}^{+}$and $\mathrm{Na}^{+}$from strong bases have no affinity for $\mathrm{H}^{+}$, nor can they produce $\mathrm{H}^{+}$, so they too have no effect on the pH of an aqueous solution. Salts that consist of the cations of strong bases and the anions of strong acids have no effect on $\left[\mathrm{H}^{1}\right]$ when dissolved in water. This means that aqueous solutions of salts such as $\mathrm{KCl}, \mathrm{NaCl}, \mathrm{NaNO}_{3}$, and $\mathrm{KNO}_{3}$ are neutral (have a pH of 7).

Major Species

## Salts That Produce Basic Solutions

In an aqueous solution of sodium acetate $\left(\mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$, the major species are

$$
\mathrm{Na}^{+}, \quad \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
$$

What are the acid-base properties of each component? The $\mathrm{Na}^{+}$ion has neither acid nor base properties. The $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}$ion is the conjugate base of acetic acid, a weak acid. This means that $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}$has a significant affinity for a proton and is a base. Finally, water is a weakly amphoteric substance.

The pH of this solution will be determined by the $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}$ion. Since $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}$is a base, it will react with the best proton donor available. In this case, water is the only source of protons, and the reaction between the acetate ion and water is

$$
\begin{equation*}
\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)+\mathrm{OH}^{-}(a q) \tag{14.7}
\end{equation*}
$$

Note that this reaction, which yields a base solution, involves a base reacting with water to produce hydroxide ion and a conjugate acid. We have defined $K_{\mathrm{b}}$ as the equilibrium constant for such a reaction. In this case,

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}
$$

The value of $K_{\mathrm{a}}$ for acetic acid is well known $\left(1.8 \times 10^{-5}\right)$. But how can we obtain the $K_{\mathrm{b}}$ value for the acetate ion? The answer lies in the relationships among $K_{\mathrm{a}}, K_{\mathrm{b}}$, and $K_{\mathrm{w}}$. Note that when the expression for $K_{\mathrm{a}}$ for acetic acid is multiplied by the expression for $K_{\mathrm{b}}$ for the acetate ion, the result is $K_{\mathrm{w}}$ :

$$
K_{\mathrm{a}} \times K_{\mathrm{b}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]} \times \frac{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=K_{\mathrm{w}}
$$

This is a very important result. For any weak acid and its conjugate base,

$$
K_{\mathrm{a}} \times K_{\mathrm{b}}=K_{\mathrm{w}}
$$

We can obtain a different form of this equation by taking - log of both sides of the above equation. This gives the equation

$$
\mathrm{p} K_{\mathrm{a}}+\mathrm{p} K_{\mathrm{b}}=\mathrm{p} K_{\mathrm{w}}
$$

At $25^{\circ} \mathrm{C}, K_{\mathrm{w}}=1.0 \times 10^{-14}$, so $\mathrm{p} K_{\mathrm{w}}=14.00$. In solutions at $25^{\circ} \mathrm{C}$, we can use the relationship

$$
\mathrm{p} K_{\mathrm{a}}+\mathrm{p} K_{\mathrm{b}}=14.00
$$

A basic solution is formed if the anion of the salt is the conjugate base of a weak acid.

Thus when either $K_{\mathrm{a}}$ or $K_{\mathrm{b}}$ is known, the other can be calculated. For the acetate ion, since $K_{\mathrm{w}}=K_{\mathrm{b}} \times K_{\mathrm{a}}$ (acetic acid), the $K_{\mathrm{b}}$ for acetate is:

$$
K_{\mathrm{b}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}\left(\text { for } \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}}=5.6 \times 10^{-10}
$$

This is the $K_{\mathrm{b}}$ value for the reaction described by Equation (14.7). Note that it is obtained from the $K_{\mathrm{a}}$ value of the parent weak acid, in this case acetic acid. The sodium acetate solution is an example of an important general case. For any salt whose cation has neutral properties (such as $\mathbf{N a}^{1}$ or $\mathrm{K}^{1}$ ) and whose anion is the conjugate base of a weak acid, the aqueous solution will be basic. The $K_{\mathrm{b}}$ value for the anion can be obtained from the relationship $K_{\mathrm{b}}=K_{\mathrm{w}} / K_{\mathrm{a}}$. Equilibrium calculations of this type are illustrated in Example 14.18.

## INTERACTVE EXAMPLE 14.18 Salts as Weak Bases

Calculate the pH of a $0.30-\mathrm{M} \mathrm{NaF}$ solution. The $K_{\mathrm{a}}$ value for HF is $7.2 \times 10^{-4}$.
SOLUTION The major species in solution are

$$
\mathrm{Na}^{+}, \quad \mathrm{F}^{-}, \quad \text { and } \mathrm{H}_{2} \mathrm{O}
$$

Major Species

$\mathrm{H}_{2} \mathrm{O}$

Since HF is a weak acid, the $\mathrm{F}^{-}$ion must have a significant affinity for protons, and the dominant reaction will be

$$
\mathrm{F}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HF}(a q)+\mathrm{OH}^{-}(a q)
$$

which yields the $K_{\mathrm{b}}$ expression

$$
K_{\mathrm{b}}=\frac{[\mathrm{HF}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{F}^{-}\right]}
$$

The value of $K_{\mathrm{b}}$ can be calculated from $K_{\mathrm{w}}$ and the $K_{\mathrm{a}}$ value for HF:

$$
K_{\mathrm{b}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}(\text { for } \mathrm{HF})}=\frac{1.0 \times 10^{-14}}{7.2 \times 10^{-4}}=1.4 \times 10^{-11}
$$

The corresponding ICE table is:

|  | $\mathrm{F}^{-}(a q)$ | + | $\mathrm{H}_{2} \mathrm{O}(I)$ | $\rightleftharpoons$ | $\mathrm{HF}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{OH}^{-}(a q)$ |  |  |  |  |  |  |
| Initial | 0.30 | - |  | 0 | $\approx 0$ |  |
| Change | $-x$ | - |  | $+x$ | $+x$ |  |
| Equilibrium | $0.30-x$ | - |  | $x$ | $x$ |  |

Thus

$$
\begin{aligned}
K_{\mathrm{b}}=1.4 \times 10^{-11} & =\frac{[\mathrm{HF}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{F}^{-}\right]}=\frac{(x)(x)}{0.30-x} \approx \frac{x^{2}}{0.30} \\
x & \approx 2.0 \times 10^{-6}
\end{aligned}
$$

The approximation is valid by the $5 \%$ rule, so

$$
\begin{aligned}
{\left[\mathrm{OH}^{-}\right] } & =x=2.0 \times 10^{-6} \mathrm{M} \\
\mathrm{pOH} & =5.69 \\
\square \mathrm{pH} & =14.00-5.69=8.31
\end{aligned}
$$

As expected, the solution is basic.

## Base Strength in Aqueous Solutions

To emphasize the concept of base strength, let us consider the basic properties of the cyanide ion. One relevant reaction is the dissociation of hydrocyanic acid in water:

$$
\mathrm{HCN}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{CN}^{-}(a q) \quad K_{\mathrm{a}}=6.2 \times 10^{-10}
$$

Since HCN is such a weak acid, $\mathrm{CN}^{-}$appears to be a strong base, showing a very high affinity for $\mathrm{H}^{+}$compared to $\mathrm{H}_{2} \mathrm{O}$, with which it is competing. However, we also need to look at the reaction in which cyanide ion reacts with water:

$$
\mathrm{CN}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HCN}(a q)+\mathrm{OH}^{-}(a q)
$$

where

$$
K_{\mathrm{b}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}=\frac{1.0 \times 10^{-14}}{6.2 \times 10^{-10}}=1.6 \times 10^{-5}
$$

In this reaction $\mathrm{CN}^{-}$appears to be a weak base; the $K_{\mathrm{b}}$ value is only $1.6 \times 10^{-5}$. What accounts for this apparent difference in base strength? The key idea is that in the reaction of $\mathrm{CN}^{-}$with $\mathrm{H}_{2} \mathrm{O}, \mathrm{CN}^{-}$is competing with $\mathrm{OH}^{2}$ for $\mathrm{H}^{+}$, instead of competing with $\mathrm{H}_{2} \mathrm{O}$, as it does in the HCN dissociation reaction. These equilibria show the following relative base strengths:

$$
\mathrm{OH}^{-}>\mathrm{CN}^{-}>\mathrm{H}_{2} \mathrm{O}
$$

Similar arguments can be made for other "weak" bases, such as ammonia, the acetate ion, the fluoride ion, and so on.

## Salts That Produce Acidic Solutions

Some salts produce acidic solutions when dissolved in water. For example, when solid $\mathrm{NH}_{4} \mathrm{Cl}$ is dissolved in water, $\mathrm{NH}_{4}^{+}$and $\mathrm{Cl}^{-}$ions are present, with $\mathrm{NH}_{4}{ }^{+}$behaving as a weak acid:

$$
\mathrm{NH}_{4}^{+}(a q) \rightleftharpoons \mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q)
$$

The $\mathrm{Cl}^{-}$ion, having virtually no affinity for $\mathrm{H}^{+}$in water, does not affect the pH of the solution.

In general, salts in which the anion is not a base and the cation is the conjugate acid of a weak base produce acidic solutions.

## INTERACTIVE EXAMPLE 14.18

SOLUTION

Major Species

## Salts as Weak Acids I

Calculate the pH of a $0.10-\mathrm{M} \mathrm{NH}_{4} \mathrm{Cl}$ solution. The $K_{\mathrm{b}}$ value for $\mathrm{NH}_{3}$ is $1.8 \times 10^{-5}$.
The major species in solution are

$$
\mathrm{NH}_{4}^{+}, \mathrm{Cl}^{-}, \text {and } \mathrm{H}_{2} \mathrm{O}
$$

Note that both $\mathrm{NH}_{4}{ }^{+}$and $\mathrm{H}_{2} \mathrm{O}$ can produce $\mathrm{H}^{+}$. The dissociation reaction for the $\mathrm{NH}_{4}{ }^{+}$ ion is
for which

$$
\begin{aligned}
\mathrm{NH}_{4}^{+}(a q) & \rightleftharpoons \mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q) \\
K_{\mathrm{a}} & =\frac{\left[\mathrm{NH}_{3}\right]\left[\mathrm{H}^{+}\right]}{\left[\mathrm{NH}_{4}^{+}\right]}
\end{aligned}
$$

Note that although the $K_{\mathrm{b}}$ value for $\mathrm{NH}_{3}$ is given, the reaction corresponding to $K_{\mathrm{b}}$ is not appropriate here, since $\mathrm{NH}_{3}$ is not a major species in the solution. Instead, the given value of $K_{\mathrm{b}}$ is used to calculate $K_{\mathrm{a}}$ for $\mathrm{NH}_{4}{ }^{+}$from the relationship

$$
\begin{gathered}
K_{\mathrm{a}} \times K_{\mathrm{b}}=K_{\mathrm{w}} \\
\text { Thus } \quad K_{\mathrm{a}}\left(\text { for } \mathrm{NH}_{4}^{+}\right)=\frac{K_{\mathrm{w}}}{K_{\mathrm{b}}\left(\text { for } \mathrm{NH}_{3}\right)}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}}=5.6 \times 10^{-10}
\end{gathered}
$$

Although $\mathrm{NH}_{4}{ }^{+}$is a very weak acid, as indicated by its $K_{\mathrm{a}}$ value, it is stronger than $\mathrm{H}_{2} \mathrm{O}$ and will dominate in the production of $\mathrm{H}^{+}$. Thus we will focus on the dissociation reaction of $\mathrm{NH}_{4}{ }^{+}$to calculate the pH in this solution.

We solve the weak acid problem in the usual way:

|  | $\mathrm{NH}_{4}+(a q)$ | $\rightleftharpoons$ | $\mathrm{H}^{+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 0.10 |  | $\approx 0$ | 0 |
| Change | $-x$ |  | $+x$ |  |
| Equilibrium | $0.10-x$ |  | $x$ | $+x$ |
|  |  |  | $x$ |  |

Thus

$$
\begin{gathered}
5.6 \times 10^{-10}=K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{NH}_{3}\right]}{\left[\mathrm{NH}_{4}^{+}\right]}=\frac{(x)(x)}{0.10-x} \approx \frac{x^{2}}{0.10} \\
x \approx 7.5 \times 10^{-6}
\end{gathered}
$$

The approximation is valid by the $5 \%$ rule, so

$$
\square\left[\mathrm{H}^{+}\right]=x=7.5 \times 10^{-6} M \quad \text { and } \quad \mathrm{pH}=5.13
$$

See Exeraise 14.118

A second type of salt that produces an acidic solution is one that contains a highly charged metal ion. For example, when solid aluminum chloride $\left(\mathrm{AlCl}_{3}\right)$ is dissolved in water, the resulting solution is significantly acidic. Although the $\mathrm{Al}^{3+}$ ion is not itself a Brønsted-Lowry acid, the hydrated ion $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ formed in water is a weak acid:

$$
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q) \rightleftharpoons \mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}{ }^{2+}(a q)+\mathrm{H}^{+}(a q)
$$

The high charge on the metal ion polarizes the $\mathrm{O}-\mathrm{H}$ bonds in the attached water molecules, making the hydrogens in these water molecules more acidic than those in free water molecules. Typically, the higher the charge on the metal ion, the stronger the acidity of the hydrated ion.

Section 14.9 contains a further discussion of the acidity of hydrated ions.

## INTERACTIVE EXAMPLE 14.20 Salts as Weak Acids II

Calculate the pH of a $0.010-\mathrm{M} \mathrm{AlCl} 3$ solution. The $K_{\mathrm{a}}$ value for $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ is $1.4 \times 10^{-5}$.

SOLUTION The major species in solution are

$$
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}, \mathrm{Cl}^{-}, \text {and } \mathrm{H}_{2} \mathrm{O}
$$

Since the $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ ion is a stronger acid than water, the dominant equilibrium is
and

$$
\begin{gathered}
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q) \rightleftharpoons \mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}{ }^{2+}(a q)+\mathrm{H}^{+}(a q) \\
1.4 \times 10^{-5}=K_{\mathrm{a}}=\frac{\left[\mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}{ }^{2+}\right]\left[\mathrm{H}^{+}\right]}{\left[\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\right]}
\end{gathered}
$$

This is a typical weak acid problem, which we can solve with the usual procedure:

|  | $\mathrm{Al}_{( }\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)$ | $\rightleftharpoons$ | $\mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}{ }^{2+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 0.010 |  | $\mathrm{H}^{+}(a q)$ |  |
| Change | $-x$ |  |  |  |
| Equilibrium | $0.010-x$ |  | $x$ | $\approx 0$ |

Thus

$$
\begin{gathered}
1.4 \times 10^{-5}=K_{\mathrm{a}}=\frac{\left[\mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}{ }^{2+}\right]\left[\mathrm{H}^{+}\right]}{\left[\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\right]}=\frac{(x)(x)}{0.010-x} \approx \frac{x^{2}}{0.010} \\
x \approx 3.7 \times 10^{-4}
\end{gathered}
$$

Since the approximation is valid by the $5 \%$ rule,

$$
\square\left[\mathrm{H}^{+}\right]=x=3.7 \times 10^{-4} M \quad \text { and } \quad \mathrm{pH}=3.43
$$

## See Exercises 14.127 and 14. 128

TABLE 14.5 | Qualitative Prediction of pH for Solutions of Salts for Which Both Cation and Anion Have Acidic or Basic Properties

| $K_{\mathrm{a}}>K_{\mathrm{b}}$ | $\mathrm{pH}<7$ (acidic) |
| :--- | :--- |
| $K_{\mathrm{b}}>K_{\mathrm{a}}$ | $\mathrm{pH}>7$ (basic) |
| $K_{\mathrm{a}}=K_{\mathrm{b}}$ | $\mathrm{pH}=7$ (neutral) |

So far we have considered salts in which only one of the ions has acidic or basic properties. For many salts, such as ammonium acetate $\left(\mathrm{NH}_{4} \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$, both ions can affect the pH of the aqueous solution. Because the equilibrium calculations for these cases can be quite complicated, we will consider only the qualitative aspects of such problems. We can predict whether the solution will be basic, acidic, or neutral by comparing the $K_{\mathrm{a}}$ value for the acidic ion with the $K_{\mathrm{b}}$ value for the basic ion. If the $K_{\mathrm{a}}$ value for the acidic ion is larger than the $K_{\mathrm{b}}$ value for the basic ion, the solution will be acidic. If the $K_{\mathrm{b}}$ value is larger than the $K_{\mathrm{a}}$ value, the solution will be basic. Equal $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ values mean a neutral solution. These facts are summarized in Table 14.5.

## INTERACTIVE EXAMPLE 14.21 The Acid-Base Properties of Salts

Predict whether an aqueous solution of each of the following salts will be acidic, basic, or neutral.
a. $\mathrm{NH}_{4} \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
b. $\mathrm{NH}_{4} \mathrm{CN}$
c. $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$

SOLUTION a. The ions in solution are $\mathrm{NH}_{4}{ }^{+}$and $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}$. As we mentioned previously, $K_{\mathrm{a}}$ for $\mathrm{NH}_{4}{ }^{+}$is $5.6 \times 10^{-10}$ and $K_{\mathrm{b}}$ for $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}$is $5.6 \times 10^{-10}$. Thus $K_{\mathrm{a}}$ for $\mathrm{NH}_{4}{ }^{+}$is equal to $K_{\mathrm{b}}$ for $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{--}$, and the solution will be neutral ( $\mathrm{pH}=7$ ).
b. The solution will contain $\mathrm{NH}_{4}{ }^{+}$and $\mathrm{CN}^{-}$ions. The $K_{\mathrm{a}}$ value for $\mathrm{NH}_{4}{ }^{+}$is $5.6 \times 10^{-10}$ and

$$
K_{\mathrm{b}}\left(\text { for } \mathrm{CN}^{-}\right)=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}(\text { for } \mathrm{HCN})}=1.6 \times 10^{-5}
$$

Since $K_{\mathrm{b}}$ for $\mathrm{CN}^{-}$is much larger than $K_{\mathrm{a}}$ for $\mathrm{NH}_{4}^{+}, \mathrm{CN}^{-}$is a much stronger base than $\mathrm{NH}_{4}^{+}$is an acid. This solution will be basic.
c. The solution will contain $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ and $\mathrm{SO}_{4} 2^{-}$ions. The $K_{\mathrm{a}}$ value for $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ is $1.4 \times 10^{-5}$, as given in Example 14.20. We must calculate $K_{\mathrm{b}}$ for $\mathrm{SO}_{4}{ }^{2-}$. The $\mathrm{HSO}_{4}{ }^{-}$ion is the conjugate acid of $\mathrm{SO}_{4}{ }^{2-}$, and its $K_{\mathrm{a}}$ value is $K_{\mathrm{a}_{2}}$ for sulfuric acid, or $1.2 \times 10^{-2}$. Therefore,

$$
\begin{aligned}
K_{\mathrm{b}}\left(\text { for } \mathrm{SO}_{4}{ }^{2-}\right) & =\frac{K_{\mathrm{w}}}{K_{\mathrm{a}_{2}}(\text { for sulfuric acid })} \\
& =\frac{1.0 \times 10^{-14}}{1.2 \times 10^{-2}}=8.3 \times 10^{-13}
\end{aligned}
$$

This solution will be acidic, since $K_{\mathrm{a}}$ for $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ is much greater than $K_{\mathrm{b}}$ for $\mathrm{SO}_{4}{ }^{2-}$.

## See Exercises 14.129 and 14.130

The acid-base properties of aqueous solutions of various salts are summarized in Table 14.6.

## TABLE 14.6 \| Acid-Base Properties of Various Types of Salts

| Type of Salt | Examples | Comment | pH of Solution |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Cation is from strong base; anion is from <br> strong acid | $\mathrm{KCl}, \mathrm{KNO}_{3},{\mathrm{NaCl}, \mathrm{NaNO}_{3}}$ | Neither acts as an acid or a base | Neutral |
| Cation is from strong base; anion is from <br> weak acid | $\mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \mathrm{KCN}, \mathrm{NaF}$ | Anion acts as a base; cation has no <br> effect on pH | Basic |

### 14.9 The Effect of Structure on Acid-Base Properties

Further aspects of acid strengths are discussed in Section 20.13.

TABLE 14.7 | Bond Strengths and Acid Strengths for Hydrogen Halides

$\left.$| $\mathrm{H}-\mathrm{X}$ |
| :--- | :---: | :---: |
| Bond |$\quad$| Bond |
| :---: |
| Strength |
| (kJ/mol) |$\quad$| Acid |
| :---: |
| Strength |
| in Water | \right\rvert\,

We have seen that when a substance is dissolved in water, it produces an acidic solution if it can donate protons and produces a basic solution if it can accept protons. What structural properties of a molecule cause it to behave as an acid or as a base?

Any molecule containing a hydrogen atom is potentially an acid. However, many such molecules show no acidic properties. For example, molecules containing $\mathrm{C}-\mathrm{H}$ bonds, such as chloroform $\left(\mathrm{CHCl}_{3}\right)$ and nitromethane $\left(\mathrm{CH}_{3} \mathrm{NO}_{2}\right)$, do not produce acidic aqueous solutions because a $\mathrm{C}-\mathrm{H}$ bond is both strong and nonpolar and thus there is no tendency to donate protons. On the other hand, although the $\mathrm{H}-\mathrm{Cl}$ bond in gaseous hydrogen chloride is slightly stronger than a $\mathrm{C}-\mathrm{H}$ bond, it is much more polar, and this molecule readily dissociates when dissolved in water.

Thus there are two main factors that determine whether a molecule containing an $\mathrm{X}-\mathrm{H}$ bond will behave as a Brønsted-Lowry acid: the strength of the bond and the polarity of the bond.

To explore these factors let's consider the relative acid strengths of the hydrogen halides. The bond polarities vary as shown

because electronegativity decreases going down the group. Based on the high polarity of the $\mathrm{H}-\mathrm{F}$ bond, we might expect hydrogen fluoride to be a very strong acid. In fact, among HX molecules, HF is the only weak acid ( $K_{\mathrm{a}}=7.2 \times 10^{-4}$ ) when dissolved in water. The $\mathrm{H}-\mathrm{F}$ bond is unusually strong, as shown in Table 14.7, and thus is difficult to break. This contributes significantly to the reluctance of the HF molecules to dissociate in water.

Another important class of acids are the oxyacids, which as we saw in Section 14.2 characteristically contain the grouping $\mathrm{H}-\mathrm{O}-\mathrm{X}$. Several series of oxyacids are listed with their $K_{\mathrm{a}}$ values in Table 14.8. Note from these data that for a given series the acid strength increases with an increase in the number of oxygen atoms attached to the central atom. For example, in the series containing chlorine and a varying number of oxygen atoms, HOCl is a weak acid, but the acid strength is successively greater as the number of oxygen atoms increases. This happens because the very electronegative oxygen atoms are able to draw electrons away from the chlorine atom and the $\mathrm{O}-\mathrm{H}$ bond (Fig. 14.9). The net effect is to both polarize and weaken the $\mathrm{O}-\mathrm{H}$ bond; this effect becomes more important as the number of attached oxygen atoms increases.

FIGURE 14.9 The effect of the number of attached oxygens on the $\mathrm{O}-\mathrm{H}$ bond in a series of chlorine oxyacids. As the number of oxygen atoms attached to the chlorine atom increases, they become more effective at withdrawing electron density from the $\mathrm{O}-\mathrm{H}$ bond, thereby weakening and polarizing it. This increases the tendency for the molecule to produce a proton, and so its acid strength increases.

TABLE 14.8 \| Several Series of Oxyacids and Their $K_{\mathrm{a}}$ Values

| Oxyacid | Structure | $K_{\text {a }}$ Value |
| :---: | :---: | :---: |
| $\mathrm{HClO}_{4}$ |  | Large ( $\sim 10^{7}$ ) |
| $\mathrm{HClO}_{3}$ |  | $\sim 1$ |
| $\mathrm{HClO}_{2}$ | $\mathrm{H}-\mathrm{O}-\mathrm{Cl}-\mathrm{O}$ | $1.2 \times 10^{-2}$ |
| HClO | $\mathrm{H}-\mathrm{O}-\mathrm{Cl}$ | $3.5 \times 10^{-8}$ |
| $\mathrm{H}_{2} \mathrm{SO}_{4}$ |  | Large |
| $\mathrm{H}_{2} \mathrm{SO}_{3}$ |  | $1.5 \times 10^{-2}$ |
| $\mathrm{HNO}_{3}$ |  | Large |
| $\mathrm{HNO}_{2}$ | $\mathrm{H}-\mathrm{O}-\mathrm{N}-\mathrm{O}$ | $4.0 \times 10^{-4}$ |

This means that a proton is most readily produced by the molecule with the largest number of attached oxygen atoms $\left(\mathrm{HClO}_{4}\right)$.

This type of behavior is also observed for hydrated metal ions. Earlier in this chapter we saw that highly charged metal ions such as $\mathrm{Al}^{3+}$ produce acidic solutions. The acidity of the water molecules attached to the metal ion is increased by the attraction of electrons to the positive metal ion:

The greater the charge on the metal ion, the more acidic the hydrated ion becomes.
For acids containing the $\mathrm{H}-\mathrm{O}-\mathrm{X}$ grouping, the greater the ability of X to draw electrons toward itself, the greater the acidity of the molecule. Since the electronegativity of X reflects its ability to attract the electrons involved in bonding, we might expect acid strength to depend on the electronegativity of X . In fact, there is an excellent correlation between the electronegativity of X and the acid strength for oxyacids, as shown in Table 14.9.

TABLE 14.9 | Comparison of Electronegativity of $X$ and $K_{\mathrm{a}}$ Value for a Series of Oxyacids

|  |  |  | $K_{a}$ for <br> Acid |
| :--- | :--- | :--- | :---: |
| XOCl | Cl | 3.0 | $4 \times 10^{-8}$ |
| HOBr | Br | 2.8 | $2 \times 10^{-9}$ |
| HOl | I | 2.5 | $2 \times 10^{-11}$ |
| $\mathrm{HOCH}_{3}$ | $\mathrm{CH}_{3}$ | 2.3 (for carbon in $\left.\mathrm{CH}_{3}\right)$ | $\sim 10^{-15}$ |

### 14.10 Acid-Base Properties of Oxides

A compound containing the $\mathrm{H}-\mathrm{O}-\mathrm{X}$ group will produce an acidic solution in water if the $\mathrm{O}-\mathrm{X}$ bond is strong and covalent. If the $\mathrm{O}-\mathrm{X}$ bond is ionic, the compound will produce a basic solution in water.

We have just seen that molecules containing the grouping $\mathrm{H}-\mathrm{O}-\mathrm{X}$ can behave as acids and that the acid strength depends on the electron-withdrawing ability of X . But substances with this grouping also can behave as bases if the hydroxide ion instead of a proton is produced. What determines which behavior will occur? The answer lies mainly in the nature of the $\mathrm{O}-\mathrm{X}$ bond. If X has a relatively high electronegativity, the $\mathrm{O}-\mathrm{X}$ bond will be covalent and strong. When the compound containing the $\mathrm{H}-\mathrm{O}-\mathrm{X}$ grouping is dissolved in water, the $\mathrm{O}-\mathrm{X}$ bond will remain intact. It will be the polar and relatively weak $\mathrm{H}-\mathrm{O}$ bond that will tend to break, releasing a proton. On the other hand, if X has a very low electronegativity, the $\mathrm{O}-\mathrm{X}$ bond will be ionic and subject to being broken in polar water. Examples are the ionic substances NaOH and KOH that dissolve in water to give the metal cation and the hydroxide ion.

We can use these principles to explain the acid-base behavior of oxides when they are dissolved in water. For example, when a covalent oxide such as sulfur trioxide is dissolved in water, an acidic solution results because sulfuric acid is formed:

$$
\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)
$$

The structure of $\mathrm{H}_{2} \mathrm{SO}_{4}$ is shown in the margin. In this case, the strong, covalent $\mathrm{O}-\mathrm{S}$ bonds remain intact and the $\mathrm{H}-\mathrm{O}$ bonds break to produce protons. Other common covalent oxides that react with water to form acidic solutions are sulfur dioxide, carbon dioxide, and nitrogen dioxide, as shown by the following reactions:

$$
\begin{aligned}
\mathrm{SO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{3}(a q) \\
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow \mathrm{H}_{2} \mathrm{CO}_{3}(a q) \\
2 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow \mathrm{HNO}_{3}(a q)+\mathrm{HNO}_{2}(a q)
\end{aligned}
$$

Thus when a covalent oxide dissolves in water, an acidic solution forms. These oxides are called acidic oxides.

On the other hand, when an ionic oxide dissolves in water, a basic solution results, as shown by the following reactions:

$$
\begin{aligned}
& \mathrm{CaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(a q) \\
& \mathrm{K}_{2} \mathrm{O}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{KOH}(a q)
\end{aligned}
$$

These reactions can be explained by recognizing that the oxide ion has a high affinity for protons and reacts with water to produce hydroxide ions:

$$
\mathrm{O}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{OH}^{-}(a q)
$$

Thus the most ionic oxides, such as those of the Group 1A and 2A metals, produce basic solutions when they are dissolved in water. As a result, these oxides are called basic oxides.

### 14.11 The Lewis Acid-Base Model

We have seen that the first successful conceptualization of acid-base behavior was proposed by Arrhenius. This useful but limited model was replaced by the more general Brønsted-Lowry model. An even more general model for acid-base behavior was suggested by G. N. Lewis in the early 1920s. A Lewis acid is an electron-pair acceptor, and a Lewis base is an electron-pair donor. Another way of saying this is that a Lewis acid has an empty atomic orbital that it can use to accept (share) an electron pair from a molecule that has a lone pair of electrons (Lewis base). The three models for acids and bases are summarized in Table 14.10.

The Lewis model encompasses the Brønsted-Lowry model, but the reverse is not true.

FIGURE 14.10 Reaction of $\mathrm{BF}_{3}$ with $\mathrm{NH}_{3}$.

## TABLE 14.10 | Three Models for Acids and Bases

| Model | Definition of Acid | Definition of Base |
| :--- | :--- | :--- |
| Arrhenius | $\mathrm{H}^{+}$producer | $\mathrm{OH}^{-}$producer |
| Brønsted-Lowry | $\mathrm{H}^{+}$donor | $\mathrm{H}^{+}$acceptor |
| Lewis | Electron-pair acceptor | Electron-pair donor |

Note that Brønsted-Lowry acid-base reactions (proton donor-proton acceptor reactions) are encompassed by the Lewis model. For example, the reaction between a proton and an ammonia molecule, that is,

$$
\begin{array}{cc}
\text { Lewis } & \text { Lewis } \\
\text { acid } & \text { base }
\end{array}
$$

can be represented as a reaction between an electron-pair acceptor $\left(\mathrm{H}^{+}\right)$and an electron-pair donor $\left(\mathrm{NH}_{3}\right)$. The same holds true for a reaction between a proton and a hydroxide ion:

The real value of the Lewis model for acids and bases is that it covers many reactions that do not involve Brønsted-Lowry acids. For example, consider the gas-phase reaction between boron trifluoride and ammonia:

Here the electron-deficient $\mathrm{BF}_{3}$ molecule (there are only six electrons around the boron) completes its octet by reacting with $\mathrm{NH}_{3}$, which has a lone pair of electrons (Fig. 14.10). In fact, as mentioned in Chapter 8, the electron deficiency of boron trifluoride makes it very reactive toward any electron-pair donor. That is, it is a strong Lewis acid.

The hydration of a metal ion, such as $\mathrm{Al}^{3+}$, also can be viewed as a Lewis acid-base reaction:

Here the $\mathrm{Al}^{3+}$ ion accepts one electron pair from each of six water molecules to form $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ (Fig. 14.11).

In addition, the reaction between a covalent oxide and water to form a BrønstedLowry acid can be defined as a Lewis acid-base reaction. An example is the reaction between sulfur trioxide and water:

Note that as the water molecule attaches to sulfur trioxide, a proton shift occurs to form sulfuric acid.

## EXAMPLE 14.22

## Lewis Acids and Bases

For each reaction, identify the Lewis acid and base.
a. $\mathrm{Ni}^{2+}(a q)+6 \mathrm{NH}_{3}(a q) \longrightarrow \mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}^{2+}(a q)$
b. $\mathrm{H}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(a q) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)$

SOLUTION a. Each $\mathrm{NH}_{3}$ molecule donates an electron pair to the $\mathrm{Ni}^{2+}$ ion:

The nickel(II) ion is the Lewis acid, and ammonia is the Lewis base.
b. The proton is the Lewis acid and the water molecule is the Lewis base:

### 14.12 Strategy for Solving Acid-Base Problems: A Summary

In this chapter we have encountered many different situations involving aqueous solutions of acids and bases, and in the next chapter we will encounter still more. In solving for the equilibrium concentrations in these aqueous solutions, it is tempting to create a pigeonhole for each possible situation and to memorize the procedures necessary to deal with that particular case. This approach is just not practical and usually leads to frustration: Too many pigeonholes are required-there seems to be an infinite number of cases. But you can handle any case successfully by taking a systematic, patient, and thoughtful approach. When analyzing an acid-base equilibrium problem, do not ask yourself how a memorized solution can be used to solve the problem. Instead, ask this question: What are the major species in the solution and what is their chemical behavior?

The most important part of doing a complicated acid-base equilibrium problem is the analysis you do at the beginning of a problem.

What major species are present?
Does a reaction occur that can be assumed to go to completion?
What equilibrium dominates the solution?
Let the problem guide you. Be patient.

## Models for acids and bases

> Arrhenius model
) Acids produce $\mathrm{H}^{+}$in solution
> Bases produce $\mathrm{OH}^{-}$in solution
> Brønsted-Lowry model
) An acid is a proton donor
> A base is a proton acceptor
) In this model an acid molecule reacts with a water molecule, which behaves as a base:

$$
\begin{aligned}
& \mathrm{HA}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{A}^{-}(a q) \\
& \text { Acid } \\
& \\
& \text { Conjugate } \\
& \text { acid }
\end{aligned}
$$

to form a new acid (conjugate acid) and a new base (conjugate base).
> Lewis model
) A Lewis acid is an electron-pair acceptor
> A Lewis base is an electron-pair donor

## Acid-base equilibrium

> The equilibrium constant for an acid dissociating (ionizing) in water is called $K_{\mathrm{a}}$
) The $K_{\mathrm{a}}$ expression is
which is often simplified as

$$
\begin{aligned}
K_{\mathrm{a}} & =\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]} \\
K_{\mathrm{a}} & =\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
\end{aligned}
$$

> $\left[\mathrm{H}_{2} \mathrm{O}\right]$ is never included because it is assumed to be constant

## Acid strength

) A strong acid has a very large $K_{\mathrm{a}}$ value
) The acid completely dissociates (ionizes) in water
> The dissociation (ionization) equilibrium position lies all the way to the right
> Strong acids have very weak conjugate bases
》 The common strong acids are nitric acid $\left[\mathrm{HNO}_{3}(a q)\right]$, hydrochloric acid $[\mathrm{HCl}(a q)]$, sulfuric acid $\left[\mathrm{H}_{2} \mathrm{SO}(a q)\right]$, and perchloric acid $\left[\mathrm{HClO}_{4}(a q)\right]$
> A weak acid has a small $K_{\mathrm{a}}$ value
> The acid dissociates (ionizes) to only a slight extent
) The dissociation (ionization) equilibrium position lies far to the left
> Weak acids have relatively strong conjugate bases
> Percent dissociation of a weak acid

$$
\% \text { dissociation }=\frac{\text { amount dissociated }(\mathrm{mol} / \mathrm{L})}{\text { initial concentration }(\mathrm{mol} / \mathrm{L})} \times 100 \%
$$

) The smaller the percent dissociation, the weaker the acid
) Dilution of a weak acid increases its percent dissociation

## Autoionization of water

) Water is an amphoteric substance: It behaves as both an acid and a base
) Water reacts with itself in an acid-base reaction

$$
\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

which leads to the equilibrium expression

$$
K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right] \text {or }\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=K_{\mathrm{w}}
$$

) $K_{\mathrm{w}}$ is the ion-product constant for water
) At $25^{\circ} \mathrm{C}$ in pure water $\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-7}$, so $K_{\mathrm{w}}=1.0 \times 10^{-14}$
) Acidic solution: $\left[\mathrm{H}^{+}\right]>\left[\mathrm{OH}^{-}\right]$
) Basic solution: $\left[\mathrm{OH}^{-}\right]>\left[\mathrm{H}^{+}\right]$
> Neutral solution: $\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]$
The pH scale
) $\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]$
) Since pH is a log scale, the pH changes by 1 for every 10 -fold change in $\left[\mathrm{H}^{+}\right]$
) The $\log$ scale is also used for $\left[\mathrm{OH}^{-}\right]$and for $K_{\mathrm{a}}$ values

$$
\begin{aligned}
\mathrm{pOH} & =-\log \left[\mathrm{OH}^{-}\right] \\
\mathrm{p} K_{\mathrm{a}} & =-\log K_{\mathrm{a}}
\end{aligned}
$$

## Bases

) Strong bases are hydroxide salts, such as NaOH and KOH
> Weak bases react with water to produce $\mathrm{OH}^{-}$

$$
\mathrm{B}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{BH}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

) The equilibrium constant for this reaction is called $K_{\mathrm{b}}$ where

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{BH}^{+}\right]\left[\mathrm{OH}^{-}\right]}{[\mathrm{B}]}
$$

> In water a base B is always competing with $\mathrm{OH}^{-}$for a proton $\left(\mathrm{H}^{+}\right)$, so $K_{\mathrm{b}}$ values tend to be very small, thus making B a weak base (compared to $\mathrm{OH}^{-}$)

## Polyprotic acids

> A polyprotic acid has more than one acidic proton
> Polyprotic acids dissociate one proton at a time
> Each step has a characteristic $K_{\mathrm{a}}$ value
> Typically for a weak polyprotic acid, $K_{\mathrm{a}_{1}}>K_{\mathrm{a}_{2}}>K_{\mathrm{a}_{3}}$
> Sulfuric acid is unique:
> It is a strong acid in the first dissociation step ( $K_{\mathrm{a}_{1}}$ is very large)
> It is a weak acid in the second step

## Acid-base properties of salts

) Can produce acidic, basic, or neutral solutions
> Salts that contain
> cations of strong bases and anions of strong acids produce neutral solutions
> cations of strong bases and anions of weak acids produce basic solutions
> cations of weak bases and anions of strong acids produce acidic solutions
> Acidic solutions are produced by salts containing a highly charged metal cation-for example, $\mathrm{Al}^{3+}$ and $\mathrm{Fe}^{3+}$

## Effect of structure on acid-base properties

) Many substances that function as acids or bases contain the $\mathrm{H}-\mathrm{O}-\mathrm{X}$ grouping
> Molecules in which the $\mathrm{O}-\mathrm{X}$ bond is strong and covalent tend to behave as acids
) As X becomes more electronegative, the acid becomes stronger
) When the $\mathrm{O}-\mathrm{X}$ bond is ionic, the substance behaves as a base, releasing $\mathrm{OH}^{-}$ions in water

## Review Questions Answers to the Review Questions can be found on the Student website (accessible from wwww.cengagebrain.com).

1. Define each of the following:
a. Arrhenius acid
b. Brønsted-Lowry acid
c. Lewis acid

Which of the definitions is most general? Write reactions to justify your answer.
2. Define or illustrate the meaning of the following terms:
a. $K_{\mathrm{a}}$ reaction
b. $K_{\mathrm{a}}$ equilibrium constant
c. $K_{\mathrm{b}}$ reaction
d. $K_{\mathrm{b}}$ equilibrium constant
e. conjugate acid-base pair
3. Define or illustrate the meaning of the following terms:
a. amphoteric
b. $K_{\mathrm{w}}$ reaction
c. $K_{\mathrm{w}}$ equilibrium constant
d. pH
e. pOH
f. $\mathrm{p} K_{\mathrm{w}}$

Give the conditions for a neutral aqueous solution at $25^{\circ} \mathrm{C}$, in terms of $\left[\mathrm{H}^{+}\right], \mathrm{pH}$, and the relationship between $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$. Do the same for an acidic solution and for a basic solution. As a solution becomes more acidic, what happens to $\mathrm{pH}, \mathrm{pOH},\left[\mathrm{H}^{+}\right]$, and $\left[\mathrm{OH}^{-}\right]$? As a solution becomes more basic, what happens to $\mathrm{pH}, \mathrm{pOH},\left[\mathrm{H}^{+}\right]$, and $\left[\mathrm{OH}^{-}\right]$?
4. How is acid strength related to the value of $K_{\mathrm{a}}$ ? What is the difference between strong acids and weak acids (see Table 14.1)? As the strength of an acid increases, what happens to the strength of the conjugate base? How is base strength related to the value of $K_{\mathrm{b}}$ ? As the strength of a base increases, what happens to the strength of the conjugate acid?
5. Two strategies are followed when solving for the pH of an acid in water. What is the strategy for calculating the pH of a strong acid in water? What major assumptions are made when solving strong acid problems? The best way to recognize strong acids is to memorize them. List the six common strong acids (the two not listed in the text are HBr and HI ).

Most acids, by contrast, are weak acids. When solving for the pH of a weak acid in water, you must have
the $K_{\mathrm{a}}$ value. List two places in this text that provide $K_{\mathrm{a}}$ values for weak acids. You can utilize these tables to help you recognize weak acids. What is the strategy for calculating the pH of a weak acid in water? What assumptions are generally made? What is the $5 \%$ rule? If the $5 \%$ rule fails, how do you calculate the pH of a weak acid in water?
6. Two strategies are also followed when solving for the pH of a base in water. What is the strategy for calculating the pH of a strong base in water? List the strong bases mentioned in the text that should be committed to memory. Why is calculating the pH of $\mathrm{Ca}(\mathrm{OH})_{2}$ solutions a little more difficult than calculating the pH of NaOH solutions?

Most bases are weak bases. The presence of what element most commonly results in basic properties for an organic compound? What is present on this element in compounds that allows it to accept a proton?

Table 14.3 and Appendix 5 of the text list $K_{\mathrm{b}}$ values for some weak bases. What strategy is used to solve for the pH of a weak base in water? What assumptions are made when solving for the pH of weak base solutions? If the $5 \%$ rule fails, how do you calculate the pH of a weak base in water?
7. Table 14.4 lists the stepwise $K_{\mathrm{a}}$ values for some polyprotic acids. What is the difference between a monoprotic acid, a diprotic acid, and a triprotic acid? Most polyprotic acids are weak acids; the major exception is $\mathrm{H}_{2} \mathrm{SO}_{4}$. To solve for the pH of a solution of $\mathrm{H}_{2} \mathrm{SO}_{4}$, you must generally solve a strong acid problem as well as a weak acid problem. Explain. Write out the reactions that refer to $K_{\mathrm{a}_{1}}$ and $K_{\mathrm{a}_{2}}$ for $\mathrm{H}_{2} \mathrm{SO}_{4}$.

For $\mathrm{H}_{3} \mathrm{PO}_{4}, K_{\mathrm{a}_{1}}=7.5 \times 10^{-3}, K_{\mathrm{a}_{2}}=6.2 \times 10^{-8}$, and $K_{\mathrm{a}_{3}}=4.8 \times 10^{-13}$. Write out the reactions that refer to the $K_{\mathrm{a}_{1}}, K_{\mathrm{a}_{2}}$, and $K_{\mathrm{a}_{3}}$ equilibrium constants. What are the three acids in a solution of $\mathrm{H}_{3} \mathrm{PO}_{4}$ ? Which acid is strongest? What are the three conjugate bases in a solution of $\mathrm{H}_{3} \mathrm{PO}_{4}$ ? Which conjugate base is strongest? Summarize the strategy for calculating the pH of a polyprotic acid in water.
8. For conjugate acid-base pairs, how are $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ related? Consider the reaction of acetic acid in water

$$
\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{CH}_{3} \mathrm{CO}_{2}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$ where $K_{\mathrm{a}}=1.8 \times 10^{-5}$.

a. Which two bases are competing for the proton?
b. Which is the stronger base?
c. In light of your answer to part b, why do we classify the acetate ion $\left(\mathrm{CH}_{3} \mathrm{CO}_{2}^{-}\right)$as a weak base? Use an appropriate reaction to justify your answer.
In general, as base strength increases, conjugate acid strength decreases. Explain why the conjugate acid of the weak base $\mathrm{NH}_{3}$ is a weak acid.

To summarize, the conjugate base of a weak acid is a weak base and the conjugate acid of a weak base is a weak acid (weak gives you weak). Assuming $K_{\mathrm{a}}$ for a monoprotic strong acid is $1 \times 10^{6}$, calculate $K_{\mathrm{b}}$ for the conjugate base of this strong acid. Why do conjugate bases of strong acids have no basic properties in water? List the conjugate bases of the six common strong acids. To tie it all together, some instructors have students think of $\mathrm{Li}^{+}, \mathrm{K}^{+}, \mathrm{Rb}^{+}, \mathrm{Cs}^{+}, \mathrm{Ca}^{2+}, \mathrm{Sr}^{2+}$, and $\mathrm{Ba}^{2+}$ as the conjugate acids of the strong bases $\mathrm{LiOH}, \mathrm{KOH}$, $\mathrm{RbOH}, \mathrm{CsOH}, \mathrm{Ca}(\mathrm{OH})_{2}, \mathrm{Sr}(\mathrm{OH})_{2}$, and $\mathrm{Ba}(\mathrm{OH})_{2}$. Although not technically correct, the conjugate acid strength of these cations is similar to the conjugate base strength of the strong acids. That is, these cations have no acidic properties in water; similarly, the conjugate bases of strong acids have no basic properties (strong gives you worthless). Fill in the blanks with the correct response. The conjugate base of a weak acid is a __ base. The conjugate acid of a weak
base is a $\qquad$ acid. The conjugate base of a strong acid is a $\qquad$ base. The conjugate acid of a strong base is a $\qquad$ acid.
(Hint: Weak gives you weak and strong gives you worthless.)
9. What is a salt? List some anions that behave as weak bases in water. List some anions that have no basic properties in water. List some cations that behave as weak acids in water. List some cations that have no acidic properties in water. Using these lists, give some formulas for salts that have only weak base properties in water. What strategy would you use to solve for the pH of these basic salt solutions? Identify some salts that have only weak acid properties in water. What strategy would you use to solve for the pH of these acidic salt solutions? Identify some salts that have no acidic or basic properties in water (produce neutral solutions). When a salt contains both a weak acid ion and a weak base ion, how do you predict whether the solution pH is acidic, basic, or neutral?
10. For oxyacids, how does acid strength depend on
a. the strength of the bond to the acidic hydrogen atom?
b. the electronegativity of the element bonded to the oxygen atom that bears the acidic hydrogen?
c. the number of oxygen atoms?

How does the strength of a conjugate base depend on these factors?

What type of solution forms when a nonmetal oxide dissolves in water? Give an example of such an oxide. What type of solution forms when a metal oxide dissolves in water? Give an example of such an oxide.

## Active Learning Questions

These questions are designed to be used by groups of students in class.

1. Consider two beakers of pure water at different temperatures. How do their pH values compare? Which is more acidic? more basic? Explain.
2. Differentiate between the terms strength and concentration as they apply to acids and bases. When is HCl strong? Weak? Concentrated? Dilute? Answer the same questions for ammonia. Is the conjugate base of a weak acid a strong base?
3. Sketch two graphs: (a) percent dissociation for weak acid HA versus the initial concentration of $\mathrm{HA}\left([\mathrm{HA}]_{0}\right)$ and $(\mathrm{b}) \mathrm{H}^{+}$concentration versus $[\mathrm{HA}]_{0}$. Explain both.
4. Consider a solution prepared by mixing a weak acid HA and HCl . What are the major species? Explain what is occurring in solution. How would you calculate the pH ? What if you added NaA to this solution? Then added NaOH ?
5. Explain why salts can be acidic, basic, or neutral, and show examples. Do this without specific numbers.
6. Consider two separate aqueous solutions: one of a weak acid HA and one of HCl . Assuming you started with 10 molecules of each:
a. Draw a picture of what each solution looks like at equilibrium.
b. What are the major species in each beaker?
c. From your pictures, calculate the $K_{\mathrm{a}}$ values of each acid.
d. Order the following from the strongest to the weakest base: $\mathrm{H}_{2} \mathrm{O}, \mathrm{A}^{-}, \mathrm{Cl}^{-}$. Explain your order.
7. You are asked to calculate the $\mathrm{H}^{+}$concentration in a solution of $\mathrm{NaOH}(a q)$. Because sodium hydroxide is a base, can we say there is no $\mathrm{H}^{+}$, since having $\mathrm{H}^{+}$would imply that the solution is acidic?
8. Consider a solution prepared by mixing a weak acid $\mathrm{HA}, \mathrm{HCl}$, and NaA . Which of the following statements best describes what happens?
a. The $\mathrm{H}^{+}$from the HCl reacts completely with the $\mathrm{A}^{-}$from the NaA . Then the HA dissociates somewhat.
b. The $\mathrm{H}^{+}$from the HCl reacts somewhat with the $\mathrm{A}^{-}$from the NaA to make HA, while the HA is dissociating. Eventually you have equal amounts of everything.
c. The $\mathrm{H}^{+}$from the HCl reacts somewhat with the $\mathrm{A}^{-}$from the NaA to make HA while the HA is dissociating. Eventually all the reactions have equal rates.
d. The $\mathrm{H}^{+}$from the HCl reacts completely with the $\mathrm{A}^{-}$from the NaA. Then the HA dissociates somewhat until "too much" $\mathrm{H}^{+}$and $\mathrm{A}^{-}$are formed, so the $\mathrm{H}^{+}$and $\mathrm{A}^{-}$react to form HA, and so on. Eventually equilibrium is reached.
Justify your choice, and for choices you did not pick, explain what is wrong with them.
9. Consider a solution formed by mixing 100.0 mL of 0.10 M HA $\left(K_{\mathrm{a}}=1.0 \times 10^{-6}\right), 100.00 \mathrm{~mL}$ of 0.10 M NaA , and
100.0 mL of 0.10 M HCl . In calculating the pH for the final solution, you would make some assumptions about the order in which various reactions occur to simplify the calculations. State these assumptions. Does it matter whether the reactions actually occur in the assumed order? Explain.
10. A certain sodium compound is dissolved in water to liberate $\mathrm{Na}^{+}$ions and a certain negative ion. What evidence would you look for to determine whether the anion is behaving as an acid or a base? How could you tell whether the anion is a strong base? Explain how the anion could behave simultaneously as an acid and a base.
11. Acids and bases can be thought of as chemical opposites (acids are proton donors, and bases are proton acceptors). Therefore, one might think that $K_{\mathrm{a}}=1 / K_{\mathrm{b}}$. Why isn't this the case? What is the relationship between $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ ? Prove it with a derivation.
12. Consider the equation:

$$
\mathrm{HA}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \leftrightharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{A}^{-}(a q)
$$

a. If water is a better base than $\mathrm{A}^{-}$, which way will the equilibrium lie?
b. If water is a better base than $\mathrm{A}^{-}$, is HA a strong or a weak acid?
c. If water is a better base than $\mathrm{A}^{-}$, is the value of $K_{\mathrm{a}}$ greater or less than 1 ?
13. You mix a solution of a strong acid with a $\mathrm{pH}=4.0$ and an equal volume of another strong acid solution having a $\mathrm{pH}=$ 6.0. Is the final pH less than 4.0 , equal to 4.0 , between 4.0 and 5.0 , equal to 5.0 , between 5.0 and 6.0 , equal to 6.0 , or greater than 6.0? Explain.
14. Consider two solutions of the salts $\mathrm{NaX}(a q)$ and $\mathrm{NaY}(a q)$ at equal concentrations. What would you need to know to determine which solution has the higher pH ? Explain how you would decide (perhaps even provide a sample calculation).
15. What is meant by pH ? True or false: A strong acid solution always has a lower pH than a weak acid solution. Explain.
16. Why is the pH of water at $25^{\circ} \mathrm{C}$ equal to 7.00 ?
17. Can the pH of a solution be negative? Explain.
18. Is the conjugate base of a weak acid a strong base? Explain. Explain why $\mathrm{Cl}^{-}$does not affect the pH of an aqueous solution.
19. Match the following pH values: $1,2,5,6,6.5,8,11,11$, and 13 with the following chemicals (of equal concentration): $\mathrm{HBr}, \mathrm{NaOH}, \mathrm{NaF}, \mathrm{NaCN}, \mathrm{NH}_{4} \mathrm{~F}, \mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{~F}, \mathrm{HF}, \mathrm{HCN}$, and $\mathrm{NH}_{3}$. Answer this question without performing calculations.
20. The salt BX, when dissolved in water, produces an acidic solution. Which of the following could be true? (There may be more than one correct answer.)
a. The acid HX is a weak acid.
b. The acid HX is a strong acid.
c. The cation $\mathrm{B}^{+}$is a weak acid.

Explain.

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

## Questions

21. Anions containing hydrogen (for example, $\mathrm{HCO}_{3}{ }^{-}$and $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$) usually show amphoteric behavior. Write equations illustrating the amphoterism of these two anions.
22. Which of the following conditions indicate an acidic solution at $25^{\circ} \mathrm{C}$ ?
a. $\mathrm{pH}=3.04$
b. $\left[\mathrm{H}^{+}\right]>1.0 \times 10^{-7} \mathrm{M}$
c. $\mathrm{pOH}=4.51$
d. $\left[\mathrm{OH}^{-}\right]=3.21 \times 10^{-12} \mathrm{M}$
23. Which of the following conditions indicate a basic solution at $25^{\circ} \mathrm{C}$ ?
a. $\mathrm{pOH}=11.21$
b. $\mathrm{pH}=9.42$
c. $\left[\mathrm{OH}^{-}\right]>\left[\mathrm{H}^{+}\right]$
d. $\left[\mathrm{OH}^{-}\right]>1.0 \times 10^{-7} \mathrm{M}$
24. What is the $\mathrm{p} K_{\mathrm{a}}$ of an acid? As the $\mathrm{p} K_{\mathrm{a}}$ value increases, does acid strength increase or decrease? Explain.
25. How many significant figures are there in the following numbers: $10.78,6.78,0.78$ ? If these were pH values, to how many significant figures can you express the $\left[\mathrm{H}^{+}\right]$? Explain any discrepancies between your answers to the two questions.
26. In terms of orbitals and electron arrangements, what must be present for a molecule or an ion to act as a Lewis acid? What must be present for a molecule or an ion to act as a Lewis base?
27. Consider the autoionization of liquid ammonia:

Label each of the species in the equation as an acid or a base and explain your answer.
28. The following are representations of acid-base reactions:

a. Label each of the species in both equations as an acid or a base and explain your answers.
b. For those species that are acids, which labels apply: Arrhenius acid, Brønsted-Lowry acid, Lewis acid? What about the bases?
29. Give three example solutions that fit each of the following descriptions.
a. a strong electrolyte solution that is very acidic
b. a strong electrolyte solution that is slightly acidic
c. a strong electrolyte solution that is very basic
d. a strong electrolyte solution that is slightly basic
e. a strong electrolyte solution that is neutral
30. Derive an expression for the relationship between $\mathrm{p} K_{\mathrm{a}}$ and $\mathrm{p} K_{\mathrm{b}}$ for a conjugate acid-base pair. $(\mathrm{p} K=-\log K$.)
31. Consider the following statements. Write out an example reaction and $K$ expression that is associated with each statement.
a. The autoionization of water.
b. An acid reacts with water to produce the conjugate base of the acid and the hydronium ion.
c. A base reacts with water to produce the conjugate acid of the base and the hydroxide ion.
32. The structures of adrenaline and aspirin are shown below:

Adrenaline

Aspirin
Label adrenaline and aspirin as a weak acid or a weak base. Explain how you can determine this from the structures.
33. Students are often surprised to learn that organic acids, such as acetic acid, contain -OH groups. Actually, all oxyacids contain hydroxyl groups. Sulfuric acid, usually written as $\mathrm{H}_{2} \mathrm{SO}_{4}$, has the structural formula $\mathrm{SO}_{2}(\mathrm{OH})_{2}$, where S is the central atom. Identify the acids whose structural formulas are shown below. Why do they behave as acids, while NaOH and KOH are bases?
a. $\mathrm{SO}(\mathrm{OH})_{2}$
b. $\mathrm{ClO}_{2}(\mathrm{OH})$
c. $\mathrm{HPO}(\mathrm{OH})_{2}$
34. Which of the following statements is(are) true? Correct the false statements.
a. When a base is dissolved in water, the lowest possible pH of the solution is 7.0.
b. When an acid is dissolved in water, the lowest possible pH is 0 .
c. A strong acid solution will have a lower pH than a weak acid solution.
d. A $0.0010-\mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ solution has a pOH that is twice the pOH value of a $0.0010-\mathrm{M} \mathrm{KOH}$ solution.
35. Consider the following mathematical expressions.
a. $\left[\mathrm{H}^{+}\right]=[\mathrm{HA}]_{0}$
b. $\left[\mathrm{H}^{+}\right]=\left(K_{\mathrm{a}} \times[\mathrm{HA}]_{0}\right)^{1 / 2}$
c. $\left[\mathrm{OH}^{-}\right]=2[\mathrm{~B}]_{0}$
d. $\left[\mathrm{OH}^{-}\right]=\left(K_{\mathrm{b}} \times[\mathrm{B}]_{0}\right)^{1 / 2}$

For each expression, give three solutions where the mathematical expression would give a good approximation for the $\left[\mathrm{H}^{+}\right]$ or $\left[\mathrm{OH}^{-}\right] .[\mathrm{HA}]_{0}$ and $[\mathrm{B}]_{0}$ represent initial concentrations of an acid or a base.
36. Consider a $0.10-M \mathrm{H}_{2} \mathrm{CO}_{3}$ solution and a $0.10-M \mathrm{H}_{2} \mathrm{SO}_{4}$ solution. Without doing any detailed calculations, choose one of the following statements that best describes the $\left[\mathrm{H}^{+}\right]$of each solution and explain your answer.
a. The $\left[\mathrm{H}^{+}\right]$is less than 0.10 M .
b. The $\left[\mathrm{H}^{+}\right]$is $0.10 M$.
c. The $\left[\mathrm{H}^{+}\right]$is between 0.10 M and 0.20 M .
d. The $\left[\mathrm{H}^{+}\right]$is 0.20 M .
37. Of the hydrogen halides, only HF is a weak acid. Give a possible explanation.
38. Explain why the following are done, both of which are related to acid-base chemistry.
a. Power plants burning coal with high sulfur content use scrubbers to help eliminate sulfur emissions.
b. A gardener mixes lime $(\mathrm{CaO})$ into the soil of his garden.

## Exercises

In this section similar exercises are paired.

## Nature of Acids and Bases

-39. Write balanced equations that describe the following reactions.
a. the dissociation of perchloric acid in water
b. the dissociation of propanoic acid $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{H}\right)$ in water
c. the dissociation of ammonium ion in water
40. Write the dissociation reaction and the corresponding $K_{\mathrm{a}}$ equilibrium expression for each of the following acids in water.
a. HCN
b. $\mathrm{HOC}_{6} \mathrm{H}_{5}$
c. $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}$
-41. For each of the following aqueous reactions, identify the acid, the base, the conjugate base, and the conjugate acid.
a. $\mathrm{H}_{2} \mathrm{O}+\mathrm{H}_{2} \mathrm{CO}_{3} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{HCO}_{3}^{-}$
b. $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}+\mathrm{H}_{3} \mathrm{O}^{+}$
c. $\mathrm{HCO}_{3}^{-}+\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+} \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}+\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$
42. For each of the following aqueous reactions, identify the acid, the base, the conjugate base, and the conjugate acid.
a. $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}(\mathrm{OH})^{2+}$
b. $\mathrm{H}_{2} \mathrm{O}+\mathrm{HONH}_{3}^{+} \rightleftharpoons \mathrm{HONH}_{2}+\mathrm{H}_{3} \mathrm{O}^{+}$
c. $\mathrm{HOCl}+\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2} \rightleftharpoons \mathrm{OCl}^{-}+\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}^{+}$
43. Classify each of the following as a strong acid or a weak acid.

a.

b.

c.

d.

S
${ }^{44}$. Consider the following illustrations:

Which beaker best illustrates what happens when the following acids are dissolved in water?
a. $\mathrm{HNO}_{2}$
b. $\mathrm{HNO}_{3}$
c. HCl
d. HF
e. $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
45. Use Table 14.2 to order the following from the strongest to the weakest acid.
$\begin{array}{llll}\mathrm{HClO}_{2}, & \mathrm{H}_{2} \mathrm{O}, & \mathrm{NH}_{4}^{+}, \quad \mathrm{HClO}_{4}\end{array}$
46. Use Table 14.2 to order the following from the strongest to the weakest base.

$$
\mathrm{ClO}_{2}^{-}, \quad \mathrm{H}_{2} \mathrm{O}, \quad \mathrm{NH}_{3}, \quad \mathrm{ClO}_{4}^{-}
$$

47. You may need Table 14.2 to answer the following questions.
a. Which is the stronger acid, HCl or $\mathrm{H}_{2} \mathrm{O}$ ?
b. Which is the stronger acid, $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{HNO}_{2}$ ?
c. Which is the stronger acid, HCN or $\mathrm{HOC}_{6} \mathrm{H}_{5}$ ?
48. You may need Table 14.2 to answer the following questions.
a. Which is the stronger base, $\mathrm{Cl}^{-}$or $\mathrm{H}_{2} \mathrm{O}$ ?
b. Which is the stronger base, $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{NO}_{2}{ }^{-}$?
c. Which is the stronger base, $\mathrm{CN}^{-}$or $\mathrm{OC}_{6} \mathrm{H}_{5}{ }^{-}$?

## Autoionization of Water and the pH Scale

49. Calculate the $\left[\mathrm{OH}^{-}\right]$of each of the following solutions at $25^{\circ} \mathrm{C}$. Identify each solution as neutral, acidic, or basic.
a. $\left[\mathrm{H}^{+}\right]=1.0 \times 10^{-7} M$
b. $\left[\mathrm{H}^{+}\right]=8.3 \times 10^{-16} \mathrm{M}$
c. $\left[\mathrm{H}^{+}\right]=12 \mathrm{M}$
d. $\left[\mathrm{H}^{+}\right]=5.4 \times 10^{-5} \mathrm{M}$

Also calculate the pH and pOH of each of these solutions.
50. Calculate the $\left[\mathrm{H}^{+}\right]$of each of the following solutions at $25^{\circ} \mathrm{C}$. Identify each solution as neutral, acidic, or basic.
a. $\left[\mathrm{OH}^{-}\right]=1.5 \mathrm{M}$
b. $\left[\mathrm{OH}^{-}\right]=3.6 \times 10^{-15} \mathrm{M}$
c. $\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-7} \mathrm{M}$
d. $\left[\mathrm{OH}^{-}\right]=7.3 \times 10^{-4} \mathrm{M}$

Also calculate the pH and pOH of each of these solutions.
-51 . Values of $K_{\mathrm{w}}$ as a function of temperature are as follows:

| Temperature $\left({ }^{\circ} \mathrm{C}\right)$ | $K_{\mathrm{w}}$ |
| :---: | :---: |
| 0 | $1.14 \times 10^{-15}$ |
| 25 | $1.00 \times 10^{-14}$ |
| 35 | $2.09 \times 10^{-14}$ |
| 40. | $2.92 \times 10^{-14}$ |
| 50. | $5.47 \times 10^{-14}$ |

a. Is the autoionization of water exothermic or endothermic?
b. Calculate $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$in a neutral solution at $50 .{ }^{\circ} \mathrm{C}$.
52. At $40 .{ }^{\circ} \mathrm{C}$ the value of $K_{\mathrm{w}}$ is $2.92 \times 10^{-14}$.
a. Calculate the $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$in pure water at $40 .{ }^{\circ} \mathrm{C}$.
b. What is the pH of pure water at $40 .{ }^{\circ} \mathrm{C}$ ?
c. If the hydroxide ion concentration in a solution is 0.10 M , what is the pH at $40 .{ }^{\circ} \mathrm{C}$ ?
-53 . Calculate $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$for each solution at $25^{\circ} \mathrm{C}$. Identify each solution as neutral, acidic, or basic.
a. $\mathrm{pH}=7.40$ (the normal pH of blood)
b. $\mathrm{pH}=15.3$
c. $\mathrm{pH}=-1.0$
d. $\mathrm{pH}=3.20$
e. $\mathrm{pOH}=5.0$
f. $\mathrm{pOH}=9.60$
54. Fill in the missing information in the following table.

|  | pH | pOH | $\left[\mathrm{H}^{+}\right]$ | [ $\mathrm{OH}^{+}$] | Acidic, Basic, or Neutral? |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Solution a | 9.63 |  |  |  |  |
| Solution b |  | $3.9 \times 10^{-6} \mathrm{M}$ |  |  |  |
| Solution c | 0.027 M |  |  |  |  |
| Solution d | 1.22 |  |  |  |  |

The pH of a sample of gastric juice in a person's stomach is 2.1. Calculate the $\mathrm{pOH},\left[\mathrm{H}^{+}\right]$, and $\left[\mathrm{OH}^{-}\right]$for this sample. Is gastric juice acidic or basic?
56. An antacid purchased at a local drug store has a pOH of 2.3. Calculate the $\mathrm{pH},\left[\mathrm{H}^{+}\right]$, and $\left[\mathrm{OH}^{-}\right]$of this solution. Is the antacid acidic or basic?

## Solutions of Acids

-57. What are the major species present in 0.250 M solutions of each of the following acids? Calculate the pH of each of these solutions.
a. $\mathrm{HClO}_{4}$
b. $\mathrm{HNO}_{3}$
58. A solution is prepared by adding 50.0 mL of 0.050 M HBr to 150.0 mL of 0.10 M HI. Calculate $\left[\mathrm{H}^{+}\right]$and the pH of this solution. HBr and HI are both considered strong acids.
-59. Calculate the pH of each of the following solutions of a strong acid in water.
a. 0.10 M HCl
b. $5.0 \mathrm{M} \mathrm{HClO}_{4}$
c. $1.0 \times 10^{-11} \mathrm{M} \mathrm{HI}$
60. Calculate the pH of each of the following solutions containing a strong acid in water.
a. $2.0 \times 10^{-2} \mathrm{M} \mathrm{HNO}_{3}$
b. $4.0 \mathrm{M} \mathrm{HNO}_{3}$
c. $6.2 \times 10^{-12} M \mathrm{HNO}_{3}$
-61. Calculate the concentration of an aqueous HBr solution that has $\mathrm{pH}=4.25$. HBr is a strong acid.
62. How many moles of $\mathrm{NO}_{3}{ }^{-}$are present in 250.0 mL of a nitric acid solution having a pH of 5.10 ?
-63. How would you prepare 1600 mL of a $\mathrm{pH}=1.50$ solution using concentrated ( 12 M ) HCl ?
64. A solution is prepared by adding 50.0 mL concentrated hydrochloric acid and 20.0 mL concentrated nitric acid to 300 mL water. More water is added until the final volume is 1.00 L. Calculate $\left[\mathrm{H}^{+}\right],\left[\mathrm{OH}^{-}\right]$, and the pH for this solution. [Hint: Concentrated HCl is $38 \% \mathrm{HCl}$ (by mass) and has a density of $1.19 \mathrm{~g} / \mathrm{mL}$; concentrated $\mathrm{HNO}_{3}$ is $70 . \% \mathrm{HNO}_{3}$ (by mass) and has a density of $1.42 \mathrm{~g} / \mathrm{mL}$.]
-65. What are the major species present in $0.250 M$ solutions of each of the following acids? Calculate the pH of each of these solutions.
a. $\mathrm{HNO}_{2}$
b. $\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$
66. What are the major species present in 0.250 M solutions of each of the following acids? Calculate the pH of each of these solutions.
a. $\mathrm{HOC}_{6} \mathrm{H}_{5}$
b. HCN

Calculate the concentration of all species present and the pH of a $0.020-M \mathrm{HF}$ solution.
68. Monochloroacetic acid, $\mathrm{HC}_{2} \mathrm{H}_{2} \mathrm{ClO}_{2}$, is a skin irritant that is used in "chemical peels" intended to remove the top layer of dead skin from the face and ultimately improve the complexion. The value of $K_{\mathrm{a}}$ for monochloroacetic acid is $1.35 \times 10^{-3}$. Calculate the pH of a $0.10-\mathrm{M}$ solution of monochloroacetic acid.
69. For propanoic acid $\left(\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}, K_{\mathrm{a}}=1.3 \times 10^{-5}\right)$, determine the concentration of all species present, the pH , and the percent dissociation of a $0.100-M$ solution.
70. A solution is prepared by dissolving 0.56 g benzoic acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2} \mathrm{H}, K_{\mathrm{a}}=6.4 \times 10^{-5}\right)$ in enough water to make 1.0 L of solution. Calculate $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2} \mathrm{H}\right],\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2}^{-}\right],\left[\mathrm{H}^{+}\right]$, $\left[\mathrm{OH}^{-}\right]$, and the pH of this solution.
71. A typical aspirin tablet contains 325 mg acetylsalicylic acid $\left(\mathrm{HC}_{9} \mathrm{H}_{7} \mathrm{O}_{4}\right)$. Calculate the pH of a solution that is prepared by dissolving two aspirin tablets in enough water to make one cup ( 237 mL ) of solution. Assume the aspirin tablets are pure acetylsalicylic acid, $K_{\mathrm{a}}=3.3 \times 10^{-4}$.
72. Saccharin, a sugar substitute, has the formula $\mathrm{HC}_{7} \mathrm{H}_{4} \mathrm{NSO}_{3}$ and is a weak acid with $K_{\mathrm{a}}=2.0 \times 10^{-12}$. If 100.0 g of saccharin is dissolved in enough water to make 340 mL of solution, calculate the pH of the resulting solution.
-73. Calculate the pH of a solution that contains 1.0 MHF and $1.0 \mathrm{M} \mathrm{HOC}_{6} \mathrm{H}_{5}$. Also calculate the concentration of $\mathrm{OC}_{6} \mathrm{H}_{5}^{-}$in this solution at equilibrium.
74. A solution contains a mixture of acids: $0.50 \mathrm{MHA}\left(K_{\mathrm{a}}=1.0\right.$ $\left.\times 10^{-3}\right), 0.20 \mathrm{MHB}\left(K_{\mathrm{a}}=1.0 \times 10^{-10}\right)$, and $0.10 \mathrm{MHC}\left(K_{\mathrm{a}}=\right.$ $1.0 \times 10^{-12}$ ). Calculate the $\left[\mathrm{H}^{+}\right]$in this solution.
75. Calculate the percent dissociation of the acid in each of the following solutions.
a. 0.50 M acetic acid
b. 0.050 M acetic acid
c. 0.0050 M acetic acid
d. Use Le Châtelier's principle to explain why percent dissociation increases as the concentration of a weak acid decreases.
e. Even though the percent dissociation increases from solutions a to c, the $\left[\mathrm{H}^{+}\right]$decreases. Explain.
76. Calculate the percent dissociation for a $0.22-M$ solution of chlorous acid $\left(\mathrm{HClO}_{2}, K_{\mathrm{a}}=0.012\right)$.
-77. A $0.15-M$ solution of a weak acid is $3.0 \%$ dissociated. Calculate $K_{\mathrm{a}}$.
78. A $1.0 \times 10^{-2}-M$ solution of cyanic acid (HOCN) is $17 \%$ dissociated. Calculate $K_{\mathrm{a}}$ for cyanic acid.
-79. Trichloroacetic acid $\left(\mathrm{CCl}_{3} \mathrm{CO}_{2} \mathrm{H}\right)$ is a corrosive acid that is used to precipitate proteins. The pH of a $0.050-M$ solution of trichloroacetic acid is the same as the pH of a $0.040-\mathrm{M} \mathrm{HClO}_{4}$ solution. Calculate $K_{\mathrm{a}}$ for trichloroacetic acid.
80. The pH of a $0.063-M$ solution of hypobromous acid ( HOBr but usually written HBrO ) is 4.95 . Calculate $K_{\mathrm{a}}$.
81. A solution of formic acid ( $\mathrm{HCOOH}, K_{\mathrm{a}}=1.8 \times 10^{-4}$ ) has a pH of 2.70. Calculate the initial concentration of formic acid in this solution.
82. A typical sample of vinegar has a pH of 3.0. Assuming that vinegar is only an aqueous solution of acetic acid ( $K_{\mathrm{a}}=1.8 \times$ $10^{-5}$ ), calculate the concentration of acetic acid in vinegar.
83. One mole of a weak acid HA was dissolved in 2.0 L of solution. After the system had come to equilibrium, the concentration of HA was found to be 0.45 M . Calculate $K_{\mathrm{a}}$ for HA.
84. An acid HX is $25 \%$ dissociated in water. If the equilibrium concentration of HX is 0.30 M , calculate the $K_{\mathrm{a}}$ value for HX.

## Solutions of Bases

85. Write the reaction and the corresponding $K_{\mathrm{b}}$ equilibrium expression for each of the following substances acting as bases in water.
a. $\mathrm{NH}_{3}$
b. $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$
86. Write the reaction and the corresponding $K_{\mathrm{b}}$ equilibrium expression for each of the following substances acting as bases in water.
a. aniline, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$
b. dimethylamine, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}$
87. Use Table 14.3 to help order the following bases from strongest to weakest.

$$
\mathrm{NO}_{3}^{-}, \quad \mathrm{H}_{2} \mathrm{O}, \quad \mathrm{NH}_{3}, \quad \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}
$$

Also order the following acids from strongest to weakest.

$$
\mathrm{HNO}_{3}, \quad \mathrm{H}_{2} \mathrm{O}, \quad \mathrm{NH}_{4}^{+}, \quad \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+}
$$

88. Use Table 14.3 to help answer the following questions.
a. Which is the stronger base, $\mathrm{ClO}_{4}^{-}$or $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ ?
b. Which is the stronger base, $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ ?
c. Which is the stronger base, $\mathrm{OH}^{-}$or $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ ?
d. Which is the stronger base, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ or $\mathrm{CH}_{3} \mathrm{NH}_{2}$ ?
e. Which is the stronger acid, $\mathrm{HClO}_{4}$ or $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}$?
f. Which is the stronger acid, $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}$?
g. Which is the stronger acid, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}$or $\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}$?
-89. Calculate the pH of the following solutions.
a. 0.10 M NaOH
b. $1.0 \times 10^{-10} \mathrm{M} \mathrm{NaOH}$
c. 2.0 M NaOH
89. Calculate $\left[\mathrm{OH}^{-}\right], \mathrm{pOH}$, and pH for each of the following.
a. $0.00040 \mathrm{M} \mathrm{Ca}(\mathrm{OH})_{2}$
b. a solution containing 25 g KOH per liter
c. a solution containing 150.0 g NaOH per liter
-91. What are the major species present in $0.015 M$ solutions of each of the following bases?
a. KOH
b. $\mathrm{Ba}(\mathrm{OH})_{2}$

What is $\left[\mathrm{OH}^{-}\right]$and the pH of each of these solutions?
92. What are the major species present in the following mixtures of bases?
a. 0.050 M NaOH and 0.050 M LiOH
b. $0.0010 \mathrm{M} \mathrm{Ca}(\mathrm{OH})_{2}$ and 0.020 M RbOH

What is $\left[\mathrm{OH}^{-}\right]$and the pH of each of these solutions?
-93. What mass of KOH is necessary to prepare 800.0 mL of a solution having a $\mathrm{pH}=11.56$ ?
94. Calculate the concentration of an aqueous $\operatorname{Sr}(\mathrm{OH})_{2}$ that has $\mathrm{pH}=10.50$.
-95. What are the major species present in a $0.150-\mathrm{M} \mathrm{NH}_{3}$ solution? Calculate the $\left[\mathrm{OH}^{-}\right]$and the pH of this solution.
96. For the reaction of hydrazine $\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)$ in water,

$$
\mathrm{H}_{2} \mathrm{NNH}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{2} \mathrm{NNH}_{3}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

$K_{\mathrm{b}}$ is $3.0 \times 10^{-6}$. Calculate the concentrations of all species and the pH of a $2.0-\mathrm{M}$ solution of hydrazine in water.
-97. Calculate $\left[\mathrm{OH}^{-}\right],\left[\mathrm{H}^{+}\right]$, and the pH of 0.40 M solutions of each of the following amines (the $K_{\mathrm{b}}$ values are found in Table 14.3).
a. aniline
b. methylamine
98. Trimethylamine, $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}$, is produced when plants and animals decompose and has a very unpleasant odor. Calculate the $\left[\mathrm{OH}^{-}\right],\left[\mathrm{H}^{+}\right]$, and pH of a $0.40-\mathrm{M}$ solution of $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}\left(K_{\mathrm{b}}=\right.$ $7.4 \times 10^{-5}$ ).

- 99. Calculate the pH of a $0.20-\mathrm{M} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2}$ solution $\left(K_{\mathrm{b}}=\right.$ $5.6 \times 10^{-4}$ ).

100. Calculate the pH of a $0.050-\mathrm{M}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{2} \mathrm{NH}$ solution $\left(K_{\mathrm{b}}=\right.$ $1.3 \times 10^{-3}$ ).
-101. What is the percent ionization in each of the following solutions?
a. $0.10 \mathrm{M} \mathrm{NH}_{3}$
b. $0.010 \mathrm{M} \mathrm{NH}_{3}$
c. $0.10 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{2}$
101. Calculate the percentage of pyridine $\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)$ that forms pyridinium ion, $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+}$, in a $0.10-\mathrm{M}$ aqueous solution of pyridine $\left(K_{\mathrm{b}}=1.7 \times 10^{-9}\right)$.
102. The pH of a $0.016-\mathrm{M}$ aqueous solution of $p$-toluidine $\left(\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{NH}_{2}\right)$ is 8.60 . Calculate $K_{\mathrm{b}}$.
103. Codeine $\left(\mathrm{C}_{18} \mathrm{H}_{21} \mathrm{NO}_{3}\right)$ is a derivative of morphine that is used as an analgesic, narcotic, or antitussive. It was once commonly used in cough syrups but is now available only by prescription because of its addictive properties. If the pH of a $1.7 \times 10^{-3}-M$ solution of codeine is 9.59 , calculate $K_{\mathrm{b}}$.

## Polyprotic Acids

105. Write out the stepwise $K_{\mathrm{a}}$ reactions for the diprotic acid $\mathrm{H}_{2} \mathrm{SO}_{3}$.
106. Write out the stepwise $K_{\mathrm{a}}$ reactions for citric acid $\left(\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)$, a triprotic acid.
107. A typical vitamin C tablet (containing pure ascorbic acid, $\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}$ ) weighs 500 . mg. One vitamin C tablet is dissolved in enough water to make 200.0 mL of solution. Calculate the pH of this solution. Ascorbic acid is a diprotic acid.
108. Arsenic acid $\left(\mathrm{H}_{3} \mathrm{AsO}_{4}\right)$ is a triprotic acid with $K_{\mathrm{a}_{1}}=5.5 \times 10^{-3}$, $K_{\mathrm{a}_{2}}=1.7 \times 10^{-7}$, and $K_{\mathrm{a}_{3}}=5.1 \times 10^{-12}$. Calculate $\left[\mathrm{H}^{+}\right]$, $\left[\mathrm{OH}^{-}\right],\left[\mathrm{H}_{3} \mathrm{AsO}_{4}\right],\left[\mathrm{H}_{2} \mathrm{AsO}_{4}^{-}\right],\left[\mathrm{HAsO}_{4}{ }^{2-}\right]$, and $\left[\mathrm{AsO}_{4}{ }^{3-}\right]$ in a $0.20-M$ arsenic acid solution.
-109. Calculate the pH and $\left[\mathrm{S}^{2-}\right]$ in a $0.10-M \mathrm{H}_{2} \mathrm{~S}$ solution. Assume $K_{\mathrm{a}_{1}}=1.0 \times 10^{-7} ; K_{\mathrm{a}_{2}}=1.0 \times 10^{-19}$.
109. Calculate $\left[\mathrm{CO}_{3}{ }^{2-}\right.$ ] in a $0.010-M$ solution of $\mathrm{CO}_{2}$ in water (usually written as $\mathrm{H}_{2} \mathrm{CO}_{3}$ ). If all the $\mathrm{CO}_{3}{ }^{2-}$ in this solution comes from the reaction

$$
\mathrm{HCO}_{3}^{-}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q)
$$

what percentage of the $\mathrm{H}^{+}$ions in the solution is a result of the dissociation of $\mathrm{HCO}_{3}{ }^{-}$? When acid is added to a solution of sodium hydrogen carbonate $\left(\mathrm{NaHCO}_{3}\right)$, vigorous bubbling occurs. How is this reaction related to the existence of carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$ molecules in aqueous solution?
111. Calculate the pH of a $2.0-\mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ solution.
112. Calculate the pH of a $5.0 \times 10^{-3}-M$ solution of $\mathrm{H}_{2} \mathrm{SO}_{4}$.

## Acid-Base Properties of Salts

-113. Arrange the following 0.10 M solutions in order of most acidic to most basic.
$\mathrm{KOH}, \quad \mathrm{KNO}_{3}, \mathrm{KCN}, \mathrm{NH}_{4} \mathrm{Cl}, \mathrm{HCl}$
114. Arrange the following 0.10 M solutions in order from most acidic to most basic. See Appendix 5 for $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ values.
$\mathrm{CaBr}_{2}, \quad \mathrm{KNO}_{2}, \quad \mathrm{HClO}_{4}, \quad \mathrm{HNO}_{2}, \quad \mathrm{HONH}_{3} \mathrm{ClO}_{4}$
115. Given that the $K_{\mathrm{a}}$ value for acetic acid is $1.8 \times 10^{-5}$ and the $K_{\mathrm{a}}$ value for hypochlorous acid is $3.5 \times 10^{-8}$, which is the stronger base, $\mathrm{OCl}^{-}$or $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}$?
116. The $K_{\mathrm{b}}$ values for ammonia and methylamine are $1.8 \times 10^{-5}$ and $4.4 \times 10^{-4}$, respectively. Which is the stronger acid, $\mathrm{NH}_{4}{ }^{+}$ or $\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}$?
-117 . Determine $\left[\mathrm{OH}^{-}\right],\left[\mathrm{H}^{+}\right]$, and the pH of each of the following solutions.
a. 1.0 M KCl
b. $1.0 \mathrm{M} \mathrm{KC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
118. Calculate the concentrations of all species present in a $0.25-M$ solution of ethylammonium chloride $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{Cl}\right)$.
111. Calculate the pH of each of the following solutions.
a. $0.10 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}$
b. 0.050 M NaCN
120. Calculate the pH of each of the following solutions.
a. $0.12 \mathrm{M} \mathrm{KNO}_{2}$
b. 0.45 M NaOCl
c. $0.40 \mathrm{M} \mathrm{NH}_{4} \mathrm{ClO}_{4}$
121. Sodium azide $\left(\mathrm{NaN}_{3}\right)$ is sometimes added to water to kill bacteria. Calculate the concentration of all species in a $0.010-M$ solution of $\mathrm{NaN}_{3}$. The $K_{\mathrm{a}}$ value for hydrazoic acid $\left(\mathrm{HN}_{3}\right)$ is $1.9 \times 10^{-5}$.
122. Papaverine hydrochloride (abbreviated $\mathrm{papH}^{+} \mathrm{Cl}^{-}$; molar mass $=378.85 \mathrm{~g} / \mathrm{mol}$ ) is a drug that belongs to a group of medicines called vasodilators, which cause blood vessels to expand, thereby increasing blood flow. This drug is the conjugate acid of the weak base papaverine (abbreviated pap; $K_{\mathrm{b}}=$ $8.33 \times 10^{-9}$ at $35.0^{\circ} \mathrm{C}$ ). Calculate the pH of a $30.0-\mathrm{mg} / \mathrm{mL}$ aqueous dose of $\mathrm{papH}^{+} \mathrm{Cl}^{-}$prepared at $35.0^{\circ} \mathrm{C}$. $K_{\mathrm{w}}$ at $35.0^{\circ} \mathrm{C}$ is $2.1 \times 10^{-14}$.
-123. An unknown salt is either $\mathrm{NaCN}, \mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \mathrm{NaF}, \mathrm{NaCl}$, or NaOCl . When 0.100 mole of the salt is dissolved in 1.00 L of solution, the pH of the solution is 8.07 . What is the identity of the salt?
124. Consider a solution of an unknown salt having the general formula BHCl , where B is one of the weak bases in Table 14.3. A $0.10-M$ solution of the unknown salt has a pH of 5.82. What is the actual formula of the salt?
-125. A $0.050-M$ solution of the salt NaB has a pH of 9.00 . Calculate the pH of a $0.010-M$ solution of HB .
126. A $0.20-M$ sodium chlorobenzoate $\left(\mathrm{NaC}_{7} \mathrm{H}_{4} \mathrm{ClO}_{2}\right)$ solution has a pH of 8.65 . Calculate the pH of a $0.20-M$ chlorobenzoic acid $\left(\mathrm{HC}_{7} \mathrm{H}_{4} \mathrm{ClO}_{2}\right)$ solution.
-127. Calculate the pH of a $0.050-M \mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$ solution. The $K_{\mathrm{a}}$ value for $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ is $1.4 \times 10^{-5}$.
128. Calculate the pH of a $0.10-\mathrm{M} \mathrm{CoCl}_{3}$ solution. The $K_{\mathrm{a}}$ value for $\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ is $1.0 \times 10^{-5}$.
-129. Are solutions of the following salts acidic, basic, or neutral? For those that are not neutral, write balanced chemical equations for the reactions causing the solution to be acidic or basic. The relevant $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ values are found in Tables 14.2 and 14.3 .
a. $\mathrm{NaNO}_{3}$
b. $\mathrm{NaNO}_{2}$
c. $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NHClO}_{4}$
d. $\mathrm{NH}_{4} \mathrm{NO}_{2}$
e. KOCl
f. $\mathrm{NH}_{4} \mathrm{OCl}$
130. Are solutions of the following salts acidic, basic, or neutral? For those that are not neutral, write balanced equations for the reactions causing the solution to be acidic or basic. The relevant $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ values are found in Tables 14.2 and 14.3.
a. $\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}$
b. $\mathrm{NH}_{4} \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
c. $\mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}$
d. $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{ClO}_{2}$
e. $\mathrm{NH}_{4} \mathrm{~F}$
f. $\mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{CN}$

## Relationships Between Structure and Strengths of Acids and Bases

-131. Place the species in each of the following groups in order of increasing acid strength. Explain the order you chose for each group.
a. $\mathrm{HIO}_{3}, \mathrm{HBrO}_{3}$
b. $\mathrm{HNO}_{2}, \mathrm{HNO}_{3}$
c. $\mathrm{HOCl}, \mathrm{HOI}$
d. $\mathrm{H}_{3} \mathrm{PO}_{4}, \mathrm{H}_{3} \mathrm{PO}_{3}$
132. Place the species in each of the following groups in order of increasing base strength. Give your reasoning in each case.
a. $\mathrm{IO}_{3}{ }^{-}, \mathrm{BrO}_{3}^{-}$
b. $\mathrm{NO}_{2}{ }^{-}, \mathrm{NO}_{3}{ }^{-}$
c. $\mathrm{OCl}^{-}, \mathrm{OI}^{-}$
-133. Place the species in each of the following groups in order of increasing acid strength.
a. $\mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{2} \mathrm{~S}, \mathrm{H}_{2} \mathrm{Se}$ (bond energies: $\mathrm{H}-\mathrm{O}, 467 \mathrm{~kJ} / \mathrm{mol}$; $\mathrm{H}-\mathrm{S}, 363 \mathrm{~kJ} / \mathrm{mol}$; $\mathrm{H}-\mathrm{Se}, 276 \mathrm{~kJ} / \mathrm{mol}$ )
b. $\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}, \mathrm{FCH}_{2} \mathrm{CO}_{2} \mathrm{H}, \mathrm{F}_{2} \mathrm{CHCO}_{2} \mathrm{H}, \mathrm{F}_{3} \mathrm{CCO}_{2} \mathrm{H}$
c. $\mathrm{NH}_{4}{ }^{+}, \mathrm{HONH}_{3}{ }^{+}$
d. $\mathrm{NH}_{4}^{+}, \mathrm{PH}_{4}^{+}$(bond energies: $\mathrm{N}-\mathrm{H}, 391 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{P}-\mathrm{H}$, $322 \mathrm{~kJ} / \mathrm{mol}$ )
Give reasons for the orders you chose.
134. Using your results from Exercise 133, place the species in each of the following groups in order of increasing base strength.
a. $\mathrm{OH}^{-}, \mathrm{SH}^{-}, \mathrm{SeH}^{-}$
b. $\mathrm{NH}_{3}, \mathrm{PH}_{3}$
c. $\mathrm{NH}_{3}, \mathrm{HONH}_{2}$
-135. Will the following oxides give acidic, basic, or neutral solutions when dissolved in water? Write reactions to justify your answers.
a. CaO
b. $\mathrm{SO}_{2}$
c. $\mathrm{Cl}_{2} \mathrm{O}$
136. Will the following oxides give acidic, basic, or neutral solutions when dissolved in water? Write reactions to justify your answers.
a. $\mathrm{Li}_{2} \mathrm{O}$
b. $\mathrm{CO}_{2}$
c. SrO

## Lewis Acids and Bases

137. Identify the Lewis acid and the Lewis base in each of the following reactions.
a. $\mathrm{B}(\mathrm{OH})_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{B}(\mathrm{OH})_{4}^{-}(a q)+\mathrm{H}^{+}(a q)$
b. $\mathrm{Ag}^{+}(a q)+2 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q)$
c. $\mathrm{BF}_{3}(g)+\mathrm{F}^{-}(a q) \rightleftharpoons \mathrm{BF}_{4}^{-}(a q)$
138. Identify the Lewis acid and the Lewis base in each of the following reactions.
a. $\mathrm{Fe}^{3+}(a q)+6 \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}(a q)$
b. $\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CN}^{-}(a q) \rightleftharpoons \mathrm{HCN}(a q)+\mathrm{OH}^{-}(a q)$
c. $\mathrm{HgI}_{2}(s)+2 \mathrm{I}^{-}(a q) \rightleftharpoons \operatorname{HgI}_{4}^{2-}(a q)$
139. Aluminum hydroxide is an amphoteric substance. It can act as either a Brønsted-Lowry base or a Lewis acid. Write a reaction showing $\mathrm{Al}(\mathrm{OH})_{3}$ acting as a base toward $\mathrm{H}^{+}$and as an acid toward $\mathrm{OH}^{-}$.
140. Zinc hydroxide is an amphoteric substance. Write equations that describe $\mathrm{Zn}(\mathrm{OH})_{2}$ acting as a Brønsted-Lowry base toward $\mathrm{H}^{+}$and as a Lewis acid toward $\mathrm{OH}^{-}$.
141. Would you expect $\mathrm{Fe}^{3+}$ or $\mathrm{Fe}^{2+}$ to be the stronger Lewis acid? Explain.
142. Use the Lewis acid-base model to explain the following reaction.

$$
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{CO}_{3}(a q)
$$

## Additional Exercises

143. A $10.0-\mathrm{mL}$ sample of an HCl solution has a pH of 2.000 . What volume of water must be added to change the pH to 4.000 ?
144. Which of the following represent conjugate acid-base pairs? For those pairs that are not conjugates, write the correct conjugate acid or base for each species in the pair.
a. $\mathrm{H}_{2} \mathrm{O}, \mathrm{OH}^{-}$
b. $\mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{SO}_{4}{ }^{2-}$
c. $\mathrm{H}_{3} \mathrm{PO}_{4}, \mathrm{H}_{2} \mathrm{PO}_{4}^{-}$
d. $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}$
145. A solution is tested for pH and conductivity as pictured below:

The solution contains one of the following substances: HCl , $\mathrm{NaOH}, \mathrm{NH}_{4} \mathrm{Cl}, \mathrm{HCN}, \mathrm{NH}_{3}, \mathrm{HF}$, or NaCN . If the solute concentration is about 1.0 M , what is the identity of the solute?
146. The pH of human blood is steady at a value of approximately 7.4 owing to the following equilibrium reactions:

$$
\mathrm{CO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}(a q) \rightleftharpoons \mathrm{HCO}_{3}^{-}(a q)+\mathrm{H}^{+}(a q)
$$

Acids formed during normal cellular respiration react with the $\mathrm{HCO}_{3}{ }^{-}$to form carbonic acid, which is in equilibrium with $\mathrm{CO}_{2}(a q)$ and $\mathrm{H}_{2} \mathrm{O}(l)$. During vigorous exercise, a person's $\mathrm{H}_{2} \mathrm{CO}_{3}$ blood levels were $26.3 \mathrm{~m} M$, whereas his $\mathrm{CO}_{2}$ levels were $1.63 \mathrm{~m} M$. On resting, the $\mathrm{H}_{2} \mathrm{CO}_{3}$ levels declined to $24.9 \mathrm{~m} M$. What was the $\mathrm{CO}_{2}$ blood level at rest?
147. Consider the equilibrium outlined in Exercise 146. A condition known as acidosis can occur for patients with very weak or slow breathing. The end result is a lowering of the blood pH to dangerous levels. Explain why the blood pH decreases for patients having respiratory acidosis.
148. When someone hyperventilates, a condition known as respiratory alkalosis can occur. Explain the cause and effect of respiratory alkalosis. Hint: Reference Exercises 146 and 147.
149. Hemoglobin (abbreviated Hb ) is a protein that is responsible for the transport of oxygen in the blood of mammals. Each hemoglobin molecule contains four iron atoms that are the binding sites for $\mathrm{O}_{2}$ molecules. The oxygen binding is pH dependent. The relevant equilibrium reaction is

$$
\mathrm{HbH}_{4}^{4+}(a q)+4 \mathrm{O}_{2}(g) \rightleftharpoons \mathrm{Hb}\left(\mathrm{O}_{2}\right)_{4}(a q)+4 \mathrm{H}^{+}(a q)
$$

Use Le Châtelier's principle to answer the following.
a. What form of hemoglobin, $\mathrm{HbH}_{4}{ }^{4+}$ or $\mathrm{Hb}\left(\mathrm{O}_{2}\right)_{4}$, is favored in the lungs? What form is favored in the cells?
b. When a person hyperventilates, the concentration of $\mathrm{CO}_{2}$ in the blood is decreased. How does this affect the oxy-gen-binding equilibrium? How does breathing into a paper bag help to counteract this effect? (See Exercise 146.)
c. When a person has suffered a cardiac arrest, injection of a sodium bicarbonate solution is given. Why is this necessary? (Hint: $\mathrm{CO}_{2}$ blood levels increase during cardiac arrest.)
150. A $0.25-\mathrm{g}$ sample of lime $(\mathrm{CaO})$ is dissolved in enough water to make 1500 mL of solution. Calculate the pH of the solution.
151. At $25^{\circ} \mathrm{C}$, a saturated solution of benzoic acid ( $K_{\mathrm{a}}=6.4 \times 10^{-5}$ ) has a pH of 2.80 . Calculate the water solubility of benzoic acid in moles per liter.
152. Calculate the pH of an aqueous solution containing $1.0 \times 10^{-2} \mathrm{M}$ $\mathrm{HCl}, 1.0 \times 10^{-2} \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$, and $1.0 \times 10^{-2} M \mathrm{HCN}$.
153. Acrylic acid $\left(\mathrm{CH}_{2}=\mathrm{CHCO}_{2} \mathrm{H}\right)$ is a precursor for many important plastics. $K_{\mathrm{a}}$ for acrylic acid is $5.6 \times 10^{-5}$.
a. Calculate the pH of a $0.10-\mathrm{M}$ solution of acrylic acid.
b. Calculate the percent dissociation of a $0.10-M$ solution of acrylic acid.
c. Calculate the pH of a $0.050-\mathrm{M}$ solution of sodium acrylate $\left(\mathrm{NaC}_{3} \mathrm{H}_{3} \mathrm{O}_{2}\right)$.
154. Classify each of the following as a strong acid, weak acid, strong base, or weak base in aqueous solution.
a. $\mathrm{HNO}_{2}$
b. $\mathrm{HNO}_{3}$
c. $\mathrm{CH}_{3} \mathrm{NH}_{2}$

d. NaOH
h. $\mathrm{Ca}(\mathrm{OH})_{2}$
e. $\mathrm{NH}_{3}$
i. $\mathrm{H}_{2} \mathrm{SO}_{4}$
f. HF
155. The following illustration displays the relative number of species when an acid, HA, is added to water.

a. Is HA a weak or strong acid? How can you tell?
b. Using the relative numbers given in the illustration, determine the value for $K_{\mathrm{a}}$ and the percent dissociation of the acid. Assume the initial acid concentration is 0.20 M .
156. Quinine $\left(\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{~N}_{2} \mathrm{O}_{2}\right)$ is the most important alkaloid derived from cinchona bark. It is used as an antimalarial drug. For quinine, $\mathrm{p} K_{\mathrm{b}_{1}}=5.1$ and $\mathrm{p} K_{\mathrm{b}_{2}}=9.7\left(\mathrm{p} K_{\mathrm{b}}=-\log K_{\mathrm{b}}\right)$. Only 1 g quinine will dissolve in 1900.0 mL of solution. Calculate the pH of a saturated aqueous solution of quinine. Consider only the reaction $\mathrm{Q}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{QH}^{+}+\mathrm{OH}^{-}$described by $\mathrm{p} K_{\mathrm{b}_{1}}$, where $\mathrm{Q}=$ quinine.
157. Calculate the mass of $\mathrm{HONH}_{2}$ required to dissolve in enough water to make 250.0 mL of solution having a pH of $10.00\left(K_{\mathrm{b}}\right.$ $=1.1 \times 10^{-8}$ ).
158. A codeine-containing cough syrup lists codeine sulfate as a major ingredient instead of codeine. The Merck Index gives $\mathrm{C}_{36} \mathrm{H}_{44} \mathrm{~N}_{2} \mathrm{O}_{10} \mathrm{~S}$ as the formula for codeine sulfate. Describe the composition of codeine sulfate. (See Exercise 104.) Why is codeine sulfate used instead of codeine?
159. The equilibrium constant $K_{\mathrm{a}}$ for the reaction

$$
\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \underset{\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}(\mathrm{OH})^{2+}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)}{\rightleftharpoons}
$$

is $6.0 \times 10^{-3}$.
a. Calculate the pH of a $0.10-\mathrm{M}$ solution of $\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$.
b. Will a $1.0-M$ solution of iron(II) nitrate have a higher or lower pH than a $1.0-M$ solution of iron(III) nitrate? Explain.
160. Rank the following $0.10 M$ solutions in order of increasing pH .
a. $\mathrm{HI}, \mathrm{HF}, \mathrm{NaF}, \mathrm{NaI}$
b. $\mathrm{NH}_{4} \mathrm{Br}, \mathrm{HBr}, \mathrm{KBr}, \mathrm{NH}_{3}$
c. $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{NO}_{3}, \mathrm{NaNO}_{3}, \mathrm{NaOH}, \mathrm{HOC}_{6} \mathrm{H}_{5}, \mathrm{KOC}_{6} \mathrm{H}_{5}$, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}, \mathrm{HNO}_{3}$
161. Is an aqueous solution of $\mathrm{NaHSO}_{4}$ acidic, basic, or neutral? What reaction occurs with water? Calculate the pH of a $0.10-M$ solution of $\mathrm{NaHSO}_{4}$.
162. Calculate the value for the equilibrium constant for each of the following aqueous reactions.
a. $\mathrm{NH}_{3}+\mathrm{H}_{3} \mathrm{O}^{+} \rightleftharpoons \mathrm{NH}_{4}^{+}+\mathrm{H}_{2} \mathrm{O}$
b. $\mathrm{NO}_{2}^{-}+\mathrm{H}_{3} \mathrm{O}^{+} \rightleftharpoons \mathrm{HNO}_{2}+\mathrm{H}_{2} \mathrm{O}$
c. $\mathrm{NH}_{4}^{+}+\mathrm{OH}^{-} \rightleftharpoons \mathrm{NH}_{3}+\mathrm{H}_{2} \mathrm{O}$
d. $\mathrm{HNO}_{2}+\mathrm{OH}^{-} \rightleftharpoons \mathrm{H}_{2} \mathrm{O}+\mathrm{NO}_{2}^{-}$
163. A solution is made by adding 50.0 mL of 0.200 M acetic acid $\left(K_{\mathrm{a}}=1.8 \times 10^{-5}\right)$ to 50.0 mL of $1.00 \times 10^{-3} \mathrm{M} \mathrm{HCl}$.
a. Calculate the pH of the solution.
b. Calculate the acetate ion concentration.
164. Calculate the pH of a $0.010-M$ solution of iodic acid $\left(\mathrm{HIO}_{3}, K_{\mathrm{a}}\right.$ $=0.17$ ).
165. When determining the pH of a weak acid solution, sometimes the $5 \%$ rule can be applied to simplify the math. At what $K_{\mathrm{a}}$ values will a $1.0-M$ solution of a weak acid follow the $5 \%$ rule?
166. When determining the pH of $\mathrm{H}_{2} \mathrm{SO}_{4}$ solutions, sometimes the $\mathrm{H}^{+}$contribution from $\mathrm{HSO}_{4}^{-}$can be ignored by the $5 \%$ rule. At what concentrations of an $\mathrm{H}_{2} \mathrm{SO}_{4}$ solution can the $\mathrm{H}^{+}$contribution from $\mathrm{HSO}_{4}^{-}$be ignored when determining the pH of the solution?
167. Phosphoric acid is a common ingredient in traditional cola drinks. It is added to provide the drinks with a pleasant tart taste. Assuming that in cola drinks the concentration of phosphoric acid is $0.007 M$, calculate the pH of this solution.

## ChemWork Problems

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
168. For solutions of the same concentration, as acid strength increases, indicate what happens to each of the following (increases, decreases, or doesn't change).
a. $\left[\mathrm{H}^{+}\right]$
b. pH
c. $\left[\mathrm{OH}^{-}\right]$
d. pOH
e. $K_{\mathrm{a}}$
169. Complete the table for each of the following solutions:

|  | $\left[\mathrm{H}^{+}\right]$ | pH | pOH |
| :--- | :--- | :--- | :--- |
| $\left.0.0070 \mathrm{M} \mathrm{HNO}_{3}\right]$ |  |  |  |
| 3.0 M KOH |  |  |  |

170. Consider a $0.60-M$ solution of $\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}$, lactic acid $\left(K_{\mathrm{a}}=\right.$ $1.4 \times 10^{-4}$ ).
a. Which of the following are major species in the solution?
i. $\quad \mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}$
ii. $\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}$
iii. $\mathrm{H}^{+}$
iv. $\mathrm{H}_{2} \mathrm{O}$
v. $\mathrm{OH}^{-}$
b. Complete the following ICE table in terms of $x$, the amount ( $\mathrm{mol} / \mathrm{L}$ ) of lactic acid that dissociates to reach equilibrium.

|  | $\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]$ | $\left[\mathrm{H}^{+}\right]$ | $\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}{ }^{-}\right]$ |
| :--- | :--- | :--- | :--- |
| Initial |  |  |  |
| Change |  |  |  |
| Equilibrium | $0.60-x$ |  |  |

c. What is the equilibrium concentration for $\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}{ }^{-}$?
d. Calculate the pH of the solution.
171. Consider a $0.67-M$ solution of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2}\left(K_{\mathrm{b}}=5.6 \times 10^{-4}\right)$.
a. Which of the following are major species in the solution?
i. $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2}$
ii. $\mathrm{H}^{+}$
iii. $\mathrm{OH}^{-}$
iv. $\mathrm{H}_{2} \mathrm{O}$
v. $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}$
b. Calculate the pH of this solution.
172. Rank the following 0.10 M solutions in order of increasing pH .
a. $\mathrm{NH}_{3}$
b. KOH
c. $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
d. KCl
e. HCl
173. Consider $0.25 M$ solutions of the following salts: NaCl , $\mathrm{RbOCl}, \mathrm{KI}, \mathrm{Ba}\left(\mathrm{ClO}_{4}\right)_{2}$, and $\mathrm{NH}_{4} \mathrm{NO}_{3}$. For each salt, indicate whether the solution is acidic, basic, or neutral.
174. Calculate the pH of the following solutions:
a. $1.2 \mathrm{M} \mathrm{CaBr}_{2}$
b. $0.84 M \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{NO}_{3}\left(K_{\mathrm{b}}\right.$ for $\left.\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}=3.8 \times 10^{-10}\right)$
c. $0.57 M \mathrm{KC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}\left(K_{\mathrm{a}}\right.$ for $\left.\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}=6.4 \times 10^{-5}\right)$
175. Consider $0.10 M$ solutions of the following compounds: $\mathrm{AlCl}_{3}$, $\mathrm{NaCN}, \mathrm{KOH}, \mathrm{CsClO}_{4}$, and NaF . Place these solutions in order of increasing pH .

## Challenge Problems

176. The pH of $1.0 \times 10^{-8} M$ hydrochloric acid is not 8.00 . The correct pH can be calculated by considering the relationship between the molarities of the three principal ions in the solution ( $\mathrm{H}^{+}, \mathrm{Cl}^{-}$, and $\mathrm{OH}^{-}$). These molarities can be calculated from algebraic equations that can be derived from the considerations given below.
a. The solution is electrically neutral.
b. The hydrochloric acid can be assumed to be $100 \%$ ionized.
c. The product of the molarities of the hydronium ions and the hydroxide ions must equal $K_{\mathrm{w}}$.
Calculate the pH of a $1.0 \times 10^{-8}-M \mathrm{HCl}$ solution.
177. Calculate the pH of a $1.0 \times 10^{-7}-M$ solution of NaOH in water.
178. Calculate $\left[\mathrm{OH}^{-}\right]$in a $3.0 \times 10^{-7}-M$ solution of $\mathrm{Ca}(\mathrm{OH})_{2}$.
179. Consider 50.0 mL of a solution of weak acid HA ( $K_{\mathrm{a}}=$ $1.00 \times 10^{-6}$ ), which has a pH of 4.000 . What volume of water must be added to make the $\mathrm{pH}=5.000$ ?
180. Making use of the assumptions we ordinarily make in calculating the pH of an aqueous solution of a weak acid, calculate the pH of a $1.0 \times 10^{-6}-\mathrm{M}$ solution of hypobromous acid ( $\mathrm{HBrO}, K_{\mathrm{a}}=2 \times 10^{-9}$ ). What is wrong with your answer? Why is it wrong? Without trying to solve the problem, explain what has to be included to solve the problem correctly.
181. Calculate the pH of a $0.200-M$ solution of $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NHF}$. Hint: $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NHF}$ is a salt composed of $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+}$and $\mathrm{F}^{-}$ions. The principal equilibrium in this solution is the best acid reacting with the best base; the reaction for the principal equilibrium is

$$
\begin{aligned}
\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+}(a q)+ & \mathrm{F}^{-}(a q) \rightleftharpoons \\
& \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}(a q)
\end{aligned}+\mathrm{HF}(a q) \quad K=8.2 \times 10^{-3}
$$

182. Determine the pH of a $0.50-\mathrm{M}$ solution of $\mathrm{NH}_{4} \mathrm{OCl}$. (See Exercise 181.)
183. Calculate $\left[\mathrm{OH}^{-}\right]$in a solution obtained by adding 0.0100 mol solid NaOH to 1.00 L of $15.0 \mathrm{M} \mathrm{NH}_{3}$.
184. What mass of $\mathrm{NaOH}(s)$ must be added to 1.0 L of 0.050 M $\mathrm{NH}_{3}$ to ensure that the percent ionization of $\mathrm{NH}_{3}$ is no greater than $0.0010 \%$ ? Assume no volume change on addition of NaOH .
185. Consider 1000. mL of a $1.00 \times 10^{-4}-M$ solution of a certain acid HA that has a $K_{\mathrm{a}}$ value equal to $1.00 \times 10^{-4}$. How much water was added or removed (by evaporation) so that a solution remains in which $25.0 \%$ of HA is dissociated at equilibrium? Assume that HA is nonvolatile.
186. Calculate the mass of sodium hydroxide that must be added to 1.00 L of $1.00-\mathrm{M} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ to double the pH of the solution (assume that the added NaOH does not change the volume of the solution).
187. Consider the species $\mathrm{PO}_{4}{ }^{3-}$, $\mathrm{HPO}_{4}{ }^{2-}$, and $\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$. Each ion can act as a base in water. Determine the $K_{\mathrm{b}}$ value for each of these species. Which species is the strongest base?
188. Calculate the pH of a $0.10-M$ solution of sodium phosphate. (See Exercise 187.)
189. Will 0.10 M solutions of the following salts be acidic, basic, or neutral? See Appendix 5 for $K_{\mathrm{a}}$ values.
a. ammonium bicarbonate
b. sodium dihydrogen phosphate
c. sodium hydrogen phosphate
d. ammonium dihydrogen phosphate
e. ammonium formate
190. a. The principal equilibrium in a solution of $\mathrm{NaHCO}_{3}$ is $\mathrm{HCO}_{3}^{-}(a q)+\mathrm{HCO}_{3}^{-}(a q) \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}(a q)+\mathrm{CO}_{3}^{2-}(a q)$
Calculate the value of the equilibrium constant for this reaction.
b. At equilibrium, what is the relationship between $\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right]$ and $\left[\mathrm{CO}_{3}{ }^{2-}\right]$ ?
c. Using the equilibrium

$$
\mathrm{H}_{2} \mathrm{CO}_{3}(a q) \rightleftharpoons 2 \mathrm{H}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q)
$$

derive an expression for the pH of the solution in terms of $K_{\mathrm{a}_{1}}$ and $K_{\mathrm{a}_{2}}$ using the result from part b .
d. What is the pH of a solution of $\mathrm{NaHCO}_{3}$ ?
191. A $0.100-\mathrm{g}$ sample of the weak acid HA (molar mass $=$ $100.0 \mathrm{~g} / \mathrm{mol}$ ) is dissolved in 500.0 g water. The freezing point of the resulting solution is $-0.0056^{\circ} \mathrm{C}$. Calculate the value of $K_{\mathrm{a}}$ for this acid. Assume molality equals molarity in this solution.
192. A sample containing 0.0500 mole of $\mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}$ is dissolved in enough water to make 1.00 L of solution. This solution contains hydrated $\mathrm{SO}_{4}{ }^{2-}$ and $\mathrm{Fe}^{3+}$ ions. The latter behaves as an acid:

$$
\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}(a q) \rightleftharpoons \mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}(a q)+\mathrm{H}^{+}(a q)
$$

a. Calculate the expected osmotic pressure of this solution at $25^{\circ} \mathrm{C}$ if the above dissociation is negligible.
b. The actual osmotic pressure of the solution is 6.73 atm at $25^{\circ} \mathrm{C}$. Calculate $K_{\mathrm{a}}$ for the dissociation reaction of $\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$. (To do this calculation, you must assume that none of the ions go through the semipermeable membrane. Actually, this is not a great assumption for the tiny $\mathrm{H}^{+}$ion.)

## Integrative Problems

These problems require the integration of multiple concepts to find the solutions.
193. A $2.14-\mathrm{g}$ sample of sodium hypoiodite is dissolved in water to make 1.25 L of solution. The solution pH is 11.32 . What is $K_{\mathrm{b}}$ for the hypoiodite ion?
194. Isocyanic acid ( HNCO ) can be prepared by heating sodium cyanate in the presence of solid oxalic acid according to the equation

$$
2 \mathrm{NaOCN}(s)+\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(s) \longrightarrow 2 \mathrm{HNCO}(l)+\mathrm{Na}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(s)
$$

Upon isolating pure $\mathrm{HNCO}(l)$, an aqueous solution of HNCO can be prepared by dissolving the liquid HNCO in water. What is the pH of a $100 .-\mathrm{mL}$ solution of HNCO prepared from the reaction of 10.0 g each of NaOCN and $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$, assuming all of the HNCO produced is dissolved in solution? ( $K_{\mathrm{a}}$ of HNCO $=1.2 \times 10^{-4}$.)
195. A certain acid, HA, has a vapor density of $5.11 \mathrm{~g} / \mathrm{L}$ when in the gas phase at a temperature of $25^{\circ} \mathrm{C}$ and a pressure of 1.00 atm . When 1.50 g of this acid is dissolved in enough water to make 100.0 mL of solution, the pH is found to be 1.80 . Calculate $K_{\mathrm{a}}$ for the acid.

## Marathon Problems

These problems are designed to incorporate several concepts and techniques into one situation.
196. An aqueous solution contains a mixture of 0.0500 MHCOOH $\left(K_{\mathrm{a}}=1.77 \times 10^{-4}\right.$ ) and $0.150 \mathrm{M} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COOH}\left(K_{\mathrm{a}}=\right.$ $1.34 \times 10^{-5}$ ). Calculate the pH of this solution. Because both acids are of comparable strength, the $\mathrm{H}^{+}$contribution from both acids must be considered.
197. For the following, mix equal volumes of one solution from Group I with one solution from Group II to achieve the indicated pH . Calculate the pH of each solution.

| Group I: | $0.20 M \mathrm{NH}_{4} \mathrm{Cl}, 0.20 M \mathrm{HCl}, 0.20 M \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{Cl}$, |
| :--- | :--- |
|  | $0.20 M\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3} \mathrm{NHCl}$ |
| Group II: | $0.20 M \mathrm{KOI}, 0.20 M \mathrm{NaCN}, 0.20 M \mathrm{KOCl}, 0.20$ |
|  | $M \mathrm{NaNO}_{2}$ |

a. the solution with the lowest pH
b. the solution with the highest pH
c. the solution with the pH closest to 7.00

Coral thrives in the ocean when the pH is undisturbed by pollutants. (Viadan Milisavijevic/ Getty Images)

## Acid-Base Equilibria

15.1 Solutions of Acids or Bases Containing a Common Ion Equilibrium Calculations
15.2 Buffered Solutions

Buffering: How Does It Work?
15.3 Buffering Capacity
15.4 Titrations and pH Curves

Strong Acid-Strong Base Titrations
Titrations of Weak Acids with Strong Bases
Calculation of $K_{\mathrm{a}}$
Titrations of Weak Bases with Strong Acids
15.5 Acid-Base Indicators
15.6 Polyprotic Acid Titrations

Much important chemistry, including almost all the chemistry of the natural world, occurs in aqueous solution. We have already introduced one very significant class of aqueous reactions, those of acids and bases. In this chapter we will explore more applications of acid-base equilibria. In particular, we will examine buffered solutions, which contain components that enable the solution to be resistant to a change in pH . Buffered systems are especially important in living systems, which can survive only in a relatively narrow pH range. For example, although human blood contains many buffering systems, the most important of these consists of a mixture of carbonic acid $(\sim 0.0012 M)$ and bicarbonate ion $(\sim 0.024 M)$. These concentrations produce a pH of 7.4 for normal blood. Because our cells are so sensitive to pH , it is important that this pH value be maintained. So when reactions occur in our bodies, such as the formation of lactic acid $\left(\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right)$ when our muscles are exerted, the buffering systems must be capable of neutralizing the effects of this acid to maintain the pH at 7.4. We will see in this chapter how a buffered solution can deal with added acid without a significant change in pH .

In this chapter we will also study acid-base titrations to explore how the pH changes when a base is added to an acid and vice versa. This process is important because titrations are often used to determine the amount of acid or base present in an unknown sample. In addition, we will see how indicators can be used to mark the end point of an acid-base titration.

### 15.1 Solutions of Acids or Bases Containing a Common Ion

In Chapter 14 we were concerned with calculating the equilibrium concentrations of species (particularly $\mathrm{H}^{+}$ions) in solutions containing an acid or a base. In this section we will discuss solutions that contain not only the weak acid HA but also its salt NaA. Although this appears to be a new type of problem, we will see that this case can be handled rather easily using the procedures developed in Chapter 14.

Suppose we have a solution containing the weak acid hydrofluoric acid (HF, $K_{\mathrm{a}}=7.2 \times 10^{-4}$ ) and its salt sodium fluoride ( NaF ). Recall that when a salt dissolves in water, it breaks up completely into its ions-it is a strong electrolyte:

$$
\mathrm{NaF}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}(t)} \mathrm{Na}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

Since hydrofluoric acid is a weak acid and only slightly dissociated, the major species in the solution are $\mathrm{HF}, \mathrm{Na}^{+}, \mathrm{F}^{-}$, and $\mathrm{H}_{2} \mathrm{O}$. The common ion in this solution is $\mathrm{F}^{-}$, since it is produced by both hydrofluoric acid and sodium fluoride. What effect does the presence of the dissolved sodium fluoride have on the dissociation equilibrium of hydrofluoric acid?

To answer this question, we compare the extent of dissociation of hydrofluoric acid in two different solutions, the first containing 1.0 M HF and the second containing 1.0 $M$ HF and $1.0 M \mathrm{NaF}$. By Le Châtelier's principle, we would expect the dissociation equilibrium for HF

$$
\mathrm{HF}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

in the second solution to be driven to the left by the presence of $F^{-}$ions from the NaF. Thus the extent of dissociation of HF will be less in the presence of dissolved NaF :

$$
\mathrm{HF}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

$$
\text { Added } \mathrm{F}^{-} \text {ions }
$$ from NaF

The common ion effect is an application of Le Châtelier's principle.

The shift in equilibrium position that occurs because of the addition of an ion already involved in the equilibrium reaction is called the common ion effect. This effect makes a solution of NaF and HF less acidic than a solution of HF alone.

The common ion effect is quite general. For example, solid $\mathrm{NH}_{4} \mathrm{Cl}$ added to a $1.0-M \mathrm{NH}_{3}$ solution produces additional ammonium ions:

$$
\mathrm{NH}_{4} \mathrm{Cl}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{NH}_{4}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

and this causes the position of the ammonia-water equilibrium to shift to the left:

$$
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

This reduces the equilibrium concentration of $\mathrm{OH}^{-}$ions.
The common ion effect is also important in solutions of polyprotic acids. The production of protons by the first dissociation step greatly inhibits the succeeding dissociation steps, which, of course, also produce protons, the common ion in this case. We will see later in this chapter that the common ion effect is also important in dealing with the solubility of salts.

## Equilibrium Calculations

The procedures for finding the pH of a solution containing a weak acid or base plus a common ion are very similar to the procedures, which we covered in Chapter 14, for solutions containing the acids or bases alone. For example, in the case of a weak acid, the only important difference is that the initial concentration of the anion $\mathrm{A}^{-}$is not zero in a solution that also contains the salt NaA. Example 15.1 illustrates a typical example using the same general approach we developed in Chapter 14.

## INTERACTIVE EXAMPLE 15.1

SOLUTION
Major Species

## Acidic Solutions Containing Common Ions

In Section 14.5 we found that the equilibrium concentration of $\mathrm{H}^{+}$in a $1.0-M \mathrm{HF}$ solution is $2.7 \times 10^{-2} M$, and the percent dissociation of HF is $2.7 \%$. Calculate $\left[\mathrm{H}^{+}\right]$and the percent dissociation of HF in a solution containing $1.0 \mathrm{MHF}\left(K_{\mathrm{a}}=7.2 \times 10^{-4}\right)$ and 1.0 M NaF .

As the aqueous solutions we consider become more complex, it is more important than ever to be systematic and to focus on the chemistry occurring in the solution before thinking about mathematical procedures. The way to do this is always to write the major species first and consider the chemical properties of each one.

In a solution containing 1.0 M HF and 1.0 M NaF , the major species are

$$
\mathrm{HF}, \quad \mathrm{~F}^{-}, \quad \mathrm{Na}^{+}, \text {and } \mathrm{H}_{2} \mathrm{O}
$$

We know that $\mathrm{Na}^{+}$ions have neither acidic nor basic properties and that water is a very weak acid (or base). Therefore, the important species are HF and $\mathrm{F}^{-}$, which participate in the acid dissociation equilibrium that controls $\left[\mathrm{H}^{+}\right]$in this solution. That is, the position of the equilibrium

$$
\mathrm{HF}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

will determine $\left[\mathrm{H}^{+}\right]$in the solution. The equilibrium expression is

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{F}^{-}\right]}{[\mathrm{HF}]}=7.2 \times 10^{-4}
$$

The important concentrations are shown in the following table.

| Initial Concentration (mol/L) |  | Equilibrium Concentration (mol/L) |
| :---: | :---: | :---: |
| $[\mathrm{HF}]_{0}=1.0$ <br> (from dissolved HF) |  | $[H F]=1.0-x$ |
| $\begin{aligned} & {\left[\mathrm{F}^{-}\right]_{0}=1.0} \\ & \quad \text { (from dissolved NaF) } \end{aligned}$ | $\xrightarrow{\text { dissociates }}$ | $\left[\mathrm{F}^{-}\right]=1.0+x$ |
| $\begin{aligned} & {\left[\mathrm{H}^{+}\right]_{0}=0} \\ & \quad \text { (neglect contribution from } \mathrm{H}_{2} \mathrm{O} \text { ) } \end{aligned}$ |  | $\left[\mathrm{H}^{+}\right]=x$ |

Note that $\left[\mathrm{F}^{-}\right]_{0}=1.0 \mathrm{M}$ because of the dissolved sodium fluoride and that at equilibrium $\left[\mathrm{F}^{-}\right]>1.0 \mathrm{M}$ because when the acid dissociates it produces $\mathrm{F}^{-}$as well as $\mathrm{H}^{+}$. Then

$$
K_{\mathrm{a}}=7.2 \times 10^{-4}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{F}^{-}\right]}{[\mathrm{HF}]}=\frac{(x)(1.0+x)}{1.0-x} \approx \frac{(x)(1.0)}{1.0}
$$

(since $x$ is expected to be small).
Solving for $x$ gives

$$
x=\frac{1.0}{1.0}\left(7.2 \times 10^{-4}\right)=7.2 \times 10^{-4}
$$

Noting that $x$ is small compared to 1.0 , we conclude that this result is acceptable. Thus

$$
\square\left[\mathrm{H}^{+}\right]=x=7.2 \times 10^{-4} M \quad \text { (The } \mathrm{pH} \text { is } 3.14 \text {.) }
$$

The percent dissociation of HF in this solution is

$$
\frac{\left[\mathrm{H}^{+}\right]}{[\mathrm{HF}]_{0}} \times 100=\frac{7.2 \times 10^{-4} \mathrm{M}}{1.0 \mathrm{M}} \times 100=0.072 \%
$$

Compare these values for $\left[\mathrm{H}^{+}\right]$and the percent dissociation of HF with those for a $1.0-M \mathrm{HF}$ solution, where $\left[\mathrm{H}^{+}\right]=2.7 \times 10^{-2} M$ and the percent dissociation is $2.7 \%$. The large difference shows clearly that the presence of the $\mathrm{F}^{-}$ions from the dissolved NaF greatly inhibits the dissociation of HF. The position of the acid dissociation equilibrium has been shifted to the left by the presence of $\mathrm{F}^{-}$ions from NaF .

$$
\text { See Exercises } 15.27 \text { and } 15.28
$$

### 15.2 Buffered Solutions

The most important application of acid-base solutions containing a common ion is for buffering. A buffered solution is one that resists a change in its pH when either hydroxide ions or protons are added. The most important practical example of a buffered solution is our blood, which can absorb the acids and bases produced in biologic reactions without changing its pH . A constant pH for blood is vital because cells can survive only in a very narrow pH range.

A buffered solution may contain a weak acid and its salt (for example, HF and NaF ) or a weak base and its salt (for example, $\mathrm{NH}_{3}$ and $\mathrm{NH}_{4} \mathrm{Cl}$ ). By choosing the appropriate components, a solution can be buffered at virtually any pH .

In treating buffered solutions in this chapter, we will start by considering the equilibrium calculations. We will then use these results to show how buffering works. That is, we will answer the question: How does a buffered solution resist changes in pH when an acid or a base is added?

The systematic approach developed in Chapter 14 for weak acids and bases applies to buffered solutions.

As you do the calculations associated with buffered solutions, keep in mind that these are merely solutions containing weak acids or bases, and the procedures required are the same ones we have already developed. Be sure to use the systematic approach introduced in Chapter 14.

## INTERACTVE EXAMPLE 15.2 The pH of a Buffered Solution I

A buffered solution contains 0.50 M acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, K_{\mathrm{a}}=1.8 \times 10^{-5}\right)$ and 0.50 M sodium acetate $\left(\mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$. Calculate the pH of this solution.

SOLUTION

Major Species

$\Delta$
A digital pH meter shows the pH of the buffered solution to be 4.740.

The major species in the solution are

Examination of the solution components leads to the conclusion that the acetic acid dissociation equilibrium, which involves both $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}$, will control the pH of the solution:

$$
\begin{gathered}
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(\mathrm{aq}) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q) \\
K_{\mathrm{a}}=1.8 \times 10^{-5}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}
\end{gathered}
$$

The concentrations are as follows:

| Initial Concentration ( $\mathrm{mol} / \mathrm{L}$ ) |  | Equilibrium Conce ( $\mathrm{mol} / \mathrm{L}$ ) |
| :---: | :---: | :---: |
| $\begin{aligned} & {\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]_{0}=0.50} \\ & {\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]_{0}=0.50} \\ & {\left[\mathrm{H}^{+}\right]_{0} \approx 0} \end{aligned}$ | $\xrightarrow[\substack{\text { dissociates to } \\ \text { reach equilibrium }}]{\substack{x \mathrm{~mol} / \mathrm{L} \text { of } \\ \mathrm{HC} / \mathrm{H}_{3} \mathrm{O}_{2}}}$ | $\begin{aligned} & {\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]=0.50-x} \\ & {\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]=0.50+x} \\ & {\left[\mathrm{H}^{+}\right]=x} \end{aligned}$ |

The corresponding ICE table is

|  | $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)$ | $\rightleftharpoons$ | $\mathrm{H}^{+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 0.50 |  | $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)$ |  |
| Change | $-x$ |  | +0 | 0.50 |
| Equilibrium | $0.50-x$ |  | $x$ | $+x$ |
|  |  |  | $0.50+x$ |  |

Then

$$
K_{\mathrm{a}}=1.8 \times 10^{-5}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}=\frac{(x)(0.50+x)}{0.50-x} \approx \frac{(x)(0.50)}{0.50}
$$

and

$$
x \approx 1.8 \times 10^{-5}
$$

The approximations are valid (by the 5\% rule), so

$$
\square\left[\mathrm{H}^{+}\right]=x=1.8 \times 10^{-5} M \quad \text { and } \quad \mathrm{pH}=4.74
$$

## INTERACTIVE EXAMPLE 15.3 pH Changes in Buffered Solutions

## SOLUTION

Major Species

Calculate the change in pH that occurs when 0.010 mole of solid NaOH is added to 1.0 L of the buffered solution described in Example 15.2. Compare this pH change with that which occurs when 0.010 mole of solid NaOH is added to 1.0 L water.

Since the added solid NaOH will completely dissociate, the major species in solution before any reaction occurs are $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \mathrm{Na}^{+}, \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}, \mathrm{OH}^{-}$, and $\mathrm{H}_{2} \mathrm{O}$. Note that the solution contains a relatively large amount of the very strong base hydroxide ion, which has a great affinity for protons. The best source of protons is the acetic acid, and the reaction that will occur is

$$
\mathrm{OH}^{-}(\mathrm{aq})+\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(\mathrm{aq}) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)
$$

Although acetic acid is a weak acid, the hydroxide ion is such a strong base that the reaction above will proceed essentially to completion (until the $\mathrm{OH}^{-}$ions are consumed).

The best approach to this problem involves two distinct steps: (1) assume that the reaction goes to completion, and carry out the stoichiometric calculations, and then (2) carry out the equilibrium calculations.

1. The stoichiometry problem. The stoichiometry for the reaction is shown below.

|  | $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)$ | + | $\mathrm{OH}^{-}(a q)$ | $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}(\mathrm{aq})$ | + | $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Before reaction | $\begin{gathered} 1.0 \mathrm{~L} \times 0.50 \mathrm{M} \\ =0.50 \mathrm{~mol} \end{gathered}$ |  | 0.010 mol | $\begin{gathered} 1.0 \mathrm{~L} \times 0.50 \mathrm{M} \\ =0.50 \mathrm{~mol} \end{gathered}$ |  |  |
| After reaction | $\begin{aligned} & 0.50-0.010 \\ & =0.49 \mathrm{~mol} \end{aligned}$ |  | $\begin{gathered} 0.010-0.010 \\ =0 \mathrm{~mol} \end{gathered}$ | $\begin{array}{r} 0.50+0.010 \\ =0.51 \mathrm{~mol} \end{array}$ |  |  |

Note that 0.010 mole of $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ has been converted to 0.010 mole of $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}$by the added $\mathrm{OH}^{-}$.
2. The equilibrium problem. After the reaction between $\mathrm{OH}^{-}$and $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ is complete, the major species in solution are

$$
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \quad \mathrm{Na}^{+}, \quad \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
$$

The dominant equilibrium involves the dissociation of acetic acid.
This problem is then very similar to that in Example 15.2. The only difference is that the addition of 0.010 mole of $\mathrm{OH}^{-}$has consumed some $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and produced some $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}$, yielding the following ICE table:

|  | $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)$ | $\rightleftharpoons$ | $\mathrm{H}^{+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 0.49 |  | $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}(a q)$ |  |
| Change | $-x$ |  | $+x$ | 0.51 |
| Equilibrium | $0.49-x$ |  | $x$ | $+x$ |

Note that the initial concentrations are defined after the reaction with $\mathrm{OH}^{-}$is complete but before the system adjusts to equilibrium. Following the usual procedure gives
and

$$
\begin{gathered}
K_{\mathrm{a}}=1.8 \times 10^{-5}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}=\frac{(x)(0.51+x)}{0.49-x} \approx \frac{(x)(0.51)}{0.49} \\
x \approx 1.7 \times 10^{-5}
\end{gathered}
$$

The approximations are valid (by the 5\% rule), so

$$
\square\left[\mathrm{H}^{+}\right]=x=1.7 \times 10^{-5} \quad \text { and } \quad \mathrm{pH}=4.76
$$

## A

(top) Pure water at pH 7.000 . (bottom) When 0.01 mole of NaOH is added to 1.0 L pure water, the pH jumps to 12.000.

The change in pH produced by the addition of 0.01 mole of $\mathrm{OH}^{-}$to this buffered solution is then

The pH increased by 0.02 pH units.
Now compare this with what happens when 0.01 mole of solid NaOH is added to 1.0 L water to give 0.01 M NaOH . In this case $\left[\mathrm{OH}^{-}\right]=0.01 \mathrm{M}$ and

$$
\begin{gathered}
{\left[\mathrm{H}^{+}\right]=\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{1.0 \times 10^{-2}}=1.0 \times 10^{-12}} \\
\mathrm{pH}=12.00
\end{gathered}
$$

Thus the change in pH is

The increase is 5.00 pH units. Note how well the buffered solution resists a change in pH as compared with pure water.

## See Exercises 15.37 and 15.38

Examples 15.2 and 15.3 represent typical buffer problems that involve all the concepts that you need to know to handle buffered solutions containing weak acids. Pay special attention to the following points:

1. Buffered solutions are simply solutions of weak acids or bases containing a common ion. The pH calculations on buffered solutions require exactly the same procedures introduced in Chapter 14. This is not a new type of problem.
2. When a strong acid or base is added to a buffered solution, it is best to deal with the stoichiometry of the resulting reaction first. After the stoichiometric calculations are completed, then consider the equilibrium calculations. This procedure can be presented as follows:

## Buffering: How Does It Work?

Examples 15.2 and 15.3 demonstrate the ability of a buffered solution to absorb hydroxide ions without a significant change in pH . But how does a buffer work? Suppose a buffered solution contains relatively large quantities of a weak acid HA and its conjugate base $\mathrm{A}^{-}$. When hydroxide ions are added to the solution, since the weak acid represents the best source of protons, the following reaction occurs:

$$
\mathrm{OH}^{-}(a q)+\mathrm{HA}(a q) \longrightarrow \mathrm{A}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

In a buffered solution the pH is governed by the ratio $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$.

The net result is that $\mathrm{OH}^{-}$ions are not allowed to accumulate but are replaced by $\mathrm{A}^{-}$ions.

The stability of the pH under these conditions can be understood by examining the equilibrium expression for the dissociation of HA:

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
$$

or, rearranging,

$$
\left[\mathrm{H}^{+}\right]=K_{\mathrm{a}} \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}
$$

In other words, the equilibrium concentration of $\mathrm{H}^{+}$, and thus the pH , is determined by the ratio $[H A] /\left[A^{-}\right]$. When $\mathrm{OH}^{-}$ions are added, HA is converted to $\mathrm{A}^{-}$, and the ratio $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$decreases. However, if the amounts of HA and $A^{-}$originally present are very large compared with the amount of $\mathrm{OH}^{-}$added, the change in the $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$ ratio will be small.

In Examples 15.2 and 15.3,

$$
\begin{aligned}
& \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}=\frac{0.50}{0.50}=1.0 \quad \text { Initially } \\
& \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}=\frac{0.49}{0.51}=0.96 \quad \text { After adding } 0.01 \mathrm{~mol} / \mathrm{L} \mathrm{OH}
\end{aligned}
$$

The change in the ratio $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$is very small. Thus the $\left[\mathrm{H}^{+}\right]$and the pH remain essentially constant.

The essence of buffering, then, is that $[\mathrm{HA}]$ and $\left[\mathrm{A}^{-}\right]$are large compared with the amount of $\mathrm{OH}^{-}$added. Thus when the $\mathrm{OH}^{-}$is added, the concentrations of HA and $\mathrm{A}^{-}$ change, but only by small amounts. Under these conditions, the $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$ratio and thus the $\left[\mathrm{H}^{+}\right]$remain virtually constant.

Similar reasoning applies when protons are added to a buffered solution of a weak acid and a salt of its conjugate base. Because the $\mathrm{A}^{-}$ion has a high affinity for $\mathrm{H}^{+}$, the added $\mathrm{H}^{+}$ions react with $\mathrm{A}^{-}$to form the weak acid:

$$
\mathrm{H}^{+}(a q)+\mathrm{A}^{-}(a q) \longrightarrow \mathrm{HA}(a q)
$$

and free $\mathrm{H}^{+}$ions do not accumulate. In this case there will be a net change of $\mathrm{A}^{-}$to HA. However, if [ $\mathrm{A}^{-}$] and [HA] are large compared with the $\left[\mathrm{H}^{+}\right]$added, little change in the pH will occur.

## LETS REVIEW

$$
\mathrm{HA}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{A}^{-}(a q)
$$

does not increase does not decrease very much. very much.

$\mathrm{H}^{+}$reacts with $\mathrm{A}^{-}$
$\mathrm{OH}^{-}$reacts with HA
Effect of added $\mathrm{H}^{+}$or $\mathrm{OH}^{-}$on a buffered system.

The form of the acid dissociation equilibrium expression

$$
\begin{equation*}
\left[\mathrm{H}^{+}\right]=K_{\mathrm{a}} \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]} \tag{15.1}
\end{equation*}
$$

is often useful for calculating $\left[\mathrm{H}^{+}\right]$in a buffered solution, since $[\mathrm{HA}]$ and $\left[\mathrm{A}^{-}\right]$are known. For example, to calculate $\left[\mathrm{H}^{+}\right]$in a buffered solution containing 0.10 M HF $\left(K_{\mathrm{a}}=7.2 \times 10^{-4}\right)$ and 0.30 M NaF , we simply substitute into Equation (15.1):

$$
\left[\mathrm{H}^{+}\right]=\left(7.2 \times 10^{-4}\right) \frac{0.10}{0.30}=2.4 \times 10^{-4} \mathrm{M}
$$

Another useful form of Equation (15.1) can be obtained by taking the negative log of both sides:

That is,

$$
\begin{aligned}
-\log \left[\mathrm{H}^{+}\right] & =-\log \left(K_{\mathrm{a}}\right)-\log \left(\frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}\right) \\
\mathrm{pH} & =\mathrm{p} K_{\mathrm{a}}-\log \left(\frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}\right)
\end{aligned}
$$

or, where inverting the log term reverses the sign:

$$
\begin{equation*}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}\right)=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{[\text { base }]}{[\text { acid }]}\right) \tag{15.2}
\end{equation*}
$$

This $\log$ form of the expression for $K_{\mathrm{a}}$ is called the Henderson-Hasselbalch equation and is useful for calculating the pH of solutions when the ratio $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$is known.

For a particular buffering system (conjugate acid-base pair), all solutions that have the same ratio $\left[A^{-}\right] /[H A]$ will have the same pH . For example, a buffered solution containing $5.0 \mathrm{M} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and $3.0 \mathrm{M} \mathrm{NaC} \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ will have the same pH as one containing $0.050 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and $0.030 M \mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$. This can be shown as follows:

| System | [A-]/[HA] |
| :--- | :---: |
| $5.0 \mathrm{M} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and $3.0 \mathrm{M} \mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ | $\frac{3.0 \mathrm{M}}{5.0 \mathrm{M}}=0.60$ |
| $0.050 \mathrm{M} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and $0.030 \mathrm{M} \mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ | $\frac{0.030 \mathrm{M}}{0.050 \mathrm{M}}=0.60$ |

Therefore,

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}\right)=4.74+\log (0.60)=4.74-0.22=4.52
$$

Note that in using this equation we have assumed that the equilibrium concentrations of $\mathrm{A}^{-}$and HA are equal to the initial concentrations. That is, we are assuming the validity of the approximations

$$
\left[\mathrm{A}^{-}\right]=\left[\mathrm{A}^{-}\right]_{0}+x \approx\left[\mathrm{~A}^{-}\right]_{0} \quad \text { and } \quad[\mathrm{HA}]=[\mathrm{HA}]_{0}-x \approx[\mathrm{HA}]_{0}
$$

where $x$ is the amount of acid that dissociates. Since the initial concentrations of HA and $\mathrm{A}^{-}$are relatively large in a buffered solution, this assumption is generally acceptable.

## INTERACTIVE EXAMPLE 15.4

## The pH of a Buffered Solution II

Calculate the pH of a solution containing $0.75 M$ lactic acid ( $K_{\mathrm{a}}=1.4 \times 10^{-4}$ ) and 0.25 M sodium lactate. Lactic acid $\left(\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right)$ is a common constituent of biologic systems. For example, it is found in milk and is present in human muscle tissue during exertion.

SOLUTION

Major Species

The major species in solution are

$$
\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}, \quad \mathrm{Na}^{+}, \quad \mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
$$

Since $\mathrm{Na}^{+}$has no acid-base properties and $\mathrm{H}_{2} \mathrm{O}$ is a weak acid or base, the pH will be controlled by the lactic acid dissociation equilibrium:

$$
\begin{gathered}
\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}(a q) \\
K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}\right]}{\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]}=1.4 \times 10^{-4}
\end{gathered}
$$

Since $\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]_{0}$ and $\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}{ }^{-}\right]_{0}$ are relatively large,

$$
\begin{aligned}
& {\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right] \approx\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]_{0}=0.75 \mathrm{M}} \\
& {\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}\right] \approx\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}\right]_{0}=0.25 \mathrm{M}}
\end{aligned}
$$

and
Thus using the rearranged $K_{\mathrm{a}}$ expression, we have
and

$$
\left[\mathrm{H}^{+}\right]=K_{\mathrm{a}} \frac{\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]}{\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}\right]}=\left(1.4 \times 10^{-4}\right) \frac{(0.75 \mathrm{M})}{(0.25 \mathrm{M})}=4.2 \times 10^{-4} \mathrm{M}
$$

Alternatively, we could use the Henderson-Hasselbalch equation:

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}^{-}\right]}{\left[\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right]}\right)=3.85+\log \left(\frac{0.25 \mathrm{M}}{0.75 \mathrm{M}}\right)=3.38
$$

## See Exercises 15.39 and 15.41

Buffered solutions also can be formed from a weak base and the corresponding conjugate acid. In these solutions, the weak base $B$ reacts with any $\mathrm{H}^{+}$added:

$$
\mathrm{B}+\mathrm{H}^{+} \longrightarrow \mathrm{BH}^{+}
$$

and the conjugate acid $\mathrm{BH}^{+}$reacts with any added $\mathrm{OH}^{-}$:

$$
\mathrm{BH}^{+}+\mathrm{OH}^{-} \longrightarrow \mathrm{B}+\mathrm{H}_{2} \mathrm{O}
$$

The approach needed to perform pH calculations for these systems is virtually identical to that used above. This makes sense because, as is true of all buffered solutions, a weak acid $\left(\mathrm{BH}^{+}\right)$and a weak base (B) are present. A typical case is illustrated in Example 15.5.

## INTERACTIVE EXAMPLE 15.5 The pH of a Buffered Solution III

A buffered solution contains $0.25 \mathrm{MNH}_{3}\left(K_{\mathrm{b}}=1.8 \times 10^{-5}\right)$ and $0.40 \mathrm{M} \mathrm{NH}_{4} \mathrm{Cl}$. Calculate the pH of this solution.

SOLUTION The major species in solution are

Major Species

$\mathrm{NH}_{3}, \quad \mathrm{NH}_{4}^{+}, \mathrm{Cl}^{-}$, and $\mathrm{H}_{2} \mathrm{O}$
From the dissolved $\mathrm{NH}_{4} \mathrm{Cl}$

Since $\mathrm{Cl}^{-}$is such a weak base and water is a weak acid or base, the important equilibrium is
and

$$
\begin{gathered}
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q) \\
K_{\mathrm{b}}=1.8 \times 10^{-5}=\frac{\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{3}\right]}
\end{gathered}
$$

The appropriate ICE table is:

|  | $\mathrm{NH}_{3}(a q)$ | + | $\mathrm{H}_{2} \mathrm{O}(l)$ | $\rightleftharpoons$ | $\mathrm{NH}_{4}{ }^{+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Initial | 0.25 | - |  | 0.40 |  | $\approx 0$ |
| Change | $-x$ | - |  | $+x$ | $+x$ |  |
| Equilibrium | $0.25-x$ |  | - |  | $0.40+x$ | $x$ |

Then

$$
\begin{gathered}
K_{\mathrm{b}}=1.8 \times 10^{-5}=\frac{\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{3}\right]}=\frac{(0.40+x)(x)}{0.25-x} \approx \frac{(0.40)(x)}{0.25} \\
x \approx 1.1 \times 10^{-5}
\end{gathered}
$$

and
The approximations are valid (by the $5 \%$ rule), so

$$
\begin{aligned}
{\left[\mathrm{OH}^{-}\right] } & =x=1.1 \times 10^{-5} \\
\mathrm{pOH} & =4.95 \\
\square \mathrm{pH} & =14.00-4.95=9.05
\end{aligned}
$$

This case is typical of a buffered solution in that the initial and equilibrium concentrations of buffering materials are essentially the same.

## ALTERNATIVE SOLUTION

There is another way of looking at this problem. Since the solution contains relatively large quantities of both $\mathrm{NH}_{4}{ }^{+}$and $\mathrm{NH}_{3}$, we can use the equilibrium

$$
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

to calculate $\left[\mathrm{OH}^{-}\right]$and then calculate $\left[\mathrm{H}^{+}\right]$from $K_{\mathrm{w}}$ as we have just done. Or we can use the dissociation equilibrium for $\mathrm{NH}_{4}{ }^{+}$, that is,

$$
\mathrm{NH}_{4}^{+}(a q) \rightleftharpoons \mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q)
$$

to calculate $\left[\mathrm{H}^{+}\right]$directly. Either choice will give the same answer, since the same equilibrium concentrations of $\mathrm{NH}_{3}$ and $\mathrm{NH}_{4}{ }^{+}$must satisfy both equilibria.

We can obtain the $K_{\mathrm{a}}$ value for $\mathrm{NH}_{4}{ }^{+}$from the given $K_{\mathrm{b}}$ value for $\mathrm{NH}_{3}$, since $K_{\mathrm{a}} \times K_{\mathrm{b}}=K_{\mathrm{w}}$ :

$$
K_{\mathrm{a}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{b}}}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}}=5.6 \times 10^{-10}
$$

Then, using the Henderson-Hasselbalch equation, we have

$$
\begin{gathered}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{[\text { base }]}{[\text { acid }]}\right) \\
=9.25+\log \left(\frac{0.25 M}{0.40 M}\right)=9.25-0.20=9.05
\end{gathered}
$$

## INTERACTIVE EXAMPLE 15.6

## SOLUTION

Remember:Think about the chemistry first. Ask yourself if a reaction will occur among the major species.

## Adding Strong Acid to a Buffered Solution I

Calculate the pH of the solution that results when 0.10 mole of gaseous HCl is added to 1.0 L of the buffered solution from Example 15.5.

Before any reaction occurs, the solution contains the following major species:

$$
\mathrm{NH}_{3}, \quad \mathrm{NH}_{4}^{+}, \quad \mathrm{Cl}^{-}, \quad \mathrm{H}^{+}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
$$

From added HCl
What reaction can occur? We know that $\mathrm{H}^{+}$will not react with $\mathrm{Cl}^{-}$to form HCl . In contrast to $\mathrm{Cl}^{-}$, the $\mathrm{NH}_{3}$ molecule has a great affinity for protons [this is demonstrated by the fact that $\mathrm{NH}_{4}^{+}$is such a weak acid $\left(K_{\mathrm{a}}=5.6 \times 10^{-10}\right)$ ]. Thus $\mathrm{NH}_{3}$ will react with $\mathrm{H}^{+}$to form $\mathrm{NH}_{4}{ }^{+}$:

$$
\mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q) \longrightarrow \mathrm{NH}_{4}^{+}(a q)
$$

Since this reaction can be assumed to go essentially to completion to form the very weak acid $\mathrm{NH}_{4}{ }^{+}$, we will do the stoichiometry calculations before we consider the equilibrium calculations. That is, we will let the reaction run to completion and then consider the equilibrium.

The stoichiometry calculations for this process are shown below.

After the reaction goes to completion, the solution contains the major species
and

$$
\mathrm{NH}_{3}, \quad \mathrm{NH}_{4}^{+}, \quad \mathrm{Cl}^{-}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
$$

$$
\left[\mathrm{NH}_{3}\right]_{0}=\frac{0.15 \mathrm{~mol}}{1.0 \mathrm{~L}}=0.15 \mathrm{M}
$$

$$
\left[\mathrm{NH}_{4}^{+}\right]_{0}=\frac{0.50 \mathrm{~mol}}{1.0 \mathrm{~L}}=0.50 \mathrm{M}
$$

We can use the Henderson-Hasselbalch equation, where

$$
\begin{aligned}
& {[\text { Base }]=\left[\mathrm{NH}_{3}\right] \approx\left[\mathrm{NH}_{3}\right]_{0}=0.15 \mathrm{M}} \\
& {[\text { Acid }]=\left[\mathrm{NH}_{4}^{+}\right] \approx\left[\mathrm{NH}_{4}^{+}\right]_{0}=0.50 \mathrm{M}}
\end{aligned}
$$

Then

$$
\begin{aligned}
\mathrm{pH} & =\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{NH}_{3}\right]}{\left[\mathrm{NH}_{4}^{+}\right]}\right) \\
& =9.25+\log \left(\frac{0.15 \mathrm{M}}{0.50 \mathrm{M}}\right)=9.25-0.52=8.73
\end{aligned}
$$

Note that the addition of HCl only slightly decreases the pH , as we would expect in a buffered solution.

## LET'S REVIEW Summary of the Most Important Characteristics of Buffered Solutions

» Buffered solutions contain relatively large concentrations of a weak acid and the corresponding weak base. They can involve a weak acid HA and the conjugate base $\mathrm{A}^{-}$or a weak base B and the conjugate acid $\mathrm{BH}^{+}$.
/" When $\mathrm{H}^{+}$is added to a buffered solution, it reacts essentially to completion with the weak base present:

$$
\mathrm{H}^{+}+\mathrm{A}^{-} \longrightarrow \mathrm{HA} \text { or } \mathrm{H}^{+}+\mathrm{B} \longrightarrow \mathrm{BH}^{+}
$$

\# When $\mathrm{OH}^{-}$is added to a buffered solution, it reacts essentially to completion with the weak acid present:

$$
\mathrm{OH}^{-}+\mathrm{HA} \longrightarrow \mathrm{~A}^{-}+\mathrm{H}_{2} \mathrm{O} \text { or } \mathrm{OH}^{-}+\mathrm{BH}^{+} \longrightarrow \mathrm{B}+\mathrm{H}_{2} \mathrm{O}
$$

" The pH in the buffered solution is determined by the ratio of the concentrations of the weak acid and weak base. As long as this ratio remains virtually constant, the pH will remain virtually constant. This will be the case as long as the concentrations of the buffering materials ( HA and $\mathrm{A}^{-}$or B and $\mathrm{BH}^{+}$) are large compared with the amounts of $\mathrm{H}^{+}$ or $\mathrm{OH}^{-}$added.

### 15.3 Buffering Capacity

The buffering capacity of a buffered solution represents the amount of protons or hydroxide ions the buffer can absorb without a significant change in pH . A buffer with a large capacity contains large concentrations of buffering components and so can absorb a relatively large amount of protons or hydroxide ions and show little pH change. The pH of a buffered solution is determined by the ratio $\left[A^{-}\right] /[H A]$. The capacity of a buffered solution is determined by the magnitudes of [HA] and [A-].

## EXAMPLE 15.7 Adding Strong Acid to a Buffered Solution II

Calculate the change in pH that occurs when 0.010 mole of gaseous HCl is added to 1.0 L of each of the following solutions:

Solution A: $5.00 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and $5.00 M \mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
Solution B: $0.050 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and $0.050 M \mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
For acetic acid, $K_{\mathrm{a}}=1.8 \times 10^{-5}$.

## SOLUTION

For both solutions the initial pH can be determined from the Henderson-Hasselbalch equation:

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}\right)
$$

In each case, $\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}\right]=\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]$. Therefore, the initial pH for both A and B is

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log (1)=\mathrm{p} K_{\mathrm{a}}=-\log \left(1.8 \times 10^{-5}\right)=4.74
$$

After the addition of HCl to each of these solutions, the major species before any reaction occurs are

$$
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \quad \mathrm{Na}^{+}, \quad \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}, \quad \mathrm{H}^{+}, \quad \mathrm{Cl}^{-}, \quad \text { and } \mathrm{H}_{2} \mathrm{O}
$$

From the added HCl
Will any reactions occur among these species? Note that we have a relatively large quantity of $\mathrm{H}^{+}$, which will readily react with any effective base. We know that $\mathrm{Cl}^{-}$will not react with $\mathrm{H}^{+}$to form HCl in water. However, $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}$will react with $\mathrm{H}^{+}$to form the weak acid $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ :

$$
\mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q) \longrightarrow \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)
$$

Because $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ is a weak acid, we assume that this reaction runs to completion; the 0.010 mole of added $\mathrm{H}^{+}$will convert 0.010 mole of $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}$to 0.010 mole of $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$.

For solution $A$ (since the solution volume is 1.0 L , the number of moles equals the molarity), the following calculations apply:

|  | $\mathrm{H}^{+}$ | + | $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}$ | $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ |
| :---: | :---: | :---: | :---: | :---: |
| Before reaction | 0.010 M |  | 5.00 M | 5.00 M |
| After reaction | 0 |  | 4.99 M | 5.01 M |

The new pH can be obtained by substituting the new concentrations into the HendersonHasselbalch equation:

$$
\begin{aligned}
\square \mathrm{pH} & =\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}\right) \\
& =4.74+\log \left(\frac{4.99}{5.01}\right)=4.74-0.0017=4.74
\end{aligned}
$$

There is virtually no change in pH for solution A when 0.010 mole of gaseous HCl is added.

For solution $B$, the following calculations apply:

|  | $\mathrm{H}^{+}$ | $+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}$ | $\longrightarrow$ | $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ |
| :---: | :---: | :---: | :---: | :---: |
| Before reaction | 0.010 M |  | 0.050 M |  |
| After reaction | 0 |  | 0.040 M |  |
|  |  |  | 0.050 M |  |
|  |  |  |  |  |

The new pH is

$$
\begin{aligned}
\mathrm{pH} & =4.74+\log \left(\frac{0.040}{0.060}\right) \\
& =4.74-0.18=4.56
\end{aligned}
$$

Although the pH change for solution B is small, a change did occur, which is in contrast to solution A.

These results show that solution A , which contains much larger quantities of buffering components, has a much higher buffering capacity than solution B.

## See Exercises 15.43 and 15.44

We have seen that the pH of a buffered solution depends on the ratio of the concentrations of buffering components. When this ratio is least affected by added protons or hydroxide ions, the solution is the most resistant to a change in pH . To find the ratio that gives optimal buffering, let's suppose we have a buffered solution containing a large concentration of acetate ion and only a small concentration of acetic acid. Addition of protons to form acetic acid will produce a relatively large percent change in the concentration of acetic acid and so will produce a relatively large change in the ratio $\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right] /\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]$ (Table 15.1). Similarly, if hydroxide ions are added to remove some acetic acid, the percent change in the concentration of acetic acid is again large. The same effects are seen if the initial concentration of acetic acid is large and that of acetate ion is small.

Because large changes in the ratio $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ will produce large changes in pH , we want to avoid this situation for the most effective buffering. This type of reasoning leads us to the general conclusion that optimal buffering occurs when [HA] is equal to $\left[\mathrm{A}^{-}\right]$. It is for this condition that the ratio $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ is most resistant to change when $\mathrm{H}^{+}$or $\mathrm{OH}^{-}$is added to the buffered solution. This means that when choosing the buffering components for a specific application, we want $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ to equal 1 . It follows that since

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}\right)=\mathrm{p} K_{\mathrm{a}}+\log (1)=\mathrm{p} K_{\mathrm{a}}
$$

the $\mathrm{p} K_{\mathrm{a}}$ of the weak acid to be used in the buffer should be as close as possible to the desired $\mathbf{p H}$. For example, suppose we need a buffered solution with a pH of 4.00. The most effective buffering will occur when [HA] is equal to [ $\mathrm{A}^{-}$]. From the Henderson-Hasselbalch equation,

TABLE 15.1 | Change in $\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right] /\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]$ for Two Solutions When 0.01 mole of $\mathrm{H}^{+}$Is Added to 1.0 L of Each

| Solution $\left(\frac{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}\right)_{\text {orig }}$ | $\left(\frac{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}\right)_{\text {new }}$ | Change | Percent <br> Change |  |
| :---: | :--- | :--- | :--- | :--- |
| A | $\frac{1.00 \mathrm{M}}{1.00 \mathrm{M}}=1.00$ | $\frac{0.99 \mathrm{M}}{1.01 \mathrm{M}}=0.98$ | $1.00 \rightarrow 0.98$ | $2.00 \%$ |
| B | $\frac{1.00 \mathrm{M}}{0.01 \mathrm{M}}=100$ | $\frac{0.99 \mathrm{M}}{0.02 \mathrm{M}}=49.5$ | $100 \rightarrow 49.5$ | $50.5 \%$ |

That is, $4.00=\mathrm{p} K_{\mathrm{a}}+\log (1)=\mathrm{p} K_{\mathrm{a}}+0 \quad$ and $\mathrm{p} K_{\mathrm{a}}=4.00$
Thus the best choice of a weak acid is one that has $\mathrm{p} K_{\mathrm{a}}=4.00$ or $K_{\mathrm{a}}=1.0 \times 10^{-4}$.
 to be used in the buffer should be as close as possible to the desired pH ." What is the problem with choosing a weak acid whose $\mathrm{p} K_{\mathrm{a}}$ is not close to the desired pH when making a buffer?

## INTERACTIVE EXAMPLE 15.8

## SOLUTION

## Preparing a Buffer

A chemist needs a solution buffered at pH 4.30 and can choose from the following acids (and their sodium salts):
a. chloroacetic acid $\left(K_{\mathrm{a}}=1.35 \times 10^{-3}\right)$
b. propanoic acid $\left(K_{\mathrm{a}}=1.3 \times 10^{-5}\right)$
c. benzoic acid $\left(K_{\mathrm{a}}=6.4 \times 10^{-5}\right)$
d. hypochlorous acid $\left(K_{\mathrm{a}}=3.5 \times 10^{-8}\right)$

Calculate the ratio $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$required for each system to yield a pH of 4.30. Which system will work best?

A pH of 4.30 corresponds to

$$
\left[\mathrm{H}^{+}\right]=10^{-4.30}=\operatorname{antilog}(-4.30)=5.0 \times 10^{-5} M
$$

Since $K_{\mathrm{a}}$ values rather than $\mathrm{p} K_{\mathrm{a}}$ values are given for the various acids, we use Equation (15.1)

$$
\left[\mathrm{H}^{+}\right]=K_{\mathrm{a}} \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}
$$

rather than the Henderson-Hasselbalch equation. We substitute the required $\left[\mathrm{H}^{+}\right]$and $K_{\mathrm{a}}$ for each acid into Equation (15.1) to calculate the ratio $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$needed in each case.

| Acid | $\left[\mathrm{H}^{+}\right]=K_{\mathrm{a}} \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}$ | $\frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}$ |
| :--- | :--- | :--- |
| a. Chloroacetic | $5.0 \times 10^{-5}=1.35 \times 10^{-3}\left(\frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}\right)$ | $3.7 \times 10^{-2}$ |
| b. Propanoic | $5.0 \times 10^{-5}=1.3 \times 10^{-5}\left(\frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}\right)$ | 3.8 |
| c. Benzoic | $5.0 \times 10^{-5}=6.4 \times 10^{-5}\left(\frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}\right)$ | 0.78 |
| d. Hypochlorous | $5.0 \times 10^{-5}=3.5 \times 10^{-8}\left(\frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}\right)$ | $1.4 \times 10^{3}$ |

$\square$ Since $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$for benzoic acid is closest to 1 , the system of benzoic acid and its sodium salt will be the best choice among those given for buffering a solution at pH 4.30. This example demonstrates the principle that the optimal buffering system has a $\mathrm{p} K_{\mathrm{a}}$ value close to the desired pH . The $\mathrm{p} K_{\mathrm{a}}$ for benzoic acid is 4.19.

$$
\text { See Exercises } 15.53 \text { and } 15.54
$$

### 15.4 Titrations and pH Curves

As we saw in Chapter 4, a titration is commonly used to determine the amount of acid or base in a solution. This process involves a solution of known concentration (the titrant) delivered from a buret into the unknown solution until the substance being analyzed is just consumed. The stoichiometric (equivalence) point is often signaled by the color change of an indicator. In this section we will discuss the pH changes that occur during an acid-base titration. We will use this information later to show how an appropriate indicator can be chosen for a particular titration.

The progress of an acid-base titration is often monitored by plotting the pH of the solution being analyzed as a function of the amount of titrant added. Such a plot is called a pH curve or titration curve.

## Strong Acid-Strong Base Titrations

The net ionic reaction for a strong acid-strong base titration is

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

To compute $\left[\mathrm{H}^{+}\right]$at a given point in the titration, we must determine the amount of $\mathrm{H}^{+}$

## A

A setup used to conduct the pH titration of an acid or a base.

```
1 mmol=1\times10-3 mol
1 mL = 1 < 10-3 L
mmol}=\frac{\textrm{mol}}{\textrm{L}}=
``` that remains at that point and divide by the total volume of the solution. Before we proceed, we need to consider a new unit, which is especially convenient for titrations. Since titrations usually involve small quantities (burets are typically graduated in milliliters), the mole is inconveniently large. Therefore, we will use the millimole (abbreviated mmol), which, as the prefix indicates, is a thousandth of a mole:
\[
1 \mathrm{mmol}=\frac{1 \mathrm{~mol}}{1000}=10^{-3} \mathrm{~mol}
\]

So far we have defined molarity only in terms of moles per liter. We can now define it in terms of millimoles per milliliter, as shown below:
\[
\text { Molarity }=\frac{\text { mol solute }}{\mathrm{L} \text { solution }}=\frac{\frac{\text { mol solute }}{1000}}{\frac{\mathrm{~L} \text { solution }}{1000}}=\frac{\mathrm{mmol} \text { solute }}{\mathrm{mL} \text { solution }}
\]

A \(1.0-M\) solution thus contains 1.0 mole of solute per liter of solution or, equivalently, 1.0 mmol of solute per milliliter of solution. Just as we obtain the number of moles of solute from the product of the volume in liters and the molarity, we obtain the number of millimoles of solute from the product of the volume in milliliters and the molarity:
\[
\text { Number of mmol }=\text { volume }(\text { in } \mathrm{mL}) \times \text { molarity }
\]

\section*{(CASE STUDYD Strong Acid-Strong Base Titration}

We will illustrate the calculations involved in a strong acid-strong base titration by considering the titration of 50.0 mL of \(0.200 \mathrm{M} \mathrm{HNO}_{3}\) with 0.100 M NaOH . We will calculate the pH of the solution at selected points during the course of the titration, where specific volumes of 0.100 M NaOH have been added.

\section*{A. No NaOH has been added.}

Since \(\mathrm{HNO}_{3}\) is a strong acid (is completely dissociated), the solution contains the major species
\[
\mathrm{H}^{+}, \quad \mathrm{NO}_{3}^{-}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
\]
and the pH is determined by the \(\mathrm{H}^{+}\)from the nitric acid. Since \(0.200 M \mathrm{HNO}_{3}\) contains \(0.200 \mathrm{M} \mathrm{H}^{+}\),
\[
\left[\mathrm{H}^{+}\right]=0.200 \mathrm{M} \quad \text { and } \quad \mathrm{pH}=0.699
\]

The final solution volume is the sum of the original volume of \(\mathrm{HNO}_{3}\) and the volume of added NaOH .

B. \(\quad 10.0 \mathrm{~mL}\) of 0.100 M NaOH has been added.

In the mixed solution before any reaction occurs, the major species are
\[
\mathrm{H}^{+}, \quad \mathrm{NO}_{3}^{-}, \quad \mathrm{Na}^{+}, \quad \mathrm{OH}^{-}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
\]

Note that large quantities of both \(\mathrm{H}^{+}\)and \(\mathrm{OH}^{-}\)are present. The 1.00 mmol \((10.0 \mathrm{~mL} \times 0.100 \mathrm{M})\) of added \(\mathrm{OH}^{-}\)will react with \(1.00 \mathrm{mmol}^{+}\)to form water:
\begin{tabular}{|c|c|c|c|c|c|}
\hline & \(\mathrm{H}^{+}\) & + & \(\mathrm{OH}^{-}\) & \(\longrightarrow\) & \(\mathrm{H}_{2} \mathrm{O}\) \\
\hline Before reaction & \[
\begin{aligned}
& 50.0 \mathrm{~mL} \times 0.200 \mathrm{M} \\
& =10.0 \mathrm{mmol}
\end{aligned}
\] & & \[
\begin{gathered}
10.0 \mathrm{~mL} \times 0.100 \mathrm{M} \\
=1.00 \mathrm{mmol}
\end{gathered}
\] & & \\
\hline After reaction & \[
\begin{aligned}
& 10.0-1.00 \\
& =9.0 \mathrm{mmol}
\end{aligned}
\] & & \(1.00-1.00=0\) & & \\
\hline
\end{tabular}

After the reaction, the solution contains
\(\mathrm{H}^{+}, \mathrm{NO}_{3}{ }^{-}, \mathrm{Na}^{+}\), and \(\mathrm{H}_{2} \mathrm{O}\) (the \(\mathrm{OH}^{-}\)ions have been consumed) and the pH will be determined by the \(\mathrm{H}^{+}\)remaining:
\[
\left[\mathrm{H}^{+}\right]=\frac{\mathrm{mmol} \mathrm{H}}{}+\mathrm{left}-\frac{9.0 \mathrm{mmol}}{\text { volume of solution }(\mathrm{mL})}=\frac{0.15 \mathrm{M}}{(50.0+10.0) \mathrm{mL}}=0
\]
\[
\begin{array}{cc}
\text { Original volume of } & \text { Volume of } \\
\mathrm{HNO}_{3} \text { solution } & \mathrm{NaOH} \text { added }
\end{array}
\]
\[
\mathrm{pH}=-\log (0.15)=0.82
\]
C. 20.0 mL (total) of 0.100 M NaOH has been added.

We consider this point from the perspective that a total of 20.0 mL NaOH has been added to the original solution, rather than that 10.0 mL has been added to the solution from point \(B\). It is best to go back to the original solution each time so that a mistake made at an earlier point does not show up in each succeeding calculation. As before, the added \(\mathrm{OH}^{-}\)will react with \(\mathrm{H}^{+}\)to form water:
\begin{tabular}{|c|c|c|c|c|c|}
\hline & \(\mathrm{H}^{+}\) & + & \(\mathrm{OH}^{-}\) & \(\longrightarrow\) & \(\mathrm{H}_{2} \mathrm{O}\) \\
\hline Before reaction & \[
\begin{gathered}
50.0 \mathrm{~mL} \times 0.200 \mathrm{M} \\
=10.0 \mathrm{mmol}
\end{gathered}
\] & & \[
\begin{aligned}
& 20.0 \mathrm{~mL} \times 0.100 \mathrm{M} \\
& =2.00 \mathrm{mmol}
\end{aligned}
\] & & \\
\hline After reaction & \[
\begin{aligned}
& 10.0-2.00 \\
& =8.00 \mathrm{mmol}
\end{aligned}
\] & & \[
\begin{array}{r}
2.00-2.00 \\
=0 \mathrm{mmol}
\end{array}
\] & & \\
\hline
\end{tabular}

After the reaction
\[
\left[\mathrm{H}^{+}\right]=\frac{8.00 \mathrm{mmol}}{(50.0+20.0) \mathrm{mL}}=0.11 \mathrm{M}
\]
D. 50.0 mL (total) of \(\mathbf{0 . 1 0 0} \mathrm{M} \mathrm{NaOH}\) has been added.

Proceeding exactly as for points B and C , the pH is found to be 1.301 .
E. \(\quad 100.0 \mathrm{~mL}\) (total) of \(\mathbf{0 . 1 0 0 ~} \mathrm{M} \mathrm{NaOH}\) has been added.

At this point the amount of NaOH that has been added is
\[
100.0 \mathrm{~mL} \times 0.100 \mathrm{M}=10.0 \mathrm{mmol}
\]

The original amount of nitric acid was
\[
50.0 \mathrm{~mL} \times 0.200 \mathrm{M}=10.0 \mathrm{mmol}
\]

Equivalence (stoichiometric) point: The point in the titration where an amount of base has been added to exactly react with all the acid originally present.

FIGURE 15.1 The pH curve for the titration of 50.0 mL of \(0.200 \mathrm{M} \mathrm{HNO}_{3}\) with 0.100 M NaOH . Note that the equivalence point occurs at 100.0 mL NaOH added, the point where exactly enough \(\mathrm{OH}^{-}\)has been added to react with all the \(\mathrm{H}^{+}\)originally present. The pH of 7 at the equivalence point is characteristic of a strong acid-strong base titration.

Enough \(\mathrm{OH}^{-}\)has been added to react exactly with the \(\mathrm{H}^{+}\)from the nitric acid. This is the stoichiometric point, or equivalence point, of the titration. At this point the major species in solution are
\[
\mathrm{Na}^{+}, \quad \mathrm{NO}_{3}^{-}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
\]

Since \(\mathrm{Na}^{+}\)has no acid or base properties and \(\mathrm{NO}_{3}{ }^{-}\)is the anion of the strong acid \(\mathrm{HNO}_{3}\) and is therefore a very weak base, neither \(\mathrm{NO}_{3}{ }^{-}\)nor \(\mathrm{Na}^{+}\)affects the pH , and the solution is neutral (the pH is 7.00 ).

\section*{F. \(\quad 150.0 \mathrm{~mL}\) (total) of \(\mathbf{0 . 1 0 0 ~} \mathrm{M} \mathrm{NaOH}\) has been added.}

The stoichiometric calculations for the titration reaction are as follows:

Now \(\mathrm{OH}^{-}\)is in excess and will determine the pH :
\[
\left[\mathrm{OH}^{-}\right]=\frac{\mathrm{mmol} \mathrm{OH}}{}{ }^{-} \text {in excess } \frac{5.0 \mathrm{mmol}}{\text { volume }(\mathrm{mL})}=\frac{5.0 \mathrm{mmol}}{(50.0+150.0) \mathrm{mL}}=\frac{200.0 \mathrm{~mL}}{20.025 \mathrm{M}}
\]

Since \(\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}\),
\[
\left[\mathrm{H}^{+}\right]=\frac{1.0 \times 10^{-14}}{2.5 \times 10^{-2}}=4.0 \times 10^{-13} M \quad \text { and } \quad \mathrm{pH}=12.40
\]

\section*{G. \(\quad 200.0 \mathrm{~mL}\) (total) of \(\mathbf{0 . 1 0 0} \mathrm{M} \mathrm{NaOH}\) has been added.}

Proceeding as for point F , the pH is found to be 12.60 .
The results of these calculations are summarized by the pH curve shown in Fig. 15.1. Note that the pH changes very gradually until the titration is close to the equivalence point, where a dramatic change occurs. This behavior is due to the fact that early in the titration there is a relatively large amount of \(\mathrm{H}^{+}\)in the solution, and the addition of a given amount of \(\mathrm{OH}^{-}\)thus produces a small change in pH . However, near the equivalence point \(\left[\mathrm{H}^{+}\right]\)is relatively small, and the addition of a small amount of \(\mathrm{OH}^{-}\) produces a large change.

The pH curve in Fig. 15.1, typical of the titration of a strong acid with a strong base, has the following characteristics:

Before the equivalence point, \(\left[\mathrm{H}^{+}\right]\)(and hence the pH ) can be calculated by dividing the number of millimoles of \(\mathrm{H}^{+}\)remaining by the total volume of the solution in milliliters.

At the equivalence point, the pH is 7.00 .
After the equivalence point, \(\left[\mathrm{OH}^{-}\right]\)can be calculated by dividing the number of millimoles of excess \(\mathrm{OH}^{-}\)by the total volume of the solution. Then \(\left[\mathrm{H}^{+}\right]\)is obtained from \(K_{\mathrm{w}}\).

The titration of a strong base with a strong acid requires reasoning very similar to that used above, except, of course, that \(\mathrm{OH}^{-}\)is in excess before the equivalence point and \(\mathrm{H}^{+}\)is in excess after the equivalence point. The pH curve for the titration of 100.0 mL of 0.50 M NaOH with 1.0 M HCl is shown in Fig. 15.2.

FIGURE 15.2 The pH curve for the titration of 100.0 mL of 0.50 M NaOH with 1.0 M HCl . The equivalence point occurs at 50.00 mL HCl added, since at this point \(5.0 \mathrm{mmol} \mathrm{H}^{+}\)has been added to react with the original \(5.0 \mathrm{mmol} \mathrm{OH}^{-}\).

Treat the stoichiometry and equilibrium problems separately.

\section*{Titrations of Weak Acids with Strong Bases}

We have seen that since strong acids and strong bases are completely dissociated, the calculations to obtain the pH curves for titrations involving the two are quite straightforward. However, when the acid being titrated is a weak acid, there is a major difference: To calculate \(\left[\mathrm{H}^{+}\right]\)after a certain amount of strong base has been added, we must deal with the weak acid dissociation equilibrium. We have dealt with this same situation earlier in this chapter when we treated buffered solutions. Calculation of the pH curve for a titration of a weak acid with a strong base really amounts to a series of buffer problems. In performing these calculations it is very important to remember that even though the acid is weak, it reacts essentially to completion with hydroxide ion, a very strong base.

This process always involves a two-step procedure.

\section*{PROBLEM-SOLVING STRATEGY}

\section*{Calculating the pH Curve for a Weak Acid-Strong Base Titration}
1. A stoichiometry problem. The reaction of hydroxide ion with the weak acid is assumed to run to completion, and the concentrations of the acid remaining and the conjugate base formed are determined.
2. An equilibrium problem. The position of the weak acid equilibrium is determined, and the pH is calculated.

It is essential to do these steps separately. Note that the procedures necessary to do these calculations have all been used before.

\section*{(CASE STUDY Weak Acid-Strong Base Titration}

As an illustration, we will consider the titration of 50.0 mL of 0.10 M acetic acid \(\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, K_{\mathrm{a}}=1.8 \times 10^{-5}\right)\) with 0.10 M NaOH . As before, we will calculate the pH at various points representing volumes of added NaOH .
A. No NaOH has been added.

This is a typical weak acid calculation of the type introduced in Chapter 14. The pH is 2.87. (Check this yourself.)
B. \(\quad 10.0 \mathrm{~mL}\) of 0.10 M NaOH has been added.

The major species in the mixed solution before any reaction takes place are
\[
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \mathrm{OH}^{-}, \quad \mathrm{Na}^{+}, \text {and } \mathrm{H}_{2} \mathrm{O}
\]

\section*{Stoichiometry Problem}

\section*{Equilibrium Problem}

The initial concentrations are defined after the reaction with \(\mathrm{OH}^{-}\)has gone to completion but before any dissociation of \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) occurs.

Note that the approximations made are well within the \(5 \%\) rule.

The strong base \(\mathrm{OH}^{-}\)will react with the strongest proton donor, which in this case is \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\).

We examine the major components left in the solution after the reaction takes place to decide on the dominant equilibrium. The major species are
\[
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \quad \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}, \quad \mathrm{Na}^{+}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
\]

Since \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) is a much stronger acid than \(\mathrm{H}_{2} \mathrm{O}\), and since \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\)is the conjugate base of \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\), the pH will be determined by the position of the acetic acid dissociation equilibrium:
where
\[
\begin{aligned}
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q) & \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q) \\
K_{\mathrm{a}} & =\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}
\end{aligned}
\]

We follow the usual steps to complete the equilibrium calculations:
\[
\begin{array}{ll}
\text { Initial Concentration } & \text { Equillbrium Concentration } \\
{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]_{0}=\frac{4.0 \mathrm{mmol}}{(50.0+10.0) \mathrm{mL}}=\frac{4.0}{60.0}} & {\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]=\frac{4.0}{60.0}-x} \\
{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]_{0}=\frac{1.0 \mathrm{mmol}}{(50.0+10.0) \mathrm{mL}}=\frac{1.0}{60.0} \xrightarrow{x \mathrm{mmol} / \mathrm{mLL}}} & \\
{\left[\mathrm{H}^{+} \mathrm{H}_{0} \mathrm{H}_{0} \mathrm{O}_{2}\right.} & {\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]=\frac{1.0}{60.0}+x} \\
&
\end{array}
\]

The appropriate ICE table is
\begin{tabular}{|lcccc|}
\hline & \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)\) & \(\rightleftharpoons\) & \(\mathrm{H}^{+}(a q)\) & + \\
\(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)\) \\
Initial & \(\frac{4.0}{60.0}\) & & \(\approx 0\) & \(\frac{1.0}{60.0}\) \\
Change & \(-x\) & & \(+x\) & \(+x\) \\
Equilibrium & \(\frac{4.0}{60.0}-x\) & & \(x\) & \(\frac{1.0}{60.0}+x\) \\
& & & &
\end{tabular}

Therefore,
\[
\begin{aligned}
1.8 \times 10^{-5}= & K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}=\frac{x\left(\frac{1.0}{60.0}+x\right)}{\frac{4.0}{60.0}-x} \approx \frac{x\left(\frac{1.0}{60.0}\right)}{\frac{4.0}{60.0}}=\left(\frac{1.0}{4.0}\right) x \\
x & =\left(\frac{4.0}{1.0}\right)\left(1.8 \times 10^{-5}\right)=7.2 \times 10^{-5}=\left[\mathrm{H}^{+}\right] \text {and } \mathrm{pH}=4.14
\end{aligned}
\]

\section*{C. \(\quad \mathbf{2 5 . 0} \mathrm{mL}\) (total) of \(\mathbf{0 . 1 0} \mathrm{M} \mathrm{NaOH}\) has been added.}

The procedure here is very similar to that used at point B and will only be summarized briefly. The stoichiometry problem is summarized as follows:

\section*{Stoichiometry Problem}

\section*{Equilibrium Problem}
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline & \(\mathrm{OH}^{-}\) & + & \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) & \(\longrightarrow\) & \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}\) & + & \(\mathrm{H}_{2} \mathrm{O}\) \\
\hline Before reaction & \[
\begin{gathered}
25.0 \mathrm{~mL} \times 0.10 \mathrm{M} \\
=2.5 \mathrm{mmol}
\end{gathered}
\] & & \[
\begin{aligned}
& 50.0 \mathrm{~mL} \times 0.10 \mathrm{M} \\
& =5.0 \mathrm{mmol}
\end{aligned}
\] & & 0 mmol & & \\
\hline After reaction & \(2.5-2.5=0\) & & \[
\begin{aligned}
& 5.0-2.5 \\
& =2.5 \mathrm{mmol}
\end{aligned}
\] & & 2.5 mmol & & \\
\hline
\end{tabular}

After the reaction, the major species in solution are
\[
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \quad \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}, \quad \mathrm{Na}^{+}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
\]

The equilibrium that will control the pH is
\[
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)
\]
and the pertinent concentrations are as follows:

The corresponding ICE table is
\begin{tabular}{|lcccc|}
\hline & \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)\) & \(\rightleftharpoons\) & \(\mathrm{H}^{+}(a q)\) & + \\
\(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}(a q)\) \\
Initial & \(\frac{2.5}{75.0}\) & & \(\approx 0\) & \(\frac{2.5}{75.0}\) \\
Change & \(-x\) & & \(+x\) & \\
Equilibrium & \(\frac{2.5}{75.0}-x\) & & \(x\) & \\
& & & & \(\frac{2.5}{75.0}+x\)
\end{tabular}

Therefore,
\[
\begin{aligned}
1.8 \times 10^{-5} & =K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}=\frac{x\left(\frac{2.5}{75.0}+x\right)}{\frac{2.5}{75.0}-x} \approx \frac{x\left(\frac{2.5}{75.0}\right)}{\frac{2.5}{75.0}} \\
x & =1.8 \times 10^{-5}=\left[\mathrm{H}^{+}\right] \text {and } \mathrm{pH}=4.74
\end{aligned}
\]

This is a special point in the titration because it is halfway to the equivalence point. The original solution, 50.0 mL of \(0.10 \mathrm{M} \mathrm{H}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\), contained \(5.0 \mathrm{mmol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\). Thus \(5.0 \mathrm{mmol} \mathrm{OH}{ }^{-}\)is required to reach the equivalence point. That is, 50 mL NaOH is required, since
\[
(50.0 \mathrm{~mL})(0.10 M)=5.0 \mathrm{mmol}
\]

After 25.0 mL NaOH has been added, half the original \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) has been converted to \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\). At this point in the titration \(\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]_{0}\) is equal to \(\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]_{0}\). We can neglect the effect of dissociation; that is,
\[
\begin{aligned}
{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right] } & =\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]_{0}-x \approx\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]_{0} \\
{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right] } & \left.=\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]_{0}+x \approx \approx \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]_{0}
\end{aligned}
\]

The expression for \(K_{\mathrm{a}}\) at the halfway point is
\[
\left.K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]_{0}}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]_{0}}=\left[\mathrm{H}^{+}\right]\right)
\]

Then, at the halfway point in the titration,
\[
\left[\mathrm{H}^{+}\right]=K_{\mathrm{a}} \quad \text { and } \quad \mathrm{pH}=\mathrm{p} K_{\mathrm{a}}
\]
D. 40.0 mL (total) of 0.10 M NaOH has been added.

The procedures required here are the same as those used for points B and C . The pH is 5.35. (Check this yourself.)

\section*{E. 50.0 mL (total) of \(\mathbf{0 . 1 0 ~} \mathrm{M} \mathrm{NaOH}\) has been added.}

\section*{Equilibrium Problem}

This is the equivalence point of the titration; \(5.0 \mathrm{mmol} \mathrm{OH}{ }^{-}\)has been added, which will just react with the \(5.0 \mathrm{mmol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) originally present. At this point the solution contains the major species
\[
\mathrm{Na}^{+}, \quad \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}, \quad \text { and } \quad \mathrm{H}_{2} \mathrm{O}
\]

Note that the solution contains \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\), which is a base. Remember that a base wants to combine with a proton, and the only source of protons in this solution is water. Thus the reaction will be
\[
\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)+\mathrm{OH}^{-}(a q)
\]

This is a weak base reaction characterized by \(K_{\mathrm{b}}\) :
\[
K_{\mathrm{b}}=\frac{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}}=5.6 \times 10^{-10}
\]

The relevant concentrations are as follows:
\[
\begin{array}{lll}
\begin{array}{l}
\text { Initial Concentration } \\
\text { (before any } \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-} \\
\text {reacts with } \left.\mathrm{H}_{2} \mathrm{O}\right)
\end{array} & \begin{array}{l}
\text { Equilibrium } \\
\text { Concentration }
\end{array} \\
{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]_{0}=\frac{5.0 \mathrm{mmol}}{(50.0+50.0) \mathrm{mL}}} & & \begin{array}{l}
\text { a mmol/mL } \\
\\
=0.050 \mathrm{M}
\end{array}
\end{array} \begin{aligned}
& {\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]=0.050-x} \\
& {\left[\mathrm{OH}^{-}\right]_{0} \approx 0}
\end{aligned}
\]

The corresponding ICE table is
\begin{tabular}{|lccccc|}
\hline & \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}(a q)\) & + & \(\mathrm{H}_{2} \mathrm{O}(I)\) & \(\rightleftharpoons\) & \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)\) \\
Initial & 0.050 & - & + & \(\mathrm{OH}^{-}(a q)\) \\
Change & \(-x\) & - & 0 & \(\approx 0\) \\
\hline Equilibrium & \(0.050-x\) & - & \(+x\) & \(+x\) \\
\hline
\end{tabular}

Therefore,
\[
\begin{gathered}
5.6 \times 10^{-10}=K_{\mathrm{b}}=\frac{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}=\frac{(x)(x)}{0.050-x} \approx \frac{x^{2}}{0.050} \\
x \approx 5.3 \times 10^{-6}
\end{gathered}
\]

The pH at the equivalence point of a titration of a weak acid with a strong base is always greater than 7 .

The approximation is valid (by the 5\% rule), so
and
\[
\begin{aligned}
{\left[\mathrm{OH}^{-}\right] } & =5.3 \times 10^{-6} M \\
{\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right] } & =K_{\mathrm{w}}=1.0 \times 10^{-14} \\
{\left[\mathrm{H}^{+}\right] } & =1.9 \times 10^{-9} \mathrm{M} \\
\mathrm{pH} & =8.72
\end{aligned}
\]

This is another important result: The pH at the equivalence point of a titration of a weak acid with a strong base is always greater than 7 . This is so because the anion of the acid, which remains in solution at the equivalence point, is a base. In contrast, for the titration of a strong acid with a strong base, the pH at the equivalence point is 7.0 , because the anion remaining in this case is not an effective base.
F. \(\quad 60.0 \mathrm{~mL}\) (total) of 0.10 M NaOH has been added.

At this point, excess \(\mathrm{OH}^{-}\)has been added. The stoichiometric calculations are as follows:
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline & \(\mathrm{OH}^{-}\) & \(+\) & \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) & \(\longrightarrow\) & \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}\) & + & \(\mathrm{H}_{2} \mathrm{O}\) \\
\hline Before reaction & \[
\begin{aligned}
& 60.0 \mathrm{~mL} \times 0.10 \mathrm{M} \\
& =6.0 \mathrm{mmol}
\end{aligned}
\] & & \[
\begin{aligned}
& 50.0 \mathrm{~mL} \times 0.10 \mathrm{M} \\
& =5.0 \mathrm{mmol}
\end{aligned}
\] & & 0 mmol & & \\
\hline After reaction & \[
\begin{aligned}
& 6.0-5.0 \\
& =1.0 \mathrm{mmol} \text { in } \\
& \quad \text { excess }
\end{aligned}
\] & & \(5.0-5.0=0\) & & 5.0 mmol & & \\
\hline
\end{tabular}

\section*{Equilibrium Problem}

After the reaction is complete, the solution contains the major species
\[
\mathrm{Na}^{+}, \quad \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}, \quad \mathrm{OH}^{-}, \quad \text { and } \mathrm{H}_{2} \mathrm{O}
\]

There are two bases in this solution, \(\mathrm{OH}^{-}\)and \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\). However, \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}\)is a weak base compared with \(\mathrm{OH}^{-}\). Therefore, the amount of \(\mathrm{OH}^{-}\)produced by reaction of \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\)with \(\mathrm{H}_{2} \mathrm{O}\) will be small compared with the excess \(\mathrm{OH}^{-}\)already in solution. You can verify this conclusion by looking at point E , where only \(5.3 \times 10^{-6} \mathrm{M} \mathrm{OH}^{-}\) was produced by \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}\). The amount in this case will be even smaller, since the excess \(\mathrm{OH}^{-}\)will push the \(K_{\mathrm{b}}\) equilibrium to the left.

Thus the pH is determined by the excess \(\mathrm{OH}^{-}\):
\[
\begin{gathered}
{\left[\mathrm{OH}^{-}\right]=\frac{\mathrm{mmol} \text { of } \mathrm{OH}^{-} \text {in excess }}{\text { volume }(\mathrm{in} \mathrm{~mL})}=\frac{1.0 \mathrm{mmol}}{(50.0+60.0) \mathrm{mL}}} \\
=9.1 \times 10^{-3} \mathrm{M} \\
{\left[\mathrm{H}^{+}\right]=\frac{1.0 \times 10^{-14}}{9.1 \times 10^{-3}}=1.1 \times 10^{-12} \mathrm{M}} \\
\mathrm{pH}=11.96
\end{gathered}
\]
G. 75.0 mL (total) of 0.10 M NaOH has been added.

The procedure needed here is very similar to that for point F . The pH is 12.30. (Check this yourself.)

The pH curve for this titration is shown in Fig. 15.3. It is important to note the differences between this curve and that in Fig. 15.1. For example, the shapes of the plots are quite different before the equivalence point, although they are very similar after that point. (The shapes of the strong and weak acid curves are the same after the equivalence points because excess \(\mathrm{OH}^{-}\)controls the pH in this region in both cases.) Near the beginning of the titration of the weak acid, the pH increases more rapidly than

FIGURE 15.3 The pH curve for the titration of 50.0 mL of \(0.100 \mathrm{M} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) with 0.100 M NaOH . Note that the equivalence point occurs at 50.0 mL NaOH added, where the amount of added \(\mathrm{OH}^{-}\) exactly equals the original amount of acid. The pH at the equivalence point is greater than 7.0 because the \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\)ion present at this point is a base and reacts with water to produce \(\mathrm{OH}^{-}\).

The equivalence point is defined by the stoichiometry, not by the pH .

it does in the strong acid case. It levels off near the halfway point and then increases rapidly again. The leveling off near the halfway point is caused by buffering effects. Earlier in this chapter we saw that optimal buffering occurs when [HA] is equal to [ \(\mathrm{A}^{-}\)]. This is exactly the case at the halfway point of the titration. As we can see from the curve, the pH changes least rapidly in this region of the titration.

The other notable difference between the curves for strong and weak acids is the value of the pH at the equivalence point. For the titration of a strong acid, the equivalence point occurs at pH 7 . For the titration of a weak acid, the pH at the equivalence point is greater than 7 because of the basicity of the conjugate base of the weak acid.

It is important to understand that the equivalence point in an acid-base titration is defined by the stoichiometry, not by the pH . The equivalence point occurs when enough titrant has been added to react exactly with all the acid or base being titrated.

\section*{INTERACTIVE EXAMPLE 15.9 Titration of a Weak Acid}

Hydrogen cyanide gas (HCN), a powerful respiratory inhibitor, is highly toxic. It is a very weak acid ( \(K_{\mathrm{a}}=6.2 \times 10^{-10}\) ) when dissolved in water. If a \(50.0-\mathrm{mL}\) sample of \(0.100 M \mathrm{HCN}\) is titrated with \(0.100 M \mathrm{NaOH}\), calculate the pH of the solution
a. after 8.00 mL of 0.100 M NaOH has been added.
b. at the halfway point of the titration.
c. at the equivalence point of the titration.

SOLUTION a. After 8.00 mL of 0.100 M NaOH has been added, the following calculations apply:

\section*{Stoichiometry Problem}

\section*{Equilibrium Problem}

The approximations made here are well within the \(5 \%\) rule.
will determine the pH .
\[
\begin{aligned}
& \text { Initial Concentration } \\
& {[\mathrm{HCN}]_{0}=\frac{4.2 \mathrm{mmol}}{(50.0+8.0) \mathrm{mL}}} \\
& {\left[\mathrm{CN}^{-}\right]_{0}=\frac{0.800 \mathrm{mmol}}{(50.0+8.0) \mathrm{mL}} \xrightarrow[\text { dissociates }]{x \mathrm{mmol} / \mathrm{mL}}} \\
& {\left[\mathrm{H}^{+}\right]_{0} \approx 0}
\end{aligned}
\]

The corresponding ICE table is
\begin{tabular}{|lcccc|}
\hline & \(\mathrm{HCN}(\mathrm{aq})\) & \(\rightleftharpoons\) & \(\mathrm{H}^{+}(a q)\) & + \\
Initial & \(\frac{4.2}{58.0}\) & & \(\approx 0\) & \(\frac{0.80}{58.0}\) \\
Change & \(-x\) & & \(+x\) & \(+x\) \\
Equilibrium & \(\frac{4.2}{58.0}-x\) & & \(x\) & \(\frac{0.80}{58.0}+x\) \\
\hline
\end{tabular}

Substituting the equilibrium concentrations into the expression for \(K_{\mathrm{a}}\) gives
\[
\begin{gathered}
6.2 \times 10^{-10}=K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{CN}^{-}\right]}{[\mathrm{HCN}]}=\frac{x\left(\frac{0.80}{58.0}+x\right)}{\frac{4.2}{58.0}-x} \approx \frac{x\left(\frac{0.80}{58.0}\right)}{\left(\frac{4.2}{58.0}\right)}=x\left(\frac{0.80}{4.2}\right) \\
\square \\
\square=3.3 \times 10^{-9} M=\left[\mathrm{H}^{+}\right] \text {and } \mathrm{pH}=8.49
\end{gathered}
\]
b. At the halfway point of the titration. The amount of HCN originally present can be obtained from the original volume and molarity:
\[
50.0 \mathrm{~mL} \times 0.100 \mathrm{M}=5.00 \mathrm{mmol}
\]

Thus the halfway point will occur when \(2.50 \mathrm{mmol} \mathrm{OH}^{-}\)has been added:
Volume of \(\mathrm{NaOH}(\) in mL\() \times 0.100 \mathrm{M}=2.50 \mathrm{mmol} \mathrm{OH}^{-}\)
or
\[
\text { Volume of } \mathrm{NaOH}=25.0 \mathrm{~mL}
\]

As was pointed out previously, at the halfway point [ HCN ] is equal to [ \(\mathrm{CN}^{-}\)] and pH is equal to \(\mathrm{p} K_{\mathrm{a}}\). Thus, after 25.0 mL of 0.100 M NaOH has been added,
\[
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}=-\log \left(6.2 \times 10^{-10}\right)=9.21
\]
c. At the equivalence point. The equivalence point will occur when a total of \(5.00 \mathrm{mmol} \mathrm{OH}^{-}\)has been added. Since the NaOH solution is 0.100 M , the equivalence point occurs when 50.0 mL NaOH has been added. This amount will form \(5.00 \mathrm{mmol} \mathrm{CN}{ }^{-}\). The major species in solution at the equivalence point are
\[
\mathrm{CN}^{-}, \quad \mathrm{Na}^{+}, \quad \text { and } \mathrm{H}_{2} \mathrm{O}
\]

Thus the reaction that will control the pH involves the basic cyanide ion extracting a proton from water:
\[
\begin{gathered}
\mathrm{CN}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HCN}(a q)+\mathrm{OH}^{-}(a q) \\
K_{\mathrm{b}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}=\frac{1.0 \times 10^{-14}}{6.2 \times 10^{-10}}=1.6 \times 10^{-5}=\frac{[\mathrm{HCN}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{CN}^{-}\right]}
\end{gathered}
\]
\begin{tabular}{lll}
\hline Initial Concentration & & Equilibrium Concentration \\
\hline\(\left[\mathrm{CN}^{-}\right]_{0}=\frac{5.00 \mathrm{mmol}}{(50.0+50.0) \mathrm{mL}}\) & & \begin{tabular}{ll}
\(x \mathrm{mmol} / \mathrm{mL}\) of \\
\(=5.00 \times 10^{-2} \mathrm{M}\) & \(\xrightarrow[\text { with } \mathrm{H}_{2} \mathrm{O}]{ }\)
\end{tabular} \\
\begin{tabular}{lll}
{\([\mathrm{CN}]=\left(5.00 \times 10^{-2}\right)-x\)} \\
{\([\mathrm{HCN}]_{0}=0\)} & & {\(\left[\mathrm{OH}^{-}\right]=x\)}
\end{tabular} \\
{\(\left[\mathrm{OH}^{-}\right]_{0} \approx 0\)} & & \\
\hline
\end{tabular}

The corresponding ICE table is
\begin{tabular}{|lcccccc|}
\hline & \(\mathrm{CN}^{-}(a q)\) & + & \(\mathrm{H}_{2} \mathrm{O}(I)\) & \(\rightleftharpoons\) & \(\mathrm{HCN}(a q)\) & + \\
\(\mathrm{OH}^{-}(a q)\) \\
Initial & 0.050 & - & & 0 & 0 \\
Change & \(-x\) & - & & \(+x\) & \(+x\) \\
Equilibrium & \(0.050-x\) & - & & \(x\) & \(x\) \\
\hline
\end{tabular}

Substituting the equilibrium concentrations into the expression for \(K_{\mathrm{b}}\) and solving in the usual way gives
\[
\left[\mathrm{OH}^{-}\right]=x=8.9 \times 10^{-4}
\]

Then, from \(K_{\mathrm{w}}\), we have
\[
\left.\square \mathrm{H}^{+}\right]=1.1 \times 10^{-11} M \quad \text { and } \quad \mathrm{pH}=10.96
\]

\section*{See Exercises 15.65, 15.67, and 15.68}

The amount of acid present, not its strength, determines the equivalence point.

FIGURE 15.4 The pH curves for the titrations of \(50.0-\mathrm{mL}\) samples of 0.10 M acids with various \(K_{\mathrm{a}}\) values with 0.10 M NaOH .

Two important conclusions can be drawn from a comparison of the titration of 50.0 mL of 0.1 M acetic acid covered earlier in this section and that of 50.0 mL of \(0.1 M\) hydrocyanic acid analyzed in Example 15.9. First, the same amount of \(0.1 M\) NaOH is required to reach the equivalence point in both cases. The fact that HCN is a much weaker acid than \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) has no bearing on the amount of base required. It is the amount of acid, not its strength, that determines the equivalence point. Second, the pH value at the equivalence point is affected by the acid strength. For the titration of acetic acid, the pH at the equivalence point is 8.72 ; for the titration of hydrocyanic acid, the pH at the equivalence point is 10.96 . This difference occurs because the \(\mathrm{CN}^{-}\) ion is a much stronger base than the \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}\)ion. Also, the pH at the halfway point of the titration is much higher for HCN than for \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\), again because of the greater base strength of the \(\mathrm{CN}^{-}\)ion (or, equivalently, the smaller acid strength of HCN).

The strength of a weak acid has a significant effect on the shape of its pH curve. Figure 15.4 shows pH curves for \(50-\mathrm{mL}\) samples of 0.10 M solutions of various acids titrated with 0.10 M NaOH . Note that the equivalence point occurs in each case when the same volume of 0.10 M NaOH has been added but that the shapes of the curves are dramatically different. The weaker the acid, the greater the pH value at the equivalence point. In particular, note that the vertical region that surrounds the equivalence point becomes shorter as the acid being titrated becomes weaker. We will see in the next section that the choice of an indicator is more limited for such a titration.

Besides being used to analyze for the amount of acid or base in a solution, titrations can be used to determine the values of equilibrium constants, as shown in Example 15.10 .

\section*{Calculation of \(K_{\text {a }}\)}

\section*{INTERACTIVE EXAMPLE 15.10}

\section*{SOLUTION We represent the monoprotic acid as HA. The stoichiometry for the titration reaction is} shown below.

\section*{Calculating \(K_{\mathrm{a}}\)}

A chemist has synthesized a monoprotic weak acid and wants to determine its \(K_{\mathrm{a}}\) value. To do so, the chemist dissolves 2.00 mmol of the solid acid in 100.0 mL water and titrates the resulting solution with 0.0500 M NaOH . After 20.0 mL NaOH has been added, the pH is 6.00 . What is the \(K_{\mathrm{a}}\) value for the acid?
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline & HA & \(+\) & \(\mathrm{OH}^{-}\) & \(\longrightarrow\) & \(\mathrm{A}^{-}\) & + & \(\mathrm{H}_{2} \mathrm{O}\) \\
\hline Before reaction & 2.00 mmol & & \[
\begin{gathered}
20.0 \mathrm{~mL} \times 0.0500 \mathrm{M} \\
=1.00 \mathrm{mmol}
\end{gathered}
\] & & 0 mmol & & \\
\hline After reaction & \[
\begin{aligned}
& 2.00-1.00 \\
& =1.00 \mathrm{mmol}
\end{aligned}
\] & & \(1.00-1.00=0\) & & 1.00 mmol & & \\
\hline
\end{tabular}

After the reaction the solution contains the major species
\[
\mathrm{HA}, \quad \mathrm{~A}^{-}, \quad \mathrm{Na}^{+}, \text {and } \mathrm{H}_{2} \mathrm{O}
\]

The pH will be determined by the equilibrium
for which
\[
\begin{aligned}
\mathrm{HA}(a q) & \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{A}^{-}(a q) \\
K_{\mathrm{a}} & =\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
\end{aligned}
\]
\[
\begin{array}{rlrl}
\text { Initial Concentration } & & \text { Equilibrium Concentration } \\
\begin{aligned}
{[\mathrm{HA}]_{0} } & =\frac{1.00 \mathrm{mmol}}{(100.0+20.0) \mathrm{mL}} & & {[\mathrm{HA}]=8.33 \times 10^{-3}-x } \\
& =8.33 \times 10^{-3} \mathrm{M} & & \\
{\left[\mathrm{~A}^{-}\right]_{0} } & =\frac{1.00 \mathrm{mmol}}{(100.0+20.0) \mathrm{mL}} & \xrightarrow[\text { dissociates }]{\mathrm{HA}} & {\left[\mathrm{~A}^{-}\right]=8.33 \times 10^{-3}+x } \\
& =8.33 \times 10^{-3} \mathrm{M} & & {\left[\mathrm{H}^{+}\right]=x }
\end{aligned} \\
{\left[\mathrm{H}^{+}\right]_{0}} & \approx 0 & &
\end{array}
\]

The corresponding ICE table is
\begin{tabular}{|ccccc|}
\hline & \(\mathrm{HA}(a q)\) & \(\rightleftharpoons\) & \(\mathrm{H}^{+}(a q)\) & + \\
Initial & \(8.33 \times 10^{-3}\) & & \(\approx 0\) & \(\mathrm{~A}^{-}(a q)\) \\
Change & \(-x\) & & \(+x\) & \(8.33 \times 10^{-3}\) \\
Equilibrium & \(8.33 \times 10^{-3}-x\) & & \(x\) & \(+x\) \\
& & & & \(8.33 \times 10^{-3}+x\) \\
\hline
\end{tabular}

Note that \(x\) is known here because the pH at this point is known to be 6.00 . Thus
\[
x=\left[\mathrm{H}^{+}\right]=\operatorname{antilog}(-\mathrm{pH})=1.0 \times 10^{-6} M
\]

Substituting the equilibrium concentrations into the expression for \(K_{\mathrm{a}}\) allows calculation of the \(K_{\mathrm{a}}\) value:
\[
\begin{aligned}
\square K_{\mathrm{a}} & =\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}=\frac{x\left(8.33 \times 10^{-3}+x\right)}{\left(8.33 \times 10^{-3}\right)-x} \\
& =\frac{\left(1.0 \times 10^{-6}\right)\left(8.33 \times 10^{-3}+1.0 \times 10^{-6}\right)}{\left(8.33 \times 10^{-3}\right)-\left(1.0 \times 10^{-6}\right)} \\
& \approx \frac{\left(1.0 \times 10^{-6}\right)\left(8.33 \times 10^{-3}\right)}{8.33 \times 10^{-3}}=1.0 \times 10^{-6}
\end{aligned}
\]

There is an easier way to think about this problem. The original solution contained 2.00 mmol of HA, and since 20.0 mL of added 0.0500 M NaOH contains 1.0 mmol \(\mathrm{OH}^{-}\), this is the halfway point in the titration (where [HA] is equal to \(\left[\mathrm{A}^{-}\right]\)). Thus
\[
\left[\mathrm{H}^{+}\right]=K_{\mathrm{a}}=1.0 \times 10^{-6}
\]

\section*{Titrations of Weak Bases with Strong Acids}

Titrations of weak bases with strong acids can be treated using the procedures we introduced previously. As always, you should think first about the major species in solution and decide whether a reaction occurs that runs essentially to completion. If such a reaction does occur, let it run to completion and do the stoichiometric calculations. Finally, choose the dominant equilibrium and calculate the pH .

\section*{(CASE STUDY Weak Base-Strong Acid Titration}

The calculations involved for the titration of a weak base with a strong acid will be illustrated by the titration of 100.0 mL of \(0.050 \mathrm{M} \mathrm{NH}_{3}\) with 0.10 M HCl .
A. Before the addition of any \(\mathbf{H C l}\).
1. Major species:
\[
\mathrm{NH}_{3} \text { and } \mathrm{H}_{2} \mathrm{O}
\]
\(\mathrm{NH}_{3}\) is a base and will seek a source of protons. In this case \(\mathrm{H}_{2} \mathrm{O}\) is the only available source.
2. No reactions occur that go to completion, since \(\mathrm{NH}_{3}\) cannot readily take a proton from \(\mathrm{H}_{2} \mathrm{O}\). This is evidenced by the small \(K_{\mathrm{b}}\) value for \(\mathrm{NH}_{3}\).
3. The equilibrium that controls the pH involves the reaction of ammonia with water:
\[
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
\]

Use \(K_{\mathrm{b}}\) to calculate \(\left[\mathrm{OH}^{-}\right.\)]. Although \(\mathrm{NH}_{3}\) is a weak base (compared with \(\mathrm{OH}^{-}\)), it produces much more \(\mathrm{OH}^{-}\)in this reaction than is produced from the autoionization of \(\mathrm{H}_{2} \mathrm{O}\).
B. Before the equivalence point.
1. Major species (before any reaction occurs):
\[
\mathrm{NH}_{3}, \underbrace{\mathrm{H}^{+}, \quad \mathrm{Cl}^{-},}_{\substack{\text { From added } \\ \mathrm{HCl}}} \text { and } \mathrm{H}_{2} \mathrm{O}
\]

FIGURE 15.5 The pH curve for the titration of 100.0 mL of \(0.050 \mathrm{M} \mathrm{NH}_{3}\) with 0.10 M HCl . Note the pH at the equivalence point is less than 7 , since the solution contains the weak acid \(\mathrm{NH}_{4}{ }^{+}\).
2. The \(\mathrm{NH}_{3}\) will react with \(\mathrm{H}^{+}\)from the added HCl :
\[
\mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)
\]

This reaction proceeds essentially to completion because the \(\mathrm{NH}_{3}\) readily reacts with a free proton. This case is much different from the previous case, where \(\mathrm{H}_{2} \mathrm{O}\) was the only source of protons. The stoichiometric calculations are then carried out using the known volume of 0.10 M HCl added.
3. After the reaction of \(\mathrm{NH}_{3}\) with \(\mathrm{H}^{+}\)is run to completion, the solution contains the following major species:
\[
\begin{aligned}
& \mathrm{NH}_{3}, \quad \underset{\uparrow}{\mathrm{NH}_{4}^{+}}, \quad \mathrm{Cl}^{-}, \text {and } \mathrm{H}_{2} \mathrm{O} \\
& \text { Formed in titration reaction }
\end{aligned}
\]

Note that the solution contains \(\mathrm{NH}_{3}\) and \(\mathrm{NH}_{4}{ }^{+}\), and the equilibria involving these species will determine \(\left[\mathrm{H}^{+}\right]\). You can use either the dissociation reaction of \(\mathrm{NH}_{4}{ }^{+}\)
\[
\mathrm{NH}_{4}^{+}(a q) \rightleftharpoons \mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q)
\]
or the reaction of \(\mathrm{NH}_{3}\) with \(\mathrm{H}_{2} \mathrm{O}\)
\[
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
\]
C. At the equivalence point.
1. By definition, the equivalence point occurs when all the original \(\mathrm{NH}_{3}\) is converted to \(\mathrm{NH}_{4}^{+}\). Thus the major species in solution are
\[
\mathrm{NH}_{4}^{+}, \mathrm{Cl}^{-}, \text {and } \mathrm{H}_{2} \mathrm{O}
\]
2. No reactions occur that go to completion.
3. The dominant equilibrium (the one that controls the \(\left[\mathrm{H}^{+}\right]\)) will be the dissociation of the weak acid \(\mathrm{NH}_{4}{ }^{+}\), for which
\[
K_{\mathrm{a}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{b}}\left(\text { for } \mathrm{NH}_{3}\right)}
\]
D. Beyond the equivalence point.
1. Excess HCl has been added, and the major species are
\[
\mathrm{H}^{+}, \quad \mathrm{NH}_{4}^{+}, \quad \mathrm{Cl}^{-}, \text {and } \mathrm{H}_{2} \mathrm{O}
\]
2. No reaction occurs that goes to completion.
3. Although \(\mathrm{NH}_{4}{ }^{+}\)will dissociate, it is such a weak acid that \(\left[\mathrm{H}^{+}\right]\)will be determined simply by the excess \(\mathrm{H}^{+}\):
\[
\left[\mathrm{H}^{+}\right]=\frac{\mathrm{mmol} \mathrm{H}^{+} \text {in excess }}{\mathrm{mL} \text { solution }}
\]

The results of these calculations are shown in Table 15.2. The pH curve is shown in Fig. 15.5.

\title{
TABLE 15.2 | Summary of Results for the Titration of \(100.0 \mathrm{~mL} 0.050 \mathrm{M} \mathrm{NH}_{3}\) with 0.10 M HCl
}
\begin{tabular}{|c|c|c|c|c|}
\hline Volume of 0.10 M HCl Added (mL) & \(\left[\mathrm{NH}_{3}\right]_{0}\) & \(\left[\mathrm{NH}_{4}{ }^{+}\right]_{0}\) & [ \(\mathrm{H}^{+}\)] & pH \\
\hline 0 & 0.05 M & 0 & \(1.1 \times 10^{-11} \mathrm{M}\) & 10.96 \\
\hline 10.0 & \[
\frac{4.0 \mathrm{mmol}}{(100+10) \mathrm{mL}}
\] & \[
\frac{1.0 \mathrm{mmol}}{(100+10) \mathrm{mL}}
\] & \(1.4 \times 10^{-10} \mathrm{M}\) & 9.85 \\

\hline 60.0才 & 0 & \[
\frac{5.0 \mathrm{mmol}}{(100+60) \mathrm{mL}}
\] & \[
\frac{1.0 \mathrm{mmol}}{160 \mathrm{~mL}}=6.2 \times 10^{-3} \mathrm{M}
\] & 2.21 \\
\hline
\end{tabular}

요나Aㄴ ThINKINE You have read about titrations of strong acids with strong bases, weak acids with strong bases, and weak bases with strong acids. What if you titrated a weak acid with a weak base? Sketch a pH curve and defend its shape. Label the equivalence point and discuss the possibilities for the pH value at the equivalence point.

\subsection*{15.5 Acid-Base Indicators}

A
The indicator phenolphthalein is colorless in acidic solution and pink in basic solution.

There are two common methods for determining the equivalence point of an acid-base titration:
1. Use a pH meter (see Fig. 14.7) to monitor the pH and then plot the titration curve. The center of the vertical region of the pH curve indicates the equivalence point (for example, see Figs. 15.1 through 15.5).
2. Use an acid-base indicator, which marks the end point of a titration by changing color. Although the equivalence point of a titration, defined by the stoichiometry, is not necessarily the same as the end point (where the indicator changes color), careful selection of the indicator will ensure that the error is negligible.

The most common acid-base indicators are complex molecules that are themselves weak acids (represented by HIn). They exhibit one color when the proton is attached to the molecule and a different color when the proton is absent. For example, phenolphthalein, a commonly used indicator, is colorless in its HIn form and pink in its \(\mathrm{In}^{-}\), or basic, form. The actual structures of the two forms of phenolphthalein are shown in Fig. 15.6.

To see how molecules such as phenolphthalein function as indicators, consider the following equilibrium for some hypothetical indicator HIn, a weak acid with \(K_{\mathrm{a}}=1.0 \times 10^{-8}\).
\[
\begin{aligned}
\underset{\operatorname{Red}}{\operatorname{HIn}(a q)} & \rightleftharpoons \mathrm{H}^{+}(a q)+\underset{\text { Blue }}{\operatorname{In}^{-}(a q)} \\
K_{\mathrm{a}} & =\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{In}^{-}\right]}{[\mathrm{Hn}]}
\end{aligned}
\]

FIGURE \(\mathbf{1 5 . 6}\) The acid and base forms of the indicator phenolphthalein. In the acid form ( HIn ), the molecule is colorless. When a proton (plus \(\mathrm{H}_{2} \mathrm{O}\) ) is removed to give the base form \(\left(\mathrm{In}^{-}\right)\), the color changes to pink.

The end point is defined by the change in color of the indicator. The equivalence point is defined by the reaction stoichiometry.

Colorless acid form, HIn

Pink base form, \(\mathbf{I n}^{-}\)

By rearranging, we get
\[
\frac{K_{\mathrm{a}}}{\left[\mathrm{H}^{+}\right]}=\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}
\]

Suppose we add a few drops of this indicator to an acidic solution whose pH is \(1.0\left(\left[\mathrm{H}^{+}\right]=1.0 \times 10^{-1}\right)\). Then
\[
\frac{K_{\mathrm{a}}}{\left[\mathrm{H}^{+}\right]}=\frac{1.0 \times 10^{-8}}{1.0 \times 10^{-1}}=10^{-7}=\frac{1}{10,000,000}=\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}
\]

This ratio shows that the predominant form of the indicator is HIn, resulting in a red solution. \(\mathrm{As}_{\mathrm{OH}}{ }^{-}\)is added to this solution in a titration, \(\left[\mathrm{H}^{+}\right]\)decreases and the equilibrium shifts to the right, changing HIn to \(\mathrm{In}^{-}\). At some point in a titration, enough of the \(\mathrm{In}^{-}\)form will be present in the solution so that a purple tint will be noticeable. That is, a color change from red to reddish purple will occur.

How much \(\mathrm{In}^{-}\)must be present for the human eye to detect that the color is different from the original one? For most indicators, about a tenth of the initial form must be converted to the other form before a new color is apparent. We will assume, then, that in the titration of an acid with a base, the color change will occur at a pH where
\[
\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}=\frac{1}{10}
\]

\section*{EXAMPLE 15.11 Indicator Color Change}

Bromthymol blue, an indicator with a \(K_{\mathrm{a}}\) value of \(1.0 \times 10^{-7}\), is yellow in its HIn form and blue in its \(\mathrm{In}^{-}\)form. Suppose we put a few drops of this indicator in a strongly acidic solution. If the solution is then titrated with NaOH , at what pH will the indicator color change first be visible?
SOLUTION For bromthymol blue,
\[
K_{\mathrm{a}}=1.0 \times 10^{-7}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}
\]

We assume that the color change is visible when
\[
\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}=\frac{1}{10}
\]

That is, we assume that we can see the first hint of a greenish tint (yellow plus a little blue) when the solution contains 1 part blue and 10 parts yellow (Fig. 15.7). Thus
\[
\begin{gathered}
K_{\mathrm{a}}=1.0 \times 10^{-7}=\frac{\left[\mathrm{H}^{+}\right](1)}{10} \\
{\left[\mathrm{H}^{+}\right]=1.0 \times 10^{-6} \text { or } \mathrm{pH}=6.00}
\end{gathered}
\]

The color change is first visible at pH 6.00 .

FIGURE 15.7 (a) Yellow acid form of bromthymol blue; (b) a greenish tint is seen when the solution contains 1 part blue and 10 parts yellow;
(c) blue basic form.

The Henderson-Hasselbalch equation is very useful in determining the pH at which an indicator changes color. For example, application of Equation (15.2) to the \(K_{\mathrm{a}}\) expression for the general indicator HIn yields
\[
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}\right)
\]
where \(K_{\mathrm{a}}\) is the dissociation constant for the acid form of the indicator (HIn). Since we assume that the color change is visible when
\[
\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}=\frac{1}{10}
\]
we have the following equation for determining the pH at which the color change occurs:
\[
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{1}{10}\right)=\mathrm{p} K_{\mathrm{a}}-1
\]

For bromthymol blue ( \(K_{\mathrm{a}}=1 \times 10^{-7}\), or \(\mathrm{p} K_{\mathrm{a}}=7\) ), the pH at the color change is
\[
\mathrm{pH}=7-1=6
\]
as we calculated in Example 15.11.
When a basic solution is titrated, the indicator HIn will initially exist as \(\mathrm{In}^{-}\)in solution, but as acid is added, more HIn will be formed. In this case the color change will be visible when there is a mixture of 10 parts \(\mathrm{In}^{-}\)and 1 part HIn. That is, a color change from blue to blue-green will occur (see Fig. 15.7) due to the presence of some of the yellow HIn molecules. This color change will be first visible when
\[
\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}=\frac{10}{1}
\]

Note that this is the reciprocal of the ratio for the titration of an acid. Substituting this ratio into the Henderson-Hasselbalch equation gives
\[
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{10}{1}\right)=\mathrm{p} K_{\mathrm{a}}+1
\]

For bromthymol blue \(\left(\mathrm{p} K_{\mathrm{a}}=7\right)\), we have a color change at
\[
\mathrm{pH}=7+1=8
\]

In summary, when bromthymol blue is used for the titration of an acid, the starting form will be HIn (yellow), and the color change occurs at a pH of about 6 . When bromthymol blue is used for the titration of a base, the starting form is \(\mathrm{In}^{-}\)(blue), and the color change occurs at a pH of about 8 . Thus the useful pH range for bromthymol blue is
\[
\mathrm{p} K_{\mathrm{a}}(\text { bromthymol blue }) \pm 1=7 \pm 1
\]
or from 6 to 8 . This is a general result. For a typical acid-base indicator with dissociation constant \(K_{\mathrm{a}}\), the color transition occurs over a range of pH values given by \(\mathrm{p} K_{\mathrm{a}} \pm 1\). The useful pH ranges for several common indicators are shown in Fig. 15.8.

The pH ranges shown are approximate. Specific transition ranges depend on the indicator solvent chosen.
FIGURE 15.8 The useful pH ranges for several common indicators. Note that most indicators have a useful range of about two pH units, as predicted by the expression \(\mathrm{p} K_{\mathrm{a}} \pm 1\).

\section*{\(\Delta\)}

Universal indicator paper can be used to estimate the pH of a solution.

TABLE 15.3 | Selected pH Values Near the Equivalence Point in the Titration of 100.0 mL of 0.10 M HCl with 0.10 M NaOH
\begin{tabular}{|cc|}
\hline NaOH Added (mL) & pH \\
\hline 99.99 & 5.3 \\
\hline 100.00 & 7.0 \\
\hline 100.01 & 8.7 \\
\hline
\end{tabular}

A
Methyl red indicator is yellow in basic solution and red in acidic solution.

When we choose an indicator for a titration, we want the indicator end point (where the color changes) and the titration equivalence point to be as close as possible. Choosing an indicator is easier if there is a large change in pH near the equivalence point of the titration. The dramatic change in pH near the equivalence point in a strong acidstrong base titration (see Figs. 15.1 and 15.2) produces a sharp end point; that is, the complete color change (from the acid-to-base or base-to-acid colors) usually occurs over one drop of added titrant.

What indicator should we use for the titration of 100.00 mL of 0.100 M HCl with 0.100 M NaOH ? We know that the equivalence point occurs at pH 7.00 . In the initially acidic solution, the indicator will be predominantly in the HIn form. As \(\mathrm{OH}^{-}\) ions are added, the pH increases rather slowly at first (see Fig. 15.1) and then rises rapidly at the equivalence point. This sharp change causes the indicator dissociation equilibrium
\[
\mathrm{HIn} \rightleftharpoons \mathrm{H}^{+}+\mathrm{In}^{-}
\]
to shift suddenly to the right, producing enough \(\mathrm{In}^{-}\)ions to give a color change. Since we are titrating an acid, the indicator is predominantly in the acid form initially. Therefore, the first observable color change will occur at a pH where
\[
\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}=\frac{1}{10}
\]

Thus
\[
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{1}{10}\right)=\mathrm{p} K_{\mathrm{a}}-1
\]

If we want an indicator that changes color at pH 7 , we can use this relationship to find the \(\mathrm{p} K_{\mathrm{a}}\) value for a suitable indicator:
\[
\mathrm{pH}=7=\mathrm{p} K_{\mathrm{a}}-1 \quad \text { or } \quad \mathrm{p} K_{\mathrm{a}}=7+1=8
\]

Thus an indicator with a \(\mathrm{p} K_{\mathrm{a}}\) value of \(8\left(K_{\mathrm{a}}=1 \times 10^{-8}\right)\) changes color at about pH 7 and is ideal for marking the end point for a strong acid-strong base titration.

How crucial is it for a strong acid-strong base titration that the indicator change color exactly at pH 7 ? We can answer this question by examining the pH change near the equivalence point of the titration of 100 mL of 0.10 M HCl and 0.10 M NaOH . The data for a few points at or near the equivalence point are shown in Table 15.3. Note that in going from 99.99 to 100.01 mL of added NaOH solution (about half of a drop), the pH changes from 5.3 to 8.7 -a very dramatic change. This behavior leads to the following general conclusions about indicators for a strong acid-strong base titration:

Indicator color changes will be sharp, occurring with the addition of a single drop of titrant.

There is a wide choice of suitable indicators. The results will agree within one drop of titrant, using indicators with end points as far apart as pH 5 and pH 9 (Fig. 15.9).
The titration of weak acids is somewhat different. Figure 15.4 shows that the weaker the acid being titrated, the smaller the vertical area around the equivalence point. This allows much less flexibility in choosing the indicator. We must choose an indicator whose useful pH range has a midpoint as close as possible to the pH at the equivalence point. For example, we saw earlier that in the titration of \(0.1 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) with \(0.1 M\) NaOH the pH at the equivalence point is 8.7 (see Fig. 15.3). A good indicator choice would be phenolphthalein, since its useful pH range is 8 to 10 . Thymol blue (changes color, \(\mathrm{pH} 8-9\) ) also would be acceptable, but methyl red would not. The choice of an indicator is illustrated graphically in Fig. 15.10.

FIGURE 15.9 The pH curve for the titration of 100.0 mL of 0.10 M HCl with 0.10 M NaOH . Note that the end points of phenolphthalein and methyl red occur at virtually the same amounts of added NaOH .

FIGURE 15.10 The pH curve for the titration of 50 mL of \(0.1 \mathrm{M} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) with 0.1 M NaOH . Phenolphthalein will give an end point very close to the equivalence point of the titration. Methyl red would change color well before the equivalence point (so the end point would be very different from the equivalence point) and would not be a suitable indicator for this titration.

\subsection*{15.6 Polyprotic Acid Titrations}

In Chapter 14 we discussed polyprotic acids, or acids that can furnish more than one proton. The acid titrations we have considered so far have involved only monoprotic acids. When a polyprotic acid is titrated, the pH curve has similar features to those of a monoprotic acid, but enough differences exist to warrant special coverage.

Recall from Chapter 14 that a polyprotic acid dissociates in a stepwise manner, one proton at a time. In a titration of a polyprotic acid, the various acidic protons are titrated in succession as well.

For example, as sodium hydroxide is used to titrate phosphoric acid, the first reaction that takes place can be represented as
\[
\mathrm{H}_{3} \mathrm{PO}_{4}(a q)+\mathrm{OH}^{-}(a q) \rightarrow \mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
\]

This reaction occurs until the \(\mathrm{H}_{3} \mathrm{PO}_{4}\) is consumed (to reach the first equivalence point). Therefore, at the first equivalence point the solution contains the major species \(\mathrm{Na}^{+}, \mathrm{H}_{2} \mathrm{PO}_{4}^{-}\), and \(\mathrm{H}_{2} \mathrm{O}\). Then, as more sodium hydroxide is added, the reaction
\[
\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{OH}^{-}(a q) \rightarrow \mathrm{HPO}_{4}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
\]
occurs to give a solution that contains \(\mathrm{Na}^{+}, \mathrm{HPO}_{4}{ }^{2-}\), and \(\mathrm{H}_{2} \mathrm{O}\) as the major species at the second equivalence point. As sodium hydroxide is added beyond the second equivalence point, the reaction that occurs can be represented as
\[
\mathrm{HPO}_{4}{ }^{2-}(a q)+\mathrm{OH}^{-}(a q) \rightarrow \mathrm{PO}_{4}{ }^{3-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
\]

Although we will not fully discuss the calculations involved in obtaining the pH curve for a polyprotic acid, the calculations are closely related to those for a monoprotic acid. The same principles apply, but we must be very careful in identifying which of the various equilibria is appropriate to use in a given case. The secret to success here is, as always, identifying the major species in solution at any given point in the titration. We summarize the various cases in Table 15.4 for a triprotic acid \(\mathrm{H}_{3} \mathrm{~A}\) with dissociation constants \(K_{\mathrm{a}_{1}}, K_{\mathrm{a}_{2}}\), and \(K_{\mathrm{a}_{3}}\).

FIGURE 15.11 A summary of the major species present at various points in the titration of a triprotic acid.

Volume added
FIGURE 15.12 A typical pH curve for the titration of a diprotic acid.

TABLE 15.4 | A Summary of Various Points in the Titration of a Triprotic Acid
\begin{tabular}{lc|}
\hline Point in the Titration & Major Species Present \\
\hline No base added & \(\mathrm{H}_{3} \mathrm{~A}, \mathrm{H}_{2} \mathrm{O}\) \\
\hline Base added & \(\mathrm{H}_{3} \mathrm{~A}, \mathrm{H}_{2} \mathrm{~A}^{-}, \mathrm{H}_{2} \mathrm{O}\) \\
\hline Before the first equivalence point & \(\mathrm{H}_{2} \mathrm{~A}^{-}, \mathrm{H}_{2} \mathrm{O}\) \\
\hline At the first equivalence point & \(\mathrm{H}_{2} \mathrm{~A}^{-}, \mathrm{HA}^{2-}, \mathrm{H}_{2} \mathrm{O}\) \\
\hline Between the first and second equivalence points & \(\mathrm{HA}^{2-}, \mathrm{H}_{2} \mathrm{O}\) \\
\hline At the second equivalence point & \(\mathrm{HA}^{2-}, \mathrm{A}^{3-}, \mathrm{H}_{2} \mathrm{O}\) \\
\hline Between the second and third equivalence points & \(\mathrm{A}^{3-}, \mathrm{H}_{2} \mathrm{O}\) \\
\hline At the third equivalence point & \(\mathrm{A}^{3-}, \mathrm{OH}^{-}, \mathrm{H}_{2} \mathrm{O}\) \\
\hline Beyond the third equivalence point & \\
\hline
\end{tabular}

Recall that at the halfway point in the titration of a monoprotic weak acid with a strong base, the pH of the solution is equal in value to the \(\mathrm{p} K_{\mathrm{a}}\) of the weak acid. Through similar reasoning, it turns out that we can use a pH curve for the titration of a polyprotic acid with a strong base to determine the \(K_{\mathrm{a}}\) values of the given acid. We can see this in a pH curve for the titration of the generic triprotic acid \(\mathrm{H}_{3} \mathrm{~A}\) with NaOH (Fig. 15.11).

Note that the pH can be easily determined at the first two equivalence points by using the average of the corresponding \(\mathrm{p} K_{\mathrm{a}}\) values. It turns out as well that the pH values at the half-equivalence points can be estimated as equal to the corresponding \(\mathrm{p} K\) values. Thus, \(\mathrm{pH} \approx \mathrm{p} K_{\mathrm{a}_{1}}\) for the first half-equivalence point, \(\mathrm{pH} \approx \mathrm{p} K_{\mathrm{a}_{2}}\) at the second half-equivalence point, and \(\mathrm{pH} \approx \mathrm{p} K_{\mathrm{a}_{3}}\) at the third half-equivalence point.

We can also use pH curves to easily determine the number of acidic protons on a particular acid. Recall that the pH curve for the titration of a monoprotic acid (one acidic proton, HA) has one equivalence point. The previous discussion shows that a pH curve for a triprotic acid (three acidic protons, \(\mathrm{H}_{3} \mathrm{~A}\) ) has three equivalence points. As expected, the pH curve for the titration of a diprotic acid (two acidic protons, \(\mathrm{H}_{2} \mathrm{~A}\) ) has two equivalence points. A typical pH curve for the titration curve for a diprotic acid is given in Fig. 15.12.

Note that we can determine the pH values at various points on the curve by using the appropriate \(\mathrm{p} K_{\mathrm{a}}\) values, just as we saw with the titration of a triprotic acid.

\section*{Buffered solutions}
> Contains a weak acid (HA) and its salt ( NaA ) or a weak base (B) and its salt ( BHCl )
> Resists a change in its pH when \(\mathrm{H}^{+}\)or \(\mathrm{OH}^{-}\)is added
> For a buffered solution containing HA and \(\mathrm{A}^{-}\)
> The Henderson-Hasselbalch equation is useful:
\[
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}\right)
\]
> The capacity of the buffered solution depends on the amounts of HA and \(\mathrm{A}^{-}\)present
, The most efficient buffering occurs when the \(\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}\) ratio is close to 1
> Buffering works because the amounts of HA (which reacts with added \(\mathrm{OH}^{-}\)) and \(\mathrm{A}^{-}\)(which reacts with added \(\mathrm{H}^{+}\)) are large enough that the \(\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}\) ratio does not change significantly when strong acids or bases are added

\section*{Acid-base titrations}
> The progress of a titration is represented by plotting the pH of the solution versus the volume of added titrant; the resulting graph is called a pH curve or titration curve
> Strong acid-strong base titrations show a sharp change in pH near the equivalence point
> The shape of the pH curve for a strong base-strong acid titration before the equivalence point is quite different from the shape of the pH curve for a strong base-weak acid titration
> The strong base-weak acid pH curve shows the effects of buffering before the equivalence point
> For a strong base-weak acid titration, the pH is greater than 7 at the equivalence point because of the basic properties of \(\mathrm{A}^{-}\)
> Indicators are sometimes used to mark the equivalence point of an acid-base titration
) The end point is where the indicator changes color
> The goal is to have the end point and the equivalence point be as close as possible

\section*{Review Questions Answers to the Review Questions can be found on the Student website (accessible from www.cengagebrain.com).}
1. What is meant by the presence of a common ion? How does the presence of a common ion affect an equilibrium such as
\[
\mathrm{HNO}_{2}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{NO}_{2}^{-}(a q)
\]

What is an acid-base solution called that contains a common ion?
2. Define a buffer solution. What makes up a buffer solution? How do buffers absorb added \(\mathrm{H}^{+}\)or \(\mathrm{OH}^{-}\)with little pH change?

Is it necessary that the concentrations of the weak acid and the weak base in a buffered solution be equal? Explain. What is the pH of a buffer when the weak acid and conjugate base concentrations are equal?

A buffer generally contains a weak acid and its weak conjugate base, or a weak base and its weak conjugate acid, in water. You can solve for the pH by setting up the equilibrium problem using the \(K_{\mathrm{a}}\) reaction of the weak acid or the \(K_{\mathrm{b}}\) reaction of the conjugate base. Both
reactions give the same answer for the pH of the solution. Explain.

A third method that can be used to solve for the pH of a buffer solution is the Henderson-Hasselbalch equation. What is the Henderson-Hasselbalch equation? What assumptions are made when using this equation?
3. One of the most challenging parts of solving acid-base problems is writing out the correct equation. When a strong acid or a strong base is added to solutions, they are great at what they do and we always react them first. If a strong acid is added to a buffer, what reacts with the \(\mathrm{H}^{+}\)from the strong acid and what are the products? If a strong base is added to a buffer, what reacts with the \(\mathrm{OH}^{-}\)from the strong base and what are the products? Problems involving the reaction of a strong acid or strong base are assumed to be stoichiometry problems and not equilibrium problems. What is assumed when a strong acid or strong base reacts to make it a stoichiometry problem?
4. A good buffer generally contains relatively equal concentrations of weak acid and conjugate base. If you wanted to buffer a solution at \(\mathrm{pH}=4.00\) or \(\mathrm{pH}=10.00\), how would you decide which weak acidconjugate base or weak base-conjugate acid pair to use? The second characteristic of a good buffer is good buffering capacity. What is the capacity of a buffer? How do the following buffers differ in capacity? How do they differ in pH ?
0.01 M acetic acid/ 0.01 M sodium acetate
\(0.1 M\) acetic acid/ 0.1 M sodium acetate
1.0 \(M\) acetic acid/1.0 \(M\) sodium acetate
5. Draw the general titration curve for a strong acid titrated by a strong base. At the various points in the titration, list the major species present before any reaction takes place and the major species present after any reaction takes place. What reaction takes place in a strong acid-strong base titration? How do you calculate the pH at the various points along the curve? What is the pH at the equivalence point for a strong acid-strong base titration? Why?
6. Instead of the titration of a strong acid by a strong base considered in Question 5, consider the titration of a strong base by a strong acid. Compare and contrast a strong acid-strong base titration with a strong basestrong acid titration.
7. Sketch the titration curve for a weak acid titrated by a strong base. When performing calculations concerning weak acid-strong base titrations, the general two-step procedure is to solve a stoichiometry problem first, then to solve an equilibrium problem to determine the pH . What reaction takes place in the stoichiometry part of the problem? What is assumed about this reaction?

At the various points in your titration curve, list the major species present after the strong base \((\mathrm{NaOH}\), for example) reacts to completion with the weak acid, HA. What equilibrium problem would you solve at the various points in your titration curve to calculate the pH ? Why is \(\mathrm{pH}>7.0\) at the equivalence point of a weak acid-strong base titration? Does the pH at the halfway point to equivalence have to be less than 7.0 ? What does the pH at the halfway point equal? Compare and contrast the titration curves for a strong acidstrong base titration and a weak acid-strong base titration.
8. Sketch the titration curve for a weak base titrated by a strong acid. Weak base-strong acid titration problems also follow a two-step procedure. What reaction takes place in the stoichiometry part of the problem? What is assumed about this reaction? At the various points in your titration curve, list the major species present after the strong acid \(\left(\mathrm{HNO}_{3}\right.\), for example) reacts to completion with the weak base, B. What equilibrium problem would you solve at the various points in your titration curve to calculate the pH ? Why is \(\mathrm{pH}<7.0\) at the equivalence point of a weak base-strong acid titration? If \(\mathrm{pH}=6.0\) at the halfway point to equivalence, what is the \(K_{\mathrm{b}}\) value for the weak base titrated? Compare and contrast the titration curves for a strong basestrong acid titration and a weak base-strong acid titration.
9. What is an acid-base indicator? Define the equivalence (stoichiometric) point and the end point of a titration. Why should you choose an indicator so that the two points coincide? Do the pH values of the two points have to be within \(\pm 0.01 \mathrm{pH}\) unit of each other? Explain.
10. Why does an indicator change from its acid color to its base color over a range of pH values? In general, when do color changes start to occur for indicators? Can the indicator thymol blue contain only a single \(-\mathrm{CO}_{2} \mathrm{H}\) group and no other acidic or basic functional group? Explain.

\section*{Active Learning Questions}

These questions are designed to be used by groups of students in class.
1. What are the major species in solution after \(\mathrm{NaHSO}_{4}\) is dissolved in water? What happens to the pH of the solution as more \(\mathrm{NaHSO}_{4}\) is added? Why? Would the results vary if baking soda \(\left(\mathrm{NaHCO}_{3}\right)\) were used instead?
2. A friend asks the following: "Consider a buffered solution made up of the weak acid HA and its salt NaA . If a strong base like NaOH is added, the HA reacts with the \(\mathrm{OH}^{-}\)to form \(\mathrm{A}^{-}\). Thus the amount of acid (HA) is decreased, and the amount of base \(\left(\mathrm{A}^{-}\right)\)is increased. Analogously, adding HCl to the buffered solution forms more of the acid (HA) by reacting with the base ( \(\mathrm{A}^{-}\)). Thus how can we claim that a buffered solution resists changes in the pH of the solution?" How would you explain buffering to this friend?
3. Mixing together solutions of acetic acid and sodium hydroxide can make a buffered solution. Explain. How does the amount of each solution added change the effectiveness of the buffer?
5. Sketch two pH curves, one for the titration of a weak acid with a strong base and one for a strong acid with a strong base. How are they similar? How are they different? Account for the similarities and the differences.
6. Sketch a pH curve for the titration of a weak acid (HA) with a strong base \((\mathrm{NaOH})\). List the major species, and explain how you would go about calculating the pH of the solution at various points, including the halfway point and the equivalence point.
7. You have a solution of the weak acid HA and add some HCl to it. What are the major species in the solution? What do you need to know to calculate the pH of the solution, and how would you use this information? How does the pH of the solution of just the HA compare with that of the final mixture? Explain.
8. You have a solution of the weak acid HA and add some of the salt NaA to it. What are the major species in the solution? What do you need to know to calculate the pH of the solution, and how would you use this information? How does the pH of the solution of just the HA compare with that of the final mixture? Explain.
9. If you wanted to prepare a \(\mathrm{pH}=7.0\) buffer, how would you choose the best components to make up this buffer? Reference Tables A5.1, A5.2, and A5.3 in Appendix 5 of this text. From each table, choose the best combination of components to make a \(\mathrm{pH}=7.0\) buffer.
10. Sketch the titration curves for a diprotic acid titrated by a strong base and a triprotic acid titrated by a strong base. List the major species present at various points in each curve. In each curve, label the halfway points to equivalence. How do you calculate the pH at these halfway points?

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

\section*{Questions}
11. The common ion effect for weak acids is to significantly decrease the dissociation of the acid in water. Explain the common ion effect.
12. Consider a buffer solution where [weak acid] \(>\) [conjugate base]. How is the pH of the solution related to the \(\mathrm{p} K_{\mathrm{a}}\) value of the weak acid? If [conjugate base] \(>\) [weak acid], how is pH related to \(\mathrm{p} K_{\mathrm{a}}\) ?
13. A best buffer has about equal quantities of weak acid and conjugate base present as well as having a large concentration of each species present. Explain.
14. Consider the following pH curves for 100.0 mL of two different acids with the same initial concentration each titrated by 0.10 M NaOH .

a. Which plot represents a pH curve of a weak acid, and which plot is for a strong acid? How can you tell? Cite three differences between the plots that help you decide.
b. In both cases the pH is relatively constant before the pH changes greatly. Does this mean that at some point in each titration each solution was a buffered solution?
c. True or false? The equivalence point volume for each titration is the same. Explain your answer.
d. True or false? The pH at the equivalence point for each titration is the same. Explain your answer.
15. An acid is titrated with NaOH . The following beakers are illustrations of the contents of the beaker at various times during the titration. These are presented out of order. Note: Counter-ions and water molecules have been omitted from the illustrations for clarity.
(a)

(b)

(c)

(e)

a. Is the acid a weak or strong acid? How can you tell?
b. Arrange the beakers in order of what the contents would look like as the titration progresses.
c. For which beaker would \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\) ? Explain your answer.
d. Which beaker represents the equivalence point of the titration? Explain your answer.
e. For which beaker would the \(K_{\mathrm{a}}\) value for the acid not be necessary to determine the pH ? Explain your answer.
16. Consider the following four titrations.
i. \(\quad 100.0 \mathrm{~mL}\) of 0.10 M HCl titrated by 0.10 M NaOH
ii. 100.0 mL of 0.10 M NaOH titrated by 0.10 M HCl
iii. 100.0 mL of \(0.10 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{2}\) titrated by 0.10 M HCl
iv. 100.0 mL of 0.10 M HF titrated by 0.10 M NaOH

Rank the titrations in order of:
a. increasing volume of titrant added to reach the equivalence point.
b. increasing pH initially before any titrant has been added.
c. increasing pH at the halfway point in equivalence.
d. increasing pH at the equivalence point.

How would the rankings change if \(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\) replaced \(\mathrm{CH}_{3} \mathrm{NH}_{2}\) and if \(\mathrm{HOC}_{6} \mathrm{H}_{5}\) replaced HF?
17. Figure 15.4 shows the pH curves for the titrations of six different acids by NaOH . Make a similar plot for the titration of three different bases by 0.10 M HCl . Assume 50.0 mL of 0.20 M of the bases and assume the three bases are a strong base \((\mathrm{KOH})\), a weak base with \(K_{\mathrm{b}}=1 \times 10^{-5}\), and another weak base with \(K_{\mathrm{b}}=1 \times 10^{-10}\).
18. Acid-base indicators mark the end point of titrations by "magically" turning a different color. Explain the "magic" behind acid-base indicators.
19. Consider the titration of 100.0 mL of \(0.10 \mathrm{M} \mathrm{H}_{3} \mathrm{AsO}_{4}\) by 0.10 \(M \mathrm{NaOH}\). What are the major species present at 50.0 mL of NaOH added? How would you calculate the pH at this point? Answer the same questions for 150.0 mL of NaOH added. At what volume of NaOH added does \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}_{3}}\) ?
20. Consider the following two acids:

\(\mathrm{p} K_{\mathrm{a}_{1}}=2.98 ; \mathrm{p} K_{\mathrm{a}_{2}}=13.40\)
\(\mathrm{HO}_{2} \mathrm{CCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{H}\)
Adipic acid
\[
\mathrm{p} K_{\mathrm{a}_{1}}=4.41 ; \mathrm{p} K_{\mathrm{a}_{2}}=5.28
\]

In two separate experiments the pH was measured during the titration of 5.00 mmol of each acid with 0.200 M NaOH . Each experiment showed only one stoichiometric point when the data were plotted. In one experiment the stoichiometric point was at 25.00 mL added NaOH , and in the other experiment the stoichiometric point was at 50.00 mL NaOH . Explain these results.

\section*{Exercises}

In this section similar exercises are paired.

\section*{Buffers}
-21. How many of the following are buffered solutions? Explain your answer. Note: Counter-ions and water molecules have been omitted from the illustrations for clarity.

22. Which of the following can be classified as buffer solutions?
a. \(0.25 \mathrm{M} \mathrm{HBr}+0.25 \mathrm{M} \mathrm{HOBr}\)
b. \(0.15 \mathrm{M} \mathrm{HClO}_{4}+0.20 \mathrm{M} \mathrm{RbOH}\)
c. \(0.50 \mathrm{M} \mathrm{HOCl}+0.35 \mathrm{M} \mathrm{KOCl}\)
d. \(0.70 \mathrm{M} \mathrm{KOH}+0.70 M \mathrm{HONH}_{2}\)
e. \(0.85 \mathrm{M} \mathrm{H}_{2} \mathrm{NNH}_{2}+0.60 \mathrm{M} \mathrm{H}_{2} \mathrm{NNH}_{3} \mathrm{NO}_{3}\)
23. A certain buffer is made by dissolving \(\mathrm{NaHCO}_{3}\) and \(\mathrm{Na}_{2} \mathrm{CO}_{3}\) in some water. Write equations to show how this buffer neutralizes added \(\mathrm{H}^{+}\)and \(\mathrm{OH}^{-}\).
24. A buffer is prepared by dissolving \(\mathrm{HONH}_{2}\) and \(\mathrm{HONH}_{3} \mathrm{NO}_{3}\) in some water. Write equations to show how this buffer neutralizes added \(\mathrm{H}^{+}\)and \(\mathrm{OH}^{-}\).
25. Calculate the pH of each of the following solutions.
a. 0.100 M propanoic acid \(\left(\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}, K_{\mathrm{a}}=1.3 \times 10^{-5}\right)\)
b. 0.100 M sodium propanoate \(\left(\mathrm{NaC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}\right)\)
c. pure \(\mathrm{H}_{2} \mathrm{O}\)
d. a mixture containing \(0.100 \mathrm{M} \mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}\) and 0.100 M \(\mathrm{NaC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}\)
26. Calculate the pH of each of the following solutions.
a. \(0.100 M \mathrm{HONH}_{2}\left(K_{\mathrm{b}}=1.1 \times 10^{-8}\right)\)
b. \(0.100 \mathrm{M} \mathrm{HONH}_{3} \mathrm{Cl}\)
c. pure \(\mathrm{H}_{2} \mathrm{O}\)
d. a mixture containing \(0.100 \mathrm{M} \mathrm{HONH}_{2}\) and 0.100 M \(\mathrm{HONH}_{3} \mathrm{Cl}\)

Compare the percent dissociation of the acid in Exercise 25a with the percent dissociation of the acid in Exercise 25d. Explain the large difference in percent dissociation of the acid.
28. Compare the percent ionization of the base in Exercise 26a with the percent ionization of the base in Exercise 26d. Explain any differences.
29. Calculate the pH after 0.020 mole of HCl is added to 1.00 L of each of the four solutions in Exercise 25.
30. Calculate the pH after 0.020 mole of HCl is added to 1.00 L of each of the four solutions in Exercise 26.
\({ }^{-31}\). Calculate the pH after 0.020 mole of NaOH is added to 1.00 L of each of the four solutions in Exercise 25.
32. Calculate the pH after 0.020 mole of NaOH is added to 1.00 L of each of the solutions in Exercise 26.
-33. Which of the solutions in Exercise 25 shows the least change in pH upon the addition of acid or base? Explain.
34. Which of the solutions in Exercise 26 is a buffered solution?

Calculate the pH of a solution that is \(1.00 \mathrm{MNO}_{2}\) and \(1.00 \mathrm{M} \mathrm{NaNO}_{2}\).
36. Calculate the pH of a solution that is 0.60 M HF and 1.00 MKF .
[37. Calculate the pH after 0.10 mole of NaOH is added to 1.00 L of the solution in Exercise 35, and calculate the pH after 0.20 mole of HCl is added to 1.00 L of the solution in Exercise 35.
38. Calculate the pH after 0.10 mole of NaOH is added to 1.00 L of the solution in Exercise 36, and calculate the pH after 0.20 mole of HCl is added to 1.00 L of the solution in Exercise 36.
\(\Gamma^{39}\) Calculate the pH of each of the following buffered solutions.
a. 0.10 M acetic acid \(/ 0.25 \mathrm{M}\) sodium acetate
b. 0.25 M acetic acid \(/ 0.10 \mathrm{M}\) sodium acetate
c. 0.080 M acetic acid \(/ 0.20 \mathrm{M}\) sodium acetate
d. 0.20 M acetic acid/ 0.080 M sodium acetate
40. Calculate the pH of each of the following buffered solutions.
a. \(0.50 M_{\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2} / 0.25} \mathrm{M}_{2} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{Cl}\)
b. \(0.25 \mathrm{M} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2} / 0.50 M \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{Cl}\)
c. \(0.50 M \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2} / 0.50 M \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{Cl}\)
41. Calculate the pH of a buffered solution prepared by dissolving 21.5 g benzoic acid \(\left(\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}\right)\) and 37.7 g sodium benzoate in 200.0 mL of solution.
42. A buffered solution is made by adding \(50.0 \mathrm{~g} \mathrm{NH}_{4} \mathrm{Cl}\) to 1.00 L of a \(0.75-\mathrm{M}\) solution of \(\mathrm{NH}_{3}\). Calculate the pH of the final solution. (Assume no volume change.)
43. Calculate the pH after 0.010 mole of gaseous HCl is added to 250.0 mL of each of the following buffered solutions.
a. \(0.050 \mathrm{M} \mathrm{NH}_{3} / 0.15 \mathrm{M} \mathrm{NH} 4 \mathrm{Cl}\)
b. \(0.50 \mathrm{M} \mathrm{NH}_{3} / 1.50 \mathrm{M} \mathrm{NH}_{4} \mathrm{Cl}\)

Do the two original buffered solutions differ in their pH or their capacity? What advantage is there in having a buffer with a greater capacity?
44. Calculate the pH after 0.15 mole of solid NaOH is added to 1.00 L of each of the following solutions:
a. \(0.050 M\) propanoic acid \(\left(\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}, K_{\mathrm{a}}=1.3 \times 10^{-5}\right)\) and 0.080 M sodium propanoate
b. 0.50 M propanoic acid and 0.80 M sodium propanoate
c. Is the solution in part a still a buffer solution after the NaOH has been added? Explain.
45. Some \(\mathrm{K}_{2} \mathrm{SO}_{3}\) and \(\mathrm{KHSO}_{3}\) are dissolved in 250.0 mL of solution and the resulting pH is 7.25 . Which is greater in this buffer solution, the concentration of \(\mathrm{SO}_{3}{ }^{2-}\) or the concentration of \(\mathrm{HSO}_{3}{ }^{-}\)? If \(\left[\mathrm{SO}_{3}{ }^{2-}\right]=1.0 \mathrm{M}\) in this solution, calculate the concentration of \(\mathrm{HSO}_{3}{ }^{-}\).
46. An aqueous solution contains dissolved \(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{Cl}\) and \(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}\). The concentration of \(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}\) is 0.50 M and pH is 4.20.
a. Calculate the concentration of \(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}\)in this buffer solution.
b. Calculate the pH after \(4.0 \mathrm{~g} \mathrm{NaOH}(s)\) is added to 1.0 L of this solution. (Neglect any volume change.)
47. Calculate the mass of sodium acetate that must be added to 500.0 mL of 0.200 M acetic acid to form a \(\mathrm{pH}=5.00\) buffer solution.
48. What volumes of \(0.50 M \mathrm{HNO}_{2}\) and \(0.50 M \mathrm{NaNO}_{2}\) must be mixed to prepare 1.00 L of a solution buffered at \(\mathrm{pH}=3.55\) ?
-49. Consider a solution that contains both \(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}^{2}\) and \(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NHNO}_{3}\). Calculate the ratio \(\left[\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right] /\left[\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+}\right]\)if the solution has the following pH values:
a. \(\mathrm{pH}=4.50\)
b. \(\mathrm{pH}=5.00\)
c. \(\mathrm{pH}=5.23\)
d. \(\mathrm{pH}=5.50\)
50. Calculate the ratio \(\left[\mathrm{NH}_{3}\right] /\left[\mathrm{NH}_{4}{ }^{+}\right]\)in ammonia/ammonium chloride buffered solutions with the following pH values:
a. \(\mathrm{pH}=9.00\)
b. \(\mathrm{pH}=8.80\)
c. \(\mathrm{pH}=10.00\)
d. \(\mathrm{pH}=9.60\)
-51. Carbonate buffers are important in regulating the pH of blood at 7.40. If the carbonic acid concentration in a sample of blood is 0.0012 M , determine the bicarbonate ion concentration required to buffer the pH of blood at \(\mathrm{pH}=7.40\).
\[
\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq}) \rightleftharpoons \mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}^{+}(a q) \quad K_{\mathrm{a}}=4.3 \times 10^{-7}
\]
52. When a person exercises, muscle contractions produce lactic acid. Moderate increases in lactic acid can be handled by the blood buffers without decreasing the pH of blood. However, excessive amounts of lactic acid can overload the blood buffer system, resulting in a lowering of the blood pH . A condition called acidosis is diagnosed if the blood pH falls to 7.35 or lower. Assume the primary blood buffer system is the carbonate buffer system described in Exercise 51. Calculate what happens to the \(\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right] /\left[\mathrm{HCO}_{3}{ }^{-}\right]\)ratio in blood when the pH decreases from 7.40 to 7.35 .
53. Consider the acids in Table 14.2. Which acid would be the best choice for preparing a \(\mathrm{pH}=7.00\) buffer? Explain how to make 1.0 L of this buffer.
54. Consider the bases in Table 14.3. Which base would be the best choice for preparing a \(\mathrm{pH}=5.00\) buffer? Explain how to make 1.0 L of this buffer.
-55. Calculate the pH of a solution that is \(0.40 \mathrm{M} \mathrm{H}_{2} \mathrm{NNH}_{2}\) and \(0.80 \mathrm{M} \mathrm{H}_{2} \mathrm{NNH}_{3} \mathrm{NO}_{3}\). In order for this buffer to have \(\mathrm{pH}=\) \(\mathrm{p} K_{\mathrm{a}}\), would you add HCl or NaOH ? What quantity (moles) of which reagent would you add to 1.0 L of the original buffer so that the resulting solution has \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\) ?
56. Calculate the pH of a solution that is 0.20 M HOCl and 0.90 M KOCl . In order for this buffer to have \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\), would you add HCl or NaOH ? What quantity (moles) of which reagent would you add to 1.0 L of the original buffer so that the resulting solution has \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\) ?
-57. Which of the following mixtures would result in buffered solutions when 1.0 L of each of the two solutions are mixed?
a. 0.1 M KOH and \(0.1 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}\)
b. 0.1 M KOH and \(0.2 \mathrm{M} \mathrm{CH} \mathrm{H}_{3} \mathrm{NH}_{2}\)
c. 0.2 M KOH and \(0.1 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}\)
d. 0.1 M KOH and \(0.2 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}\)
58. Which of the following mixtures would result in a buffered solution when 1.0 L of each of the two solutions are mixed?
a. \(0.2 \mathrm{M} \mathrm{HNO}_{3}\) and \(0.4 \mathrm{M} \mathrm{NaNO}_{3}\)
b. \(0.2 \mathrm{M} \mathrm{HNO}_{3}\) and 0.4 M HF
c. \(0.2 \mathrm{M} \mathrm{HNO}_{3}\) and 0.4 M NaF
d. \(0.2 M \mathrm{HNO}_{3}\) and 0.4 M NaOH
-59. What quantity (moles) of NaOH must be added to 1.0 L of \(2.0 \mathrm{M} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) to produce a solution buffered at each pH ?
a. \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\)
b. \(\mathrm{pH}=4.00\)
c. \(\mathrm{pH}=5.00\)
60. Calculate the number of moles of \(\mathrm{HCl}(g)\) that must be added to 1.0 L of \(1.0 \mathrm{M} \mathrm{NaC} \mathrm{N}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\) to produce a solution buffered at each pH .
a. \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\)
b. \(\mathrm{pH}=4.20\)
c. \(\mathrm{pH}=5.00\)

\section*{Acid-Base Titrations}
-61. Consider the titration of a generic weak acid HA with a strong base that gives the following titration curve:

On the curve, indicate the points that correspond to the following:
a. the stoichiometric (equivalence) point
b. the region with maximum buffering
c. \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\)
d. pH depends only on [HA]
e. pH depends only on \(\left[\mathrm{A}^{-}\right.\)]
f. pH depends only on the amount of excess strong base added
62. Sketch the titration curve for the titration of a generic weak base B with a strong acid. The titration reaction is
\[
\mathrm{B}+\mathrm{H}^{+} \rightleftharpoons \mathrm{BH}^{+}
\]

On this curve, indicate the points that correspond to the following:
a. the stoichiometric (equivalence) point
b. the region with maximum buffering
c. \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\)
d. pH depends only on [B]
e. pH depends only on \(\left[\mathrm{BH}^{+}\right]\)
f. pH depends only on the amount of excess strong acid added
63. Consider the titration of 40.0 mL of \(0.200 \mathrm{M} \mathrm{HClO}_{4}\) by 0.100 M KOH . Calculate the pH of the resulting solution after the following volumes of KOH have been added.
a. 0.0 mL
b. 10.0 mL
c. 40.0 mL
d. 80.0 mL
e. 100.0 mL
64. Consider the titration of 80.0 mL of \(0.100 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}\) by 0.400 M HCl . Calculate the pH of the resulting solution after the following volumes of HCl have been added.
a. 0.0 mL
b. 20.0 mL
c. 30.0 mL
d. 40.0 mL
e. 80.0 mL
-65. Consider the titration of 100.0 mL of 0.200 M acetic acid \(\left(K_{\mathrm{a}}=1.8 \times 10^{-5}\right)\) by 0.100 MKOH . Calculate the pH of the resulting solution after the following volumes of KOH have been added.
a. 0.0 mL
b. 50.0 mL
c. 100.0 mL
d. 150.0 mL
e. 200.0 mL
f. 250.0 mL
66. Consider the titration of 100.0 mL of \(0.100 \mathrm{M} \mathrm{H}_{2} \mathrm{NNH}_{2}\) \(\left(K_{\mathrm{b}}=3.0 \times 10^{-6}\right.\) ) by \(0.200 \mathrm{M} \mathrm{HNO}_{3}\). Calculate the pH of the resulting solution after the following volumes of \(\mathrm{HNO}_{3}\) have been added.
a. 0.0 mL
b. 20.0 mL
c. 25.0 mL
d. 40.0 mL
e. 50.0 mL
f. 100.0 mL
-67. Lactic acid is a common by-product of cellular respiration and is often said to cause the "burn" associated with strenuous activity. A \(25.0-\mathrm{mL}\) sample of 0.100 M lactic acid \(\left(\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right.\), \(\mathrm{p} K_{\mathrm{a}}=3.86\) ) is titrated with 0.100 M NaOH solution. Calculate the pH after the addition of \(0.0 \mathrm{~mL}, 4.0 \mathrm{~mL}, 8.0 \mathrm{~mL}, 12.5 \mathrm{~mL}\), \(20.0 \mathrm{~mL}, 24.0 \mathrm{~mL}, 24.5 \mathrm{~mL}, 24.9 \mathrm{~mL}, 25.0 \mathrm{~mL}, 25.1 \mathrm{~mL}\), \(26.0 \mathrm{~mL}, 28.0 \mathrm{~mL}\), and 30.0 mL of the NaOH . Plot the results of your calculations as pH versus milliliters of NaOH added.
68. Repeat the procedure in Exercise 67, but for the titration of 25.0 mL of 0.100 M propanoic acid \(\left(\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}, K_{\mathrm{a}}=1.3 \times 10^{-5}\right)\) with 0.100 M NaOH .
69. Repeat the procedure in Exercise 67, but for the titration of 25.0 mL of \(0.100 \mathrm{M} \mathrm{H}_{3}\left(K_{\mathrm{b}}=1.8 \times 10^{-5}\right)\) with 0.100 M HCl .
70. Repeat the procedure in Exercise 67, but for the titration of 25.0 mL of 0.100 M pyridine with 0.100 M hydrochloric acid ( \(K_{\mathrm{b}}\) for pyridine is \(1.7 \times 10^{-9}\) ). Do not calculate the points at 24.9 and 25.1 mL .
71. Calculate the pH at the halfway point and at the equivalence point for each of the following titrations.
a. 100.0 mL of \(0.10 M \mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}\left(K_{\mathrm{a}}=6.4 \times 10^{-5}\right)\) titrated by 0.10 M NaOH
b. 100.0 mL of \(0.10 \mathrm{M}_{2} \mathrm{H}_{5} \mathrm{NH}_{2}\left(K_{\mathrm{b}}=5.6 \times 10^{-4}\right)\) titrated by \(0.20 \mathrm{M} \mathrm{HNO}_{3}\)
c. 100.0 mL of 0.50 M HCl titrated by 0.25 M NaOH
72. In the titration of 50.0 mL of 1.0 M methylamine, \(\mathrm{CH}_{3} \mathrm{NH}_{2}\) ( \(K_{\mathrm{b}}=4.4 \times 10^{-4}\) ), with 0.50 M HCl , calculate the pH under the following conditions.
a. after 50.0 mL of 0.50 M HCl has been added
b. at the stoichiometric point
-73. You have 75.0 mL of 0.10 M HA. After adding 30.0 mL of 0.10 M NaOH , the pH is 5.50 . What is the \(K_{\mathrm{a}}\) value of HA?
74. A student dissolves 0.0100 mol of an unknown weak base in 100.0 mL water and titrates the solution with \(0.100 \mathrm{M} \mathrm{HNO}_{3}\). After 40.0 mL of \(0.100 \mathrm{M} \mathrm{HNO}_{3}\) was added, the pH of the resulting solution was 8.00 . Calculate the \(K_{\mathrm{b}}\) value for the weak base.

\section*{Indicators}
75. Two drops of indicator \(\operatorname{HIn}\left(K_{\mathrm{a}}=1.0 \times 10^{-9}\right)\), where HIn is yellow and \(\mathrm{In}^{-}\)is blue, are placed in 100.0 mL of 0.10 M HCl .
a. What color is the solution initially?
b. The solution is titrated with 0.10 M NaOH . At what pH will the color change (yellow to greenish yellow) occur?
c. What color will the solution be after 200.0 mL NaOH has been added?
76. Methyl red has the following structure:

\[
K_{\mathrm{a}}=5.0 \times 10^{-6}
\]

It undergoes a color change from red to yellow as a solution gets more basic. Calculate an approximate pH range for which methyl red is useful. What is the color change and the pH at the color change when a weak acid is titrated with a strong base using methyl red as an indicator? What is the color change and the pH at the color change when a weak base is titrated with a strong acid using methyl red as an indicator? For which of these two types of titrations is methyl red a possible indicator?
7. Potassium hydrogen phthalate, known as KHP (molar mass \(=\) \(204.22 \mathrm{~g} / \mathrm{mol}\) ), can be obtained in high purity and is used to determine the concentration of solutions of strong bases by the reaction
\[
\mathrm{HP}^{-}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{P}^{2-}(a q)
\]

If a typical titration experiment begins with approximately 0.5 g KHP and has a final volume of about 100 mL , what is an appropriate indicator to use? The \(\mathrm{p} K_{\mathrm{a}}\) for \(\mathrm{HP}^{-}\)is 5.51.
78. A certain indicator HIn has a \(\mathrm{p} K_{\mathrm{a}}\) of 3.00 and a color change becomes visible when \(7.00 \%\) of the indicator has been converted to \(\mathrm{In}^{-}\). At what pH is this color change visible?
-79. Which of the indicators in Fig. 15.8 could be used for the titrations in Exercises 63 and 65?
80. Which of the indicators in Fig. 15.8 could be used for the titrations in Exercises 64 and 66?
81. Which of the indicators in Fig. 15.8 could be used for the titrations in Exercises 67 and 69?
82. Which of the indicators in Fig. 15.8 could be used for the titrations in Exercises 68 and 70?
83. Estimate the pH of a solution in which bromcresol green is blue and thymol blue is yellow. (See Fig. 15.8.)
84. Estimate the pH of a solution in which crystal violet is yellow and methyl orange is red. (See Fig. 15.8.)
85. A solution has a pH of 7.0 . What would be the color of the solution if each of the following indicators were added? (See Fig. 15.8.)
a. thymol blue
c. methyl red
b. bromthymol blue
d. crystal violet
86. A solution has a pH of 4.5 . Which indicator in Figure 15.8 would be best to indicate the pH of this solution?

\section*{Additional Exercises}
87. When a diprotic acid, \(\mathrm{H}_{2} \mathrm{~A}\), is titrated with NaOH , the protons on the diprotic acid are generally removed one at a time, resulting in a pH curve that has the following generic shape:

a. Notice that the plot has essentially two titration curves. If the first equivalence point occurs at 100.0 mL NaOH added, what volume of NaOH added corresponds to the second equivalence point?
b. For the following volumes of NaOH added, list the major species present after the \(\mathrm{OH}^{-}\)reacts completely.
i. \(\quad 0 \mathrm{~mL} \mathrm{NaOH}\) added
ii. between 0 and 100.0 mL NaOH added
iii. 100.0 mL NaOH added
iv. between 100.0 and 200.0 mL NaOH added
v. \(\quad 200.0 \mathrm{~mL} \mathrm{NaOH}\) added
vi. after 200.0 mL NaOH added
c. If the pH at 50.0 mL NaOH added is 4.0 and the pH at 150.0 mL NaOH added is 8.0 , determine the values \(K_{\mathrm{a}_{1}}\) and \(K_{\mathrm{a}_{2}}\) for the diprotic acid.
88. Consider the titration of 50.0 mL of \(0.10 \mathrm{M} \mathrm{H}_{3} \mathrm{~A}\left(K_{\mathrm{a}_{1}}=\right.\) \(\left.5.0 \times 10^{-4}, K_{\mathrm{a}_{2}}=1.0 \times 10^{-8}, K_{\mathrm{a}_{3}}=1.0 \times 10^{-11}\right)\) titrated by 0.10 M KOH .
a. Calculate the pH of the resulting solution at 125 mL of KOH added.
b. At what volume of KOH added does \(\mathrm{pH}=3.30\) ?
c. At 75.0 mL of KOH added, is the solution acidic or basic?
89. Derive an equation analogous to the Henderson-Hasselbalch equation but relating pOH and \(\mathrm{p} K_{\mathrm{b}}\) of a buffered solution composed of a weak base and its conjugate acid, such as \(\mathrm{NH}_{3}\) and \(\mathrm{NH}_{4}{ }^{+}\).
90. a. Calculate the pH of a buffered solution that is 0.100 M in \(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2} \mathrm{H}\) (benzoic acid, \(K_{\mathrm{a}}=6.4 \times 10^{-5}\) ) and 0.100 M in \(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2} \mathrm{Na}\).
b. Calculate the pH after \(20.0 \%\) (by moles) of the benzoic acid is converted to benzoate anion by addition of a strong base. Use the dissociation equilibrium
\[
\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2} \mathrm{H}(a q) \rightleftharpoons \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2}^{-}(a q)+\mathrm{H}^{+}(a q)
\]
to calculate the pH .
c. Do the same as in part b, but use the following equilibrium to calculate the pH :
\[
\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2} \mathrm{H}(a q)+\mathrm{OH}^{-}(a q)
\]
d. Do your answers in parts b and c agree? Explain.
91. Tris(hydroxymethyl)aminomethane, commonly called TRIS or Trizma, is often used as a buffer in biochemical studies. Its buffering range is pH 7 to 9 , and \(K_{\mathrm{b}}\) is \(1.19 \times 10^{-6}\) for the aqueous reaction
\[
\underset{\text { TRIS }}{\left(\mathrm{HOCH}_{2}\right)_{3} \mathrm{CNH}_{2}}+\underset{\text { TRISH }}{ }+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \underset{\text { TROCH }}{\left(\mathrm{HOCNH}_{3} \mathrm{CNH}_{3}^{+}\right.}+\mathrm{OH}^{-}
\]
a. What is the optimal pH for TRIS buffers?
b. Calculate the ratio [TRIS]/[TRISH \({ }^{+}\)] at \(\mathrm{pH}=7.00\) and at \(\mathrm{pH}=9.00\).
c. A buffer is prepared by diluting 50.0 g TRIS base and 65.0 g TRIS hydrochloride (written as TRISHCl) to a total volume of 2.0 L . What is the pH of this buffer? What is the pH after 0.50 mL of 12 M HCl is added to a \(200.0-\mathrm{mL}\) portion of the buffer?
92. You make 1.00 L of a buffered solution \((\mathrm{pH}=4.00)\) by mixing acetic acid and sodium acetate. You have 1.00 M solutions of each component of the buffered solution. What volume of each solution do you mix to make such a buffered solution?
93. You have the following reagents on hand:
\begin{tabular}{|ll|}
\hline Solids (pK \(K_{\mathrm{a}}\) of Acid Form Is Civen) & Solutions \\
\hline Benzoic acid (4.19) & 5.0 M HCl \\
\hline Sodium acetate (4.74) & 1.0 M acetic acid (4.74) \\
\hline Potassium fluoride (3.14) & 2.6 M NaOH \\
\hline Ammonium chloride (9.26) & \(1.0 \mathrm{M} \mathrm{HOCl}(7.46)\) \\
\hline
\end{tabular}

What combinations of reagents would you use to prepare buffers at the following pH values?
a. 3.0
b. 4.0
c. 5.0
d. 7.0
e. 9.0
94. Amino acids are the building blocks for all proteins in our bodies. A structure for the amino acid alanine is

All amino acids have at least two functional groups with acidic or basic properties. In alanine, the carboxylic acid group has \(K_{\mathrm{a}}=4.5 \times 10^{-3}\) and the amino group has \(K_{\mathrm{b}}=7.4 \times 10^{-5}\). Because of the two groups with acidic or basic properties, three different charged ions of alanine are possible when alanine is dissolved in water. Which of these ions would predominate in a solution with \(\left[\mathrm{H}^{+}\right]=1.0 \mathrm{M}\) ? In a solution with \(\left[\mathrm{OH}^{-}\right]=1.0 \mathrm{M}\) ?
95. Phosphate buffers are important in regulating the pH of intracellular fluids at pH values generally between 7.1 and 7.2.
a. What is the concentration ratio of \(\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}\)to \(\mathrm{HPO}_{4}{ }^{2-}\) in intracellular fluid at \(\mathrm{pH}=7.15\) ?
\[
\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}(a q) \rightleftharpoons \mathrm{HPO}_{4}{ }^{2-}(a q)+\mathrm{H}^{+}(a q) \quad K_{\mathrm{a}}=6.2 \times 10^{-8}
\]
b. Why is a buffer composed of \(\mathrm{H}_{3} \mathrm{PO}_{4}\) and \(\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}\)ineffective in buffering the pH of intracellular fluid?
\[
\mathrm{H}_{3} \mathrm{PO}_{4}(a q) \rightleftharpoons \mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{H}^{+}(a q) \quad K_{\mathrm{a}}=7.5 \times 10^{-3}
\]
96. Th pH of blood is steady at a value of approximately 7.4 as a result of the following equilibrium reactions:
\(\mathrm{CO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \leftrightharpoons \mathrm{H}_{2} \mathrm{CO}_{3}(a q) \leftrightharpoons \mathrm{HCO}_{3}^{-}(a q)+\mathrm{H}^{+}(a q)\)
The actual buffer system in blood is made up of \(\mathrm{H}_{2} \mathrm{CO}_{3}\) and \(\mathrm{HCO}_{3}{ }^{-}\). One way the body keeps the pH of blood at 7.4 is by regulating breathing. Under what blood pH conditions will the body increase breathing and under what blood pH conditions will the body decrease breathing? Explain.
97. Consider the blood buffer system discussed in the Exercise 96. Patients with severe diarrhea can have an excessive loss of sodium bicarbonate (sodium hydrogen carbonate). How would this affect the pH of blood? Explain. What would be the treatment of such a condition?
98. What quantity (moles) of \(\mathrm{HCl}(g)\) must be added to 1.0 L of 2.0 M NaOH to achieve a pH of 0.00 ? (Neglect any volume changes.)
99. Calculate the value of the equilibrium constant for each of the following reactions in aqueous solution.
a. \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}+\mathrm{OH}^{-} \rightleftharpoons \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}+\mathrm{H}_{2} \mathrm{O}\)
b. \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}+\mathrm{H}^{+} \rightleftharpoons \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\)
c. \(\mathrm{HCl}+\mathrm{NaOH} \rightleftharpoons \mathrm{NaCl}+\mathrm{H}_{2} \mathrm{O}\)
100. The following plot shows the pH curves for the titrations of various acids by 0.10 M NaOH (all of the acids were \(50.0-\mathrm{mL}\) samples of 0.10 M concentration).

Vol \(0.10 M \mathrm{NaOH}\) added \((\mathrm{mL})\)
a. Which pH curve corresponds to the weakest acid?
b. Which pH curve corresponds to the strongest acid? Which point on the pH curve would you examine to see if this acid is a strong acid or a weak acid (assuming you did not know the initial concentration of the acid)?
c. Which pH curve corresponds to an acid with \(K_{\mathrm{a}} \approx\) \(1 \times 10^{-6}\) ?
101. Calculate the volume of \(1.50 \times 10^{-2} \mathrm{M} \mathrm{NaOH}\) that must be added to 500.0 mL of 0.200 M HCl to give a solution that has \(\mathrm{pH}=2.15\).
102. Repeat the procedure in Exercise 67, but for the titration of 25.0 mL of \(0.100 \mathrm{M} \mathrm{HNO}_{3}\) with 0.100 M NaOH .
103. A certain acetic acid solution has \(\mathrm{pH}=2.68\). Calculate the volume of 0.0975 M KOH required to reach the equivalence point in the titration of 25.0 mL of the acetic acid solution.
104. A \(0.210-\mathrm{g}\) sample of an acid (molar mass \(=192 \mathrm{~g} / \mathrm{mol}\) ) is titrated with 30.5 mL of 0.108 M NaOH to a phenolphthalein end point. Is the acid monoprotic, diprotic, or triprotic?
105. The active ingredient in aspirin is acetylsalicylic acid. A \(2.51-\mathrm{g}\) sample of acetylsalicylic acid required 27.36 mL of 0.5106 M NaOH for complete reaction. Addition of 13.68 mL of 0.5106 M HCl to the flask containing the aspirin and the sodium hydroxide produced a mixture with \(\mathrm{pH}=3.48\). Determine the molar mass of acetylsalicylic acid and its \(K_{\mathrm{a}}\) value. State any assumptions you must make to reach your answer.
106. One method for determining the purity of aspirin \(\left(\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}\right)\) is to hydrolyze it with NaOH solution and then to titrate the remaining NaOH . The reaction of aspirin with NaOH is as follows:
\[
\underset{\text { Aspirin }}{\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}(s)} \xrightarrow[\text { a min }]{\text { Boil }} \underset{\text { Salicylate ion }}{2 \mathrm{OH}_{7}^{-}(a q)} \mathrm{H}_{5} \mathrm{O}_{3}^{-}(a q)+\underset{\text { Acetate ion }}{\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)}
\]

A sample of aspirin with a mass of 1.427 g was boiled in 50.00 mL of 0.500 M NaOH . After the solution was cooled, it took 31.92 mL of 0.289 M HCl to titrate the excess NaOH . Calculate the purity of the aspirin. What indicator should be used for this titration? Why?
107. A student intends to titrate a solution of a weak monoprotic acid with a sodium hydroxide solution but reverses the two solutions and places the weak acid solution in the buret. After 23.75 mL of the weak acid solution has been added to 50.0 mL of the 0.100 M NaOH solution, the pH of the resulting solution is 10.50 . Calculate the original concentration of the solution of weak acid.
108. A student titrates an unknown weak acid, HA, to a pale pink phenolphthalein end point with 25.0 mL of 0.100 M NaOH . The student then adds 13.0 mL of 0.100 M HCl . The pH of the resulting solution is 4.70 . How is the value of \(\mathrm{p} K_{\mathrm{a}}\) for the unknown acid related to 4.70 ?
109. A sample of a certain monoprotic weak acid was dissolved in water and titrated with 0.125 M NaOH , requiring 16.00 mL to reach the equivalence point. During the titration, the pH after adding 2.00 mL NaOH was 6.912 . Calculate \(K_{\mathrm{a}}\) for the weak acid.
110. The pigment cyanidin aglycone is one of the anthocyanin molecules that gives red cabbage (Brassica oleracea var. capitataf. rubra) its characteristic red coloration. Many chemistry students have used this "red cabbage indicator" to study acidbase chemistry. Estimate the pH range at which cyanidin aglycone shows a color change.
\[
\text { Anth- } \mathrm{H}(a q) \leftrightharpoons \text { Anth }^{-}(a q)+\mathrm{H}^{+}(a q) \quad K_{\mathrm{a}}=1.3 \times 10^{-7}
\]

Cyanidin aglycone (Anth-H)
111. Calculate the pH of a solution formed by mixing 100.0 mL of 0.100 M NaF and 100.0 mL of 0.025 M HCl .

\section*{ChemWork Problems}

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
112. Consider 1.0 L of a solution that is \(0.85 M \mathrm{HOC}_{6} \mathrm{H}_{5}\) and \(0.80 \mathrm{M} \mathrm{NaOC}_{6} \mathrm{H}_{5} .\left(K_{\mathrm{a}}\right.\) for \(\mathrm{HOC}_{6} \mathrm{H}_{5}=1.6 \times 10^{-10}\). \()\)
a. Calculate the pH of this solution.
b. Calculate the pH after 0.10 mole of HCl has been added to the original solution. Assume no volume change on addition of HCl .
c. Calculate the pH after 0.20 mole of NaOH has been added to the original buffer solution. Assume no volume change on addition of NaOH .
113. What concentration of \(\mathrm{NH}_{4} \mathrm{Cl}\) is necessary to buffer a \(0.52-M\) \(\mathrm{NH}_{3}\) solution at \(\mathrm{pH}=9.00 ?\left(K_{\mathrm{b}}\right.\) for \(\mathrm{NH}_{3}=1.8 \times 10^{-5}\). \()\)
114. Consider the following acids and bases:
\begin{tabular}{|ll}
\hline \(\mathrm{HCO}_{2} \mathrm{H}\) & \(K_{\mathrm{a}}=1.8 \times 10^{-4}\) \\
\hline HOBr & \(K_{\mathrm{a}}=2.0 \times 10^{-9}\) \\
\hline\(\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{2} \mathrm{NH}\) & \(K_{\mathrm{b}}=1.3 \times 10^{-3}\) \\
\hline \(\mathrm{HONH}_{2}\) & \(K_{\mathrm{b}}=1.1 \times 10^{-8}\) \\
\hline
\end{tabular}

Choose substances from the following list that would be the best choice to prepare a \(\mathrm{pH}=9.0\) buffer solution.
a. \(\mathrm{HCO}_{2} \mathrm{H}\)
b. HOBr
c. \(\mathrm{KHCO}_{2}\)
d. \(\mathrm{HONH}_{3} \mathrm{NO}_{3}\)
e. \(\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{2} \mathrm{NH}\)
f. \(\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{2} \mathrm{NH}_{2} \mathrm{Cl}\)
g. \(\mathrm{HONH}_{2}\)
h. NaOBr
115. Consider a buffered solution containing \(\mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}\) and \(\mathrm{CH}_{3} \mathrm{NH}_{2}\). Which of the following statements concerning this solution is(are) true? \(\left(K_{\mathrm{a}}\right.\) for \(\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}=2.3 \times 10^{-11}\).)
a. A solution consisting of \(0.10 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}\) and 0.10 M \(\mathrm{CH}_{3} \mathrm{NH}_{2}\) would have a greater buffering capacity than one containing \(1.0 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}\) and \(1.0 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{2}\).
b. If \(\left[\mathrm{CH}_{3} \mathrm{NH}_{2}\right]>\left[\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}\right]\), then the pH is larger than the \(\mathrm{p} K_{\mathrm{a}}\) value.
c. Adding more \(\left[\mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}\right]\) to the initial buffer solution will decrease the pH .
d. If \(\left[\mathrm{CH}_{3} \mathrm{NH}_{2}\right]<\left[\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}\right]\), then \(\mathrm{pH}<3.36\).
e. If \(\left[\mathrm{CH}_{3} \mathrm{NH}_{2}\right]=\left[\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}\right]\), then \(\mathrm{pH}=10.64\).
116. Consider the titration of 150.0 mL of 0.100 M HI by 0.250 M NaOH .
a. Calculate the pH after 20.0 mL of NaOH has been added.
b. What volume of NaOH must be added so that the \(\mathrm{pH}=7.00\) ?
117. Consider the titration of 100.0 mL of \(0.100 M \mathrm{HCN}\) by 0.100 M KOH at \(25^{\circ} \mathrm{C}\). ( \(K_{\mathrm{a}}\) for \(\mathrm{HCN}=6.2 \times 10^{-10}\).)
a. Calculate the pH after 0.0 mL of KOH has been added.
b. Calculate the pH after 50.0 mL of KOH has been added.
c. Calculate the pH after 75.0 mL of KOH has been added.
d. Calculate the pH at the equivalence point.
e. Calculate the pH after 125 mL of KOH has been added.
118. Consider the titration of 100.0 mL of 0.200 M HONH 2 by 0.100 M HCl . \(\left(K_{\mathrm{b}}\right.\) for \(\mathrm{HONH}_{2}=1.1 \times 10^{-8}\).)
a. Calculate the pH after 0.0 mL of HCl has been added.
b. Calculate the pH after 25.0 mL of HCl has been added.
c. Calculate the pH after 70.0 mL of HCl has been added.
d. Calculate the pH at the equivalence point.
e. Calculate the pH after 300.0 mL of HCl has been added.
f. At what volume of HCl added does the \(\mathrm{pH}=6.04\) ?
119. Consider the following four titrations (i-iv):
i. \(\quad 150 \mathrm{~mL}\) of \(0.2 \mathrm{MNH}_{3}\left(K_{\mathrm{b}}=1.8 \times 10^{-5}\right)\) by 0.2 M HCl
ii. \(\quad 150 \mathrm{~mL}\) of 0.2 M HCl by 0.2 M NaOH
iii. 150 mL of \(0.2 \mathrm{M} \mathrm{HOCl}\left(K_{\mathrm{a}}=3.5 \times 10^{-8}\right)\) by 0.2 M NaOH
iv. 150 mL of \(0.2 \mathrm{M} \mathrm{HF}\left(K_{\mathrm{a}}=7.2 \times 10^{-4}\right)\) by 0.2 M NaOH
a. Rank the four titrations in order of increasing pH at the halfway point to equivalence (lowest to highest pH ).
b. Rank the four titrations in order of increasing pH at the equivalence point.
c. Which titration requires the largest volume of titrant \((\mathrm{HCl}\) or NaOH ) to reach the equivalence point?

\section*{Challenge Problems}
120. Another way to treat data from a pH titration is to graph the absolute value of the change in pH per change in milliliters added versus milliliters added ( \(\Delta \mathrm{pH} / \Delta \mathrm{mL}\) versus mL added). Make this graph using your results from Exercise 67. What advantage might this method have over the traditional method for treating titration data?
121. A buffer is made using 45.0 mL of \(0.750 M \mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}\left(K_{\mathrm{a}}=\right.\) \(1.3 \times 10^{-5}\) ) and 55.0 mL of \(0.700 \mathrm{M} \mathrm{NaC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}\). What volume of 0.10 M NaOH must be added to change the pH of the original buffer solution by \(2.5 \%\) ?
122. A \(0.400-M\) solution of ammonia was titrated with hydrochloric acid to the equivalence point, where the total volume was 1.50 times the original volume. At what pH does the equivalence point occur?
123. What volume of 0.0100 M NaOH must be added to 1.00 L of 0.0500 M HOCl to achieve a pH of 8.00 ?
124. Consider a solution formed by mixing 50.0 mL of 0.100 M \(\mathrm{H}_{2} \mathrm{SO}_{4}, 30.0 \mathrm{~mL}\) of \(0.100 \mathrm{M} \mathrm{HOCl}, 25.0 \mathrm{~mL}\) of 0.200 M \(\mathrm{NaOH}, 25.0 \mathrm{~mL}\) of \(0.100 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}\), and 10.0 mL of 0.150 \(M \mathrm{KOH}\). Calculate the pH of this solution.
125. Cacodylic acid, \(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{AsO}_{2} \mathrm{H}\), is a toxic compound that is a weak acid with \(\mathrm{p} K_{\mathrm{a}}=6.19\). It is used to prepare buffered solutions. Calculate the masses of cacodylic acid and sodium cacodylate that should be used to prepare 500.0 mL of a \(\mathrm{pH}=\) 6.60 buffer so that the buffer has a total of arsenic-containing species equal to 0.25 M , that is, so that:
\[
\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{AsO}_{2} \mathrm{H}\right]+\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{AsO}_{2}^{-}\right]=0.25 \mathrm{M}
\]
126. Consider the titration of 100.0 mL of 0.10 M phosphoric acid with 0.10 M NaOH .
a. Determine the pH at the third half-equivalence point by making the typical assumptions.
b. Calculate the pH at the third equivalence point.
c. Why must the answer to part a be incorrect? Which assumption made in part a is invalid?
d. Calculate the pH at the third half-equivalence point.
127. The titration of \(\mathrm{Na}_{2} \mathrm{CO}_{3}\) with HCl has the following qualitative profile:

\section*{mL HCl}
a. Identify the major species in solution at points A-F.
b. Calculate the pH at the halfway points to equivalence, B and D.)
128. Consider the titration curve in Exercise 127 for the titration of \(\mathrm{Na}_{2} \mathrm{CO}_{3}\) with HCl .
a. If a mixture of \(\mathrm{NaHCO}_{3}\) and \(\mathrm{Na}_{2} \mathrm{CO}_{3}\) was titrated, what would be the relative sizes of \(V_{1}\) and \(V_{2}\) ?
b. If a mixture of NaOH and \(\mathrm{Na}_{2} \mathrm{CO}_{3}\) was titrated, what would be the relative sizes of \(V_{1}\) and \(V_{2}\) ?
c. A sample contains a mixture of \(\mathrm{NaHCO}_{3}\) and \(\mathrm{Na}_{2} \mathrm{CO}_{3}\). When this sample was titrated with 0.100 M HCl , it took 18.9 mL to reach the first stoichiometric point and an additional 36.7 mL to reach the second stoichiometric point. What is the composition in mass percent of the sample?
129. A few drops of each of the indicators shown in the accompanying table were placed in separate portions of a \(1.0-M\) solution of a weak acid, HX. The results are shown in the last column of the table. What is the approximate pH of the solution containing HX? Calculate the approximate value of \(K_{\mathrm{a}}\) for HX.
\begin{tabular}{|lllll|}

\end{tabular}
130. Malonic acid \(\left(\mathrm{HO}_{2} \mathrm{CCH}_{2} \mathrm{CO}_{2} \mathrm{H}\right)\) is a diprotic acid. In the titration of malonic acid with NaOH , stoichiometric points occur at \(\mathrm{pH}=3.9\) and 8.8. A \(25.00-\mathrm{mL}\) sample of malonic acid of unknown concentration is titrated with 0.0984 M NaOH , requiring 31.50 mL of the NaOH solution to reach the phenolphthalein end point. Calculate the concentration of the initial malonic acid solution.

\section*{Integrative Problems}

These problems require the integration of multiple concepts to find the solutions.
131. A buffer solution is prepared by mixing 75.0 mL of 0.275 M fluorobenzoic acid \(\left(\mathrm{C}_{7} \mathrm{H}_{5} \mathrm{O}_{2} \mathrm{~F}\right)\) with 55.0 mL of 0.472 M sodium fluorobenzoate. The \(\mathrm{p} K_{\mathrm{a}}\) of this weak acid is 2.90 . What is the pH of the buffer solution?
132. A \(10.00-\mathrm{g}\) sample of the ionic compound NaA , where \(\mathrm{A}^{-}\)is the anion of a weak acid, was dissolved in enough water to make 100.0 mL of solution and was then titrated with 0.100 M HCl . After 500.0 mL HCl was added, the pH was 5.00 . The experimenter found that 1.00 L of 0.100 M HCl was required to reach the stoichiometric point of the titration.
a. What is the molar mass of NaA ?
b. Calculate the pH of the solution at the stoichiometric point of the titration.
133. Calculate the pH of a solution prepared by mixing \(250 . \mathrm{mL}\) of 0.174 m aqueous HF (density \(=1.10 \mathrm{~g} / \mathrm{mL}\) ) with 38.7 g of an aqueous solution that is \(1.50 \% \mathrm{NaOH}\) by mass (density \(=\) \(1.02 \mathrm{~g} / \mathrm{mL}) .\left(K_{\mathrm{a}}\right.\) for \(\left.\mathrm{HF}=7.2 \times 10^{-4}.\right)\)

\section*{Marathon Problem \\ This problem is designed to incorporate several concepts and techniques into one situation.}
134. Consider a solution prepared by mixing the following: 50.0 mL of \(0.100 \mathrm{M} \mathrm{Na}_{3} \mathrm{PO}_{4}\)
100.0 mL of 0.0500 M KOH
200.0 mL of 0.0750 M HCl
50.0 mL of 0.150 M NaCN

Determine the volume of \(0.100 \mathrm{M} \mathrm{HNO}_{3}\) that must be added to this mixture to achieve a final pH value of 7.21 .

Stalactites and stalagmites in the Drapery Room at Mammoth Cave in Kentucky. These formations are created when carbonate minerals dissolve in groundwater acidified by carbon dioxide and then solidify when the water evaporates. (Adam Jones/Danita Delimont)

\section*{Solubility and Complex Ion Equilibria}
16.1 Solubility Equilibria and the Solubility Product Relative Solubilities Common Ion Effect pH and Solubility
16.2 Precipitation and Qualitative Analysis
Selective Precipitation
Qualitative Analysis
16.3 Equilibria Involving Complex Ions Complex Ions and Solubility have already introduced one very significant class of aqueous equilibria, acid-base reactions. In this chapter we will consider more applications of aqueous equilibria, those involving the solubility of salts and those involving the formation of complex ions.

The interplay of acid-base, solubility, and complex ion equilibria is often important in natural processes, such as the weathering of minerals, the uptake of nutrients by plants, and tooth decay. For example, limestone \(\left(\mathrm{CaCO}_{3}\right)\) will dissolve in water made acidic by dissolved carbon dioxide:
\[
\begin{aligned}
\mathrm{CO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q) \\
\mathrm{H}^{+}(a q)+\mathrm{CaCO}_{3}(s) & \rightleftharpoons \mathrm{Ca}^{2+}(a q)+\mathrm{HCO}_{3}^{-}(a q)
\end{aligned}
\]

This two-step process and its reverse account for the formation of limestone caves and the stalactites and stalagmites found therein. In the forward direction of the process, the acidic water (containing carbon dioxide) dissolves the underground limestone deposits, thereby forming a cavern. The reverse process occurs as the water drips from the ceiling of the cave, and the carbon dioxide is lost to the air. This causes solid calcium carbonate to form, producing stalactites on the ceiling and stalagmites where the drops hit the cave floor.

In this chapter we will discuss the formation of solids from an aqueous solution and the resulting equilibria. We will also show how selective precipitation and the formation of complex ions can be used to do qualitative analysis.

\subsection*{16.1 Solubility Equilibria and the Solubility Product}

Solubility is a very important phenomenon. The fact that substances such as sugar and table salt dissolve in water allows us to flavor foods easily. The fact that calcium sulfate is less soluble in hot water than in cold water causes it to coat tubes in boilers, reducing thermal efficiency. Tooth decay involves solubility: When food lodges between the teeth, acids form that dissolve tooth enamel, which contains a mineral called hydroxyapatite, \(\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\). Tooth decay can be reduced by treating teeth with fluoride (see Chemical Connections, p. 645). Fluoride replaces the hydroxide in hydroxyapatite to produce the corresponding fluorapatite, \(\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}\), and calcium fluoride, \(\mathrm{CaF}_{2}\), both of which are less soluble in acids than the original enamel. Another important consequence of solubility involves the use of a suspension of barium sulfate to improve the clarity of X rays of the gastrointestinal tract. The very low solubility of barium sulfate, which contains the toxic ion \(\mathrm{Ba}^{2+}\), makes ingestion of the compound safe.

In this section we will consider the equilibria associated with solids dissolving to form aqueous solutions. We will assume that when a typical ionic solid dissolves in water, it dissociates completely into separate hydrated cations and anions. For example, calcium fluoride dissolves in water as follows:
\[
\mathrm{CaF}_{2}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Ca}^{2+}(a q)+2 \mathrm{~F}^{-}(a q)
\]

When the solid salt is first added to the water, no \(\mathrm{Ca}^{2+}\) and \(\mathrm{F}^{-}\)ions are present. However, as the dissolution proceeds, the concentrations of \(\mathrm{Ca}^{2+}\) and \(\mathrm{F}^{-}\)increase, making it more and more likely that these ions will collide and re-form the solid phase. Thus two competing processes are occurring-the dissolution reaction and its reverse:
\[
\mathrm{Ca}^{2+}(a q)+2 \mathrm{~F}^{-}(a q) \longrightarrow \mathrm{CaF}_{2}(s)
\]

Ultimately, dynamic equilibrium is reached:
\[
\mathrm{CaF}_{2}(s) \rightleftharpoons \mathrm{Ca}^{2+}(a q)+2 \mathrm{~F}^{-}(a q)
\]

At this point no more solid dissolves (the solution is said to be saturated).

\section*{A}

An X ray of the lower gastrointestinal tract using barium sulfate.

Pure liquids and pure solids are never included in an equilibrium expression (Section 13.4).
\(K_{\text {sp }}\) is an equilibrium constant; solubility is an equilibrium position.

We can write an equilibrium expression for this process according to the law of mass action:
\[
K_{\mathrm{sp}}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}
\]
where \(\left[\mathrm{Ca}^{2+}\right]\) and \(\left[\mathrm{F}^{-}\right]\)are expressed in \(\mathrm{mol} / \mathrm{L}\). The constant \(K_{\text {sp }}\) is called the solubility product constant or simply the solubility product for the equilibrium expression.

Since \(\mathrm{CaF}_{2}\) is a pure solid, it is not included in the equilibrium expression. The fact that the amount of excess solid present does not affect the position of the solubility equilibrium might seem strange at first; more solid means more surface area exposed to the solvent, which would seem to result in greater solubility. This is not the case, however. When the ions in solution re-form the solid, they do so on the surface of the solid. Thus doubling the surface area of the solid not only doubles the rate of dissolving, but also doubles the rate of re-formation of the solid. The amount of excess solid present therefore has no effect on the equilibrium position. Similarly, although either increasing the surface area by grinding up the solid or stirring the solution speeds up the attainment of equilibrium, neither procedure changes the amount of solid dissolved at equilibrium. Neither the amount of excess solid nor the size of the particles present will shift the position of the solubility equilibrium.

It is very important to distinguish between the solubility of a given solid and its solubility product. The solubility product is an equilibrium constant and has only one value for a given solid at a given temperature. Solubility, on the other hand, is an equilibrium position. In pure water at a specific temperature a given salt has a particular solubility. On the other hand, if a common ion is present in the solution, the solubility varies according to the concentration of the common ion. However, in all cases the product of the ion concentrations must satisfy the \(K_{\text {sp }}\) expression. The \(K_{\text {sp }}\) values at \(25^{\circ} \mathrm{C}\) for many common ionic solids are listed in Table 16.1. The units are customarily omitted.

Solving solubility equilibria problems requires many of the same procedures we have used to deal with acid-base equilibria, as illustrated in Examples 16.1 and 16.2.

\section*{INTERACTVE EXAMPLE 16.1 Calculating \(K_{\text {sp }}\) from Solubility I}

Copper(I) bromide has a measured solubility of \(2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\) at \(25^{\circ} \mathrm{C}\). Calculate its \(K_{\text {sp }}\) value.

\section*{SOLUTION}

In this experiment the solid was placed in contact with water. Thus, before any reaction occurred, the system contained solid CuBr and \(\mathrm{H}_{2} \mathrm{O}\). The process that occurs is the dissolving of CuBr to form the separated \(\mathrm{Cu}^{+}\)and \(\mathrm{Br}^{-}\)ions:
where \(\quad K_{\text {sp }}=\left[\mathrm{Cu}^{+}\right]\left[\mathrm{Br}^{-}\right]\)
Initially, the solution contains no \(\mathrm{Cu}^{+}\)or \(\mathrm{Br}^{-}\), so the initial concentrations are
\[
\left[\mathrm{Cu}^{+}\right]_{0}=\left[\mathrm{Br}^{-}\right]_{0}=0
\]

The equilibrium concentrations can be obtained from the measured solubility of CuBr , which is \(2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\). This means that \(2.0 \times 10^{-4}\) mole of solid CuBr dissolves per 1.0 L of solution to come to equilibrium with the excess solid. The reaction is
\[
\mathrm{CuBr}(s) \longrightarrow \mathrm{Cu}^{+}(a q)+\mathrm{Br}^{-}(a q)
\]

Thus
\[
2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \mathrm{CuBr}(s) \xrightarrow{\operatorname{Cu}} 2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \mathrm{Cu}^{+}(\mathrm{aq})+2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \mathrm{Br}^{-}(a q)
\]

We can now write the equilibrium concentrations:
\[
\begin{aligned}
{\left[\mathrm{Cu}^{+}\right] } & =\left[\mathrm{Cu}^{+}\right]_{0}+\text { change to reach equilibrium } \\
& =0+2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L}
\end{aligned}
\]
and
\[
\begin{aligned}
{\left[\mathrm{Br}^{-}\right] } & =\left[\mathrm{Br}^{-}\right]_{0}+\text { change to reach equilibrium } \\
& =0+2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L}
\end{aligned}
\]

These equilibrium concentrations allow us to calculate the value of \(K_{\text {sp }}\) for CuBr :
\[
\begin{aligned}
K_{\text {sp }} & =\left[\mathrm{Cu}^{+}\right]\left[\mathrm{Br}^{-}\right]=\left(2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\right)\left(2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\right) \\
& =4.0 \times 10^{-8} \mathrm{~mol}^{2} / \mathrm{L}^{2}=4.0 \times 10^{-8}
\end{aligned}
\]

The units for \(K_{\text {sp }}\) values are usually omitted.

See Exercises 16.25 and 16.26

TABLE \(16.1 \| K_{\text {sp }}\) Values at \(25^{\circ} \mathrm{C}\) for Common lonic Solids
\begin{tabular}{|c|c|c|c|c|c|}

\hline & & \(\mathrm{Pb}(\mathrm{OH})_{2}\) & \(1.2 \times 10^{-15}\) & \(\mathrm{Ba}_{3}\left(\mathrm{PO}_{4}\right)_{2}\) & \(6 \times 10^{-39}\) \\
\hline
\end{tabular}
*Contains \(\mathrm{Hg}_{2}{ }^{2+}\) ions. \(K=\left[\mathrm{Hg}_{2}{ }^{2+}\right]\left[\mathrm{X}^{-}\right]^{2}\) for \(\mathrm{Hg}_{2} \mathrm{X}_{2}\) salts, for example.

\section*{INTERACTIVE EXAMPLE 16.2 Calculating \(\boldsymbol{K}_{\text {sp }}\) from Solubility II}

Calculate the \(K_{\text {sp }}\) value for bismuth sulfide \(\left(\mathrm{Bi}_{2} \mathrm{~S}_{3}\right)\), which has a solubility of \(1.0 \times 10^{-15} \mathrm{~mol} / \mathrm{L}\) at \(25^{\circ} \mathrm{C}\).

\section*{SOLUTION}

The system initially contains \(\mathrm{H}_{2} \mathrm{O}\) and solid \(\mathrm{Bi}_{2} \mathrm{~S}_{3}\), which dissolves as follows:

Sulfide is a very basic anion and really exists in water as \(\mathrm{HS}^{-}\). We will not consider this complication.

\footnotetext{
Solubilities must be expressed in \(\mathrm{mol} / \mathrm{L}\) in \(K_{\text {sp }}\) calculations.
\(K_{\text {sp }}\) calculations.
}

\[
\mathrm{Bi}_{2} \mathrm{~S}_{3}(s) \rightleftharpoons 2 \mathrm{Bi}^{3+}(a q)+3 \mathrm{~S}^{2-}(a q)
\]

Therefore,
\[
K_{\mathrm{sp}}=\left[\mathrm{Bi}^{3+}\right]^{2}\left[\mathrm{~S}^{2-}\right]^{3}
\]

Since no \(\mathrm{Bi}^{3+}\) and \(\mathrm{S}^{2-}\) ions were present in solution before the \(\mathrm{Bi}_{2} \mathrm{~S}_{3}\) dissolved,
\[
\left[\mathrm{Bi}^{3+}\right]_{0}=\left[\mathrm{S}^{2-}\right]_{0}=0
\]

Thus the equilibrium concentrations of these ions will be determined by the amount of salt that dissolves to reach equilibrium, which in this case is \(1.0 \times 10^{-15} \mathrm{~mol} / \mathrm{L}\). Since each \(\mathrm{Bi}_{2} \mathrm{~S}_{3}\) unit contains \(2 \mathrm{Bi}^{3+}\) and \(3 \mathrm{~S}^{2-}\) ions:
\[
\begin{aligned}
& 1.0 \times 10^{-15} \mathrm{~mol} / \mathrm{L} \mathrm{Bi}_{2} \mathrm{~S}_{3}(s) \\
& 2\left(1.0 \times 10^{-15} \mathrm{~mol} / \mathrm{L}\right) \mathrm{Bi}^{3+}(a q)+3\left(1.0 \times 10^{-15} \mathrm{~mol} / \mathrm{L}\right) \mathrm{S}^{2-}(a q)
\end{aligned}
\]

The equilibrium concentrations are
\[
\begin{aligned}
{\left[\mathrm{Bi}^{3+}\right] } & =\left[\mathrm{Bi}^{3+}\right]_{0}+\text { change }=0+2.0 \times 10^{-15} \mathrm{~mol} / \mathrm{L} \\
{\left[\mathrm{~S}^{2-}\right] } & =\left[\mathrm{S}^{2-}\right]_{0}+\text { change }=0+3.0 \times 10^{-15} \mathrm{~mol} / \mathrm{L}
\end{aligned}
\]

Then
\[
K_{\mathrm{sp}}=\left[\mathrm{Bi}^{3+}\right]^{2}\left[\mathrm{~S}^{2-}\right]^{3}=\left(2.0 \times 10^{-15}\right)^{2}\left(3.0 \times 10^{-15}\right)^{3}=1.1 \times 10^{-73}
\]

\section*{See Exercises 16.27 through 16.30}

We have seen that the experimentally determined solubility of an ionic solid can be used to calculate its \(K_{\text {sp }}\) value.* The reverse is also possible: The solubility of an ionic solid can be calculated if its \(K_{\text {sp }}\) value is known.

\section*{INTERACTIVE EXAMPLE 16.3 Calculating Solubility from \(\boldsymbol{K}_{\text {sp }}\)}

The \(K_{\text {sp }}\) value for copper(II) iodate, \(\mathrm{Cu}\left(\mathrm{IO}_{3}\right)_{2}\), is \(1.4 \times 10^{-7}\) at \(25^{\circ} \mathrm{C}\). Calculate its solubility at \(25^{\circ} \mathrm{C}\).

\section*{SOLUTION}

The system initially contains \(\mathrm{H}_{2} \mathrm{O}\) and solid \(\mathrm{Cu}\left(\mathrm{IO}_{3}\right)_{2}\), which dissolves according to the following equilibrium:

Therefore,
\[
\mathrm{Cu}\left(\mathrm{IO}_{3}\right)_{2}(s) \rightleftharpoons \mathrm{Cu}^{2+}(a q)+2 \mathrm{IO}_{3}^{-}(a q)
\]

To find the solubility of \(\mathrm{Cu}\left(\mathrm{IO}_{3}\right)_{2}\), we must find the equilibrium concentrations of the \(\mathrm{Cu}^{2+}\) and \(\mathrm{IO}_{3}{ }^{-}\)ions. We do this in the usual way by specifying the initial concentrations (before any solid has dissolved) and then defining the change required to reach equilibrium. Since in this case we do not know the solubility, we will assume that \(x \mathrm{~mol} / \mathrm{L}\) of the solid dissolves to reach equilibrium. The \(1: 2\) stoichiometry of the salt means that
\[
x \mathrm{~mol} / \mathrm{L} \mathrm{Cu}\left(\mathrm{IO}_{3}\right)_{2}(s) \longrightarrow x \mathrm{~mol} / \mathrm{L} \mathrm{Cu}^{2+}(a q)+2 x \mathrm{~mol} / \mathrm{L} \mathrm{IO}_{3}^{-}(a q)
\]
*This calculation assumes that all the dissolved solid is present as separated ions. In some cases, such as \(\mathrm{CaSO}_{4}\), large numbers of ion pairs exist in solution, so this method yields an incorrect value for \(K_{\text {sp }}\).

\section*{CHEMICAL CDNNECTIDNS}

\section*{The Chemistry of Teeth}
f dental chemistry continues to progress at the present rate, tooth decay may soon be a thing of the past. Cavities are holes that develop in tooth enamel, which is composed of the mineral hydroxyapatite, \(\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\). Recent research has shown that there is constant dissolving and re-forming of the tooth mineral in the saliva at the tooth's surface. Demineralization (dissolving of tooth enamel) is mainly caused by weak acids in the saliva created by bacteria as they metabolize carbohydrates in food. (The solubility of \(\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\) in acidic saliva should come as no surprise to you if you understand how pH affects the solubility of a salt with basic anions.)

In the first stages of tooth decay, parts of the tooth surface become porous and spongy and develop Swiss-cheese-like holes that, if untreated, eventually turn into cavities (see photo). However, recent results indicate that if the affected tooth is bathed in a solution containing appropriate amounts of \(\mathrm{Ca}^{2+}, \mathrm{PO}_{4}{ }^{3-}\), and \(\mathrm{F}^{-}\), it remineralizes. Because the \(\mathrm{F}^{-}\)replaces \(\mathrm{OH}^{-}\)in the tooth mineral \(\left(\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\right.\)

\(\Delta\)
X-ray photo showing decay (dark area) on the molar (right).
is changed to \(\left.\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}\right)\), the remineralized area is more resistant to future decay, since fluoride is a weaker base than hydroxide ion. In addition, it has been shown that the presence of \(\mathrm{Sr}^{2+}\) in the remineralizing fluid significantly increases resistance to decay.

If these results hold up under further study, the work of dentists will
change dramatically. Dentists will be much more involved in preventing damage to teeth than in repairing damage that has already occurred. One can picture the routine use of a remineralization rinse that will repair problem areas before they become cavities. Dental drills could join leeches as a medical anachronism.

The concentrations are as follows:

Substituting the equilibrium concentrations into the expression for \(K_{\text {sp }}\) gives

Then
\[
\begin{gathered}
1.4 \times 10^{-7}=K_{\mathrm{sp}}=\left[\mathrm{Cu}^{2+}\right]\left[\mathrm{IO}_{3}^{-}\right]^{2}=(x)(2 x)^{2}=4 x^{3} \\
x=\sqrt[3]{3.5 \times 10^{-8}}=3.3 \times 10^{-3} \mathrm{~mol} / \mathrm{L}
\end{gathered}
\]
- Thus the solubility of solid \(\mathrm{Cu}\left(\mathrm{IO}_{3}\right)_{2}\) is \(3.3 \times 10^{-3} \mathrm{~mol} / \mathrm{L}\).

\section*{Relative Solubilities}

A salt's \(K_{\text {sp }}\) value gives us information about its solubility. However, we must be careful in using \(K_{\text {sp }}\) values to predict the relative solubilities of a group of salts. There are two possible cases:
1. The salts being compared produce the same number of ions. For example, consider
\begin{tabular}{ll}
\(\operatorname{AgI}(s)\) & \(K_{\text {sp }}=1.5 \times 10^{-16}\) \\
\(\operatorname{CuI}(s)\) & \(K_{\text {sp }}=5.0 \times 10^{-12}\) \\
\(\mathrm{CaSO}_{4}(s)\) & \(K_{\text {sp }}=6.1 \times 10^{-5}\)
\end{tabular}

Each of these solids dissolves to produce two ions:
\[
\begin{aligned}
& \text { Salt } \rightleftharpoons \text { cation }+ \text { anion } \\
& K_{\mathrm{sp}}=[\text { cation }][\text { anion }]
\end{aligned}
\]

If \(x\) is the solubility in \(\mathrm{mol} / \mathrm{L}\), then at equilibrium
\[
\begin{aligned}
& {[\text { Cation }]=x} \\
& {[\text { Anion }]=x} \\
& K_{\text {sp }}=[\text { cation }][\text { anion }]=x^{2} \\
& x=\sqrt{K_{\text {sp }}}=\text { solubility }
\end{aligned}
\]

Therefore, in this case we can compare the solubilities for these solids by comparing the \(K_{\text {sp }}\) values:
\[
\underset{\substack{\text { Most soluble; } \\ \text { largest } K_{\text {sp }}}}{\mathrm{CaSO}_{4}(s)}>\mathrm{CuI}(s)>\underset{\substack{\text { Least soluble; } \\ \text { smallest } K_{\text {sp }}}}{\mathrm{AgI}(s)}
\]
2. The salts being compared produce different numbers of ions. For example, consider
\[
\begin{array}{ll}
\mathrm{CuS}(s) & K_{\text {sp }}=8.5 \times 10^{-45} \\
\mathrm{Ag}_{2} \mathrm{~S}(s) & K_{\text {sp }}=1.6 \times 10^{-49} \\
\mathrm{Bi}_{2} \mathrm{~S}_{3}(s) & K_{\text {sp }}=1.1 \times 10^{-73}
\end{array}
\]

Because these salts produce different numbers of ions when they dissolve, the \(K_{\text {sp }}\) values cannot be compared directly to determine relative solubilities. In fact, if we calculate the solubilities (using the procedure in Example 16.3), we obtain the results summarized in Table 16.2. The order of solubilities is
\[
\underset{\text { Most soluble }}{\mathrm{Bi}_{2} \mathrm{~S}_{3}(s)}>\mathrm{Ag}_{2} \mathrm{~S}(s)>\underset{\text { Least soluble }}{\mathrm{CuS}(s)}
\]
which is opposite to the order of the \(K_{\text {sp }}\) values.
Remember that relative solubilities can be predicted by comparing \(K_{\text {sp }}\) values only for salts that produce the same total number of ions.

\section*{TABLE 16.2 | Calculated Solubilities for CuS,} \(\mathrm{Ag}_{2} \mathrm{~S}\), and \(\mathrm{Bi}_{2} \mathrm{~S}_{3}\) at \(25^{\circ} \mathrm{C}\)
\begin{tabular}{lcc} 
Salt & \(\boldsymbol{K}_{\text {sp }}\) & \begin{tabular}{c} 
Calculated \\
Solubility \((\mathrm{mol} / \mathrm{L})\)
\end{tabular} \\
\hline CuS & \(8.5 \times 10^{-45}\) & \(9.2 \times 10^{-23}\) \\
\hline \(\mathrm{Ag}_{2} \mathrm{~S}\) & \(1.6 \times 10^{-49}\) & \(3.4 \times 10^{-17}\) \\
\hline \(\mathrm{Bi}_{2} \mathrm{~S}_{3}\) & \(1.1 \times 10^{-73}\) & \(1.0 \times 10^{-15}\) \\
\hline
\end{tabular}

\section*{A}

A potassium chromate solution being added to aqueous silver nitrate, forming silver chromate.

\section*{Common Ion Effect}

So far we have considered ionic solids dissolved in pure water. We will now see what happens when the water contains an ion in common with the dissolving salt. For example, consider the solubility of solid silver chromate \(\left(\mathrm{Ag}_{2} \mathrm{CrO}_{4}, K_{\text {sp }}=9.0 \times 10^{-12}\right)\) in a \(0.100-M\) solution of \(\mathrm{AgNO}_{3}\). Before any \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) dissolves, the solution contains the major species \(\mathrm{Ag}^{+}, \mathrm{NO}_{3}{ }^{-}\), and \(\mathrm{H}_{2} \mathrm{O}\), with solid \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) on the bottom of the container. Since \(\mathrm{NO}_{3}{ }^{-}\)is not found in \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\), we can ignore it. The relevant initial concentrations (before any \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) dissolves) are
\[
\begin{aligned}
& {\left[\mathrm{Ag}^{+}\right]_{0}=0.100 M\left(\text { from the dissolved } \mathrm{AgNO}_{3}\right)} \\
& {\left[\mathrm{CrO}_{4}^{2-}\right]_{0}=0}
\end{aligned}
\]

The system comes to equilibrium as the solid \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) dissolves according to the reaction
for which
\[
\mathrm{Ag}_{2} \mathrm{CrO}_{4}(s) \rightleftharpoons 2 \mathrm{Ag}^{+}(a q)+\mathrm{CrO}_{4}{ }^{2-}(a q)
\]
\(K_{\text {sp }}\left[\mathrm{Ag}^{+}\right]\left[\mathrm{CrO}_{4}^{2-}\right]=9.0 \times 10^{-12}\)
We assume that \(x \mathrm{~mol} / \mathrm{L}\) of \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) dissolves to reach equilibrium, which means that
\[
x \mathrm{~mol} / \mathrm{L} \mathrm{Ag}_{2} \mathrm{CrO}_{4}(s) \longrightarrow 2 x \mathrm{~mol} / \mathrm{L} \mathrm{Ag}^{+}(a q)+x \mathrm{~mol} / \mathrm{L} \mathrm{CrO}_{4}{ }^{2-}
\]

Now we can specify the equilibrium concentrations in terms of \(x\) :
\[
\begin{aligned}
& {\left[\mathrm{Ag}^{+}\right]=\left[\mathrm{Ag}^{+}\right]_{0}+\text { change }=0.100+2 x} \\
& {\left[\mathrm{CrO}_{4}{ }^{2-}\right]=\left[\mathrm{CrO}_{4}{ }^{2-}\right]_{0}+\text { change }=0+x=x}
\end{aligned}
\]

Substituting these concentrations into the expression for \(K_{\mathrm{sp}}\) gives
\[
9.0 \times 10^{-12}=\left[\mathrm{Ag}^{+}\right]^{2}\left[\mathrm{CrO}_{4}^{2-}\right]=(0.100+2 x)^{2}(x)
\]

The mathematics required here appear to be complicated, since the multiplication of terms on the right-hand side produces an expression that contains an \(x^{3}\) term. However, as is usually the case, we can make simplifying assumptions. Since the \(K_{\mathrm{sp}}\) value for \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) is small (the position of the equilibrium lies far to the left), \(x\) is expected to be small compared with \(0.100 M\). Therefore, \(0.100+2 x \approx 0.100\), which allows simplification of the expression:

Then
\[
\begin{gathered}
9.0 \times 10^{-12}=(0.100+2 x)^{2}(x) \approx(0.100)^{2}(x) \\
x \approx \frac{9.0 \times 10^{-12}}{(0.100)^{2}}=9.0 \times 10^{-10} \mathrm{~mol} / \mathrm{L}
\end{gathered}
\]

Since \(x\) is much less than \(0.100 M\), the approximation is valid (by the \(5 \%\) rule). Thus
Solubility of \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) in \(0.100 M \mathrm{AgNO}_{3}=x=9.0 \times 10^{-10} \mathrm{~mol} / \mathrm{L}\)
and the equilibrium concentrations are
\[
\begin{aligned}
& {\left[\mathrm{Ag}^{+}\right]=0.100+2 x=0.100+2\left(9.0 \times 10^{-10}\right)=0.100 \mathrm{M}} \\
& {\left[\mathrm{CrO}_{4}^{2-}\right]=x=9.0 \times 10^{-10} \mathrm{M}}
\end{aligned}
\]

Now we compare the solubilities of \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) in pure water and in \(0.100 \mathrm{M} \mathrm{AgNO}_{3}\) :
Solubility of \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) in pure water \(=1.3 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\)
Solubility of \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) in \(0.100 \mathrm{M} \mathrm{AgNO} 3=9.0 \times 10^{-10} \mathrm{~mol} / \mathrm{L}\)
Note that the solubility of \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\) is much less in the presence of \(\mathrm{Ag}^{+}\)ions from \(\mathrm{AgNO}_{3}\). This is another example of the common ion effect. The solubility of a solid is lowered if the solution already contains ions common to the solid.

What if all you know about two salts is that the value of \(K_{\text {sp }}\) for salt A is greater than that of salt B ? Why can we not compare relative solubilities of the salts? Use numbers to show how salt \(A\) could be more soluble than salt \(B\), and how salt \(B\) could be more soluble than salt \(A\).

\section*{INTERACTIVE EXAMPLE 16.4}

SOLUTION Before any \(\mathrm{CaF}_{2}\) dissolves, the solution contains the major species \(\mathrm{Na}^{+}, \mathrm{F}^{-}\), and \(\mathrm{H}_{2} \mathrm{O}\). The solubility equilibrium for \(\mathrm{CaF}_{2}\) is
\[
\begin{array}{ll} 
& \mathrm{CaF}_{2}(s) \rightleftharpoons \mathrm{Ca}^{2+}(a q)+2 \mathrm{~F}^{-}(a q) \\
\text { and } & K_{\mathrm{sp}}=4.0 \times 10^{-11}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}
\end{array}
\]

\section*{Solubility and Common Ions}

Calculate the solubility of solid \(\mathrm{CaF}_{2}\left(K_{\text {sp }}=4.0 \times 10^{-11}\right)\) in a \(0.025-\mathrm{M} \mathrm{NaF}\) solution.
\begin{tabular}{|c|c|c|}
\hline Initial Concentration (mol/L) (before any \(\mathrm{CaF}_{2}\) dissolves) & & Equilibrium
Concentration (mol/L) \\
\hline \[
\begin{aligned}
& {\left[\mathrm{Ca}^{2+}\right]_{0}=0} \\
& {\left[\mathrm{~F}^{-}\right]_{0}=0.025 \mathrm{M}}
\end{aligned}
\] & \(x\) mol/ CaF dissolves & \[
\begin{aligned}
& {\left[\mathrm{Ca}^{2+}\right]=x} \\
& {\left[\mathrm{~F}^{-}\right]=0.025+2 x}
\end{aligned}
\] \\
\hline 7 & &  \\
\hline From 0.025 M NaF & equilibrium & From NaF From \(\mathrm{CaF}_{2}\) \\
\hline
\end{tabular}

Substituting the equilibrium concentrations into the expression for \(K_{\text {sp }}\) gives
\[
K_{\mathrm{sp}}=4.0 \times 10^{-11}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}=(x)(0.025+2 x)^{2}
\]

Assuming that \(2 x\) is negligible compared with 0.025 (since \(K_{\text {sp }}\) is small) gives
\[
\begin{aligned}
4.0 \times 10^{-11} & \approx(x)(0.025)^{2} \\
x & \approx 6.4 \times 10^{-8}
\end{aligned}
\]

The approximation is valid (by the \(5 \%\) rule), and
\[
\square \text { Solubility }=x=6.4 \times 10^{-8} \mathrm{~mol} / \mathrm{L}
\]

Thus \(6.4 \times 10^{-8}\) mole of solid \(\mathrm{CaF}_{2}\) dissolves per liter of the \(0.025-\mathrm{M} \mathrm{NaF}\) solution.
\[
\text { See Exergises } 16.41 \text { through } 16.46
\]

\section*{pH and Solubility}

The pH of a solution can greatly affect a salt's solubility. For example, magnesium hydroxide dissolves according to the equilibrium
\[
\mathrm{Mg}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Mg}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
\]

Addition of \(\mathrm{OH}^{-}\)ions (an increase in pH ) will, by the common ion effect, force the equilibrium to the left, decreasing the solubility of \(\mathrm{Mg}(\mathrm{OH})_{2}\). On the other hand, an addition of \(\mathrm{H}^{+}\)ions (a decrease in pH ) increases the solubility, because \(\mathrm{OH}^{-}\)ions are removed from solution by reacting with the added \(\mathrm{H}^{+}\)ions. In response to the lower concentration of \(\mathrm{OH}^{-}\), the equilibrium position moves to the right. This is why a suspension of solid \(\mathrm{Mg}(\mathrm{OH})_{2}\), known as milk of magnesia, dissolves as required in the stomach to combat excess acidity.

\(\Delta\)
Stalactites and stalagmites in Luray Cavern in Virginia.

This idea also applies to salts with other types of anions. For example, the solubility of silver phosphate \(\left(\mathrm{Ag}_{3} \mathrm{PO}_{4}\right)\) is greater in acid than in pure water because the \(\mathrm{PO}_{4}{ }^{3-}\) ion is a strong base that reacts with \(\mathrm{H}^{+}\)to form the \(\mathrm{HPO}_{4}{ }^{2-}\) ion. The reaction
\[
\mathrm{H}^{+}(\mathrm{aq})+\mathrm{PO}_{4}^{3-}(a q) \longrightarrow \mathrm{HPO}_{4}^{2-}(a q)
\]
occurs in acidic solution, thus lowering the concentration of \(\mathrm{PO}_{4}{ }^{3-}\) and shifting the solubility equilibrium
\[
\mathrm{Ag}_{3} \mathrm{PO}_{4}(s) \rightleftharpoons 3 \mathrm{Ag}^{+}(a q)+\mathrm{PO}_{4}{ }^{3-}(a q)
\]
to the right. This, in turn, increases the solubility of silver phosphate.
Silver chloride \((\mathrm{AgCl})\), however, has the same solubility in acid as in pure water. Why? Since the \(\mathrm{Cl}^{-}\)ion is a very weak base (that is, HCl is a very strong acid), no HCl molecules are formed. Thus the addition of \(\mathrm{H}^{+}\)to a solution containing \(\mathrm{Cl}^{-}\)does not affect \(\left[\mathrm{Cl}^{-}\right]\)and has no effect on the solubility of a chloride salt.

The general rule is that if the anion \(\mathrm{X}^{-}\)is an effective base-that is, if HX is a weak acid-the salt MX will show increased solubility in an acidic solution. Examples of common anions that are effective bases are \(\mathrm{OH}^{-}, \mathrm{S}^{2-}, \mathrm{CO}_{3}{ }^{2-}, \mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}\), and \(\mathrm{CrO}_{4}{ }^{2-}\). Salts containing these anions are much more soluble in an acidic solution than in pure water.

As mentioned at the beginning of this chapter, one practical result of the increased solubility of carbonates in acid is the formation of huge limestone caves such as Mammoth Cave in Kentucky and Carlsbad Caverns in New Mexico. Carbon dioxide dissolved in groundwater makes it acidic, increasing the solubility of calcium carbonate and eventually producing huge caverns. As the carbon dioxide escapes to the air, the pH of the dripping water goes up and the calcium carbonate precipitates, forming stalactites and stalagmites.
 chemistry exam. What if your friend tells you that since acids are very reactive, all salts are more soluble in aqueous solutions of acids than in water? How would you explain to your friend that this is not true? Use a specific example to defend your answer.

\subsection*{16.2 Precipitation and Qualitative Analysis}

So far we have considered solids dissolving in solutions. Now we will consider the reverse process-the formation of a solid from solution. When solutions are mixed, various reactions can occur. We have already considered acid-base reactions in some detail. In this section we show how to predict whether a precipitate will form when two solutions are mixed. We will use the ion product, which is defined just like the expression for \(K_{\mathrm{sp}}\) for a given solid except that initial concentrations are used instead of equilibrium concentrations. For solid \(\mathrm{CaF}_{2}\), the expression for the ion product \(Q\) is written
\[
Q=\left[\mathrm{Ca}^{2+}\right]_{0}\left[\mathrm{~F}^{-}\right]_{0}^{2}
\]

If we add a solution containing \(\mathrm{Ca}^{2+}\) ions to a solution containing \(\mathrm{F}^{-}\)ions, a precipitate may or may not form, depending on the concentrations of these ions in the resulting mixed solution. To predict whether precipitation will occur, we consider the relationship between \(Q\) and \(K_{\text {sp }}\).

If \(Q\) is greater than \(K_{\mathrm{sp}}\), precipitation occurs and will continue until the concentrations are reduced to the point that they satisfy \(K_{\text {sp }}\).
If \(Q\) is less than \(K_{\text {sp }}\), no precipitation occurs.

\section*{INTERACTIVE EXAMPLE 16.5 Determining Precipitation Conditions}

\section*{SOLUTION}

The equilibrium constant for formation of solid \(\mathrm{Pbl}_{2}\) is \(1 / K_{\text {sp, }}\) or \(7 \times 10^{7}\), so this equilibrium lies far to the right.

A solution is prepared by adding 750.0 mL of \(4.00 \times 10^{-3} \mathrm{M} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{3}\) to 300.0 mL of \(2.00 \times 10^{-2} M \mathrm{KIO}_{3}\). Will \(\mathrm{Ce}\left(\mathrm{IO}_{3}\right)_{3}\left(K_{\text {sp }}=1.9 \times 10^{-10}\right)\) precipitate from this solution?

First, we calculate \(\left[\mathrm{Ce}^{3+}\right]_{0}\) and \(\left[\mathrm{IO}_{3}{ }^{-}\right]_{0}\) in the mixed solution before any reaction occurs:
\[
\begin{aligned}
& {\left[\mathrm{Ce}^{3+}\right]_{0}=\frac{(750.0 \mathrm{~mL})\left(4.00 \times 10^{-3} \mathrm{mmol} / \mathrm{mL}\right)}{(750.0+300.0) \mathrm{mL}}=2.86 \times 10^{-3} M} \\
& {\left[\mathrm{IO}_{3}^{-}\right]_{0}=\frac{(300.0 \mathrm{~mL})\left(2.00 \times 10^{-2} \mathrm{mmol} / \mathrm{mL}\right)}{(750.0+300.0) \mathrm{mL}}=5.71 \times 10^{-3} M}
\end{aligned}
\]

The ion product for \(\mathrm{Ce}\left(\mathrm{IO}_{3}\right)_{3}\) is
\[
Q=\left[\mathrm{Ce}^{3+}\right]_{0}\left[\mathrm{IO}_{3}^{-}\right]_{0}^{3}=\left(2.86 \times 10^{-3}\right)\left(5.71 \times 10^{-3}\right)^{3}=5.32 \times 10^{-10}
\]

Since \(Q\) is greater than \(K_{\text {sp }}, \mathrm{Ce}\left(\mathrm{IO}_{3}\right)_{3}\) will precipitate from the mixed solution.

\section*{See Exeraises 16.53 through 16.56}

Sometimes we want to do more than simply predict whether precipitation will occur; we may want to calculate the equilibrium concentrations in the solution after precipitation occurs. For example, let us calculate the equilibrium concentrations of \(\mathrm{Pb}^{2+}\) and \(\mathrm{I}^{-}\)ions in a solution formed by mixing 100.0 mL of \(0.0500 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}\) and 200.0 mL of 0.100 M NaI . First, we must determine whether solid \(\mathrm{PbI}_{2}\left(K_{\text {sp }}=1.4 \times 10^{-8}\right)\) forms when the solutions are mixed. To do so, we need to calculate \(\left[\mathrm{Pb}^{2+}\right]_{0}\) and \(\left[\mathrm{I}^{-}\right]_{0}\) before any reaction occurs:
\[
\begin{aligned}
{\left[\mathrm{Pb}^{2+}\right]_{0} } & =\frac{\mathrm{mmol} \mathrm{~Pb}^{2+}}{\mathrm{mL} \text { solution }}=\frac{(100.0 \mathrm{~mL})(0.0500 \mathrm{mmol} / \mathrm{mL})}{300.0 \mathrm{~mL}}=1.67 \times 10^{-2} \mathrm{M} \\
{\left[\mathrm{I}^{-}\right]_{0} } & =\frac{\mathrm{mmol} \mathrm{I}}{\mathrm{~mL} \text { solution }}=\frac{(200.0 \mathrm{~mL})(0.100 \mathrm{mmol} / \mathrm{mL})}{300.0 \mathrm{~mL}}=6.67 \times 10^{-2} \mathrm{M}
\end{aligned}
\]

The ion product for \(\mathrm{PbI}_{2}\) is
\[
Q=\left[\mathrm{Pb}^{2+}\right]_{0}\left[\mathrm{I}^{-}\right]_{0}^{2}=\left(1.67 \times 10^{-2}\right)\left(6.67 \times 10^{-2}\right)^{2}=7.43 \times 10^{-5}
\]

Since \(Q\) is greater than \(K_{\text {sp }}\), a precipitate of \(\mathrm{PbI}_{2}\) will form.
Since the \(K_{\text {sp }}\) for \(\mathrm{PbI}_{2}\) is quite small \(\left(1.4 \times 10^{-8}\right)\), only very small quantities of \(\mathrm{Pb}^{2+}\) and \(\mathrm{I}^{-}\)can coexist in aqueous solution. In other words, when \(\mathrm{Pb}^{2+}\) and \(\mathrm{I}^{-}\)are mixed, most of these ions will precipitate out as \(\mathrm{PbI}_{2}\). That is, the reaction
\[
\mathrm{Pb}^{2+}(a q)+2 \mathrm{I}^{-}(a q) \longrightarrow \mathrm{PbI}_{2}(s)
\]
(which is the reverse of the dissolution reaction) goes essentially to completion.
If, when two solutions are mixed, a reaction occurs that goes virtually to completion, it is essential to do the stoichiometry calculations before considering the equilibrium calculations. Therefore, in this case we let the system go completely in the direction toward which it tends. Then we will let it adjust back to equilibrium. If we let \(\mathrm{Pb}^{2+}\) and \(\mathrm{I}^{-}\)react to completion, we have the following concentrations:
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multirow{4}{*}{Before reaction} & \(\mathrm{Pb}^{2+}\) & + & \(21^{-}\) & \(\longrightarrow\) & \(\mathrm{PbI}_{2}\) \\
\hline & \((100.0 \mathrm{~mL})(0.0500 \mathrm{M})\) & & \((200.0 \mathrm{~mL})(0.100 \mathrm{M})\) & & The amount of \\
\hline & \(=5.00 \mathrm{mmol}\) & & \(=20.0 \mathrm{mmol}\) & & \(\mathrm{PbI}_{2}\) formed does \\
\hline & 0 mmol & & 20.0-2(5.00) & & not influence the equilibrium \\
\hline reaction & O & & \(=10.0 \mathrm{mmol}\) & & equilibrium. \\
\hline
\end{tabular}

Next we must allow the system to adjust to equilibrium. At equilibrium \(\left[\mathrm{Pb}^{2+}\right]\) is not actually zero because the reaction does not go quite to completion. The best way to think about this is that once the \(\mathrm{PbI}_{2}\) is formed, a very small amount redissolves to reach equilibrium. Since \(\mathrm{I}^{-}\)is in excess, the \(\mathrm{PbI}_{2}\) is dissolving into a solution that contains \(10.0 \mathrm{mmol}^{-}\)per 300.0 mL solution, or \(3.33 \times 10^{-2} \mathrm{M}^{-}\).

We could state this problem as follows: What is the solubility of solid \(\mathrm{PbI}_{2}\) in a \(3.33 \times 10^{-2} M-\mathrm{NaI}\) solution? The lead iodide dissolves according to the equation
\[
\operatorname{PbI}_{2}(s) \rightleftharpoons \mathrm{Pb}^{2+}(a q)+2 \mathrm{I}^{-}(a q)
\]

The concentrations are as follows:
\begin{tabular}{ll}
\begin{tabular}{c} 
Initial Concentration \\
\((\mathrm{mol} / \mathrm{L})\)
\end{tabular} & \begin{tabular}{l} 
Equilibrium Concentration \\
\((\mathrm{mol} / \mathrm{L})\)
\end{tabular} \\
\begin{tabular}{lll}
{\(\left[\mathrm{Pb}^{2+}\right]_{0}=0\)}
\end{tabular} & \begin{tabular}{l}
{\(\left[\mathrm{Pb}^{2+}\right]=x\)} \\
{\(\left[\mathrm{l}^{-}\right]_{0}=3.33 \times 10^{-2}\)} \\
\end{tabular} \\
\hline
\end{tabular}

Substituting into the expression for \(K_{\text {sp }}\) gives
\[
K_{\mathrm{sp}}=1.4 \times 10^{-8}=\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{I}^{-}\right]^{2}=(x)\left(3.33 \times 10^{-2}+2 x\right)^{2} \approx(x)\left(3.33 \times 10^{-2}\right)^{2}
\]

Then
\[
\begin{aligned}
{\left[\mathrm{Pb}^{2+}\right] } & =x=1.3 \times 10^{-5} M \\
{\left[\mathrm{I}^{-}\right] } & =3.33 \times 10^{-2} M
\end{aligned}
\]

Note that \(3.33 \times 10^{-2} \gg 2 x\), so the approximation is valid. These \(\mathrm{Pb}^{2+}\) and \(\mathrm{I}^{-}\)concentrations thus represent the equilibrium concentrations present in a solution formed by mixing 100.0 mL of \(0.0500 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}\) and 200.0 mL of 0.100 M NaI .

\section*{INTERACTVE EXAMPLE 16.6 Precipitation}

A solution is prepared by mixing 150.0 mL of \(1.00 \times 10^{-2} \mathrm{M} \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}\) and 250.0 mL of \(1.00 \times 10^{-1} M \mathrm{NaF}\). Calculate the concentrations of \(\mathrm{Mg}^{2+}\) and \(\mathrm{F}^{-}\)at equilibrium with solid \(\mathrm{MgF}_{2}\left(K_{\text {sp }}=6.4 \times 10^{-9}\right)\).

SOLUTION The first step is to determine whether solid \(\mathrm{MgF}_{2}\) forms. To do this, we need to calculate the concentrations of \(\mathrm{Mg}^{2+}\) and \(\mathrm{F}^{-}\)in the mixed solution and find \(Q\) :
\[
\begin{aligned}
& {\left[\mathrm{Mg}^{2+}\right]_{0}=\frac{\mathrm{mmol} \mathrm{Mg}}{}{ }^{2+} \mathrm{mL} \text { solution }^{(150.0 \mathrm{~mL})\left(1.00 \times 10^{-2} \mathrm{M}\right)} \frac{400.0 \mathrm{~mL}}{}=3.75 \times 10^{-3} \mathrm{M}} \\
& {\left[\mathrm{~F}^{-}\right]_{0}=\frac{\mathrm{mmol} \mathrm{~F}^{-}}{\mathrm{mL} \text { solution }}=\frac{(250.0 \mathrm{~mL})\left(1.00 \times 10^{-1} \mathrm{M}\right)}{400.0 \mathrm{~mL}}=6.25 \times 10^{-2} \mathrm{M}} \\
& Q=\left[\mathrm{Mg}^{2+}\right]_{0}\left[\mathrm{~F}^{-}\right]_{0}{ }^{2}=\left(3.75 \times 10^{-3}\right)\left(6.25 \times 10^{-2}\right)^{2}=1.46 \times 10^{-5}
\end{aligned}
\]

Since \(Q\) is greater than \(K_{\text {sp }}\), solid \(\mathrm{MgF}_{2}\) will form.
The next step is to run the precipitation reaction to completion:

The approximations made here fall within the \(5 \%\) rule.

Note that excess \(\mathrm{F}^{-}\)remains after the precipitation reaction goes to completion. The concentration is
\[
\left[\mathrm{F}^{-}\right]_{\mathrm{excess}}=\frac{22.0 \mathrm{mmol}}{400.0 \mathrm{~mL}}=5.50 \times 10^{-2} \mathrm{M}
\]

Although we have assumed that the \(\mathrm{Mg}^{2+}\) is completely consumed, we know that \(\left[\mathrm{Mg}^{2+}\right]\) will not be zero at equilibrium. We can compute the equilibrium \(\left[\mathrm{Mg}^{2+}\right]\) by letting \(\mathrm{MgF}_{2}\) redissolve to satisfy the expression for \(K_{\mathrm{sp}}\). How much \(\mathrm{MgF}_{2}\) will dissolve in a \(5.50 \times 10^{-2}-M \mathrm{NaF}\) solution? We proceed as usual:

\section*{See Exercises 16.57 through 16.60}

\section*{Selective Precipitation}

Mixtures of metal ions in aqueous solution are often separated by selective precipitation, that is, by using a reagent whose anion forms a precipitate with only one or a few of the metal ions in the mixture. For example, suppose we have a solution containing both \(\mathrm{Ba}^{2+}\) and \(\mathrm{Ag}^{+}\)ions. If NaCl is added to the solution, AgCl precipitates as a white solid, but since \(\mathrm{BaCl}_{2}\) is soluble, the \(\mathrm{Ba}^{2+}\) ions remain in solution.

\section*{EXAMPLE 16.7}

SOLUTION For \(\mathrm{PbI}_{2}\), the \(K_{\text {sp }}\) expression is
\[
1.4 \times 10^{-8}=K_{\mathrm{sp}}=\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{I}^{-}\right]^{2}
\]

Since \(\left[\mathrm{Pb}^{2+}\right]\) in this solution is known to be \(2.0 \times 10^{-3} M\), the greatest concentration of \(\mathrm{I}^{-}\)that can be present without causing precipitation of \(\mathrm{PbI}_{2}\) can be calculated from the \(K_{\text {sp }}\) expression:
\[
\begin{aligned}
1.4 \times 10^{-8} & =\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{I}^{-}\right]^{2}=\left(2.0 \times 10^{-3}\right)\left[\mathrm{I}^{-}\right]^{2} \\
\square\left[\mathrm{I}^{-}\right] & =2.6 \times 10^{-3} M
\end{aligned}
\]

Any \(\mathrm{I}^{-}\)in excess of this concentration will cause solid \(\mathrm{PbI}_{2}\) to form.
Similarly, for CuI, the \(K_{\text {sp }}\) expression is
and
\[
\begin{aligned}
5.3 \times 10^{-12}= & K_{\text {sp }}=\left[\mathrm{Cu}^{+}\right]\left[\mathrm{I}^{-}\right]=\left(1.0 \times 10^{-4}\right)\left[\mathrm{I}^{-}\right] \\
& {\left[\mathrm{I}^{-}\right]=5.3 \times 10^{-8} \mathrm{M} }
\end{aligned}
\]

A concentration of \(\mathrm{I}^{-}\)in excess of \(5.3 \times 10^{-8} M\) will cause formation of solid CuI .
As \(I^{-}\)is added to the mixed solution, CuI will precipitate first, since the \(\left[\mathrm{I}^{-}\right]\)required is less. Therefore, \(\mathrm{Cu}^{+}\)would be separated from \(\mathrm{Pb}^{2+}\) using this reagent.

\section*{See Exeraises 16.61 through 16.64}

We can compare \(K_{\text {sp }}\) values to find relative solubilities because FeS and MnS produce the same number of ions in solution.

Since metal sulfide salts differ dramatically in their solubilities, the sulfide ion is often used to separate metal ions by selective precipitation. For example, consider a solution containing a mixture of \(10^{-3} M \mathrm{Fe}^{2+}\) and \(10^{-3} M \mathrm{Mn}^{2+}\). Since \(\mathrm{FeS}\left(K_{\text {sp }}=\right.\) \(\left.3.7 \times 10^{-19}\right)\) is much less soluble than \(\mathrm{MnS}\left(K_{\mathrm{sp}}=2.3 \times 10^{-13}\right)\), careful addition of \(\mathrm{S}^{2-}\) to the mixture will precipitate \(\mathrm{Fe}^{2+}\) as FeS , leaving \(\mathrm{Mn}^{2+}\) in solution.

One real advantage of the sulfide ion as a precipitating reagent is that because it is basic, its concentration can be controlled by regulating the pH of the solution. \(\mathrm{H}_{2} \mathrm{~S}\) is a diprotic acid that dissociates in two steps:
\[
\begin{aligned}
\mathrm{H}_{2} \mathrm{~S} \rightleftharpoons \mathrm{H}^{+}+\mathrm{HS}^{-} & K_{\mathrm{a}_{1}}=1.0 \times 10^{-7} \\
\mathrm{HS}^{-} \rightleftharpoons \mathrm{H}^{+}+\mathrm{S}^{2-} & K_{\mathrm{a}_{2}} \approx 10^{-19}
\end{aligned}
\]

Note from the small \(K_{\mathrm{a}_{2}}\) value that \(\mathrm{S}^{2-}\) ions have a high affinity for protons. In an acidic solution (large \(\left[\mathrm{H}^{+}\right]\)), \(\left[\mathrm{S}^{2-}\right]\) will be relatively small, since under these conditions the dissociation equilibria will lie far to the left. On the other hand, in basic solutions \(\left[\mathrm{S}^{2-}\right]\) will be relatively large, since the very small value of \(\left[\mathrm{H}^{+}\right]\)will pull both equilibria to the right, producing \(\mathrm{S}^{2-}\).

This means that the most insoluble sulfide salts, such as CuS ( \(K_{\mathrm{sp}}=8.5 \times 10^{-45}\) ) and \(\mathrm{HgS}\left(K_{\mathrm{sp}}=1.6 \times 10^{-54}\right)\), can be precipitated from an acidic solution, leaving the more soluble ones, such as \(\mathrm{MnS}\left(K_{\text {sp }}=2.3 \times 10^{-13}\right)\) and \(\mathrm{NiS}\left(K_{\text {sp }}=3 \times 10^{-21}\right)\), still dissolved. The manganese and nickel sulfides can then be precipitated by making the solution slightly basic. This procedure is diagramed in Fig. 16.1.

FIGURE 16.1 The separation of \(\mathrm{Cu}^{2+}\) and \(\mathrm{Hg}^{2+}\) from \(\mathrm{Ni}^{2+}\) and \(\mathrm{Mn}^{2+}\) using \(\mathrm{H}_{2} \mathrm{~S}\). At a low \(\mathrm{pH},\left[\mathrm{S}^{2-}\right]\) is relatively low and only the very insoluble HgS and CuS precipitate. When \(\mathrm{OH}^{-}\)is added to lower \(\left[\mathrm{H}^{+}\right]\), the value of \(\left[\mathrm{S}^{2-}\right]\) increases, and MnS and NiS precipitate.

A
Flame test for potassium.

Note at this point in the analysis that some solutions containing \(\mathrm{Na}^{+}\)have been added. Thus the flame test for \(\mathrm{Na}^{+}\)must be performed on the original solution.

\section*{Qualitative Analysis}

The classic scheme for qualitative analysis of a mixture containing all the common cations (listed in Fig. 16.2) involves first separating them into five major groups based on solubilities. (These groups are not directly related to the groups of the periodic table.) Each group is then treated further to separate and identify the individual ions. We will be concerned here only with separation of the major groups.

\section*{Group I-Insoluble chlorides}

When dilute aqueous HCl is added to a solution containing a mixture of the common cations, only \(\mathrm{Ag}^{+}, \mathrm{Pb}^{2+}\), and \(\mathrm{Hg}_{2}{ }^{2+}\) will precipitate out as insoluble chlorides. All other chlorides are soluble and remain in solution. The Group I precipitate is removed, leaving the other ions in solution for treatment with sulfide ion.

\section*{Group II—Sulfides insoluble in acid solution}

After the insoluble chlorides are removed, the solution is still acidic, since HCl was added. If \(\mathrm{H}_{2} \mathrm{~S}\) is added to this solution, only the most insoluble sulfides (those of \(\mathrm{Hg}^{2+}, \mathrm{Cd}^{2+}, \mathrm{Bi}^{3+}, \mathrm{Cu}^{2+}\), and \(\mathrm{Sn}^{4+}\) ) will precipitate, since \(\left[\mathrm{S}^{2-}\right]\) is relatively low because of the high concentration of \(\mathrm{H}^{+}\). The more soluble sulfides will remain dissolved under these conditions, and the precipitate of the insoluble salt is removed.

\section*{Group III—Sulfides insoluble in basic solution}

The solution is made basic at this stage, and more \(\mathrm{H}_{2} \mathrm{~S}\) is added. As we saw earlier, a basic solution produces a higher [ \(\mathrm{S}^{2-}\) ], which leads to precipitation of the more soluble sulfides. The cations precipitated as sulfides at this stage are \(\mathrm{Co}^{2+}, \mathrm{Zn}^{2+}, \mathrm{Mn}^{2+}, \mathrm{Ni}^{2+}\), and \(\mathrm{Fe}^{2+}\). If any \(\mathrm{Cr}^{3+}\) and \(\mathrm{Al}^{3+}\) ions are present, they also will precipitate, but as insoluble hydroxides (remember the solution is now basic). The precipitate is separated from the solution containing the rest of the ions.

\section*{Group IV-Insoluble carbonates}

At this point, all the cations have been precipitated except those from Groups 1A and 2A of the periodic table. The Group 2A cations form insoluble carbonates and can be precipitated by the addition of \(\mathrm{CO}_{3}{ }^{2-}\). For example, \(\mathrm{Ba}^{2+}, \mathrm{Ca}^{2+}\), and \(\mathrm{Mg}^{2+}\) form solid carbonates and can be removed from the solution.

\section*{Group V-Alkali metal and ammonium ions}

The only ions remaining in solution at this point are the Group 1A cations and the \(\mathrm{NH}_{4}{ }^{+}\)ion, all of which form soluble salts with the common anions. The Group 1A cations are usually identified by the characteristic colors they produce when heated in a flame. These colors are due to the emission spectra of these ions.
The qualitative analysis scheme for cations based on the selective precipitation procedure described above is summarized in Fig. 16.2.

FIGURE 16.2 A schematic diagram of the classic method for separating the common cations by selective precipitation.

From left to right, cadmium sulfide, chromium (III) hydroxide, aluminum hydroxide, and nickel(II) hydroxide.

\subsection*{16.3 Equilibria Involving Complex Ions}

\(\mathrm{CoCl}_{4}{ }^{2-}\)

A complex ion is a charged species consisting of a metal ion surrounded by ligands. A ligand is simply a Lewis base-a molecule or ion having a lone electron pair that can be donated to an empty orbital on the metal ion to form a covalent bond. Some common ligands are \(\mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{Cl}^{-}\), and \(\mathrm{CN}^{-}\). The number of ligands attached to a metal ion is called the coordination number. The most common coordination numbers are 6 , for example, in \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\) and \(\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}\); 4, for example, in \(\mathrm{CoCl}_{4}{ }^{2-}\) and \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\); and 2, for example, in \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\); but others are known.

The properties of complex ions will be discussed in more detail in Chapter 21. For now, we will just look at the equilibria involving these species. Metal ions add ligands one at a time in steps characterized by equilibrium constants called formation constants or stability constants. For example, when solutions containing \(\mathrm{Ag}^{+}\)ions and \(\mathrm{NH}_{3}\) molecules are mixed, the following reactions take place:
\[
\begin{aligned}
\mathrm{Ag}^{+}(a q)+\mathrm{NH}_{3}(a q) & \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}(a q) \quad
\end{aligned} \begin{aligned}
& K_{1}=2.1 \times 10^{3} \\
& \mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q) \quad
\end{aligned} K_{2}=8.2 \times 10^{3} .
\]
where \(K_{1}\) and \(K_{2}\) are the formation constants for the two steps. In a solution containing \(\mathrm{Ag}^{+}\)and \(\mathrm{NH}_{3}\), all the species \(\mathrm{NH}_{3}, \mathrm{Ag}^{+}, \mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\), and \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)exist at equilibrium. Calculating the concentrations of all these components can be complicated. However, usually the total concentration of the ligand is much larger than the total concentration of the metal ion, and approximations can greatly simplify the problems.

For example, consider a solution prepared by mixing 100.0 mL of \(2.0 M \mathrm{NH}_{3}\) with 100.0 mL of \(1.0 \times 10^{-3} \mathrm{M} \mathrm{AgNO}_{3}\). Before any reaction occurs, the mixed solution contains the major species \(\mathrm{Ag}^{+}, \mathrm{NO}_{3}{ }^{-}, \mathrm{NH}_{3}\), and \(\mathrm{H}_{2} \mathrm{O}\). What reaction or reactions will occur in this solution? From our discussions of acid-base chemistry, we know that one reaction is
\[
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
\]

However, we are interested in the reaction between \(\mathrm{NH}_{3}\) and \(\mathrm{Ag}^{+}\)to form complex ions, and since the position of the preceding equilibrium lies far to the left ( \(K_{\mathrm{b}}\) for \(\mathrm{NH}_{3}\) is \(1.8 \times 10^{-5}\) ), we can neglect the amount of \(\mathrm{NH}_{3}\) used up in the reaction with water. Therefore, before any complex ion formation, the concentrations in the mixed solution are
\[
\begin{gathered}
{\left[\mathrm{Ag}^{+}\right]_{0}=\frac{(100.0 \mathrm{~mL})\left(1.0 \times 10^{-3} \mathrm{M}\right)}{(200.0 \mathrm{~mL})}=5.0 \times 10^{-4} \mathrm{M}} \\
\text { Total volume } \\
{\left[\mathrm{NH}_{3}\right]_{0}=\frac{(100.0 \mathrm{~mL})(2.0 \mathrm{M})}{(200.0 \mathrm{~mL})}=1.0 \mathrm{M}}
\end{gathered}
\]

As mentioned already, the \(\mathrm{Ag}^{+}\)ion reacts with \(\mathrm{NH}_{3}\) in a stepwise fashion to form \(\mathrm{AgNH}_{3}{ }^{+}\)and then \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\):
\[
\begin{aligned}
\mathrm{Ag}^{+}(a q)+\mathrm{NH}_{3}(a q) & \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}(a q) \quad
\end{aligned} K_{1}=2.1 \times 10^{3}, ~=\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q) \quad K_{2}=8.2 \times 10^{3} .
\]

Since both \(K_{1}\) and \(K_{2}\) are large, and since there is a large excess of \(\mathrm{NH}_{3}\), both reactions can be assumed to go essentially to completion. This is equivalent to writing the net reaction in the solution as follows:
\[
\mathrm{Ag}^{+}+2 \mathrm{NH}_{3} \longrightarrow \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}
\]

The relevant stoichiometric calculations are as follows:
\begin{tabular}{|c|c|c|c|c|c|}
\hline & \(\mathrm{Ag}^{+}\) & + & \(2 \mathrm{NH}_{3}\) & \(\longrightarrow\) & \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\) \\
\hline Before reaction & \(5.0 \times 10^{-4} \mathrm{M}\) & & 1.0 M & & 0 \\
\hline After reaction & 0 & & \begin{tabular}{l}
\[
1.0-2\left(5.0 \times 10^{-4}\right) \approx 1.0 \mathrm{M}
\] \\
Twice as much \(\mathrm{NH}_{3}\) as \(\mathrm{Ag}^{+}\)is required
\end{tabular} & & \(5.0 \times 10^{-4} \mathrm{M}\) \\
\hline
\end{tabular}

Note that in this case we have used molarities when performing the stoichiometry calculations and we have assumed this reaction to be complete, using all the original \(\mathrm{Ag}^{+}\)to form \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\). In reality, a very small amount of the \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)formed will dissociate to produce small amounts of \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\)and \(\mathrm{Ag}^{+}\). However, since the amount of \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)dissociating will be so small, we can safely assume that \(\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\right]\)is \(5.0 \times 10^{-4} M\) at equilibrium. Also, we know that since so little \(\mathrm{NH}_{3}\) has been consumed, \(\left[\mathrm{NH}_{3}\right]\) is 1.0 M at equilibrium. We can use these concentrations to calculate [ \(\mathrm{Ag}^{+}\)] and \(\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\right]\)using the \(K_{1}\) and \(K_{2}\) expressions.

To calculate the equilibrium concentration of \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\), we use
\[
K_{2}=8.2 \times 10^{3}=\frac{\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}\right]}{\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\right]\left[\mathrm{NH}_{3}\right]}
\]
since \(\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\right]\)and \(\left[\mathrm{NH}_{3}\right]\) are known. Rearranging and solving for \(\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\right]\) gives
\[
\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\right]=\frac{\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}\right]}{K_{2}\left[\mathrm{NH}_{3}\right]}=\frac{5.0 \times 10^{-4}}{\left(8.2 \times 10^{3}\right)(1.0)}=6.1 \times 10^{-8} \mathrm{M}
\]

Now the equilibrium concentration of \(\mathrm{Ag}^{+}\)can be calculated using \(K_{1}\) :
\[
\begin{aligned}
K_{1} & =2.1 \times 10^{3}=\frac{\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\right]}{\left[\mathrm{Ag}^{+}\right]\left[\mathrm{NH}_{3}\right]}=\frac{6.1 \times 10^{-8}}{\left[\mathrm{Ag}^{+}\right](1.0)} \\
{\left[\mathrm{Ag}^{+}\right] } & =\frac{6.1 \times 10^{-8}}{\left(2.1 \times 10^{3}\right)(1.0)}=2.9 \times 10^{-11} \mathrm{M}
\end{aligned}
\]

So far we have assumed that \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)is the dominant silver-containing species in solution. Is this a valid assumption? The calculated concentrations are
\[
\begin{aligned}
{\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}\right] } & =5.0 \times 10^{-4} \mathrm{M} \\
{\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\right] } & =6.1 \times 10^{-8} \mathrm{M} \\
{\left[\mathrm{Ag}^{+}\right] } & =2.9 \times 10^{-11} \mathrm{M}
\end{aligned}
\]

These values clearly support the conclusion that
\[
\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}\right] \gtrdot\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\right] \gtrdot\left[\mathrm{Ag}^{+}\right]
\]

Thus the assumption that \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)is the dominant \(\mathrm{Ag}^{+}\)-containing species is valid, and the calculated concentrations are correct.

This analysis shows that although complex ion equilibria have many species present and look complicated, the calculations are actually quite straightforward, especially if the ligand is present in large excess.

\section*{INTERACTIVE EXAMPLE 16.8 Complex lons}

Calculate the concentrations of \(\mathrm{Ag}^{+}, \mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)^{-}\), and \(\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\) in a solution prepared by mixing 150.0 mL of \(1.00 \times 10^{-3} \mathrm{M} \mathrm{AgNO}_{3}\) with 200.0 mL of 5.00 M \(\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}\). The stepwise formation equilibria are
\[
\begin{array}{cl}
\mathrm{Ag}^{+}+\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-} \rightleftharpoons \mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)^{-} & K_{1}=7.4 \times 10^{8} \\
\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)^{-}+\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-} \rightleftharpoons \mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}^{3-} & K_{2}=3.9 \times 10^{4}
\end{array}
\]

SOLUTION

\(\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\)

The concentrations of the ligand and metal ion in the mixed solution before any reaction occurs are
\[
\begin{aligned}
{\left[\mathrm{Ag}^{+}\right]_{0} } & =\frac{(150.0 \mathrm{~mL})\left(1.00 \times 10^{-3} \mathrm{M}\right)}{(150.0 \mathrm{~mL}+200.0 \mathrm{~mL})}=4.29 \times 10^{-4} \mathrm{M} \\
{\left[\mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}\right]_{0} } & =\frac{(200.0 \mathrm{~mL})(5.00 \mathrm{M})}{(150.0 \mathrm{~mL}+200.0 \mathrm{~mL})}=2.86 \mathrm{M}
\end{aligned}
\]

Since \(\left[\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\right]_{0} \geqslant\left[\mathrm{Ag}^{+}\right]_{0}\), and since \(K_{1}\) and \(K_{2}\) are large, both formation reactions can be assumed to go to completion, and the net reaction in the solution is as follows:
\begin{tabular}{|c|c|c|c|c|c|}
\hline & \(\mathrm{Ag}^{+}\) & \(+\) & \(2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}\) & \(\longrightarrow\) & \(\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\) \\
\hline Before reaction & \(4.29 \times 10^{-4} \mathrm{M}\) & & 2.86 M & & 0 \\
\hline After reaction & \(\sim 0\) & & \[
\begin{aligned}
& 2.86-2\left(4.29 \times 10^{-4}\right) \\
& \quad \approx 2.86 \mathrm{M}
\end{aligned}
\] & & \(4.29 \times 10^{-4} \mathrm{M}\) \\
\hline
\end{tabular}

Note that \(\mathrm{Ag}^{+}\)is limiting and that the amount of \(\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\) consumed is negligible. Also note that since all these species are in the same solution, the molarities can be used to do the stoichiometry problem.

Of course, the concentration of \(\mathrm{Ag}^{+}\)is not zero at equilibrium, and there is some \(\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)^{-}\)in the solution. To calculate the concentrations of these species, we must use the \(K_{1}\) and \(K_{2}\) expressions. We can calculate the concentration of \(\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)^{-}\) from \(K_{2}\) :
\[
\begin{aligned}
3.9 \times 10^{4} & =K_{2}=\frac{\left[\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\right]}{\left[\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)^{-}\right]\left[\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\right]}=\frac{4.29 \times 10^{-4}}{\left[\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)^{-}\right](2.86)} \\
{\left[\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)^{-}\right] } & =3.8 \times 10^{-9} \mathrm{M}
\end{aligned}
\]

We can calculate \(\left[\mathrm{Ag}^{+}\right]\)from \(K_{1}\) :
\[
\begin{aligned}
& 7.4 \times 10^{8}=K_{1}=\frac{\left[\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)^{-}\right]}{\left[\mathrm{Ag}^{+}\right]\left[\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\right]}=\frac{3.8 \times 10^{-9}}{\left[\mathrm{Ag}^{+}\right](2.86)} \\
& \square\left[\mathrm{Ag}^{+}\right]=1.8 \times 10^{-18} \mathrm{M}
\end{aligned}
\]

These results show that \(\left[\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\right] \gtrdot\left[\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)^{-}\right] \gg\left[\mathrm{Ag}^{+}\right]\)
Thus the assumption is valid that essentially all the original \(\mathrm{Ag}^{+}\)is converted to \(\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\) at equilibrium.

\section*{See Exercises 16.71 through 16.74}

\section*{Complex Ions and Solubility}

Often ionic solids that are very nearly water-insoluble must be dissolved somehow in aqueous solutions. For example, when the various qualitative analysis groups are precipitated out, the precipitates must be redissolved to separate the ions within each

\section*{A}
(top) Aqueous ammonia is added to silver chloride (white). (bottom) Silver chloride, insoluble in water, dissolves to form \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}(\mathrm{aq})\) and \(\mathrm{Cl}^{-}(\mathrm{aq})\).

\section*{When reactions are added, the} equilibrium constant for the overall process is the product of the constants for the individual reactions.
group. Consider a solution of cations that contains \(\mathrm{Ag}^{+}, \mathrm{Pb}^{2+}\), and \(\mathrm{Hg}_{2}{ }^{2+}\), among others. When dilute aqueous HCl is added to this solution, the Group I ions will form the insoluble chlorides \(\mathrm{AgCl}, \mathrm{PbCl}_{2}\), and \(\mathrm{Hg}_{2} \mathrm{Cl}_{2}\). Once this mixed precipitate is separated from the solution, it must be redissolved to identify the cations individually. How can this be done? We know that some solids are more soluble in acidic than in neutral solutions. What about chloride salts? For example, can AgCl be dissolved by using a strong acid? The answer is no, because \(\mathrm{Cl}^{-}\)ions have virtually no affinity for \(\mathrm{H}^{+}\)ions in aqueous solution. The position of the dissolution equilibrium
\[
\mathrm{AgCl}(s) \rightleftharpoons \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q)
\]
is not affected by the presence of \(\mathrm{H}^{+}\).
How can we pull the dissolution equilibrium to the right, even though \(\mathrm{Cl}^{-}\)is an extremely weak base? The key is to lower the concentration of \(\mathrm{Ag}^{+}\)in solution by forming complex ions. For example, \(\mathrm{Ag}^{+}\)reacts with excess \(\mathrm{NH}_{3}\) to form the stable complex ion \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\). As a result, AgCl is quite soluble in concentrated ammonia solutions. The relevant reactions are
\[
\begin{aligned}
\mathrm{AgCl}(s) & \rightleftharpoons \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) & & K_{\text {sp }}=1.6 \times 10^{-10} \\
\mathrm{Ag}^{+}(a q)+\mathrm{NH}_{3}(a q) & \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}(a q) & & K_{1}=2.1 \times 10^{3} \\
\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}(a q)+\mathrm{NH}_{3}(a q) & \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q) & & K_{2}=8.2 \times 10^{3}
\end{aligned}
\]

The \(\mathrm{Ag}^{+}\)ion produced by dissolving solid AgCl combines with \(\mathrm{NH}_{3}\) to form \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\), which causes more AgCl to dissolve, until the point at which
\[
\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]=K_{\mathrm{sp}}=1.6 \times 10^{-10}
\]

Here \(\left[\mathrm{Ag}^{+}\right]\)refers only to the \(\mathrm{Ag}^{+}\)ion that is present as a separate species in solution. It is not the total silver content of the solution, which is
\[
[\mathrm{Ag}]_{\text {total dissolved }}=\left[\mathrm{Ag}^{+}\right]+\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}\right]+\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}\right]
\]

For reasons discussed in the previous section, virtually all the \(\mathrm{Ag}^{+}\)from the dissolved AgCl ends up in the complex ion \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\). Thus we can represent the dissolving of solid AgCl in excess \(\mathrm{NH}_{3}\) by the equation
\[
\mathrm{AgCl}(s)+2 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q)+\mathrm{Cl}^{-}(a q)
\]

Since this equation is the sum of the three stepwise reactions given above, the equilibrium constant for the reaction is the product of the constants for the three reactions. (Demonstrate this to yourself by multiplying together the three expressions for \(K_{\mathrm{sp}}, K_{1}\), and \(K_{2}\).) The equilibrium expression is
\[
\begin{aligned}
K & =\frac{\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}\right]\left[\mathrm{Cl}^{-}\right]}{\left[\mathrm{NH}_{3}\right]^{2}} \\
& =K_{\text {sp }} \times K_{1} \times K_{2}=\left(1.6 \times 10^{-10}\right)\left(2.1 \times 10^{3}\right)\left(8.2 \times 10^{3}\right)=2.8 \times 10^{-3}
\end{aligned}
\]

Using this expression, we will now calculate the solubility of solid AgCl in a \(10.0-M \mathrm{NH}_{3}\) solution. If we let \(x\) be the solubility (in \(\mathrm{mol} / \mathrm{L}\) ) of AgCl in the solution, we can then write the following expressions for the equilibrium concentrations of the pertinent species:

Substituting these concentrations into the equilibrium expression gives
\[
K=2.8 \times 10^{-3}=\frac{\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}\right]\left[\mathrm{Cl}^{-}\right]}{\left[\mathrm{NH}_{3}\right]^{2}}=\frac{(x)(x)}{(10.0-2 x)^{2}}=\frac{x^{2}}{(10.0-2 x)^{2}}
\]

No approximations are necessary here. Taking the square root of both sides of the equation gives
\[
\begin{aligned}
\sqrt{2.8 \times 10^{-3}} & =\frac{x}{10.0-2 x} \\
x & =0.48 \mathrm{~mol} / \mathrm{L}=\text { solubility of } \mathrm{AgCl}(s) \text { in } 10.0 \mathrm{M} \mathrm{H}_{3}
\end{aligned}
\]

Thus the solubility of AgCl in \(10.0 \mathrm{M} \mathrm{NH}_{3}\) is much greater than its solubility in pure water, which is
\[
\sqrt{K_{\mathrm{sp}}}=1.3 \times 10^{-5} \mathrm{~mol} / \mathrm{L}
\]

In this chapter we have considered two strategies for dissolving a water-insoluble ionic solid. If the anion of the solid is a good base, the solubility is greatly increased by acidifying the solution. In cases where the anion is not sufficiently basic, the ionic solid often can be dissolved in a solution containing a ligand that forms stable complex ions with its cation.

Sometimes solids are so insoluble that combinations of reactions are needed to dissolve them. For example, to dissolve the extremely insoluble \(\mathrm{HgS}\left(K_{\text {sp }}=10^{-54}\right)\), it is necessary to use a mixture of concentrated HCl and concentrated \(\mathrm{HNO}_{3}\), called aqua regia. The \(\mathrm{H}^{+}\)ions in the aqua regia react with the \(\mathrm{S}^{2-}\) ions to form \(\mathrm{H}_{2} \mathrm{~S}\), and \(\mathrm{Cl}^{-}\)reacts with \(\mathrm{Hg}^{2+}\) to form various complex ions, including \(\mathrm{HgCl}_{4}{ }^{2-}\). In addition, \(\mathrm{NO}_{3}{ }^{-}\)oxidizes \(\mathrm{S}^{2-}\) to elemental sulfur. These processes lower the concentrations of \(\mathrm{Hg}^{2+}\) and \(\mathrm{S}^{2-}\) and thus promote the solubility of HgS .

Since the solubility of many salts increases with temperature, simple heating is sometimes enough to make a salt sufficiently soluble. For example, earlier in this section we considered the mixed chloride precipitates of the Group I ions- \(\mathrm{PbCl}_{2}\), AgCl , and \(\mathrm{Hg}_{2} \mathrm{Cl}_{2}\). The effect of temperature on the solubility of \(\mathrm{PbCl}_{2}\) is such that we can precipitate \(\mathrm{PbCl}_{2}\) with cold aqueous HCl and then redissolve it by heating the solution to near boiling. The silver and mercury(I) chlorides remain precipitated, since they are not significantly soluble in hot water. However, solid AgCl can be dissolved using aqueous ammonia. The solid \(\mathrm{Hg}_{2} \mathrm{Cl}_{2}\) reacts with \(\mathrm{NH}_{3}\) to form a mixture of elemental mercury and \(\mathrm{HgNH}_{2} \mathrm{Cl}\) :
\[
\mathrm{Hg}_{2} \mathrm{Cl}_{2}(s)+2 \mathrm{NH}_{3}(a q) \longrightarrow \underset{\text { White }}{\mathrm{HgNH}_{2} \mathrm{Cl}(s)}+\underset{\text { Black }}{\mathrm{Hg}(l)}+\mathrm{NH}_{4}^{+}(a q)+\mathrm{Cl}^{-}(a q)
\]

The mixed precipitate appears gray. This is an oxidation-reduction reaction in which one mercury(I) ion in \(\mathrm{Hg}_{2} \mathrm{Cl}_{2}\) is oxidized to \(\mathrm{Hg}^{2+}\) in \(\mathrm{HgNH}_{2} \mathrm{Cl}\) and the other mercury(I) ion is reduced to Hg , or elemental mercury.

The treatment of the Group I ions is summarized in Fig. 16.3. Note that the presence of \(\mathrm{Pb}^{2+}\) is confirmed by adding \(\mathrm{CrO}_{4}{ }^{2-}\), which forms bright yellow lead(II) chromate \(\left(\mathrm{PbCrO}_{4}\right)\). Also note that \(\mathrm{H}^{+}\)added to a solution containing \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)reacts with the \(\mathrm{NH}_{3}\) to form \(\mathrm{NH}_{4}{ }^{+}\), destroying the \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)complex. Silver chloride then re-forms:
\[
2 \mathrm{H}^{+}(a q)+\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow 2 \mathrm{NH}_{4}^{+}(a q)+\mathrm{AgCl}(s)
\]

Note that the qualitative analysis of cations by selective precipitation involves all the types of reactions we have discussed and represents an excellent application of the principles of chemical equilibrium.

FIGURE 16.3 The separation of the Group I ions in the classic scheme of qualitative analysis.

formation (stability) constants

\section*{Solids dissolving in water}
) For a slightly soluble salt, an equilibrium is set up between the excess solid (MX) and the ions in solution:
\[
\mathrm{MX}(s) \rightleftharpoons \mathrm{M}^{+}(a q)+\mathrm{X}^{-}(a q)
\]
) The corresponding constant is called \(K_{\mathrm{sp}}\) :
\[
K_{\mathrm{sp}}=\left[\mathrm{M}^{+}\right]\left[\mathrm{X}^{-}\right]
\]
) The solubility of \(\operatorname{MX}(s)\) is decreased by the presence of another source of either \(\mathrm{M}^{+}\)or \(\mathrm{X}^{-}\); this is called the common ion effect
> Predicting whether precipitation will occur when two solutions are mixed involves calculating \(Q\) for the initial concentrations:
> If \(Q>K_{\text {sp }}\), precipitation occurs
) If \(Q \leq K_{\text {sp }}\), no precipitation occurs

\section*{Qualitative analysis}
) A mixture of ions can be separated by selective precipitation
> The ions are first separated into groups by adding \(\mathrm{HCl}(a q)\), then \(\mathrm{H}_{2} \mathrm{~S}(a q)\), then \(\mathrm{NaOH}(a q)\), and finally \(\mathrm{Na}_{2} \mathrm{CO}_{3}(\) aq \()\)
> The ions in the groups are separated and identified by further selective dissolution and precipitation

\section*{Complex ions}
> Complex ions consist of a metal ion surrounded by attached ligands
> A ligand is a Lewis base
> The number of ligands is called the coordination number, which is commonly 2, 4, or 6
> Complex ion equilibria in solution are described by formation (stability) constants
> The formation of complex ions can be used to selectively dissolve solids in the qualitative analysis scheme

\section*{Review Questions Answers to the Review Questions can be found on the Student website (accessible from www.cengagelrain.com).}
1. To what reaction does the solubility product constant, \(K_{\text {sp }}\), refer? Table 16.1 lists \(K_{\text {sp }}\) values for several ionic solids. For any of these ionic compounds, you should be able to calculate the solubility. What is the solubility of a salt, and what procedures do you follow to calculate the solubility of a salt? How would you calculate the \(K_{\text {sp }}\) value for a salt given the solubility?
2. Under what circumstances can you compare the relative solubilities of two salts directly by comparing the values of their solubility products? When can relative solubilities not be compared based on \(K_{\text {sp }}\) values?
3. What is a common ion and how does its presence affect the solubility?
4. List some salts whose solubility increases as the pH becomes more acidic. What is true about the anions in these salts? List some salts whose solubility remains unaffected by the solution pH . What is true about the anions in these salts?
5. What is the difference between the ion product, \(Q\), and the solubility product, \(K_{\text {sp }}\) ? What happens when \(Q>K_{\text {sp }} ? Q<K_{\text {sp }} ? Q=K_{\text {sp }}\) ?
6. Mixtures of metal ions in aqueous solution can sometimes be separated by selective precipitation. What is selective precipitation? If a solution contained 0.10 M \(\mathrm{Mg}^{2+}, 0.10 \mathrm{M} \mathrm{Ca}^{2+}\), and \(0.10 \mathrm{M} \mathrm{Ba}^{2+}\), how could addition of NaF be used to separate the cations out of
solution-that is, what would precipitate first, then second, then third? How could addition of \(\mathrm{K}_{3} \mathrm{PO}_{4}\) be used to separate out the cations in a solution that is \(1.0 \mathrm{M} \mathrm{Ag}^{+}, 1.0 \mathrm{M} \mathrm{P}^{2+}\), and \(1.0 \mathrm{M} \mathrm{S}^{2+}\) ?
7. Figure 16.2 summarizes the classic method for separating a mixture of common cations by selective precipitation. Explain the chemistry involved with each of the four steps in the diagram.
8. What is a complex ion? The stepwise formation constants for the complex ion \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\) are \(K_{1} \approx 1 \times 10^{3}, K_{2} \approx 1 \times 10^{4}, K_{3} \approx 1 \times 10^{3}\), and \(K_{4} \approx 1 \times 10^{3}\). Write the reactions that refer to each of these formation constants. Given that the values of the formation constants are large, what can you deduce about the equilibrium concentration of \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\) versus the equilibrium concentration of \(\mathrm{Cu}^{2+}\) ?
9. When \(5 M\) ammonia is added to a solution containing \(\mathrm{Cu}(\mathrm{OH})_{2}(s)\), the precipitate will eventually dissolve in solution. Why? If \(5 M \mathrm{HNO}_{3}\) is then added, the \(\mathrm{Cu}(\mathrm{OH})_{2}\) precipitate re-forms. Why? In general, what effect does the ability of a cation to form a complex ion have on the solubility of salts containing that cation?
10. Figure 16.3 outlines the classic scheme for separating a mixture of insoluble chloride salts from one another. Explain the chemistry involved in the various steps of the figure.
3. You are browsing through the Handbook of Hypothetical Chemistry when you come across a solid that is reported to have a \(K_{\text {sp }}\) value of zero in water at \(25^{\circ} \mathrm{C}\). What does this mean?
4. A friend tells you: "The constant \(K_{\text {sp }}\) of a salt is called the solubility product constant and is calculated from the concentrations of ions in the solution. Thus, if salt A dissolves to a greater extent than salt B , salt A must have a higher \(K_{\mathrm{sp}}\) than salt B." Do you agree with your friend? Explain.
5. Explain the following phenomenon: You have a test tube with an aqueous solution of silver nitrate as shown in test tube 1 below. A few drops of aqueous sodium chromate solution was added with the end result shown in test tube 2 . A few drops of aqueous sodium chloride solution was then added with the end result shown in test tube 3 .

Use the \(K_{\text {sp }}\) values in the book to support your explanation, and include the balanced equations. Also, list the ions that are present in solution in each test tube.
6. What happens to the \(K_{\text {sp }}\) value of a solid as the temperature of the solution changes? Consider both increasing and decreasing temperatures, and explain your answer.
7. Which is more likely to dissolve in an acidic solution, silver sulfide or silver chloride? Why?
8. Two different compounds have about the same molar solubility. Do they also have about the same \(K_{\text {sp }}\) value?
9. Sodium chloride is listed in the solubility rules as a soluble compound. Therefore, the \(K_{\text {sp }}\) value for NaCl is infinite. Is this statement true or false? Explain.

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

\section*{Questions}
10. For which of the following is the \(K_{\text {sp }}\) value of the ionic compound the largest? The smallest? Explain your answer.

11. \(\mathrm{Ag}_{2} \mathrm{~S}(s)\) has a larger molar solubility than CuS even though \(\mathrm{Ag}_{2} \mathrm{~S}\) has the smaller \(K_{\mathrm{sp}}\) value. Explain how this is possible.
12. Solubility is an equilibrium position, whereas \(K_{\text {sp }}\) is an equilibrium constant. Explain the difference.
13. The salts in Table 16.1, with the possible exception of the hydroxide salts, generally have one of the following mathematical relationships between the \(K_{\text {sp }}\) value and the molar solubility \(s\).
i. \(K_{\text {sp }}=s^{2}\)
ii. \(K_{\mathrm{sp}}=4 s^{3}\)
iii. \(K_{\text {sp }}=27 s^{4}\)
iv. \(K_{\text {sp }}=108 s^{5}\)

For each mathematical relationship, give an example of a salt in Table 16.1 that exhibits that relationship.
14. When \(\mathrm{Na}_{3} \mathrm{PO}_{4}(a q)\) is added to a solution containing a metal ion and a precipitate forms, the precipitate generally could be one of two possibilities. What are the two possibilities?
15. The common ion effect for ionic solids (salts) is to significantly decrease the solubility of the ionic compound in water. Explain the common ion effect.
16. Sulfide precipitates are generally grouped as sulfides insoluble in acidic solution and sulfides insoluble in basic solution. Explain why there is a difference between the two groups of sulfide precipitates.
17. List some ways one can increase the solubility of a salt in water.
18. The solubility of \(\mathrm{PbCl}_{2}\) increases with an increase in temperature. Is the dissolution of \(\mathrm{PbCl}_{2}(s)\) in water exothermic or endothermic? Explain.
19. You have two salts, AgX and AgY , both with very similar \(K_{\text {sp }}\) values. You know that the \(K_{\mathrm{a}}\) for HX is much greater than the \(K_{\mathrm{a}}\) for HY. Which salt is more soluble in acidic solution? Explain.
20. The stepwise formation constants for a complex ion usually have values much greater than 1 . What is the significance of this?
21. Silver chloride dissolves readily in \(2 \mathrm{MNH}_{3}\) but is quite insoluble in \(2 \mathrm{M} \mathrm{NH}_{4} \mathrm{NO}_{3}\). Explain.
22. If a solution contains either \(\mathrm{Pb}^{2+}(a q)\) or \(\mathrm{Ag}^{+}(a q)\), how can temperature be manipulated to help identify the ion in solution?

\section*{Exercises}

In this section similar exercises are paired.

\section*{Solubility Equilibria}
-23. Write balanced equations for the dissolution reactions and the corresponding solubility product expressions for each of the following solids.
a. \(\mathrm{AgC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\)
b. \(\mathrm{Al}(\mathrm{OH})_{3}\)
c. \(\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}\)
24. Write balanced equations for the dissolution reactions and the corresponding solubility product expressions for each of the following solids.
a. \(\mathrm{Ag}_{2} \mathrm{CO}_{3}\)
b. \(\mathrm{Ce}\left(\mathrm{IO}_{3}\right)_{3}\)
c. \(\mathrm{BaF}_{2}\)
25. Use the following data to calculate the \(K_{\text {sp }}\) value for each solid.
a. The solubility of \(\mathrm{CaC}_{2} \mathrm{O}_{4}\) is \(4.8 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\).
b. The solubility of \(\mathrm{BiI}_{3}\) is \(1.32 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\).
26. Use the following data to calculate the \(K_{\text {sp }}\) value for each solid.
a. The solubility of \(\mathrm{Pb}_{3}\left(\mathrm{PO}_{4}\right)_{2}\) is \(6.2 \times 10^{-12} \mathrm{~mol} / \mathrm{L}\).
b. The solubility of \(\mathrm{Li}_{2} \mathrm{CO}_{3}\) is \(7.4 \times 10^{-2} \mathrm{~mol} / \mathrm{L}\).
27. Approximately 0.14 g nickel(II) hydroxide, \(\mathrm{Ni}(\mathrm{OH})_{2}(s)\), dissolves per liter of water at \(20^{\circ} \mathrm{C}\). Calculate \(K_{\text {sp }}\) for \(\mathrm{Ni}(\mathrm{OH})_{2}(s)\) at this temperature.
28. The solubility of the ionic compound \(\mathrm{M}_{2} \mathrm{X}_{3}\), having a molar mass of \(288 \mathrm{~g} / \mathrm{mol}\), is \(3.60 \times 10^{-7} \mathrm{~g} / \mathrm{L}\). Calculate the \(K_{\mathrm{sp}}\) of the compound.
29. The concentration of \(\mathrm{Pb}^{2+}\) in a solution saturated with \(\mathrm{PbBr}_{2}(s)\) is \(2.14 \times 10^{-2} M\). Calculate \(K_{\text {sp }}\) for \(\mathrm{PbBr}_{2}\).
30. The concentration of \(\mathrm{Ag}^{+}\)in a solution saturated with \(\mathrm{Ag}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(s)\) is \(2.2 \times 10^{-4} M\). Calculate \(K_{\text {sp }}\) for \(\mathrm{Ag}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\).
\({ }^{31}\). Calculate the solubility of each of the following compounds in moles per liter. Ignore any acid-base properties.
a. \(\mathrm{Ag}_{3} \mathrm{PO}_{4}, K_{\text {sp }}=1.8 \times 10^{-18}\)
b. \(\mathrm{CaCO}_{3}, K_{\text {sp }}=8.7 \times 10^{-9}\)
c. \(\mathrm{Hg}_{2} \mathrm{Cl}_{2}, K_{\text {sp }}=1.1 \times 10^{-18}\left(\mathrm{Hg}_{2}{ }^{2+}\right.\) is the cation in solution.)
32. Calculate the solubility of each of the following compounds in moles per liter. Ignore any acid-base properties.
a. \(\mathrm{PbI}_{2}, K_{\text {sp }}=1.4 \times 10^{-8}\)
b. \(\mathrm{CdCO}_{3}, K_{\text {sp }}=5.2 \times 10^{-12}\)
c. \(\mathrm{Sr}_{3}\left(\mathrm{PO}_{4}\right)_{2}, K_{\text {sp }}=1 \times 10^{-31}\)
33. Cream of tartar, a common ingredient in cooking, is the common name for potassium bitartrate (abbreviated KBT, molar mass \(=188.2 \mathrm{~g} / \mathrm{mol}\) ). Historically, KBT was a crystalline solid that formed on the casks of wine barrels during the fermentation process. Calculate the maximum mass of KBT that can dissolve in 250.0 mL of solution to make a saturated solution. The \(K_{\text {sp }}\) value for KBT is \(3.8 \times 10^{-4}\).
34. Barium sulfate is a contrast agent for X -ray scans that are most often associated with the gastrointestinal tract. Calculate the mass of \(\mathrm{BaSO}_{4}\) that can dissolve in 100.0 mL of solution. The \(K_{\text {sp }}\) value for \(\mathrm{BaSO}_{4}\) is \(1.5 \times 10^{-9}\).
-35. Calculate the molar solubility of \(\mathrm{Cd}(\mathrm{OH})_{2}, K_{\text {sp }}=5.9 \times 10^{-15}\).
36. The solubility rules outlined in Chapter 4 say that \(\mathrm{Ba}(\mathrm{OH})_{2}\), \(\mathrm{Sr}(\mathrm{OH})_{2}\), and \(\mathrm{Ca}(\mathrm{OH})_{2}\) are marginally soluble hydroxides. Calculate the pH of a saturated solution of each of these marginally soluble hydroxides.
\(\Gamma^{37 .}\) Calculate the molar solubility of \(\mathrm{Al}(\mathrm{OH})_{3}, K_{\mathrm{sp}}=2 \times 10^{-32}\).
38. Calculate the molar solubility of \(\mathrm{Co}(\mathrm{OH})_{3}, K_{\text {sp }}=2.5 \times 10^{-43}\).
-39. For each of the following pairs of solids, determine which solid has the smallest molar solubility.
a. \(\mathrm{CaF}_{2}(s), K_{\text {sp }}=4.0 \times 10^{-11}\), or \(\mathrm{BaF}_{2}(s), K_{\text {sp }}=2.4 \times 10^{-5}\)
b. \(\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s), K_{\text {sp }}=1.3 \times 10^{-32}\), or \(\mathrm{FePO}_{4}(s)\), \(K_{\text {sp }}=1.0 \times 10^{-22}\)
40. For each of the following pairs of solids, determine which solid has the smallest molar solubility.
a. \(\mathrm{FeC}_{2} \mathrm{O}_{4}, K_{\text {sp }}=2.1 \times 10^{-7}\), or \(\mathrm{Cu}\left(\mathrm{IO}_{4}\right)_{2}, K_{\text {sp }}=1.4 \times 10^{-7}\)
b. \(\mathrm{Ag}_{2} \mathrm{CO}_{3}, K_{\text {sp }}=8.1 \times 10^{-12}\), or \(\mathrm{Mn}(\mathrm{OH})_{2}\), \(K_{\text {sp }}=2 \times 10^{-13}\)
41. Calculate the solubility (in moles per liter) of \(\mathrm{Fe}(\mathrm{OH})_{3}\) \(\left(K_{\text {sp }}=4 \times 10^{-38}\right)\) in each of the following.
a. water
b. a solution buffered at \(\mathrm{pH}=5.0\)
c. a solution buffered at \(\mathrm{pH}=11.0\)
42. Calculate the solubility of \(\mathrm{Co}(\mathrm{OH})_{2}(s)\left(K_{\mathrm{sp}}=2.5 \times 10^{-16}\right)\) in a buffered solution with a pH of 11.00 .
43. The \(K_{\text {sp }}\) for silver sulfate \(\left(\mathrm{Ag}_{2} \mathrm{SO}_{4}\right)\) is \(1.2 \times 10^{-5}\). Calculate the solubility of silver sulfate in each of the following.
a. water
b. \(0.10 \mathrm{M} \mathrm{AgNO}_{3}\)
c. \(0.20 \mathrm{M} \mathrm{K}_{2} \mathrm{SO}_{4}\)
44. The \(K_{\text {sp }}\) for lead iodide \(\left(\mathrm{PbI}_{2}\right)\) is \(1.4 \times 10^{-8}\). Calculate the solubility of lead iodide in each of the following.
a. water
b. \(0.10 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}\)
c. 0.010 M NaI
45. Calculate the solubility of solid \(\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}\left(K_{\text {sp }}=1.3 \times 10^{-32}\right)\) in a \(0.20-M \mathrm{Na}_{3} \mathrm{PO}_{4}\) solution.
46. Calculate the solubility of solid \(\mathrm{Pb}_{3}\left(\mathrm{PO}_{4}\right)_{2}\left(K_{\text {sp }}=1 \times 10^{-54}\right)\) in a \(0.10-\mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}\) solution.
-47. The solubility of \(\mathrm{Ce}\left(\mathrm{IO}_{3}\right)_{3}\) in a \(0.20-M \mathrm{KIO}_{3}\) solution is \(4.4 \times 10^{-8} \mathrm{~mol} / \mathrm{L}\). Calculate \(K_{\text {sp }}\) for \(\mathrm{Ce}\left(\mathrm{IO}_{3}\right)_{3}\).
48. The solubility of \(\mathrm{Pb}\left(\mathrm{IO}_{3}\right)_{2}(s)\) in a \(0.10-M \mathrm{KIO}_{3}\) solution is \(2.6 \times 10^{-11} \mathrm{~mol} / \mathrm{L}\). Calculate \(K_{\text {sp }}\) for \(\mathrm{Pb}\left(\mathrm{IO}_{3}\right)_{2}\).
49. Which of the substances in Exercises 31 and 32 show increased solubility as the pH of the solution becomes more acidic? Write equations for the reactions that occur to increase the solubility.
50. For which salt in each of the following groups will the solubility depend on pH ?
a. \(\mathrm{AgF}, \mathrm{AgCl}, \mathrm{AgBr}\)
b. \(\mathrm{Pb}(\mathrm{OH})_{2}, \mathrm{PbCl}_{2}\)
c. \(\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}, \mathrm{Sr}\left(\mathrm{NO}_{2}\right)_{2}\)
d. \(\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2}, \mathrm{Ni}(\mathrm{CN})_{2}\)

\section*{Precipitation Conditions}
51. What mass of \(\mathrm{ZnS}\left(K_{\text {sp }}=2.5 \times 10^{-22}\right)\) will dissolve in 300.0 mL of \(0.050 \mathrm{M} \mathrm{Zn}\left(\mathrm{NO}_{3}\right)_{2}\) ? Ignore the basic properties of \(\mathrm{S}^{2-}\).
52. The concentration of \(\mathrm{Mg}^{2+}\) in seawater is 0.052 M . At what pH will \(99 \%\) of the \(\mathrm{Mg}^{2+}\) be precipitated as the hydroxide salt? \(\left[K_{\text {sp }}\right.\) for \(\mathrm{Mg}(\mathrm{OH})_{2}=8.9 \times 10^{-12}\).]
53. Will a precipitate form when 100.0 mL of \(4.0 \times 10^{-4} \mathrm{M}\) \(\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}\) is added to 100.0 mL of \(2.0 \times 10^{-4} \mathrm{M} \mathrm{NaOH}\) ?
54. A solution contains \(1.0 \times 10^{-6} \mathrm{M} \mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}\) and \(5.0 \times 10^{-7} \mathrm{M}\) \(\mathrm{K}_{3} \mathrm{PO}_{4}\). Will \(\mathrm{Sr}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)\) precipitate? \(\left[K_{\text {sp }}\right.\) for \(\mathrm{Sr}_{3}\left(\mathrm{PO}_{4}\right)_{2}=\) \(1.0 \times 10^{-31}\).]
-55. A solution is prepared by mixing 100.0 mL of \(1.0 \times 10^{-2} \mathrm{M}\) \(\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}\) and 100.0 mL of \(1.0 \times 10^{-3} M \mathrm{NaF}\). Will \(\mathrm{PbF}_{2}(s)\) \(\left(K_{\text {sp }}=4 \times 10^{-8}\right)\) precipitate?
56. If 10.0 mL of \(2.0 \times 10^{-3} \mathrm{MCr}\left(\mathrm{NO}_{3}\right)_{3}\) is added to 10.0 mL of a \(\mathrm{pH}=10.0 \mathrm{NaOH}\) solution, will a precipitate form?
-57. Calculate the final concentrations of \(\mathrm{K}^{+}(a q), \mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(a q)\), \(\mathrm{Ba}^{2+}(a q)\), and \(\mathrm{Br}^{-}(a q)\) in a solution prepared by adding 0.100 L of \(0.200 M \mathrm{~K}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\) to 0.150 L of \(0.250 M \mathrm{BaBr}_{2}\). (For \(\mathrm{BaC}_{2} \mathrm{O}_{4}, K_{\text {sp }}=2.3 \times 10^{-8}\).)
58. When 100.0 mL of \(2.00 \mathrm{M} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{3}\) is added to 100.0 mL of \(3.00 \mathrm{M} \mathrm{KIO}_{3}\), a precipitate of \(\mathrm{Ce}\left(\mathrm{IO}_{3}\right)_{3}(s)\) forms. Calculate the equilibrium concentrations of \(\mathrm{Ce}^{3+}\) and \(\mathrm{IO}_{3}{ }^{-}\)in this solution. \(\left[K_{\text {sp }}\right.\) for \(\mathrm{Ce}\left(\mathrm{IO}_{3}\right)_{3}=3.2 \times 10^{-10}\).]
59. A \(50.0-\mathrm{mL}\) sample of \(0.00200 \mathrm{M} \mathrm{AgNO}_{3}\) is added to 50.0 mL of \(0.0100 \mathrm{M} \mathrm{NaIO}_{3}\). What is the equilibrium concentration of \(\mathrm{Ag}^{+}\)in solution? ( \(K_{\text {sp }}\) for \(\mathrm{AgIO}_{3}\) is \(3.2 \times 10^{-8}\).)
60. A solution is prepared by mixing 50.0 mL of \(0.10 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}\) with 50.0 mL of 1.0 M KCl . Calculate the concentrations of \(\mathrm{Pb}^{2+}\) and \(\mathrm{Cl}^{-}\)at equilibrium. [ \(K_{\text {sp }}\) for \(\mathrm{PbCl}_{2}(s)\) is \(1.6 \times 10^{-5}\).]
61. A solution contains \(1.0 \times 10^{-5} M \mathrm{Na}_{3} \mathrm{PO}_{4}\). What concentrations of \(\mathrm{AgNO}_{3}\) will cause precipitation of solid \(\mathrm{Ag}_{3} \mathrm{PO}_{4}\) \(\left(K_{\text {sp }}=1.8 \times 10^{-18}\right)\) ?
62. A solution contains \(3.0 \times 10^{-3} M \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}\). What concentrations of KF will cause precipitation of solid \(\mathrm{MgF}_{2}\left(K_{\text {sp }}=6.4 \times 10^{-9}\right)\) ?
[63. A solution is \(1 \times 10^{-4} M\) in \(\mathrm{NaF}, \mathrm{Na}_{2} \mathrm{~S}\), and \(\mathrm{Na}_{3} \mathrm{PO}_{4}\). What would be the order of precipitation as a source of \(\mathrm{Pb}^{2+}\) is added gradually to the solution? The relevant \(K_{\text {sp }}\) values are \(K_{\mathrm{sp}}\left(\mathrm{PbF}_{2}\right)=4 \times 10^{-8}, K_{\mathrm{sp}}(\mathrm{PbS})=7 \times 10^{-29}\), and \(K_{\text {sp }}\left[\mathrm{Pb}_{3}\left(\mathrm{PO}_{4}\right)_{2}\right]=1 \times 10^{-54}\).
64. A solution contains \(0.25 \mathrm{M} \mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2}\) and \(0.25 \mathrm{M} \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}\). Can the metal ions be separated by slowly adding \(\mathrm{Na}_{2} \mathrm{CO}_{3}\) ? Assume that for successful separation \(99 \%\) of the metal ion must be precipitated before the other metal ion begins to precipitate, and assume no volume change on addition of \(\mathrm{Na}_{2} \mathrm{CO}_{3}\).

\section*{Complex Ion Equilibria}

Write equations for the stepwise formation of each of the following complex ions.
a. \(\mathrm{Ni}(\mathrm{CN})_{4}{ }^{2-}\)
b. \(\mathrm{V}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}{ }^{3-}\)
66. Write equations for the stepwise formation of each of the following complex ions.
a. \(\mathrm{CoF}_{6}{ }^{3-}\)
b. \(\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\)
67. In the presence of \(\mathrm{CN}^{-}, \mathrm{Fe}^{3+}\) forms the complex ion \(\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}\). The equilibrium concentrations of \(\mathrm{Fe}^{3+}\) and \(\mathrm{Fe}(\mathrm{CN}) 6^{3-}\) are \(8.5 \times 10^{-40} M\) and \(1.5 \times 10^{-3} M\), respectively, in a \(0.11-M \mathrm{KCN}\) solution. Calculate the value for the overall formation constant of \(\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}\).
\[
\mathrm{Fe}^{3+}(a q)+6 \mathrm{CN}^{-}(a q) \rightleftharpoons \mathrm{Fe}(\mathrm{CN})_{6}^{3-}(a q) \quad K_{\text {overall }}=?
\]
68. In the presence of \(\mathrm{NH}_{3}, \mathrm{Cu}^{2+}\) forms the complex ion \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\). If the equilibrium concentrations of \(\mathrm{Cu}^{2+}\) and \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\) are \(1.8 \times 10^{-17} \mathrm{M}\) and \(1.0 \times 10^{-3} \mathrm{M}\), respectively, in a \(1.5-M \mathrm{NH}_{3}\) solution, calculate the value for the overall formation constant of \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\).
\[
\mathrm{Cu}^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q) \quad K_{\text {overall }}=?
\]
-69. When aqueous KI is added gradually to mercury(II) nitrate, an orange precipitate forms. Continued addition of KI causes the precipitate to dissolve. Write balanced equations to explain these observations. (Hint: \(\mathrm{Hg}^{2+}\) reacts with \(\mathrm{I}^{-}\)to form \(\mathrm{HgI}_{4}{ }^{2-}\).)
70. As sodium chloride solution is added to a solution of silver nitrate, a white precipitate forms. Ammonia is added to the mixture and the precipitate dissolves. When potassium bromide solution is then added, a pale yellow precipitate appears. When a solution of sodium thiosulfate is added, the yellow precipitate dissolves. Finally, potassium iodide is added to the solution and a yellow precipitate forms. Write equations for all the changes mentioned above. What conclusions can you draw concerning the sizes of the \(K_{\text {sp }}\) values for \(\mathrm{AgCl}, \mathrm{AgBr}\), and AgI ?
-71. The overall formation constant for \(\mathrm{HgI}_{4}{ }^{2-}\) is \(1.0 \times 10^{30}\). That is,
\[
1.0 \times 10^{30}=\frac{\left[\mathrm{HgI}_{4}{ }^{2-}\right]}{\left[\mathrm{Hg}^{2+}\right]\left[\mathrm{I}^{-}\right]^{4}}
\]

What is the concentration of \(\mathrm{Hg}^{2+}\) in 500.0 mL of a solution that was originally \(0.010 \mathrm{M} \mathrm{Hg}^{2+}\) and \(0.78 \mathrm{M}^{-}\)? The reaction is
\[
\operatorname{Hg}^{2+}(a q)+4 \mathrm{I}^{-}(a q) \rightleftharpoons \operatorname{HgI}_{4}^{2-}(a q)
\]
72. A solution is prepared by adding 0.10 mole of \(\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6} \mathrm{Cl}_{2}\) to 0.50 L of 3.0 M NH 3 . Calculate \(\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}\right]\) and \(\left[\mathrm{Ni}^{2+}\right]\) in this solution. \(K_{\text {overall }}\) for \(\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}\) is \(5.5 \times 10^{8}\). That is,
\[
5.5 \times 10^{8}=\frac{\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}\right]}{\left[\mathrm{Ni}^{2+}\right]\left[\mathrm{NH}_{3}\right]^{6}}
\]
for the overall reaction
\[
\mathrm{Ni}^{2+}(a q)+6 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}(a q)
\]
-73. A solution is formed by mixing 50.0 mL of 10.0 M NaX with 50.0 mL of \(2.0 \times 10^{-3} M \mathrm{CuNO}_{3}\). Assume that \(\mathrm{Cu}^{+}\)forms complex ions with \(\mathrm{X}^{-}\)as follows:
\[
\begin{aligned}
\mathrm{Cu}^{+}(a q)+\mathrm{X}^{-}(a q) & \rightleftharpoons \mathrm{CuX}(a q) & & K_{1}=1.0 \times 10^{2} \\
\mathrm{CuX}(a q)+\mathrm{X}^{-}(a q) & \rightleftharpoons \mathrm{CuX}_{2}^{-}(a q) & & K_{2}=1.0 \times 10^{4} \\
\mathrm{CuX}_{2}^{-}(a q)+\mathrm{X}^{-}(a q) & \mathrm{CuX}_{3}^{2-}(a q) & & K_{3}=1.0 \times 10^{3}
\end{aligned}
\]
with an overall reaction
\[
\mathrm{Cu}^{+}(a q)+3 \mathrm{X}^{-}(a q) \rightleftharpoons \mathrm{CuX}_{3}^{2-}(a q) \quad K=1.0 \times 10^{9}
\]

Calculate the following concentrations at equilibrium.
a. \(\mathrm{CuX}_{3}{ }^{2-}\)
b. \(\mathrm{CuX}_{2}{ }^{-}\)
c. \(\mathrm{Cu}^{+}\)
74. A solution is prepared by mixing 100.0 mL of \(1.0 \times 10^{-4} \mathrm{M}\) \(\mathrm{Be}\left(\mathrm{NO}_{3}\right)_{2}\) and 100.0 mL of 8.0 M NaF .
\[
\begin{array}{cl}
\mathrm{Be}^{2+}(a q)+\mathrm{F}^{-}(a q) \rightleftharpoons \mathrm{BeF}^{+}(a q) & K_{1}=7.9 \times 10^{4} \\
\mathrm{BeF}^{+}(a q)+\mathrm{F}^{-}(a q) \rightleftharpoons \mathrm{BeF}_{2}(a q) & K_{2}=5.8 \times 10^{3} \\
\mathrm{BeF}_{2}(a q)+\mathrm{F}^{-}(a q) \rightleftharpoons \mathrm{BeF}_{3}^{-}(a q) & K_{3}=6.1 \times 10^{2} \\
\mathrm{BeF}_{3}^{-}(a q)+\mathrm{F}^{-}(a q) \rightleftharpoons \mathrm{BeF}_{4}^{2-}(a q) & K_{4}=2.7 \times 10^{1}
\end{array}
\]

Calculate the equilibrium concentrations of \(\mathrm{F}^{-}, \mathrm{Be}^{2+}, \mathrm{BeF}^{+}\), \(\mathrm{BeF}_{2}, \mathrm{BeF}_{3}{ }^{-}\), and \(\mathrm{BeF}_{4}^{2-}\) in this solution.
a. Calculate the molar solubility of AgI in pure water. \(K_{\text {sp }}\) for AgI is \(1.5 \times 10^{-16}\).
b. Calculate the molar solubility of AgI in \(3.0 \mathrm{M} \mathrm{NH}_{3}\). The overall formation constant for \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)is \(1.7 \times 10^{7}\).
c. Compare the calculated solubilities from parts a and \(b\). Explain any differences.
76. Solutions of sodium thiosulfate are used to dissolve unexposed \(\mathrm{AgBr}\left(K_{\text {sp }}=5.0 \times 10^{-13}\right)\) in the developing process for black-and-white film. What mass of AgBr can dissolve in 1.00 L of \(0.500 \mathrm{M} \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}\) ? \(\mathrm{Ag}^{+}\)reacts with \(\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\) to form a complex ion:
\[
\begin{aligned}
\mathrm{Ag}^{+}(a q)+2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(a q) & \rightleftharpoons \mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}(a q) \\
K=2.9 & \times 10^{13}
\end{aligned}
\]
[77. \(K_{\mathrm{f}}\) for the complex ion \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)is \(1.7 \times 10^{7} . K_{\text {sp }}\) for AgCl is \(1.6 \times 10^{-10}\). Calculate the molar solubility of AgCl in \(1.0 \mathrm{M} \mathrm{H}_{3}\).
78. The copper(I) ion forms a chloride salt that has \(K_{\text {sp }}=\) \(1.2 \times 10^{-6}\). Copper(I) also forms a complex ion with \(\mathrm{Cl}^{-}\):
\[
\mathrm{Cu}^{+}(a q)+2 \mathrm{Cl}^{-}(a q) \rightleftharpoons \mathrm{CuCl}_{2}^{-}(a q) \quad K=8.7 \times 10^{4}
\]
a. Calculate the solubility of copper(I) chloride in pure water. (Ignore \(\mathrm{CuCl}_{2}{ }^{-}\)formation for part a.)
b. Calculate the solubility of copper(I) chloride in 0.10 M NaCl .
79. A series of chemicals were added to some \(\mathrm{AgNO}_{3}(a q)\). \(\mathrm{NaCl}(a q)\) was added first to the silver nitrate solution with the end result shown below in test tube \(1, \mathrm{NH}_{3}(\mathrm{aq})\) was then added with the end result shown in test tube 2, and \(\mathrm{HNO}_{3}(a q)\) was added last with the end result shown in test tube 3 .

Explain the results shown in each test tube. Include a balanced equation for the reaction(s) taking place.
80. The solubility of copper(II) hydroxide in water can be increased by adding either the base \(\mathrm{NH}_{3}\) or the acid \(\mathrm{HNO}_{3}\). Explain. Would added \(\mathrm{NH}_{3}\) or \(\mathrm{HNO}_{3}\) have the same effect on the solubility of silver acetate or silver chloride? Explain.

\section*{Additional Exercises}
81. A solution contains 0.018 mole each of \(\mathrm{I}^{-}, \mathrm{Br}^{-}\), and \(\mathrm{Cl}^{-}\). When the solution is mixed with 200 mL of \(0.24 \mathrm{M} \mathrm{AgNO}_{3}\), what mass of \(\mathrm{AgCl}(s)\) precipitates out, and what is \(\left[\mathrm{Ag}^{+}\right]\)? Assume no volume change.
\[
\begin{aligned}
\text { AgI: } K_{\text {sp }} & =1.5 \times 10^{-16} \\
\mathrm{AgBr}: K_{\text {sp }} & =5.0 \times 10^{-13} \\
\mathrm{AgCl}: K_{\text {sp }} & =1.6 \times 10^{-10}
\end{aligned}
\]
82. Magnesium hydroxide, \(\mathrm{Mg}(\mathrm{OH})_{2}\), is the active ingredient in the antacid TUMS and has a \(K_{\mathrm{sp}}\) value of \(8.9 \times 10^{-12}\). If a \(10.0-\mathrm{g}\) sample of \(\mathrm{Mg}(\mathrm{OH})_{2}\) is placed in 500.0 mL of solution, calculate the moles of \(\mathrm{OH}^{-}\)ions present. Because the \(K_{\text {sp }}\) value for \(\mathrm{Mg}(\mathrm{OH})_{2}\) is much less than 1 , not a lot of solid dissolves in solution. Explain how \(\operatorname{Mg}(\mathrm{OH})_{2}\) works to neutralize large amounts of stomach acid.
83. Tooth enamel is composed of the mineral hydroxyapatite. The \(K_{\text {sp }}\) of hydroxyapatite, \(\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\), is \(6.8 \times 10^{-37}\). Calculate the solubility of hydroxyapatite in pure water in moles per liter. How is the solubility of hydroxyapatite affected by adding acid? When hydroxyapatite is treated with fluoride, the mineral fluorapatite, \(\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}\), forms. The \(K_{\text {sp }}\) of this substance is \(1 \times 10^{-60}\). Calculate the solubility of fluorapatite in water. How do these calculations provide a rationale for the fluoridation of drinking water?
84. The U.S. Public Health Service recommends the fluoridation of water as a means for preventing tooth decay. The recommended concentration is \(1 \mathrm{mg} \mathrm{F}^{-}\)per liter. The presence of calcium ions in hard water can precipitate the added fluoride. What is the maximum molarity of calcium ions in hard water if the fluoride concentration is at the USPHS recommended level? \(\left(K_{\text {sp }}\right.\) for \(\left.\mathrm{CaF}_{2}=4.0 \times 10^{-11}\right)\)
85. The \(K_{\text {sp }}\) of \(\mathrm{Al}(\mathrm{OH})_{3}\) is \(2 \times 10^{-32}\). At what pH will a \(0.2-\mathrm{M} \mathrm{Al}^{3+}\) solution begin to show precipitation of \(\mathrm{Al}(\mathrm{OH})_{3}\) ?
86. Calculate the mass of manganese hydroxide that dissolves to form 1300 mL of a saturated manganese hydroxide solution. For \(\mathrm{Mn}(\mathrm{OH})_{2}, K_{\text {sp }}=2.0 \times 10^{-13}\).
87. On a hot day, a \(200.0-\mathrm{mL}\) sample of a saturated solution of \(\mathrm{PbI}_{2}\) was allowed to evaporate until dry. If 240 mg of solid \(\mathrm{PbI}_{2}\) was collected after evaporation was complete, calculate the \(K_{\mathrm{sp}}\) value for \(\mathrm{PbI}_{2}\) on this hot day.
88. The active ingredient of Pepto-Bismol is the compound bismuth subsalicylate, which undergoes the following dissociation when added to water:
\[
\begin{aligned}
\mathrm{C}_{7} \mathrm{H}_{5} \mathrm{BiO}_{4}(s)+\mathrm{H}_{2} \mathrm{O}(l) & \underset{\sim}{\rightleftharpoons} \mathrm{Ci}_{7} \mathrm{H}_{4} \mathrm{O}_{3}{ }^{2-}(a q) \\
& \mathrm{OH}^{-}(a q) \quad K
\end{aligned}
\]

If the maximum amount of bismuth subsalicylate that reacts by this reaction is \(3.2 \times 10^{-19} \mathrm{~mol} / \mathrm{L}\), calculate the equilibrium constant for the preceding reaction.
89. Consider saturated solutions of the following compounds:
a. AgOH
b. \(\mathrm{Cd}(\mathrm{OH})_{2}\)
c. \(\mathrm{Pb}(\mathrm{OH})_{2}\)

Calculate the pH of each saturated solution.
90. Silver cyanide \((\mathrm{AgCN})\) is an insoluble salt with \(K_{\mathrm{sp}}=2.2 \times 10^{-12}\). Compare the effects on the solubility of silver cyanide by addition of \(\mathrm{HNO}_{3}(a q)\) or by addition of \(\mathrm{NH}_{3}(a q)\).
91. Nanotechnology has become an important field, with applications ranging from high-density data storage to the design of "nano machines." One common building block of nanostructured architectures is manganese oxide nanoparticles. The particles can be formed from manganese oxalate nanorods, the formation of which can be described as follows:
\[
\begin{aligned}
& \mathrm{Mn}^{2+}(a q)+\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(a q) \rightleftharpoons \mathrm{MnC}_{2} \mathrm{O}_{4}(a q) \\
& K_{1}=7.9 \times 10^{3} \\
& \mathrm{MnC}_{2} \mathrm{O}_{4}(a q)+\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(a q) \rightleftharpoons \mathrm{Mn}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}{ }^{2-}(a q) \\
& K_{2}=7.9 \times 10^{1}
\end{aligned}
\]

Calculate the value for the overall formation constant for \(\mathrm{Mn}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}{ }^{2-}\) :
\[
K=\frac{\left[\mathrm{Mn}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}{ }^{2-}\right]}{\left[\mathrm{Mn}^{2+}\right]\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}\right]^{2}}
\]
92. The equilibrium constant for the following reaction is \(1.0 \times 10^{23}\) :
\(\mathrm{Cr}^{3+}(a q)+\mathrm{H}_{2}\) EDTA \(^{2-}(a q) \rightleftharpoons \operatorname{CrEDTA}^{-}(a q)+2 \mathrm{H}^{+}(a q)\)
EDTA \(^{4-}=\)

EDTA is used as a complexing agent in chemical analysis. Solutions of EDTA, usually containing the disodium salt \(\mathrm{Na}_{2} \mathrm{H}_{2}\) EDTA, are used to treat heavy metal poisoning. Calculate \(\left[\mathrm{Cr}^{3+}\right]\) at equilibrium in a solution originally 0.0010 M in \(\mathrm{Cr}^{3+}\) and \(0.050 M\) in \(\mathrm{H}_{2}\) EDTA \(^{2-}\) and buffered at \(\mathrm{pH}=6.00\).
93. Calculate the concentration of \(\mathrm{Pb}^{2+}\) in each of the following.
a. a saturated solution of \(\mathrm{Pb}(\mathrm{OH})_{2}, K_{\text {sp }}=1.2 \times 10^{-15}\)
b. a saturated solution of \(\mathrm{Pb}(\mathrm{OH})_{2}\) buffered at \(\mathrm{pH}=13.00\)
c. Ethylenediaminetetraacetate (EDTA \({ }^{4-}\) ) is used as a complexing agent in chemical analysis and has the following structure:

Solutions of EDTA \({ }^{4-}\) are used to treat heavy metal poisoning by removing the heavy metal in the form of a soluble complex ion. The reaction of EDTA \({ }^{4-}\) with \(\mathrm{Pb}^{2+}\) is
\[
\begin{array}{r}
\mathrm{Pb}^{2+}(a q)+\operatorname{EDTA}^{4-}(a q) \rightleftharpoons \operatorname{PbEDTA}^{2-}(a q) \\
K=1.1 \times 10^{18}
\end{array}
\]

Consider a solution with 0.010 mole of \(\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}\) added to 1.0 L of an aqueous solution buffered at \(\mathrm{pH}=13.00\) and containing \(0.050 M \mathrm{Na}_{4} \mathrm{EDTA}\). Does \(\mathrm{Pb}(\mathrm{OH})_{2}\) precipitate from this solution?
94. Will a precipitate of \(\mathrm{Cd}(\mathrm{OH})_{2}\) form if 1.0 mL of 1.0 M \(\mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2}\) is added to 1.0 L of \(5.0 \mathrm{M} \mathrm{H}_{3}\) ?
\(\mathrm{Cd}^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Cd}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q)\)
\[
K=1.0 \times 10^{7}
\]
\[
\mathrm{Cd}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Cd}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
\]
\[
K_{\mathrm{sp}}=5.9 \times 10^{-15}
\]
95. a. Using the \(K_{\text {sp }}\) value for \(\mathrm{Cu}(\mathrm{OH})_{2}\left(1.6 \times 10^{-19}\right)\) and the overall formation constant for \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\left(1.0 \times 10^{13}\right)\), calculate the value for the equilibrium constant for the following reaction:
\(\mathrm{Cu}(\mathrm{OH})_{2}(s)+4 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q)+2 \mathrm{OH}^{-}(a q)\)
b. Use the value of the equilibrium constant you calculated in part a to calculate the solubility (in \(\mathrm{mol} / \mathrm{L}\) ) of \(\mathrm{Cu}(\mathrm{OH})_{2}\) in \(5.0 \mathrm{M} \mathrm{NH}_{3}\). In \(5.0 \mathrm{M} \mathrm{N}_{3}\) the concentration of \(\mathrm{OH}^{-}\)is 0.0095 M.
96. Describe how you could separate the ions in each of the following groups by selective precipitation.
a. \(\mathrm{Ag}^{+}, \mathrm{Mg}^{2+}, \mathrm{Cu}^{2+}\)
b. \(\mathrm{Pb}^{2+}, \mathrm{Ca}^{2+}, \mathrm{Fe}^{2+}\)
c. \(\mathrm{Pb}^{2+}, \mathrm{Bi}^{3+}\)
97. Nitrate salts are generally considered to be soluble salts. One of the least soluble nitrate salts is barium nitrate. Approximately 15 g of \(\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}\) will dissolve per liter of solution. Calculate the \(K_{\text {sp }}\) value for barium nitrate.
98. In the chapter discussion of precipitate formation, we ran the precipitation reaction to completion and then let some of the precipitate redissolve to get back to equilibrium. To see why, redo Example 16.6, where
\begin{tabular}{cc}
\begin{tabular}{c} 
Initial \\
Concentration \\
\((\mathrm{mol} / \mathrm{L})\)
\end{tabular} & \begin{tabular}{c} 
Equilibrium \\
Concentration \\
\((\mathrm{mol} / \mathrm{L})\)
\end{tabular}
\end{tabular}

\section*{ChemWork Problems}

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
99. Assuming that the solubility of \(\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)\) is \(1.6 \times 10^{-7} \mathrm{~mol} / \mathrm{L}\) at \(25^{\circ} \mathrm{C}\), calculate the \(K_{\text {sp }}\) for this salt. Ignore any potential reactions of the ions with water.
100. Order the following solids (a-d) from least soluble to most soluble. Ignore any potential reactions of the ions with water.
\begin{tabular}{ll} 
a. AgCl & \(K_{\text {sp }}=1.6 \times 10^{-10}\) \\
b. \(\mathrm{Ag}_{2} \mathrm{~S}\) & \(K_{\mathrm{sp}}=1.6 \times 10^{-49}\) \\
c. \(\mathrm{CaF}_{2}\) & \(K_{\text {sp }}=4.0 \times 10^{-11}\) \\
d. CuS & \(K_{\text {sp }}=8.5 \times 10^{-45}\)
\end{tabular}
101. The \(K_{\text {sp }}\) for \(\mathrm{PbI}_{2}(s)\) is \(1.4 \times 10^{-8}\). Calculate the solubility of \(\mathrm{PbI}_{2}(s)\) in 0.048 M NaI .
102. The solubility of \(\mathrm{Pb}\left(\mathrm{IO}_{3}\right)_{2}(s)\) in a \(7.2 \times 10^{-2}-M \mathrm{KIO}_{3}\) solution is \(6.0 \times 10^{-9} \mathrm{~mol} / \mathrm{L}\). Calculate the \(K_{\text {sp }}\) value for \(\mathrm{Pb}\left(\mathrm{IO}_{3}\right)_{2}(s)\).
103. A \(50.0-\mathrm{mL}\) sample of \(0.0413 \mathrm{MAgNO}_{3}(a q)\) is added to 50.0 mL of \(0.100 \mathrm{M} \mathrm{NaIO}_{3}(a q)\). Calculate the \(\left[\mathrm{Ag}^{+}\right]\)at equilibrium in the resulting solution. [ \(K_{\text {sp }}\) for \(\mathrm{AgIO}_{3}(s)=3.17 \times 10^{-8}\).]
104. The \(\mathrm{Hg}^{2+}\) ion forms complex ions with \(\mathrm{I}^{-}\)as follows:
\[
\begin{aligned}
\mathrm{Hg}^{2+}(a q)+\mathrm{I}^{-}(a q) & \rightleftharpoons \mathrm{HgI}^{+}(a q) & & K_{1}=1.0 \times 10^{8} \\
\mathrm{HgI}^{+}(a q)+\mathrm{I}^{-}(a q) & \rightleftharpoons \mathrm{HgI}_{2}(a q) & & K_{2}=1.0 \times 10^{5} \\
\mathrm{HgI}_{2}(a q)+\mathrm{I}^{-}(a q) & \rightleftharpoons \mathrm{HgI}_{3}{ }^{-}(a q) & & K_{3}=1.0 \times 10^{9} \\
\mathrm{HgI}_{3}{ }^{-}(a q)+\mathrm{I}^{-}(a q) & \rightleftharpoons \mathrm{HgI}_{4}{ }^{2-}(a q) & & K_{4}=1.0 \times 10^{8}
\end{aligned}
\]

A solution is prepared by dissolving 0.088 mole of \(\mathrm{Hg}\left(\mathrm{NO}_{3}\right)_{2}\) and 5.00 mole of NaI in enough water to make 1.0 L of solution.
a. Calculate the equilibrium concentration of \(\left[\mathrm{HgI}_{4}{ }^{2-}\right]\).
b. Calculate the equilibrium concentration of \(\left[I^{-}\right]\).
c. Calculate the equilibrium concentration of \(\left[\mathrm{Hg}^{2+}\right]\).

\section*{Challenge Problems}
105. The copper(I) ion forms a complex ion with \(\mathrm{CN}^{-}\)according to the following equation:
\[
\mathrm{Cu}^{+}(a q)+3 \mathrm{CN}^{-}(a q) \rightleftharpoons \mathrm{Cu}(\mathrm{CN})_{3}{ }^{2-}(a q) \quad K=1.0 \times 10^{11}
\]
a. Calculate the solubility of \(\operatorname{CuBr}(s)\left(K_{\text {sp }}=1.0 \times 10^{-5}\right)\) in 1.0 L of 1.0 M NaCN .
b. Calculate the concentration of \(\mathrm{Br}^{-}\)at equilibrium.
c. Calculate the concentration of \(\mathrm{CN}^{-}\)at equilibrium.
106. Consider a solution made by mixing 500.0 mL of \(4.0 \mathrm{M} \mathrm{NH}_{3}\) and 500.0 mL of \(0.40 \mathrm{M} \mathrm{AgNO}_{3} . \mathrm{Ag}^{+}\)reacts with \(\mathrm{NH}_{3}\) to form \(\mathrm{AgNH}_{3}{ }^{+}\)and \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\):
\[
\begin{aligned}
\mathrm{Ag}^{+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{AgNH}_{3}^{+}(a q) & K_{1}=2.1 \times 10^{3} \\
\mathrm{AgNH}_{3}^{+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q) & K_{2}=8.2 \times 10^{3}
\end{aligned}
\]

Determine the concentration of all species in solution.
107. a. Calculate the molar solubility of AgBr in pure water. \(K_{\text {sp }}\) for AgBr is \(5.0 \times 10^{-13}\).
b. Calculate the molar solubility of AgBr in \(3.0 \mathrm{M} \mathrm{NH}_{3}\). The overall formation constant for \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)is \(1.7 \times 10^{7}\), that is,
\(\mathrm{Ag}^{+}(a q)+2 \mathrm{NH}_{3}(a q) \longrightarrow \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}(a q) \quad K=1.7 \times 10^{7}\).
c. Compare the calculated solubilities from parts \(a\) and \(b\). Explain any differences.
d. What mass of AgBr will dissolve in 250.0 mL of \(3.0 \mathrm{MH}_{3}\) ?
e. What effect does adding \(\mathrm{HNO}_{3}\) have on the solubilities calculated in parts a and b ?
108. Calculate the equilibrium concentrations of \(\mathrm{NH}_{3}, \mathrm{Cu}^{2+}\), \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)^{2+}, \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{2}{ }^{2+}, \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{3}{ }^{2+}\), and \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\) in a solution prepared by mixing 500.0 mL of \(3.00 \mathrm{M} \mathrm{H}_{3}\) with 500.0 mL of \(2.00 \times 10^{-3} \mathrm{M} \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}\). The stepwise equilibria are
\[
\begin{aligned}
& \mathrm{Cu}^{2+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{CuNH}_{3}{ }^{2+}(a q) \\
& K_{1}=1.86 \times 10^{4} \\
& \mathrm{CuNH}_{3}{ }^{2+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{2}^{2+}(a q) \\
& K_{2}=3.88 \times 10^{3} \\
& \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{2}{ }^{2+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{3}{ }^{2+}(a q) \\
& K_{3}=1.00 \times 10^{3} \\
& \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{3}{ }^{2+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q) \\
& K_{4}=1.55 \times 10^{2}
\end{aligned}
\]
109. Calculate the solubility of \(\operatorname{AgCN}(s)\left(K_{\text {sp }}=2.2 \times 10^{-12}\right)\) in a solution containing \(1.0 \mathrm{M} \mathrm{H}^{+}\). ( \(K_{\mathrm{a}}\) for HCN is \(6.2 \times 10^{-10}\).)
110. Calcium oxalate \(\left(\mathrm{CaC}_{2} \mathrm{O}_{4}\right)\) is relatively insoluble in water ( \(K_{\text {sp }}=2 \times 10^{-9}\) ). However, calcium oxalate is more soluble in acidic solution. How much more soluble is calcium oxalate in \(0.10 \mathrm{M} \mathrm{H}^{+}\)than in pure water? In pure water, ignore the basic properties of \(\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}\).
111. What is the maximum possible concentration of \(\mathrm{Ni}^{2+}\) ion in water at \(25^{\circ} \mathrm{C}\) that is saturated with \(0.10 \mathrm{M} \mathrm{H}_{2} \mathrm{~S}\) and maintained at pH 3.0 with HCl ?
112. A mixture contains \(1.0 \times 10^{-3} \mathrm{M} \mathrm{Cu}^{2+}\) and \(1.0 \times 10^{-3} \mathrm{M}\) \(\mathrm{Mn}^{2+}\) and is saturated with \(0.10 \mathrm{M}_{2} \mathrm{~S}\). Determine a pH where CuS precipitates but MnS does not precipitate. \(K_{\text {sp }}\) for \(\mathrm{CuS}=8.5 \times 10^{-45}\) and \(K_{\text {sp }}\) for \(\mathrm{MnS}=2.3 \times 10^{-13}\).
113. Sodium tripolyphosphate \(\left(\mathrm{Na}_{5} \mathrm{P}_{3} \mathrm{O}_{10}\right)\) is used in many synthetic detergents. Its major effect is to soften the water by complexing \(\mathrm{Mg}^{2+}\) and \(\mathrm{Ca}^{2+}\) ions. It also increases the efficiency of surfactants, or wetting agents that lower a liquid's surface tension. The \(K\) value for the formation of \(\mathrm{MgP}_{3} \mathrm{O}_{10}{ }^{3-}\) is \(4.0 \times 10^{8}\). The reaction is \(\mathrm{Mg}^{2+}(\mathrm{aq})+\mathrm{P}_{3} \mathrm{O}_{10}{ }^{5-}(\mathrm{aq})\) \(\rightleftharpoons \mathrm{MgP}_{3} \mathrm{O}_{10}{ }^{3-}(a q)\). Calculate the concentration of \(\mathrm{Mg}^{2+}\) in a solution that was originally \(50 . \mathrm{ppm} \mathrm{Mg}^{2+}(50 . \mathrm{mg} / \mathrm{L}\) of solution) after 40. \(\mathrm{g} \mathrm{Na}_{5} \mathrm{P}_{3} \mathrm{O}_{10}\) is added to 1.0 L of the solution.
114. You add an excess of solid MX in 250 g water. You measure the freezing point and find it to be \(-0.028^{\circ} \mathrm{C}\). What is the \(K_{\text {sp }}\) of the solid? Assume the density of the solution is \(1.0 \mathrm{~g} / \mathrm{cm}^{3}\).
115. a. Calculate the molar solubility of \(\mathrm{SrF}_{2}\) in water, ignoring the basic properties of \(\mathrm{F}^{-}\). (For \(\mathrm{SrF}_{2}, K_{\mathrm{sp}}=7.9 \times 10^{-10}\).)
b. Would the measured molar solubility of \(\mathrm{SrF}_{2}\) be greater than or less than the value calculated in part a? Explain.
c. Calculate the molar solubility of \(\mathrm{SrF}_{2}\) in a solution buffered at \(\mathrm{pH}=2.00\). ( \(K_{\mathrm{a}}\) for HF is \(7.2 \times 10^{-4}\).)
116. The salt MX has a solubility of \(3.17 \times 10^{-8} \mathrm{~mol} / \mathrm{L}\) in a solution with \(\mathrm{pH}=0.000\). If \(K_{\mathrm{a}}\) for HX is \(1.00 \times 10^{-15}\), calculate the \(K_{\mathrm{sp}}\) value for MX.
117. Consider 1.0 L of an aqueous solution that contains 0.10 M sulfuric acid to which 0.30 mole of barium nitrate is added. Assuming no change in volume of the solution, determine the pH , the concentration of barium ions in the final solution, and the mass of solid formed.

\section*{Integrative Problems}

These problems require the integration of multiple concepts to find the solutions.
118. A solution saturated with a salt of the type \(\mathrm{M}_{3} \mathrm{X}_{2}\) has an osmotic pressure of \(2.64 \times 10^{-2} \mathrm{~atm}\) at \(25^{\circ} \mathrm{C}\). Calculate the \(K_{\text {sp }}\) value for the salt, assuming ideal behavior.
119. What mass of \(\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}\) must be added to 1.0 L of a 1.0-M HF solution to begin precipitation of \(\mathrm{CaF}_{2}(s)\) ? For \(\mathrm{CaF}_{2}, K_{\text {sp }}=\) \(4.0 \times 10^{-11}\) and \(K_{\mathrm{a}}\) for \(\mathrm{HF}=7.2 \times 10^{-4}\). Assume no volume change on addition of \(\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{~s})\).
120. The \(K_{\text {sp }}\) for \(Q\), a slightly soluble ionic compound composed of \(\mathrm{M}_{2}{ }^{2+}\) and \(\mathrm{X}^{-}\)ions, is \(4.5 \times 10^{-29}\). The electron configuration of \(\mathrm{M}^{+}\)is \([\mathrm{Xe}] 6 s^{1} 4 f^{14} 5 d^{10}\). The \(\mathrm{X}^{-}\)anion has 54 electrons. What is the molar solubility of \(Q\) in a solution of NaX prepared by dissolving 1.98 g NaX in 150 . mL solution?

\section*{Marathon Problem}

This problem is designed to incorporate several concepts and
techniques into one situation.
121. Aluminum ions react with the hydroxide ion to form the precipitate \(\mathrm{Al}(\mathrm{OH})_{3}(s)\), but can also react to form the soluble complex ion \(\mathrm{Al}(\mathrm{OH})_{4}{ }^{-}\). In terms of solubility, \(\mathrm{Al}(\mathrm{OH})_{3}(s)\) will be more soluble in very acidic solutions as well as more soluble in very basic solutions.
a. Write equations for the reactions that occur to increase the solubility of \(\mathrm{Al}(\mathrm{OH})_{3}(s)\) in very acidic solutions and in very basic solutions.
b. Let's study the pH dependence of the solubility of \(\mathrm{Al}(\mathrm{OH})_{3}(s)\) in more detail. Show that the solubility of \(\mathrm{Al}(\mathrm{OH})_{3}\), as a function of \(\left[\mathrm{H}^{+}\right]\), obeys the equation
\[
S=\left[\mathrm{H}^{+}\right]^{3} K_{\mathrm{sp}} / K_{\mathrm{w}}{ }^{3}+K K_{\mathrm{w}} /\left[\mathrm{H}^{+}\right]
\]
where \(S=\) solubility \(=\left[\mathrm{Al}^{3+}\right]+\left[\mathrm{Al}(\mathrm{OH})_{4}{ }^{-}\right]\)and \(K\) is the equilibrium constant for
\[
\mathrm{Al}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q) \rightleftharpoons \mathrm{Al}(\mathrm{OH})_{4}^{-}(a q)
\]
c. The value of \(K\) is 40.0 and \(K_{\text {sp }}\) for \(\mathrm{Al}(\mathrm{OH})_{3}\) is \(2 \times 10^{-32}\). Plot the solubility of \(\mathrm{Al}(\mathrm{OH})_{3}\) in the pH range 4-12.

The first law of thermodynamics: The energy of the universe is constant.

The first law of thermodynamics is a statement of the law of conservation of energy: Energy can be neither created nor destroyed. In other words, the energy of the universe is constant. Although the total energy is constant, the various forms of energy can be interchanged in physical and chemical processes. For example, if you drop a book, some of the initial potential energy of the book is changed to kinetic energy, which is then transferred to the atoms in the air and the floor as random motion. The net effect of this process is to change a given quantity of potential energy to exactly the same quantity of thermal energy. Energy has been converted from one form to another, but the same quantity of energy exists before and after the process.

Now let's consider a chemical example. When methane is burned in excess oxygen, the major reaction is
\[
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)+\text { energy }
\]

This reaction produces a quantity of energy, which is released as heat. This energy flow results from the lowering of the potential energy stored in the bonds of \(\mathrm{CH}_{4}\) and \(\mathrm{O}_{2}\) as they react to form \(\mathrm{CO}_{2}\) and \(\mathrm{H}_{2} \mathrm{O}\). This is illustrated in Fig. 17.1. Potential energy has been converted to thermal energy, but the energy content of the universe has remained constant in accordance with the first law of thermodynamics.

The first law of thermodynamics is used mainly for energy bookkeeping, that is, to answer such questions as

How much energy is involved in the change?
Does energy flow into or out of the system?
What form does the energy finally assume?
Although the first law of thermodynamics provides the means for accounting for energy, it gives no hint as to why a particular process occurs in a given direction. This is the main question to be considered in this chapter.

\subsection*{17.1 Spontaneous Processes and Entropy}

A process is said to be spontaneous if it occurs without outside intervention. Spontaneous processes may be fast or slow. As we will see in this chapter, thermodynamics can tell us the direction in which a process will occur but can say nothing about the speed of the process. As we saw in Chapter 12, the rate of a reaction depends on many factors, such as activation energy, temperature, concentration, and catalysts, and we were able to explain these effects using a simple collision model. In describing a chemical reaction, the discipline of chemical kinetics focuses on the pathway between reactants and products; thermodynamics considers only the initial and final states and does not require knowledge of the pathway between reactants and products (Fig. 17.2).

In summary, thermodynamics lets us predict whether a process will occur but gives no information about the amount of time required for the process. For example, according to the principles of thermodynamics, a diamond should change spontaneously to graphite. The fact that we do not observe this process does not mean the prediction is wrong; it simply means the process is very slow. Thus we need both thermodynamics and kinetics to describe reactions fully.

The process of diamond turning to graphite, while thermodynamically favored, is said to be under kinetic control; that is, it does not proceed at a noticeable rate.

FIGURE 17.1 When methane and oxygen react to form carbon dioxide and water, the products have lower potential energy than the reactants. This change in potential energy results in energy flow (heat) to the surroundings.

FIGURE 17.2 The rate of a reaction depends on the pathway from reactants to products; this is the domain of kinetics. Thermodynamics tells us whether a reaction is spontaneous based only on the properties of the reactants and products. The predictions of thermodynamics do not require knowledge of the pathway between reactants and products.

Iron spontaneously rusts when it comes in contact with water.

To explore the idea of spontaneity, consider the following physical and chemical processes:

A ball rolls down a hill but never spontaneously rolls back up the hill.
If exposed to air and moisture, steel rusts spontaneously. However, the iron oxide in rust does not spontaneously change back to iron metal and oxygen gas.

A gas fills its container uniformly. It never spontaneously collects at one end of the container.

Heat flow always occurs from a hot object to a cooler one. The reverse process never occurs spontaneously.

Wood burns spontaneously in an exothermic reaction to form carbon dioxide and water, but wood is not formed when carbon dioxide and water are heated together.

At temperatures below \(0^{\circ} \mathrm{C}\), water spontaneously freezes, and at temperatures above \(0^{\circ} \mathrm{C}\), ice spontaneously melts.

What thermodynamic principle will provide an explanation of why, under a given set of conditions, each of these diverse processes occurs in one direction and never in the reverse? In searching for an answer, we could explain the behavior of a ball on a hill in terms of gravity. But what does gravity have to do with the rusting of a nail or the freezing of water? Early developers of thermodynamics thought that exothermicity might be the key-that a process would be spontaneous if it were exothermic. Although

A A disordered pile of playing cards.

Probability refers to likelihood.

FIGURE 17.3 The expansion of an ideal gas into an evacuated bulb.
this factor does appear to be important, since many spontaneous processes are exothermic, it is not the total answer. For example, the melting of ice, which occurs spontaneously at temperatures greater than \(0^{\circ} \mathrm{C}\), is an endothermic process.

What common characteristic causes the processes listed above to be spontaneous in one direction only? After many years of observation, scientists have concluded that the characteristic common to all spontaneous processes is an increase in a property called entropy, denoted by the symbol \(S\). The driving force for a spontaneous process is an increase in the entropy of the universe.

What is entropy? Although there is no simple definition that is completely accurate, entropy can be viewed as a measure of molecular randomness or disorder. The natural progression of things is from order to disorder, from lower entropy to higher entropy. To illustrate the natural tendency toward disorder, you only have to think about the condition of your room. Your room naturally tends to get messy (disordered), because an ordered room requires everything to be in its place. There are simply many more ways for things to be out of place than for them to be in their places.

As another example, suppose you have a deck of playing cards ordered in some particular way. You throw these cards into the air and pick them all up at random. Looking at the new sequence of the cards, you would be very surprised to find that it matched the original order. Such an event would be possible, but very improbable. There are billions of ways for the deck to be disordered, but only one way to be ordered according to your definition. Thus the chances of picking the cards up out of order are much greater than the chance of picking them up in order. It is natural for disorder to increase.

Entropy is a thermodynamic function that describes the number of arrangements (positions and/or energy levels) that are available to a system existing in a given state. Entropy is closely associated with probability. The key concept is that the more ways a particular state can be achieved, the greater is the likelihood (probability) of finding that state. In other words, nature spontaneously proceeds toward the states that have the highest probabilities of existing. This conclusion is not surprising at all. The difficulty comes in connecting this concept to real-life processes. For example, what does the spontaneous rusting of steel have to do with probability? Understanding the connection between entropy and spontaneity will allow us to answer such questions. We will begin to explore this connection by considering a very simple process, the expansion of an ideal gas into a vacuum, as represented in Fig. 17.3. Why is this process spontaneous? The driving force is probability. Because there are more ways of having

Arrangement I

Arrangement II

Arrangement III

Arrangement IV

Arrangement V
FIGURE 17.4 Possible arrangements (states) of four molecules in a two-bulbed flask.

TABLE 17.1 | The Microstates That Give a Particular Arrangement (State)
Arrangement
the gas evenly spread throughout the container than there are ways for it to be in any other possible state, the gas spontaneously attains the uniform distribution.

To understand this conclusion, we will greatly simplify the system and consider the possible arrangements of only four gas molecules in the two-bulbed container (Fig. 17.4). How many ways can each arrangement (state) be achieved? Arrangements I and V can be achieved in only one way-all the molecules must be in one end. Arrangements II and IV can be achieved in four ways, as shown in Table 17.1. Each configuration that gives a particular arrangement is called a microstate. Arrangement I has one microstate, and arrangement II has four microstates. Arrangement III can be achieved in six ways (six microstates), as shown in Table 17.1. Which arrangement is most likely to occur? The one that can be achieved in the greatest number of ways. Thus arrangement III is most probable. The relative probabilities of arrangements III, II, and I are 6:4:1. We have discovered an important principle: The probability of occurrence of a particular arrangement (state) depends on the number of ways (microstates) in which that arrangement can be achieved.

The consequences of this principle are dramatic for large numbers of molecules. One gas molecule in the flask in Fig. 17.4 has one chance in two of being in the left bulb. We say that the probability of finding the molecule in the left bulb is \(\frac{1}{2}\). For two molecules in the flask, there is one chance in two of finding each molecule in the left bulb, so there is one chance in four \(\left(\frac{1}{2} \times \frac{1}{2}=\frac{1}{4}\right)\) that both molecules will be in the left bulb. As the number of molecules increases, the relative probability of finding all of them in the left bulb decreases, as shown in Table 17.2. For 1 mole of gas, the probability of finding all the molecules in the left bulb is so small that this arrangement would "never" occur.

Thus a gas placed in one end of a container will spontaneously expand to fill the entire vessel evenly because, for a large number of gas molecules, there is a huge

For two molecules in the flask, there are four possible microstates:

Thus there is one chance in four of finding this microstate:

Solid, liquid, and gaseous states were compared in Chapter 10.

Solids are more ordered than liquids or gases and thus have lower entropy.

\section*{TABLE 17.2 \| Probability of Finding All the Molecules in the Left Bulb as a Function of the Total Number of Molecules}
\begin{tabular}{|c|c|}
\hline Number of Molecules & Relative Probability of Finding All Molecules in the Left Bulb \\
\hline 1 & \[
\frac{1}{2}
\] \\
\hline 2 & \[
\frac{1}{2} \times \frac{1}{2}=\frac{1}{2^{2}}=\frac{1}{4}
\] \\
\hline 3 & \[
\frac{1}{2} \times \frac{1}{2} \times \frac{1}{2}=\frac{1}{2^{3}}=\frac{1}{8}
\] \\
\hline 5 & \[
\frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2}=\frac{1}{2^{5}}=\frac{1}{32}
\] \\
\hline 10 & \[
\frac{1}{2^{10}}=\frac{1}{1024}
\] \\
\hline \(n\) & \(\frac{1}{2^{n}}=\left(\frac{1}{2}\right)^{n}\) \\
\hline \(6 \times 10^{23}\) (1 mole) & \(\left(\frac{1}{2}\right)^{6 \times 10^{23}} \approx 10^{-\left(2 \times 10^{23}\right)}\) \\
\hline
\end{tabular}
number of microstates in which equal numbers of molecules are in both ends. On the other hand, the opposite process,

although not impossible, is highly improbable, since only one microstate leads to this arrangement. Therefore, this process does not occur spontaneously.

The type of probability we have been considering in this example is called positional probability because it depends on the number of configurations in space (positional microstates) that yield a particular state. A gas expands into a vacuum to give a uniform distribution because the expanded state has the highest positional probability, that is, the largest entropy, of the states available to the system.

Positional probability is also illustrated by changes of state. In general, positional entropy increases in going from solid to liquid to gas. A mole of a substance has a much smaller volume in the solid state than it does in the gaseous state. In the solid state, the molecules are close together, with relatively few positions available to them; in the gaseous state, the molecules are far apart, with many more positions available to them. The liquid state is closer to the solid state than it is to the gaseous state in these terms. We can summarize these comparisons as follows:

The tendency to mix is due to the increased volume available to the particles of each component of the mixture. For example, when two liquids are mixed, the molecules of each liquid have more available volume and thus more available positions.

Positional entropy is also very important in the formation of solutions. In Chapter 11 we saw that solution formation is favored by the natural tendency for substances to mix. We can now be more precise. The entropy change associated with the mixing of two pure substances is expected to be positive. An increase in entropy is expected because there are many more microstates for the mixed condition than for the separated condition. This effect is due principally to the increased volume available to a given "particle" after mixing occurs. For example, when two liquids are mixed to form a solution, the molecules of each liquid have more available volume and thus more available positions. Therefore, the increase in positional entropy associated with mixing favors the formation of solutions.

\section*{INTERACTIVE EXAMPLE 17.1}

SOLUTION

\section*{Positional Entropy}

For each of the following pairs, choose the substance with the higher positional entropy (per mole) at a given temperature.
a. Solid \(\mathrm{CO}_{2}\) and gaseous \(\mathrm{CO}_{2}\)
b. \(\mathrm{N}_{2}\) gas at 1 atm and \(\mathrm{N}_{2}\) gas at \(1.0 \times 10^{-2} \mathrm{~atm}\)
a. Since a mole of gaseous \(\mathrm{CO}_{2}\) has the greater volume by far, the molecules have many more available positions than in a mole of solid \(\mathrm{CO}_{2}\). Thus gaseous \(\mathrm{CO}_{2}\) has the higher positional entropy.
b. A mole of \(\mathrm{N}_{2}\) gas at \(1 \times 10^{-2}\) atm has a volume 100 times that (at a given temperature) of a mole of \(\mathrm{N}_{2}\) gas at 1 atm . Thus \(\mathrm{N}_{2}\) gas at \(1 \times 10^{-2} \mathrm{~atm}\) has the higher positional entropy.

\section*{INTERACTIVE EXAMPLE 17.2 Predicting Entropy Changes}

Predict the sign of the entropy change for each of the following processes.
a. Solid sugar is added to water to form a solution.
b. Iodine vapor condenses on a cold surface to form crystals.

\section*{SOLUTION}
a. The sugar molecules become randomly dispersed in the water when the solution forms and thus have access to a larger volume and a larger number of possible positions. The positional disorder is increased, and there will be an increase in entropy. \(\Delta S\) is positive, since the final state has a larger entropy than the initial state, and \(\Delta S=S_{\text {final }}-S_{\text {initial }}\).
b. Gaseous iodine is forming a solid. This process involves a change from a relatively large volume to a much smaller volume, which results in lower positional disorder. For this process \(\Delta S\) is negative (the entropy decreases).

\section*{CHEMICAL CDNNECTIDNS}

\section*{Entropy: An Organizing Force?}
| n this text we have emphasized the meaning of the second law of thermo-dynamics-that the entropy of the universe is always increasing. Although the results of all our experiments support this conclusion, this does not mean that order cannot appear spontaneously in a given part of the universe. The best example of this phenomenon involves the assembly of cells in living organisms. Of course, when a process that creates an ordered system is examined in detail, it is found that other parts of the process involve an increase in disorder such that the sum of all the entropy changes is positive. In fact, scientists are now finding that the search for maximum entropy in one part of a system can be a powerful force for organization in another part of the system.

To understand how entropy can be an organizing force, look at the accompanying figure. In a system containing large and small "balls" as shown in the figure, the small balls can "herd" the large balls into clumps in the corners and near the walls. This clears out the
maximum space for the small balls so that they can move more freely, thus maximizing the entropy of the system, as demanded by the second law of thermodynamics.

In essence, the ability to maximize entropy by sorting different-sized objects creates a kind of attractive force, called a depletion, or excluded-volume, force. These "entropic forces" operate for objects in the size range of approximately \(10^{-8}\) to approximately \(10^{-6} \mathrm{~m}\). For entropy-induced ordering to occur, the particles must be constantly jostling each other and must be constantly agitated by solvent molecules, thus making gravity unimportant.

There is increasing evidence that entropic ordering is important in many biological systems. For example, this phenomenon seems to be responsible for the clumping of sickle-cell hemoglobin in the presence of much smaller proteins that act as the "smaller balls." Entropic forces also have been linked to the clustering of DNA in cells without nuclei, and Allen Minton of the

National Institutes of Health in Bethesda, Maryland, is studying the role of entropic forces in the binding of proteins to cell membranes.

Entropic ordering also appears in nonbiological settings, especially in the ways polymer molecules clump together. For example, polymers added to paint to improve the flow characteristics of the paint actually caused it to coagulate because of depletion forces.

Thus, as you probably have concluded already, entropy is a complex issue. As entropy drives the universe to its ultimate death of maximum chaos, it provides some order along the way.

\subsection*{17.2 Entropy and the Second Law of Thermodynamics}

We have seen that processes are spontaneous when they result in an increase in disorder. Nature always moves toward the most probable state available to it. We can state this principle in terms of entropy: In any spontaneous process there is always an increase in the entropy of the universe. This is the second law of thermodynamics. Contrast this with the first law of thermodynamics, which tells us that the energy of the universe is constant. Energy is conserved in the universe, but entropy is not. In fact, the second law can be paraphrased as follows: The entropy of the universe is increasing.

As in Chapter 6, we find it convenient to divide the universe into a system and the surroundings. Thus we can represent the change in the entropy of the universe as
\[
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}
\]
where \(\Delta S_{\text {sys }}\) and \(\Delta S_{\text {surr }}\) represent the changes in entropy that occur in the system and surroundings, respectively.

To predict whether a given process will be spontaneous, we must know the sign of \(\Delta S_{\text {univ. }}\). If \(\Delta S_{\text {univ }}\) is positive, the entropy of the universe increases, and the process is spontaneous in the direction written. If \(\Delta S_{\text {univ }}\) is negative, the process is spontaneous in the opposite direction. If \(\Delta S_{\text {univ }}\) is zero, the process has no tendency to occur, and the system is at equilibrium. To predict whether a process is spontaneous, we must consider the entropy changes that occur both in the system and in the surroundings and then take their sum.
e日: would the world be different?

\section*{EXAMPLE 17.3 The Second Law}

SOLUTION To reconcile the operation of an order-producing cell with the second law of thermodynamics, we must remember that \(\Delta S_{\text {univ }}\), not \(\Delta S_{\text {sys }}\), must be positive for a process to be spontaneous. A process for which \(\Delta S_{\text {sys }}\) is negative can be spontaneous if the associated \(\Delta S_{\text {surr }}\) is both larger and positive. The operation of a cell is such a process.

See Questions 17.11 and 17.12

A
Boiling water to form steam increases its volume and thus its entropy.

\subsection*{17.3 The Effect of Temperature on Spontaneity}

To explore the interplay of \(\Delta S_{\text {sys }}\) and \(\Delta S_{\text {surr }}\) in determining the sign of \(\Delta S_{\text {univ }}\), we will first discuss the change of state for 1 mole of water from liquid to gas,
\[
\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g)
\]
considering the water to be the system and everything else the surroundings.
What happens to the entropy of water in this process? A mole of liquid water \((18 \mathrm{~g})\) has a volume of approximately 18 mL . A mole of gaseous water at 1 atmosphere and \(100^{\circ} \mathrm{C}\) occupies a volume of approximately 31 L . Clearly, there are many more positions available to the water molecules in a volume of 31 L than in 18 mL , and the vaporization of water is favored by this increase in positional probability. That is, for this process the entropy of the system increases; \(\Delta S_{\text {sys }}\) has a positive sign.

What about the entropy change in the surroundings? Although we will not prove it here, entropy changes in the surroundings are determined primarily by the flow of energy into or out of the system as heat. To understand this, suppose an exothermic process transfers 50 J of energy as heat to the surroundings, where it becomes thermal energy, that is, kinetic energy associated with the random motions of atoms. Thus this flow of energy into the surroundings increases the random motions of atoms there and thereby increases the entropy of the surroundings. The sign of \(\Delta S_{\text {surr }}\) is positive. When an endothermic process occurs in the system, it produces the opposite effect. Heat flows from the surroundings to the system, and the random motions of the atoms in the surroundings decrease, decreasing the entropy of the surroundings. The vaporization of water is an endothermic process. Thus, for this change of state, \(\Delta S_{\text {surr }}\) is negative.

In an endothermic process, heat flows from the surroundings into the system. In an exothermic process, heat flows into the surroundings from the system.

In a process occurring at constant temperature, the tendency for the system to lower its energy results from the positive value of \(\Delta S_{\text {surr }}\).

Remember it is the sign of \(\Delta S_{\text {univ }}\) that tells us whether the vaporization of water is spontaneous. We have seen that \(\Delta S_{\text {sys }}\) is positive and favors the process and that \(\Delta S_{\text {surr }}\) is negative and unfavorable. Thus the components of \(\Delta S_{\text {univ }}\) are in opposition. Which one controls the situation? The answer depends on the temperature. We know that at a pressure of 1 atmosphere, water changes spontaneously from liquid to gas at all temperatures above \(100^{\circ} \mathrm{C}\). Below \(100^{\circ} \mathrm{C}\), the opposite process (condensation) is spontaneous.

Since \(\Delta S_{\text {sys }}\) and \(\Delta S_{\text {surr }}\) are in opposition for the vaporization of water, the temperature must have an effect on the relative importance of these two terms. To understand why this is so, we must discuss in more detail the factors that control the entropy changes in the surroundings. The central idea is that the entropy changes in the surroundings are primarily determined by heat flow. An exothermic process in the system increases the entropy of the surroundings, because the resulting energy flow increases the random motions in the surroundings. This means that exothermicity is an important driving force for spontaneity. In earlier chapters we have seen that a system tends to undergo changes that lower its energy. We now understand the reason for this tendency. When a system at constant temperature moves to a lower energy, the energy it gives up is transferred to the surroundings, leading to an increase in entropy there.

The significance of exothermicity as a driving force depends on the temperature at which the process occurs. That is, the magnitude of \(\Delta S_{\text {surr }}\) depends on the temperature at which the heat is transferred. We will not attempt to prove this fact here. Instead, we offer an analogy. Suppose that you have \(\$ 50\) to give away. Giving it to a millionaire would not create much of an impression-a millionaire has money to spare. However, to a poor college student, \(\$ 50\) would represent a significant sum and would be received with considerable joy. The same principle can be applied to energy transfer via the flow of heat. If 50 J of energy is transferred to the surroundings, the impact of that event depends greatly on the temperature. If the temperature of the surroundings is very high, the atoms there are in rapid motion. The 50 J of energy will not make a large percent change in these motions. On the other hand, if 50 J of energy is transferred to the surroundings at a very low temperature, where atomic motion is slow, the energy will cause a large percent change in these motions. The impact of the transfer of a given quantity of energy as heat to or from the surroundings will be greater at lower temperatures.

For our purposes, there are two important characteristics of the entropy changes that occur in the surroundings:
1. The sign of \(\Delta S_{\text {surr }}\) depends on the direction of the heat flow. At constant temperature, an exothermic process in the system causes heat to flow into the surroundings, increasing the random motions and thus the entropy of the surroundings. For this case, \(\Delta S_{\text {surr }}\) is positive. The opposite is true for an endothermic process in a system at constant temperature. Note that although the driving force described here really results from the change in entropy, it is often described in terms of energy: Nature tends to seek the lowest possible energy.
2. The magnitude of \(\Delta S_{\text {surr }}\) depends on the temperature. The transfer of a given quantity of energy as heat produces a much greater percent change in the randomness of the surroundings at a low temperature than it does at a high temperature. Thus \(\Delta S_{\text {surr }}\) depends directly on the quantity of heat transferred and inversely on temperature. In other words, the tendency for the system to lower its energy becomes a more important driving force at lower temperatures.
\begin{tabular}{c}
\begin{tabular}{c}

the surroundings
\end{tabular}\(=\frac{\text { quantity of heat }(\mathrm{J})}{\text { temperature }(\mathrm{K})}\)

\section*{Exothermic process:}
\(\Delta S_{\text {surr }}=\) positive

Endothermic process:
\(\Delta S_{\text {surr }}=\) negative

When no subscript is present, the quantity (for example, \(\Delta H\) ) refers to the system.

The minus sign changes the point of view from the system to the surroundings.

These ideas are summarized as follows:
\[
\begin{array}{ll}
\text { Exothermic process: } & \Delta S_{\text {surr }}=+\frac{\text { quantity of heat }(\mathrm{J})}{\text { temperature }(\mathrm{K})} \\
\text { Endothermic process: } & \Delta S_{\text {surr }}=-\frac{\text { quantity of heat }(\mathrm{J})}{\text { temperature }(\mathrm{K})}
\end{array}
\]

We can express \(\Delta S_{\text {surr }}\) in terms of the change in enthalpy \(\Delta H\) for a process occurring at constant pressure, since
\[
\text { Heat flow }(\text { constant } P)=\text { change in enthalpy }=\Delta H
\]

Recall that \(\Delta H\) consists of two parts: a sign and a number. The sign indicates the direction of flow, where a plus sign means into the system (endothermic) and a minus sign means out of the system (exothermic). The number indicates the quantity of energy.

Combining all these concepts produces the following definition of \(\Delta S_{\text {surr }}\) for a reaction that takes place under conditions of constant temperature (in kelvins) and pressure:
\[
\Delta S_{\text {surr }}=-\frac{\Delta H}{T}
\]

The minus sign is necessary because the sign of \(\Delta H\) is determined with respect to the reaction system, and this equation expresses a property of the surroundings. This means that if the reaction is exothermic, \(\Delta H\) has a negative sign, but since heat flows into the surroundings, \(\Delta S_{\text {surr }}\) is positive.

\section*{INTERACTIVE EXAMPLE 17.4 Determining \(\boldsymbol{\Delta} \boldsymbol{S}_{\text {surr }}\)}

In the metallurgy of antimony, the pure metal is recovered via different reactions, depending on the composition of the ore. For example, iron is used to reduce antimony in sulfide ores:
\[
\mathrm{Sb}_{2} \mathrm{~S}_{3}(s)+3 \mathrm{Fe}(s) \longrightarrow 2 \mathrm{Sb}(s)+3 \mathrm{FeS}(s) \quad \Delta H=-125 \mathrm{~kJ}
\]

Carbon is used as the reducing agent for oxide ores:
\[
\mathrm{Sb}_{4} \mathrm{O}_{6}(s)+6 \mathrm{C}(s) \longrightarrow 4 \mathrm{Sb}(s)+6 \mathrm{CO}(g) \quad \Delta H=778 \mathrm{~kJ}
\]

Calculate \(\Delta S_{\text {surr }}\) for each of these reactions at \(25^{\circ} \mathrm{C}\) and 1 atm .

SOLUTION

A
The mineral stibnite contains \(\mathrm{Sb}_{2} \mathrm{~S}_{3}\).

We use
where
\[
\begin{gathered}
\Delta S_{\text {surr }}=-\frac{\Delta H}{T} \\
T=25+273=298 \mathrm{~K}
\end{gathered}
\]

For the sulfide ore reaction,
\[
\Delta S_{\mathrm{surr}}=-\frac{-125 \mathrm{~kJ}}{298 \mathrm{~K}}=0.419 \mathrm{~kJ} / \mathrm{K}=419 \mathrm{~J} / \mathrm{K}
\]

Note that \(\Delta S_{\text {surr }}\) is positive, as it should be, since this reaction is exothermic and heat flow occurs to the surroundings, increasing the randomness of the surroundings.

For the oxide ore reaction,
\[
\Delta S_{\text {surr }}=-\frac{778 \mathrm{~kJ}}{298}=-2.61 \mathrm{~kJ} / \mathrm{K}=-2.61 \times 10^{3} \mathrm{~J} / \mathrm{K}
\]

In this case \(\Delta S_{\text {surr }}\) is negative because heat flow occurs from the surroundings to the system.

\section*{TABLE 17.3 | Interplay of \(\Delta S_{\text {sys }}\) and \(\Delta S_{\text {surr }}\) in Determining the Sign of \(\Delta S_{\text {univ }}\)}
\begin{tabular}{|c|c|c|c|}
\hline \multicolumn{3}{|l|}{Signs of Entropy Changes} & \multirow[b]{2}{*}{Process Spontaneous?} \\
\hline \(\Delta S_{\text {sys }}\) & \(\Delta S_{\text {surr }}\) & \(\Delta S_{\text {univ }}\) & \\
\hline + & + & + & Yes \\
\hline - & - & - & No (reaction will occur in opposite direction) \\
\hline + & - & ? & Yes, if \(\Delta S_{\text {sys }}\) has a larger magnitude than \(\Delta S_{\text {surr }}\) \\
\hline - & + & ? & Yes, if \(\Delta S_{\text {surr }}\) has a larger magnitude than \(\Delta S_{\text {sys }}\) \\
\hline
\end{tabular}

We have seen that the spontaneity of a process is determined by the entropy change it produces in the universe. We also have seen that \(\Delta S_{\text {univ }}\) has two components, \(\Delta S_{\text {sys }}\) and \(\Delta S_{\text {surr }}\). If for some process both \(\Delta S_{\text {sys }}\) and \(\Delta S_{\text {surr }}\) are positive, then \(\Delta S_{\text {univ }}\) is positive, and the process is spontaneous. If, on the other hand, both \(\Delta S_{\text {sys }}\) and \(\Delta S_{\text {surr }}\) are negative, the process does not occur in the direction indicated but is spontaneous in the opposite direction. Finally, if \(\Delta S_{\text {sys }}\) and \(\Delta S_{\text {surr }}\) have opposite signs, the spontaneity of the process depends on the sizes of the opposing terms. These cases are summarized in Table 17.3.

We can now understand why spontaneity is often dependent on temperature and thus why water spontaneously freezes below \(0^{\circ} \mathrm{C}\) and melts above \(0^{\circ} \mathrm{C}\). The term \(\Delta S_{\text {surr }}\) is temperature-dependent. Since
\[
\Delta S_{\text {surr }}=-\frac{\Delta H}{T}
\]
at constant pressure, the value of \(\Delta S_{\text {surr }}\) changes markedly with temperature. The magnitude of \(\Delta S_{\text {surr }}\) will be very small at high temperatures and will increase as the temperature decreases. That is, exothermicity is most important as a driving force at low temperatures.

\subsection*{17.4 Free Energy}

The symbol \(G\) for free energy honors Josiah Willard Gibbs (1839-1903), who was professor of mathematical physics at Yale University from 1871 to 1903 . He laid the foundations of many areas of thermodynamics, particularly as they apply to chemistry.

So far we have used \(\Delta S_{\text {univ }}\) to predict the spontaneity of a process. However, another thermodynamic function is also related to spontaneity and is especially useful in dealing with the temperature dependence of spontaneity. This function is called the free energy, which is symbolized by \(G\) and defined by the relationship
\[
G=H-T S
\]
where \(H\) is the enthalpy, \(T\) is the Kelvin temperature, and \(S\) is the entropy.
For a process that occurs at constant temperature, the change in free energy \((\Delta G)\) is given by the equation
\[
\Delta G=\Delta H-T \Delta S
\]

Note that all quantities here refer to the system. From this point on we will follow the usual convention that when no subscript is included, the quantity refers to the system.

To see how this equation relates to spontaneity, we divide both sides of the equation by \(-T\) to produce
\[
-\frac{\Delta G}{T}=-\frac{\Delta H}{T}+\Delta S
\]

Remember that at constant temperature and pressure
\[
\Delta S_{\mathrm{surr}}=-\frac{\Delta H}{T}
\]

So we can write
\[
-\frac{\Delta G}{T}=-\frac{\Delta H}{T}+\Delta S=\Delta S_{\text {surr }}+\Delta S=\Delta S_{\text {univ }}
\]

The superscript degree symbol ( \({ }^{\circ}\) ) indicates all substances are in their standard states.

To review the definitions of standard states, see Section 6.4.

We have shown that
\[
\Delta S_{\text {univ }}=-\frac{\Delta G}{T} \quad \text { at constant } T \text { and } P
\]

This result is very important. It means that a process carried out at constant temperature and pressure will be spontaneous only if \(\Delta G\) is negative. A process (at constant \(T\) and \(P\) ) is spontaneous in the direction in which the free energy decreases \((-\Delta G\) means \(+\Delta \mathrm{S}_{\text {univ }}\) ).

Now we have two functions that can be used to predict spontaneity: the entropy of the universe, which applies to all processes, and free energy, which can be used for processes carried out at constant temperature and pressure. Since so many chemical reactions occur under the latter conditions, free energy is the more useful to chemists.

Let's use the free energy equation to predict the spontaneity of the melting of ice:
\[
\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
\]
for which \(\quad \Delta H^{\circ}=6.03 \times 10^{3} \mathrm{~J} / \mathrm{mol} \quad\) and \(\quad \Delta S^{\circ}=22.1 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\)
Results of the calculations of \(\Delta S_{\text {univ }}\) and \(\Delta G^{\circ}\) at \(-10^{\circ} \mathrm{C}, 0^{\circ} \mathrm{C}\), and \(10^{\circ} \mathrm{C}\) are shown in Table 17.4. These data predict that the process is spontaneous at \(10^{\circ} \mathrm{C}\); that is, ice melts at this temperature because \(\Delta S_{\text {univ }}\) is positive and \(\Delta G^{\circ}\) is negative. The opposite is true at \(-10^{\circ} \mathrm{C}\), where water freezes spontaneously.

Why is this so? The answer lies in the fact that \(\Delta S_{\text {sys }}\left(\Delta S^{\circ}\right)\) and \(\Delta S_{\text {surr }}\) oppose each other. The term \(\Delta S^{\circ}\) favors the melting of ice because of the increase in positional entropy, and \(\Delta S_{\text {surr }}\) favors the freezing of water because it is an exothermic process. At temperatures below \(0^{\circ} \mathrm{C}\), the change of state occurs in the exothermic direction because \(\Delta S_{\text {surr }}\) is larger in magnitude than \(\Delta S_{\text {sys }}\). But above \(0^{\circ} \mathrm{C}\) the change occurs in the direction in which \(\Delta S_{\text {sys }}\) is favorable, since in this case \(\Delta S_{\text {sys }}\) is larger in magnitude than \(\Delta S_{\text {surr }}\) At \(0^{\circ} \mathrm{C}\) the opposing tendencies just balance, and the two states coexist; there is no driving force in either direction. An equilibrium exists between the two states of water. Note that \(\Delta S_{\text {univ }}\) is equal to 0 at \(0^{\circ} \mathrm{C}\).

We can reach the same conclusions by examining \(\Delta G^{\circ}\). At \(-10^{\circ}, \Delta G^{\circ}\) is positive because the \(\Delta H^{\circ}\) term is larger than the \(T \Delta S^{\circ}\) term. The opposite is true at \(10^{\circ} \mathrm{C}\). At \(0^{\circ} \mathrm{C}, \Delta H^{\circ}\) is equal to \(T \Delta S^{\circ}\) and \(\Delta G^{\circ}\) is equal to 0 . This means that solid \(\mathrm{H}_{2} \mathrm{O}\) and liquid \(\mathrm{H}_{2} \mathrm{O}\) have the same free energy at \(0^{\circ} \mathrm{C}\left(\Delta G^{\circ}=G_{\text {liquid }}-G_{\text {solid }}\right)\), and the system is at equilibrium.

We can understand the temperature dependence of spontaneity by examining the behavior of \(\Delta G\). For a process occurring at constant temperature and pressure,
\[
\Delta G=\Delta H-T \Delta S
\]

If \(\Delta H\) and \(\Delta S\) favor opposite processes, spontaneity will depend on temperature in such a way that the exothermic direction will be favored at low temperatures. For example, for the process
\[
\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
\]

TABLE 17.4 | Results of the Calculation of \(\Delta S_{\text {univ }}\) and \(\Delta G^{\circ}\) for the Process \(\mathrm{H}_{2} \mathrm{O}(\mathrm{s}) \rightarrow \mathrm{H}_{2} \mathrm{O}(I)\) at \(-10^{\circ} \mathrm{C}, 0^{\circ} \mathrm{C}\), and \(10^{\circ} \mathrm{C}^{*}\)
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline \[

\hline -10 & 263 & \(6.03 \times 10^{3}\) & 22.1 & -22.9 & -0.8 & \(5.81 \times 10^{3}\) & \(+2.2 \times 10^{2}\) \\
\hline 0 & 273 & \(6.03 \times 10^{3}\) & 22.1 & -22.1 & 0 & \(6.03 \times 10^{3}\) & 0 \\
\hline 10 & 283 & \(6.03 \times 10^{3}\) & 22.1 & -21.3 & +0.8 & \(6.25 \times 10^{3}\) & \(-2.2 \times 10^{2}\) \\
\hline
\end{tabular}
\({ }^{*}\) Note that at \(10^{\circ} \mathrm{C}, \Delta S^{\circ}\left(\Delta S_{\text {sys }}\right)\) controls, and the process occurs even though it is endothermic. At \(-10^{\circ} \mathrm{C}\), the magnitude of \(\Delta S_{\text {surr }}\) is larger than that of \(\Delta S^{\circ}\), so the process is spontaneous in the opposite (exothermic) direction.

Note that although \(\Delta H\) and \(\Delta S\) are somewhat temperature-dependent, it is a good approximation to assume they are constant over a relatively small temperature range.

\section*{TABLE 17.5 | Various Possible Combinations of \(\Delta H\) and \(\Delta S\) for a Process and the Resulting Dependence of Spontaneity on Temperature}
\begin{tabular}{|c|c|}
\hline Case & Result \\
\hline \(\Delta S\) positive, \(\Delta H\) negative & Spontaneous at all temperatures \\
\hline \(\Delta S\) positive, \(\Delta H\) positive & Spontaneous at high temperatures (where exothermicity is relatively unimportant) \\
\hline \(\Delta S\) negative, \(\Delta H\) negative & Spontaneous at low temperatures (where exothermicity is dominant) \\
\hline \(\Delta S\) negative, \(\Delta H\) positive & Process not spontaneous at any temperature (reverse process is spontaneous at all temperatures) \\
\hline
\end{tabular}
\(\Delta H\) is positive and \(\Delta S\) is positive. The natural tendency for this system to lower its energy is in opposition to its natural tendency to increase its positional randomness. At low temperatures, \(\Delta H\) dominates, and at high temperatures, \(\Delta S\) dominates. The various possible cases are summarized in Table 17.5.

Consider an ideal gas in a container fitted with a frictionless, massless piston. What if weight is added to the top of the piston? We would expect the gas to be compressed at constant temperature. For this to be true, \(\Delta S\) would be negative (since the gas is compressed) and \(\Delta H\) would be zero (since the process is at constant temperature). This would make \(\Delta G\) positive. Does this mean the isothermal compression of the gas is not spontaneous? Defend your answer.

\section*{INTERACTIVE EXAMPLE 17.5 Free Energy and Spontaneity}

At what temperatures is the following process spontaneous at 1 atm ?
\[
\begin{gathered}
\mathrm{Br}_{2}(l) \longrightarrow \mathrm{Br}_{2}(g) \\
\Delta H^{\circ}=31.0 \mathrm{~kJ} / \mathrm{mol} \quad \text { and } \quad \Delta S^{\circ}=93.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{gathered}
\]

What is the normal boiling point of liquid \(\mathrm{Br}_{2}\) ?
SOLUTION The vaporization process will be spontaneous at all temperatures where \(\Delta G^{\circ}\) is negative. Note that \(\Delta S^{\circ}\) favors the vaporization process because of the increase in positional entropy, and \(\Delta H^{\circ}\) favors the opposite process, which is exothermic. These opposite tendencies will exactly balance at the boiling point of liquid \(\mathrm{Br}_{2}\), since at this temperature liquid and gaseous \(\mathrm{Br}_{2}\) are in equilibrium \(\left(\Delta G^{\circ}=0\right)\). We can find this temperature by setting \(\Delta G^{\circ}=0\) in the equation

Then
\[
\begin{gathered}
\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ} \\
0=\Delta H^{\circ}-T \Delta S^{\circ} \\
\Delta H^{\circ}=T \Delta S^{\circ} \\
T=\frac{\Delta H^{\circ}}{\Delta S^{\circ}}=\frac{3.10 \times 10^{4} \mathrm{~J} / \mathrm{mol}}{93.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}}=333 \mathrm{~K}
\end{gathered}
\]

At temperatures above \(333 \mathrm{~K}, T \Delta S^{\circ}\) has a larger magnitude than \(\Delta H^{\circ}\), and \(\Delta G^{\circ}\) (or \(\Delta H^{\circ}-T \Delta S^{\circ}\) ) is negative. Above 333 K , the vaporization process is spontaneous; the opposite process occurs spontaneously below this temperature. At 333 K , liquid and
gaseous \(\mathrm{Br}_{2}\) coexist in equilibrium. These observations can be summarized as follows (the pressure is 1 atm in each case):
1. \(T>333 \mathrm{~K}\). The term \(\Delta S^{\circ}\) controls. The increase in entropy when liquid \(\mathrm{Br}_{2}\) is vaporized is dominant.
2. \(T<333 \mathrm{~K}\). The process is spontaneous in the direction in which it is exothermic. The term \(\Delta H^{\circ}\) controls.
3. \(T=333 \mathrm{~K}\). The opposing driving forces are just balanced \(\left(\Delta G^{\circ}=0\right)\), and the liquid and gaseous phases of bromine coexist. This is the normal boiling point.

\subsection*{17.5 Entropy Changes in Aqueous Solutions}

In Chapter 11 we discussed the concept of like dissolves like. This implies that an ionic solute [such as table salt, \(\mathrm{NaCl}(s)\) ] should dissolve in a polar solvent [such as water]. The process of forming a solution was given as a series of three steps as shown in Figs. 11.1 and 11.2 , and the overall \(\Delta H^{\circ}\) soln for dissolving \(\mathrm{NaCl}(s)\) in water was found to be positive (requires energy). Recall that to predict whether a given process (at constant temperature and pressure) is spontaneous, we must consider the change in free energy:
\[
\Delta G=\Delta H-T \Delta S
\]

It is an experimental fact that \(\mathrm{NaCl}(s)\) dissolves in water to form 1.0 M NaCl . Thus, \(\Delta G^{\circ}\) for this process must be negative. Since \(\Delta H_{\text {soln }}^{\circ}\) is positive and unfavorable, \(\Delta S_{\text {soln }}^{\circ}\) must be positive and large enough to make \(\Delta G^{\circ}\) negative (through the \(-T \Delta S^{\circ}\) term). It is certainly not surprising that \(\Delta S_{\text {soln }}^{\circ}\) would be positive for this process. In considering the three steps of dissolution of a solute mentioned in Chapter 11, we would expect \(\Delta S_{1}\) and \(\Delta S_{2}\) to be positive since the solute and solvent are "expanded" in these steps. Also, \(\Delta S_{3}\) would be expected to be positive in a general case because a solute is randomly dispersed in the relatively large volume of solvent.

Thus, we might generalize for an ionic (or polar) solute dissolving in a polar solvent as follows: because \(\Delta H_{\text {soln }}^{\circ}\) contains large positive and negative contributions, it is difficult to predict the sign of \(\Delta H_{\text {soln }}^{\circ}\). However, even if \(\Delta H_{\text {soln }}^{\circ}\) is positive, it is not expected to be so large that it would overwhelm the expected positive value of \(\Delta S_{\text {soln }}^{\circ}\) for this process. The overall effect is to make \(\Delta G_{\text {soln }}^{\circ}\) negative, thus the solution forms spontaneously.

However, as we noted in Chapter 10, water is not a typical liquid, with most of its unusual properties arising from the extensive hydrogen bonding present among the molecules. Because of water's unique nature, we must be very cautious in using simple arguments to account for the solvent properties of water.

To illustrate the unusual nature of water as a solvent, consider the following values of \(\Delta S_{\text {soln }}^{\circ}\) for \(\mathrm{KCl}(s), \mathrm{LiF}(s)\), and \(\mathrm{CaS}(s)\) forming aqueous solutions.
\begin{tabular}{|cc|}
\hline Process & \(\boldsymbol{\Delta} \mathbf{S}_{\text {soln }}^{\circ}(\mathrm{J} / \mathrm{Kmol})\) \\
\hline \(\mathrm{KCl}(s) \rightarrow \mathrm{K}^{+}(a q)+\mathrm{Cl}^{-}(a q)\) & 75 \\
\hline \(\mathrm{LiF}(s) \rightarrow \mathrm{Li}^{+}(a q)+\mathrm{F}^{-}(a q)\) & -36 \\
\hline \(\mathrm{CaS}(s) \rightarrow \mathrm{Ca}^{2+}(a q)+\mathrm{S}^{2-}(a q)\) & -138 \\
\hline
\end{tabular}

Note that when \(\mathrm{KCl}(s)\) is dissolved in water to form a 1.0 M solution, the value of \(\Delta S_{\text {soln }}^{\circ}\) is positive, as expected from the previous discussion. However, note that \(\Delta S_{\text {soln }}^{\circ}\) is negative for the other two salts. Why? How could the random dispersal in water of ions formerly present in a highly ordered solid produce a negative entropy change?

Obviously, something must be occurring in the solution process that leads to increased order, which in some cases is large enough to dominate \(\Delta S_{\text {soln. }}^{\circ}\). There is little doubt that this ordering effect arises from the hydration of the ions. In describing aqueous solutions containing ionic solutes in Chapter 4, we discussed the fact that the polar water molecules are attracted to the ions to form hydrated species. The assembling of a group of water molecules around the ions is an order-producing phenomenon and would be expected to make a negative contribution to \(\Delta S_{\text {soln }}^{\circ}\). Studies show that the more charge density an ion possesses, the greater this hydration effect will be. This idea is borne out by the data in the table above. For example, note that \(\Delta S_{\text {soln }}^{\circ}\) for \(\mathrm{KCl}(s)\) is positive, but the value for \(\operatorname{LiF}(s)\) is negative. This probably results from the smaller sizes (and larger charge densities) of \(\mathrm{Li}^{+}\)and \(\mathrm{F}^{-}\)compared with \(\mathrm{K}^{+}\)and \(\mathrm{Cl}^{-}\). The smaller ions presumably are able to bind to the hydrating water molecules more firmly and thus show a more negative value for \(\Delta S_{\text {soln }}^{\circ}\). The charges on the ions are also important. Note that \(\mathrm{CaS}(s)\) exhibits a value for \(\Delta S_{\text {soln }}^{\circ}\) that is more negative than that for \(\mathrm{LiF}(s)\), as might be expected for the more highly charged \(\mathrm{Ca}^{2+}\) and \(\mathrm{S}^{2-}\) ions.

As we can see, enthalpy changes alone are not enough to predict solubility-we must also consider entropic effects. However, the dissolution process is so complex that successfully predicting whether a particular solute will dissolve in a given solvent is almost impossible. The only way to be certain about the solubility of a given solute in a solvent is to do the experiment.

\subsection*{17.6 Entropy Changes in Chemical Reactions}

The second law of thermodynamics tells us that a process will be spontaneous if the entropy of the universe increases when the process occurs. We saw in Section 17.4 that for a process at constant temperature and pressure, we can use the change in free energy of the system to predict the sign of \(\Delta S_{\text {univ }}\) and thus the direction in which it is spontaneous. So far we have applied these ideas only to physical processes, such as changes of state and the formation of solutions. However, the main business of chemistry is studying chemical reactions, and, therefore, we want to apply the second law to reactions.

First, we will consider the entropy changes accompanying chemical reactions that occur under conditions of constant temperature and pressure. As for the other types of processes we have considered, the entropy changes in the surroundings are determined by the heat flow that occurs as the reaction takes place. However, the entropy changes in the system (the reactants and products of the reaction) are determined by positional probability.

For example, in the ammonia synthesis reaction
\[
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
\]
four reactant molecules become two product molecules, lowering the number of independent units in the system, which leads to less positional disorder.

Fewer molecules mean fewer possible configurations. To help clarify this idea, consider a special container with a million compartments, each large enough to hold a hydrogen molecule. Thus there are a million ways one \(\mathrm{H}_{2}\) molecule can be placed in this container. But suppose we break the \(\mathrm{H}-\mathrm{H}\) bond and place the two independent H atoms in the same container. A little thought will convince you that there are many more than a million ways to place the two separate atoms. The number of arrangements possible for the two independent atoms is much greater than the number for the molecule. Thus for the process
\[
\mathrm{H}_{2} \longrightarrow 2 \mathrm{H}
\]
positional entropy increases.
Does positional entropy increase or decrease when the following reaction takes place?
\[
4 \mathrm{NH}_{3}(\mathrm{~g})+5 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 4 \mathrm{NO}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
\]

In this case 9 gaseous molecules are changed to 10 gaseous molecules, and the positional entropy increases. There are more independent units as products than as reactants. In general, when a reaction involves gaseous molecules, the change in positional entropy is dominated by the relative numbers of molecules of gaseous reactants and products. If the number of molecules of the gaseous products is greater than the number of molecules of the gaseous reactants, positional entropy typically increases, and \(\Delta S\) will be positive for the reaction.

\section*{INTERACTIVE EXAMPLE 17.6}

\section*{SOLUTION}

A perfect crystal at 0 K is an unattainable ideal, taken as a standard but never actually observed.

\section*{Predicting the Sign of \(\Delta \boldsymbol{S}^{\circ}\)}

Predict the sign of \(\Delta S^{\circ}\) for each of the following reactions.
a. The thermal decomposition of solid calcium carbonate:
\[
\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
\]
b. The oxidation of \(\mathrm{SO}_{2}\) in air:
\[
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)
\]
a. Since in this reaction a gas is produced from a solid reactant, the positional entropy increases, and \(\Delta S^{\circ}\) is positive.
b. Here three molecules of gaseous reactants become two molecules of gaseous products. Since the number of gas molecules decreases, positional entropy decreases, and \(\Delta S^{\circ}\) is negative.

\section*{See Exercises 17.45 and 17.46}

In thermodynamics it is the change in a certain function that usually is important. The change in enthalpy determines if a reaction is exothermic or endothermic at constant pressure. The change in free energy determines if a process is spontaneous at constant temperature and pressure. It is fortunate that changes in thermodynamic functions are sufficient for most purposes, since absolute values for many thermodynamic characteristics of a system, such as enthalpy or free energy, cannot be determined.

However, we can assign absolute entropy values. Consider a solid at 0 K , where molecular motion virtually ceases. If the substance is a perfect crystal, its internal arrangement is absolutely regular [Fig. 17.5(a)]. There is only one way to achieve this perfect order: Every particle must be in its place. For example, with \(N\) coins there is only one way to achieve the state of all heads. Thus a perfect crystal represents the lowest possible entropy; that is, the entropy of a perfect crystal at \(0 K\) is zero. This is a statement of the third law of thermodynamics.

The standard entropy values represent the increase in entropy that occurs when a substance is heated from 0 K to 298 K at 1 atm pressure.

-b

FIGURE 17.5 (a) An idealized perfect crystal of hydrogen chloride at 0 K ; the dipolar HCl molecules are represented by \(->\). The entropy is zero \((S=0)\) for this crystal at 0 K . (b) As the temperature rises above 0 K , lattice vibrations allow some dipoles to change their orientations, producing some disorder and an increase in entropy ( \(S>0\) ).

As the temperature of a perfect crystal is increased, the random vibrational motions increase, and disorder increases within the crystal [Fig. 17.5(b)]. Thus the entropy of a substance increases with temperature. Since \(S\) is zero for a perfect crystal at 0 K , the entropy value for a substance at a particular temperature can be calculated by knowing the temperature dependence of entropy. (We will not show such calculations here.)

The standard entropy values ( \(S^{\circ}\) ) of many common substances at 298 K and 1 atm are listed in Appendix 4. From these values you will see that the entropy of a substance does indeed increase in going from solid to liquid to gas. One especially interesting feature of this table is the very low \(S^{\circ}\) value for diamond. The structure of diamond is highly ordered, with each carbon strongly bound to a tetrahedral arrangement of four other carbon atoms (see Section 10.5, Fig. 10.22). This type of structure allows very little disorder and has a very low entropy, even at 298 K . Graphite has a slightly higher entropy because its layered structure allows for a little more disorder.

Because entropy is a state function of the system (it is not pathway-dependent), the entropy change for a given chemical reaction can be calculated by taking the difference between the standard entropy values of products and those of the reactants:
\[
\Delta S_{\text {reaction }}^{\circ}=\Sigma n_{\mathrm{p}} S_{\text {products }}^{\circ}-\Sigma n_{\mathrm{r}} S_{\text {reactants }}^{\circ}
\]
where, as usual, \(\Sigma\) represents the sum of the terms. It is important to note that entropy is an extensive property (it depends on the amount of substance present). This means that the number of moles of a given reactant \(\left(n_{\mathrm{r}}\right)\) or product \(\left(n_{\mathrm{p}}\right)\) must be taken into account.

\section*{INTERACTIVE EXAMPLE 17.1 Calculating \(\boldsymbol{\Delta} \boldsymbol{S}^{\circ}\)}

Calculate \(\Delta S^{\circ}\) at \(25^{\circ} \mathrm{C}\) for the reaction
\[
2 \mathrm{NiS}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{2}(g)+2 \mathrm{NiO}(s)
\]
given the following standard entropy values:
\begin{tabular}{|cc|}
\hline Substance & \(S^{\circ}(J / K \cdot\) mol \()\) \\
\hline \(\mathrm{SO}_{2}(g)\) & 248 \\
\hline \(\mathrm{NiO}(s)\) & 38 \\
\hline \(\mathrm{O}_{2}(g)\) & 205 \\
\hline \(\mathrm{NiS}(s)\) & 53 \\
\hline
\end{tabular}

\section*{SOLUTION}

Since
\[
\begin{aligned}
\Delta S^{\circ}= & \sum n_{\mathrm{p}} S_{\mathrm{Sroducts}_{\circ}^{\circ}-\sum n_{\mathrm{r}} S_{\mathrm{reactants}}^{\circ}}^{=} \\
= & 2 S_{\mathrm{SO}_{2}(g)}^{\circ}+2 S_{\mathrm{NiO}(s)}^{\circ}-2 S_{\mathrm{NiS}(s)}^{\circ}-3 S_{\mathrm{O}_{2}(s)}^{\circ} \\
= & 2 \mathrm{~mol}\left(248 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)+2 \mathrm{~mol}\left(38 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\right) \\
& -2 \mathrm{~mol}\left(53 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)-3 \mathrm{~mol}\left(205 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\right) \\
= & 496 \mathrm{~J} / \mathrm{K}+76 \mathrm{~J} / \mathrm{K}-106 \mathrm{~J} / \mathrm{K}-615 \mathrm{~J} / \mathrm{K} \\
= & -149 \mathrm{~J} / \mathrm{K}
\end{aligned}
\]

We would expect \(\Delta S^{\circ}\) to be negative because the number of gaseous molecules decreases in this reaction.

See Exercise 17.49

\section*{INTERACTIVE EXAMPLE 17.8 Calculating \(\boldsymbol{\Delta} \mathbf{S}^{\circ}\)}

Calculate \(\Delta S^{\circ}\) for the reduction of aluminum oxide by hydrogen gas:
\[
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+3 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{Al}(\mathrm{~s})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
\]

Use the following standard entropy values:
\begin{tabular}{lc}
\hline Substance & \(\boldsymbol{S}^{\circ}(\mathrm{J} / \mathrm{K} \cdot \mathrm{mol})\) \\
\hline \(\mathrm{Al}_{2} \mathrm{O}_{3}(s)\) & 51 \\
\hline \(\mathrm{H}_{2}(g)\) & 131 \\
\hline \(\mathrm{Al}(s)\) & 28 \\
\hline \(\mathrm{H}_{2} \mathrm{O}(g)\) & 189 \\
\hline
\end{tabular}

\section*{SOLUTION}
\[
\begin{aligned}
& \Delta S^{\circ}=\Sigma n_{\mathrm{p}} S_{\text {products }}^{\circ}-\Sigma n_{\mathrm{r}} S_{\text {reactants }}^{\circ} \\
&= 2 S_{\mathrm{Al}(s)}^{\circ}+3 S_{\mathrm{H}_{2} \mathrm{O}(\mathrm{~s})}^{\circ}-3 S_{\mathrm{H}_{2}(g)}^{\circ}-S_{\mathrm{Al}_{2} \mathrm{O}_{3}(s)}^{\circ} \\
&= 2 \mathrm{~mol}\left(28 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)+3 \mathrm{~mol}\left(189 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\right) \\
&-3 \mathrm{~mol}\left(131 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)-1 \mathrm{~mol}\left(51 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\right) \\
&= 56 \mathrm{~J} / \mathrm{K}+567 \mathrm{~J} / \mathrm{K}-393 \mathrm{~J} / \mathrm{K}-51 \mathrm{~J} / \mathrm{K} \\
&= 179 \mathrm{~J} / \mathrm{K}
\end{aligned}
\]

The reaction considered in Example 17.8 involves 3 moles of hydrogen gas on the reactant side and 3 moles of water vapor on the product side. Would you expect \(\Delta S\) to be large or small for such a case? We have assumed that \(\Delta S\) depends on the relative numbers of molecules of gaseous reactants and products. Based on this assumption,

FIGURE 17.6 The \(\mathrm{H}_{2} \mathrm{O}\) molecule can vibrate and rotate in several ways, some of which are shown here. This freedom of motion leads to a higher entropy for water than for a substance like hydrogen, a simple diatomic molecule with fewer possible motions.

\(\Delta S\) should be near zero for this reaction. However, \(\Delta S\) is large and positive. Why is this so? The large value for \(\Delta S\) results from the difference in the entropy values for hydrogen gas and water vapor. The reason for this difference can be traced to the difference in molecular structure. Because it is a nonlinear, triatomic molecule, \(\mathrm{H}_{2} \mathrm{O}\) has more rotational and vibrational motions (Fig. 17.6) than does the diatomic \(\mathrm{H}_{2}\) molecule. Thus the standard entropy value for \(\mathrm{H}_{2} \mathrm{O}(g)\) is greater than that for \(\mathrm{H}_{2}(g)\). Generally, the more complex the molecule, the higher the standard entropy value.

\subsection*{17.1 Free Energy and Chemical Reactions}

For chemical reactions we are often interested in the standard free energy change \(\left(\Delta G^{\circ}\right)\), the change in free energy that will occur if the reactants in their standard states are converted to the products in their standard states. For example, for the ammonia synthesis reaction at \(25^{\circ} \mathrm{C}\),
\[
\begin{equation*}
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g) \quad \Delta G^{\circ}=-33.3 \mathrm{~kJ} \tag{17.1}
\end{equation*}
\]

This \(\Delta G^{\circ}\) value represents the change in free energy when 1 mole of nitrogen gas at 1 atm reacts with 3 moles of hydrogen gas at 1 atm to produce 2 moles of gaseous \(\mathrm{NH}_{3}\) at 1 atm .

It is important to recognize that the standard free energy change for a reaction is not measured directly. For example, we can measure heat flow in a calorimeter to determine \(\Delta H^{\circ}\), but we cannot measure \(\Delta G^{\circ}\) this way. The value of \(\Delta G^{\circ}\) for the ammonia synthesis in Equation (17.1) was not obtained by mixing 1 mole of \(\mathrm{N}_{2}\) and 3 moles of \(\mathrm{H}_{2}\) in a flask and measuring the change in free energy as 2 moles of \(\mathrm{NH}_{3}\) formed. For one thing, if we mixed 1 mole of \(\mathrm{N}_{2}\) and 3 moles of \(\mathrm{H}_{2}\) in a flask, the system would go to equilibrium rather than to completion. Also, we have no instrument that measures free energy. However, while we cannot directly measure \(\Delta G^{\circ}\) for a reaction, we can calculate it from other measured quantities, as we will see later in this section.

The value of \(\Delta G^{\circ}\) tells us nothing about the rate of a reaction, only its eventual equilibrium position.

Why is it useful to know \(\Delta G^{\circ}\) for a reaction? As we will see in more detail later in this chapter, knowing the \(\Delta G^{\circ}\) values for several reactions allows us to compare the relative tendency of these reactions to occur. The more negative the value of \(\Delta G^{\circ}\), the further a reaction will go to the right to reach equilibrium. We must use standard-state free energies to make this comparison because free energy varies with pressure or concentration. Thus, to get an accurate comparison of reaction tendencies, we must compare all reactions under the same pressure or concentration conditions. We will have more to say about the significance of \(\Delta G^{\circ}\) later.

There are several ways to calculate \(\Delta G^{\circ}\). One common method uses the equation
\[
\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}
\]
which applies to a reaction carried out at constant temperature. For example, for the reaction
\[
\mathrm{C}(s)+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})
\]
the values of \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) are known to be -393.5 kJ and \(3.05 \mathrm{~J} / \mathrm{K}\), respectively, and \(\Delta G^{\circ}\) can be calculated at 298 K as follows:
\[
\begin{aligned}
\Delta G^{\circ} & =\Delta H^{\circ}-T \Delta S^{\circ} \\
& =-3.935 \times 10^{5} \mathrm{~J}-(298 \mathrm{~K})(3.05 \mathrm{~J} / \mathrm{K}) \\
& =-3.944 \times 10^{5} \mathrm{~J} \\
& =-394.4 \mathrm{~kJ}\left(\text { per mole of } \mathrm{CO}_{2}\right)
\end{aligned}
\]

\section*{INTERACTIVE EXAMPLE 17.9 Calculating \(\boldsymbol{\Delta} \boldsymbol{H}^{\circ}, \Delta \boldsymbol{S}^{\circ}\), and \(\boldsymbol{\Delta} \boldsymbol{G}^{\circ}\)}

Consider the reaction
\[
2 \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{SO}_{3}(\mathrm{~g})
\]
carried out at \(25^{\circ} \mathrm{C}\) and 1 atm . Calculate \(\Delta H^{\circ}, \Delta S^{\circ}\), and \(\Delta G^{\circ}\) using the following data:
\begin{tabular}{ccc}
\hline Substance & \(\boldsymbol{H}_{\mathrm{f}}^{\mathrm{o}}(\mathrm{kJ} / \mathrm{mol})\) & \(\boldsymbol{S}^{\circ}(\mathrm{J} / \mathrm{K} \cdot \mathrm{mol})\) \\
\hline \(\mathrm{SO}_{2}(\mathrm{~g})\) & -297 & 248 \\
\hline \(\mathrm{SO}_{3}(\mathrm{~g})\) & -396 & 257 \\
\hline \(\mathrm{O}_{2}(\mathrm{~g})\) & 0 & 205 \\
\hline
\end{tabular}

\section*{SOLUTION}

The value of \(\Delta H^{\circ}\) can be calculated from the enthalpies of formation using the equation we discussed in Section 6.4:

Then
\[
\begin{aligned}
& \Delta H^{\circ}=\Sigma n_{\mathrm{p}} \Delta H_{\mathrm{f}(\text { products })}^{\circ}-\Sigma n_{\mathrm{r}} \Delta H_{\mathrm{f}(\text { reactants })}^{\circ} \\
\Delta H^{\circ}= & 2 \Delta H_{\mathrm{f}\left(\mathrm{SO}_{3}(\mathrm{~g})\right)}^{\circ}-2 \Delta H_{\mathrm{f}\left(\mathrm{SO}_{2}(\mathrm{~g})\right)}^{\circ}-\Delta H_{\mathrm{f}\left(\mathrm{O}_{2}(g)\right)}^{\circ} \\
= & 2 \mathrm{~mol}(-396 \mathrm{~kJ} / \mathrm{mol})-2 \mathrm{~mol}(-297 \mathrm{~kJ} / \mathrm{mol})-0 \\
= & -792 \mathrm{~kJ}+594 \mathrm{~kJ} \\
= & -198 \mathrm{~kJ}
\end{aligned}
\]

The value of \(\Delta S^{\circ}\) can be calculated using the standard entropy values and the equation discussed in Section 17.6:
\[
\Delta S^{\circ}=\Sigma n_{\mathrm{p}} S_{\text {products }}^{\circ}-\Sigma n_{\mathrm{r}} S_{\text {reactants }}^{\circ}
\]

Thus
\[
\begin{aligned}
\Delta S^{\circ} & =2 S_{\mathrm{SO}_{3}(g)}^{\circ}-2 S_{\mathrm{SO}_{2}(g)}^{\circ}-S_{\mathrm{O}_{2}(g)}^{\circ} \\
& =2 \mathrm{~mol}(257 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})-2 \mathrm{~mol}(248 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})-1 \mathrm{~mol}(205 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}) \\
& =514 \mathrm{~J} / \mathrm{K}-496 \mathrm{~J} / \mathrm{K}-205 \mathrm{~J} / \mathrm{K} \\
& =-187 \mathrm{~J} / \mathrm{K}
\end{aligned}
\]

We would expect \(\Delta S^{\circ}\) to be negative because three molecules of gaseous reactants give two molecules of gaseous products.

The value of \(\Delta G^{\circ}\) can now be calculated from the equation
\[
\begin{aligned}
\Delta G^{\circ} & =\Delta H^{\circ}-T \Delta S^{\circ} \\
& =-198 \mathrm{~kJ}-(298 \mathrm{~K})\left(-187 \frac{\mathrm{~J}}{\mathrm{~K}}\right)\left(\frac{1 \mathrm{~kJ}}{1000 \mathrm{~J}}\right) \\
& =-198 \mathrm{~kJ}+55.7 \mathrm{~kJ}=-142 \mathrm{~kJ}
\end{aligned}
\]

\section*{See Exeraises 17.57 and 17.58}

A second method for calculating \(\Delta G\) for a reaction takes advantage of the fact that, like enthalpy, free energy is a state function. Therefore, we can use procedures for finding \(\Delta G\) that are similar to those for finding \(\Delta H\) using Hess's law.

To illustrate this method for calculating the free energy change, we will obtain \(\Delta G^{\circ}\) for the reaction
\[
\begin{equation*}
2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g) \tag{17.2}
\end{equation*}
\]
from the following data:
\[
\begin{align*}
2 \mathrm{CH}_{4}(g)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}(g)+4 \mathrm{H}_{2} \mathrm{O}(g) & \Delta G^{\circ} & =-1088 \mathrm{~kJ}  \tag{17.3}\\
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g) & \Delta G^{\circ} & =-801 \mathrm{~kJ} \tag{17.4}
\end{align*}
\]

Note that \(\mathrm{CO}(g)\) is a reactant in Equation (17.2). This means that Equation (17.3) must be reversed, since \(\mathrm{CO}(g)\) is a product in that reaction as written. When a reaction is reversed, the sign of \(\Delta G^{\circ}\) is also reversed. In Equation (17.4), \(\mathrm{CO}_{2}(g)\) is a product, as it is in Equation (17.2), but only one molecule of \(\mathrm{CO}_{2}\) is formed. Thus Equation (17.4) must be multiplied by 2 , which means the \(\Delta G^{\circ}\) value for Equation (17.4) also must be multiplied by 2 . Free energy is an extensive property, since it is defined by two extensive properties, \(H\) and \(S\).
\[
\begin{aligned}
& \text { Reversed Equation }(17.3) \\
& 2 \mathrm{CO}(g)+4 \mathrm{H}_{2} \mathrm{O}(g) \longrightarrow 2 \mathrm{CH}_{4}(g)+3 \mathrm{O}_{2}(g) \Delta G^{\circ}= \\
&\left.\begin{array}{rl}
2 \times \text { Equation }(17.4) & \\
2 \mathrm{CH}_{4}(g)+4 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(g) & \Delta G^{\circ}=
\end{array}\right) 2(-801 \mathrm{~kJ}) \\
& \hline 2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g) \Delta G^{\circ}=-(-1088 \mathrm{~kJ}) \\
& \\
&+2(-801 \mathrm{~kJ}) \\
&=-514 \mathrm{~kJ}
\end{aligned}
\]

This example shows that the \(\Delta G\) values for reactions are manipulated in exactly the same way as the \(\Delta H\) values.

\section*{INTERACTIVE EXAMPLE 17.10}

The standard state of an element is its most stable state of \(25^{\circ} \mathrm{C}\) and 1 atm .

\section*{Calculating \(\Delta G^{\circ}\) is very similar to} calculating \(\Delta H^{\circ}\), as shown in Section 6.4.

\section*{Calculating \(\Delta \mathbf{G}^{\circ}\)}

Using the following data (at \(25^{\circ} \mathrm{C}\) )
\[
\begin{array}{ll}
\mathrm{C}_{\text {diamond }}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta G^{\circ}=-397 \mathrm{~kJ} \\
\mathrm{C}_{\text {graphite }}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta G^{\circ}=-394 \mathrm{~kJ} \tag{17.6}
\end{array}
\]
calculate \(\Delta G^{\circ}\) for the reaction
\[
\mathrm{C}_{\text {diamond }}(s) \longrightarrow \mathrm{C}_{\text {graphite }}(s)
\]

We reverse Equation (17.6) to make graphite a product, as required, and then add the new equation to Equation (17.5):
\[
\begin{aligned}
\mathrm{C}_{\text {diamond }}(s)+\mathrm{O}_{2}(g) & \Delta G^{\circ} & =-397 \mathrm{~kJ} \\
\text { Reversed Equation (17.6) } & \mathrm{CO}_{2}(g) & \\
\mathrm{CO}_{2}(g) \longrightarrow \mathrm{C}_{\text {graphite }}(s)+\mathrm{O}_{2}(g) & \Delta G^{\circ} & =-(-394 \mathrm{~kJ}) \\
\hline \mathrm{C}_{\text {diamond }}(s) \longrightarrow \mathrm{C}_{\text {graphite }}(s) & \Delta G^{\circ} & =-397 \mathrm{~kJ}+394 \mathrm{~kJ} \\
& & =-3 \mathrm{~kJ}
\end{aligned}
\]

Since \(\Delta G^{\circ}\) is negative for this process, diamond should spontaneously change to graphite at \(25^{\circ} \mathrm{C}\) and 1 atm . However, the reaction is so slow under these conditions that we do not observe the process. This is another example of kinetic rather than thermodynamic control of a reaction. We can say that diamond is kinetically stable with respect to graphite even though it is thermodynamically unstable.

\section*{See Exercises 17.63 and 17.64}

In Example 17.10 we saw that the process
\[
\mathrm{C}_{\text {diamond }}(s) \longrightarrow \mathrm{C}_{\text {graphite }}(s)
\]
is spontaneous but very slow at \(25^{\circ} \mathrm{C}\) and 1 atm . The reverse process can be made to occur at high temperatures and pressures. Diamond has a more compact structure and thus a higher density than graphite, so exerting very high pressure causes it to become thermodynamically favored. If high temperatures are also used to make the process fast enough to be feasible, diamonds can be made from graphite. The conditions typically used involve temperatures greater than \(1000^{\circ} \mathrm{C}\) and pressures of about \(10^{5} \mathrm{~atm}\). About half of all industrial diamonds are made this way.

A third method for calculating the free energy change for a reaction uses standard free energies of formation. The standard free energy of formation \(\left(\Delta G_{f}^{\circ}\right)\) of a substance is defined as the change in free energy that accompanies the formation of 1 mole of that substance from its constituent elements with all reactants and products in their standard states. For the formation of glucose \(\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)\), the appropriate reaction is
\[
6 \mathrm{C}(s)+6 \mathrm{H}_{2}(g)+3 \mathrm{O}_{2}(g) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)
\]

The standard free energy associated with this process is called the free energy of formation of glucose. Values of the standard free energy of formation are useful in calculating \(\Delta G^{\circ}\) for specific chemical reactions using the equation
\[
\Delta G^{\circ}=\Sigma n_{\mathrm{p}} \Delta G_{\mathrm{f}(\text { products })}^{\circ}-\Sigma n_{\mathrm{r}} \Delta G_{\mathrm{f}(\text { reactants })}^{\circ}
\]

Values of \(\Delta G_{\mathrm{f}}^{\circ}\) for many common substances are listed in Appendix 4. Note that, analogous to the enthalpy of formation, the standard free energy of formation of an element in its standard state is zero. Also note that the number of moles of each reactant \(\left(n_{\mathrm{r}}\right)\) and product \(\left(n_{\mathrm{p}}\right)\) must be used when calculating \(\Delta G^{\circ}\) for a reaction.

\section*{INTERACTIVE EXAMPLE 17.11 Calculating \(\boldsymbol{\Delta} \boldsymbol{G}^{\circ}\)}

Methanol is a high-octane fuel used in high-performance racing engines. Calculate \(\Delta G^{\circ}\) for the reaction
\[
2 \mathrm{CH}_{3} \mathrm{OH}(g)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(g)
\]
given the following free energies of formation:
\begin{tabular}{lc}
\hline Substance & \(\Delta G_{f}^{\rho}(\mathrm{kJ} / \mathrm{mol})\) \\
\hline \(\mathrm{CH}_{3} \mathrm{OH}(\mathrm{g})\) & -163 \\
\hline \(\mathrm{O}_{2}(g)\) & 0 \\
\hline \(\mathrm{CO}_{2}(\mathrm{~g})\) & -394 \\
\hline \(\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\) & -229 \\
\hline
\end{tabular}

SOLUTION We use the equation
\[
\begin{aligned}
\Delta G^{\circ} & \left.=\Sigma n_{\mathrm{p}} \Delta G_{\mathrm{f}}^{\mathrm{o}} \mathrm{products}\right) \\
& =2 \Delta{G_{\mathrm{r}} \Delta G_{\mathrm{f}(\text { reactants })}^{\circ}\left(\mathrm{CO}_{2}(\mathrm{~g})\right)}_{\mathrm{o}}+4 \Delta G_{\mathrm{f}\left(\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})\right)}^{\circ}-3 \Delta G_{\mathrm{f}\left(\mathrm{O}_{2}(\mathrm{~g})\right)}^{\circ}-2 \Delta G_{\mathrm{f}\left(\mathrm{CH}_{3} \mathrm{OH}(g)\right)}^{\circ} \\
& =2 \mathrm{~mol}(-394 \mathrm{~kJ} / \mathrm{mol})+4 \mathrm{~mol}(-229 \mathrm{~kJ} / \mathrm{mol})-3(0)-2 \mathrm{~mol}(-163 \mathrm{~kJ} / \mathrm{mol}) \\
& =-1378 \mathrm{~kJ}
\end{aligned}
\]

The large magnitude and the negative sign of \(\Delta G^{\circ}\) indicate that this reaction is very favorable thermodynamically.

See Exercises 17.65 and 17.66

\section*{INTERACTVE EXAMPLE 17.12 Free Energy and Spontaneity}

A chemical engineer wants to determine the feasibility of making ethanol \(\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)\) by reacting water with ethylene \(\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)\) according to the equation
\[
\mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)
\]

Is this reaction spontaneous under standard conditions?
SOLUTION To determine the spontaneity of this reaction under standard conditions, we must determine \(\Delta G^{\circ}\) for the reaction. We can do this using standard free energies of formation at

Ethylene

Ethanol \(25^{\circ} \mathrm{C}\) from Appendix 4:
\[
\begin{gathered}
\Delta G_{\mathrm{f}\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)\right)}^{\circ}=-175 \mathrm{~kJ} / \mathrm{mol} \\
\Delta G_{\mathrm{f}\left(\mathrm{H}_{2} \mathrm{O}(l)\right)}^{\circ}=-237 \mathrm{~kJ} / \mathrm{mol} \\
\Delta G_{\mathrm{f}\left(\mathrm{C}_{2} \mathrm{H}_{4}(g)\right)}^{\circ}=68 \mathrm{~kJ} / \mathrm{mol} \\
\Delta G^{\circ}=\Delta G_{\mathrm{f}}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)\right)-\Delta G_{\mathrm{f}}^{\circ}\left(\mathrm{H}_{2} \mathrm{O}(l)\right)-\Delta G_{\mathrm{f}}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{4}(g)\right) \\
=-175 \mathrm{~kJ}-(-237 \mathrm{~kJ})-68 \mathrm{~kJ} \\
=-6 \mathrm{~kJ}
\end{gathered}
\]

Thus the process is spontaneous under standard conditions at \(25^{\circ} \mathrm{C}\).

Although the reaction considered in Example 17.12 is spontaneous, other features of the reaction must be studied to see if the process is feasible. For example, the chemical engineer will need to study the kinetics of the reaction to determine whether it is fast enough to be useful and, if it is not, whether a catalyst can be found to enhance the rate. In doing these studies, the engineer must remember that \(\Delta G^{\circ}\) depends on temperature:
\[
\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}
\]

Thus, if the process must be carried out at high temperatures to be fast enough to be feasible, \(\Delta G^{\circ}\) must be recalculated at that temperature from the \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) values for the reaction.

\section*{Nonspontaneous Reactions}

In order for a reaction to be spontaneous (thermodynamically favored), the value of \(\Delta G\) must be less than zero (negative) at constant pressure and temperature. But reactions for which \(\Delta G>0\) can be made to proceed. We can cause these so-called thermodynamically unfavorable reactions to occur by either applying external energy or by coupling these unfavorable reactions to thermodynamically favorable ones.

As we will see in Chapter 18 that we can use electrical energy to produce a chemical change by means of an electrolytic cell. In addition, electromagnetic radiation may be used because the absorption of photons can initiate a reaction. This is what happens when carbon dioxide is converted to glucose through photosynthesis:
\[
6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \rightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q)+\mathrm{O}_{2}(g)
\]

For this reaction, \(\Delta G^{\circ}=+2880 \mathrm{~kJ} / \mathrm{mol}\), making it thermodynamically unfavorable. However, light energy is used to initiate a series of steps that provide energy to carry out the reaction above. Note, then, that it is not the light energy itself that is used to carry out the reaction. For example, in photosynthesis, the absorption of photons in the visible range causes the formation of adenosine triphosphate (ATP) from adenosine diphosphate (ADP). When the plant converts ATP back to ADP, a great deal of energy is released, which is then used to convert carbon dioxide to glucose. Thus, a thermodynamically favorable reaction drives the thermodynamically unfavorable reaction. We say these reactions are coupled. Many biological systems use the energy derived from the conversion of ATP to ADP to run thermodynamically unfavorable reactions.

For reactions to be coupled, the reactions must have common intermediates. We have seen this idea in Section 16.3 when considering the dissolving of \(\mathrm{AgCl}(s)\) in \(\mathrm{NH}_{3}\). The series of relevant reactions are:
\[
\begin{aligned}
\mathrm{AgCl}(s) & \rightleftharpoons \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) & K_{\text {sp }} & =1.6 \times 10^{-10} \\
\mathrm{Ag}^{+}+\mathrm{NH}_{3} & \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+} & K_{1} & =2.1 \times 10^{3} \\
\mathrm{Ag}\left(\mathrm{NH}_{3}\right)^{+}+\mathrm{NH}_{3} & \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}+ & K_{2} & =8.2 \times 10^{3}
\end{aligned}
\]

The overall reaction is given as:
\[
\mathrm{AgCl}(s)+2 \mathrm{NH}_{3} \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}+\mathrm{Cl}^{-} \quad K=2.8 \times 10^{-3}
\]
where \(K=K_{\text {sp }} \times K_{1} \times K_{2}\).
We can see that the dissolution of \(\mathrm{AgCl}(s)\) in water (as shown in the first reaction in the series) is very unfavorable. Recall that \(\Delta G^{\circ}=-R T \ln (K)\). Thus, for \(\mathrm{AgCl}(s)\) dissolving in water, \(\Delta G^{\circ}=+55.9 \mathrm{~kJ} / \mathrm{mol}\), which is thermodynamically unfavorable.

For the second and third reactions in the series, \(\Delta G^{\circ}=-19.0 \mathrm{~kJ} / \mathrm{mol}\) and \(-22.3 \mathrm{~kJ} / \mathrm{mol}\), respectively. These reactions are thermodynamically favorable.

For the overall reaction of dissolving \(\mathrm{AgCl}(s)\) in \(\mathrm{NH}_{3}, \Delta G^{\circ}=+14.6 \mathrm{~kJ} / \mathrm{mol}\). Although this is still not thermodynamically favorable, it is more favorable (that is, less positive) than the reaction of dissolving \(\mathrm{AgCl}(s)\) in water.

We can also drive the overall reaction to the right by using an excess of \(\mathrm{NH}_{3}\), as described by Le Châtelier's principle. As seen in Section 16.3, the solubility of \(\mathrm{AgCl}(s)\) in \(\mathrm{NH}_{3}\) is more than 36,000 times as soluble in \(10.0 \mathrm{MNH}_{3}\) as it is in water. Thus, even though the reaction is thermodynamically unfavorable, we can still obtain a relatively large amount of products depending on our initial conditions.

\subsection*{17.8 The Dependence of Free Energy on Pressure}

In this chapter we have seen that a system at constant temperature and pressure will proceed spontaneously in the direction that lowers its free energy. This is why reactions proceed until they reach equilibrium. The equilibrium position represents the lowest free energy value available to a particular reaction system. The free energy of a reaction system changes as the reaction proceeds, because free energy is dependent on the pressure of a gas or on the concentration of species in solution. We will deal only with the pressure dependence of the free energy of an ideal gas. The dependence of free energy on concentration can be developed using similar reasoning.

To understand the pressure dependence of free energy, we need to know how pressure affects the thermodynamic functions that comprise free energy, that is, enthalpy and entropy (recall that \(G=H-T S\) ). For an ideal gas, enthalpy is not pressuredependent. However, entropy does depend on pressure because of its dependence on volume. Consider 1 mole of an ideal gas at a given temperature. At a volume of 10.0 L , the gas has many more positions available for its molecules than if its volume is 1.0 L . The positional entropy is greater in the larger volume. In summary, at a given temperature for 1 mole of ideal gas
\[
S_{\text {large volume }}>S_{\text {small volume }}
\]
or, since pressure and volume are inversely related,
\[
S_{\text {low pressure }}>S_{\text {high pressure }}
\]

We have shown qualitatively that the entropy and therefore the free energy of an ideal gas depend on its pressure. Using a more detailed argument, which we will not consider here, it can be shown that
\[
G=G^{\circ}+R T \ln (P)
\]
where \(G^{\circ}\) is the free energy of the gas at a pressure of \(1 \mathrm{~atm}, G\) is the free energy of the gas at a pressure of \(P \mathrm{~atm}, R\) is the universal gas constant, and \(T\) is the Kelvin temperature.

To see how the change in free energy for a reaction depends on pressure, we will consider the ammonia synthesis reaction

In general,
\[
\begin{aligned}
\mathrm{N}_{2}(g) & +3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g) \\
\Delta G & =\Sigma n_{\mathrm{p}} G_{\text {products }}-\Sigma n_{\mathrm{r}} G_{\text {reactants }} \\
\Delta G & =2 G_{\mathrm{NH}_{3}}-G_{\mathrm{N}_{2}}-3 G_{\mathrm{H}_{2}} \\
G_{\mathrm{NH}_{3}} & =G_{\mathrm{NH}_{3}}^{\circ}+R T \ln \left(P_{\mathrm{NH}_{3}}\right) \\
G_{\mathrm{N}_{2}} & =G_{\mathrm{N}_{2}}^{\circ}+R T \ln \left(P_{\mathrm{N}_{2}}\right) \\
G_{\mathrm{H}_{2}} & =G_{\mathrm{H}_{2}}^{\circ}+R T \ln \left(P_{\mathrm{H}_{2}}\right)
\end{aligned}
\]

For this reaction
where

Substituting these values into the equation gives
\[
\begin{aligned}
\Delta G & =2\left[G_{\mathrm{NH}_{3}}^{\circ}+R T \ln \left(P_{\mathrm{NH}_{3}}\right)\right]-\left[G_{\mathrm{N}_{2}}^{\circ}+R T \ln \left(P_{\mathrm{N}_{2}}\right)\right]-3\left[G_{\mathrm{H}_{2}}^{\circ}+R T \ln \left(P_{\mathrm{H}_{2}}\right)\right] \\
& =2 G_{\mathrm{NH}_{3}}^{\circ}-G_{\mathrm{N}_{2}}^{\circ}-3 G_{\mathrm{H}_{2}}^{\circ}+2 R T \ln \left(P_{\mathrm{NH}_{3}}\right)-R T \ln \left(P_{\mathrm{N}_{2}}\right)-3 R T \ln \left(P_{\mathrm{H}_{2}}\right) \\
& =\left(2 G_{\mathrm{NH}_{3}}^{\circ}-G_{\mathrm{N}_{2}}^{\circ}-3 G_{\mathrm{H}_{2}}^{\circ}\right)+R T\left[2 \ln \left(P_{\mathrm{NH}_{3}}\right)-\ln \left(P_{\mathrm{N}_{2}}\right)-3 \ln \left(P_{\mathrm{H}_{2}}\right)\right]
\end{aligned}
\]

The first term (in parentheses) is \(\Delta G^{\circ}\) for the reaction. Thus we have
\[
\Delta G=\Delta G_{\text {reaction }}^{\circ}+R T\left[2 \ln \left(P_{\mathrm{NH}_{3}}\right)-\ln \left(P_{\mathrm{N}_{2}}\right)-3 \ln \left(P_{\mathrm{H}_{2}}\right)\right]
\]
and since
\[
\begin{aligned}
2 \ln \left(P_{\mathrm{NH}_{3}}\right) & =\ln \left(P_{\mathrm{NH}_{3}}^{2}\right) \\
-\ln \left(P_{\mathrm{N}_{2}}\right) & =\ln \left(\frac{1}{P_{\mathrm{N}_{2}}}\right) \\
-3 \ln \left(P_{\mathrm{H}_{2}}\right) & =\ln \left(\frac{1}{P_{\mathrm{H}_{2}}^{3}}\right)
\end{aligned}
\]
the equation becomes
\[
\Delta G=\Delta G^{\circ}+R T \ln \left(\frac{P_{\mathrm{NH}_{3}}^{2}}{\left(P_{\mathrm{N}_{2}}\right)\left(P_{\mathrm{H}_{2}}^{3}\right)}\right)
\]

But the term
\[
\frac{P_{\mathrm{NH}_{3}}^{2}}{\left(P_{\mathrm{N}_{2}}\right)\left(P_{\mathrm{H}_{2}}^{3}\right)}
\]
is the reaction quotient \(Q\) discussed in Section 13.5. Therefore, we have
\[
\Delta G=\Delta G^{\circ}+R T \ln (Q)
\]
where \(Q\) is the reaction quotient (from the law of mass action), \(T\) is the temperature \((\mathrm{K}), R\) is the gas law constant and is equal to \(8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, \Delta G^{\circ}\) is the free energy change for the reaction with all reactants and products at a pressure of 1 atm , and \(\Delta G\) is the free energy change for the reaction for the specified pressures of reactants and products.

\section*{INTERACTIVE EXAMPLE \(17.13 \quad\) Calculating \(\boldsymbol{\Delta} \boldsymbol{G}^{\circ}\)}

One method for synthesizing methanol \(\left(\mathrm{CH}_{3} \mathrm{OH}\right)\) involves reacting carbon monoxide and hydrogen gases:
\[
\mathrm{CO}(g)+2 \mathrm{H}_{2}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(l)
\]

Calculate \(\Delta G\) at \(25^{\circ} \mathrm{C}\) for this reaction where carbon monoxide gas at 5.0 atm and hydrogen gas at 3.0 atm are converted to liquid methanol.

SOLUTION To calculate \(\Delta G\) for this process, we use the equation
\[
\Delta G=\Delta G^{\circ}+R T \ln (Q)
\]

We must first compute \(\Delta G^{\circ}\) from standard free energies of formation (see Appendix 4). Since
\[
\begin{aligned}
\Delta G_{\mathrm{f}\left(\mathrm{CH}_{3} \mathrm{OH}(l)\right)}^{\circ} & =-166 \mathrm{~kJ} \\
\Delta G_{\mathrm{f}\left(\mathrm{H}_{2}(g)\right)}^{\circ} & =0 \\
\Delta G_{\mathrm{f}(\mathrm{CO}(\mathrm{~g}))}^{\circ} & =-137 \mathrm{~kJ} \\
\Delta G^{\circ}=-166 \mathrm{~kJ}-(-137 \mathrm{~kJ})-0 & =-29 \mathrm{~kJ}=-2.9 \times 10^{4} \mathrm{~J}
\end{aligned}
\]

Note in this case that \(\Delta G\) is defined for " 1 mole of the reaction," that is, for 1 mole of \(\mathrm{CO}(\mathrm{g})\) reacting with 2 moles of \(\mathrm{H}_{2}(\mathrm{~g})\) to form 1 mole of \(\mathrm{CH}_{3} \mathrm{OH}(/)\). Thus \(\Delta G, \Delta G^{\circ}\), and \(R T \ln (Q)\) all have units of \(J / \mathrm{mol}\) of reaction. In this case the units of \(R\) are actually J/K . mol of reaction, although they are usually not written this way.

Note that this is the value of \(\Delta G^{\circ}\) for the reaction of 1 mole of CO with 2 moles of \(\mathrm{H}_{2}\) to produce 1 mole of \(\mathrm{CH}_{3} \mathrm{OH}\). We might call this the value of \(\Delta G^{\circ}\) for one "round" of the reaction or for 1 mole of the reaction. Thus the \(\Delta G^{\circ}\) value might better be written as \(-2.9 \times 10^{4} \mathrm{~J} / \mathrm{mol}\) of reaction, or \(-2.9 \times 10^{4} \mathrm{~J} / \mathrm{mol} \mathrm{rxn}\).

We can now calculate \(\Delta G\) using
\[
\begin{gathered}
\Delta G^{\circ}=-2.9 \times 10^{4} \mathrm{~J} / \mathrm{mol} \mathrm{rxn} \\
R=8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \\
T=273+25=298 \mathrm{~K} \\
Q=\frac{1}{\left(P_{\mathrm{CO}}\right)\left(P_{\mathrm{H}_{2}}^{2}\right)}=\frac{1}{(5.0)(3.0)^{2}}=2.2 \times 10^{-2}
\end{gathered}
\]

Note that the pure liquid methanol is not included in the calculation of \(Q\). Then
\[
\begin{aligned}
\Delta G & =\Delta G^{\circ}+R T \ln (Q) \\
& =\left(-2.9 \times 10^{4} \mathrm{~J} / \mathrm{mol} \mathrm{rxn}\right)+(8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \mathrm{rxn})(298 \mathrm{~K}) \ln \left(2.2 \times 10^{-2}\right) \\
& =\left(-2.9 \times 10^{4} \mathrm{~J} / \mathrm{mol} \mathrm{rxn}\right)-\left(9.4 \times 10^{3} \mathrm{~J} / \mathrm{mol} \mathrm{rxn}\right)=-3.8 \times 10^{4} \mathrm{~J} / \mathrm{mol} \mathrm{rxn} \\
& =-38 \mathrm{~kJ} / \mathrm{mol} \mathrm{rxn}
\end{aligned}
\]

Note that \(\Delta G\) is significantly more negative than \(\Delta G^{\circ}\), implying that the reaction is more spontaneous at reactant pressures greater than 1 atm . We might expect this result from Le Châtelier's principle.

\section*{The Meaning of \(\Delta G\) for a Chemical Reaction}

In this section we have learned to calculate \(\Delta G\) for chemical reactions under various conditions. For example, in Example 17.13 the calculations show that the formation of \(\mathrm{CH}_{3} \mathrm{OH}(l)\) from \(\mathrm{CO}(g)\) at 5.0 atm reacting with \(\mathrm{H}_{2}(g)\) at 3.0 atm is spontaneous. What does this result mean? Does it mean that if we mixed 1.0 mole of \(\mathrm{CO}(g)\) and 2.0 moles of \(\mathrm{H}_{2}(\mathrm{~g})\) together at pressures of 5.0 and 3.0 atm , respectively, that 1.0 mole of \(\mathrm{CH}_{3} \mathrm{OH}(l)\) would form in the reaction flask? The answer is no. This answer may surprise you in view of what has been said in this section. It is true that 1.0 mole of \(\mathrm{CH}_{3} \mathrm{OH}(l)\) has a lower free energy than 1.0 mole of \(\mathrm{CO}(g)\) at 5.0 atm plus 2.0 moles of \(\mathrm{H}_{2}(g)\) at 3.0 atm . However, when \(\mathrm{CO}(g)\) and \(\mathrm{H}_{2}(g)\) are mixed under these conditions, there is an even lower free energy available to this system than 1.0 mole of pure \(\mathrm{CH}_{3} \mathrm{OH}(l)\). For reasons we will discuss shortly, the system can achieve the lowest possible free energy by going to equilibrium, not by going to completion. At the equilibrium position, some of the \(\mathrm{CO}(g)\) and \(\mathrm{H}_{2}(g)\) will remain in the reaction flask. So even though 1.0 mole of pure \(\mathrm{CH}_{3} \mathrm{OH}(l)\) is at a lower free energy than 1.0 mole of \(\mathrm{CO}(g)\) and 2.0 moles of \(\mathrm{H}_{2}(g)\) at 5.0 and 3.0 atm , respectively, the reaction system will stop short of forming 1.0 mole of \(\mathrm{CH}_{3} \mathrm{OH}(l)\). The reaction stops short of completion because the equilibrium mixture of \(\mathrm{CH}_{3} \mathrm{OH}(l), \mathrm{CO}(g)\), and \(\mathrm{H}_{2}(g)\) exists at the lowest possible free energy available to the system.

To illustrate this point, we will explore a mechanical example. Consider balls rolling down the two hills shown in Fig. 17.7. Note that in both cases point \(B\) has a lower potential energy than point \(A\).

In Fig. 17.7(a) the ball will roll to point \(B\). This diagram is analogous to a phase change. For example, at \(25^{\circ} \mathrm{C}\) ice will spontaneously change completely to liquid

FIGURE 17.7 Schematic representations of balls rolling down two types of hills.

a

b
water, because the latter has the lowest free energy. In this case liquid water is the only choice. There is no intermediate mixture of ice and water with lower free energy.

The situation is different for a chemical reaction system, as illustrated in Fig. 17.7(b). In Fig. 17.7(b) the ball will not get to point \(B\) because there is a lower potential energy at point \(C\). Like the ball, a chemical system will seek the lowest possible free energy, which, for reasons we will discuss below, is the equilibrium position.

Therefore, although the value of \(\Delta G\) for a given reaction system tells us whether the products or reactants are favored under a given set of conditions, it does not mean that the system will proceed to pure products (if \(\Delta G\) is negative) or remain at pure reactants (if \(\Delta G\) is positive). Instead, the system will spontaneously go to the equilibrium position, the lowest possible free energy available to it. In the next section we will see that the value of \(\Delta G^{\circ}\) for a particular reaction tells us exactly where this position will be.

\subsection*{17.9 Free Energy and Equilibrium}

When the components of a given chemical reaction are mixed, they will proceed, rapidly or slowly depending on the kinetics of the process, to the equilibrium position. In Chapter 13 we defined the equilibrium position as the point at which the forward and reverse reaction rates are equal. In this chapter we look at equilibrium from a thermodynamic point of view, and we find that the equilibrium point occurs at the lowest value of free energy available to the reaction system. As it turns out, the two definitions give the same equilibrium state, which must be the case for both the kinetic and thermodynamic models to be valid.

To understand the relationship of free energy to equilibrium, let's consider the following simple hypothetical reaction:
\[
\mathrm{A}(g) \rightleftharpoons \mathrm{B}(g)
\]
where 1.0 mole of gaseous A is initially placed in a reaction vessel at a pressure of 2.0 atm . The free energies for A and B are diagramed as shown in Fig. 17.8(a). As A reacts to form \(B\), the total free energy of the system changes, yielding the following results:
\[
\begin{aligned}
\text { Free energy of } \mathrm{A} & =G_{\mathrm{A}}=G_{\mathrm{A}}^{\circ}+R T \ln \left(P_{\mathrm{A}}\right) \\
\text { Free energy of } \mathrm{B} & =G_{\mathrm{B}}=G_{\mathrm{B}}^{\circ}+R T \ln \left(P_{\mathrm{B}}\right) \\
\text { Total free energy of system } & =G=G_{\mathrm{A}}+G_{\mathrm{B}}
\end{aligned}
\]

As A changes to \(\mathrm{B}, G_{\mathrm{A}}\) will decrease because \(P_{\mathrm{A}}\) is decreasing [Fig. 17.8(b)]. In contrast, \(G_{\mathrm{B}}\) will increase because \(P_{\mathrm{B}}\) is increasing. The reaction will proceed to the right as long as the total free energy of the system decreases (as long as \(G_{\mathrm{B}}\) is less than \(G_{\mathrm{A}}\) ). At some point the pressures of A and B reach the values \(P_{\mathrm{A}}^{\mathrm{e}}\) and \(P_{\mathrm{B}}^{\mathrm{e}}\) that make \(G_{\mathrm{A}}\) equal to \(G_{\mathrm{B}}\). The system has reached equilibrium [Fig. 17.8(c)]. Since A at pressure \(P_{\mathrm{A}}^{\mathrm{e}}\) and

For the reaction \(A(g) \rightleftharpoons B(g)\), the pressure is constant during the reaction, since the same number of gas molecules is always present.

FIGURE 17.8 (a) The initial free energies of \(A\) and \(B\). (b) As \(A(g)\) changes to \(B(g)\), the free energy of \(A\) decreases and that of \(B\) increases. (c) Eventually, pressures of \(A\) and \(B\) are achieved such that \(G_{A}=G_{B}\), the equilibrium position.

B at pressure \(P_{\mathrm{B}}^{\mathrm{e}}\) have the same free energy \(\left(G_{\mathrm{A}}\right.\) equals \(\left.G_{\mathrm{B}}\right), \Delta G\) is zero for A at pressure \(P_{\mathrm{A}}^{\mathrm{e}}\) changing to B at pressure \(P_{\mathrm{B}}^{\mathrm{e}}\). The system has reached minimum free energy. There is no longer any driving force to change A to B or B to A , so the system remains at this position (the pressures of \(A\) and \(B\) remain constant).

Suppose that for the experiment described above, the plot of free energy versus the mole fraction of A reacted is defined as shown in Fig. 17.9(a). In this experiment, minimum free energy is reached when \(75 \%\) of A has been changed to \(B\). At this point, the pressure of A is 0.25 times the original pressure, or
\[
(0.25)(2.0 \mathrm{~atm})=0.50 \mathrm{~atm}
\]

The pressure of \(B\) is
\[
(0.75)(2.0 \mathrm{~atm})=1.5 \mathrm{~atm}
\]

Since this is the equilibrium position, we can use the equilibrium pressures to calculate a value for \(K\) for the reaction in which A is converted to B at this temperature:
\[
K=\frac{P_{\mathrm{B}}^{\mathrm{e}}}{P_{\mathrm{A}}^{\mathrm{e}}}=\frac{1.5 \mathrm{~atm}}{0.50 \mathrm{~atm}}=3.0
\]

Exactly the same equilibrium point would be achieved if we placed 1.0 mole of pure \(\mathrm{B}(g)\) in the flask at a pressure of 2.0 atm . In this case B would change to A until equilibrium \(\left(G_{\mathrm{B}}=G_{\mathrm{A}}\right)\) is reached. This is shown in Fig. 17.9(b).

The overall free energy curve for this system is shown in Fig. 17.9(c). Note that any mixture of \(\mathrm{A}(g)\) and \(\mathrm{B}(g)\) containing 1.0 mole of gas (A plus B) at a total pressure of 2.0 atm will react until it reaches the minimum in the curve.

In summary, when substances undergo a chemical reaction, the reaction proceeds to the minimum free energy (equilibrium), which corresponds to the point where
\[
G_{\text {products }}=G_{\text {reactants }} \text { or } \Delta G=G_{\text {products }}-G_{\text {reactants }}=0
\]

FIGURE 17.9 (a) The change in free energy to reach equilibrium, beginning with 1.0 mole of \(\mathrm{A}(g)\) at \(P_{\mathrm{A}}\) \(=2.0 \mathrm{~atm}\). (b) The change in free energy to reach equilibrium, beginning with 1.0 mole of \(\mathrm{B}(g)\) at \(P_{\mathrm{B}}=2.0 \mathrm{~atm}\). (c) The free energy profile for \(\mathrm{A}(\mathrm{g}) \rightleftharpoons \mathrm{B}(\mathrm{g})\) in a system containing 1.0 mole of gas (A plus B ) at \(P_{\text {TOTAL }}=2.0\) atm. Each point on the curve corresponds to the total free energy of the system for a given combination of \(A\) and \(B\).

\section*{INTERACTIVE EXAMPLE 17.14 Free Energy and Equilibrium I}

Consider the ammonia synthesis reaction
\[
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
\]
where \(\Delta G^{\circ}=-33.3 \mathrm{~kJ}\) per mole of \(\mathrm{N}_{2}\) consumed at \(25^{\circ} \mathrm{C}\). For each of the following mixtures of reactants and products at \(25^{\circ} \mathrm{C}\), predict the direction in which the system will shift to reach equilibrium.
a. \(P_{\mathrm{NH}_{3}}=1.00 \mathrm{~atm}, P_{\mathrm{N}_{2}}=1.47 \mathrm{~atm}, P_{\mathrm{H}_{2}}=1.00 \times 10^{-2} \mathrm{~atm}\)
b. \(\quad P_{\mathrm{NH}_{3}}=1.00 \mathrm{~atm}, P_{\mathrm{N}_{2}}=1.00 \mathrm{~atm}, P_{\mathrm{H}_{2}}=1.00 \mathrm{~atm}\)

SOLUTION a. We can predict the direction of reaction to equilibrium by calculating the value of

The units of \(\Delta G, \Delta G^{\circ}\), and \(R T \ln (Q)\) all refer to the balanced reaction with all amounts expressed in moles. We might say that the units are joules per "mole of reaction," although only the "per mole" is indicated for \(R\) (as is customary).
\(\Delta G\) using the equation
\[
\Delta G=\Delta G^{\circ}+R T \ln (Q)
\]
where
\[
\begin{aligned}
Q & =\frac{P_{\mathrm{NH}_{3}}^{2}}{\left(P_{\mathrm{N}_{2}}\right)\left(P_{\mathrm{H}_{2}}^{3}\right)}=\frac{(1.00)^{2}}{(1.47)\left(1.00 \times 10^{-2}\right)^{3}}=6.80 \times 10^{5} \\
T & =25+273=298 \mathrm{~K} \\
R & =8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
\]
and
\[
\Delta G^{\circ}=-33.3 \mathrm{~kJ} / \mathrm{mol}=-3.33 \times 10^{4} \mathrm{~J} / \mathrm{mol}
\]

Then
\[
\begin{aligned}
\Delta G & =\left(-3.33 \times 10^{4} \mathrm{~J} / \mathrm{mol}\right)+(8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K}) \ln \left(6.8 \times 10^{5}\right) \\
& =\left(-3.33 \times 10^{4} \mathrm{~J} / \mathrm{mol}\right)+\left(3.33 \times 10^{4} \mathrm{~J} / \mathrm{mol}\right)=0
\end{aligned}
\]

Since \(\Delta G=0\), the reactants and products have the same free energies at these partial pressures. The system is already at equilibrium, and no shift will occur.
b. The partial pressures given here are all 1.00 atm , which means that the system is in the standard state. That is,
\[
\begin{aligned}
\Delta G & =\Delta G^{\circ}+R T \ln (Q)=\Delta G^{\circ}+R T \ln \frac{(1.00)^{2}}{(1.00)(1.00)^{3}} \\
& =\Delta G^{\circ}+R T \ln (1.00)=\Delta G^{\circ}+0=\Delta G^{\circ}
\end{aligned}
\]

For this reaction at \(25^{\circ} \mathrm{C}\),
\[
\Delta G^{\circ}=-33.3 \mathrm{~kJ} / \mathrm{mol}
\]

The negative value for \(\Delta G^{\circ}\) means that in their standard states the products have a lower free energy than the reactants. Thus the system will move to the right to reach equilibrium. That is, \(K\) is greater than 1 .

\section*{INTERACTIVE EXAMPLE 17.15 Free Energy and Equilibrium II}

The overall reaction for the corrosion (rusting) of iron by oxygen is
\[
4 \mathrm{Fe}(s)+3 \mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)
\]

Using the following data, calculate the equilibrium constant for this reaction at \(25^{\circ} \mathrm{C}\).
\begin{tabular}{|ccc|}
\hline Substance & \(\Delta H_{\mathfrak{f}}(\mathrm{kJ} / \mathrm{mol})\) & \(\boldsymbol{S}^{\circ}(\mathrm{J} / \mathrm{K} \cdot \mathrm{mol})\) \\
\hline \(\mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})\) & -826 & 90 \\
\hline \(\mathrm{Fe}(\mathrm{s})\) & 0 & 27 \\
\hline \(\mathrm{O}_{2}(\mathrm{~g})\) & 0 & 205 \\
\hline
\end{tabular}

SOLUTION To calculate \(K\) for this reaction, we will use the equation

Thinkstock/Getty images
\(\Delta\)
Formation of rust on bare steel is a spontaneous process.
\[
\Delta G^{\circ}=-R T \ln (K)
\]

We must first calculate \(\Delta G^{\circ}\) from
\[
\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}
\]
where
\[
\begin{aligned}
\Delta H^{\circ} & =2 \Delta H_{\mathrm{f}\left(\mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})\right)}^{\circ}-3 \Delta H_{\mathrm{f}\left(\mathrm{O}_{2}(g)\right)}^{\circ}-4 \Delta H_{\mathrm{f}}^{\circ}(\mathrm{Fe}(s)) \\
& =2 \mathrm{~mol}(-826 \mathrm{~kJ} / \mathrm{mol})-0-0 \\
& =-1652 \mathrm{~kJ}=-1.652 \times 10^{6} \mathrm{~J} \\
\Delta S^{\circ} & =2 S_{\mathrm{Fe}_{2} \mathrm{O}_{3}}^{\circ}-3 S_{\mathrm{O}_{2}}^{\circ}-4 S_{\mathrm{Fe}}^{\circ} \\
& =2 \mathrm{~mol}(90 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})-3 \mathrm{~mol}(205 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})-4 \mathrm{~mol}(27 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}) \\
& =-543 \mathrm{~J} / \mathrm{K}
\end{aligned}
\]
and
\[
T=273+25=298 \mathrm{~K}
\]

Then
\[
\begin{aligned}
& \Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}=\left(-1.652 \times 10^{6} \mathrm{~J}\right)-(298 \mathrm{~K})(-543 \mathrm{~J} / \mathrm{K}) \\
& =-1.490 \times 10^{6} \mathrm{~J}
\end{aligned}
\]
and
\[
\Delta G^{\circ}=-R T \ln (K)=-1.490 \times 10^{6} \mathrm{~J}=-(8.3145 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K}) \ln (K)
\]

Thus
\[
\ln (K)=\frac{1.490 \times 10^{6}}{2.48 \times 10^{3}}=601
\]
and
\[
K=e^{601}
\]

This is a very large equilibrium constant. The rusting of iron is clearly very favorable from a thermodynamic point of view.

\section*{See Exercises 17.75 and 17.76}

\section*{The Temperature Dependence of \(K\)}

In Chapter 13 we used Le Châtelier's principle to predict qualitatively how the value of \(K\) for a given reaction would change with a change in temperature. Now we can specify the quantitative dependence of the equilibrium constant on temperature from the relationship
\[
\Delta G^{\circ}=-R T \ln (K)=\Delta H^{\circ}-T \Delta S^{\circ}
\]

We can rearrange this equation to give
\[
\ln (K)=-\frac{\Delta H^{\circ}}{R T}+\frac{\Delta S^{\circ}}{R}=-\frac{\Delta H^{\circ}}{R}\left(\frac{1}{T}\right)+\frac{\Delta S^{\circ}}{R}
\]

Note that this is a linear equation of the form \(y=m x+b\), where \(y=\ln (K), m=-\Delta H^{\circ} /\) \(R=\) slope, \(x=1 / T\), and \(b=\Delta S^{\circ} / R=\) intercept. This means that if values of \(K\) for a given reaction are determined at various temperatures, a plot of \(\ln (K)\) versus \(1 / T\) will be linear, with slope \(-\Delta H^{\circ} / R\) and intercept \(\Delta S^{\circ} / R\). This result assumes that both \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) are independent of temperature over the temperature range considered. This assumption is a good approximation over a relatively small temperature range.

\subsection*{17.10 Free Energy and Work}

One of the main reasons we are interested in physical and chemical processes is that we want to use them to do work for us, and we want this work done as efficiently and economically as possible. We have already seen that at constant temperature and pressure, the sign of the change in free energy tells us whether a given process is spontaneous. This is very useful information because it prevents us from wasting effort on a process that has no inherent tendency to occur. Although a thermodynamically favorable chemical reaction may not occur to any appreciable extent because it is too slow, it makes sense in this case to try to find a catalyst to speed up the reaction. On the other hand, if the reaction is prevented from occurring by its thermodynamic characteristics, we would be wasting our time looking for a catalyst.

In addition to its qualitative usefulness (telling us whether a process is spontaneous), the change in free energy is important quantitatively because it can tell us how much work can be done with a given process. The maximum possible useful work obtainable from a process at constant temperature and pressure is equal to the change in free energy:
\[
w_{\max }=\Delta G
\]

This relationship explains why this function is called the free energy. Under certain conditions, \(\Delta G\) for a spontaneous process represents the energy that is free to do useful work. On the other hand, for a process that is not spontaneous, the value of \(\Delta G\) tells us the minimum amount of work that must be expended to make the process occur.

Knowing the value of \(\Delta G\) for a process thus gives us valuable information about how close the process is to \(100 \%\) efficiency. For example, when gasoline is burned in a car's engine, the work produced is about \(20 \%\) of the maximum work available.

For reasons we will only briefly introduce in this book, the amount of work we actually obtain from a spontaneous process is always less than the maximum possible amount.

To explore this idea more fully, let's consider an electric current flowing through the starter motor of a car. The current is generated from a chemical change in a battery, and we can calculate \(\Delta G\) for the battery reaction and so determine the energy available to do work. Can we use all this energy to do work? No, because a current flowing through a wire causes frictional heating, and the greater the current, the greater the heat. This heat represents wasted energy-it is not useful for running the starter motor. We can minimize this energy waste by running very low currents through the motor circuit. However, zero current flow would be necessary to eliminate frictional heating entirely, and we cannot derive any work from the motor if no current flows. This represents the difficulty in which nature places us. Using a process to do work requires that some of the energy be wasted, and usually the faster we run the process, the more energy we waste.

Achieving the maximum work available from a spontaneous process can occur only via a hypothetical pathway. Any real pathway wastes energy. If we could discharge the battery infinitely slowly by an infinitesimal current flow, we would achieve the maximum useful work. Also, if we could then recharge the battery using

When energy is used to do work, it becomes less organized and less concentrated and thus less useful.
an infinitesimally small current, exactly the same amount of energy would be used to return the battery to its original state. After we cycle the battery in this way, the universe (the system and surroundings) is exactly the same as it was before the cyclic process. This is a reversible process (Fig. 17.11).

However, if the battery is discharged to run the starter motor and then recharged using a finite current flow, as is the case in reality, more work will always be required to recharge the battery than the battery produces as it discharges. This means that even though the battery (the system) has returned to its original state, the surroundings have not, because the surroundings had to furnish a net amount of work as the battery was cycled. The universe is different after this cyclic process is performed, and this function is called an irreversible process. All real processes are irreversible.

In general, after any real cyclic process is carried out in a system, the surroundings have less ability to do work and contain more thermal energy. In any real cyclic process in the system, work is changed to heat in the surroundings, and the entropy of the universe increases. This is another way of stating the second law of thermodynamics.

Thus thermodynamics tells us the work potential of a process and then tells us that we can never achieve this potential. In this spirit, thermodynamicist Henry Bent has paraphrased the first two laws of thermodynamics as follows:

First law: You can't win, you can only break even.
Second law: You can't break even.
The ideas we have discussed in this section are applicable to the energy crisis that will probably increase in severity over the next 25 years. The crisis is obviously not one of supply; the first law tells us that the universe contains a constant supply of energy. The problem is the availability of useful energy. As we use energy, we degrade its usefulness. For example, when gasoline reacts with oxygen in the combustion reaction, the change in potential energy results in heat flow. Thus the energy concentrated in the bonds of the gasoline and oxygen molecules ends up spread over the surroundings as thermal energy, where it is much more difficult to harness for useful work. This is a way in which the entropy of the universe increases: Concentrated energy becomes spread out-more disordered and less useful. Thus the crux of the energy problem is that we are rapidly consuming the concentrated energy found in fossil fuels. It took millions of years to concentrate the sun's energy in these fuels, and we will consume these same fuels in a few hundred years. Thus we must use these energy sources as wisely as possible.

\section*{} was true but the second law was not? How would the world be different?

\section*{For Review}

\section*{Key terms}

Section 17.1
spontaneous
(thermodynamically
favored) process
entropy
positional probability
Section 17.2
second law of thermodynamics

Section 17.4
free energy
Section 17.6
third law of thermodynamics
Section 17.7
standard free energy change
standard free energy of formation

Section 17.9
equilibrium point
(thermodynamic definition)
Section 17.10
reversible process
irreversible process

\section*{First law of thermodynamics}
) States that the energy of the universe is constant
> Provides a way to keep track of energy as it changes form
) Gives no information about why a particular process occurs in a given direction

\section*{Second law of thermodynamics}
> States that for any spontaneous (thermodynamically favored) process there is always an increase in the entropy of the universe
) Entropy \((S)\) is a thermodynamic function that describes the number of arrangements (positions and/or energy levels) available to a system existing in a given state
》 Nature spontaneously proceeds toward states that have the highest probability of occurring
) Using entropy, thermodynamics can predict the direction in which a process will occur spontaneously:
\[
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}
\]
) For a spontaneous process, \(\Delta S_{\text {univ }}\) must be positive
> For a process at constant temperature and pressure:
> \(\Delta S_{\text {sys }}\) is dominated by "positional" entropy
> For a chemical reaction, \(\Delta S_{\text {sys }}\) is dominated by changes in the number of gaseous molecules
> \(\Delta S_{\text {surr }}\) is determined by heat:
\[
\Delta S_{\text {surr }}=-\frac{\Delta H}{T}
\]
> \(\Delta S_{\text {surr }}\) is positive for an exothermic process ( \(\Delta H\) is negative)
> Because \(\Delta S_{\text {surr }}\) depends inversely on \(T\), exothermicity becomes a more important driving force at low temperatures
) Thermodynamics cannot predict the rate at which a system will spontaneously change; the principles of kinetics are necessary to do this

\section*{Third law of thermodynamics}
> States that the entropy of a perfect crystal at 0 K is zero

\section*{Free energy ( \(G\) ]}
> Free energy is a state function:
\[
G=H-T S
\]
> A process occurring at constant temperature and pressure is spontaneous in the direction in which its free energy decreases \((\Delta G<0)\)
> For a reaction the standard free energy change \(\left(\Delta G^{\circ}\right)\) is the change in free energy that occurs when reactants in their standard states are converted to products in their standard states
) The standard free energy change for a reaction can be determined from the standard free energies of formation \(\left(\Delta G_{f}^{\circ}\right)\) of the reactants and products:
\[
\Delta G^{\circ}=\Sigma n_{\mathrm{p}} \Delta G_{\mathrm{f}}^{\circ}(\text { products })-\Sigma n_{\mathrm{r}} \Delta G_{\mathrm{f}}^{\circ}(\text { reactants })
\]
> Free energy depends on temperature and pressure:
\[
G=G^{\circ}+R T \ln P
\]
> This relationship can be used to derive the relationship between \(\Delta G^{\circ}\) for a reaction and the value of its equilibrium constant \(K\) :
\[
\Delta G^{\circ}=-R T \ln K
\]
) For \(\Delta G^{\circ}=0, K=1\)
) For \(\Delta G^{\circ}<0, K>1\)
> For \(\Delta G^{\circ}>0, K<1\)
> The maximum possible useful work obtainable from a process at constant temperature and pressure is equal to the change in free energy:
\[
w_{\max }=\Delta G
\]
> In any real process, \(w<w_{\text {max }}\)
, When energy is used to do work in a real process, the energy of the universe remains constant but the usefulness of the energy decreases
) Concentrated energy is spread out in the surroundings as thermal energy
Review Questions Answers to the Review Questions can be found on the Student website (accessible from wwww.cengagebrain.com).
1. Define the following:
a. spontaneous process
b. entropy
c. positional probability
d. system
e. surroundings
f. universe
2. What is the second law of thermodynamics? For any process, there are four possible sign combinations for \(\Delta S_{\text {sys }}\) and \(\Delta S_{\text {surr }}\). Which sign combination(s) always give a spontaneous process? Which sign combination(s) always give a nonspontaneous process? Which sign combination(s) may or may not give a spontaneous process?
3. What determines \(\Delta S_{\text {surr }}\) for a process? To calculate \(\Delta S_{\text {surr }}\) at constant pressure and temperature, we use the following equation: \(\Delta S_{\text {surr }}=-\Delta H / T\). Why does a minus sign appear in the equation, and why is \(\Delta S_{\text {surr }}\) inversely proportional to temperature?
4. The free energy change, \(\Delta G\), for a process at constant temperature and pressure is related to \(\Delta S_{\text {univ }}\) and reflects the spontaneity of the process. How is \(\Delta G\) related to \(\Delta S_{\text {univ }}\) ? When is a process spontaneous? Nonspontaneous? At equilibrium? \(\Delta G\) is a composite term composed of \(\Delta H, T\), and \(\Delta S\). What is the \(\Delta G\) equation? Give the four possible sign combinations for \(\Delta H\) and \(\Delta S\). What temperatures are required for each sign combination to yield a spontaneous process? If \(\Delta G\) is positive, what does it say about the reverse process? How does the \(\Delta G=\Delta H-T \Delta S\) equation reduce when at the meltingpoint temperature of a solid-to-liquid phase change or at the boiling-point temperature of a liquid-to-gas phase change? What is the sign of \(\Delta G\) for the solid-to-liquid phase change at temperatures above the freezing point? What is the sign of \(\Delta G\) for the liquid-to-gas phase change at temperatures below the boiling point?
5. What is the third law of thermodynamics? What are standard entropy values, \(S^{\circ}\), and how are these \(S^{\circ}\) values (listed in Appendix 4) used to calculate \(\Delta S^{\circ}\) for a reaction? How would you use Hess's law to calculate \(\Delta S^{\circ}\) for a reaction? What does the superscript \({ }^{\circ}\) indicate?

Predicting the sign of \(\Delta S^{\circ}\) for a reaction is an important skill to master. For a gas-phase reaction, what do you concentrate on to predict the sign of \(\Delta S^{\circ}\) ? For a phase change, what do you concentrate on to predict the sign of \(\Delta S^{\circ}\) ? That is, how are \(S_{\text {solid }}^{\circ}, S_{\text {liquid }}^{\circ}\), and \(S_{\text {gas }}^{\circ}\) related to one another? When a solute dissolves in water, what is usually the sign of \(\Delta S^{\circ}\) for this process?
6. What is the standard free energy change, \(\Delta G^{\circ}\), for a reaction? What is the standard free energy of formation, \(\Delta G_{\mathrm{f}}^{\circ}\), for a substance? How are \(\Delta G_{\mathrm{f}}^{\circ}\) values used to calculate \(\Delta G_{\mathrm{rxn}}^{\circ}\) ? How can you use Hess's law to calculate \(\Delta G_{\mathrm{rxn}}^{\circ}\) ? How can you use \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) values to calculate \(\Delta G_{\mathrm{rxn}}^{\circ}\) ? Of the functions \(\Delta H^{\circ}, \Delta S^{\circ}\), and \(\Delta G^{\circ}\), which depends most strongly on temperature? When \(\Delta G^{\circ}\) is calculated at temperatures other than \(25^{\circ} \mathrm{C}\), what assumptions are generally made concerning \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) ?
7. If you calculate a value for \(\Delta G^{\circ}\) for a reaction using the values of \(\Delta G_{f}^{\circ}\) in Appendix 4 and get a negative number, is it correct to say that the reaction is always spontaneous? Why or why not? Free energy changes also depend on concentration. For gases, how is \(G\) related to the pressure of the gas? What are standard pressures for gases and standard concentrations for solutes? How do you calculate \(\Delta G\) for a reaction at nonstandard conditions? The equation to determine \(\Delta G\) at nonstandard conditions has \(Q\) in it: What is \(Q\) ? A reaction is spontaneous as long as \(\Delta G\) is negative; that is, reactions always proceed as long as the products have a lower free energy than the reactants. What is so special about equilibrium? Why don't reactions move away from equilibrium?
8. Consider the equation \(\Delta G=\Delta G^{\circ}+R T \ln (Q)\). What is the value of \(\Delta G\) for a reaction at equilibrium? What does \(Q\) equal at equilibrium? At equilibrium, the previous equation reduces to \(\Delta G^{\circ}=-R T \ln (K)\).
When \(\Delta G^{\circ}>0\), what does it indicate about \(K\) ? When \(\Delta G^{\circ}<0\), what does it indicate about \(K\) ? When \(\Delta G^{\circ}=0\), what does it indicate about \(K ? \Delta G\) predicts spontaneity for a reaction, whereas \(\Delta G^{\circ}\) predicts the equilibrium position. Explain what this statement means. Under what conditions can you use \(\Delta G^{\circ}\) to determine the spontaneity of a reaction?

\section*{Active Learning Questions}

These questions are designed to be used by groups of students in class.
1. For the process \(\mathrm{A}(l) \longrightarrow \mathrm{A}(g)\), which direction is favored by changes in energy probability? Positional probability? Explain your answers. If you wanted to favor the process as written, would you raise or lower the temperature of the system? Explain.
2. For a liquid, which would you expect to be larger, \(\Delta S_{\text {fusion }}\) or \(\Delta S_{\text {evaporation }}\) ? Why?
3. Gas \(\mathrm{A}_{2}\) reacts with gas \(\mathrm{B}_{2}\) to form gas AB at a constant temperature. The bond energy of \(A B\) is much greater than that of either reactant. What can be said about the sign of \(\Delta H ? \Delta S_{\text {surr }}\) ? \(\Delta S\) ? Explain how potential energy changes for this process. Explain how random kinetic energy changes during the process.
4. What types of experiments can be carried out to determine whether a reaction is spontaneous? Does spontaneity have any relationship to the final equilibrium position of a reaction? Explain.
5. A friend tells you, "Free energy \(G\) and pressure \(P\) are related by the equation \(G=G^{\circ}+R T \ln (P)\). Also, \(G\) is related to the equilibrium constant \(K\) in that when \(G_{\text {products }}=G_{\text {reactants }}\), the system is at equilibrium. Therefore, it must be true that a system is at equilibrium when all the pressures are equal." Do you agree with this friend? Explain.
6. You remember that \(\Delta G^{\circ}\) is related to \(R T \ln (K)\) but cannot remember if it's \(R T \ln (K)\) or \(-R T \ln (K)\). Realizing what \(\Delta G^{\circ}\) and \(K\) mean, how can you figure out the correct sign?
7. Predict the sign of \(\Delta S\) for each of the following and explain.
a. the evaporation of alcohol
b. the freezing of water
c. compressing an ideal gas at constant temperature
d. dissolving NaCl in water
8. Is \(\Delta S_{\text {surr }}\) favorable or unfavorable for exothermic reactions? Endothermic reactions? Explain.
9. Even if \(\Delta G\) is negative, the reaction may not occur. Explain the interplay between the thermodynamics and the kinetics of a reaction. High temperatures are favorable to a reaction kinetically but may be unfavorable to a reaction thermodynamically. Explain.
10. Discuss the relationship between \(w_{\max }\) and the magnitude and sign of the free energy change for a reaction. Also discuss \(w_{\max }\) for real processes. What is a reversible process?
9. At 1 atm , liquid water is heated above \(100^{\circ} \mathrm{C}\). For this process, which of the following choices (i-iv) is correct for \(\Delta S_{\text {surr }}\) ? \(\Delta S\) ? \(\Delta S_{\text {univ }}\) ? Explain each answer.
i. greater than zero
ii. less than zero
iii. equal to zero
iv. cannot be determined
10. True or false: High temperatures are favorable to a reaction both kinetically and thermodynamically. Explain.

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

\section*{Questions}
11. The synthesis of glucose directly from \(\mathrm{CO}_{2}\) and \(\mathrm{H}_{2} \mathrm{O}\) and the synthesis of proteins directly from amino acids are both nonspontaneous processes under standard conditions. Yet it is necessary for these to occur for life to exist. In light of the second law of thermodynamics, how can life exist?
12. When the environment is contaminated by a toxic or potentially toxic substance (for example, from a chemical spill or the use of insecticides), the substance tends to disperse. How is this consistent with the second law of thermodynamics? In terms of the second law, which requires the least work: cleaning the environment after it has been contaminated or trying to prevent the contamination before it occurs? Explain.
13. Entropy has been described as "time's arrow." Interpret this view of entropy.
14. Human DNA contains almost twice as much information as is needed to code for all the substances produced in the body. Likewise, the digital data sent from Voyager II contained one redundant bit out of every two bits of information. The Hubble space telescope transmits three redundant bits for every bit of information. How is entropy related to the transmission of information? What do you think is accomplished by having so many redundant bits of information in both DNA and the space probes?
15. A mixture of hydrogen gas and chlorine gas remains unreacted until it is exposed to ultraviolet light from a burning magnesium strip. Then the following reaction occurs very rapidly:
\[
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{HCl}(\mathrm{~g})
\]

Explain.
16. Consider the following potential energy plots:

a. Rank the reactions from fastest to slowest and explain your answer. If any reactions have equal rates, explain why.
b. Label the reactions as endothermic or exothermic, and support your answer.
c. Rank the exothermic reactions from greatest to least change in potential energy, and support your answer.
17. \(\Delta S_{\text {surr }}\) is sometimes called the energy disorder term. Explain.
18. Given the following illustration, what can be said about the sign of \(\Delta S\) for the process of solid NaCl dissolving in water? What can be said about \(\Delta H\) for this process?

19. Describe how the following changes affect the positional probability of a substance.
a. increase in volume of a gas at constant \(T\)
b. increase in temperature of a gas at constant \(V\)
c. increase in pressure of a gas at constant \(T\)
20. The melting point for carbon diselenide \(\left(\mathrm{CSe}_{2}\right)\) is \(-46^{\circ} \mathrm{C}\). At a temperature of \(-75^{\circ} \mathrm{C}\), predict the signs for \(\Delta S_{\text {surr }}\) and \(\Delta S_{\text {univ }}\) for the following process: \(\mathrm{CSe}_{2}(l) \rightarrow \mathrm{CSe}_{2}(s)\).
21. The third law of thermodynamics states that the entropy of a perfect crystal at 0 K is zero. In Appendix 4, \(\mathrm{F}^{-}(a q), \mathrm{OH}^{-}(a q)\), and \(\mathrm{S}^{2-}(a q)\) all have negative standard entropy values. How can \(S^{\circ}\) values be less than zero?
22. The deciding factor on why HF is a weak acid and not a strong acid like the other hydrogen halides is entropy. What occurs when HF dissociates in water as compared to the other hydrogen halides?
23. List three different ways to calculate the standard free energy change, \(\Delta G^{\circ}\), for a reaction at \(25^{\circ} \mathrm{C}\). How is \(\Delta G^{\circ}\) estimated at temperatures other than \(25^{\circ} \mathrm{C}\) ? What assumptions are made?
24. What information can be determined from \(\Delta G\) for a reaction? Does one get the same information from \(\Delta G^{\circ}\), the standard free energy change? \(\Delta G^{\circ}\) allows determination of the equilibrium constant \(K\) for a reaction. How? How can one estimate the value of \(K\) at temperatures other than \(25^{\circ} \mathrm{C}\) for a reaction? How can one estimate the temperature where \(K=1\) for a reaction? Do all reactions have a specific temperature where \(K=1\) ?
25. Monochloroethane \(\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}\right)\) can be produced by the direct reaction of ethane gas \(\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)\) with chlorine gas or by the reaction of ethylene gas \(\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)\) with hydrogen chloride gas. The second reaction gives almost a \(100 \%\) yield of pure \(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}\) at a rapid rate without catalysis. The first method requires light as an energy source or the reaction would not occur. Yet \(\Delta G^{\circ}\) for the first reaction is considerably more negative than \(\Delta G^{\circ}\) for the second reaction. Explain how this can be so.
26. Consider the following relationships:
\[
\Delta G^{o}=1, \Delta H=T \Delta S, Q=1, \Delta G=\Delta G^{\circ}, K=1
\]

Which of these relationships is(are) always true for a reaction at equilibrium?
27. Consider the reaction
\[
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightarrow 2 \mathrm{NO}_{2}(g)
\]
where \(P_{\mathrm{NO}_{2}}=0.29 \mathrm{~atm}\) and \(P_{\mathrm{N}_{2} \mathrm{O}_{4}}=1.6 \mathrm{~atm}\). For this reaction at these conditions, \(\Delta G=-1000 \mathrm{~J}\) and \(\Delta G^{\circ}=6000 \mathrm{~J}\). Which of the following statements about this reaction is(are) true?
a. The reverse reaction is spontaneous at these conditions.
b. At equilibrium, \(P_{\mathrm{N}_{2} \mathrm{O}_{4}}\) will be greater than 1.6 atm .
c. The value of \(K\) for this reaction is greater than 1 .
d. The maximum amount of work this reaction can produce at these conditions is -6000 J .
e. The reaction is endothermic.
28. At 1500 K , the process
\[
\begin{array}{r}
\mathrm{I}_{2}(\mathrm{~g}) \\
10 \mathrm{~atm}
\end{array} \longrightarrow \underset{10 \mathrm{~atm}}{\longrightarrow 2 \mathrm{I}(\mathrm{~g})}
\]
is not spontaneous. However, the process
\[
\begin{gathered}
\mathrm{I}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{I}(\mathrm{~g}) \\
0.10 \mathrm{~atm} \\
0.10 \mathrm{~atm}
\end{gathered}
\]
is spontaneous at 1500 K . Explain.

\section*{Exercises}

In this section similar exercises are paired.

\section*{Spontaneity, Entropy, and the Second Law of Thermodynamics: Free Energy}
29. Which of the following processes are spontaneous?
a. Salt dissolves in \(\mathrm{H}_{2} \mathrm{O}\).
b. A clear solution becomes a uniform color after a few drops of dye are added.
c. Iron rusts.
d. You clean your bedroom.
30. Which of the following processes are spontaneous?
a. A house is built.
b. A satellite is launched into orbit.
c. A satellite falls back to earth.
d. The kitchen gets cluttered.
-31. Table 17.1 shows the possible arrangements of four molecules in a two-bulbed flask. What are the possible arrangements if there is one molecule in this two-bulbed flask or two molecules or three molecules? For each, what arrangement is most likely?
32. Consider the following illustration of six molecules of gas in a two-bulbed flask.

a. What is the most likely arrangement of molecules? How many microstates are there for this arrangement?
b. Determine the probability of finding the gas in its most likely arrangement.
33. Consider the following energy levels, each capable of holding two particles:
\[
\begin{aligned}
E & =2 \mathrm{~kJ} \\
E & =1 \mathrm{~kJ} \_ \\
E & =0 \quad \underline{X X}
\end{aligned}
\]

Draw all the possible arrangements of the two identical particles (represented by \(X\) ) in the three energy levels. What total energy is most likely, that is, occurs the greatest number of times? Assume that the particles are indistinguishable from each other.
34. Redo Exercise 33 with two particles \(A\) and B, which can be distinguished from each other.
-35. Choose the substance with the larger positional probability in each case.
a. 1 mole of \(\mathrm{H}_{2}\) (at STP) or 1 mole of \(\mathrm{H}_{2}\) (at \(100^{\circ} \mathrm{C}, 0.5 \mathrm{~atm}\) )
b. 1 mole of \(\mathrm{N}_{2}\) (at STP) or 1 mole of \(\mathrm{N}_{2}\) (at \(100 \mathrm{~K}, 2.0 \mathrm{~atm}\) )
c. 1 mole of \(\mathrm{H}_{2} \mathrm{O}(s)\left(\right.\) at \(\left.0^{\circ} \mathrm{C}\right)\) or 1 mole of \(\mathrm{H}_{2} \mathrm{O}(l)\left(\right.\) at \(\left.20^{\circ} \mathrm{C}\right)\)
36. Which of the following involve an increase in the entropy of the system?
a. melting of a solid
b. sublimation
c. freezing
d. mixing
e. separation
f. boiling
-37. Predict the sign of \(\Delta S_{\text {surr }}\) for the following processes.
a. \(\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g)\)
b. \(\mathrm{I}_{2}(g) \longrightarrow \mathrm{I}_{2}(s)\)
38. Calculate \(\Delta S_{\text {surr }}\) for the following reactions at \(25^{\circ} \mathrm{C}\) and 1 atm .
a. \(\mathrm{C}_{3} \mathrm{H}_{8}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 3 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)\) \(\Delta H^{\circ}=-2221 \mathrm{~kJ}\)
b. \(2 \mathrm{NO}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \quad \Delta H^{\circ}=112 \mathrm{~kJ}\)
-39. Given the values of \(\Delta H\) and \(\Delta S\), which of the following changes will be spontaneous at constant \(T\) and \(P\) ?
a. \(\Delta H=+25 \mathrm{~kJ}, \Delta S=+5.0 \mathrm{~J} / \mathrm{K}, T=300\). K
b. \(\Delta H=+25 \mathrm{~kJ}, \Delta S=+100 . \mathrm{J} / \mathrm{K}, T=300 . \mathrm{K}\)
c. \(\Delta H=-10 . \mathrm{kJ}, \Delta S=+5.0 \mathrm{~J} / \mathrm{K}, T=298 \mathrm{~K}\)
d. \(\Delta H=-10 . \mathrm{kJ}, \Delta S=-40 . \mathrm{J} / \mathrm{K}, T=200\). K
40. At what temperatures will the following processes be spontaneous?
a. \(\Delta H=-18 \mathrm{~kJ}\) and \(\Delta S=-60 . \mathrm{J} / \mathrm{K}\)
b. \(\Delta H=+18 \mathrm{~kJ}\) and \(\Delta S=+60 . \mathrm{J} / \mathrm{K}\)
c. \(\Delta H=+18 \mathrm{~kJ}\) and \(\Delta S=-60 . \mathrm{J} / \mathrm{K}\)
d. \(\Delta H=-18 \mathrm{~kJ}\) and \(\Delta S=+60\). J/K
41. Ethanethiol \(\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{SH}\right.\); also called ethyl mercaptan) is commonly added to natural gas to provide the "rotten egg" smell of a gas leak. The boiling point of ethanethiol is \(35^{\circ} \mathrm{C}\) and its heat of vaporization is \(27.5 \mathrm{~kJ} / \mathrm{mol}\). What is the entropy of vaporization for this substance?
42. For mercury, the enthalpy of vaporization is \(58.51 \mathrm{~kJ} / \mathrm{mol}\) and the entropy of vaporization is \(92.92 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\). What is the normal boiling point of mercury?
-43. For ammonia \(\left(\mathrm{NH}_{3}\right)\), the enthalpy of fusion is \(5.65 \mathrm{~kJ} / \mathrm{mol}\) and the entropy of fusion is \(28.9 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\).
a. Will \(\mathrm{NH}_{3}(s)\) spontaneously melt at 200 . K?
b. What is the approximate melting point of ammonia?
44. The enthalpy of vaporization of ethanol is \(38.7 \mathrm{~kJ} / \mathrm{mol}\) at its boiling point \(\left(78^{\circ} \mathrm{C}\right)\). Determine \(\Delta S_{\text {sys }}, \Delta S_{\text {surr }}\), and \(\Delta S_{\text {univ }}\) when 1.00 mole of ethanol is vaporized at \(78^{\circ} \mathrm{C}\) and 1.00 atm .

\section*{Chemical Reactions: Entropy Changes and Free Energy}
45. Predict the sign of \(\Delta S^{\circ}\) for each of the following changes. Assume all equations are balanced.

a.
b.

c.

d.

46 Predict the sign of \(\Delta S^{\circ}\) for each of the following changes.
a. \(\mathrm{K}(s)+\frac{1}{2} \mathrm{Br}_{2}(g) \longrightarrow \mathrm{KBr}(s)\)
b. \(\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)\)
c. \(\mathrm{KBr}(s) \longrightarrow \mathrm{K}^{+}(a q)+\mathrm{Br}^{-}(a q)\)
d. \(\mathrm{KBr}(s) \longrightarrow \mathrm{KBr}(l)\)
-47. For each of the following pairs of substances, which substance has the greater value of \(S^{\circ}\) ?
a. \(\mathrm{C}_{\text {graphite }}(s)\) or \(\mathrm{C}_{\text {diamond }}(s)\)
b. \(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)\) or \(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(g)\)
c. \(\mathrm{CO}_{2}(s)\) or \(\mathrm{CO}_{2}(g)\)
48. For each of the following pairs, which substance has the greater value of \(S\) ?
a. \(\mathrm{N}_{2} \mathrm{O}\) (at 0 K ) or He (at 10 K )
b. \(\mathrm{N}_{2} \mathrm{O}(\mathrm{g})\left(\right.\) at \(\left.1 \mathrm{~atm}, 25^{\circ} \mathrm{C}\right)\) or \(\mathrm{He}(\mathrm{g})\left(\right.\) at \(\left.1 \mathrm{~atm}, 25^{\circ} \mathrm{C}\right)\)
c. \(\mathrm{NH}_{3}(s)(\) at 196 K\() \longrightarrow \mathrm{NH}_{3}(l)(\) at 196 K\()\)
-49. Predict the sign of \(\Delta S^{\circ}\) and then calculate \(\Delta S^{\circ}\) for each of the following reactions.
a. \(2 \mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{SO}_{2}(g) \longrightarrow 3 \mathrm{~S}_{\text {rhombic }}(s)+2 \mathrm{H}_{2} \mathrm{O}(g)\)
b. \(2 \mathrm{SO}_{3}(\mathrm{~g}) \longrightarrow 2 \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})\)
c. \(\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{Fe}(s)+3 \mathrm{H}_{2} \mathrm{O}(g)\)
50. Predict the sign of \(\Delta S^{\circ}\) and then calculate \(\Delta S^{\circ}\) for each of the following reactions.
a. \(\mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)\)
b. \(2 \mathrm{CH}_{3} \mathrm{OH}(\mathrm{g})+3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CO}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})\)
c. \(\mathrm{HCl}(g) \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q)\)
-51 . For the reaction
\[
\mathrm{C}_{2} \mathrm{H}_{2}(g)+4 \mathrm{~F}_{2}(g) \longrightarrow 2 \mathrm{CF}_{4}(g)+\mathrm{H}_{2}(g)
\]
\(\Delta S^{\circ}\) is equal to \(-358 \mathrm{~J} / \mathrm{K}\). Use this value and data from Appendix 4 to calculate the value of \(S^{\circ}\) for \(\mathrm{CF}_{4}(\mathrm{~g})\).
52. For the reaction
\[
\mathrm{CS}_{2}(g)+3 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{SO}_{2}(g)
\]
\(\Delta S^{\circ}\) is equal to \(-143 \mathrm{~J} / \mathrm{K}\). Use this value and data from Appendix 4 to calculate the value of \(S^{\circ}\) for \(\mathrm{CS}_{2}(g)\).
-53. It is quite common for a solid to change from one structure to another at a temperature below its melting point. For example, sulfur undergoes a phase change from the rhombic crystal structure to the monoclinic crystal form at temperatures above \(95^{\circ} \mathrm{C}\).
a. Predict the signs of \(\Delta H\) and \(\Delta S\) for the process
\[
\mathrm{S}_{\text {rhombic }}(s) \longrightarrow \mathrm{S}_{\text {monoclinic }}(s) .
\]
b. Which form of sulfur has the more ordered crystalline structure (has the smaller positional probability)?
54. Two crystalline forms of white phosphorus are known. Both forms contain \(\mathrm{P}_{4}\) molecules, but the molecules are packed together in different ways. The \(\alpha\) form is always obtained when the liquid freezes. However, below \(-76.9^{\circ} \mathrm{C}\), the \(\alpha\) form spontaneously converts to the \(\beta\) form:
\[
\mathrm{P}_{4}(s, \alpha) \longrightarrow \mathrm{P}_{4}(s, \beta)
\]
a. Predict the signs of \(\Delta H\) and \(\Delta S\) for this process.
b. Predict which form of phosphorus has the more ordered crystalline structure (has the smaller positional probability).

Consider the reaction
\[
2 \mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{O}_{2}(\mathrm{~g})
\]
a. Predict the signs of \(\Delta H\) and \(\Delta S\).
b. Would the reaction be more spontaneous at high or low temperatures?
56. Hydrogen cyanide is produced industrially by the following exothermic reaction:
\(2 \mathrm{NH}_{3}(\mathrm{~g})+3 \mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{CH}_{4}(\mathrm{~g}) \xrightarrow[\mathrm{Pt}-\mathrm{Rh}]{100^{\circ} \mathrm{C}} 2 \mathrm{HCN}(\mathrm{g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})\)
Is the high temperature needed for thermodynamic or kinetic reasons?
-57. From data in Appendix 4, calculate \(\Delta H^{\circ}, \Delta S^{\circ}\), and \(\Delta G^{\circ}\) for each of the following reactions at \(25^{\circ} \mathrm{C}\).
a. \(\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})\)
b. \(6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \underset{\text { Glucose }}{\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g)}\)
c. \(\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{4}(s)\)
d. \(\mathrm{HCl}(\mathrm{g})+\mathrm{NH}_{3}(\mathrm{~g}) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(\mathrm{s})\)
58. Calculate \(\Delta H^{\circ}, \Delta S^{\mathrm{o}}\), and \(\Delta G^{\circ}\) at \(25^{\circ} \mathrm{C}\) for each of the following reactions that occur in the atmosphere.
a. \(\mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{O}_{3}(g) \rightarrow \mathrm{CH}_{3} \mathrm{CHO}(g)+\mathrm{O}_{2}(g)\)
b. \(\mathrm{O}_{3}(g)+\mathrm{NO}(g) \rightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)\)
c. \(\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)\)
59. The major industrial use of hydrogen is in the production of ammonia by the Haber process:
\[
3 \mathrm{H}_{2}(g)+\mathrm{N}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
\]
a. Using data from Appendix 4, calculate \(\Delta H^{\circ}, \Delta S^{\circ}\), and \(\Delta G^{\circ}\) for the Haber process reaction.
b. Is the reaction spontaneous at standard conditions?
c. At what temperatures is the reaction spontaneous at standard conditions? Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
60. For the reaction at 298 K ,
\[
2 \mathrm{NO}_{2}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}_{4}(g)
\]
the values of \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) are -58.03 kJ and \(-176.6 \mathrm{~J} / \mathrm{K}\), respectively. What is the value of \(\Delta G^{\circ}\) at 298 K ? Assuming that \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature, at what temperature is \(\Delta G^{\circ}=0\) ? Is \(\Delta G^{\circ}\) negative above or below this temperature?
\(\Gamma^{61}\). At \(100 .{ }^{\circ} \mathrm{C}\) and \(1.00 \mathrm{~atm}, \Delta H^{\circ}=40.6 \mathrm{~kJ} / \mathrm{mol}\) for the vaporization of water. Estimate \(\Delta G^{\circ}\) for the vaporization of water at \(90 .{ }^{\circ} \mathrm{C}\) and \(110 .{ }^{\circ} \mathrm{C}\). Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) at \(100 .{ }^{\circ} \mathrm{C}\) and 1.00 atm do not depend on temperature.
62. For the sublimation of iodine at \(25^{\circ} \mathrm{C}\)
\[
\mathrm{I}_{2}(s) \rightarrow \mathrm{I}_{2}(g)
\]
the values of \(\Delta H^{\circ}\) and \(\Delta G^{\circ}\) are, respectively, 62 kJ and 19 kJ . Estimate the temperature at which iodine sublimes. Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
\({ }^{63}\). Given the following data:
\[
\begin{aligned}
& 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{C}(\mathrm{~s}) \longrightarrow \mathrm{CH}_{4}(\mathrm{~g}) \quad \Delta G^{\circ}=-51 \mathrm{~kJ} \\
& 2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad \Delta G^{\circ}=-474 \mathrm{~kJ} \\
& \mathrm{C}(s)+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g}) \quad \Delta G^{\circ}=-394 \mathrm{~kJ}
\end{aligned}
\]

Calculate \(\Delta G^{\circ}\) for \(\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \rightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)\).
64. Given the following data:
\[
\begin{aligned}
& 2 \mathrm{C}_{6} \mathrm{H}_{6}(l)+15 \mathrm{O}_{2}(g) \longrightarrow 12 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \\
& \Delta G^{\circ}=-6399 \mathrm{~kJ} \\
& \mathrm{C}(s)+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g}) \quad \Delta G^{\circ}=-394 \mathrm{~kJ} \\
& \mathrm{H}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad \Delta G^{\circ}=-237 \mathrm{~kJ}
\end{aligned}
\]
calculate \(\Delta G^{\circ}\) for the reaction
\[
6 \mathrm{C}(s)+3 \mathrm{H}_{2}(g) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{6}(l)
\]
-65. For the reaction
\[
\mathrm{SF}_{4}(g)+\mathrm{F}_{2}(g) \longrightarrow \mathrm{SF}_{6}(g)
\]
the value of \(\Delta G^{\circ}\) is -374 kJ . Use this value and data from Appendix 4 to calculate the value of \(\Delta G_{f}^{\circ}\) for \(\mathrm{SF}_{4}(g)\).
66. The value of \(\Delta G^{\circ}\) for the reaction
\[
2 \mathrm{C}_{4} \mathrm{H}_{10}(g)+13 \mathrm{O}_{2}(g) \longrightarrow 8 \mathrm{CO}_{2}(g)+10 \mathrm{H}_{2} \mathrm{O}(l)
\]
is -5490 . kJ. Use this value and data from Appendix 4 to calculate the standard free energy of formation for \(\mathrm{C}_{4} \mathrm{H}_{10}(g)\).
67. Consider the reaction
\[
\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+3 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{Fe}(s)+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
\]
a. Use \(\Delta G_{\mathrm{f}}^{\circ}\) values in Appendix 4 to calculate \(\Delta G^{\circ}\) for this reaction.
b. Is this reaction spontaneous under standard conditions at 298 K?
c. The value of \(\Delta H^{\circ}\) for this reaction is 100 . kJ . At what temperatures is this reaction spontaneous at standard conditions? Assume that \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
68. Consider the reaction
\[
2 \mathrm{POCl}_{3}(\mathrm{~g}) \longrightarrow 2 \mathrm{PCl}_{3}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
\]
a. Calculate \(\Delta G^{\circ}\) for this reaction. The \(\Delta G_{\mathrm{f}}^{\circ}\) values for \(\mathrm{POCl}_{3}(g)\) and \(\mathrm{PCl}_{3}(g)\) are \(-502 \mathrm{~kJ} / \mathrm{mol}\) and \(-270 . \mathrm{kJ} / \mathrm{mol}\), respectively.
b. Is this reaction spontaneous under standard conditions at 298 K ?
c. The value of \(\Delta S^{\circ}\) for this reaction is \(179 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\). At what temperatures is this reaction spontaneous at standard conditions? Assume that \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
69. Using data from Appendix 4 , calculate \(\Delta H^{\circ}, \Delta S^{\circ}\), and \(\Delta G^{\circ}\) for the following reactions that produce acetic acid:

Which reaction would you choose as a commercial method for producing acetic acid \(\left(\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}\right)\) at standard conditions? What temperature conditions would you choose for the reaction? Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
70. Consider two reactions for the production of ethanol:
\[
\begin{aligned}
& \mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(l) \\
& \mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(\mathrm{l})+\mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
\]

Which would be the more thermodynamically feasible at standard conditions? Why?

\section*{Free Energy: Pressure Dependence and Equilibrium}
-71. Using data from Appendix 4, calculate \(\Delta G\) for the reaction
\[
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \rightleftharpoons \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
\]
for these conditions:
\[
\begin{aligned}
T & =298 \mathrm{~K} \\
P_{\mathrm{NO}} & =1.00 \times 10^{-6} \mathrm{~atm}, P_{\mathrm{O}_{3}}=2.00 \times 10^{-6} \mathrm{~atm} \\
P_{\mathrm{NO}_{2}} & =1.00 \times 10^{-7} \mathrm{~atm}, P_{\mathrm{O}_{2}}=1.00 \times 10^{-3} \mathrm{~atm}
\end{aligned}
\]
72. Using data from Appendix 4, calculate \(\Delta G\) for the reaction
\[
2 \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})+\mathrm{SO}_{2}(\mathrm{~g}) \rightleftharpoons 3 \mathrm{~S}_{\text {rhombic }}(\mathrm{s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
\]
for the following conditions at \(25^{\circ} \mathrm{C}\) :
\[
\begin{aligned}
P_{\mathrm{H}_{2} \mathrm{~S}} & =1.0 \times 10^{-4} \mathrm{~atm} \\
P_{\mathrm{SO}_{2}} & =1.0 \times 10^{-2} \mathrm{~atm} \\
P_{\mathrm{H}_{2} \mathrm{O}} & =3.0 \times 10^{-2} \mathrm{~atm}
\end{aligned}
\]
-73. Consider the reaction
\[
2 \mathrm{NO}_{2}(g) \rightleftharpoons \mathrm{N}_{2} \mathrm{O}_{4}(g)
\]

For each of the following mixtures of reactants and products at \(25^{\circ} \mathrm{C}\), predict the direction in which the reaction will shift to reach equilibrium.
a. \(P_{\mathrm{NO}_{2}}=P_{\mathrm{N}_{2} \mathrm{O}_{4}}=1.0 \mathrm{~atm}\)
b. \(P_{\mathrm{NO}_{2}}=0.21 \mathrm{~atm}, P_{\mathrm{N}_{2} \mathrm{O}_{4}}=0.50 \mathrm{~atm}\)
c. \(P_{\mathrm{NO}_{2}}=0.29 \mathrm{~atm}, P_{\mathrm{N}_{2} \mathrm{O}_{4}}=1.6 \mathrm{~atm}\)
74. Consider the following reaction:
\[
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
\]

Calculate \(\Delta G\) for this reaction under the following conditions (assume an uncertainty of \(\pm 1\) in all quantities):
a. \(T=298 \mathrm{~K}, P_{\mathrm{N}_{2}}=P_{\mathrm{H}_{2}}=200 \mathrm{~atm}, P_{\mathrm{NH}_{3}}=50 \mathrm{~atm}\)
b. \(T=298 \mathrm{~K}, P_{\mathrm{N}_{2}}=200 \mathrm{~atm}, P_{\mathrm{H}_{2}}=600 \mathrm{~atm}\),
\(P_{\mathrm{NH}_{3}}=200 \mathrm{~atm}\)
75. One of the reactions that destroys ozone in the upper atmosphere is
\[
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \rightleftharpoons \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
\]

Using data from Appendix 4, calculate \(\Delta G^{\circ}\) and \(K\) (at 298 K ) for this reaction.
76. Hydrogen sulfide can be removed from natural gas by the reaction
\[
2 \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})+\mathrm{SO}_{2}(\mathrm{~g}) \rightleftharpoons 3 \mathrm{~S}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
\]

Calculate \(\Delta G^{\circ}\) and \(K\) (at 298 K ) for this reaction. Would this reaction be favored at a high or low temperature?
-77 . Consider the following reaction at \(25.0^{\circ} \mathrm{C}\) :
\[
2 \mathrm{NO}_{2}(g) \rightleftharpoons \mathrm{N}_{2} \mathrm{O}_{4}(g)
\]

The values of \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) are \(-58.03 \mathrm{~kJ} / \mathrm{mol}\) and \(-176.6 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\), respectively. Calculate the value of \(K\) at \(25.0^{\circ} \mathrm{C}\). Assuming \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) are temperature independent, estimate the value of \(K\) at \(100.0^{\circ} \mathrm{C}\).
78. The standard free energies of formation and the standard enthalpies of formation at 298 K for difluoroacetylene \(\left(\mathrm{C}_{2} \mathrm{~F}_{2}\right)\) and hexafluorobenzene \(\left(\mathrm{C}_{6} \mathrm{~F}_{6}\right)\) are

For the following reaction:
\[
\mathrm{C}_{6} \mathrm{~F}_{6}(\mathrm{~g}) \rightleftharpoons 3 \mathrm{C}_{2} \mathrm{~F}_{2}(\mathrm{~g})
\]
a. calculate \(\Delta S^{\circ}\) at 298 K .
b. calculate \(K\) at 298 K .
c. estimate \(K\) at \(3000 . \mathrm{K}\), assuming \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
[79. Calculate \(\Delta G^{\circ}\) for \(\mathrm{H}_{2} \mathrm{O}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{~g})\) at \(600 . \mathrm{K}\), using the following data:
\[
\begin{aligned}
\mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}_{2}(g) & K=2.3 \times 10^{6} \text { at } 600 . \mathrm{K} \\
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{H}_{2} \mathrm{O}(g) & K=1.8 \times 10^{37} \text { at } 600 . \mathrm{K}
\end{aligned}
\]
80. The Ostwald process for the commercial production of nitric acid involves three steps:
\[
\begin{aligned}
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) & \stackrel{\mathrm{Pt}}{825^{\circ} \mathrm{C}} 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g) \\
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) & \longrightarrow 2 \mathrm{NO}_{2}(g) \\
3 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{HNO}_{3}(l)+\mathrm{NO}(g)
\end{aligned}
\]
a. Calculate \(\Delta H^{\circ}, \Delta S^{\circ}, \Delta G^{\circ}\), and \(K\) (at 298 K ) for each of the three steps in the Ostwald process (see Appendix 4).
b. Calculate the equilibrium constant for the first step at \(825^{\circ} \mathrm{C}\), assuming \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
c. Is there a thermodynamic reason for the high temperature in the first step, assuming standard conditions?
-81. Cells use the hydrolysis of adenosine triphosphate, abbreviated as ATP, as a source of energy. Symbolically, this reaction can be written as
\[
\operatorname{ATP}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \operatorname{ADP}(a q)+\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)
\]
where ADP represents adenosine diphosphate. For this reaction, \(\Delta G^{\circ}=-30.5 \mathrm{~kJ} / \mathrm{mol}\).
a. Calculate \(K\) at \(25^{\circ} \mathrm{C}\).
b. If all the free energy from the metabolism of glucose
\[
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g) \longrightarrow 6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)
\]
goes into forming ATP from ADP, how many ATP molecules can be produced for every molecule of glucose?
82. One reaction that occurs in human metabolism is

For this reaction \(\Delta G^{\circ}=14 \mathrm{~kJ}\) at \(25^{\circ} \mathrm{C}\).
a. Calculate \(K\) for this reaction at \(25^{\circ} \mathrm{C}\).
b. In a living cell this reaction is coupled with the hydrolysis of ATP. (See Exercise 81.) Calculate \(\Delta G^{\circ}\) and \(K\) at \(25^{\circ} \mathrm{C}\) for the following reaction:
Glutamic \(\operatorname{acid}(a q)+\operatorname{ATP}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons\)
\[
\text { Glutamine }(a q)+\mathrm{ADP}(a q)+\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)
\]
83. Consider the following reaction at 800. K :
\[
\mathrm{N}_{2}(g)+3 \mathrm{~F}_{2}(g) \rightleftharpoons 2 \mathrm{NF}_{3}(g)
\]

An equilibrium mixture contains the following partial pressures: \(P_{\mathrm{N}_{2}}=0.021 \mathrm{~atm}, P_{\mathrm{F}_{2}}=0.063 \mathrm{~atm}, P_{\mathrm{NF}_{3}}=0.48 \mathrm{~atm}\). Calculate \(\Delta G^{\circ}\) for the reaction at 800 . K.
84. Consider the following reaction at 298 K :
\[
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{SO}_{3}(g)
\]

An equilibrium mixture contains \(\mathrm{O}_{2}(g)\) and \(\mathrm{SO}_{3}(g)\) at partial pressures of 0.50 atm and 2.0 atm , respectively. Using data from Appendix 4, determine the equilibrium partial pressure of \(\mathrm{SO}_{2}\) in the mixture. Will this reaction be most favored at a high or a low temperature, assuming standard conditions?
85. Consider the relationship
\[
\ln (K)=\frac{-\Delta H^{\circ}}{R T}+\frac{\Delta S^{\circ}}{R}
\]

The equilibrium constant for some hypothetical process was determined as a function of temperature (Kelvin) with the results plotted below.

From the plot, determine the values of \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) for this process. What would be the major difference in the \(\ln (K)\) versus \(1 / T\) plot for an endothermic process as compared to an exothermic process?
86. The equilibrium constant \(K\) for the reaction
\[
2 \mathrm{Cl}(\mathrm{~g}) \rightleftharpoons \mathrm{Cl}_{2}(\mathrm{~g})
\]
was measured as a function of temperature (Kelvin). A graph of \(\ln (K)\) versus \(1 / T\) for this reaction gives a straight line with a slope of \(1.352 \times 10^{4} \mathrm{~K}\) and a \(y\)-intercept of -14.51 . Determine the values of \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) for this reaction. See Exercise 85.
87. A reaction has \(K=1.9 \times 10^{-14}\) at \(25^{\circ} \mathrm{C}\) and \(K=9.1 \times 10^{3}\) at \(227^{\circ} \mathrm{C}\). Predict the signs for \(\Delta G^{\circ}, \Delta H^{\circ}\), and \(\Delta S^{\circ}\) for this reaction at \(25^{\circ} \mathrm{C}\). Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
88. Consider the following equilibrium constant versus temperature data for some reaction:
\begin{tabular}{cc}
\(\mathbf{T}\left({ }^{\circ} \mathrm{C}\right)\) & \(\boldsymbol{K}\) \\
\hline 109 & \(2.54 \times 10^{4}\) \\
\hline 225 & \(5.04 \times 10^{2}\) \\
\hline 303 & \(6.33 \times 10^{1}\) \\
\hline 412 & \(2.25 \times 10^{-1}\) \\
\hline 539 & \(3.03 \times 10^{-3}\) \\
\hline
\end{tabular}

Predict the signs for \(\Delta G^{\circ}, \Delta H^{\circ}\), and \(\Delta S^{\circ}\) for this reaction at \(25^{\circ} \mathrm{C}\). Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.

\section*{Additional Exercises}
89. Using Appendix 4 and the following data, determine \(S^{\circ}\) for \(\mathrm{Fe}(\mathrm{CO})_{5}(g)\).
\[
\begin{aligned}
& \mathrm{Fe}(s)+5 \mathrm{CO}(g) \longrightarrow \mathrm{Fe}(\mathrm{CO})_{5}(g) \quad \Delta S^{\circ}=? \\
& \mathrm{Fe}(\mathrm{CO})_{5}(l) \longrightarrow \mathrm{Fe}(\mathrm{CO})_{5}(g) \quad \Delta S^{\circ}=107 \mathrm{~J} / \mathrm{K} \\
& \mathrm{Fe}(s)+5 \mathrm{CO}(g) \longrightarrow \mathrm{Fe}(\mathrm{CO})_{5}(l) \quad \Delta S^{\circ}=-677 \mathrm{~J} / \mathrm{K}
\end{aligned}
\]
90. Some water is placed in a coffee-cup calorimeter. When 1.0 g of an ionic solid is added, the temperature of the solution increases from \(21.5^{\circ} \mathrm{C}\) to \(24.2^{\circ} \mathrm{C}\) as the solid dissolves. For the dissolving process, what are the signs for \(\Delta S_{\text {sys }}, \Delta S_{\text {surr }}\), and \(\Delta S_{\text {univ }}\) ?
91. A green plant synthesizes glucose by photosynthesis, as shown in the reaction:
\[
6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \rightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g)
\]

Animals use glucose as a source of energy:
\[
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g) \rightarrow 6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)
\]

If we were to assume that both of these processes occur to the same extent in a cyclic process, what thermodynamic property must have a nonzero value?
92. When most biological enzymes are heated, they lose their catalytic activity. This process is called denaturing. The change
\[
\text { original enzyme } \rightarrow \text { new form }
\]
that occurs on heating is endothermic and spontaneous. Is the structure of the original enzyme or its new form more ordered (has the smaller positional probability)? Explain.
93. Acrylonitrile is the starting material used in the manufacture of acrylic fibers (U.S. annual production capacity is more than two million pounds). Three industrial processes for the production of acrylonitrile are given below. Using data from Appendix 4, calculate \(\Delta S^{\circ}, \Delta H^{\circ}\), and \(\Delta G^{\circ}\) for each process. For part a, assume that \(T=25^{\circ} \mathrm{C}\); for part \(\mathrm{b}, T=70 .{ }^{\circ} \mathrm{C}\); and for part \(\mathrm{c}, T=700 .{ }^{\circ} \mathrm{C}\). Assume that \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
a. \(\underset{\mathrm{O}}{\mathrm{CH}_{2}-} \mathrm{CH}_{2}(g)+\mathrm{HCN}(g)\)

Ethylene oxide
\[
\longrightarrow \mathrm{CH}_{2}=\mathrm{CHCN}(g)+\mathrm{H}_{2} \mathrm{O}(l)
\]

Acrylonitrile
b. \(\mathrm{HC} \equiv \mathrm{CH}(g)+\mathrm{HCN}(g) \xrightarrow[70^{\circ} \mathrm{C}-90^{\circ} \mathrm{C}]{\mathrm{CaCl}_{2} \cdot \mathrm{HCl}} \mathrm{CH}_{2}=\mathrm{CHCN}(g)\)
c. \(4 \mathrm{CH}_{2}=\mathrm{CHCH}_{3}(g)+6 \mathrm{NO}(g)\)
\[
\xrightarrow[\mathrm{Ag}]{700^{\circ} \mathrm{C}} 4 \mathrm{CH}_{2}=\mathrm{CHCN}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)+\mathrm{N}_{2}(g)
\]
94. Calculate the entropy change for the vaporization of liquid methane and liquid hexane using the following data.
\begin{tabular}{|lcc|}
\hline & \begin{tabular}{c} 
Boiling Point \\
(1 atm)
\end{tabular} & \multicolumn{1}{c|}{\(H_{\text {vap }}\)} \\
\hline Methane & 112 K & \(8.20 \mathrm{~kJ} / \mathrm{mol}\) \\
\hline Hexane & 342 K & \(28.9 \mathrm{~kJ} / \mathrm{mol}\) \\
\hline
\end{tabular}

Compare the molar volume of gaseous methane at 112 K with that of gaseous hexane at 342 K . How do the differences in molar volume affect the values of \(\Delta S_{\text {vap }}\) for these liquids?
95. As \(\mathrm{O}_{2}(l)\) is cooled at 1 atm , it freezes at 54.5 K to form solid I. At a lower temperature, solid I rearranges to solid II, which has a different crystal structure. Thermal measurements show that \(\Delta H\) for the I \(\rightarrow\) II phase transition is \(-743.1 \mathrm{~J} / \mathrm{mol}\), and \(\Delta S\) for the same transition is \(-17.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\). At what temperature are solids I and II in equilibrium?
96. Consider the following reaction:
\[
\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+\mathrm{Cl}_{2} \mathrm{O}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HOCl}(\mathrm{~g}) \quad K_{298}=0.090
\]

For \(\mathrm{Cl}_{2} \mathrm{O}(g)\),
\[
\begin{aligned}
\Delta G_{\mathrm{f}}^{\circ} & =97.9 \mathrm{~kJ} / \mathrm{mol} \\
\Delta H_{\mathrm{f}}^{\circ} & =80.3 \mathrm{~kJ} / \mathrm{mol} \\
S^{\circ} & =266.1 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
\]
a. Calculate \(\Delta G^{\circ}\) for the reaction using the equation \(\Delta G^{\circ}=-R T \ln (K)\).
b. Use bond energy values (Table 8.5) to estimate \(\Delta H^{\circ}\) for the reaction.
c. Use the results from parts a and b to estimate \(\Delta S^{\circ}\) for the reaction.
d. Estimate \(\Delta H^{\circ}\) and \(S^{\circ}\) for \(\mathrm{HOCl}(g)\).
e. Estimate the value of \(K\) at 500 . K.
f. Calculate \(\Delta G\) at \(25^{\circ} \mathrm{C}\) when \(P_{\mathrm{H}_{2} \mathrm{O}}=18\) torr, \(P_{\mathrm{C}_{2} \mathrm{O}}=\) 2.0 torr, and \(P_{\text {HoCl }}=0.10\) torr.
97. Using the following data, calculate the value of \(K_{\text {sp }}\) for \(\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}\), one of the least soluble of the common nitrate salts.
\begin{tabular}{lc|}
\hline Species & \(\Delta G_{\mathrm{f}}^{\circ}\) \\
\hline \(\mathrm{Ba}^{2+}(a q)\) & \(-561 \mathrm{~kJ} / \mathrm{mol}\) \\
\hline \(\mathrm{NO}_{3}^{-}(a q)\) & \(-109 \mathrm{~kJ} / \mathrm{mol}\) \\
\hline \(\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{~s})\) & \(-797 \mathrm{~kJ} / \mathrm{mol}\) \\
\hline
\end{tabular}
98. Many biochemical reactions that occur in cells require relatively high concentrations of potassium ion ( \(\mathrm{K}^{+}\)). The concentration of \(\mathrm{K}^{+}\)in muscle cells is about 0.15 M . The concentration of \(\mathrm{K}^{+}\)in blood plasma is about 0.0050 M . The high internal concentration in cells is maintained by pumping \(\mathrm{K}^{+}\)from the plasma. How much work must be done to transport 1.0 mole of \(\mathrm{K}^{+}\)from the blood to the inside of a muscle cell at \(37^{\circ} \mathrm{C}\), normal body temperature? When 1.0 mole of \(\mathrm{K}^{+}\)is transferred from blood to the cells, do any other ions have to be transported? Why or why not?
99. Carbon monoxide is toxic because it bonds much more strongly to the iron in hemoglobin \((\mathrm{Hgb})\) than does \(\mathrm{O}_{2}\). Consider the following reactions and approximate standard free energy changes:
\[
\begin{aligned}
\mathrm{Hgb}+\mathrm{O}_{2} & \longrightarrow \mathrm{HgbO}_{2}
\end{aligned} \begin{aligned}
& \Delta G^{\circ}=-70 \mathrm{~kJ} \\
& \mathrm{Hgb}+\mathrm{CO} \longrightarrow \mathrm{HgbCO}
\end{aligned} \quad \Delta G^{\circ}=-80 \mathrm{~kJ} \text { }
\]

Using these data, estimate the equilibrium constant value at \(25^{\circ} \mathrm{C}\) for the following reaction:
\[
\mathrm{HgbO}_{2}+\mathrm{CO} \rightleftharpoons \mathrm{HgbCO}+\mathrm{O}_{2}
\]
100. In the text, the equation
\[
\Delta G=\Delta G^{\circ}+R T \ln (Q)
\]
was derived for gaseous reactions where the quantities in \(Q\) were expressed in units of pressure. We also can use units of \(\mathrm{mol} / \mathrm{L}\) for the quantities in \(Q\), specifically for aqueous reactions. With this in mind, consider the reaction
\[
\mathrm{HF}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
\]
for which \(K_{\mathrm{a}}=7.2 \times 10^{-4}\) at \(25^{\circ} \mathrm{C}\). Calculate \(\Delta G\) for the reaction under the following conditions at \(25^{\circ} \mathrm{C}\).
a. \([\mathrm{HF}]=\left[\mathrm{H}^{+}\right]=\left[\mathrm{F}^{-}\right]=1.0 \mathrm{M}\)
b. \([\mathrm{HF}]=0.98 \mathrm{M},\left[\mathrm{H}^{+}\right]=\left[\mathrm{F}^{-}\right]=2.7 \times 10^{-2} M\)
c. \([\mathrm{HF}]=\left[\mathrm{H}^{+}\right]=\left[\mathrm{F}^{-}\right]=1.0 \times 10^{-5} \mathrm{M}\)
d. \([\mathrm{HF}]=\left[\mathrm{F}^{-}\right]=0.27 M,\left[\mathrm{H}^{+}\right]=7.2 \times 10^{-4} M\)
e. \([\mathrm{HF}]=0.52 \mathrm{M},\left[\mathrm{F}^{-}\right]=0.67 \mathrm{M},\left[\mathrm{H}^{+}\right]=1.0 \times 10^{-3} \mathrm{M}\)

Based on the calculated \(\Delta G\) values, in what direction will the reaction shift to reach equilibrium for each of the five sets of conditions?
101. Consider the reactions
\[
\begin{align*}
\mathrm{Ni}^{2+}(a q)+6 \mathrm{NH}_{3}(a q) & \longrightarrow \mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}^{2+}(a q)  \tag{1}\\
\mathrm{Ni}^{2+}(a q)+3 \mathrm{en}(a q) & \longrightarrow \mathrm{Ni}(\mathrm{en})_{3}^{2+}(a q) \tag{2}
\end{align*}
\]
where
\[
\mathrm{en}=\mathrm{H}_{2} \mathrm{~N}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{NH}_{2}
\]

The \(\Delta H\) values for the two reactions are quite similar, yet \(\mathrm{K}_{\text {reaction 2 }}>K_{\text {reaction 1 }}\). Explain.
102. Use the equation in Exercise 85 to determine \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) for the autoionization of water:
\[
\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
\]
\begin{tabular}{|cc|}
\hline\(T\left({ }^{\circ} \mathrm{C}\right)\) & \(K_{w}\) \\
\hline 0 & \(1.14 \times 10^{-15}\) \\
\hline 25 & \(1.00 \times 10^{-14}\) \\
\hline 35 & \(2.09 \times 10^{-14}\) \\
\hline 40. & \(2.92 \times 10^{-14}\) \\
\hline 50. & \(5.47 \times 10^{-14}\) \\
\hline
\end{tabular}
103. Consider the reaction
\[
\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{Fe}(s)+3 \mathrm{H}_{2} \mathrm{O}(g)
\]

Assuming \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature, calculate the temperature where \(K=1.00\) for this reaction.
104. Consider the following diagram of free energy \((G)\) versus fraction of \(A\) reacted in terms of moles for the reaction \(2 \mathrm{~A}(g) \rightarrow \mathrm{B}(g)\).

Before any A has reacted, \(P_{\mathrm{A}}=3.0 \mathrm{~atm}\) and \(P_{\mathrm{B}}=0\). Determine the sign of \(\Delta G^{\circ}\) and the value of \(K\) for this reaction.

\section*{ChemWork Problems}

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
105. Which of the following reactions (or processes) are expected to have a negative value for \(\Delta S^{\circ}\) ?
a. \(\mathrm{SiF}_{6}(a q)+\mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{HF}(g)+\mathrm{SiF}_{4}(g)\)
b. \(4 \mathrm{Al}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Al}_{2} \mathrm{O}_{3}(s)\)
c. \(\mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{COCl}_{2}(g)\)
d. \(\mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)\)
e. \(\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)\)
106. For rubidium \(\Delta H^{\circ}\) vap \(=69.0 \mathrm{~kJ} / \mathrm{mol}\) at \(686^{\circ} \mathrm{C}\), its boiling point. Calculate \(\Delta S^{\circ}, q, w\), and \(\Delta E\) for the vaporization of 1.00 mole of rubidium at \(686^{\circ} \mathrm{C}\) and 1.00 atm pressure.
107. Given the thermodynamic data below, calculate \(\Delta S^{\circ}\) and \(\Delta S_{\text {surr }}\) for the following reaction at \(25^{\circ} \mathrm{C}\) and 1 atm :
\[
\mathrm{XeF}_{6}(g) \longrightarrow \mathrm{XeF}_{4}(s)+\mathrm{F}_{2}(g)
\]
\begin{tabular}{|ccc|}
\hline\(\Delta H_{\mathbf{f}}^{\circ}(\mathrm{kJ} /\) \\
\(\mathrm{mol})\)
\end{tabular}\(\quad \boldsymbol{S}^{\circ}(\mathrm{J} / \mathrm{K} \cdot \mathrm{mol})\)
108. Consider the reaction:
\[
\mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{SO}_{2}(g) \longrightarrow 3 \mathrm{~S}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
\]
for which \(\Delta H\) is -233 kJ and \(\Delta S\) is \(-424 \mathrm{~J} / \mathrm{K}\).
a. Calculate the free energy change for the reaction \((\Delta G)\) at 393 K.
b. Assuming \(\Delta H\) and \(\Delta S\) do not depend on temperature, at what temperatures is this reaction spontaneous?
109. The following reaction occurs in pure water:
\[
\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{OH}^{-}(a q)
\]
which is often abbreviated as
\[
\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
\]

For this reaction, \(\Delta G^{\circ}=79.9 \mathrm{~kJ} / \mathrm{mol}\) at \(25^{\circ} \mathrm{C}\). Calculate the value of \(\Delta G\) for this reaction at \(25^{\circ} \mathrm{C}\) when \(\left[\mathrm{OH}^{-}\right]=0.15 \mathrm{M}\) and \(\left[\mathrm{H}^{+}\right]=0.71 \mathrm{M}\).
110. Consider the dissociation of a weak acid HA \(\left(K_{\mathrm{a}}=4.5 \times 10^{-3}\right)\) in water:
\[
\mathrm{HA}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{A}^{-}(a q)
\]

Calculate \(\Delta G^{\circ}\) for this reaction at \(25^{\circ} \mathrm{C}\).
111. Consider the reaction:
\[
\mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{PCl}_{5}(g)
\]

At \(25^{\circ} \mathrm{C}, \Delta G^{\circ}=-92.50 \mathrm{~kJ}\).
Which of the following statements is(are) true?
a. This is an endothermic reaction.
b. \(\Delta S^{\circ}\) for this reaction is negative.
b. \(\Delta S^{\circ}\) for this reaction is negative.
c. If the temperature is increased, the ratio \(\frac{\mathrm{PCl}_{5}}{\mathrm{PCl}_{3}}\) will
increase.
d. \(\Delta G^{\circ}\) for this reaction has to be negative at all temperatures.
e. When \(\Delta G^{\circ}\) for this reaction is negative, then \(K\) is greater than 1.00 .
112. The equilibrium constant for a certain reaction increases by a factor of 6.67 when the temperature is increased from 300.0 K to 350.0 K . Calculate the standard change in enthalpy \(\left(\Delta H^{\circ}\right)\) for this reaction (assuming \(\Delta H^{\circ}\) is temperature-independent).

\section*{Challenge Problems}
113. Consider two perfectly insulated vessels. Vessel 1 initially contains an ice cube at \(0^{\circ} \mathrm{C}\) and water at \(0^{\circ} \mathrm{C}\). Vessel 2 initially contains an ice cube at \(0^{\circ} \mathrm{C}\) and a saltwater solution at \(0^{\circ} \mathrm{C}\). Consider the process \(\mathrm{H}_{2} \mathrm{O}(s) \rightarrow \mathrm{H}_{2} \mathrm{O}(l)\).
a. Determine the sign of \(\Delta S, \Delta S_{\text {surr }}\), and \(\Delta S_{\text {univ }}\) for the process in vessel 1.
b. Determine the sign of \(\Delta S, \Delta S_{\text {surr }}\), and \(\Delta S_{\text {univ }}\) for the process in vessel 2.
(Hint: Think about the effect that a salt has on the freezing point of a solvent.)
114. Liquid water at \(25^{\circ} \mathrm{C}\) is introduced into an evacuated, insulated vessel. Identify the signs of the following thermodynamic functions for the process that occurs: \(\Delta H, \Delta S, \Delta T_{\text {water }}, \Delta S_{\text {surr }}\), \(\Delta S_{\text {univ. }}\).
115. Using data from Appendix 4 , calculate \(\Delta H^{\circ}, \Delta G^{\circ}\), and \(K\) (at 298 K ) for the production of ozone from oxygen:
\[
3 \mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{O}_{3}(g)
\]

At 30 km above the surface of the earth, the temperature is about 230 . K and the partial pressure of oxygen is about \(1.0 \times 10^{-3} \mathrm{~atm}\). Estimate the partial pressure of ozone in equilibrium with oxygen at 30 km above the earth's surface. Is it reasonable to assume that the equilibrium between oxygen and ozone is maintained under these conditions? Explain.
116. Entropy can be calculated by a relationship proposed by Ludwig Boltzmann:
\[
S=k \ln (W)
\]
where \(k=1.38 \times 10^{-23} \mathrm{~J} / \mathrm{K}\) and \(W\) is the number of ways a particular state can be obtained. (This equation is engraved on Boltzmann's tombstone.) Calculate \(S\) for the five arrangements of particles in Table 17.1.
117. a. Using the free energy profile for a simple one-step reaction, show that at equilibrium \(K=k_{\mathrm{f}} / k_{\mathrm{r}}\), where \(k_{\mathrm{f}}\) and \(k_{\mathrm{r}}\) are the rate constants for the forward and reverse reactions. Hint: Use the relationship \(\Delta G^{\circ}=-R T \ln (K)\) and represent \(k_{\mathrm{f}}\) and \(k_{\mathrm{r}}\) using the Arrhenius equation \(\left(k=A e^{-E_{\mathrm{a}} / R T}\right)\).

b. Why is the following statement false? "A catalyst can increase the rate of a forward reaction but not the rate of the reverse reaction."
118. Consider the reaction
\[
\mathrm{H}_{2}(g)+\mathrm{Br}_{2}(g) \rightleftharpoons 2 \mathrm{HBr}(g)
\]
where \(\Delta H^{\circ}=-103.8 \mathrm{~kJ} / \mathrm{mol}\). In a particular experiment, equal moles of \(\mathrm{H}_{2}(g)\) at 1.00 atm and \(\mathrm{Br}_{2}(g)\) at 1.00 atm were mixed in a \(1.00-\mathrm{L}\) flask at \(25^{\circ} \mathrm{C}\) and allowed to reach equilibrium. Then the molecules of \(\mathrm{H}_{2}\) at equilibrium were counted using a very sensitive technique, and \(1.10 \times 10^{13}\) molecules were found. For this reaction, calculate the values of \(K, \Delta G^{\circ}\), and \(\Delta S^{\circ}\).
119. Consider the system
\[
\mathrm{A}(g) \rightleftharpoons \mathrm{B}(g)
\]
at \(25^{\circ} \mathrm{C}\).
a. Assuming that \(G_{\mathrm{A}}^{\circ}=8996 \mathrm{~J} / \mathrm{mol}\) and \(G_{\mathrm{B}}^{\circ}=11,718 \mathrm{~J} / \mathrm{mol}\), calculate the value of the equilibrium constant for this reaction.
b. Calculate the equilibrium pressures that result if 1.00 mole of \(\mathrm{A}(g)\) at 1.00 atm and 1.00 mole of \(\mathrm{B}(g)\) at 1.00 atm are mixed at \(25^{\circ} \mathrm{C}\).
c. Show by calculations that \(\Delta G=0\) at equilibrium.
120. The equilibrium constant for a certain reaction decreases from 8.84 to \(3.25 \times 10^{-2}\) when the temperature increases from \(25^{\circ} \mathrm{C}\) to \(75^{\circ} \mathrm{C}\). Estimate the temperature where \(K=1.00\) for this reaction. Estimate the value of \(\Delta S^{\circ}\) for this reaction. (Hint: Manipulate the equation in Exercise 85.)
121. If wet silver carbonate is dried in a stream of hot air, the air must have a certain concentration level of carbon dioxide to prevent silver carbonate from decomposing by the reaction
\[
\mathrm{Ag}_{2} \mathrm{CO}_{3}(s) \rightleftharpoons \mathrm{Ag}_{2} \mathrm{O}(s)+\mathrm{CO}_{2}(g)
\]
\(\Delta H^{\circ}\) for this reaction is \(79.14 \mathrm{~kJ} / \mathrm{mol}\) in the temperature range of 25 to \(125^{\circ} \mathrm{C}\). Given that the partial pressure of carbon dioxide in equilibrium with pure solid silver carbonate is \(6.23 \times 10^{-3}\) torr at \(25^{\circ} \mathrm{C}\), calculate the partial pressure of \(\mathrm{CO}_{2}\) necessary to prevent decomposition of \(\mathrm{Ag}_{2} \mathrm{CO}_{3}\) at \(110 .{ }^{\circ} \mathrm{C}\). (Hint: Manipulate the equation in Exercise 85.)
122. Carbon tetrachloride \(\left(\mathrm{CCl}_{4}\right)\) and benzene \(\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)\) form ideal solutions. Consider an equimolar solution of \(\mathrm{CCl}_{4}\) and \(\mathrm{C}_{6} \mathrm{H}_{6}\) at \(25^{\circ} \mathrm{C}\). The vapor above the solution is collected and condensed. Using the following data, determine the composition in mole fraction of the condensed vapor.
\begin{tabular}{|cc|}
\hline Substance & \(\Delta \boldsymbol{G}_{\mathfrak{f}}^{\circ}\) \\
\hline \(\mathrm{C}_{6} \mathrm{H}_{6}(I)\) & \(124.50 \mathrm{~kJ} / \mathrm{mol}\) \\
\hline \(\mathrm{C}_{6} \mathrm{H}_{6}(g)\) & \(129.66 \mathrm{~kJ} / \mathrm{mol}\) \\
\hline \(\mathrm{CCl}_{4}(I)\) & \(-65.21 \mathrm{~kJ} / \mathrm{mol}\) \\
\hline \(\mathrm{CCl}_{4}(g)\) & \(-60.59 \mathrm{~kJ} / \mathrm{mol}\) \\
\hline
\end{tabular}
123. Sodium chloride is added to water (at \(25^{\circ} \mathrm{C}\) ) until it is saturated. Calculate the \(\mathrm{Cl}^{-}\)concentration in such a solution.
\begin{tabular}{|lc|}
\hline Species & \(\Delta \boldsymbol{C}^{\circ}(\mathrm{kJ} / \mathrm{mol})\) \\
\hline \(\mathrm{NaCl}(\mathrm{s})\) & -384 \\
\hline \(\mathrm{Na}^{+}(a q)\) & -262 \\
\hline \(\mathrm{Cl}^{-}(\mathrm{aq})\) & -131 \\
\hline
\end{tabular}
124. You have a \(1.00-\mathrm{L}\) sample of hot water \(\left(90.0^{\circ} \mathrm{C}\right)\) sitting open in a \(25.0^{\circ} \mathrm{C}\) room. Eventually the water cools to \(25.0^{\circ} \mathrm{C}\) while the temperature of the room remains unchanged. Calculate \(\Delta S_{\text {sur }}\) for this process. Assume the density of water is \(1.00 \mathrm{~g} / \mathrm{cm}^{3}\) over this temperature range, and the heat capacity of water is constant over this temperature range and equal to \(75.4 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\).
125. Consider a weak acid, HX. If a \(0.10-M\) solution of HX has a pH of 5.83 at \(25^{\circ} \mathrm{C}\), what is \(\Delta G^{\circ}\) for the acid's dissociation reaction at \(25^{\circ} \mathrm{C}\) ?
126. The vaporization of ethanol
\[
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l) \rightarrow \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(g)
\]
at its normal boiling point, 351 K , has \(\Delta S=110 . \mathrm{J} / \mathrm{K} \cdot \mathrm{mol}\). Calculate \(\Delta E\) for the vaporization process at 1 atm and 351 K .
127. Consider the following reaction at \(35^{\circ} \mathrm{C}\) :
\[
2 \mathrm{NOCl}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \Delta G^{\mathrm{o}}=20 . \mathrm{kJ}
\]

If 2.0 atm of NOCl are reacted in a rigid container at \(35^{\circ} \mathrm{C}\), calculate the equilibrium partial pressure of NO.

\section*{Integrative Problems}

These problems require the integration of multiple concepts to find the solutions.
128. Some nonelectrolyte solute (molar mass \(=142 \mathrm{~g} / \mathrm{mol}\) ) was dissolved in 150. mL of a solvent (density \(=0.879 \mathrm{~g} / \mathrm{cm}^{3}\) ). The elevated boiling point of the solution was 355.4 K . What mass of solute was dissolved in the solvent? For the solvent, the enthalpy of vaporization is \(33.90 \mathrm{~kJ} / \mathrm{mol}\), the entropy of vaporization is \(95.95 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\), and the boiling-point elevation constant is \(2.5 \mathrm{~K} \cdot \mathrm{~kg} / \mathrm{mol}\).
129. For the equilibrium
\[
\mathrm{A}(g)+2 \mathrm{~B}(g) \rightleftharpoons \mathrm{C}(g)
\]
the initial concentrations are \(P_{\mathrm{A}}=P_{\mathrm{B}}=P_{\mathrm{C}}=0.100 \mathrm{~atm}\). Once equilibrium has been established, it is found that \(P_{\mathrm{C}}=0.040 \mathrm{~atm}\). What is \(\Delta G^{\circ}\) for this reaction at \(25^{\circ} \mathrm{C}\) ?
130. What is the pH of a \(0.125-M\) solution of the weak base B if \(\Delta H^{\circ}=-28.0 \mathrm{~kJ}\) and \(\Delta S^{\circ}=-175 \mathrm{~J} / \mathrm{K}\) for the following equilibrium reaction at \(25^{\circ} \mathrm{C}\) ?
\[
\mathrm{B}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{BH}^{+}(a q)+\mathrm{OH}^{-}(a q)
\]

\section*{Marathon Problem}

This problem is designed to incorporate several concepts and techniques into one situation.
131. Impure nickel, refined by smelting sulfide ores in a blast furnace, can be converted into metal from \(99.90 \%\) to \(99.99 \%\) purity by the Mond process. The primary reaction involved in the Mond process is
\[
\mathrm{Ni}(s)+4 \mathrm{CO}(g) \rightleftharpoons \mathrm{Ni}(\mathrm{CO})_{4}(g)
\]
a. Without referring to Appendix 4, predict the sign of \(\Delta S^{\circ}\) for the above reaction. Explain.
b. The spontaneity of the above reaction is temperaturedependent. Predict the sign of \(\Delta S_{\text {surr }}\) for this reaction. Explain.
c. For \(\mathrm{Ni}(\mathrm{CO})_{4}(g), \Delta H_{\mathrm{f}}^{\circ}=-607 \mathrm{~kJ} / \mathrm{mol}\) and \(S^{\circ}=417 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\) at 298 K . Using these values and data in Appendix 4, calculate \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) for the above reaction.
d. Calculate the temperature at which \(\Delta G^{\circ}=0(K=1)\) for the above reaction, assuming that \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
e. The first step of the Mond process involves equilibrating impure nickel with \(\mathrm{CO}(g)\) and \(\mathrm{Ni}(\mathrm{CO})_{4}(g)\) at about \(50^{\circ} \mathrm{C}\). The purpose of this step is to convert as much nickel as possible into the gas phase. Calculate the equilibrium constant for the above reaction at \(50 .{ }^{\circ} \mathrm{C}\).
f. In the second step of the Mond process, the gaseous \(\mathrm{Ni}(\mathrm{CO})_{4}\) is isolated and heated to \(227^{\circ} \mathrm{C}\). The purpose of this step is to deposit as much nickel as possible as pure solid (the reverse of the preceding reaction). Calculate the equilibrium constant for the preceding reaction at \(227^{\circ} \mathrm{C}\).
g. Why is temperature increased for the second step of the Mond process?
h. The Mond process relies on the volatility of \(\mathrm{Ni}(\mathrm{CO})_{4}\) for its success. Only pressures and temperatures at which \(\mathrm{Ni}(\mathrm{CO})_{4}\) is a gas are useful. A recently developed variation of the Mond process carries out the first step at higher pressures and a temperature of \(152^{\circ} \mathrm{C}\). Estimate the maximum pressure of \(\mathrm{Ni}(\mathrm{CO})_{4}(g)\) that can be attained before the gas will liquefy at \(152^{\circ} \mathrm{C}\). The boiling point for \(\mathrm{Ni}(\mathrm{CO})_{4}\) is \(42^{\circ} \mathrm{C}\) and the enthalpy of vaporization is \(29.0 \mathrm{~kJ} / \mathrm{mol}\).
[Hint: The phase change reaction and the corresponding equilibrium expression are
\[
\mathrm{Ni}(\mathrm{CO})_{4}(l) \rightleftharpoons \mathrm{Ni}(\mathrm{CO})_{4}(g) \quad K=P_{\mathrm{Ni}(\mathrm{CO})_{4}}
\]
\(\mathrm{Ni}(\mathrm{CO})_{4}(g)\) will liquefy when the pressure of \(\mathrm{Ni}(\mathrm{CO})_{4}\) is greater than the \(K\) value.]

The Hiriko (meaning urban in Basque) is an electric car that folds up to park in a 1.5-meter space. The car was designed at MIT and is produced in Spain by a consortium of small businesses. (© Kika/ZumaPress/Newscom.com)

Electrochemistry constitutes one of the most important interfaces between chemistry and everyday life. Every time you start your car, turn on your calculator, use your smartphone, or listen to a radio at the beach, you are depending on electrochemical reactions. Our society sometimes seems to run almost entirely on batteries. Certainly the advent of small, dependable batteries along with silicon-chip technology has made possible the tiny calculators, portable audio players, and cell phones that we take for granted.

Electrochemistry is important in other less obvious ways. For example, the corrosion of iron, which has tremendous economic implications, is an electrochemical process. In addition, many important industrial materials such as aluminum, chlorine, and sodium hydroxide are prepared by electrolytic processes. In analytical chemistry, electrochemical techniques use electrodes that are specific for a given molecule or ion, such as \(\mathrm{H}^{+}\)( pH meters), \(\mathrm{F}^{-}, \mathrm{Cl}^{-}\), and many others. These increasingly important methods are used to analyze for trace pollutants in natural waters or for the tiny quantities of chemicals in human blood that may signal the development of a specific disease.

Electrochemistry is best defined as the study of the interchange of chemical and electrical energy. It is primarily concerned with two processes that involve oxidationreduction reactions: the generation of an electric current from a spontaneous chemical reaction and, the opposite process, the use of a current to produce chemical change.

\subsection*{18.1 Galvanic Cells}

To understand how a redox reaction can be used to generate a current, let's consider the reaction between \(\mathrm{MnO}_{4}^{-}\)and \(\mathrm{Fe}^{2+}\) :
\[
8 \mathrm{H}^{+}(a q)+\mathrm{MnO}_{4}^{-}(a q)+5 \mathrm{Fe}^{2+}(a q) \longrightarrow \mathrm{Mn}^{2+}(a q)+5 \mathrm{Fe}^{3+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)
\]

In this reaction, \(\mathrm{Fe}^{2+}\) is oxidized and \(\mathrm{MnO}_{4}^{-}\)is reduced; electrons are transferred from \(\mathrm{Fe}^{2+}\) (the reducing agent) to \(\mathrm{MnO}_{4}^{-}\)(the oxidizing agent).

It is useful to break a redox reaction into half-reactions, one involving oxidation and one involving reduction. For the previous reaction, the half-reactions are
\[
\begin{array}{ll}
\text { Reduction: } & 8 \mathrm{H}^{+}+\mathrm{MnO}_{4}^{-}+5 \mathrm{e}^{-} \longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O} \\
\text { Oxidation: } & 5\left(\mathrm{Fe}^{2+} \longrightarrow \mathrm{Fe}^{3+}+\mathrm{e}^{-}\right)
\end{array}
\]

The multiplication of the second half-reaction by 5 indicates that this reaction must occur five times for each time the first reaction occurs. The balanced overall reaction is the sum of the half-reactions.

When \(\mathrm{MnO}_{4}^{-}\)and \(\mathrm{Fe}^{2+}\) are present in the same solution, the electrons are transferred directly when the reactants collide. Under these conditions, no useful work is obtained from the chemical energy involved in the reaction, which instead is released as heat. How can we harness this energy? The key is to separate the oxidizing agent from the reducing agent, thus requiring the electron transfer to occur through a wire. The current produced in the wire by the electron flow can then be directed through a device, such as an electric motor, to provide useful work.

For example, consider the system illustrated in Fig. 18.1. If our reasoning has been correct, electrons should flow through the wire from \(\mathrm{Fe}^{2+}\) to \(\mathrm{MnO}_{4}^{-}\). However, when we construct the apparatus as shown, no flow of electrons is apparent. Why? Careful observation shows that when we connect the wires from the two compartments, current flows for an instant and then ceases. The current stops flowing because of charge buildups in the two compartments. If electrons flowed from the right to the left compartment in the apparatus as shown, the left compartment (receiving electrons) would become negatively charged, and the right compartment (losing electrons) would become positively charged. Creating a charge separation of this type requires a large amount of energy. Thus sustained electron flow cannot occur under these conditions.

However, we can solve this problem very simply. The solutions must be connected so that ions can flow to keep the net charge in each compartment zero. This connection

FIGURE 18.1 Schematic of a method to separate the oxidizing and reducing agents of a redox reaction. (The solutions also contain counterions to balance the charge.)

A galvanic cell uses a spontaneous redox reaction to produce a current that can be used to do work.

Oxidation occurs at the anode. Reduction occurs at the cathode.

FIGURE 18.2 Galvanic cells can contain a salt bridge as in (a) or a porousdisk connection as in (b). A salt bridge contains a strong electrolyte held in a Jello-like matrix. A porous disk contains tiny passages that allow hindered flow of ions.

might involve a salt bridge (a U-tube filled with an electrolyte) or a porous disk in a tube connecting the two solutions (Fig. 18.2). Either of these devices allows ions to flow without extensive mixing of the solutions. When we make the provision for ion flow, the circuit is complete. Electrons flow through the wire from reducing agent to oxidizing agent, and ions flow from one compartment to the other to keep the net charge zero.

We now have covered all the essential characteristics of a galvanic cell, a device in which chemical energy is changed to electrical energy. (The opposite process is called electrolysis and will be considered in Section 18.7.)

The reaction in an electrochemical cell occurs at the interface between the electrode and the solution where the electron transfer occurs. The electrode compartment in which oxidation occurs is called the anode; the electrode compartment in which reduction occurs is called the cathode (Fig. 18.3).

\section*{Cell Potential}

A galvanic cell consists of an oxidizing agent in one compartment that pulls electrons through a wire from a reducing agent in the other compartment. The "pull," or driving force, on the electrons is called the cell potential ( \(\mathscr{E}_{\text {cell }}\) ), or the electromotive force (emf) of the cell. The unit of electrical potential is the volt (abbreviated V), which is defined as 1 joule of work per coulomb of charge transferred.

b

FIGURE 18.3 An electrochemical process involves electron transfer at the interface between the electrode and the solution. (a) The species in the solution acting as the reducing agent supplies electrons to the anode. (b) The species in the solution acting as the oxidizing agent receives electrons from the cathode.

FIGURE 18.4 Digital voltmeters draw only a negligible current and are convenient to use to measure the cell potential.

A volt is 1 joule of work per coulomb of charge transferred: \(1 \mathrm{~V}=1 \mathrm{~J} / \mathrm{C}\).

\subsection*{18.2 Standard Reduction Potentials}

The name galvanic cell honors Luigi Galvani (1737-1798), an Italian scientist generally credited with the discovery of electricity. These cells are sometimes called voltaic cells after Alessandro Volta (1745-1827), another Italian, who first constructed cells of this type around 1800.

How can we measure the cell potential? One possible instrument is a crude voltmeter, which works by drawing current through a known resistance. However, when current flows through a wire, the frictional heating that occurs wastes some of the potentially useful energy of the cell. A traditional voltmeter will therefore measure a potential that is less than the maximum cell potential. The key to determining the maximum potential is to do the measurement under conditions of zero current so that no energy is wasted. Traditionally, this has been accomplished by inserting a variablevoltage device (powered from an external source) in opposition to the cell potential. The voltage on this instrument (called a potentiometer) is adjusted until no current flows in the cell circuit. Under such conditions, the cell potential is equal in magnitude and opposite in sign to the voltage setting of the potentiometer. This value represents the maximum cell potential, since no energy is wasted heating the wire. More recently, advances in electronic technology have allowed the design of digital voltmeters that draw only a negligible amount of current (Fig. 18.4). Since these instruments are more convenient to use, they have replaced potentiometers in the modern laboratory.

The reaction in a galvanic cell is always an oxidation-reduction reaction that can be broken down into two half-reactions. It would be convenient to assign a potential to each half-reaction so that when we construct a cell from a given pair of half-reactions we can obtain the cell potential by summing the half-cell potentials. For example, the observed potential for the cell shown in Fig. 18.5(a) is 0.76 V, and the cell reaction* is
\[
2 \mathrm{H}^{+}(a q)+\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{H}_{2}(g)
\]

\footnotetext{
*In this text we will follow the convention of indicating the physical states of the reactants and products only in the overall redox reaction. For simplicity, half-reactions will not include the physical states.
}

FIGURE 18.5 (a) A galvanic cell involving the reactions \(\mathrm{Zn} \rightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-}\) (at the anode) and \(2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \rightarrow \mathrm{H}_{2}\) (at the cathode) has a potential of 0.76 V . (b) The standard hydrogen electrode where \(\mathrm{H}_{2}(g)\) at 1 atm is passed over a platinum electrode in contact with \(1 \mathrm{M} \mathrm{H}^{+}\)ions. This electrode process (assuming ideal behavior) is arbitrarily assigned a value of exactly zero volts.

For this cell, the anode compartment contains a zinc metal electrode with \(\mathrm{Zn}^{2+}\) and \(\mathrm{SO}_{4}{ }^{2-}\) ions in aqueous solution. The anode reaction is the oxidation half-reaction:
\[
\mathrm{Zn} \longrightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-}
\]

The zinc metal, in producing \(\mathrm{Zn}^{2+}\) ions that go into solution, is giving up electrons, which flow through the wire. For now, we will assume that all cell components are in their standard states, so in this case the solution in the anode compartment will contain \(1 M \mathrm{Zn}^{2+}\). The cathode reaction of this cell is the reduction half-reaction:
\[
2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}
\]

The cathode consists of a platinum electrode (used because it is a chemically inert conductor) in contact with \(1 M \mathrm{H}^{+}\)ions and bathed by hydrogen gas at 1 atm . Such an electrode, called the standard hydrogen electrode, is shown in Fig. 18.5(b).

Although we can measure the total potential of this cell \((0.76 \mathrm{~V})\), there is no way to measure the potentials of the individual electrode processes. Thus, if we want potentials for the half-reactions (half-cells), we must arbitrarily divide the total cell potential. For example, if we assign the reaction

\footnotetext{
Standard states were discussed in Section 6.4.
}
where
\[
\begin{gathered}
2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2} \\
{\left[\mathrm{H}^{+}\right]=1 M \quad \text { and } \quad P_{\mathrm{H}_{2}}=1 \mathrm{~atm}}
\end{gathered}
\]
a potential of exactly zero volts, then the reaction
\[
\mathrm{Zn} \longrightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-}
\]
will have a potential of 0.76 V because
where the superscript \({ }^{\circ}\) indicates that standard states are used. In fact, by setting the standard potential for the half-reaction \(2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \rightarrow \mathrm{H}_{2}\) equal to zero, we can assign values to all other half-reactions.

For example, the measured potential for the cell shown in Fig. 18.6 is 1.10 V . The cell reaction is
\[
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s)
\]
which can be divided into the half-reactions
\[
\begin{array}{ll}
\text { Anode: } & \mathrm{Zn} \longrightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-} \\
\text {Cathode: } & \mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}
\end{array}
\]

Then
\[
\mathscr{E}_{\text {cell }}^{\circ}=\mathscr{E}_{\mathrm{Zn}}^{\circ} \longrightarrow \mathrm{Zn}^{2+}+\mathscr{E}_{\mathrm{Cu}^{2+}}^{\circ} \longrightarrow \mathrm{Cu}
\]

Since \(\mathscr{E}_{\mathrm{Zn} \rightarrow \mathrm{Zn}^{2+}}^{\circ}\) was earlier assigned a value of 0.76 V , the value of \(\mathscr{E}_{\mathrm{Cu}^{2+} \rightarrow \mathrm{Cu}}^{\circ}\) must be 0.34 V because
\[
1.10 \mathrm{~V}=0.76 \mathrm{~V}+0.34 \mathrm{~V}
\]

The standard hydrogen potential is the reference potential against which all half-reaction potentials are assigned.

All half-reactions are given as reduction processes in standard tables.

The scientific community has universally accepted the half-reaction potentials based on the assignment of 0 V to the process \(2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \rightarrow \mathrm{H}_{2}\) (under standard conditions where ideal behavior is assumed). However, before we can use these values to calculate cell potentials, we need to understand several essential characteristics of half-cell potentials.

The accepted convention is to give the potentials of half-reactions as reduction processes. For example:
\[
\begin{aligned}
2 \mathrm{H}^{+}+2 \mathrm{e}^{-} & \longrightarrow \mathrm{H}_{2} \\
\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} & \longrightarrow \mathrm{Cu} \\
\mathrm{Zn}^{2+}+2 \mathrm{e}^{-} & \longrightarrow \mathrm{Zn}
\end{aligned}
\]

The \(\mathscr{E}^{\circ}\) values corresponding to reduction half-reactions with all solutes at \(1 M\) and all gases at 1 atm are called standard reduction potentials. Standard reduction potentials for the most common half-reactions are given in Table 18.1 and Appendix 5.5.

TABLE 18.1 \| Standard Reduction Potentials at \(25^{\circ} \mathrm{C}(298 \mathrm{~K})\) for Many Common Half-Reactions
\begin{tabular}{|c|c|c|c|}
\hline Half-Reaction & \(\mathscr{E}^{\circ}(\mathrm{V})\) & Half-Reaction & \(\mathscr{E}^{\circ}(\mathrm{V})\) \\
\hline \(\mathrm{F}_{2}+2 \mathrm{e}^{-} \rightarrow 2 \mathrm{~F}^{-}\) & 2.87 & \(\mathrm{O}_{2}+2 \mathrm{H}_{2} \mathrm{O}+4 \mathrm{e}^{-} \rightarrow 4 \mathrm{OH}^{-}\) & 0.40 \\
\hline \(\mathrm{Ag}^{2+}+\mathrm{e}^{-} \rightarrow \mathrm{Ag}^{+}\) & 1.99 & \(\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \rightarrow \mathrm{Cu}\) & 0.34 \\
\hline \(\mathrm{Co}^{3-}+\mathrm{e}^{-} \rightarrow \mathrm{Co}^{2-}\) & 1.82 & \(\mathrm{Hg}_{2} \mathrm{Cl}_{2}+2 \mathrm{e}^{-} \rightarrow 2 \mathrm{Hg}+2 \mathrm{Cl}^{-}\) & 0.27 \\
\hline \(\mathrm{H}_{2} \mathrm{O}_{2}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \rightarrow 2 \mathrm{H}_{2} \mathrm{O}\) & 1.78 & \(\mathrm{AgCl}+\mathrm{e}^{-} \rightarrow \mathrm{Ag}+\mathrm{Cl}^{-}\) & 0.22 \\

\hline
\end{tabular}

When a half-reaction is reversed, the sign of \(\mathscr{E}^{\circ}\) is reversed.

When a half-reaction is multiplied by an integer, \(\mathscr{E}^{\circ}\) remains the same.

Combining two half-reactions to obtain a balanced oxidation-reduction reaction often requires two manipulations:
1. One of the reduction half-reactions must be reversed (since redox reactions must involve a substance being oxidized and a substance being reduced). The halfreaction with the largest positive potential will run as written (as a reduction), and the other half-reaction will be forced to run in reverse (will be the oxidation reaction). The net potential of the cell will be the difference between the two. Since the reduction process occurs at the cathode and the oxidation process occurs at the anode, we can write
\[
\mathscr{E}_{\text {cell }}^{\circ}=\mathscr{E}^{\circ}(\text { cathode })-\mathscr{E}^{\circ}(\text { anode })
\]

Because subtraction means "change the sign and add," in the examples done here we will change the sign of the oxidation (anode) reaction when we reverse it and add it to the reduction (cathode) reaction.
2. Since the number of electrons lost must equal the number gained, the halfreactions must be multiplied by integers as necessary to achieve the balanced equation. However, the value of \(\mathscr{E}^{\circ}\) is not changed when a half-reaction is multiplied by an integer. Since a standard reduction potential is an intensive property (it does not depend on how many times the reaction occurs), the potential is not multiplied by the integer required to balance the cell reaction.

Consider a galvanic cell based on the redox reaction
\[
\mathrm{Fe}^{3+}(a q)+\mathrm{Cu}(s) \longrightarrow \mathrm{Cu}^{2+}(a q)+\mathrm{Fe}^{2+}(a q)
\]

The pertinent half-reactions are
\[
\begin{array}{rlrl}
\mathrm{Fe}^{3+}+\mathrm{e}^{-} & \mathrm{Fe}^{2+} & \mathscr{E}^{\circ}=0.77 \mathrm{~V} \\
\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu} & \mathscr{E}^{\circ}=0.34 \mathrm{~V} \tag{2}
\end{array}
\]

To balance the cell reaction and calculate the standard cell potential, reaction (2) must be reversed:
\[
\mathrm{Cu} \longrightarrow \mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \quad-\mathscr{E}^{\circ}=-0.34 \mathrm{~V}
\]

Note the change in sign for the \(\mathscr{E}^{\circ}\) value. Now, since each Cu atom produces two electrons but each \(\mathrm{Fe}^{3+}\) ion accepts only one electron, reaction (1) must be multiplied by 2 :
\[
2 \mathrm{Fe}^{3+}+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{Fe}^{2+} \quad \mathscr{E} \circ=0.77 \mathrm{~V}
\]

Note that \(\mathscr{E}^{\circ}\) is not changed in this case.
Now we can obtain the balanced cell reaction by summing the appropriately modified half-reactions:
\begin{tabular}{rlrl}
\(2 \mathrm{Fe}^{3+}+2 \mathrm{e}^{-}\) & \(\longrightarrow 2 \mathrm{Fe}^{2+}\) & \(\mathscr{E}\) (cathode) \(=-0.77 \mathrm{~V}\) \\
\(\mathrm{Cu} \longrightarrow \mathrm{Cu}^{2+}+2 \mathrm{e}^{-}\) & \(-\mathscr{E}\) (anode) \(=-0.34 \mathrm{~V}\) \\
\hline Cellr eaction: \(\mathrm{Cu}(s)+2 \mathrm{Fe}^{3+}(a q) \longrightarrow \mathrm{Cu}^{2+}(a q)+2 \mathrm{Fe}^{2+}(a q)\) & \(\mathscr{E}_{\text {cell }}^{\circ}=\mathscr{E}^{\circ}(\) cathode \()-\mathscr{E}^{\circ}(\) anode \()\) \\
& & \(=0.77 \mathrm{~V}-0.34 \mathrm{~V}=0.43 \mathrm{~V}\)
\end{tabular}
 metal from an aqueous \(\mathrm{Cu}^{2+}\) solution? Use Table 18.1 to determine several metals you can place in the solution to plate copper metal from the solution. Defend your choices. Why can Zn not be plated out from an aqueous solution of \(\mathrm{Zn}^{2+}\) using the choices in Table 18.1?

\section*{INTERACTIVE EXAMPLE 18.1 Galvanic Cells}
a. Consider a galvanic cell based on the reaction
\[
\mathrm{Al}^{3+}(a q)+\mathrm{Mg}(s) \longrightarrow \mathrm{Al}(s)+\mathrm{Mg}^{2+}(a q)
\]

The half-reactions are
\[
\begin{array}{cl}
\mathrm{Al}^{3+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al} & \mathscr{C}^{\circ}=-1.66 \mathrm{~V} \\
\mathrm{Mg}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Mg} & \mathscr{E}^{\circ}=-2.37 \mathrm{~V} \tag{2}
\end{array}
\]

Give the balanced cell reaction, and calculate \(\mathscr{E}^{\circ}\) for the cell.
b. A galvanic cell is based on the reaction
\[
\mathrm{MnO}_{4}^{-}(a q)+\mathrm{H}^{+}(a q)+\mathrm{ClO}_{3}^{-}(a q) \longrightarrow \mathrm{ClO}_{4}^{-}(a q)+\mathrm{Mn}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
\]

The half-reactions are
\[
\begin{align*}
\mathrm{MnO}_{4}^{-}+5 \mathrm{e}^{-}+8 \mathrm{H}^{+} \longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ}=1.51 \mathrm{~V}  \tag{1}\\
\mathrm{ClO}_{4}^{-}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{ClO}_{3}^{-}+\mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ}=1.19 \mathrm{~V} \tag{2}
\end{align*}
\]

Give the balanced cell reaction, and calculate \(\mathscr{E}^{\circ}\) for the cell.

\section*{SOLUTION}
a. The half-reaction involving magnesium must be reversed and since this is the oxidation process, it is the anode:
\[
\mathrm{Mg} \longrightarrow \mathrm{Mg}^{2+}+2 \mathrm{e}^{-} \quad-\mathscr{E}^{\circ}(\text { anode })=-(-2.37 \mathrm{~V})=2.37 \mathrm{~V}
\]

Also, since the two half-reactions involve different numbers of electrons, they must be multiplied by integers as follows:
\begin{tabular}{rlrl}
\(2\left(\mathrm{Al}^{3+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al}\right)\) & \begin{tabular}{rl}
\(\mathscr{E}^{\circ}(\) cathode \()\) & \(=-1.66 \mathrm{~V}\) \\
\(3\left(\mathrm{Mg} \longrightarrow \mathrm{Mg}^{2+}+2 \mathrm{e}^{-}\right)\) & \(-\mathscr{E}^{\circ}(\) anode \()\)
\end{tabular}\(=2.37 \mathrm{~V}\) \\
\hline \(2 \mathrm{Al}^{3+}(a q)+3 \mathrm{Mg}(s) \longrightarrow 2 \mathrm{Al}(s)+3 \mathrm{Mg}^{2+}(a q)\) & \(\mathscr{E}_{\text {cell }}^{\circ}\) & \(=\mathscr{E}^{\circ}(\) cathode \()-\mathscr{E}^{\circ}(\) anode \()\) \\
& & \(=-1.66 \mathrm{~V}+2.37 \mathrm{~V}=0.71 \mathrm{~V}\)
\end{tabular}
b. Half-reaction (2) must be reversed (it is the anode), and both half-reactions must be multiplied by integers to make the number of electrons equal:
\[
\begin{array}{rlrl}
2\left(\mathrm{MnO}_{4}^{-}+5 \mathrm{e}^{-}+8 \mathrm{H}^{+}\right. & \left.\longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O}\right) & \mathscr{E} \circ(\text { cathode }) & =1.51 \mathrm{~V} \\
5\left(\mathrm{ClO}_{3}^{-}+\mathrm{H}_{2} \mathrm{O}\right. & \left.\longrightarrow \mathrm{ClO}_{4}^{-}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-}\right) & -\mathscr{E}^{\circ}(\text { anode }) & =-1.19 \mathrm{~V} \\
\hline 2 \mathrm{MnO}_{4}^{-}(a q)+6 \mathrm{H}^{+}(a q)+5 \mathrm{ClO}_{3}^{-}(a q) \longrightarrow & \mathscr{E}_{\text {cell }} & =\mathscr{E}^{\circ}(\text { cathode })-\mathscr{E}^{\circ}(\text { anode }) \\
2 \mathrm{Mn}^{2+}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)+5 \mathrm{ClO}_{4}^{-}(a q) & & =1.51 \mathrm{~V}-1.19 \mathrm{~V}=0.32 \mathrm{~V}
\end{array}
\]

See Exercises 18.39 and 18.40

\section*{Line Notation}

We now will introduce a handy line notation used to describe electrochemical cells. In this notation the anode components are listed on the left and the cathode components are listed on the right, separated by double vertical lines (indicating the salt bridge or porous disk). For example, the line notation for the cell described in Example 18.1(a) is
\[
\operatorname{Mg}(s)\left|\mathrm{Mg}^{2+}(a q)\right|\left|\mathrm{Al}^{3+}(a q)\right| \mathrm{Al}(s)
\]

In this notation a phase difference (boundary) is indicated by a single vertical line. Thus, in this case, vertical lines occur between the solid Mg metal and the \(\mathrm{Mg}^{2+}\) in

A galvanic cell runs spontaneously in the direction that gives a positive value for \(\mathscr{E}_{\text {cell }}\).

FIGURE 18.7 The schematic of a galvanic cell based on the half-reactions:
\[
\begin{array}{r}
\mathrm{Fe} \longrightarrow \mathrm{Fe}^{2+}+2 \mathrm{e}^{-} \\
\mathrm{MnO}_{4}^{-}+5 \mathrm{e}^{-}+8 \mathrm{H}^{+} \longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O}
\end{array}
\]
aqueous solution and between solid Al and \(\mathrm{Al}^{3+}\) in aqueous solution. Also note that the substance constituting the anode is listed at the far left and the substance constituting the cathode is listed at the far right.

For the cell described in Example 18.1(b), all the components involved in the oxidation-reduction reaction are ions. Since none of these dissolved ions can serve as an electrode, a nonreacting (inert) conductor must be used. The usual choice is platinum. Thus, for the cell described in Example 18.1(b), the line notation is
\[
\mathrm{Pt}(s)\left|\mathrm{ClO}_{3}^{-}(a q), \mathrm{ClO}_{4}^{-}(a q), \mathrm{H}^{+}(a q)\right|\left|\mathrm{H}^{+}(a q), \mathrm{MnO}_{4}^{-}(a q), \mathrm{Mn}^{2+}(a q)\right| \operatorname{Pt}(s)
\]

\section*{Complete Description of a Galvanic Cell}

Next we want to consider how to describe a galvanic cell fully, given just its halfreactions. This description will include the cell reaction, the cell potential, and the physical setup of the cell. Let's consider a galvanic cell based on the following half-reactions:
\[
\begin{array}{clrl}
\mathrm{Fe}^{2+}+2 \mathrm{e}^{-} & \mathrm{Fe} & \mathscr{E}^{\circ}=-0.44 \mathrm{~V} \\
\mathrm{MnO}_{4}^{-}+5 \mathrm{e}^{-}+8 \mathrm{H}^{+} \longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ}=1.51 \mathrm{~V}
\end{array}
\]

In a working galvanic cell, one of these reactions must run in reverse. Which one?
We can answer this question by considering the sign of the potential of a working cell: A cell will always run spontaneously in the direction that produces a positive cell potential. Thus, in the present case, it is clear that the half-reaction involving iron must be reversed, since this choice leads to a positive cell potential:
\[
\begin{gathered}
\mathrm{Fe} \longrightarrow \mathrm{Fe}^{2+}+2 \mathrm{e}^{-} \quad-\mathscr{E}^{\circ}=0.44 \mathrm{~V} \quad \text { Anode reaction } \\
\mathrm{MnO}_{4}^{-}+5 \mathrm{e}^{-}+8 \mathrm{H}^{+} \longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O} \quad \mathscr{E}^{\circ}=1.51 \mathrm{~V} \quad \text { Cathode reaction } \\
\text { where } \quad \mathscr{E}_{\text {cell }}^{\circ}=\mathscr{E}^{\circ}(\text { cathode })-\mathscr{E}^{\circ}(\text { anode })=1.51 \mathrm{~V}+0.44 \mathrm{~V}=1.95 \mathrm{~V}
\end{gathered}
\]

The balanced cell reaction is obtained as follows:
\[
\begin{aligned}
5(\mathrm{Fe} & \left.\longrightarrow \mathrm{Fe}^{2+}+2 \mathrm{e}^{-}\right) \\
2\left(\mathrm{MnO}_{4}^{-}+5 \mathrm{e}^{-}+8 \mathrm{H}^{+}\right. & \left.\longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O}\right) \\
2 \mathrm{MnO}_{4}^{-}(a q)+5 \mathrm{Fe}(s)+16 \mathrm{H}^{+}(a q) & \longrightarrow 5 \mathrm{Fe}^{2+}(a q)+2 \mathrm{Mn}^{2+}(a q)+8 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
\]

Now consider the physical setup of the cell, shown schematically in Fig. 18.7. In the left compartment the active components in their standard states are pure metallic iron \((\mathrm{Fe})\) and \(1.0 \mathrm{M} \mathrm{Fe}^{2+}\). The anion present depends on the iron salt used. In this compartment the anion does not participate in the reaction but simply balances the charge. The half-reaction that takes place at this electrode is
\[
\mathrm{Fe} \longrightarrow \mathrm{Fe}^{2+}+2 \mathrm{e}^{-}
\]
which is an oxidation reaction, so this compartment is the anode. The electrode consists of pure iron metal.

In the right compartment the active components in their standard states are 1.0 M \(\mathrm{MnO}_{4}{ }^{-}, 1.0 \mathrm{M} \mathrm{H}^{+}\), and \(1.0 \mathrm{M} \mathrm{Mn}^{2+}\), with appropriate unreacting ions (often called counterions) to balance the charge. The half-reaction in this compartment is
\[
\mathrm{MnO}_{4}^{-}+5 \mathrm{e}^{-}+8 \mathrm{H}^{+} \longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O}
\]
which is a reduction reaction, so this compartment is the cathode. Since neither \(\mathrm{MnO}_{4}{ }^{-}\) nor \(\mathrm{Mn}^{2+}\) ions can serve as the electrode, a nonreacting conductor such as platinum must be used.

The next step is to determine the direction of electron flow. In the left compartment the half-reaction involves the oxidation of iron:
\[
\mathrm{Fe} \longrightarrow \mathrm{Fe}^{2+}+2 \mathrm{e}^{-}
\]

In the right compartment the half-reaction is the reduction of \(\mathrm{MnO}_{4}{ }^{-}\):
\[
\mathrm{MnO}_{4}^{-}+5 \mathrm{e}^{-}+8 \mathrm{H}^{+} \longrightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O}
\]

Thus the electrons flow from Fe to \(\mathrm{MnO}_{4}{ }^{-}\)in this cell, or from the anode to the cathode, as is always the case. The line notation for this cell is
\[
\mathrm{Fe}(s)\left|\mathrm{Fe}^{2+}(a q)\right|\left|\mathrm{MnO}_{4}^{-}(a q), \mathrm{Mn}^{2+}(a q)\right| \operatorname{Pt}(s)
\]

\section*{LET'S REVIEW Description of a Galvanic Cell}

A complete description of a galvanic cell usually includes four items:
" The cell potential (always positive for a galvanic cell where
\(\mathscr{E}_{\text {cell }}^{\circ}=\mathscr{E}^{\circ}(\) cathode \()-\mathscr{E}^{\circ}(\) anode \(\left.)\right)\) and the balanced cell reaction.
» The direction of electron flow, obtained by inspecting the half-reactions and using the direction that gives a positive \(\mathscr{E}_{\text {cell }}\).
" Designation of the anode and cathode.
" The nature of each electrode and the ions present in each compartment. A chemically inert conductor is required if none of the substances participating in the half-reaction is a conducting solid.

\section*{EXAMPLE 18.2 Description of a Galvanic Cell}

Describe completely the galvanic cell based on the following half-reactions under standard conditions:
\[
\begin{array}{ll}
\mathrm{Ag}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Ag} \\
\mathrm{Fe}^{3+}+\mathrm{e}^{-} \longrightarrow \mathrm{Fe}^{2+} & \mathscr{E}^{\circ}=0.80 \mathrm{~V}  \tag{2}\\
\mathscr{E}^{\circ}=0.77 \mathrm{~V}
\end{array}
\]

SOLUTION

FIGURE 18.8 Schematic diagram for the galvanic cell based on the half-reactions:
\[
\begin{aligned}
\mathrm{Ag}^{+}+\mathrm{e}^{-} & \longrightarrow \mathrm{Ag} \\
\mathrm{Fe}^{2+} & \longrightarrow \mathrm{Fe}^{3+}+\mathrm{e}^{-}
\end{aligned}
\]
\[
\begin{aligned}
& \text { - Since a positive } \mathscr{E}_{\text {cell }}^{\circ} \text { value is required, reaction (2) must run in reverse: } \\
& \mathrm{Ag}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Ag} \quad \mathscr{E}^{\circ}(\text { cathode })=0.80 \mathrm{~V} \\
& \mathrm{Fe}^{2+} \longrightarrow \mathrm{Fe}^{3+}+\mathrm{e}^{-} \quad-\mathscr{E}^{\circ}(\text { anode })=-0.77 \mathrm{~V}
\end{aligned}
\]
- Since \(\mathrm{Ag}^{+}\)receives electrons and \(\mathrm{Fe}^{2+}\) loses electrons in the cell reaction, the electrons will flow from the compartment containing \(\mathrm{Fe}^{2+}\) to the compartment containing \(\mathrm{Ag}^{+}\).
- Oxidation occurs in the compartment containing \(\mathrm{Fe}^{2+}\) (electrons flow from \(\mathrm{Fe}^{2+}\) to \(\mathrm{Ag}^{+}\)). Hence this compartment functions as the anode. Reduction occurs in the compartment containing \(\mathrm{Ag}^{+}\), so this compartment functions as the cathode.
- The electrode in the \(\mathrm{Ag} / \mathrm{Ag}^{+}\)compartment is silver metal, and an inert conductor, such as platinum, must be used in the \(\mathrm{Fe}^{2+} / \mathrm{Fe}^{3+}\) compartment. Appropriate counterions are assumed to be present. The diagram for this cell is shown in Fig. 18.8. The line notation for this cell is
\[
\operatorname{Pt}(s)\left|\mathrm{Fe}^{2+}(a q), \mathrm{Fe}^{3+}(a q)\right|\left|\mathrm{Ag}^{+}(a q)\right| \mathrm{Ag}(s)
\]

\subsection*{18.3 Cell Potential, Electrical Work, and Free Energy}

So far we have considered electrochemical cells in a very practical fashion without much theoretical background. The next step will be to explore the relationship between thermodynamics and electrochemistry.

The work that can be accomplished when electrons are transferred through a wire depends on the "push" (the thermodynamic driving force) behind the electrons. This driving force (the emf) is defined in terms of a potential difference (in volts) between two points in the circuit. Recall that a volt represents a joule of work per coulomb of charge transferred:
\[
\mathrm{emf}=\text { potential difference }(\mathrm{V})=\frac{\text { work }(\mathrm{J})}{\text { charge }(\mathrm{C})}
\]

Thus 1 joule of work is produced or required (depending on the direction) when 1 coulomb of charge is transferred between two points in the circuit that differ by a potential of 1 volt.

In this book, work is viewed from the point of view of the system. Thus work flowing out of the system is indicated by a minus sign. When a cell produces a current, the cell potential is positive, and the current can be used to do work-to run a motor, for instance. Thus the cell potential \(\mathscr{E}\) and the work \(w\) have opposite signs:

\(\Delta\)
A workman using a battery-powered drill on a construction site.

\footnotetext{
Work is never the maximum possible if any current is flowing.
}
\[
\begin{aligned}
& \mathscr{E}=\frac{-w}{q} \leftarrow \text { Work } \\
& -w=q \mathscr{E}
\end{aligned}
\]

Therefore,
From this equation it can be seen that the maximum work in a cell would be obtained at the maximum cell potential:
\[
-w_{\max }=q \mathscr{E}_{\max } \quad \text { or } \quad w_{\max }=-q \mathscr{E}_{\max }
\]

However, there is a problem. To obtain electrical work, current must flow. When current flows, some energy is inevitably wasted through frictional heating, and the maximum work is not obtained. This reflects the important general principle introduced in Section 17.10: In any real, spontaneous process some energy is always wasted-the actual work realized is always less than the calculated maximum. This is a consequence of the fact that the entropy of the universe must increase in any spontaneous process. Recall from Section 17.10 that the only process from which maximum work could be realized is the hypothetical reversible process. For a galvanic cell this would involve an infinitesimally small current flow and thus an infinite amount of time to do the work. Even though we can never achieve the maximum work through the actual discharge of a galvanic cell, we can measure the maximum potential. There is negligible current flow when a cell potential is measured with a potentiometer or an efficient digital voltmeter. No current flow implies no waste of energy, so the potential measured is the maximum.

Although we can never actually realize the maximum work from a cell reaction, the value for it is still useful in evaluating the efficiency of a real process based on the cell reaction. For example, suppose a certain galvanic cell has a maximum potential (at zero current) of 2.50 V . In a particular experiment 1.33 moles of electrons were passed through this cell at an average actual potential of 2.10 V . The actual work done is
\[
w=-q_{\mathscr{E}}
\]

A
Michael Faraday lecturing at the Royal Institution before Prince Albert and others (1855). The faraday was named in honor of Michael Faraday (1791-1867), an Englishman who may have been the greatest experimental scientist of the nineteenth century. Among his many achievements were the invention of the electric motor and generator and the development of the principles of electrolysis.
where \(\mathscr{E}\) represents the actual potential difference at which the current flowed \((2.10 \mathrm{~V}\) or \(2.10 \mathrm{~J} / \mathrm{C}\) ) and \(q\) is the quantity of charge in coulombs transferred. The charge on 1 mole of electrons is a constant called the faraday (abbreviated \(F\) ), which has the value 96,485 coulombs of charge per mole of electrons. Thus \(q\) equals the number of moles of electrons times the charge per mole of electrons:
\[
q=n F=1.33 \mathrm{~mol} \mathrm{e}{ }^{-} \times 96,485 \mathrm{C} / \mathrm{mol} \mathrm{e}^{-}
\]

Then, for the preceding experiment, the actual work is
\[
\begin{aligned}
w & =-q \mathscr{E}=-(1.33 \mathrm{~mol} \mathrm{e} \\
& =-2.69 \times 10^{5} \mathrm{~J}
\end{aligned}
\]

For the maximum possible work, the calculation is similar, except that the maximum potential is used:
\[
\begin{aligned}
w_{\max } & =-q \mathscr{E} \\
& =-\left(1.33 \mathrm{~mol} \mathrm{e}^{-} \times 96,485 \frac{\mathrm{C}}{\mathrm{~mol} \mathrm{e}^{-}}\right)\left(2.50 \frac{\mathrm{~J}}{\mathrm{C}}\right) \\
& =-3.21 \times 10^{5} \mathrm{~J}
\end{aligned}
\]

Thus, in its actual operation, the efficiency of this cell is
\[
\frac{w}{w_{\max }} \times 100 \%=\frac{-2.69 \times 10^{5} \mathrm{~J}}{-3.21 \times 10^{5} \mathrm{~J}} \times 100 \%=83.8 \%
\]

Next we want to relate the potential of a galvanic cell to free energy. In Section 17.10 we saw that for a process carried out at constant temperature and pressure, the change in free energy equals the maximum useful work obtainable from that process:
\[
w_{\max }=\Delta G
\]

For a galvanic cell,
\[
w_{\max }=-q \mathscr{E}_{\max }=\Delta G
\]

Since
\[
q=n F
\]
we have
\[
\Delta G=-q \mathscr{E}_{\max }=-n F \mathscr{E}_{\max }
\]

From now on the subscript on \(\mathscr{E}_{\text {max }}\) will be deleted, with the understanding that any potential given in this book is the maximum potential. Thus
\[
\Delta G=-n F_{\mathscr{C}}^{\mathscr{C}}
\]

For standard conditions,
\[
\Delta G^{\circ}=-n F^{\subset \circ}
\]

This equation states that the maximum cell potential is directly related to the free energy difference between the reactants and the products in the cell. This relationship is important because it provides an experimental means to obtain \(\Delta G\) for a reaction. It also confirms that a galvanic cell will run in the direction that gives a positive value for \(\mathscr{E}_{\text {cell }}\); a positive \(\mathscr{E}_{\text {cell }}\) value corresponds to a negative \(\Delta G\) value, which is the condition for spontaneity.

\section*{INTERACTIVE EXAMPLE \(18.3 \quad\) Calculating \(\boldsymbol{\Delta} \boldsymbol{G}^{\circ}\) for a Cell Reaction}

Using the data in Table 18.1, calculate \(\Delta G^{\circ}\) for the reaction
\[
\mathrm{Cu}^{2+}(a q)+\mathrm{Fe}(s) \longrightarrow \mathrm{Cu}(s)+\mathrm{Fe}^{2+}(a q)
\]

Is this reaction spontaneous?

\section*{SOLUTION}

The half-reactions are
\[
\begin{array}{rr}
\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu} & \begin{array}{l}
\mathscr{E}^{\circ}(\text { cathode }) \\
\mathrm{Fe} \longrightarrow \\
-\mathrm{Fe}^{2+}+2 \mathrm{e}^{-}(\text {anode })
\end{array}=0.34 \mathrm{~V} \\
-\mathscr{E}^{\circ} \\
\mathrm{Cu}^{2+}+\mathrm{Fe} \longrightarrow \mathrm{Fe}^{2+}+\mathrm{Cu} & \mathscr{E}_{\text {cell }}^{\circ}=0.78 \mathrm{~V}
\end{array}
\]

We can calculate \(\Delta G^{\circ}\) from the equation
\[
\Delta G^{\circ}=-n F^{\mathscr{C}}{ }^{\circ}
\]

Since two electrons are transferred per atom in the reaction, 2 moles of electrons are required per mole of reactants and products. Thus \(n=2 \mathrm{~mol} \mathrm{e}^{-}, F=96,485 \mathrm{C} / \mathrm{mol} \mathrm{e}^{-}\), and \(\mathscr{E}^{\circ}=0.78 \mathrm{~V}=0.78 \mathrm{~J} / \mathrm{C}\). Therefore,
\[
\begin{aligned}
\Delta G^{\circ} & =-\left(2 \mathrm{~mol} \mathrm{e}^{-}\right)\left(96,485 \frac{\mathrm{C}}{\mathrm{~mol} \mathrm{e}^{-}}\right)\left(0.78 \frac{\mathrm{~J}}{\mathrm{C}}\right) \\
& =-1.5 \times 10^{5} \mathrm{~J}
\end{aligned}
\]

The process is spontaneous, as indicated by both the negative sign of \(\Delta G^{\circ}\) and the positive sign of \(\mathscr{E}_{\text {cell }}^{\circ}\).

This reaction is used industrially to deposit copper metal from solutions resulting from the dissolving of copper ores.

See Exercises 18.49 and 18.50

\section*{EXAMPLE 18.4 Predicting Spontaneity}

Using the data from Table 18.1, predict whether \(1 M \mathrm{HNO}_{3}\) will dissolve gold metal to form a \(1-M \mathrm{Au}^{3+}\) solution.

\section*{SOLUTION}

A
A gold ring does not dissolve in nitric acid.

The half-reaction for \(\mathrm{HNO}_{3}\) acting as an oxidizing agent is
\[
\mathrm{NO}_{3}^{-}+4 \mathrm{H}^{+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{NO}+2 \mathrm{H}_{2} \mathrm{O} \quad \mathscr{E} \circ(\text { cathode })=0.96 \mathrm{~V}
\]

The reaction for the oxidation of solid gold to \(\mathrm{Au}^{3+}\) ions is
\[
\mathrm{Au} \longrightarrow \mathrm{Au}^{3+}+3 \mathrm{e}^{-} \quad-\mathscr{E}^{\circ}(\text { anode })=-1.50 \mathrm{~V}
\]

The sum of these half-reactions gives the required reaction:
\[
\begin{aligned}
& \mathrm{Au}(s)+\mathrm{NO}_{3}^{-}(a q)+4 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Au}^{3+}(a q)+\mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \\
& \mathscr{E}_{\text {cell }}^{\circ}=\mathscr{E}^{\circ}(\text { cathode })-\mathscr{E}^{\circ}(\text { anode })=0.96 \mathrm{~V}-1.50 \mathrm{~V}=-0.54 \mathrm{~V}
\end{aligned}
\]

Since the \(\mathscr{E}^{\circ}\) value is negative, the process will not occur under standard conditions. That is, gold will not dissolve in \(1 M \mathrm{HNO}_{3}\) to give \(1 M \mathrm{Au}^{3+}\). In fact, a mixture ( \(1: 3\) by volume) of concentrated nitric and hydrochloric acids, called aqua regia, is required to dissolve gold.

\subsection*{18.4 Dependence of Cell Potential on Concentration}

So far we have described cells under standard conditions. In this section we consider the dependence of the cell potential on concentration. Under standard conditions (all concentrations \(1 M\) ), the cell with the reaction
\[
\mathrm{Cu}(s)+2 \mathrm{Ce}^{4+}(a q) \longrightarrow \mathrm{Cu}^{2+}(a q)+2 \mathrm{Ce}^{3+}(a q)
\]
has a potential of 1.36 V . What will the cell potential be if \(\left[\mathrm{Ce}^{4+}\right.\) ] is greater than 1.0 M ? An increase in the concentration of \(\mathrm{Ce}^{4+}\) will favor the forward reaction and thus increase the driving force on the electrons. The cell potential will increase. On the other hand, an increase in the concentration of a product \(\left(\mathrm{Cu}^{2+}\right.\) or \(\left.\mathrm{Ce}^{3+}\right)\) will oppose the forward reaction, thus decreasing the cell potential.

These ideas are illustrated in Example 18.5.

\section*{INTERACTIVE EXAMPLE 18.5}

\section*{The Effects of Concentration on \(\mathscr{E}\)}

For the cell reaction
\[
2 \mathrm{Al}(s)+3 \mathrm{Mn}^{2+}(a q) \longrightarrow 2 \mathrm{Al}^{3+}(a q)+3 \mathrm{Mn}(s) \quad \mathscr{E}_{\text {cell }}^{\circ}=0.48 \mathrm{~V}
\]
predict whether \(\mathscr{E}_{\text {cell }}\) is larger or smaller than \(\mathscr{E}_{\text {cell }}^{\circ}\) for the following cases.
a. \(\left[\mathrm{Al}^{3+}\right]=2.0 \mathrm{M},\left[\mathrm{Mn}^{2+}\right]=1.0 \mathrm{M}\)
b. \(\left[\mathrm{Al}^{3+}\right]=1.0 \mathrm{M},\left[\mathrm{Mn}^{2+}\right]=3.0 \mathrm{M}\)

SOLUTION a. A product concentration has been raised above 1.0 M . This will oppose the cell reaction and will cause \(\mathscr{E}_{\text {cell }}\) to be less than \(\mathscr{E}_{\text {cell }}^{\circ}\left(\mathscr{E}_{\text {cell }}<0.48 \mathrm{~V}\right)\).
b. A reactant concentration has been increased above \(1.0 M\), and \(\mathscr{E}_{\text {cell }}\) will be greater than \(\mathscr{E}_{\text {cell }}^{\circ}\left(\mathscr{E}_{\text {cell }}>0.48 \mathrm{~V}\right)\).

\(\Delta\)
A concentration cell with \(1.0 \mathrm{M} \mathrm{Cu}^{2+}\) on the right and \(0.010 \mathrm{M} \mathrm{Cu}^{2+}\) on the left.

\section*{Concentration Cells}

Because cell potentials depend on concentration, we can construct galvanic cells where both compartments contain the same components but at different concentrations. For example, in the cell in Fig. 18.9, both compartments contain aqueous \(\mathrm{AgNO}_{3}\), but with different molarities. Let's consider the potential of this cell and the direction of electron flow. The half-reaction relevant to both compartments of this cell is
\[
\mathrm{Ag}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Ag} \quad \mathscr{E}^{\circ}=0.80 \mathrm{~V}
\]

If the cell had \(1 \mathrm{M} \mathrm{Ag}^{+}\)in both compartments,
\[
\mathscr{E}_{\text {cell }}^{\circ}=0.80 \mathrm{~V}-0.80 \mathrm{~V}=0 \mathrm{~V}
\]

However, in the cell described here, the concentrations of \(\mathrm{Ag}^{+}\)in the two compartments are 1 M and 0.1 M . Because the concentrations of \(\mathrm{Ag}^{+}\)are unequal, the half-cell potentials will not be identical, and the cell will exhibit a positive voltage. In which direction will the electrons flow in this cell? The best way to think about this question is to recognize that nature will try to equalize the concentrations of \(\mathrm{Ag}^{+}\)in the two compartments. This can be done by transferring electrons from the compartment containing \(0.1 \mathrm{M} \mathrm{Ag}^{+}\)to the one containing \(1 \mathrm{M} \mathrm{Ag}^{+}\)(left to right in Fig. 18.9). This

FIGURE 18.9 A concentration cell that contains a silver electrode and aqueous silver nitrate in both compartments. Because the right compartment contains \(1 \mathrm{M} \mathrm{Ag}^{+}\)and the left compartment contains \(0.1 \mathrm{M} \mathrm{Ag}^{+}\), there will be a driving force to transfer electrons from left to right. Silver will be deposited on the right electrode, thus lowering the concentration of \(\mathrm{Ag}^{+}\) in the right compartment. In the left compartment the silver electrode dissolves (producing \(\mathrm{Ag}^{+}\)ions) to raise the concentration of \(\mathrm{Ag}^{+}\)in solution.
electron transfer will produce more \(\mathrm{Ag}^{+}\)in the left compartment and consume \(\mathrm{Ag}^{+}\)(to form Ag ) in the right compartment.

A cell in which both compartments have the same components but at different concentrations is called a concentration cell. The difference in concentration is the only factor that produces a cell potential in this case, and the voltages are typically small.

\section*{EXAMPLE 18.6 Concentration Cells}

Determine the direction of electron flow, and designate the anode and cathode for the cell represented in Fig. 18.10.

SOLUTION The concentrations of \(\mathrm{Fe}^{2+}\) ion in the two compartments can (eventually) be equalized by transferring electrons from the left compartment to the right. This will cause \(\mathrm{Fe}^{2+}\) to be formed in the left compartment, and iron metal will be deposited (by reducing \(\mathrm{Fe}^{2+}\) ions to Fe ) on the right electrode. Since electron flow is from left to right, oxidation occurs in the left compartment (the anode) and reduction occurs in the right (the cathode).

\section*{See Exercise 18.66}

\section*{The Nernst Equation}

The dependence of the cell potential on concentration results directly from the dependence of free energy on concentration. Recall from Chapter 17 that the equation
\[
\Delta G=\Delta G^{\circ}+R T \ln (Q)
\]
where \(Q\) is the reaction quotient, was used to calculate the effect of concentration on \(\Delta G\). Since \(\Delta G=-n F \mathscr{E}\) and \(\Delta G^{\circ}=-n F^{\circ} \mathscr{E}^{\circ}\), the equation becomes
\[
-n F^{\mathscr{E}}=-n F_{\mathscr{C}}^{\mathscr{\circ}}+R T \ln (Q)
\]

Dividing each side of the equation by \(-n F\) gives
\[
\begin{equation*}
\mathscr{E}=\mathscr{E} \circ-\frac{R T}{n F} \ln (Q) \tag{18.1}
\end{equation*}
\]

Equation (18.1), which gives the relationship between the cell potential and the concentrations of the cell components, is commonly called the Nernst equation, after the German chemist Walther Hermann Nernst (1864-1941).

\footnotetext{
Nernst was one of the pioneers in the development of electrochemical theory and is generally given credit for first stating the third law of thermodynamics. He won the Nobel Prize in chemistry in 1920.
}

FIGURE 18.10 A concentration cell containing iron electrodes and different concentrations of \(\mathrm{Fe}^{2+}\) ion in the two compartments.

The Nernst equation is often given in a form that is valid at \(25^{\circ} \mathrm{C}\) :
\[
\mathscr{E}=\mathscr{E}^{\circ}-\frac{0.0591}{n} \log (Q)
\]

Using this relationship, we can calculate the potential of a cell in which some or all of the components are not in their standard states.

For example, \(\mathscr{E}_{\text {cell }}^{\circ}\) is 0.48 V for the galvanic cell based on the reaction
\[
2 \mathrm{Al}(s)+3 \mathrm{Mn}^{2+}(a q) \longrightarrow 2 \mathrm{Al}^{3+}(a q)+3 \mathrm{Mn}(s)
\]

Consider a cell in which
\[
\left[\mathrm{Mn}^{2+}\right]=0.50 \mathrm{M} \quad \text { and } \quad\left[\mathrm{Al}^{3+}\right]=1.50 M
\]

The cell potential at \(25^{\circ} \mathrm{C}\) for these concentrations can be calculated using the Nernst equation:
\[
\mathscr{E}_{\text {cell }}=\mathscr{E}_{\text {cell }}^{\circ}-\frac{0.0591}{n} \log (Q)
\]

We know that
and
\[
\begin{gathered}
\mathscr{E}_{\text {cell }}^{\circ}=0.48 \mathrm{~V} \\
Q=\frac{\left[\mathrm{Al}^{3+}\right]^{2}}{\left[\mathrm{Mn}^{2+}\right]^{3}}=\frac{(1.50)^{2}}{(0.50)^{3}}=18
\end{gathered}
\]

Since the half-reactions are
\[
\begin{array}{ll}
\text { Oxidation: } & 2 \mathrm{Al} \longrightarrow 2 \mathrm{Al}^{3+}+6 \mathrm{e}^{-} \\
\text {Reduction: } & 3 \mathrm{Mn}^{2+}+6 \mathrm{e}^{-} \longrightarrow 3 \mathrm{Mn}
\end{array}
\]
we know that
\[
n=6
\]

Thus \(\quad \mathscr{E}_{\text {cell }}=0.48-\frac{0.0591}{6} \log (18)\)
\[
=0.48-\frac{0.0591}{6}(1.26)=0.48-0.01=0.47 \mathrm{~V}
\]

Note that the cell voltage decreases slightly because of the nonstandard concentrations. In this case, since the reactant concentration is lower than 1.0 M and the product concentration is higher than \(1.0 \mathrm{M}, \mathscr{E}_{\text {cell }}\) is less than \(\mathscr{E}_{\text {cell }}^{\circ}\) -

The potential calculated from the Nernst equation is the maximum potential before any current flow has occurred. As the cell discharges and current flows from anode to cathode, the concentrations will change, and as a result, \(\mathscr{E}_{\text {cell }}\) will change. In fact, the cell will spontaneously discharge until it reaches equilibrium, at which point
\[
Q=K \text { (the equilibrium constant) } \quad \text { and } \quad \mathscr{E}_{\text {cell }}=0
\]

A "dead" battery is one in which the cell reaction has reached equilibrium, and there is no longer any chemical driving force to push electrons through the wire. In other words, at equilibrium, the components in the two cell compartments have the same free energy, and \(\Delta G=0\) for the cell reaction at the equilibrium concentrations. The cell no longer has the ability to do work.

\footnotetext{
 electrolytic cell? Does this mean the cell is "dead"? What if \(\mathscr{E}=0\) ? Explain your answer in each case.
}

\section*{EXAMPLE 18.7 The Nernst Equation}

Describe the cell based on the following half-reactions:
\[
\begin{align*}
\mathrm{VO}_{2}^{+}+2 \mathrm{H}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{VO}^{2+}+\mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ} & =1.00 \mathrm{~V}  \tag{1}\\
\mathrm{Zn}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Zn} & \mathscr{E}^{\circ} & =-0.76 \mathrm{~V}
\end{align*}
\]
where
\[
\begin{aligned}
& T=25^{\circ} \mathrm{C} \\
& {\left[\mathrm{VO}_{2}^{+}\right]=2.0 \mathrm{M}} \\
& {\left[\mathrm{H}^{+}\right]=0.50 \mathrm{M}} \\
& {\left[\mathrm{VO}^{2+}\right]=1.0 \times 10^{-2} \mathrm{M}} \\
& {\left[\mathrm{Zn}^{2+}\right]=1.0 \times 10^{-1} \mathrm{M}}
\end{aligned}
\]

SOLUTION The balanced cell reaction is obtained by reversing reaction (2) and multiplying reaction (1) by 2 :
\(2 \times\) reaction (1)
Reaction (2) reversed
\[
\begin{array}{rlrl}
2 \mathrm{VO}_{2}^{+}+4 \mathrm{H}^{+}+2 \mathrm{e}^{-} & \longrightarrow 2 \mathrm{VO}^{2+}+2 \mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ}(\text { cathode })=1.00 \mathrm{~V} \\
\mathrm{Zn} & \longrightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-} & -\mathscr{E}^{\circ}(\text { anode })=0.76 \mathrm{~V} \\
\hline 2 \mathrm{VO}_{2}^{+}(a q)+4 \mathrm{H}^{+}(a q)+\mathrm{Zn}(s) \longrightarrow 2 \mathrm{VO}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Zn}^{2+}(a q) & \mathscr{E}_{\text {cell }}=1.76 \mathrm{~V}
\end{array}
\]

Cell reaction:
Since the cell contains components at concentrations other than \(1 M\), we must use the Nernst equation, where \(n=2\) (since two electrons are transferred), to calculate the cell potential. At \(25^{\circ} \mathrm{C}\) we can use the equation
\[
\begin{aligned}
\mathscr{E} & =\mathscr{E}_{\text {cell }}^{\circ}-\frac{0.0591}{n} \log (Q) \\
& =1.76-\frac{0.0591}{2} \log \left(\frac{\left[\mathrm{Zn}^{2+}\right]\left[\mathrm{VO}^{2+}\right]^{2}}{\left[\mathrm{VO}_{2}^{+}\right]^{2}\left[\mathrm{H}^{+}\right]^{4}}\right) \\
& =1.76-\frac{0.0591}{2} \log \left(\frac{\left(1.0 \times 10^{-1}\right)\left(1.0 \times 10^{-2}\right)^{2}}{(2.0)^{2}(0.50)^{4}}\right) \\
& =1.76-\frac{0.0591}{2} \log \left(4 \times 10^{-5}\right)=1.76+0.13=1.89 \mathrm{~V}
\end{aligned}
\]

The cell diagram is given in Fig. 18.11.

FIGURE 18.11 Schematic diagram of the cell described in Example 18.7.

TABLE 18.2 \({ }^{\text {| }}\) Some Ions Whose Concentrations Can Be Detected by Ion-Selective Electrodes
\begin{tabular}{|ll|}

\hline \(\mathrm{Na}^{+}\) & \\
\hline
\end{tabular}

FIGURE 18.12 A glass electrode contains a reference solution of dilute hydrochloric acid in contact with a thin glass membrane in which a silver wire coated with silver chloride has been embedded. When the electrode is dipped into a solution containing \(\mathrm{H}^{+}\)ions, the electrode potential is determined by the difference in \(\left[\mathrm{H}^{+}\right]\)between the two solutions.

\section*{Ion-Selective Electrodes}

Because the cell potential is sensitive to the concentrations of the reactants and products involved in the cell reaction, measured potentials can be used to determine the concentration of an ion. A pH meter (see Fig. 14.7) is a familiar example of an instrument that measures concentration using an observed potential. The pH meter has three main components: a standard electrode of known potential, a special glass electrode that changes potential depending on the concentration of \(\mathrm{H}^{+}\)ions in the solution into which it is dipped, and a potentiometer that measures the potential between the electrodes. The potentiometer reading is automatically converted electronically to a direct reading of the pH of the solution being tested.

The glass electrode (Fig. 18.12) contains a reference solution of dilute hydrochloric acid in contact with a thin glass membrane. The electrical potential of the glass electrode depends on the difference in \(\left[\mathrm{H}^{+}\right]\)between the reference solution and the solution into which the electrode is dipped. Thus the electrical potential varies with the pH of the solution being tested.

Electrodes that are sensitive to the concentration of a particular ion are called ionselective electrodes, of which the glass electrode for pH measurement is just one example. Glass electrodes can be made sensitive to such ions as \(\mathrm{Na}^{+}, \mathrm{K}^{+}\), or \(\mathrm{NH}_{4}{ }^{+}\)by changing the composition of the glass. Other ions can be detected if an appropriate crystal replaces the glass membrane. For example, a crystal of lanthanum(III) fluoride \(\left(\mathrm{LaF}_{3}\right)\) can be used in an electrode to measure \(\left[\mathrm{F}^{-}\right]\). Solid silver sulfide \(\left(\mathrm{Ag}_{2} \mathrm{~S}\right)\) can be used to measure \(\left[\mathrm{Ag}^{+}\right]\)and \(\left[\mathrm{S}^{2-}\right]\). Some of the ions that can be detected by ionselective electrodes are listed in Table 18.2.

\section*{Calculation of Equilibrium Constants for Redox Reactions}

The quantitative relationship between \(\mathscr{E}^{\circ}\) and \(\Delta G^{\circ}\) allows calculation of equilibrium constants for redox reactions. For a cell at equilibrium,
\[
\mathscr{E}_{\text {cell }}=0 \quad \text { and } \quad Q=K
\]

Applying these conditions to the Nernst equation valid at \(25^{\circ} \mathrm{C}\),
gives
\[
\begin{gathered}
\mathscr{E}=\mathscr{E}^{\circ}-\frac{0.0591}{n} \log (Q) \\
0=\mathscr{E}^{\circ}-\frac{0.0591}{n} \log (K) \\
\log (K)=\frac{n \mathscr{C}^{\circ}}{0.0591} \quad \text { at } 25^{\circ} \mathrm{C}
\end{gathered}
\]
or

\section*{INTERACTIVE EXAMPLE 18.8 Equilibrium Constants from Cell Potentials}

For the oxidation-reduction reaction
\[
\mathrm{S}_{4} \mathrm{O}_{6}^{2-}(a q)+\mathrm{Cr}^{2+}(a q) \longrightarrow \mathrm{Cr}^{3+}(a q)+\mathrm{S}_{2} \mathrm{O}_{3}^{2-}(a q)
\]
the appropriate half-reactions are
\[
\begin{array}{rlr}
\mathrm{S}_{4} \mathrm{O}_{6}^{2-}+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{~S}_{2} \mathrm{O}_{3}^{2-} & \mathscr{E}^{\circ}=0.17 \mathrm{~V} \\
\mathrm{Cr}^{3+}+\mathrm{e}^{-} \longrightarrow \mathrm{Cr}^{2+} & \mathscr{E}^{\circ}=-0.50 \mathrm{~V} \tag{2}
\end{array}
\]

Balance the redox reaction, and calculate \(\mathscr{E}^{\circ}\) and \(K\left(\right.\) at \(\left.25^{\circ} \mathrm{C}\right)\).
SOLUTION To obtain the balanced reaction, we must reverse reaction (2), multiply it by 2, and add it to reaction (1):

The blue solution contains \(\mathrm{Cr}^{2+}\) ions, and the green solution contains \(\mathrm{Cr}^{3+}\) ions.

In this reaction, 2 moles of electrons are transferred for every unit of reaction, that is, for every 2 moles of \(\mathrm{Cr}^{2+}\) reacting with 1 mole of \(\mathrm{S}_{4} \mathrm{O}_{6}{ }^{2-}\) to form 2 moles of \(\mathrm{Cr}^{3+}\) and 2 moles of \(\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\). Thus \(n=2\). Then
\[
\log (K)=\frac{n \mathscr{E}^{\circ}}{0.0591}=\frac{2(0.67)}{0.0591}=22.6
\]

The value of \(K\) is found by taking the antilog of 22.6:
\[
K=10^{22.6}=4 \times 10^{22}
\]

This very large equilibrium constant is not unusual for a redox reaction.
\[
\text { See Exeraises } 18.73 \text { through } 18.76
\]

\subsection*{18.5 Batteries}

A battery is a galvanic cell or, more commonly, a group of galvanic cells connected in series, where the potentials of the individual cells add to give the total battery potential. Batteries are a source of direct current and have become an essential source of portable power in our society. In this section we examine the most common types of batteries. Some new batteries currently being developed are described at the end of the chapter.

\section*{Lead Storage Battery}

Since about 1915 when self-starters were first used in automobiles, the lead storage battery has been a major factor in making the automobile a practical means of transportation. This type of battery can function for several years under temperature extremes from \(-30^{\circ} \mathrm{F}\) to \(120^{\circ} \mathrm{F}\) and under incessant punishment from rough roads.

In this battery, lead serves as the anode, and lead coated with lead dioxide serves as the cathode. Both electrodes dip into an electrolyte solution of sulfuric acid. The electrode reactions are
Anode reaction: \begin{tabular}{l}
\(\mathrm{Pb}+\mathrm{HSO}_{4}^{-} \longrightarrow \mathrm{PbSO}_{4}+\mathrm{H}^{+}+2 \mathrm{e}^{-}\) \\
Cathode reaction: \(\quad \mathrm{PbO}_{2}+\mathrm{HSO}_{4}^{-}+3 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{PbSO}_{4}+2 \mathrm{H}_{2} \mathrm{O}\) \\
\hline Cell reaction: \(\mathrm{Pb}(s)+\mathrm{PbO}_{2}(s)+2 \mathrm{H}^{+}(a q)+2 \mathrm{HSO}_{4}^{-}(a q) \longrightarrow 2 \mathrm{PbSO}_{4}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)\)
\end{tabular}

FIGURE 18.13 One of the six cells in a 12 -V lead storage battery. The anode consists of a lead grid filled with spongy lead, and the cathode is a lead grid filled with lead dioxide. The cell also contains \(38 \%\) (by mass) sulfuric acid.

FIGURE 18.14 A common dry cell battery.

The typical automobile lead storage battery has six cells connected in series. Each cell contains multiple electrodes in the form of grids (Fig. 18.13) and produces approximately 2 V , to give a total battery potential of about 12 V . Note from the cell reaction that sulfuric acid is consumed as the battery discharges. This lowers the density of the electrolyte solution from its initial value of about \(1.28 \mathrm{~g} / \mathrm{cm}^{3}\) in the fully charged battery. As a result, the condition of the battery can be monitored by measuring the density of the sulfuric acid solution. The solid lead sulfate formed in the cell reaction during discharge adheres to the grid surfaces of the electrodes. The battery is recharged by forcing current through it in the opposite direction to reverse the cell reaction. A car's battery is continuously charged by an alternator driven by the automobile engine.

An automobile with a dead battery can be "jump-started" by connecting its battery to the battery in a running automobile. This process can be dangerous, however, because the resulting flow of current causes electrolysis of water in the dead battery, producing hydrogen and oxygen gases (see Section 18.7 for details). Disconnecting the jumper cables after the disabled car starts causes an arc that can ignite the gaseous mixture. If this happens, the battery may explode, ejecting corrosive sulfuric acid. This problem can be avoided by connecting the ground jumper cable to a part of the engine remote from the battery. Any arc produced when this cable is disconnected will then be harmless.

Traditional types of storage batteries require periodic "topping off" because the water in the electrolyte solution is depleted by the electrolysis that accompanies the charging process. Recent types of batteries have electrodes made of an alloy of calcium and lead that inhibits the electrolysis of water. These batteries can be sealed, since they require no addition of water.

It is rather amazing that in the 100 years in which lead storage batteries have been used, no better system has been found. Although a lead storage battery does provide excellent service, it has a useful lifetime of 3 to 5 years in an automobile. While it might seem that the battery could undergo an indefinite number of discharge/charge cycles, physical damage from road shock and chemical side-reactions eventually cause the battery to fail.

\section*{Other Batteries}

The calculators, electronic games, digital watches, and portable audio players that are so familiar to us are all powered by small, efficient batteries. The common dry cell battery was invented more than 100 years ago by Georges Leclanché (1839-1882), a French chemist. In its acid version, the dry cell battery contains a zinc inner case that acts as the anode and a carbon rod in contact with a moist paste of solid \(\mathrm{MnO}_{2}\), solid \(\mathrm{NH}_{4} \mathrm{Cl}\), and carbon that acts as the cathode (Fig. 18.14). The half-reactions are complex but can be approximated as follows:
\[
\begin{aligned}
& \text { Anode reaction: } \\
& \text { Cathode reaction: } \\
& \text { Zn } 2 \mathrm{NH}_{4}^{+}+2 \mathrm{MnO}_{2}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-} \\
& \mathrm{Mn}_{2} \mathrm{O}_{3}+2 \mathrm{NH}_{3}+\mathrm{H}_{2} \mathrm{O}
\end{aligned}
\]

This cell produces a potential of about 1.5 V .
In the alkaline version of the dry cell battery, the solid \(\mathrm{NH}_{4} \mathrm{Cl}\) is replaced with KOH or NaOH . In this case the half-reactions can be approximated as follows:
\[
\begin{array}{lr}
\text { Anode reaction: } & \mathrm{Zn}+2 \mathrm{OH}^{-} \longrightarrow \mathrm{ZnO}+\mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \\
\text {Cathode reaction: } & 2 \mathrm{MnO}_{2}+\mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Mn}_{2} \mathrm{O}_{3}+2 \mathrm{OH}^{-}
\end{array}
\]

FIGURE 18.15 A mercury battery of the type used in calculators.

-
Batteries for electronic watches are, by necessity, very tiny.

FIGURE 18.16 Schematic of the hydrogen-oxygen fuel cell.

The alkaline dry cell lasts longer mainly because the zinc anode corrodes less rapidly under basic conditions than under acidic conditions.

Other types of useful batteries include the silver cell, which has a Zn anode and a cathode that uses \(\mathrm{Ag}_{2} \mathrm{O}\) as the oxidizing agent in a basic environment. Mercury cells, often used in calculators, have a Zn anode and a cathode involving HgO as the oxidizing agent in a basic medium (Fig. 18.15).

An especially important type of battery is the nickel-cadmium battery, in which the electrode reactions are
\[
\begin{array}{lr}
\text { Anode reaction: } & \mathrm{Cd}+2 \mathrm{OH}^{-} \longrightarrow \mathrm{Cd}(\mathrm{OH})_{2}+2 \mathrm{e}^{-} \\
\text {Cathode reaction: } & \mathrm{NiO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Ni}(\mathrm{OH})_{2}+2 \mathrm{OH}^{-}
\end{array}
\]

As in the lead storage battery, the products adhere to the electrodes. Therefore, a nickelcadmium battery can be recharged an indefinite number of times.

Lithium-ion batteries involve the migration of \(\mathrm{Li}^{+}\)ions from the cathode to the anode, where they intercalate (enter the interior) as the battery is charged. At the same time, charge-balancing electrons travel to the anode through the external circuit in the charger. On discharge, the opposite process occurs. The cathode of the first successful lithium-ion batteries originally contained \(\mathrm{LiCoO}_{2}\) and a lithium-intercalated carbon \(\left(\mathrm{LiC}_{6}\right)\) anode. More recently manufacturers have included transition metals such as nickel and manganese in the cathode in addition to cobalt. The mixed-metal cathodes have greater charge capacity and power output and shorter recharge times.

Lithium-ion batteries are used in a wide variety of applications, including cell phones, laptop computers, power tools, and even electric drive systems in automobiles and motorcycles.

\section*{Fuel Cells}

A fuel cell is a galvanic cell for which the reactants are continuously supplied. To illustrate the principles of fuel cells, let's consider the exothermic redox reaction of methane with oxygen:
\[
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)+\text { energy }
\]

Usually the energy from this reaction is released as heat to warm homes and to run machines. However, in a fuel cell designed to use this reaction, the energy is used to produce an electric current: The electrons flow from the reducing agent \(\left(\mathrm{CH}_{4}\right)\) to the oxidizing agent \(\left(\mathrm{O}_{2}\right)\) through a conductor.

The U.S. space program has supported extensive research to develop fuel cells. The space shuttle uses a fuel cell based on the reaction of hydrogen and oxygen to form water:
\[
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
\]

A schematic of a fuel cell that uses this reaction is shown in Fig. 18.16. The halfreactions are
\[
\begin{array}{lr}
\text { Anode reaction: } & 2 \mathrm{H}_{2}+4 \mathrm{OH}^{-} \longrightarrow 4 \mathrm{H}_{2} \mathrm{O}+4 \mathrm{e}^{-} \\
\text {Cathode reaction: } & 4 \mathrm{e}^{-}+\mathrm{O}_{2}+2 \mathrm{H}_{2} \mathrm{O} \longrightarrow 4 \mathrm{OH}^{-}
\end{array}
\]

\section*{CHEMICAL CDNNECTIDNS}

\section*{Fuel Cells-Portable Energy}

The promise of an energy-efficient, environmentally sound source of electrical power has spurred an intense interest in fuel cells in recent years. Although fuel cells have long been used in the U.S. space program, no practical fuel cell for powering automobiles has been developed. However, we are now on the verge of practical fuel-cell-powered cars. The Toyota FCV, which is powered by a hydrogenoxygen fuel cell, is now available in the United States. Toyota reports that this vehicle, which costs about \(\$ 70,000\), has a range of 400 miles on a single fill-up of hydrogen gas and emits only water vapor. The main advantages of fuel-cell driven cars are the much smaller size and lower weight of the fuel cell compared to conventional battery packs and the shorter fill-up time of about 3 minutes compared to the hours required for battery recharging. The main disadvantages of fuel-cell vehicles are their relatively high cost and the lack of hydrogen refueling stations. To combat the latter issue, California has provided \(\$ 50\) million to fund about 30 new hydrogen refueling stations.

Besides providing power for automobiles, fuel cells are being considered for powering small electronic devices such as cameras, cell phones, and laptop computers. Many of these micro
fuel cells currently use methanol as the fuel (reducing agent) rather than \(\mathrm{H}_{2}\). However, these direct-methanol fuel cells are rife with problems. A major difficulty is water management. Water is needed at the anode to react with the methanol and is produced at the cathode. Water is also needed to moisten the electrolyte to promote charge migration.

Although the direct-methanol fuel cell is currently the leader among micro fuel-cell designs, its drawbacks have encouraged the development of other designs. For example, Richard Masel at the University of Illinois at UrbanaChampaign has designed a micro fuel
cell that uses formic acid as the fuel. Masel and others are also experimenting with mini hot chambers external to the fuel cell that break down hydrogenrich fuels into hydrogen gas, which is then fed into the tiny fuel cells.

To replace batteries, fuel cells must be demonstrated to be economically feasible, safe, and dependable. Today, rapid progress is being made to overcome the current problems. A recent estimate indicates that by late in this decade annual sales of the little power plants may reach 200 million units per year. It appears that after years of hype about the virtues of fuel cells, we are finally going to realize their potential.

A cell of this type weighing about 500 pounds has been designed for space vehicles, but this fuel cell is not practical enough for general use as a source of portable power. However, current research on portable electrochemical power is now proceeding at a rapid pace. In fact, cars powered by fuel cells are now being tested on the streets.

Fuel cells are also finding use as permanent power sources. For example, a power plant built in New York City contains stacks of hydrogen-oxygen fuel cells, which can be rapidly put on-line in response to fluctuating power demands. The hydrogen gas is obtained by decomposing the methane in natural gas. A plant of this type also has been constructed in Tokyo.

In addition, new fuel cells are under development that can use fuels such as methane and diesel directly without having to produce hydrogen first.

Some metals, such as copper, gold, silver, and platinum, are relatively difficult to oxidize. These are often called noble metals.

FIGURE 18.17 The electrochemical corrosion of iron.

Corrosion can be viewed as the process of returning metals to their natural state-the ores from which they were originally obtained. Corrosion involves oxidation of the metal. Since corroded metal often loses its structural integrity and attractiveness, this spontaneous process has great economic impact. Approximately one-fifth of the iron and steel produced annually is used to replace rusted metal.

Metals corrode because they oxidize easily. Table 18.1 shows that, with the exception of gold, those metals commonly used for structural and decorative purposes all have standard reduction potentials less positive than that of oxygen gas. When any of these half-reactions is reversed (to show oxidation of the metal) and combined with the reduction half-reaction for oxygen, the result is a positive \(\mathscr{E} \mathscr{E}^{\circ}\) value. Thus the oxidation of most metals by oxygen is spontaneous (although we cannot tell from the potential how fast it will occur).

In view of the large difference in reduction potentials between oxygen and most metals, it is surprising that the problem of corrosion does not completely prevent the use of metals in air. However, most metals develop a thin oxide coating, which tends to protect their internal atoms against further oxidation. The metal that best demonstrates this phenomenon is aluminum. With a reduction potential of -1.7 V , aluminum should be easily oxidized by \(\mathrm{O}_{2}\). According to the apparent thermodynamics of the reaction, an aluminum airplane could dissolve in a rainstorm. The fact that this very active metal can be used as a structural material is due to the formation of a thin, adherent layer of aluminum oxide \(\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)\), more properly represented as \(\mathrm{Al}_{2}(\mathrm{OH})_{6}\), which greatly inhibits further corrosion. The potential of the "passive," oxide-coated aluminum is -0.6 V , a value that causes it to behave much like a noble metal.

Iron also can form a protective oxide coating. This coating is not an infallible shield against corrosion, however; when steel is exposed to oxygen in moist air, the oxide that forms tends to scale off and expose new metal surfaces to corrosion.

The corrosion products of noble metals such as copper and silver are complex and affect the use of these metals as decorative materials. Under normal atmospheric conditions, copper forms an external layer of greenish copper carbonate called patina. Silver tarnish is silver sulfide \(\left(\mathrm{Ag}_{2} \mathrm{~S}\right)\), which in thin layers gives the silver surface a richer appearance. Gold, with a positive standard reduction potential of 1.50 V , significantly larger than that for oxygen \((1.23 \mathrm{~V})\), shows no appreciable corrosion in air.

\section*{Corrosion of Iron}

Since steel is the main structural material for bridges, buildings, and automobiles, controlling its corrosion is extremely important. To do this, we must understand the corrosion mechanism. Instead of being a direct oxidation process as we might expect, the corrosion of iron is an electrochemical reaction, as shown in Fig. 18.17.

Steel has a nonuniform surface because the chemical composition is not completely homogeneous. Also, physical strains leave stress points in the metal. These nonuniformities cause areas where the iron is more easily oxidized (anodic regions) than it is at

others (cathodic regions). In the anodic regions each iron atom gives up two electrons to form the \(\mathrm{Fe}^{2+}\) ion:
\[
\mathrm{Fe} \longrightarrow \mathrm{Fe}^{2+}+2 \mathrm{e}^{-}
\]

The electrons that are released flow through the steel, as they do through the wire of a galvanic cell, to a cathodic region, where they react with oxygen:
\[
\mathrm{O}_{2}+2 \mathrm{H}_{2} \mathrm{O}+4 \mathrm{e}^{-} \longrightarrow 4 \mathrm{OH}^{-}
\]

The \(\mathrm{Fe}^{2+}\) ions formed in the anodic regions travel to the cathodic regions through the moisture on the surface of the steel, just as ions travel through a salt bridge in a galvanic cell. In the cathodic regions \(\mathrm{Fe}^{2+}\) ions react with oxygen to form rust, which is hydrated iron(III) oxide of variable composition:
\[
4 \mathrm{Fe}^{2+}(a q)+\mathrm{O}_{2}(g)+(4+2 n) \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \underset{\text { Rust }}{2 \mathrm{Fe}_{2} \mathrm{O}_{3} \cdot n \mathrm{H}_{2} \mathrm{O}(s)+8 \mathrm{H}^{+}(a q)}
\]

Because of the migration of ions and electrons, rust often forms at sites that are remote from those where the iron dissolved to form pits in the steel. The degree of hydration of the iron oxide affects the color of the rust, which may vary from black to yellow to the familiar reddish brown.

The electrochemical nature of the rusting of iron explains the importance of moisture in the corrosion process. Moisture must be present to act as a kind of salt bridge between anodic and cathodic regions. Steel does not rust in dry air, a fact that explains why cars last much longer in the arid Southwest than in the relatively humid Midwest. Salt also accelerates rusting, a fact all too easily recognized by car owners in the colder parts of the United States, where salt is used on roads to melt snow and ice. The severity of rusting is greatly increased because the dissolved salt on the moist steel surface increases the conductivity of the aqueous solution formed there and thus accelerates the electrochemical corrosion process. Chloride ions also form very stable complex ions with \(\mathrm{Fe}^{3+}\), and this factor tends to encourage the dissolving of the iron, again accelerating the corrosion.

\section*{Prevention of Corrosion}

Prevention of corrosion is an important way of conserving our natural resources of energy and metals. The primary means of protection is the application of a coating, most commonly paint or metal plating, to protect the metal from oxygen and moisture. Chromium and tin are often used to plate steel (see Section 18.8) because they oxidize to form a durable, effective oxide coating. Zinc, also used to coat steel in a process called galvanizing, forms a mixed oxide-carbonate coating. Since zinc is a more active metal than iron, as the potentials for the oxidation half-reactions show,
\[
\begin{array}{ll}
\mathrm{Fe} \longrightarrow \mathrm{Fe}^{2+}+2 \mathrm{e}^{-} & -\mathscr{E}^{\circ}=0.44 \mathrm{~V} \\
\mathrm{Zn} \longrightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-} & -\mathscr{E}^{\circ}=0.76 \mathrm{~V}
\end{array}
\]
any oxidation that occurs dissolves zinc rather than iron. Recall that the reaction with the most positive standard potential has the greatest thermodynamic tendency to occur. Thus zinc acts as a "sacrificial" coating on steel.

Alloying is also used to prevent corrosion. Stainless steel contains chromium and nickel, both of which form oxide coatings that change steel's reduction potential to one characteristic of the noble metals. In addition, a new technology is now being developed to create surface alloys. That is, instead of forming a metal alloy such as stainless steel, which has the same composition throughout, a cheaper carbon steel is treated by ion bombardment to produce a thin layer of stainless steel or other desirable alloy on the surface. In this process, a "plasma" or "ion gas" of the alloying ions is formed at high temperatures and is then directed onto the surface of the metal.

FIGURE 18.18 Cathodic protection of an underground pipe.

Cathodic protection is a method most often used to protect steel in buried fuel tanks and pipelines. An active metal, such as magnesium, is connected by a wire to the pipeline or tank to be protected (Fig. 18.18). Because the magnesium is a better reducing agent than iron, electrons are furnished by the magnesium rather than by the iron, keeping the iron from being oxidized. As oxidation occurs, the magnesium anode dissolves, and so it must be replaced periodically. Ships' hulls are protected in a similar way by attaching bars of titanium metal to the steel hull. In salt water the titanium acts as the anode and is oxidized instead of the steel hull (the cathode).

\subsection*{18.7 Electrolysis}

An electrolytic cell uses electrical energy to produce a chemical change that would otherwise not occur spontaneously.

A galvanic cell produces current when an oxidation-reduction reaction proceeds spontaneously. A similar apparatus, an electrolytic cell, uses electrical energy to produce chemical change. The process of electrolysis involves forcing a current through a cell to produce a chemical change for which the cell potential is negative; that is, electrical work causes an otherwise nonspontaneous chemical reaction to occur. Electrolysis has great practical importance; for example, charging a battery, producing aluminum metal, and chrome plating an object are all done electrolytically.

To illustrate the difference between a galvanic cell and an electrolytic cell, consider the cell shown in Fig. 18.19(a) as it runs spontaneously to produce 1.10 V . In this galvanic cell, the reaction at the anode is
\[
\mathrm{Zn} \longrightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-}
\]
whereas at the cathode the reaction is
\[
\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}
\]

Figure 18.19(b) shows an external power source forcing electrons through the cell in the opposite direction to that in (a). This requires an external potential greater than 1.10 V , which must be applied in opposition to the natural cell potential. This device is an electrolytic cell. Notice that since electron flow is opposite in the two cases, the anode and cathode are reversed between (a) and (b). Also, ion flow through the salt bridge is opposite in the two cells.

Now we will consider the stoichiometry of electrolytic processes, that is, how much chemical change occurs with the flow of a given current for a specified time. Suppose we wish to determine the mass of copper that is plated out when a current of 10.0 amps (an ampere [amp], abbreviated A, is 1 coulomb of charge per second) is passed for 30.0 minutes through a solution containing \(\mathrm{Cu}^{2+}\). Plating means depositing the neutral metal on the electrode by reducing the metal ions in solution. In this case each \(\mathrm{Cu}^{2+}\) ion requires two electrons to become an atom of copper metal:
\[
\mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s)
\]

This reduction process will occur at the cathode of the electrolytic cell.

To solve this stoichiometry problem, we need the following steps:

1. Since an amp is a coulomb of charge per second, we multiply the current by the time in seconds to obtain the total coulombs of charge passed into the \(\mathrm{Cu}^{2+}\) solution at the cathode:
\[
\begin{aligned}
\text { Coulombs of charge } & =\mathrm{amps} \times \text { seconds }=\frac{\mathrm{C}}{\mathrm{~s}} \times \mathrm{s} \\
& =10.0 \frac{\mathrm{C}}{\mathrm{~s}} \times 30.0 \mathrm{~min} \times 60.0 \frac{\mathrm{~s}}{\mathrm{~min}} \\
& =1.80 \times 10^{4} \mathrm{C}
\end{aligned}
\]
2. Since 1 mole of electrons carries a charge of 1 faraday, or 96,485 coulombs, we can calculate the number of moles of electrons required to carry \(1.80 \times 10^{4}\) coulombs of charge:
\[
1.80 \times 10^{4} \mathrm{C} \times \frac{1 \mathrm{~mol} \mathrm{e}^{-}}{96,485 \mathrm{C}}=1.87 \times 10^{-1} \mathrm{~mol} \mathrm{e}^{-}
\]

This means that 0.187 mole of electrons flowed into the \(\mathrm{Cu}^{2+}\) solution.
3. Each \(\mathrm{Cu}^{2+}\) ion requires two electrons to become a copper atom. Thus each mole of electrons produces \(\frac{1}{2}\) mole of copper metal:
\[
1.87 \times 10^{-1} \mathrm{~mol} \mathrm{e}^{-} \times \frac{1 \mathrm{~mol} \mathrm{Cu}}{2 \mathrm{~mol} \mathrm{e}^{-}}=9.35 \times 10^{-2} \mathrm{~mol} \mathrm{Cu}
\]
4. We now know the moles of copper metal plated onto the cathode, and we can calculate the mass of copper formed:
\[
9.35 \times 10^{-2} \mathrm{~mol} \mathrm{Cu} \times \frac{63.546 \mathrm{~g}}{\mathrm{~mol} \mathrm{Cu}}=5.94 \mathrm{~g} \mathrm{Cu}
\]

FIGURE 18.19 (a) A standard galvanic cell based on the spontaneous reaction
\[
\mathrm{Zn}+\mathrm{Cu}^{2+} \longrightarrow \mathrm{Zn}^{2+}+\mathrm{Cu}
\]
(b) A standard electrolytic cell. A power source forces the opposite reaction
\[
\mathrm{Cu}+\mathrm{Zn}^{2+} \longrightarrow \mathrm{Cu}^{2+}+\mathrm{Zn}
\]

\section*{INTERACTIVE EXAMPLE 18.9}

\section*{SOLUTION}

Example 18.9 describes only the half-cell of interest. There also must be an anode at which oxidation is occurring.

\section*{Electroplating}

How long must a current of 5.00 A be applied to a solution of \(\mathrm{Ag}^{+}\)to produce 10.5 g silver metal?

In this case, we must use the steps given earlier in reverse:

Each \(\mathrm{Ag}^{+}\)ion requires one electron to become a silver atom:
\[
\mathrm{Ag}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Ag}
\]

Thus \(9.73 \times 10^{-2}\) mole of electrons is required, and we can calculate the quantity of charge carried by these electrons:
\[
9.73 \times 10^{-2} \mathrm{~mol} \mathrm{e}^{-} \times \frac{96,485 \mathrm{C}}{\mathrm{~mol} \mathrm{e}^{-}}=9.39 \times 10^{3} \mathrm{C}
\]

The \(5.00 \mathrm{~A}(5.00 \mathrm{C} / \mathrm{s})\) of current must produce \(9.39 \times 10^{3} \mathrm{C}\) of charge. Thus
\[
\begin{gathered}
\left(5.00 \frac{\mathrm{C}}{\mathrm{~s}}\right) \times(\text { time, in s })=9.39 \times 10^{3} \mathrm{C} \\
\text { Time }=\frac{9.39 \times 10^{3}}{5.00} \mathrm{~s}=1.88 \times 10^{3} \mathrm{~s}=31.3 \mathrm{~min}
\end{gathered}
\]

See Exercises 18.91 through 18.94

FIGURE 18.20 The electrolysis of water produces hydrogen gas at the cathode (on the right) and oxygen gas at the anode (on the left). Note that twice as much hydrogen is produced as oxygen.

\section*{Electrolysis of Water}

We have seen that hydrogen and oxygen combine spontaneously to form water and that the accompanying decrease in free energy can be used to run a fuel cell to produce electricity. The reverse process, which is of course nonspontaneous, can be forced by electrolysis:

Anode reaction:
\[
\begin{array}{lcr}
\text { Anode reaction: } & 2 \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{O}_{2}+4 \mathrm{H}^{+}+4 \mathrm{e}^{-} & -\mathscr{E}^{\circ}=-1.23 \mathrm{~V} \\
\text { Cathode reaction: } & 4 \mathrm{H}_{2} \mathrm{O}+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{H}_{2}+4 \mathrm{OH}^{-} & \mathscr{E}^{\circ}=-0.83 \mathrm{~V} \\
\text { Net reaction: } & 6 \mathrm{H}_{2} \mathrm{O} \longrightarrow 2 \mathrm{H}_{2}+\mathrm{O}_{2}+\underbrace{4\left(\mathrm{H}^{+}+\mathrm{OH}^{-}\right)}_{4 \mathrm{H}_{2} \mathrm{O}} & \mathscr{E}^{\circ}=-2.06 \mathrm{~V} \\
\text { or } & 2 \mathrm{H}_{2} \mathrm{O} \longrightarrow 2 \mathrm{H}_{2}+\mathrm{O}_{2} &
\end{array}
\]

Net reaction:
or
Note that these potentials assume an anode chamber with \(1 M \mathrm{H}^{+}\)and a cathode chamber with \(1 \mathrm{M} \mathrm{OH}^{-}\). In pure water, where \(\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]=10^{-7} M\), the potential for the overall process is -1.23 V .

In practice, however, if platinum electrodes connected to a 6-V battery are dipped into pure water, no reaction is observed because pure water contains so few ions that only a negligible current can flow. However, addition of even a small amount of a soluble salt causes an immediate evolution of bubbles of hydrogen and oxygen, as illustrated in Fig. 18.20.

\section*{Electrolysis of Mixtures of Ions}

Suppose a solution in an electrolytic cell contains the ions \(\mathrm{Cu}^{2+}, \mathrm{Ag}^{+}\), and \(\mathrm{Zn}^{2+}\). If the voltage is initially very low and is gradually turned up, in which order will the metals be plated out onto the cathode? This question can be answered by looking at the standard reduction potentials of these ions:
\[
\begin{aligned}
\mathrm{Ag}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Ag} & \mathscr{E}^{\circ}=0.80 \mathrm{~V} \\
\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu} & \mathscr{E}^{\circ}=0.34 \mathrm{~V} \\
\mathrm{Zn}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Zn} & \mathscr{E}^{\circ}=-0.76 \mathrm{~V}
\end{aligned}
\]

Remember that the more positive the \(\mathscr{E}^{\circ}\) value, the more the reaction has a tendency to proceed in the direction indicated. Of the three reactions listed, the reduction of \(\mathrm{Ag}^{+}\) occurs most easily, and the order of oxidizing ability is
\[
\mathrm{Ag}^{+}>\mathrm{Cu}^{2+}>\mathrm{Zn}^{2+}
\]

This means that silver will plate out first as the potential is increased, followed by copper, and finally zinc.

\section*{INTERACTIVE EXAMPLE 18.10}

\section*{Relative Oxidizing Abilities}

An acidic solution contains the ions \(\mathrm{Ce}^{4+}, \mathrm{VO}_{2}{ }^{+}\), and \(\mathrm{Fe}^{3+}\). Using the \(\mathscr{E}^{\circ}\) values listed in Table 18.1, give the order of oxidizing ability of these species, and predict which one will be reduced at the cathode of an electrolytic cell at the lowest voltage.

\section*{SOLUTION}

The half-reactions and \(\mathscr{E}^{\circ}\) values are
\[
\begin{array}{cl}
\mathrm{Ce}^{4+}+\mathrm{e}^{-} \longrightarrow \mathrm{Ce}^{3+} & \mathscr{E} \circ=1.70 \mathrm{~V} \\
\mathrm{VO}_{2}^{+}+2 \mathrm{H}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{VO}^{2+}+\mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ}=1.00 \mathrm{~V} \\
\mathrm{Fe}^{3+}+\mathrm{e}^{-} \longrightarrow \mathrm{Fe}^{2+} & \mathscr{E}^{\circ}=0.77 \mathrm{~V}
\end{array}
\]

The order of oxidizing ability is therefore
\[
\mathrm{Ce}^{4+}>\mathrm{VO}_{2}^{+}>\mathrm{Fe}^{3+}
\]
- The \(\mathrm{Ce}^{4+}\) ion will be reduced at the lowest voltage in an electrolytic cell.

See Exercise 18.103

The principle described in this section is very useful, but it must be applied with some caution. For example, in the electrolysis of an aqueous solution of sodium chloride, we should be able to use \(\mathscr{E}^{\circ}\) values to predict the products. Of the major species in the solution \(\left(\mathrm{Na}^{+}, \mathrm{Cl}^{-}\right.\), and \(\left.\mathrm{H}_{2} \mathrm{O}\right)\), only \(\mathrm{Cl}^{-}\)and \(\mathrm{H}_{2} \mathrm{O}\) can be readily oxidized. The half-reactions (written as oxidization processes) are
\[
\begin{aligned}
2 \mathrm{Cl}^{-} \longrightarrow \mathrm{Cl}_{2}+2 \mathrm{e}^{-} & -\mathscr{E}^{\circ}=-1.36 \mathrm{~V} \\
2 \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{O}_{2}+4 \mathrm{H}^{+}+4 \mathrm{e}^{-} & -\mathscr{E}^{\circ}=-1.23 \mathrm{~V}
\end{aligned}
\]

Since water has the more positive potential, we would expect to see \(\mathrm{O}_{2}\) produced at the anode because it is easier (thermodynamically) to oxidize \(\mathrm{H}_{2} \mathrm{O}\) than \(\mathrm{Cl}^{-}\). Actually, this does not happen. As the voltage is increased in the cell, the \(\mathrm{Cl}^{-}\)ion is the first to be oxidized. A much higher potential than expected is required to oxidize water. The voltage required in excess of the expected value (called the overvoltage) is much greater for the production of \(\mathrm{O}_{2}\) than for \(\mathrm{Cl}_{2}\), which explains why chlorine is produced first.

The causes of overvoltage are very complex. Basically, the phenomenon is caused by difficulties in transferring electrons from the species in the solution to the atoms on the electrode across the electrode-solution interface. Because of this situation, \(\mathscr{E}^{\circ}\) values must be used cautiously in predicting the actual order of oxidation or reduction of species in an electrolytic cell.

\section*{CHEMICAL CONNECTIONS}

\section*{The Chemistry of Sunken Treasure}

When the galleon Atocha was destroyed on a reef by a hurricane in 1622, it was bound for Spain carrying approximately 47 tons of copper, gold, and silver from the New World. The bulk of the treasure was silver bars and coins packed in wooden chests. When treasure hunter Mel Fisher salvaged the silver in 1985, corrosion and marine growth had transformed the shiny metal into something that looked like coral. Restoring the silver to its original condition required an understanding of the chemical changes that had occurred in 350 years of being submerged in the ocean. Much of this chemistry we have already considered at various places in this text.

As the wooden chests containing the silver decayed, the oxygen supply was depleted, favoring the growth of certain bacteria that use the sulfate ion rather than oxygen as an oxidizing agent to generate energy. As these bacteria consume sulfate ions, they release hydrogen sulfide gas that reacts with silver to form black silver sulfide:
\[
2 \mathrm{Ag}(s)+\mathrm{H}_{2} \mathrm{~S}(a q) \longrightarrow \mathrm{Ag}_{2} \mathrm{~S}(\mathrm{~s})+\mathrm{H}_{2}(g)
\]

Thus, over the years, the surface of the silver became covered with a tightly adhering layer of corrosion, which fortunately protected the silver underneath and thus prevented total conversion of the silver to silver sulfide.

Another change that took place as the wood decomposed was the formation of carbon dioxide. This shifted the equilibrium that is present in the ocean,
\[
\mathrm{CO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \underset{\mathrm{HCO}_{3}^{-}(a q)}{\rightleftharpoons}+\mathrm{H}^{+}(a q)
\]
to the right, producing higher concentrations of \(\mathrm{HCO}_{3}{ }^{-}\). In turn, the \(\mathrm{HCO}_{3}{ }^{-}\)

\section*{A}

Silver coins and tankards salvaged from the wreck of the Atocha.
reacted with \(\mathrm{Ca}^{2+}\) ions present in the seawater to form calcium carbonate:
\[
\mathrm{Ca}^{2+}(a q)+\mathrm{HCO}_{3}^{-}(a q) \underset{\mathrm{CaCO}_{3}(s)}{\rightleftharpoons}+\mathrm{H}^{+}(a q)
\]

Calcium carbonate is the main component of limestone. Thus, over time, the corroded silver coins and bars became encased in limestone.

Both the limestone formation and the corrosion had to be dealt with. Since \(\mathrm{CaCO}_{3}\) contains the basic anion \(\mathrm{CO}_{3}{ }^{2-}\), acid dissolves limestone:
\[
\begin{aligned}
& 2 \mathrm{H}^{+}(a q)+\mathrm{CaCO}_{3}(s) \\
& \mathrm{Ca}^{2+}(a q)
\end{aligned} \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
\]

Soaking the mass of coins in a buffered acidic bath for several hours allowed the individual pieces to be separated, and the black \(\mathrm{Ag}_{2} \mathrm{~S}\) on the surfaces was revealed. An abrasive could not be
used to remove this corrosion; it would have destroyed the details of the engraving-a very valuable feature of the coins to a historian or a collectorand it would have washed away some of the silver. Instead, the corrosion reaction was reversed through electrolytic reduction. The coins were connected to the cathode of an electrolytic cell in a dilute sodium hydroxide solution as represented in the figure.

As electrons flow, the \(\mathrm{Ag}^{+}\)ions in the silver sulfide are reduced to silver metal:
\[
\mathrm{Ag}_{2} \mathrm{~S}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Ag}+\mathrm{S}^{2-}
\]

As a by-product, bubbles of hydrogen gas from the reduction of water form on the surface of the coins:
\[
2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{OH}^{-}
\]

The agitation caused by the bubbles loosens the flakes of metal sulfide and helps clean the coins.

These procedures have made it possible to restore the treasure to very nearly its condition when the Atocha sailed many years ago.

\subsection*{18.8 Commercial Electrolytic}

FIGURE 18.21 Charles Martin Hall (1863-1914) was a student at Oberlin College in Ohio when he first became interested in aluminum. One of his professors commented that anyone who could manufacture aluminum cheaply would make a fortune, and Hall decided to give it a try. The 21-year-old Hall worked in a wooden shed near his house with an iron frying pan as a container, a blacksmith's forge as a heat source, and galvanic cells constructed from fruit jars. Using these crude galvanic cells, Hall found that he could produce aluminum by passing a current through a molten \(\mathrm{Al}_{2} \mathrm{O}_{3} / \mathrm{Na}_{3} \mathrm{AlF}_{6}\) mixture. By a strange coincidence, Paul Heroult, a Frenchman who was born and died in the same years as Hall, made the same discovery at about the same time.

TABLE 18.3 | The Price of Aluminum over the Past Century
\begin{tabular}{|cc|}
\hline Date & \begin{tabular}{r} 
Price of Aluminum \\
\((\$ / / b) *\)
\end{tabular} \\
\hline 1855 & 100,000 \\
\hline 1885 & 100 \\
\hline 1890 & 2 \\
\hline 1895 & 0.50 \\
\hline 1970 & 0.30 \\
\hline 1980 & 0.80 \\
\hline 1990 & 0.74 \\
\hline
\end{tabular}
*Note the precipitous drop in price after the discovery of the Hall-Heroult process.

\section*{Production of Aluminum}

Aluminum is one of the most abundant elements on earth, ranking third behind oxygen and silicon. Since aluminum is a very active metal, it is found in nature as its oxide in an ore called bauxite (named after Les Baux, France, where it was discovered in 1821). Production of aluminum metal from its ore proved to be more difficult than production of most other metals. In 1782 Lavoisier recognized aluminum to be a metal "whose affinity for oxygen is so strong that it cannot be overcome by any known reducing agent." As a result, pure aluminum metal remained unknown. Finally, in 1854 a process was found for producing metallic aluminum using sodium, but aluminum remained a very expensive rarity. In fact, it is said that Napoleon III served his most honored guests with aluminum forks and spoons, while the others had to settle for gold and silver utensils.

The breakthrough came in 1886 when two men, Charles M. Hall in the United States and Paul Heroult in France, almost simultaneously discovered a practical electrolytic process for producing aluminum (Fig. 18.21). The key factor in the HallHeroult process is the use of molten cryolite \(\left(\mathrm{Na}_{3} \mathrm{AlF}_{6}\right)\) as the solvent for the aluminum oxide.

Electrolysis is possible only if ions can move to the electrodes. A common method for producing ion mobility is dissolving the substance to be electrolyzed in water. This is not possible in the case of aluminum because water is more easily reduced than \(\mathrm{Al}^{3+}\), as the following standard reduction potentials show:
\[
\begin{array}{rlr}
\mathrm{Al}^{3+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al} & \mathscr{E} \circ=-1.66 \mathrm{~V} \\
2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}+2 \mathrm{OH}^{-} & \mathscr{E} \circ=-0.83 \mathrm{~V}
\end{array}
\]

Thus aluminum metal cannot be plated out of an aqueous solution of \(\mathrm{Al}^{3+}\).
Ion mobility also can be produced by melting the salt. But the melting point of solid \(\mathrm{Al}_{2} \mathrm{O}_{3}\) is much too high \(\left(2050^{\circ} \mathrm{C}\right)\) to allow practical electrolysis of the molten oxide. A mixture of \(\mathrm{Al}_{2} \mathrm{O}_{3}\) and \(\mathrm{Na}_{3} \mathrm{AlF}_{6}\), however, has a melting point of \(1000^{\circ} \mathrm{C}\), and the resulting molten mixture can be used to obtain aluminum metal electrolytically. Because of this discovery by Hall and Heroult, the price of aluminum plunged (Table 18.3), and its use became economically feasible.

Bauxite is not pure aluminum oxide (called alumina); it also contains the oxides of iron, silicon, and titanium, and various silicate materials. To obtain the pure hydrated alumina \(\left(\mathrm{Al}_{2} \mathrm{O}_{3} \cdot n \mathrm{H}_{2} \mathrm{O}\right)\), the crude bauxite is treated with aqueous sodium hydroxide. Being amphoteric, alumina dissolves in the basic solution:
\[
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+2 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{AlO}_{2}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
\]

The other metal oxides, which are basic, remain as solids. The solution containing the aluminate ion \(\left(\mathrm{AlO}_{2}^{-}\right)\)is separated from the sludge of the other oxides and is acidified with carbon dioxide gas, causing the hydrated alumina to reprecipitate:
\[
2 \mathrm{CO}_{2}(g)+2 \mathrm{AlO}_{2}^{-}(a q)+(n+1) \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{HCO}_{3}^{-}(a q)+\mathrm{Al}_{2} \mathrm{O}_{3} \cdot n \mathrm{H}_{2} \mathrm{O}(s)
\]

The purified alumina is then mixed with cryolite and melted, and the aluminum ion is reduced to aluminum metal in an electrolytic cell of the type shown in Fig. 18.22.

FIGURE 18.22 A schematic diagram of an electrolytic cell for producing aluminum by the Hall-Heroult process. Because molten aluminum is more dense than the mixture of molten cryolite and alumina, it settles to the bottom of the cell and is drawn off periodically. The graphite electrodes are gradually eaten away and must be replaced from time to time. The cell operates at a current flow of up to \(250,000 \mathrm{~A}\).

Because the electrolyte solution contains a large number of aluminum-containing ions, the chemistry is not completely clear. However, the alumina probably reacts with the cryolite anion as follows:
\[
\mathrm{Al}_{2} \mathrm{O}_{3}+4 \mathrm{AlF}_{6}^{3-} \longrightarrow 3 \mathrm{Al}_{2} \mathrm{OF}_{6}^{2-}+6 \mathrm{~F}^{-}
\]

The electrode reactions are thought to be
Cathode reaction: \(\quad \mathrm{AlF}_{6}{ }^{3-}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al}+6 \mathrm{~F}^{-}\)
Anode reaction: \(\quad 2 \mathrm{Al}_{2} \mathrm{OF}_{6}{ }^{2-}+12 \mathrm{~F}^{-}+\mathrm{C} \longrightarrow 4 \mathrm{AlF}_{6}{ }^{3-}+\mathrm{CO}_{2}+4 \mathrm{e}^{-}\)
The overall cell reaction can be written as
\[
2 \mathrm{Al}_{2} \mathrm{O}_{3}+3 \mathrm{C} \longrightarrow 4 \mathrm{Al}+3 \mathrm{CO}_{2}
\]

The aluminum produced in this electrolytic process is \(99.5 \%\) pure. To be useful as a structural material, aluminum is alloyed with metals such as zinc (used for trailer and aircraft construction) and manganese (used for cooking utensils, storage tanks, and highway signs). The production of aluminum consumes about \(5 \%\) of all the electricity used in the United States.

\section*{Electrorefining of Metals}

Purification of metals is another important application of electrolysis. For example, impure copper from the chemical reduction of copper ore is cast into large slabs that serve as the anodes for electrolytic cells. Aqueous copper sulfate is the electrolyte, and thin sheets of ultrapure copper function as the cathodes (Fig. 18.23).

The main reaction at the anode is
\[
\mathrm{Cu} \longrightarrow \mathrm{Cu}^{2+}+2 \mathrm{e}^{-}
\]

Other metals such as iron and zinc are also oxidized from the impure anode:
\[
\begin{aligned}
& \mathrm{Zn} \longrightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-} \\
& \mathrm{Fe} \longrightarrow \mathrm{Fe}^{2+}+2 \mathrm{e}^{-}
\end{aligned}
\]

Noble metal impurities in the anode are not oxidized at the voltage used; they fall to the bottom of the cell to form a sludge, which is processed to remove the valuable silver, gold, and platinum.

The \(\mathrm{Cu}^{2+}\) ions from the solution are deposited onto the cathode
\[
\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}
\]
producing copper that is \(99.95 \%\) pure.

FIGURE 18.23 Ultrapure copper sheets serve as cathodes.

\section*{Metal Plating}

Metals that readily corrode can often be protected by the application of a thin coating of a metal that resists corrosion. Examples are "tin" cans, which are actually steel cans with a thin coating of tin, and chrome-plated steel bumpers for automobiles.

An object can be plated by making it the cathode in a tank containing ions of the plating metal. The silver plating of a spoon is shown schematically in Fig. 18.24(b). In an actual plating process, the solution also contains ligands that form complexes with the silver ion. By lowering the concentration of \(\mathrm{Ag}^{+}\)in this way, a smooth, even coating of silver is obtained.

FIGURE 18.24 (a) Art Nouveau silver plated milk jug. (b) Schematic of the electroplating of a spoon. The item to be plated is the cathode, and the anode is a silver bar. Silver is plated out at the cathode: \(\mathrm{Ag}^{+}+\mathrm{e}^{-} \rightarrow \mathrm{Ag}\). Note that a salt bridge is not needed here because \(\mathrm{Ag}^{+}\)ions are involved at both electrodes.

-b

Addition of a nonvolatile solute lowers the melting point of the solvent, molten NaCl in this case.

\section*{Electrolysis of Sodium Chloride}

Sodium metal is mainly produced by the electrolysis of molten sodium chloride. Because solid NaCl has a rather high melting point \(\left(800^{\circ} \mathrm{C}\right)\), it is usually mixed with solid \(\mathrm{CaCl}_{2}\) to lower the melting point to about \(\left(600^{\circ} \mathrm{C}\right)\). The mixture is then electrolyzed in a Downs cell, as illustrated in Fig. 18.25, where the reactions are
\[
\begin{array}{lr}
\text { Anode reaction: } & \quad 2 \mathrm{Cl}^{-} \longrightarrow \mathrm{Cl}_{2}+2 \mathrm{e}^{-} \\
\text {Cathode reaction: } & \mathrm{Na}^{+}+e^{-} \longrightarrow \mathrm{Na}
\end{array}
\]

At the temperatures in the Downs cell, the sodium is liquid and is drained off, then cooled, and cast into blocks. Because it is so reactive, sodium must be stored in an inert solvent, such as mineral oil, to prevent its oxidation.

Electrolysis of aqueous sodium chloride (brine) is an important industrial process for the production of chlorine and sodium hydroxide. In fact, this process is the second largest consumer of electricity in the United States, after the production of aluminum. Sodium is not produced in this process under normal circumstances because \(\mathrm{H}_{2} \mathrm{O}\) is more easily reduced than \(\mathrm{Na}^{+}\), as the standard reduction potentials show:
\[
\begin{array}{rlrl}
\mathrm{Na}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Na} & \mathscr{E} \circ & =-2.71 \mathrm{~V} \\
2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}+2 \mathrm{OH}^{-} & \mathscr{E}^{\circ}=-0.83 \mathrm{~V}
\end{array}
\]

Hydrogen, not sodium, is produced at the cathode.
For the reasons we discussed in Section 18.7, chlorine gas is produced at the anode. Thus the electrolysis of brine produces hydrogen and chlorine:

It leaves a solution containing dissolved NaOH and NaCl .

FIGURE 18.25 The Downs cell for the electrolysis of molten sodium chloride. The cell is designed so that the sodium and chlorine produced cannot come into contact with each other to re-form NaCl .

The contamination of the sodium hydroxide by NaCl can be virtually eliminated using a special mercury cell for electrolyzing brine (Fig. 18.26). In this cell, mercury is the conductor at the cathode, and because hydrogen gas has an extremely high overvoltage with a mercury electrode, \(\mathrm{Na}^{+}\)is reduced instead of \(\mathrm{H}_{2} \mathrm{O}\). The resulting sodium metal dissolves in the mercury, forming a liquid alloy, which is then pumped to a chamber where the dissolved sodium reacts with water to produce hydrogen:
\[
2 \mathrm{Na}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{Na}^{+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
\]

Relatively pure solid NaOH can be recovered from the aqueous solution, and the regenerated mercury is then pumped back to the electrolysis cell. This process, called the chlor-alkali process, was the main method for producing chlorine and sodium hydroxide in the United States for many years. However, because of the environmental problems associated with the mercury cell, it has been largely displaced in the chloralkali industry by other technologies. In the United States, nearly \(75 \%\) of the chloralkali production is now carried out in diaphragm cells. In a diaphragm cell the cathode and anode are separated by a diaphragm that allows passage of \(\mathrm{H}_{2} \mathrm{O}\) molecules, \(\mathrm{Na}^{+}\)ions, and, to a limited extent, \(\mathrm{Cl}^{-}\)ions. The diaphragm does not allow \(\mathrm{OH}^{-}\)ions to pass through it. Thus the \(\mathrm{H}_{2}\) and \(\mathrm{OH}^{-}\)formed at the cathode are kept separate from the \(\mathrm{Cl}_{2}\) formed at the anode. The major disadvantage of this process is that the aqueous effluent pumped from the cathode compartment contains a mixture of sodium hydroxide and unreacted sodium chloride, which must be separated if pure sodium hydroxide is a desired product.

In the past 30 years, a new process has been developed in the chlor-alkali industry that uses a membrane to separate the anode and cathode compartments in brine electrolysis cells. The membrane is superior to a diaphragm because the membrane is impermeable to anions. Only cations can flow through the membrane. Because neither \(\mathrm{Cl}^{-}\)nor \(\mathrm{OH}^{-}\)ions can pass through the membrane separating the anode and cathode compartments, NaCl contamination of the NaOH formed at the cathode does not occur. Although membrane technology is now just becoming prominent in the United States, it is the dominant method for chlor-alkali production in Japan.

FIGURE 18.26 The mercury cell for production of chlorine and sodium hydroxide. The large overvoltage required to produce hydrogen at a mercury electrode means that \(\mathrm{Na}^{+}\)ions are reduced rather than water. The sodium formed dissolves in the liquid mercury and is pumped to a chamber, where it reacts with water.

\section*{Electrochemistry}
> The study of the interchange of chemical and electrical energy
> Uses oxidation-reduction reactions
> Galvanic cell: chemical energy is transformed into electrical energy by separating the oxidizing and reducing agents and forcing the electrons to travel through a wire
> Electrolytic cell: electrical energy is used to produce a chemical change

\section*{Galvanic cell}
) Anode: the electrode where oxidation occurs
) Cathode: the electrode where reduction occurs
) The driving force behind the electron transfer is called the cell potential ( \(\mathscr{E}_{\text {cell }}\) )
> The potential is measured in units of volts (V), defined as a joule of work per coulomb of charge:
\[
\mathscr{E}(\mathrm{V})=\frac{-\operatorname{work}(\mathrm{J})}{\operatorname{charge}(\mathrm{C})}=-\frac{w}{q}
\]
) A system of half-reactions, called standard reduction potentials, can be used to calculate the potentials of various cells
> The half-reaction \(2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}\) is arbitrarily assigned a potential of 0 V

\section*{Free energy and work}
) The maximum work that a cell can perform is
\[
-w_{\max }=q \mathscr{\mathscr { C } _ { \operatorname { m a x } }}
\]
where \(\mathscr{E}_{\text {max }}\) represents the cell potential when no current is flowing
> The actual work obtained from a cell is always less than the maximum because energy is lost through frictional heating of the wire when current flows
> For a process carried out at constant temperature and pressure, the change in free energy equals the maximum useful work obtainable from that process:
\[
\Delta G=w_{\max }=-q \mathscr{E} \mathscr{E}_{\max }=-n F_{\mathscr{E}}^{\mathscr{E}}
\]
where \(F\) (faraday) equals \(96,485 \mathrm{C}\) and \(n\) is the number of moles of electrons transferred in the process

\section*{Concentration cell}
) A galvanic cell in which both compartments have the same components but at different concentrations
) The electrons flow in the direction that tends to equalize the concentrations

\section*{Nernst equation}
> Shows how the cell potential depends on the concentrations of the cell components:
\[
\mathscr{E}=\mathscr{E}^{0}-\frac{0.0591}{n} \log Q \quad \text { at } 25^{\circ} \mathrm{C}
\]
) When a galvanic cell is at equilibrium, \(\mathscr{E}=0\) and \(Q=K\)

\section*{Batteries}
> A battery consists of a galvanic cell or group of cells connected in series that serve as a source of direct current.

\section*{Key terms}

Section 18.6
corrosion galvanizing cathodic protection
Section 18.7
electrolytic cell electrolysis ampere

Section 18.8
Downs cell mercury cell chlor-alkali process
> Lead storage battery
> Anode: lead
) Cathode: lead coated with \(\mathrm{PbO}_{2}\)
) Electrolyte: \(\mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})\)
> Dry cell battery
> Contains a moist paste instead of a liquid electrolyte
> Anode: usually Zn
> Cathode: carbon rod in contact with an oxidizing agent (which varies depending on the application)

\section*{Fuel cells}
> Galvanic cells in which the reactants are continuously supplied
) The \(\mathrm{H}_{2} / \mathrm{O}_{2}\) fuel cell is based on the reaction between \(\mathrm{H}_{2}\) and \(\mathrm{O}_{2}\) to form water

\section*{Corrosion}
) Involves the oxidation of metals to form mainly oxides and sulfides
) Some metals, such as aluminum and chromium, form a thin, protective oxide coating that prevents further corrosion
) The corrosion of iron to form rust is an electrochemical process
> \(\mathrm{The} \mathrm{Fe}^{2+}\) ions formed at anodic areas of the surface migrate through the moisture layer to cathodic regions, where they react with oxygen from the air
> Iron can be protected from corrosion by coating it with paint or with a thin layer of metal such as chromium, tin, or zinc; by alloying; and by cathodic protection

\section*{Electrolysis}
) Used to place a thin coating of metal onto steel
) Used to produce pure metals such as aluminum and copper

\section*{Review Questions Answers to the Review Questions can be found on the Student website (accessible from www.cengagehrain.com).}
1. What is a redox reaction? Is the substance reduced the oxidizing agent or the reducing agent? How about the substance oxidized? Explain. What is a half-reaction? Why must the number of electrons lost in the oxidation half-reaction equal the number of electrons gained in the reduction half-reaction when balancing a redox reaction?
2. Galvanic cells harness spontaneous oxidation-reduction reactions to produce work by producing a current. They do so by controlling the flow of electrons from the species oxidized to the species reduced. How is a galvanic cell designed? What is in the cathode compartment? The anode compartment? What purpose do electrodes serve? Which way do electrons always flow in the wire connecting the two electrodes in a galvanic cell? Why is it necessary to use a salt bridge or a porous disk in a galvanic cell? Which way do cations flow in the salt bridge? Which way do the anions flow? What is a cell potential and what is a volt?
3. Table 18.1 lists common half-reactions along with the standard reduction potential associated with each
half-reaction. These standard reduction potentials are all relative to some standard. What is the standard (zero point)? If \(\mathscr{E}^{\circ}\) is positive for a half-reaction, what does it mean? If \(\mathscr{E}^{\circ}\) is negative for a half-reaction, what does it mean? Which species in Table 18.1 is most easily reduced? Least easily reduced? The reverse of the halfreactions in Table 18.1 are the oxidation half-reactions. How are standard oxidation potentials determined? In Table 18.1, which species is the best reducing agent? The worst reducing agent?

To determine the standard cell potential for a redox reaction, the standard reduction potential is added to the standard oxidation potential. What must be true about this sum if the cell is to be spontaneous (produce a galvanic cell)? Standard reduction and oxidation potentials are intensive. What does this mean? Summarize how line notation is used to describe galvanic cells.
4. Consider the equation \(\Delta G^{\circ}=-n F_{\mathscr{E}}{ }^{\circ}\). What are the four terms in this equation? Why does a minus sign appear in the equation? What does the superscript \({ }^{\circ}\) indicate?
5. The Nernst equation allows determination of the cell potential for a galvanic cell at nonstandard conditions. Write out the Nernst equation. What are nonstandard conditions? What do \(\mathscr{E}, \mathscr{E}^{\circ}, n\), and \(Q\) stand for in the Nernst equation? What does the Nernst equation reduce to when a redox reaction is at equilibrium? What are the signs of \(\Delta G^{\circ}\) and \(\mathscr{E}^{\circ}\) when \(K<1\) ? When \(K>1\) ? When \(K=1\) ? Explain the following statement: \(\mathscr{E}\) determines spontaneity, while \(\mathscr{E}{ }^{\circ}\) determines the equilibrium position. Under what conditions can you use \(\mathscr{E}^{\circ}\) to predict spontaneity?
6. What are concentration cells? What is \(\mathscr{E}^{\circ}\) in a concentration cell? What is the driving force for a concentration cell to produce a voltage? Is the higher or the lower ion concentration solution present at the anode? When the anode ion concentration is decreased and/or the cathode ion concentration is increased, both give rise to larger cell potentials. Why? Concentration cells are commonly used to calculate the value of equilibrium constants for various reactions. For example, the silver concentration cell illustrated in Fig. 18.9 can be used to determine the \(K_{\text {sp }}\) value for \(\mathrm{AgCl}(s)\). To do so, NaCl is added to the anode compartment until no more precipitate forms. The \(\left[\mathrm{Cl}^{-}\right]\)in solution is then determined somehow. What happens to \(\mathscr{E}_{\text {cell }}\) when NaCl is added to the anode compartment? To calculate the \(K_{\text {sp }}\) value, \(\left[\mathrm{Ag}^{+}\right]\)must be calculated. Given the value of \(\mathscr{E}_{\text {cell }}\), how is \(\left[\mathrm{Ag}^{+}\right]\)determined at the anode?
7. Batteries are galvanic cells. What happens to \(\mathscr{E}_{\text {cell }}\) as a battery discharges? Does a battery represent a system at equilibrium? Explain. What is \(\mathscr{E}_{\text {cell }}\) when a battery reaches equilibrium? How are batteries and fuel cells alike? How are they different? The U.S. space program

\section*{Active Learning Questions}

These questions are designed to be used by groups of students in class.
1. Which of the following statements is(are) true? Explain.
a. Oxidation and reduction cannot occur independently of each other.
b. Oxidation and reduction accompany all chemical reactions.
c. A substance that reacts with oxygen gas will always be oxidized.
2. When balancing reactions in Chapter 3, we did not mention that reactions must be charge balanced as well as mass balanced. What do charge balance and mass balance mean? What happens in a redox reaction that requires charge to be balanced?
3. Sketch a galvanic cell, and explain how it works. Look at Figs. 18.1 and 18.2. Explain what is occurring in each container and why the cell in Fig. 18.2 "works" but the one in Fig. 18.1 does not.
4. In making a specific galvanic cell, explain how one decides on the electrodes and the solutions to use in the cell.
utilizes hydrogen-oxygen fuel cells to produce power for its spacecraft. What is a hydrogen-oxygen fuel cell?
8. Not all spontaneous redox reactions produce wonderful results. Corrosion is an example of a spontaneous redox process that has negative effects. What happens in the corrosion of a metal such as iron? What must be present for the corrosion of iron to take place? How can moisture and salt increase the severity of corrosion? Explain how the following protect metals from corrosion:
a. paint
b. durable oxide coatings
c. galvanizing
d. sacrificial metal
e. alloying
f. cathodic protection
9. What characterizes an electrolytic cell? What is an ampere? When the current applied to an electrolytic cell is multiplied by the time in seconds, what quantity is determined? How is this quantity converted to moles of electrons required? How are moles of electrons required converted to moles of metal plated out? What does plating mean? How do you predict the cathode and the anode half-reactions in an electrolytic cell? Why is the electrolysis of molten salts much easier to predict in terms of what occurs at the anode and cathode than the electrolysis of aqueous dissolved salts? What is overvoltage?
10. Electrolysis has many important industrial applications. What are some of these applications? The electrolysis of molten NaCl is the major process by which sodium metal is produced. However, the electrolysis of aqueous NaCl does not produce sodium metal under normal circumstances. Why? What is purification of a metal by electrolysis?
5. You want to "plate out" nickel metal from a nickel nitrate solution onto a piece of metal inserted into the solution. Should you use copper or zinc? Explain.
6. A copper penny can be dissolved in nitric acid but not in hydrochloric acid. Using reduction potentials from the book, show why this is so. What are the products of the reaction? Newer pennies contain a mixture of zinc and copper. What happens to the zinc in the penny when the coin is placed in nitric acid? Hydrochloric acid? Support your explanations with data from the book, and include balanced equations for all reactions.
7. Sketch a cell that forms iron metal from iron(II) while changing chromium metal to chromium(III). Calculate the voltage, show the electron flow, label the anode and cathode, and balance the overall cell equation.
8. Which of the following is the best reducing agent: \(\mathrm{F}_{2}, \mathrm{H}_{2}, \mathrm{Na}\), \(\mathrm{Na}^{+}, \mathrm{F}^{-}\)? Explain. Order as many of these species as possible from the best to the worst oxidizing agent. Why can't you order all of them? From Table 18.1 choose the species that is the best oxidizing agent. Choose the best reducing agent. Explain.
9. You are told that metal A is a better reducing agent than metal B. What, if anything, can be said about \(\mathrm{A}^{+}\)and \(\mathrm{B}^{+}\)? Explain.
10. Explain the following relationships: \(\Delta G\) and \(w\), cell potential and \(w\), cell potential and \(\Delta G\), cell potential and \(Q\). Using these relationships, explain how you could make a cell in which both electrodes are the same metal and both solutions contain the same compound, but at different concentrations. Why does such a cell run spontaneously?
11. Explain why cell potentials are not multiplied by the coefficients in the balanced redox equation. (Use the relationship between \(\Delta G\) and cell potential to do this.)
12. What is the difference between \(\mathscr{E}\) and \(\mathscr{E}^{\circ}\) ? When is \(\mathscr{E}\) equal to zero? When is \(\mathscr{E}^{\circ}\) equal to zero? (Consider "regular" galvanic cells as well as concentration cells.)
13. Consider the following galvanic cell:

What happens to \(\mathscr{E}\) as the concentration of \(\mathrm{Zn}^{2+}\) is increased? As the concentration of \(\mathrm{Ag}^{+}\)is increased? What happens to \(\mathscr{E}^{\circ}\) in these cases?
14. Look up the reduction potential for \(\mathrm{Fe}^{3+}\) to \(\mathrm{Fe}^{2+}\). Look up the reduction potential for \(\mathrm{Fe}^{2+}\) to Fe . Finally, look up the reduction potential for \(\mathrm{Fe}^{3+}\) to Fe . You should notice that adding the reduction potentials for the first two does not give the potential for the third. Why not? Show how you can use the first two potentials to calculate the third potential.
15. If the cell potential is proportional to work and the standard reduction potential for the hydrogen ion is zero, does this mean that the reduction of the hydrogen ion requires no work?
16. Is the following statement true or false? Concentration cells work because standard reduction potentials are dependent on concentration. Explain.
A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

\section*{Review of Oxidation-Reduction Reactions}

If you have trouble with these exercises, you should review Section 4.9 and 4.10.
17. Define oxidation and reduction in terms of both change in oxidation number and electron loss or gain.
18. Assign oxidation numbers to all the atoms in each of the following:
a. \(\mathrm{HNO}_{3}\)
b. \(\mathrm{CuCl}_{2}\)
c. \(\mathrm{O}_{2}\)
d. \(\mathrm{H}_{2} \mathrm{O}_{2}\)
e. \(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\)
f. Ag
g. \(\mathrm{PbSO}_{4}\)
h. \(\mathrm{PbO}_{2}\)
i. \(\mathrm{Na}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\)
j. \(\mathrm{CO}_{2}\)
k. \(\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Ce}\left(\mathrm{SO}_{4}\right)_{3}\)
l. \(\mathrm{Cr}_{2} \mathrm{O}_{3}\)
19. Specify which of the following equations represent oxidationreduction reactions, and indicate the oxidizing agent, the reducing agent, the species being oxidized, and the species being reduced.
a. \(\mathrm{CH}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightarrow \mathrm{CO}(g)+3 \mathrm{H}_{2}(g)\)
b. \(2 \mathrm{AgNO}_{3}(a q)+\mathrm{Cu}(s) \rightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(a q)+2 \mathrm{Ag}(s)\)
c. \(\mathrm{Zn}(s)+2 \mathrm{HCl}(a q) \rightarrow \mathrm{ZnCl}_{2}(a q)+\mathrm{H}_{2}(g)\)
d. \(2 \mathrm{H}^{+}(a q)+2 \mathrm{CrO}_{4}{ }^{2-}(a q) \rightarrow \mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)\)
20. The Ostwald process for the commercial production of nitric acid involves the following three steps:
\[
\begin{aligned}
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) & \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g) \\
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) & \longrightarrow 2 \mathrm{NO}_{2}(g) \\
3 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{HNO}_{3}(a q)+\mathrm{NO}(g)
\end{aligned}
\]
a. Which reactions in the Ostwald process are oxidationreduction reactions?
b. Identify each oxidizing agent and reducing agent.
21. Balance the following oxidation-reduction reactions that occur in acidic solution using the half-reaction method.
a. \(\mathrm{Cr}(s)+\mathrm{NO}_{3}^{-}(a q) \rightarrow \mathrm{Cr}^{3+}(a q)+\mathrm{NO}(g)\)
b. \(\mathrm{CH}_{3} \mathrm{OH}(a q)+\mathrm{Ce}^{4+}(a q) \rightarrow \mathrm{CO}_{2}(a q)+\mathrm{Ce}^{3+}(a q)\)
c. \(\mathrm{SO}_{3}{ }^{2-}(a q)+\mathrm{MnO}_{4}^{-}(a q) \rightarrow \mathrm{SO}_{4}{ }^{2-}(a q)+\mathrm{Mn}^{2+}(a q)\)
22. Balance the following oxidation-reduction reactions that occur in basic solution using the half-reaction method.
a. \(\mathrm{PO}_{3}{ }^{3-}(a q)+\mathrm{MnO}_{4}{ }^{-}(a q) \rightarrow \mathrm{PO}_{4}{ }^{3-}(a q)+\mathrm{MnO}_{2}(s)\)
b. \(\mathrm{Mg}(s)+\mathrm{OCl}^{-}(a q) \rightarrow \mathrm{Mg}(\mathrm{OH})_{2}(s)+\mathrm{Cl}^{-}(a q)\)
c. \(\mathrm{H}_{2} \mathrm{CO}(a q)+\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}(a q) \rightarrow\)
\[
\mathrm{HCO}_{3}^{-}(a q)+\mathrm{Ag}(s)+\mathrm{NH}_{3}(a q)
\]

\section*{Questions}
23. What is electrochemistry? What are redox reactions? Explain the difference between a galvanic and an electrolytic cell.
24. The general rule for salt bridges is that anions flow to the anode and cations flow to the cathode. Explain why this is true.
25. When magnesium metal is added to a beaker of \(\mathrm{HCl}(a q)\), a gas is produced. Knowing that magnesium is oxidized and that hydrogen is reduced, write the balanced equation for the reaction. How many electrons are transferred in the balanced equation? What quantity of useful work can be obtained when Mg is added directly to the beaker of HCl ? How can you harness this reaction to do useful work?
26. How can one construct a galvanic cell from two substances, each having a negative standard reduction potential?
27. The free energy change for a reaction, \(\Delta G\), is an extensive property. What is an extensive property? Surprisingly, one can calculate \(\Delta G\) from the cell potential, \(\mathscr{E}\), for the reaction. This is surprising because \(\mathscr{E}\) is an intensive property. How can the extensive property \(\Delta G\) be calculated from the intensive property \(\mathscr{E}\) ?
28. What is wrong with the following statement: The best concentration cell will consist of the substance having the most positive standard reduction potential. What drives a concentration cell to produce a large voltage?
29. When jump-starting a car with a dead battery, the ground jumper should be attached to a remote part of the engine block. Why?
30. In theory, most metals should easily corrode in air. Why? A group of metals called the noble metals are relatively difficult to corrode in air. Some noble metals include gold, platinum, and silver. Reference Table 18.1 to come up with a possible reason why the noble metals are relatively difficult to corrode.
31. Consider the electrolysis of a molten salt of some metal. What information must you know to calculate the mass of metal plated out in the electrolytic cell?
32. Consider the following electrochemical cell:

a. If silver metal is a product of the reaction, is the cell a galvanic cell or electrolytic cell? Label the cathode and anode, and describe the direction of the electron flow.
b. If copper metal is a product of the reaction, is the cell a galvanic cell or electrolytic cell? Label the cathode and anode, and describe the direction of the electron flow.
c. If the above cell is a galvanic cell, determine the standard cell potential.
d. If the above cell is an electrolytic cell, determine the minimum external potential that must be applied to cause the reaction to occur.
33. Which of the following statements concerning corrosion is(are) true? For the false statements, correct them.
a. Corrosion is an example of an electrolytic process.
b. Corrosion of steel involves the reduction of iron coupled with the oxidation of oxygen.
c. Steel rusts more easily in the dry (arid) Southwest states than in the humid Midwest states.
d. Salting roads in the winter has the added benefit of hindering the corrosion of steel.
e. The key to cathodic protection is to connect via a wire a metal more easily oxidized than iron to the steel surface to be protected.
34. Mercury is a toxic substance and specifically hazardous when present in the +1 or +2 oxidation state. However, the American Dental Association has determined that dental fillings composed of elemental mercury pose minimal health risks, even if the filling is swallowed. Use Table 18.1 to propose a possible explanation for this apparent contradiction.

\section*{Exercises}

In this section similar exercises are paired.

\section*{Galvanic Cells, Cell Potentials, Standard Reduction Potentials, and Free Energy}
\({ }^{35}\). Consider the following galvanic cell:

Label the reducing agent and the oxidizing agent, and describe the direction of the electron flow.
36. Consider the following galvanic cell:

a. Label the reducing agent and the oxidizing agent, and describe the direction of the electron flow.
b. Determine the standard cell potential.
c. Which electrode increases in mass as the reaction proceeds, and which electrode decreases in mass?
-37. Sketch the galvanic cells based on the following overall reactions. Show the direction of electron flow, and identify the cathode and anode. Give the overall balanced equation. Assume that all concentrations are 1.0 M and that all partial pressures are 1.0 atm .
a. \(\mathrm{Cr}^{3+}(a q)+\mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}(a q)+\mathrm{Cl}^{-}(a q)\)
b. \(\mathrm{Cu}^{2+}(a q)+\mathrm{Mg}(s) \rightleftharpoons \mathrm{Mg}^{2+}(a q)+\mathrm{Cu}(s)\)
-38. Sketch the galvanic cells based on the following overall reactions. Show the direction of electron flow, the direction of ion migration through the salt bridge, and identify the cathode and anode. Give the overall balanced equation. Assume that all concentrations are 1.0 M and that all partial pressures are 1.0 atm .
a. \(\mathrm{IO}_{3}^{-}(a q)+\mathrm{Fe}^{2+}(a q) \rightleftharpoons \mathrm{Fe}^{3+}(a q)+\mathrm{I}_{2}(a q)\)
b. \(\mathrm{Zn}(s)+\mathrm{Ag}^{+}(a q) \rightleftharpoons \mathrm{Zn}^{2+}(a q)+\mathrm{Ag}(s)\)
[39. Calculate \(\mathscr{E}^{\circ}\) values for the galvanic cells in Exercise 37.
40. Calculate \(\mathscr{E}^{\circ}\) values for the galvanic cells in Exercise 38.
41. Sketch the galvanic cells based on the following half-reactions. Show the direction of electron flow, show the direction of ion migration through the salt bridge, and identify the cathode and anode. Give the overall balanced equation, and determine \(\mathscr{E}^{\circ}\) for the galvanic cells. Assume that all concentrations are 1.0 M and that all partial pressures are 1.0 atm .
a. \(\mathrm{Cl}_{2}+2 \mathrm{e}^{-} \rightarrow 2 \mathrm{Cl}^{-} \quad \mathscr{E}^{\circ}=1.36 \mathrm{~V}\)
\[
\mathrm{Br}_{2}+2 \mathrm{e}^{-} \rightarrow 2 \mathrm{Br}^{-} \quad \mathscr{E}^{\circ}=1.09 \mathrm{~V}
\]
b. \(\mathrm{MnO}_{4}^{-}+8 \mathrm{H}^{+}+5 \mathrm{e}^{-} \rightarrow \mathrm{Mn}^{2+}+4 \mathrm{H}_{2} \mathrm{O} \quad \mathscr{E}{ }^{\circ}=1.51 \mathrm{~V}\)
\(\mathrm{IO}_{4}^{-}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \rightarrow \mathrm{IO}_{3}^{-}+\mathrm{H}_{2} \mathrm{O} \quad \mathscr{E}^{\circ}=1.60 \mathrm{~V}\)
-42. Sketch the galvanic cells based on the following half-reactions. Show the direction of electron flow, show the direction of ion migration through the salt bridge, and identify the cathode and anode. Give the overall balanced equation, and determine \(\mathscr{E}^{\circ}\) for the galvanic cells. Assume that all concentrations are 1.0 M and that all partial pressures are 1.0 atm .
a. \(\mathrm{H}_{2} \mathrm{O}_{2}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \rightarrow 2 \mathrm{H}_{2} \mathrm{O} \quad \mathscr{E}^{\circ}=1.78 \mathrm{~V}\) \(\mathrm{O}_{2}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}_{2}\)
\(\mathscr{E}^{\circ}=0.68 \mathrm{~V}\)
b. \(\mathrm{Mn}^{2+}+2 \mathrm{e}^{-} \rightarrow \mathrm{Mn}\)
\(\mathscr{E} \mathscr{E}^{\circ}=-1.18 \mathrm{~V}\)
\(\mathrm{Fe}^{3+}+3 \mathrm{e}^{-} \rightarrow \mathrm{Fe}\)
\(\mathscr{E}^{\circ}=-0.036 \mathrm{~V}\)
43. Give the standard line notation for each cell in Exercises 37 and 41 .
44. Give the standard line notation for each cell in Exercises 38 and 42.
45. Consider the following galvanic cells:

For each galvanic cell, give the balanced cell equation and determine \(\mathscr{E}^{\circ}\). Standard reduction potentials are found in Table 18.1.
46. Give the balanced cell equation and determine \(\mathscr{E}^{\circ}\) for the galvanic cells based on the following half-reactions. Standard reduction potentials are found in Table 18.1.
a. \(\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}+14 \mathrm{H}^{+}+6 \mathrm{e}^{-} \rightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}\) \(\mathrm{H}_{2} \mathrm{O}_{2}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \rightarrow 2 \mathrm{H}_{2} \mathrm{O}\)
b. \(2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \rightarrow \mathrm{H}_{2}\)
\(\mathrm{Al}^{3+}+3 \mathrm{e}^{-} \rightarrow \mathrm{Al}\)
47. Calculate \(\mathscr{C}^{\circ}\) values for the following cells. Which reactions are spontaneous as written (under standard conditions)? Balance the equations. Standard reduction potentials are found in Table 18.1.
a. \(\mathrm{MnO}_{4}^{-}(a q)+\mathrm{I}^{-}(a q) \longrightarrow \mathrm{I}_{2}(a q)+\mathrm{Mn}^{2+}(a q)\)
b. \(\mathrm{MnO}_{4}^{-}(a q)+\mathrm{F}^{-}(a q) \longrightarrow \mathrm{F}_{2}(g)+\mathrm{Mn}^{2+}(a q)\)
48. Calculate \(\mathscr{E}^{\circ}\) values for the following cells. Which reactions are spontaneous as written (under standard conditions)? Balance the equations that are not already balanced. Standard reduction potentials are found in Table 18.1.
a. \(\mathrm{H}_{2}(g) \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{H}^{-}(a q)\)
b. \(\mathrm{Au}^{3+}(a q)+\mathrm{Ag}(s) \longrightarrow \mathrm{Ag}^{+}(a q)+\mathrm{Au}(s)\)
-49. Chlorine dioxide \(\left(\mathrm{ClO}_{2}\right)\), which is produced by the reaction
\[
2 \mathrm{NaClO}_{2}(a q)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{ClO}_{2}(g)+2 \mathrm{NaCl}(a q)
\]
has been tested as a disinfectant for municipal water treatment. Using data from Table 18.1, calculate \(\mathscr{E}^{\circ}\) and \(\Delta G^{\circ}\) at \(25^{\circ} \mathrm{C}\) for the production of \(\mathrm{ClO}_{2}\).
50. The amount of manganese in steel is determined by changing it to permanganate ion. The steel is first dissolved in nitric acid, producing \(\mathrm{Mn}^{2+}\) ions. These ions are then oxidized to the deeply colored \(\mathrm{MnO}_{4}^{-}\)ions by periodate ion \(\left(\mathrm{IO}_{4}^{-}\right)\)in acid solution.
a. Complete and balance an equation describing each of the above reactions.
b. Calculate \(\mathscr{E}^{\circ}\) and \(\Delta G^{\circ}\) at \(25^{\circ} \mathrm{C}\) for each reaction.
-51. Calculate the maximum amount of work that can be obtained from the galvanic cells at standard conditions in Exercise 45.
52. Calculate the maximum amount of work that can be obtained from the galvanic cells at standard conditions in Exercise 46.
-53. Estimate \(\mathscr{E}^{\circ}\) for the half-reaction
\[
2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}+2 \mathrm{OH}^{-}
\]
given the following values of \(\Delta G_{f}^{\circ}\) :
\[
\begin{aligned}
\mathrm{H}_{2} \mathrm{O}(l) & =-237 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{H}_{2}(g) & =0.0 \\
\mathrm{OH}^{-}(a q) & =-157 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{e}^{-} & =0.0
\end{aligned}
\]

Compare this value of \(\mathscr{E}^{\circ}\) with the value of \(\mathscr{E}^{\circ}\) given in Table 18.1.
54. The equation \(\Delta G^{\circ}=-n F^{\mathscr{C}}{ }^{\circ}\) also can be applied to halfreactions. Use standard reduction potentials to estimate \(\Delta G_{f}^{\circ}\) for \(\mathrm{Fe}^{2+}(a q)\) and \(\mathrm{Fe}^{3+}(a q) .\left(\Delta G_{\mathrm{f}}^{\mathrm{o}}\right.\) for \(\mathrm{e}^{-}=0\).)
-55. Glucose is the major fuel for most living cells. The oxidative breakdown of glucose by our body to produce energy is called respiration. The reaction for the complete combustion of glucose is
\[
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 6 \mathrm{CO}_{2}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\]

If this combustion reaction could be harnessed as a fuel cell, calculate the theoretical voltage that could be produced at standard conditions. (Hint: Use \(\Delta G_{\mathrm{f}}^{\circ}\) values from Appendix 4.)
56. Direct methanol fuel cells (DMFCs) have shown some promise as a viable option for providing "green" energy to small electrical devices. Calculate \(\mathscr{E}^{\circ}\) for the reaction that takes place in DMFCs:
\[
\mathrm{CH}_{3} \mathrm{OH}(l)+3 / 2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
\]

Use values of \(\Delta G_{\mathrm{f}}^{\circ}\) from Appendix 4.
-57. Using data from Table 18.1, place the following in order of increasing strength as oxidizing agents (all under standard conditions).
\[
\mathrm{MnO}_{4}^{-}, \mathrm{Cl}_{2}, \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}, \mathrm{Mg}^{2+}, \mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}
\]
58. Using data from Table 18.1, place the following in order of increasing strength as reducing agents (all under standard conditions).
\[
\mathrm{Cr}^{3+}, \mathrm{H}_{2}, \mathrm{Zn}, \mathrm{Li}, \mathrm{~F}^{-}, \mathrm{Fe}^{2+}
\]
\({ }^{59}\). Answer the following questions using data from Table 18.1 (all under standard conditions).
a. Is \(\mathrm{H}^{+}(a q)\) capable of oxidizing \(\mathrm{Cu}(s)\) to \(\mathrm{Cu}^{2+}(a q)\) ?
b. Is \(\mathrm{Fe}^{3+}(a q)\) capable of oxidizing \(\mathrm{I}^{-}(a q)\) ?
c. Is \(\mathrm{H}_{2}(g)\) capable of reducing \(\mathrm{Ag}^{+}(a q)\) ?
60. Answer the following questions using data from Table 18.1 (all under standard conditions).
a. Is \(\mathrm{H}_{2}(g)\) capable of reducing \(\mathrm{Ni}^{2+}(a q)\) ?
b. Is \(\mathrm{Fe}^{2+}(a q)\) capable of reducing \(\mathrm{VO}_{2}{ }^{+}(a q)\) ?
c. Is \(\mathrm{Fe}^{2+}(a q)\) capable of reducing \(\mathrm{Cr}^{3+}(a q)\) to \(\mathrm{Cr}^{2+}(a q)\) ?
-61. Consider only the species (at standard conditions)
\[
\begin{array}{lllll} 
& \mathrm{Na}^{+}, & \mathrm{Cl}^{-}, & \mathrm{Ag}^{+}, & \mathrm{Ag}, \quad \mathrm{Zn}^{2+}, \\
\mathrm{Zn}, & \mathrm{~Pb}
\end{array}
\]
in answering the following questions. Give reasons for your answers. (Use data from Table 18.1.)
a. Which is the strongest oxidizing agent?
b. Which is the strongest reducing agent?
c. Which species can be oxidized by \(\mathrm{SO}_{4}{ }^{2-}(a q)\) in acid?
d. Which species can be reduced by \(\mathrm{Al}(s)\) ?
62. Consider only the species (at standard conditions)
\[
\begin{array}{llllll}
\mathrm{Br}^{-} & \mathrm{Br}_{2}, & \mathrm{H}^{+}, & \mathrm{H}_{2}, & \mathrm{La}^{3+}, \quad \mathrm{Ca}, \quad \mathrm{Cd}
\end{array}
\]
in answering the following questions. Give reasons for your answers.
a. Which is the strongest oxidizing agent?
b. Which is the strongest reducing agent?
c. Which species can be oxidized by \(\mathrm{MnO}_{4}^{-}\)in acid?
d. Which species can be reduced by \(\mathrm{Zn}(s)\) ?
-63. Use the table of standard reduction potentials (Table 18.1) to pick a reagent that is capable of each of the following oxidations (under standard conditions in acidic solution).
a. oxidize \(\mathrm{Br}^{-}\)to \(\mathrm{Br}_{2}\) but not oxidize \(\mathrm{Cl}^{-}\)to \(\mathrm{Cl}_{2}\)
b. oxidize Mn to \(\mathrm{Mn}^{2+}\) but not oxidize Ni to \(\mathrm{Ni}^{2+}\)
64. Use the table of standard reduction potentials (Table 18.1) to pick a reagent that is capable of each of the following reductions (under standard conditions in acidic solution).
a. reduce \(\mathrm{Fe}^{3+}\) to \(\mathrm{Fe}^{2+}\) but not reduce \(\mathrm{Fe}^{2+}\) to Fe
b. reduce \(\mathrm{Ag}^{+}\)to Ag but not reduce \(\mathrm{O}_{2}\) to \(\mathrm{H}_{2} \mathrm{O}_{2}\)

\section*{The Nernst Equation}

A galvanic cell is based on the following half-reactions at \(25^{\circ} \mathrm{C}\) :
\[
\begin{gathered}
\mathrm{Ag}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Ag} \\
\mathrm{H}_{2} \mathrm{O}_{2}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}
\end{gathered}
\]

Predict whether \(\mathscr{E}_{\text {cell }}\) is larger or smaller than \(\mathscr{E}_{\text {cell }}^{\circ}\) for the following cases.
a. \(\left[\mathrm{Ag}^{+}\right]=1.0 \mathrm{M},\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]=2.0 \mathrm{M},\left[\mathrm{H}^{+}\right]=2.0 \mathrm{M}\)
b. \(\left[\mathrm{Ag}^{+}\right]=2.0 \mathrm{M},\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]=1.0 \mathrm{M},\left[\mathrm{H}^{+}\right]=1.0 \times 10^{-7} \mathrm{M}\)
66. Consider the concentration cell in Fig. 18.10. If the \(\mathrm{Fe}^{2+}\) concentration in the right compartment is changed from 0.1 M to \(1 \times 10^{-7} M \mathrm{Fe}^{2+}\), predict the direction of electron flow, and designate the anode and cathode compartments.
67. Consider the concentration cell shown below. Calculate the cell potential at \(25^{\circ} \mathrm{C}\) when the concentration of \(\mathrm{Ag}^{+}\)in the compartment on the right is the following.
a. 1.0 M
b. 2.0 M
c. 0.10 M
d. \(4.0 \times 10^{-5} \mathrm{M}\)
e. Calculate the potential when both solutions are 0.10 M in \(\mathrm{Ag}^{+}\).
For each case, also identify the cathode, the anode, and the direction in which electrons flow.

68. Consider a concentration cell similar to the one shown in Exercise 67, except that both electrodes are made of Ni and in the left-hand compartment \(\left[\mathrm{Ni}^{2+}\right]=1.0 \mathrm{M}\). Calculate the cell potential at \(25^{\circ} \mathrm{C}\) when the concentration of \(\mathrm{Ni}^{2+}\) in the compartment on the right has each of the following values.
a. 1.0 M
b. 2.0 M
c. 0.10 M
d. \(4.0 \times 10^{-5} \mathrm{M}\)
e. Calculate the potential when both solutions are 2.5 M in \(\mathrm{Ni}^{2+}\).
For each case, also identify the cathode, anode, and the direction in which electrons flow.
69. The overall reaction in the lead storage battery is
\[
\mathrm{Pb}(s)+\mathrm{PbO}_{2}(s)+2 \mathrm{H}^{+}(a q)+2 \mathrm{HSO}_{4}^{-}(a q) \longrightarrow
\]
\[
2 \mathrm{PbSO}_{4}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)
\]

Calculate \(\mathscr{E}\) at \(25^{\circ} \mathrm{C}\) for this battery when \(\left[\mathrm{H}_{2} \mathrm{SO}_{4}\right]=4.5 \mathrm{M}\), that is, \(\left[\mathrm{H}^{+}\right]=\left[\mathrm{HSO}_{4}^{-}\right]=4.5 \mathrm{M}\). At \(25^{\circ} \mathrm{C}, \mathscr{E}^{\circ}=2.04 \mathrm{~V}\) for the lead storage battery.
70. Calculate the pH of the cathode compartment for the following reaction given \(\mathscr{E}_{\text {cell }}=3.01 \mathrm{~V}\) when \(\left[\mathrm{Cr}^{3+}\right]=0.15 \mathrm{M}\), \(\left[\mathrm{Al}^{3+}\right]=0.30 \mathrm{M}\), and \(\left[\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}\right]=0.55 \mathrm{M}\).
\[
\begin{aligned}
& 2 \mathrm{Al}(s)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+ 14 \mathrm{H}^{+}(a q) \longrightarrow \\
& 2 \mathrm{Al}^{3+}(a q)+2 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
\]
71. Consider the cell described below:
\[
\mathrm{Zn}\left|\mathrm{Zn}^{2+}(1.00 M)\right|\left|\mathrm{Ag}^{+}(1.00 M)\right| \mathrm{Ag}
\]

Calculate the cell potential after the reaction has operated long enough for the \(\left[\mathrm{Zn}^{2+}\right]\) to have changed by \(0.20 \mathrm{~mol} / \mathrm{L}\). (Assume \(T=25^{\circ} \mathrm{C}\).)
72. Consider the cell described below:
\[
\mathrm{Al}\left|\mathrm{Al}^{3+}(1.00 M)\right|\left|\mathrm{Pb}^{2+}(1.00 M)\right| \mathrm{Pb}
\]

Calculate the cell potential after the reaction has operated long enough for the \(\left[\mathrm{Al}^{3+}\right]\) to have changed by \(0.60 \mathrm{~mol} / \mathrm{L}\). (Assume \(T=25^{\circ} \mathrm{C}\).)
[73. Calculate \(\Delta G^{\circ}\) and \(K\) at \(25^{\circ} \mathrm{C}\) for the reactions in Exercises 37 and 41.
74. Calculate \(\Delta G^{\circ}\) and \(K\) at \(25^{\circ} \mathrm{C}\) for the reactions in Exercises 38 and 42.
[75. Consider the galvanic cell based on the following halfreactions:
\[
\begin{array}{ll}
\mathrm{Zn}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Zn} & \mathscr{E}^{\circ}=-0.76 \mathrm{~V} \\
\mathrm{Fe}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Fe} & \mathscr{E}^{\circ}=-0.44 \mathrm{~V}
\end{array}
\]
a. Determine the overall cell reaction and calculate \(\mathscr{E}_{\text {cell }}^{\circ}\)
b. Calculate \(\Delta G^{\circ}\) and \(K\) for the cell reaction at \(25^{\circ} \mathrm{C}\).
c. Calculate \(\mathscr{E}_{\text {cell }}\) at \(25^{\circ} \mathrm{C}\) when \(\left[\mathrm{Zn}^{2+}\right]=0.10 \mathrm{M}\) and \(\left[\mathrm{Fe}^{2+}\right]=1.0 \times 10^{-5} \mathrm{M}\).
76. Consider the galvanic cell based on the following halfreactions:
\[
\begin{array}{ll}
\mathrm{Au}^{3+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Au} & \mathscr{E}^{\circ}=1.50 \mathrm{~V} \\
\mathrm{Tl}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Tl} & \mathscr{E}^{\circ}=-0.34 \mathrm{~V}
\end{array}
\]
a. Determine the overall cell reaction and calculate \(\mathscr{E}_{\text {cell }}^{\circ}\) -
b. Calculate \(\Delta G^{\circ}\) and \(K\) for the cell reaction at \(25^{\circ} \mathrm{C}\).
c. Calculate \(\mathscr{E}_{\text {cell }}\) at \(25^{\circ} \mathrm{C}\) when \(\left[\mathrm{Au}^{3+}\right]=1.0 \times 10^{-2} \mathrm{M}\) and \(\left[\mathrm{Tl}^{+}\right]=1.0 \times 10^{-4} \mathrm{M}\).
77. An electrochemical cell consists of a standard hydrogen electrode and a copper metal electrode.
a. What is the potential of the cell at \(25^{\circ} \mathrm{C}\) if the copper electrode is placed in a solution in which \(\left[\mathrm{Cu}^{2+}\right]=\) \(2.5 \times 10^{-4} \mathrm{M}\) ?
b. The copper electrode is placed in a solution of unknown \(\left[\mathrm{Cu}^{2+}\right]\). The measured potential at \(25^{\circ} \mathrm{C}\) is 0.195 V . What is \(\left[\mathrm{Cu}^{2+}\right]\) ? (Assume \(\mathrm{Cu}^{2+}\) is reduced.)
78. An electrochemical cell consists of a nickel metal electrode immersed in a solution with \(\left[\mathrm{Ni}^{2+}\right]=1.0 \mathrm{M}\) separated by a porous disk from an aluminum metal electrode.
a. What is the potential of this cell at \(25^{\circ} \mathrm{C}\) if the aluminum electrode is placed in a solution in which \(\left[\mathrm{Al}^{3+}\right]=7.2 \times 10^{-3} \mathrm{M}\) ?
b. When the aluminum electrode is placed in a certain solution in which \(\left[\mathrm{Al}^{3+}\right]\) is unknown, the measured cell potential at \(25^{\circ} \mathrm{C}\) is 1.62 V . Calculate \(\left[\mathrm{Al}^{3+}\right]\) in the unknown solution. (Assume Al is oxidized.)
-79. An electrochemical cell consists of a standard hydrogen electrode and a copper metal electrode. If the copper electrode is placed in a solution of 0.10 M NaOH that is saturated with \(\mathrm{Cu}(\mathrm{OH})_{2}\), what is the cell potential at \(25^{\circ} \mathrm{C}\) ? \(\left[\mathrm{For} \mathrm{Cu}(\mathrm{OH})_{2}\right.\), \(K_{\text {sp }}=1.6 \times 10^{-19}\).]
80. An electrochemical cell consists of a nickel metal electrode immersed in a solution with \(\left[\mathrm{Ni}^{2+}\right]=1.0 \mathrm{M}\) separated by a porous disk from an aluminum metal electrode immersed in a solution with \(\left[\mathrm{Al}^{3+}\right]=1.0 \mathrm{M}\). Sodium hydroxide is added to the aluminum compartment, causing \(\mathrm{Al}(\mathrm{OH})_{3}(s)\) to precipitate. After precipitation of \(\mathrm{Al}(\mathrm{OH})_{3}\) has ceased, the concentration of \(\mathrm{OH}^{-}\)is \(1.0 \times 10^{-4} \mathrm{M}\) and the measured cell potential is 1.82 V . Calculate the \(K_{\text {sp }}\) value for \(\mathrm{Al}(\mathrm{OH})_{3}\).
\[
\mathrm{Al}(\mathrm{OH})_{3}(s) \rightleftharpoons \mathrm{Al}^{3+}(a q)+3 \mathrm{OH}^{-}(a q) \quad K_{\mathrm{sp}}=?
\]
81. Consider a concentration cell that has both electrodes made of some metal M . Solution A in one compartment of the cell contains \(1.0 \mathrm{M} \mathrm{M}^{2+}\). Solution B in the other cell compartment has a volume of 1.00 L . At the beginning of the experiment 0.0100 mole of \(\mathrm{M}\left(\mathrm{NO}_{3}\right)_{2}\) and 0.0100 mole of \(\mathrm{Na}_{2} \mathrm{SO}_{4}\) are dissolved in solution B (ignore volume changes), where the reaction
\[
\mathrm{M}^{2+}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q) \rightleftharpoons \mathrm{MSO}_{4}(s)
\]
occurs. For this reaction equilibrium is rapidly established, whereupon the cell potential is found to be 0.44 V at \(25^{\circ} \mathrm{C}\). Assume that the process
\[
\mathrm{M}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{M}
\]
has a standard reduction potential of -0.31 V and that no other redox process occurs in the cell. Calculate the value of \(K_{\text {sp }}\) for \(\mathrm{MSO}_{4}(s)\) at \(25^{\circ} \mathrm{C}\).
82. You have a concentration cell in which the cathode has a silver electrode with \(0.10 \mathrm{M} \mathrm{Ag}^{+}\). The anode also has a silver electrode with \(\mathrm{Ag}^{+}(a q), 0.050 \mathrm{M} \mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\), and \(1.0 \times 10^{-3} \mathrm{M}\) \(\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\). You read the voltage to be 0.76 V .
a. Calculate the concentration of \(\mathrm{Ag}^{+}\)at the anode.
b. Determine the value of the equilibrium constant for the formation of \(\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\).
\[
\mathrm{Ag}^{+}(a q)+2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(a q) \rightleftharpoons \mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}(a q) \quad K=?
\]
83. Under standard conditions, what reaction occurs, if any, when each of the following operations is performed?
a. Crystals of \(\mathrm{I}_{2}\) are added to a solution of NaCl .
b. \(\mathrm{Cl}_{2}\) gas is bubbled into a solution of NaI.
c. A silver wire is placed in a solution of \(\mathrm{CuCl}_{2}\).
d. An acidic solution of \(\mathrm{FeSO}_{4}\) is exposed to air.

For the reactions that occur, write a balanced equation and calculate \(\mathscr{E}^{\circ}, \Delta G^{\circ}\), and \(K\) at \(25^{\circ} \mathrm{C}\).
84. A disproportionation reaction involves a substance that acts as both an oxidizing and a reducing agent, producing higher and lower oxidation states of the same element in the products. Which of the following disproportionation reactions are spontaneous under standard conditions? Calculate \(\Delta G^{\circ}\) and \(K\) at \(25^{\circ} \mathrm{C}\) for those reactions that are spontaneous under standard conditions.
a. \(2 \mathrm{Cu}^{+}(a q) \longrightarrow \mathrm{Cu}^{2+}(a q)+\mathrm{Cu}(s)\)
b. \(3 \mathrm{Fe}^{2+}(a q) \longrightarrow 2 \mathrm{Fe}^{3+}(a q)+\mathrm{Fe}(s)\)
c. \(\mathrm{HClO}_{2}(a q) \longrightarrow \mathrm{ClO}_{3}^{-}(a q)+\mathrm{HClO}(a q) \quad\) (unbalanced)

Use the half-reactions:
\(\begin{array}{ll}\mathrm{ClO}_{3}{ }^{-}+3 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{HClO}_{2}+\mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ}=1.21 \mathrm{~V} \\ \mathrm{HClO}_{2}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{HClO}+\mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ}=1.65 \mathrm{~V}\end{array}\)
85. Consider the following galvanic cell at \(25^{\circ} \mathrm{C}\) :
\[
\mathrm{Pt}\left|\mathrm{Cr}^{2+}(0.30 M), \mathrm{Cr}^{3+}(2.0 M)\right|\left|\mathrm{Co}^{2+}(0.20 M)\right| \mathrm{Co}
\]

The overall reaction and equilibrium constant value are
\[
2 \mathrm{Cr}^{2+}(a q)+\mathrm{Co}^{2+}(a q) \underset{2 \mathrm{Cr}^{3+}(a q)}{\rightleftharpoons}+\mathrm{Co}(s) \quad K=2.79 \times 10^{7}
\]

Calculate the cell potential, \(\mathscr{E}\), for this galvanic cell and \(\Delta G\) for the cell reaction at these conditions.
86. An electrochemical cell consists of a silver metal electrode immersed in a solution with \(\left[\mathrm{Ag}^{+}\right]=1.0 \mathrm{M}\) separated by a porous disk from a copper metal electrode. If the copper electrode is placed in a solution of \(5.0 \mathrm{M} \mathrm{NH}_{3}\) that is also 0.010 M in \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\), what is the cell potential at \(25^{\circ} \mathrm{C}\) ?
\[
\mathrm{Cu}^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q) \quad K=1.0 \times 10^{13}
\]
-87. Cadmium sulfide is used in some semiconductor applications. Calculate the value of the solubility product constant ( \(K_{\text {sp }}\) ) for CdS given the following standard reduction potentials:
\[
\begin{array}{rlrl}
\mathrm{CdS}(s)+2 \mathrm{e}^{-} & \rightarrow \mathrm{Cd}(s)+\mathrm{S}^{2-}(a q) & \mathscr{E}^{\circ}=-1.21 \mathrm{~V} \\
\mathrm{Cd}^{2+}(a q)+2 \mathrm{e}^{-} \rightarrow \mathrm{Cd}(s) & \mathscr{E}^{\circ}=-0.402 \mathrm{~V}
\end{array}
\]
88. For the following half-reaction, \(\mathscr{E} \mathscr{C}^{\circ}=-2.07 \mathrm{~V}\) :
\[
\mathrm{AlF}_{6}{ }^{3-}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al}(s)+6 \mathrm{~F}^{-}(a q)
\]

Using data from Table 18.1, calculate the equilibrium constant at \(25^{\circ} \mathrm{C}\) for the reaction
\[
\mathrm{Al}^{3+}(a q)+6 \mathrm{~F}^{-}(a q) \rightleftharpoons \mathrm{AlF}_{6}{ }^{3-}(a q) \quad K=?
\]
89. Calculate \(\mathscr{E}^{\circ}\) for the following half-reaction:
\[
\operatorname{AgI}(s)+\mathrm{e}^{-} \longrightarrow \operatorname{Ag}(s)+\mathrm{I}^{-}(a q)
\]
(Hint: Reference the \(K_{\text {sp }}\) value for AgI and the standard reduction potential for \(\mathrm{Ag}^{+}\).)
90. The solubility product for \(\mathrm{CuI}(s)\) is \(1.1 \times 10^{-12}\). Calculate the value of \(\mathscr{E}^{\circ}\) for the half-reaction
\[
\mathrm{CuI}(s)+\mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s)+\mathrm{I}^{-}(a q)
\]

\section*{Electrolysis}
-91. How long will it take to plate out each of the following with a current of 100.0 A ?
a. 1.0 kg Al from aqueous \(\mathrm{Al}^{3+}\)
b. 1.0 g Ni from aqueous \(\mathrm{Ni}^{2+}\)
c. 5.0 moles of Ag from aqueous \(\mathrm{Ag}^{+}\)
92. The electrolysis of \(\mathrm{BiO}^{+}\)produces pure bismuth. How long would it take to produce 10.0 g Bi by the electrolysis of a \(\mathrm{BiO}^{+}\)solution using a current of 25.0 A ?
-93. What mass of each of the following substances can be produced in 1.0 h with a current of 15 A ?
a. Co from aqueous \(\mathrm{Co}^{2+}\)
b. Hf from aqueous \(\mathrm{Hf}^{4+}\)
c. \(\mathrm{I}_{2}\) from aqueous KI
d. Cr from molten \(\mathrm{CrO}_{3}\)
94. Aluminum is produced commercially by the electrolysis of \(\mathrm{Al}_{2} \mathrm{O}_{3}\) in the presence of a molten salt. If a plant has a continuous capacity of 1.00 million A , what mass of aluminum can be produced in 2.00 h ?
95. Electrolysis of an alkaline earth metal chloride using a current of 5.00 A for 748 s deposits 0.471 g of metal at the cathode. What is the identity of the alkaline earth metal chloride?
96. Electrolysis of a molten metal chloride \(\left(\mathrm{MCl}_{3}\right)\) using a current of 6.50 A for 1397 s deposits 1.41 g of the metal at the cathode. What is the metal?
\({ }^{97}\). What volume of \(\mathrm{F}_{2}\) gas, at \(25^{\circ} \mathrm{C}\) and 1.00 atm , is produced when molten KF is electrolyzed by a current of 10.0 A for 2.00 h ? What mass of potassium metal is produced? At which electrode does each reaction occur?
98. What volumes of \(\mathrm{H}_{2}(g)\) and \(\mathrm{O}_{2}(g)\) at STP are produced from the electrolysis of water by a current of 2.50 A in 15.0 min ?
- 99. A single Hall-Heroult cell (as shown in Fig. 18.22) produces about 1 ton of aluminum in 24 h . What current must be used to accomplish this?
100. A factory wants to produce \(1.00 \times 10^{3} \mathrm{~kg}\) barium from the electrolysis of molten barium chloride. What current must be applied for 4.00 h to accomplish this?
-101. It took 2.30 min using a current of 2.00 A to plate out all the silver from 0.250 L of a solution containing \(\mathrm{Ag}^{+}\). What was the original concentration of \(\mathrm{Ag}^{+}\)in the solution?
102. A solution containing \(\mathrm{Pt}^{4+}\) is electrolyzed with a current of 4.00 A . How long will it take to plate out \(99 \%\) of the platinum in 0.50 L of a \(0.010-M\) solution of \(\mathrm{Pt}^{4+}\) ?
-103. A solution at \(25^{\circ} \mathrm{C}\) contains \(1.0 \mathrm{M} \mathrm{Cd}{ }^{2+}, 1.0 \mathrm{M} \mathrm{Ag}^{+}, 1.0 \mathrm{M}\) \(\mathrm{Au}^{3+}\), and \(1.0 \mathrm{M} \mathrm{Ni}^{2+}\) in the cathode compartment of an electrolytic cell. Predict the order in which the metals will plate out as the voltage is gradually increased.
104. A solution at \(25^{\circ} \mathrm{C}\) contains \(1.0 \mathrm{M} \mathrm{Cu}^{2+}\) and \(1.0 \times 10^{-4} \mathrm{M}\) \(\mathrm{Ag}^{+}\). Which metal will plate out first as the voltage is gradually increased when this solution is electrolyzed? (Hint: Use the Nernst equation to calculate \(\mathscr{E}\) for each half-reaction.)
-105. In the electrolysis of an aqueous solution of \(\mathrm{Na}_{2} \mathrm{SO}_{4}\), what reactions occur at the anode and the cathode (assuming standard conditions)?
\begin{tabular}{lr} 
& \multicolumn{1}{c}{\(\mathscr{E}^{\circ}\)} \\
\(\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{SO}_{4}{ }^{2-}\) & 2.01 V \\
\(\mathrm{O}_{2}+4 \mathrm{H}^{+}+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}\) & 1.23 V \\
\(2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}+2 \mathrm{OH}^{-}\) & -0.83 V \\
\(\mathrm{Na}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Na}\) & -2.71 V \\
& \\
&

106. Copper can be plated onto a spoon by placing the spoon in an acidic solution of \(\mathrm{CuSO}_{4}(\mathrm{aq})\) and connecting it to a copper strip via a power source as illustrated below:

a. Label the anode and cathode, and describe the direction of the electron flow.
b. Write out the chemical equations for the reactions that occur at each electrode.
107. What reactions take place at the cathode and the anode when each of the following is electrolyzed?
a. molten \(\mathrm{NiBr}_{2}\)
b. molten \(\mathrm{AlF}_{3}\)
c. molten \(\mathrm{MnI}_{2}\)
108. What reaction will take place at the cathode and the anode when each of the following is electrolyzed?
a. molten KF
b. molten \(\mathrm{CuCl}_{2}\)
c. molten \(\mathrm{MgI}_{2}\)
-109. What reactions take place at the cathode and the anode when each of the following is electrolyzed? (Assume standard conditions.)
a. 1.0 M NiBr 2 solution
b. \(1.0 \mathrm{M} \mathrm{AlF}_{3}\) solution
c. \(1.0 \mathrm{M} \mathrm{MnI}_{2}\) solution
110. What reaction will take place at the cathode and the anode when each of the following is electrolyzed? (Assume standard conditions.)
a. 1.0 MKF solution
b. \(1.0 \mathrm{M} \mathrm{CuCl} 2_{2}\) solution
c. \(1.0 \mathrm{M} \mathrm{MgI}_{2}\) solution

\section*{Additional Exercises}
111. The saturated calomel electrode, abbreviated SCE, is often used as a reference electrode in making electrochemical measurements. The SCE is composed of mercury in contact with a saturated solution of calomel \(\left(\mathrm{Hg}_{2} \mathrm{Cl}_{2}\right)\). The electrolyte solution is saturated KCl . \(\mathscr{C}_{\text {SCE }}\) is +0.242 V relative to the standard hydrogen electrode. Calculate the potential for each of the following galvanic cells containing a saturated calomel electrode and the given half-cell components at standard conditions. In each case, indicate whether the SCE is the cathode or the anode. Standard reduction potentials are found in Table 18.1.
a. \(\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}\)
b. \(\mathrm{Fe}^{3+}+\mathrm{e}^{-} \longrightarrow \mathrm{Fe}^{2+}\)
c. \(\mathrm{AgCl}+\mathrm{e}^{-} \longrightarrow \mathrm{Ag}+\mathrm{Cl}^{-}\)
d. \(\mathrm{Al}^{3+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al}\)
e. \(\mathrm{Ni}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Ni}\)
112. Consider the following half-reactions:
\[
\begin{array}{cl}
\mathrm{Pt}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Pt} & \mathscr{C}^{\circ}=1.188 \mathrm{~V} \\
\mathrm{PtCl}_{4}^{2-}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Pt}+4 \mathrm{Cl}^{-} & \mathscr{E}^{\circ}=0.755 \mathrm{~V} \\
\mathrm{NO}_{3}{ }^{-}+4 \mathrm{H}^{+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{NO}+2 \mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ}=0.96 \mathrm{~V}
\end{array}
\]

Explain why platinum metal will dissolve in aqua regia (a mixture of hydrochloric and nitric acids) but not in either concentrated nitric or concentrated hydrochloric acid individually.
113. Consider the standard galvanic cell based on the following half-reactions:
\[
\begin{aligned}
\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} & \longrightarrow \mathrm{Cu} \\
\mathrm{Ag}^{+}+\mathrm{e}^{-} & \longrightarrow \mathrm{Ag}
\end{aligned}
\]

The electrodes in this cell are \(\mathrm{Ag}(s)\) and \(\mathrm{Cu}(s)\). Does the cell potential increase, decrease, or remain the same when the following changes occur to the standard cell?
a. \(\mathrm{CuSO}_{4}(s)\) is added to the copper half-cell compartment (assume no volume change).
b. \(\mathrm{NH}_{3}(\mathrm{aq})\) is added to the copper half-cell compartment. [Hint: \(\mathrm{Cu}^{2+}\) reacts with \(\mathrm{NH}_{3}\) to form \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q)\).]
c. \(\mathrm{NaCl}(s)\) is added to the silver half-cell compartment. [Hint: \(\mathrm{Ag}^{+}\)reacts with \(\mathrm{Cl}^{-}\)to form \(\mathrm{AgCl}(s)\).]
d. Water is added to both half-cell compartments until the volume of solution is doubled.
e. The silver electrode is replaced with a platinum electrode.
\[
\mathrm{Pt}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Pt} \quad \mathscr{E}^{\circ}=1.19 \mathrm{~V}
\]
114. A standard galvanic cell is constructed so that the overall cell reaction is
\[
2 \mathrm{Al}^{3+}(a q)+3 \mathrm{M}(s) \longrightarrow 3 \mathrm{M}^{2+}(a q)+2 \mathrm{Al}(s)
\]
where M is an unknown metal. If \(\Delta G^{\circ}=-411 \mathrm{~kJ}\) for the overall cell reaction, identify the metal used to construct the standard cell.
115. The black silver sulfide discoloration of silverware can be removed by heating the silver article in a sodium carbonate solution in an aluminum pan. The reaction is
\[
3 \mathrm{Ag}_{2} \mathrm{~S}(s)+2 \mathrm{Al}(s) \rightleftharpoons 6 \mathrm{Ag}(s)+3 \mathrm{~S}^{2-}(a q)+2 \mathrm{Al}^{3+}(a q)
\]
a. Using data in Appendix 4 , calculate \(\Delta G^{\circ}, K\), and \(\mathscr{E}{ }^{\circ}\) for the above reaction at \(25^{\circ} \mathrm{C}\). [For \(\mathrm{Al}^{3+}(a q), \Delta G_{\mathrm{f}}^{\circ}=-480 . \mathrm{kJ} / \mathrm{mol}\).]
b. Calculate the value of the standard reduction potential for the following half-reaction:
\[
2 \mathrm{e}^{-}+\mathrm{Ag}_{2} \mathrm{~S}(s) \longrightarrow 2 \mathrm{Ag}(s)+\mathrm{S}^{2-}(a q)
\]
116. In 1973 the wreckage of the Civil War ironclad USS Monitor was discovered near Cape Hatteras, North Carolina. [The Monitor and the CSS Virginia (formerly the USS Merrimack) fought the first battle between iron-armored ships.] In 1987 investigations were begun to see if the ship could be salvaged. It was reported in Time (June 22, 1987) that scientists were considering adding sacrificial anodes of zinc to the rapidly corroding metal hull of the Monitor. Describe how attaching zinc to the hull would protect the Monitor from further corrosion.
117. When aluminum foil is placed in hydrochloric acid, nothing happens for the first 30 seconds or so. This is followed by vigorous bubbling and the eventual disappearance of the foil. Explain these observations.
118. Calculate the value of the equilibrium constant for the reaction of lead metal in a solution of silver nitrate at \(25^{\circ} \mathrm{C}\).
119. Hydrogen peroxide can function either as an oxidizing agent or as a reducing agent. At standard conditions, is \(\mathrm{H}_{2} \mathrm{O}_{2}\) a better oxidizing agent or reducing agent? Explain.
120. A galvanic cell consists of a standard hydrogen electrode and a copper electrode immersed in a \(\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(a q)\) solution. If you wish to construct a calibration curve to show how the cell potential varies with \(\left[\mathrm{Cu}^{2+}\right]\), what should you plot to obtain a straight line? What will be the slope of this line?
121. A fuel cell designed to react grain alcohol with oxygen has the following net reaction:
\[
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CO}_{2}(\mathrm{~g})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\]

The maximum work that 1 mole of alcohol can do is \(1.32 \times 10^{3} \mathrm{~kJ}\). What is the theoretical maximum voltage this cell can achieve at \(25^{\circ} \mathrm{C}\) ?
122. The overall reaction and equilibrium constant value for a hydrogen-oxygen fuel cell at 298 K is
\[
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) \quad K=1.28 \times 10^{83}
\]
a. Calculate \(\mathscr{E}^{\circ}\) and \(\Delta G^{\circ}\) at 298 K for the fuel cell reaction.
b. Predict the signs of \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) for the fuel cell reaction.
c. As temperature increases, does the maximum amount of work obtained from the fuel cell reaction increase, decrease, or remain the same? Explain.
123. What is the maximum work that can be obtained from a hydrogen-oxygen fuel cell at standard conditions that produces 1.00 kg water at \(25^{\circ} \mathrm{C}\) ? Why do we say that this is the maximum work that can be obtained? What are the advantages and disadvantages in using fuel cells rather than the corresponding combustion reactions to produce electricity?
124. The overall reaction and standard cell potential at \(25^{\circ} \mathrm{C}\) for the rechargeable nickel-cadmium alkaline battery is
\[
\begin{aligned}
& \mathrm{Cd}(s)+\mathrm{NiO}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \\
& \mathrm{Ni}(\mathrm{OH})_{2}(s)+\mathrm{Cd}(\mathrm{OH})_{2}(s) \quad \mathscr{E} \circ=1.10 \mathrm{~V}
\end{aligned}
\]

For every mole of Cd consumed in the cell, what is the maximum useful work that can be obtained at standard conditions?
125. An experimental fuel cell has been designed that uses carbon monoxide as fuel. The overall reaction is
\[
2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)
\]

The two half-cell reactions are
\[
\begin{aligned}
& \mathrm{CO}+\mathrm{O}^{2-} \longrightarrow \mathrm{CO}_{2}+2 \mathrm{e}^{-} \\
& \mathrm{O}_{2}+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{O}^{2-}
\end{aligned}
\]

The two half-reactions are carried out in separate compartments connected with a solid mixture of \(\mathrm{CeO}_{2}\) and \(\mathrm{Gd}_{2} \mathrm{O}_{3}\). Oxide ions can move through this solid at high temperatures (about \(800^{\circ} \mathrm{C}\) ). \(\Delta G\) for the overall reaction at \(800^{\circ} \mathrm{C}\) under certain concentration conditions is -380 kJ . Calculate the cell potential for this fuel cell at the same temperature and concentration conditions.
126. The ultimate electron acceptor in the respiration process is molecular oxygen. Electron transfer through the respiratory chain takes place through a complex series of oxidationreduction reactions. Some of the electron transport steps use iron-containing proteins called cytochromes. All cytochromes transport electrons by converting the iron in the cytochromes from the +3 to the +2 oxidation state. Consider the following reduction potentials for three different cytochromes used in the transfer process of electrons to oxygen (the potentials have been corrected for pH and for temperature):
\[
\begin{gathered}
\text { cytochrome } \mathrm{a}\left(\mathrm{Fe}^{3+}\right)+\mathrm{e}^{-} \longrightarrow \text { cytochrome } \mathrm{a}\left(\mathrm{Fe}^{2+}\right) \\
\mathscr{E}=0.385 \mathrm{~V} \\
\text { cytochrome } \mathrm{b}\left(\mathrm{Fe}^{3+}\right)+\mathrm{e}^{-} \longrightarrow \text { cytochrome } \mathrm{b}\left(\mathrm{Fe}^{2+}\right) \\
\mathscr{\mathscr { E }}=0.030 \mathrm{~V} \\
\text { cytochrome } \mathrm{c}\left(\mathrm{Fe}^{3+}\right)+\mathrm{e}^{-} \longrightarrow \text { cytochrome } \mathrm{c}\left(\mathrm{Fe}^{2+}\right) \\
\mathscr{E}=0.254 \mathrm{~V}
\end{gathered}
\]

In the electron transfer series, electrons are transferred from one cytochrome to another. Using this information, determine the cytochrome order necessary for spontaneous transport of electrons from one cytochrome to another, which eventually will lead to electron transfer to \(\mathrm{O}_{2}\).
127. One of the few industrial-scale processes that produce organic compounds electrochemically is used by the Monsanto Company to produce 1,4 -dicyanobutane. The reduction reaction is
\[
2 \mathrm{CH}_{2}=\mathrm{CHCN}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{NC}-\left(\mathrm{CH}_{2}\right)_{4}-\mathrm{CN}
\]

The \(\mathrm{NC}-\left(\mathrm{CH}_{2}\right)_{4}-\mathrm{CN}\) is then chemically reduced using hydrogen gas to \(\mathrm{H}_{2} \mathrm{~N}-\left(\mathrm{CH}_{2}\right)_{6}-\mathrm{NH}_{2}\), which is used in the production of nylon. What current must be used to produce 150. kg NC- \(\left(\mathrm{CH}_{2}\right)_{4}-\mathrm{CN}\) per hour?
128. It took 150 . s for a current of 1.25 A to plate out 0.109 g of a metal from a solution containing its cations. Show that it is not possible for the cations to have a charge of \(1+\).
129. It takes 15 kWh (kilowatt-hours) of electrical energy to produce 1.0 kg aluminum metal from aluminum oxide by the Hall-Heroult process. Compare this to the amount of energy necessary to melt 1.0 kg aluminum metal. Why is it economically feasible to recycle aluminum cans? [The enthalpy of fusion for aluminum metal is \(10.7 \mathrm{~kJ} / \mathrm{mol}\) ( \(1 \mathrm{watt}=1 \mathrm{~J} / \mathrm{s}\) ).]
130. In the electrolysis of a sodium chloride solution, what volume of \(\mathrm{H}_{2}(g)\) is produced in the same time it takes to produce 257 \(\mathrm{L} \mathrm{Cl}_{2}(g)\), with both volumes measured at \(50 .{ }^{\circ} \mathrm{C}\) and 2.50 atm ?
131. An aqueous solution of an unknown salt of ruthenium is electrolyzed by a current of 2.50 A passing for 50.0 min . If 2.618 g Ru is produced at the cathode, what is the charge on the ruthenium ions in solution?

\section*{ChemWork Problems}

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
132. Which of the following statement(s) is(are) true?
a. Copper metal can be oxidized by \(\mathrm{Ag}^{+}\)(at standard conditions).
b. In a galvanic cell the oxidizing agent in the cell reaction is present at the anode.
c. In a cell using the half reactions \(\mathrm{Al}^{3+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al}\) and \(\mathrm{Mg}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Mg}\), aluminum functions as the anode.
d. In a concentration cell electrons always flow from the compartment with the lower ion concentration to the compartment with the higher ion concentration.
e. In a galvanic cell the negative ions in the salt bridge flow in the same direction as the electrons.
133. Consider a galvanic cell based on the following half-reactions:

a. What is the expected cell potential with all components in their standard states?
b. What is the oxidizing agent in the overall cell reaction?
c. What substances make up the anode compartment?
d. In the standard cell, in which direction do the electrons flow?
e. How many electrons are transferred per unit of cell reaction?
f. If this cell is set up at \(25^{\circ} \mathrm{C}\) with \(\left[\mathrm{Fe}^{2+}\right]=2.00 \times 10^{-4} \mathrm{M}\) and \(\left[\mathrm{La}^{3+}\right]=3.00 \times 10^{-3} \mathrm{M}\), what is the expected cell potential?
134. Consider a galvanic cell based on the following theoretical half-reactions:

What is the value of \(\Delta G^{\circ}\) and \(K\) for this cell?
135. Consider a galvanic cell based on the following half-reactions:

a. What is the standard potential for this cell?
b. A nonstandard cell is set up at \(25^{\circ} \mathrm{C}\) with \(\left[\mathrm{Mg}^{2+}\right]=\) \(1.00 \times 10^{-5} \mathrm{M}\). The cell potential is observed to be 4.01 V . Calculate \(\left[\mathrm{Au}^{3+}\right]\) in this cell.
136. An electrochemical cell consists of a silver metal electrode immersed in a solution with \(\left[\mathrm{Ag}^{+}\right]=1.00 \mathrm{M}\) separated by a porous disk from a compartment with a copper metal electrode immersed in a solution of \(10.00 \mathrm{M} \mathrm{H}_{3}\) that also contains \(2.4 \times 10^{-3} \mathrm{M} \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\). The equilibrium between \(\mathrm{Cu}^{2+}\) and \(\mathrm{NH}_{3}\) is:
\(\mathrm{Cu}^{2+}(\mathrm{aq})+4 \mathrm{NH}_{3}(\mathrm{aq}) \rightleftharpoons \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(\mathrm{aq}) \quad K=1.0 \times 10^{13}\) and the two cell half-reactions are:
\[
\begin{array}{rr}
\mathrm{Ag}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Ag} & \mathscr{E}^{\circ}=0.80 \mathrm{~V} \\
\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu} & \mathscr{E}^{\circ}=0.34 \mathrm{~V}
\end{array}
\]

Assuming \(\mathrm{Ag}^{+}\)is reduced, what is the cell potential at \(25^{\circ} \mathrm{C}\) ?
137. An aqueous solution of \(\mathrm{PdCl}_{2}\) is electrolyzed for 48.6 seconds, and during this time 0.1064 g of Pd is deposited on the cathode. What is the average current used in the electrolysis?

\section*{Challenge Problems}
138. Consider the following half-reactions:
\[
\begin{array}{cl}
\mathrm{IrCl}_{6}{ }^{3-}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Ir}+6 \mathrm{Cl}^{-} & \mathscr{E}^{\circ}=0.77 \mathrm{~V} \\
\mathrm{PtCl}_{4}{ }^{2-}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Pt}+4 \mathrm{Cl}^{-} & \mathscr{E}^{\circ}=0.73 \mathrm{~V} \\
\mathrm{PdCl}_{4}{ }^{2-}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Pd}+4 \mathrm{Cl}^{-} & \mathscr{E}^{\circ}=0.62 \mathrm{~V}
\end{array}
\]

A hydrochloric acid solution contains platinum, palladium, and iridium as chloro-complex ions. The solution is a constant \(1.0 M\) in chloride ion and \(0.020 M\) in each complex ion. Is it feasible to separate the three metals from this solution by electrolysis? (Assume that \(99 \%\) of a metal must be plated out before another metal begins to plate out.)
139. Consider the following reduction potentials:
\[
\begin{array}{ll}
\mathrm{Co}^{3+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Co} & \mathscr{E}^{\circ}=1.26 \mathrm{~V} \\
\mathrm{Co}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Co} & \mathscr{E}^{\circ}=-0.28 \mathrm{~V}
\end{array}
\]
a. When cobalt metal dissolves in 1.0 M nitric acid, will \(\mathrm{Co}^{3+}\) or \(\mathrm{Co}^{2+}\) be the primary product (assuming standard conditions)?
b. Is it possible to change the concentration of \(\mathrm{HNO}_{3}\) to get a different result in part a? Concentrated \(\mathrm{HNO}_{3}\) is about 16 M.
140. Calculate \(\mathscr{E}^{\circ}\) and \(\Delta G^{\circ}\) for the reaction
\[
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g)
\]
at 298 K . Using thermodynamic data in Appendix 4, estimate \(\mathscr{E}^{\circ}\) and \(\Delta G^{\circ}\) at \(0^{\circ} \mathrm{C}\) and \(90 .^{\circ} \mathrm{C}\). Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
141. Combine the equations
\[
\Delta G^{\circ}=-n F_{\mathscr{C}}^{\circ} \quad \text { and } \quad \Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}
\]
to derive an expression for \(\mathscr{E}^{\circ}\) as a function of temperature. Describe how one can graphically determine \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) from measurements of \(\mathscr{E}^{\circ}\) at different temperatures, assuming that \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature. What property would you look for in designing a reference half-cell that would produce a potential relatively stable with respect to temperature?
142. The overall reaction in the lead storage battery is
\(\mathrm{Pb}(s)+\mathrm{PbO}_{2}(s)+2 \mathrm{H}^{+}(a q)+2 \mathrm{HSO}_{4}^{-}(a q) \longrightarrow\)
\[
2 \mathrm{PbSO}_{4}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)
\]
a. For the cell reaction \(\Delta H^{\circ}=-315.9 \mathrm{~kJ}\) and \(\Delta S^{\circ}=\) \(263.5 \mathrm{~J} / \mathrm{K}\). Calculate \(\mathscr{E}^{\circ}\) at \(-20 .{ }^{\circ} \mathrm{C}\). Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
b. Calculate \(\mathscr{E}\) at \(-20 .{ }^{\circ} \mathrm{C}\) when \(\left[\mathrm{HSO}_{4}^{-}\right]=\left[\mathrm{H}^{+}\right]=4.5 \mathrm{M}\).
c. Consider your answer to Exercise 69. Why does it seem that batteries fail more often on cold days than on warm days?
143. Consider the following galvanic cell:

Calculate the \(K_{\text {sp }}\) value for \(\mathrm{Ag}_{2} \mathrm{SO}_{4}(s)\). Note that to obtain silver ions in the right compartment (the cathode compartment), excess solid \(\mathrm{Ag}_{2} \mathrm{SO}_{4}\) was added and some of the salt dissolved.
144. A zinc-copper battery is constructed as follows at \(25^{\circ} \mathrm{C}\) :
\[
\mathrm{Zn}\left|\mathrm{Zn}^{2+}(0.10 M)\right|\left|\mathrm{Cu}^{2+}(2.50 M)\right| \mathrm{Cu}
\]

The mass of each electrode is 200 . g .
a. Calculate the cell potential when this battery is first connected.
b. Calculate the cell potential after 10.0 A of current has flowed for 10.0 h . (Assume each half-cell contains 1.00 L of solution.)
c. Calculate the mass of each electrode after 10.0 h .
d. How long can this battery deliver a current of 10.0 A before it goes dead?
145. A galvanic cell is based on the following half-reactions:
\[
\begin{array}{ll}
\mathrm{Fe}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Fe}(s) & \mathscr{E}^{\circ}=-0.440 \mathrm{~V} \\
2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g) & \mathscr{E}^{\circ}=0.000 \mathrm{~V}
\end{array}
\]
where the iron compartment contains an iron electrode and \(\left[\mathrm{Fe}^{2+}\right]=1.00 \times 10^{-3} \mathrm{M}\) and the hydrogen compartment
contains a platinum electrode, \(P_{\mathrm{H}_{2}}=1.00 \mathrm{~atm}\), and a weak acid, HA, at an initial concentration of 1.00 M . If the observed cell potential is 0.333 V at \(25^{\circ} \mathrm{C}\), calculate the \(K_{\mathrm{a}}\) value for the weak acid HA.
146. Consider a cell based on the following half-reactions:
\[
\begin{aligned}
\mathrm{Au}^{3+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Au} & \mathscr{E}^{\circ}=1.50 \mathrm{~V} \\
\mathrm{Fe}^{3+}+\mathrm{e}^{-} \longrightarrow \mathrm{Fe}^{2+} & \mathscr{E}^{\circ}=0.77 \mathrm{~V}
\end{aligned}
\]
a. Draw this cell under standard conditions, labeling the anode, the cathode, the direction of electron flow, and the concentrations, as appropriate.
b. When enough \(\mathrm{NaCl}(s)\) is added to the compartment containing gold to make the \(\left[\mathrm{Cl}^{-}\right]=0.10 \mathrm{M}\), the cell potential is observed to be 0.31 V . Assume that \(\mathrm{Au}^{3+}\) is reduced and assume that the reaction in the compartment containing gold is
\[
\mathrm{Au}^{3+}(a q)+4 \mathrm{Cl}^{-}(a q) \rightleftharpoons \mathrm{AuCl}_{4}^{-}(a q)
\]

Calculate the value of \(K\) for this reaction at \(25^{\circ} \mathrm{C}\).
147. The measurement of pH using a glass electrode obeys the Nernst equation. The typical response of a pH meter at \(25.00^{\circ} \mathrm{C}\) is given by the equation
\[
\mathscr{E}_{\text {meas }}=\mathscr{E}_{\text {ref }}+0.05916 \mathrm{pH}
\]
where \(\mathscr{E}_{\text {ref }}\) contains the potential of the reference electrode and all other potentials that arise in the cell that are not related to the hydrogen ion concentration. Assume that \(\mathscr{E}_{\text {ref }}=0.250 \mathrm{~V}\) and that \(\mathscr{E}_{\text {meas }}=0.480 \mathrm{~V}\).
a. What is the uncertainty in the values of pH and \(\left[\mathrm{H}^{+}\right]\)if the uncertainty in the measured potential is \(\pm 1 \mathrm{mV}\) \(( \pm 0.001 \mathrm{~V})\) ?
b. To what precision must the potential be measured for the uncertainty in pH to be \(\pm 0.02 \mathrm{pH}\) unit?
148. You have a concentration cell with Cu electrodes and \(\left[\mathrm{Cu}^{2+}\right]=1.00 M\) (right side) and \(1.0 \times 10^{-4} M\) (left side) .
a. Calculate the potential for this cell at \(25^{\circ} \mathrm{C}\).
b. The \(\mathrm{Cu}^{2+}\) ion reacts with \(\mathrm{NH}_{3}\) to form \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\) by the following equation:
\[
\begin{aligned}
\mathrm{Cu}^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \rightleftharpoons & \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q) \\
& K=1.0 \times 10^{13}
\end{aligned}
\]

Calculate the new cell potential after enough \(\mathrm{NH}_{3}\) is added to the left cell compartment such that at equilibrium \(\left[\mathrm{NH}_{3}\right]=2.0 \mathrm{M}\).
149. A galvanic cell is based on the following half-reactions:
\[
\begin{aligned}
\mathrm{Ag}^{+}+\mathrm{e}^{-} \longrightarrow \mathrm{Ag}(s) & \mathscr{E}^{\circ}=0.80 \mathrm{~V} \\
\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s) & \mathscr{E}^{\circ}=0.34 \mathrm{~V}
\end{aligned}
\]

In this cell, the silver compartment contains a silver electrode and excess \(\mathrm{AgCl}(s)\left(K_{\text {sp }}=1.6 \times 10^{-10}\right)\), and the copper compartment contains a copper electrode and \(\left[\mathrm{Cu}^{2+}\right]=2.0 \mathrm{M}\).
a. Calculate the potential for this cell at \(25^{\circ} \mathrm{C}\).
b. Assuming 1.0 L of \(2.0 \mathrm{M} \mathrm{Cu}^{2+}\) in the copper compartment, calculate the moles of \(\mathrm{NH}_{3}\) that would have to be added to give a cell potential of 0.52 V at \(25^{\circ} \mathrm{C}\) (assume no volume change on addition of \(\mathrm{NH}_{3}\) ).
\[
\mathrm{Cu}^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \rightleftharpoons
\]
150. Given the following two standard reduction potentials,
\[
\begin{array}{ll}
\mathrm{M}^{3+}+3 \mathrm{e}^{-} \longrightarrow \mathrm{M} & \mathscr{E}^{\circ}=-0.10 \mathrm{~V} \\
\mathrm{M}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{M} & \mathscr{E}^{\circ}=-0.50 \mathrm{~V}
\end{array}
\]
solve for the standard reduction potential of the half-reaction
\[
\mathrm{M}^{3+}+\mathrm{e}^{-} \longrightarrow \mathrm{M}^{2+}
\]
(Hint: You must use the extensive property \(\Delta G^{\circ}\) to determine the standard reduction potential.)
151. Consider the following galvanic cell:

Calculate the concentrations of \(\mathrm{Ag}^{+}(a q)\) and \(\mathrm{Ni}^{2+}(a q)\) once the cell is "dead."
152. A chemist wishes to determine the concentration of \(\mathrm{CrO}_{4}{ }^{2-}\) electrochemically. A cell is constructed consisting of a saturated calomel electrode (SCE; see Exercise 111) and a silver wire coated with \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\). The \(\mathscr{E}^{\circ}\) value for the following half-reaction is 0.446 V relative to the standard hydrogen electrode:
\[
\mathrm{Ag}_{2} \mathrm{CrO}_{4}+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{Ag}+\mathrm{CrO}_{4}^{2-}
\]
a. Calculate \(\mathscr{E}_{\text {cell }}\) and \(\Delta G\) at \(25^{\circ} \mathrm{C}\) for the cell reaction when \(\left[\mathrm{CrO}_{4}{ }^{2-}\right]=1.00 \mathrm{~mol} / \mathrm{L}\).
b. Write the Nernst equation for the cell. Assume that the SCE concentrations are constant.
c. If the coated silver wire is placed in a solution (at \(25^{\circ} \mathrm{C}\) ) in which \(\left[\mathrm{CrO}_{4}{ }^{2-}\right]=1.00 \times 10^{-5} \mathrm{M}\), what is the expected cell potential?
d. The measured cell potential at \(25^{\circ} \mathrm{C}\) is 0.504 V when the coated wire is dipped into a solution of unknown \(\left[\mathrm{CrO}_{4}{ }^{2-}\right]\). What is \(\left[\mathrm{CrO}_{4}{ }^{2-}\right]\) for this solution?
e. Using data from this problem and from Table 18.1, calculate the solubility product \(\left(K_{\mathrm{sp}}\right)\) for \(\mathrm{Ag}_{2} \mathrm{CrO}_{4}\).
153. Consider the following galvanic cell:

A 15.0-mole sample of \(\mathrm{NH}_{3}\) is added to the Ag compartment (assume 1.00 L of total solution after the addition). The silver ion reacts with ammonia to form complex ions as shown:
\[
\begin{aligned}
& \mathrm{Ag}^{+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{AgNH}_{3}^{+}(a q) \quad K_{1}=2.1 \times 10^{3} \\
& \mathrm{AgNH}_{3}^{+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q) \\
& K_{2}=8.2 \times 10^{3}
\end{aligned}
\]

Calculate the cell potential after the addition of 15.0 moles of \(\mathrm{NH}_{3}\).
154. When copper reacts with nitric acid, a mixture of \(\mathrm{NO}(g)\) and \(\mathrm{NO}_{2}(g)\) is evolved. The volume ratio of the two product gases depends on the concentration of the nitric acid according to the equilibrium
\[
2 \mathrm{H}^{+}(a q)+2 \mathrm{NO}_{3}^{-}(a q)+\mathrm{NO}(g) \rightleftharpoons 3 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
\]

Consider the following standard reduction potentials at \(25^{\circ} \mathrm{C}\) :
\[
\begin{gathered}
3 \mathrm{e}^{-}+4 \mathrm{H}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q) \longrightarrow \mathrm{NO}(g)+\underset{\mathscr{E}}{2 \mathrm{H}_{2} \mathrm{O}(l)} \\
\mathscr{E}^{\circ}=0.957 \mathrm{~V} \\
\mathrm{e}^{-}+2 \mathrm{H}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q) \longrightarrow \mathrm{NO}_{2}(g)+\underset{\mathscr{E}^{\circ}=0.775 \mathrm{~V}}{2 \mathrm{H}_{2} \mathrm{O}(l)}
\end{gathered}
\]
a. Calculate the equilibrium constant for the above reaction.
b. What concentration of nitric acid will produce a NO and \(\mathrm{NO}_{2}\) mixture with only \(0.20 \% \mathrm{NO}_{2}\) (by moles) at \(25^{\circ} \mathrm{C}\) and 1.00 atm ? Assume that no other gases are present and that the change in acid concentration can be neglected.

\section*{Integrative Problems}

These problems require the integration of multiple concepts to find the solutions.
155. The following standard reduction potentials have been determined for the aqueous chemistry of indium:
\[
\begin{aligned}
\mathrm{In}^{3+}(a q)+2 \mathrm{e}^{-} \longrightarrow \operatorname{In}^{+}(a q) & \mathscr{E}^{\circ}=-0.444 \mathrm{~V} \\
\mathrm{In}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \operatorname{In}(s) & \mathscr{E}^{\circ}=-0.126 \mathrm{~V}
\end{aligned}
\]
a. What is the equilibrium constant for the disproportionation reaction, where a species is both oxidized and reduced, shown below?
\[
3 \operatorname{In}^{+}(a q) \longrightarrow 2 \operatorname{In}(s)+\operatorname{In}^{3+}(a q)
\]
b. What is \(\Delta G_{\mathrm{f}}^{\circ}\) for \(\operatorname{In}^{+}(a q)\) if \(\Delta G_{\mathrm{f}}^{\circ}=-97.9 \mathrm{~kJ} / \mathrm{mol}\) for \(\operatorname{In}^{3+}(a q)\) ?
156. An electrochemical cell is set up using the following unbalanced reaction:
\[
\mathrm{M}^{a+}(a q)+\mathrm{N}(s) \longrightarrow \mathrm{N}^{2+}(a q)+\mathrm{M}(s)
\]

The standard reduction potentials are:
\[
\begin{array}{cl}
\mathrm{M}^{a+}+a \mathrm{e}^{-} \longrightarrow \mathrm{M} & \mathscr{E}^{\circ}=0.400 \mathrm{~V} \\
\mathrm{~N}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{N} & \mathscr{E}^{\circ}=0.240 \mathrm{~V}
\end{array}
\]

The cell contains \(0.10 \mathrm{M} \mathrm{N}^{2+}\) and produces a voltage of 0.180 V . If the concentration of \(\mathrm{M}^{a+}\) is such that the value of the reaction quotient \(Q\) is \(9.32 \times 10^{-3}\), calculate \(\left[\mathrm{M}^{a+}\right]\). Calculate \(w_{\text {max }}\) for this electrochemical cell.
157. Three electrochemical cells were connected in series so that the same quantity of electrical current passes through all three cells. In the first cell, 1.15 g chromium metal was deposited from a chromium(III) nitrate solution. In the second cell, 3.15 g osmium was deposited from a solution made of \(\mathrm{Os}^{n+}\) and nitrate ions. What is the name of the salt? In the third cell, the electrical charge passed through a solution containing \(\mathrm{X}^{2+}\) ions caused deposition of 2.11 g metallic X . What is the electron configuration of X ?
158. A silver concentration cell is set up at \(25^{\circ} \mathrm{C}\) as shown below:

The \(\mathrm{AgCl}(s)\) is in excess in the left compartment.
a. Label the anode and cathode, and describe the direction of the electron flow.
b. Determine the value of \(K_{\mathrm{sp}}\) for AgCl at \(25^{\circ} \mathrm{C}\).

\section*{Marathon Problems}

These problems are designed to incorporate several concepts and techniques into one situation.
159. A galvanic cell is based on the following half-reactions:
\[
\begin{array}{cl}
\mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s) & \mathscr{E}^{\circ}=0.34 \mathrm{~V} \\
\mathrm{~V}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{V}(s) & \mathscr{E}^{\circ}=-1.20 \mathrm{~V}
\end{array}
\]

In this cell, the copper compartment contains a copper electrode and \(\left[\mathrm{Cu}^{2+}\right]=1.00 \mathrm{M}\), and the vanadium compartment contains a vanadium electrode and \(\mathrm{V}^{2+}\) at an unknown concentration. The compartment containing the vanadium ( 1.00 L of solution) was titrated with \(0.0800 M \mathrm{H}_{2} \mathrm{EDTA}^{2-}\), resulting in the reaction
\[
\begin{array}{r}
\mathrm{H}_{2} \mathrm{EDTA}^{2-}(a q)+\mathrm{V}^{2+}(a q) \rightleftharpoons \operatorname{VEDTA}^{2-}(a q)+2 \mathrm{H}^{+}(a q) \\
K=?
\end{array}
\]

The potential of the cell was monitored to determine the stoichiometric point for the process, which occurred at a volume of \(500.0 \mathrm{~mL} \mathrm{H}_{2} \mathrm{EDTA}^{2-}\) solution added. At the stoichiometric point, \(\mathscr{E}_{\text {cell }}\) was observed to be 1.98 V . The solution was buffered at a pH of 10.00 .
a. Calculate \(\mathscr{E}_{\text {cell }}\) before the titration was carried out.
b. Calculate the value of the equilibrium constant, \(K\), for the titration reaction.
c. Calculate \(\mathscr{E}_{\text {cell }}\) at the halfway point in the titration.
160. The table below lists the cell potentials for the 10 possible galvanic cells assembled from the metals A, B, C, D, and E, and their respective \(1.00 \mathrm{M} 2+\) ions in solution. Using the data in the table, establish a standard reduction potential table similar to Table 18.1 in the text. Assign a reduction potential of 0.00 V to the half-reaction that falls in the middle of the series. You should get two different tables. Explain why, and discuss what you could do to determine which table is correct.
\begin{tabular}{|ccccc|}

The atomic number \(Z\) is the number of protons in a nucleus; the mass number \(A\) is the sum of protons and neutrons in a nucleus.

The term isotopes refers to a group of nuclides with the same atomic number. Each individual atom is properly called a nuclide, not an isotope.

Since the chemistry of an atom is determined by the number and arrangement of its electrons, the properties of the nucleus are not of primary importance to chemists. In the simplest view, the nucleus provides the positive charge to bind the electrons in atoms and molecules. However, a quick reading of any daily newspaper will show you that the nucleus and its properties have an important impact on our society. This chapter considers those aspects of the nucleus about which everyone should have some knowledge.

Several aspects of the nucleus are immediately impressive: its very small size, its very large density, and the magnitude of the energy that holds it together. The radius of a typical nucleus appears to be about \(10^{-13} \mathrm{~cm}\). This can be compared to the radius of a typical atom, which is on the order of \(10^{-8} \mathrm{~cm}\). A visualization will help you appreciate the small size of the nucleus: If the nucleus of the hydrogen atom were the size of a Ping-Pong ball, the electron in the \(1 s\) orbital would be, on average, 0.5 kilometer ( 0.3 mile) away. The density of the nucleus is equally impressiveapproximately \(1.6 \times 10^{14} \mathrm{~g} / \mathrm{cm}^{3}\). A sphere of nuclear material the size of a PingPong ball would have a mass of 2.5 billion tons! In addition, the energies involved in nuclear processes are typically millions of times larger than those associated with normal chemical reactions. This fact makes nuclear processes very attractive for feeding the voracious energy appetite of our civilization.

Atomos, the Greek root of the word atom, means "indivisible." It was originally believed that the atom was the ultimate indivisible particle of which all matter was composed. However, as we discussed in Chapter 2, Lord Rutherford showed in 1911 that the atom is not homogeneous, but rather has a dense, positively charged center surrounded by electrons. Subsequently, scientists have learned that the nucleus of the atom can be subdivided into particles called neutrons and protons. In fact, in the past two decades it has become apparent that even the protons and neutrons are composed of smaller particles called quarks.

For most purposes, the nucleus can be regarded as a collection of nucleons (neutrons and protons), and the internal structures of these particles can be ignored. As we discussed in Chapter 2, the number of protons in a particular nucleus is called the atomic number \((Z)\), and the sum of the neutrons and protons is the mass number \((A)\). Atoms that have identical atomic numbers but different mass number values are called isotopes. However, we usually do not use the singular form isotope to refer to a particular member of a group of isotopes. Rather, we use the term nuclide. A nuclide is a unique atom, represented by the symbol
where X represents the symbol for a particular element. For example, the following nuclides constitute the isotopes of carbon: carbon-12 \(\left({ }_{6}^{12} \mathrm{C}\right)\), carbon-13 \(\left({ }_{6}^{13} \mathrm{C}\right)\), and carbon-14 \(\left({ }_{6}^{14} \mathrm{C}\right)\).

\title{
19.1 Nuclear Stability and Radioactive Decay
}

Nuclear stability is the central topic of this chapter and forms the basis for all the important applications related to nuclear processes. Nuclear stability can be considered from both a kinetic and a thermodynamic point of view. Thermodynamic stability, as we will use the term here, refers to the potential energy of a particular nucleus as compared with the sum of the potential energies of its component protons and neutrons. We will use the term kinetic stability to describe the probability that a nucleus will undergo decomposition to form a different nucleus-a process called radioactive decay. We will consider radioactivity in this section.

Many nuclei are radioactive; that is, they decompose, forming another nucleus and producing one or more particles. An example is carbon-14, which decays as follows:
\[
{ }_{6}^{14} \mathrm{C} \longrightarrow{ }_{7}^{14} \mathrm{~N}+{ }_{-1}^{0} \mathrm{e}
\]
where \({ }_{-1}^{0} \mathrm{e}\) represents an electron, which is called a beta particle, or \(\boldsymbol{\beta}\) particle, in nuclear terminology. This equation is typical of those representing radioactive decay in that both \(A\) and \(Z\) must be conserved. That is, the \(Z\) values must give the same sum on both sides of the equation \((6=7-1)\), as must the \(A\) values \((14=14+0)\).

Of the approximately 2000 known nuclides, only 279 are stable with respect to radioactive decay. Tin has the largest number of stable isotopes- 10 .

It is instructive to examine how the numbers of neutrons and protons in a nucleus are related to its stability with respect to radioactive decay. Figure 19.1 shows a plot of the positions of the stable nuclei as a function of the number of protons \((Z)\) and the number of neutrons \((A-Z)\). The stable nuclides are said to reside in the zone of stability.

The following are some important observations concerning radioactive decay:
- All nuclides with 84 or more protons are unstable with respect to radioactive decay.
- Light nuclides are stable when \(Z\) equals \(A-Z\), that is, when the neutron-to-proton ratio is 1 . However, for heavier elements the neutron-to-proton ratio required for stability is greater than 1 and increases with \(Z\).
- Certain combinations of protons and neutrons seem to confer special stability. For example, nuclides with even numbers of protons and neutrons are more often stable than those with odd numbers, as shown by the data in Table 19.1.
- There are also certain specific numbers of protons or neutrons that produce especially stable nuclides. These magic numbers are \(2,8,20,28,50,82\), and 126. This behavior parallels that for atoms in which certain numbers of electrons \((2,10,18\), 36,54 , and 86 ) produce special chemical stability (the noble gases).

FIGURE 19.1 The zone of stability. The red dots indicate the nuclides that do not undergo radioactive decay. Note that as the number of protons in a nuclide increases, the neutron-to-proton ratio required for stability also increases.

\footnotetext{
\(\alpha\)-Particle production involves a change in \(A\) for the decaying nucleus; \(\beta\)-particle production has no effect on \(A\).
}

\section*{TABLE 19.1 | Number of Stable Nuclides Related to Numbers of Protons and Neutrons}

Stable Nuclides
\end{tabular} & Examples
\end{tabular}

Note: Even numbers of protons and neutrons seem to favor stability.

\section*{Types of Radioactive Decay}

Radioactive nuclei can undergo decomposition in various ways. These decay processes fall into two categories: those that involve a change in the mass number of the decaying nucleus and those that do not. We will consider the former type of process first.

An alpha particle, or \(\boldsymbol{\alpha}\) particle, is a helium nucleus \(\left({ }_{2}^{4} \mathrm{He}\right)\). Alpha-particle production is a very common mode of decay for heavy radioactive nuclides. For example, \({ }_{92}^{238} \mathrm{U}\), the predominant ( \(99.3 \%\) ) isotope of natural uranium, decays by \(\alpha\)-particle production:
\[
{ }_{92}^{238} \mathrm{U} \longrightarrow{ }_{2}^{4} \mathrm{He}+{ }_{90}^{234} \mathrm{Th}
\]

Another \(\alpha\)-particle producer is \({ }_{90}^{230} \mathrm{Th}\) :
\[
{ }_{90}^{230} \mathrm{Th} \longrightarrow{ }_{2}^{4} \mathrm{He}+{ }_{88}^{226} \mathrm{Ra}
\]

Another decay process in which the mass number of the decaying nucleus changes is spontaneous fission, the splitting of a heavy nuclide into two lighter nuclides with similar mass numbers. Although this process occurs at an extremely slow rate for most nuclides, it is important in some cases, such as for \({ }_{98}^{254} \mathrm{Cf}\), where spontaneous fission is the predominant mode of decay.

The most common decay process in which the mass number of the decaying nucleus remains constant is \(\boldsymbol{\beta}\)-particle production. For example, the thorium-234 nuclide produces a \(\beta\) particle and is converted to protactinium-234:
\[
{ }_{90}^{234} \mathrm{Th} \longrightarrow{ }_{91}^{234} \mathrm{~Pa}+{ }_{-1}^{0} \mathrm{e}
\]

Iodine-131 is also a \(\beta\)-particle producer:
\[
{ }_{53}^{131} \mathrm{I} \longrightarrow{ }_{-1}^{0} \mathrm{e}+{ }_{54}^{131} \mathrm{Xe}
\]

The \(\beta\) particle is assigned the mass number 0 , since its mass is tiny compared with that of a proton or neutron. Because the value of \(Z\) is -1 for the \(\beta\) particle, the atomic number for the new nuclide is greater by 1 than for the original nuclide. Thus the net effect of \(\beta\)-particle production is to change a neutron to a proton. We therefore expect nuclides that lie above the zone of stability (those nuclides whose neutron/proton ratios are too high) to be \(\beta\)-particle producers.

It should be pointed out that although the \(\beta\) particle is an electron, the emitting nucleus does not contain electrons. As we shall see later in this chapter, a given quantity of energy (which is best regarded as a form of matter) can become a particle (another form of matter) under certain circumstances. The unstable nuclide creates an electron as it releases energy in the decay process. The electron thus results from the decay process rather than being present before the decay occurs. Think of this as somewhat like talking: Words are not stored inside us but are formed as we speak. Later in this chapter we will discuss in more detail this very interesting phenomenon where matter in the form of particles and matter in the form of energy can interchange.

A gamma ray, or \(\boldsymbol{\gamma}\) ray, refers to a high-energy photon. Frequently, \(\gamma\)-ray production accompanies nuclear decays and particle reactions, such as in the \(\alpha\)-particle decay of \({ }_{92}^{238} \mathrm{U}\) :
\[
{ }_{92}^{238} \mathrm{U} \longrightarrow{ }_{2}^{4} \mathrm{He}+{ }_{90}^{234} \mathrm{Th}+2{ }_{0}^{0} \gamma
\]
where two \(\gamma\) rays of different energies are produced in addition to the \(\alpha\) particle. The emission of \(\gamma\) rays is one way a nucleus with excess energy (in an excited nuclear state) can relax to its ground state.

Positron production occurs for nuclides that are below the zone of stability (those nuclides whose neutron/proton ratios are too small). The positron is a particle with the same mass as the electron but opposite charge. An example of a nuclide that decays by positron production is sodium- 22 :
\[
{ }_{11}^{22} \mathrm{Na} \longrightarrow{ }_{1}^{0} \mathrm{e}+{ }_{10}^{22} \mathrm{Ne}
\]

Note that the net effect is to change a proton to a neutron, causing the product nuclide to have a higher neutron/proton ratio than the original nuclide.

Besides being oppositely charged, the positron shows an even more fundamental difference from the electron: It is the antiparticle of the electron. When a positron collides with an electron, the particulate matter is changed to electromagnetic radiation in the form of high-energy photons:
\[
{ }_{-1}^{0} \mathrm{e}+{ }_{1}^{0} \mathrm{e} \longrightarrow 2{ }_{0}^{0} \gamma
\]

This process, which is characteristic of matter-antimatter collisions, is called annihilation and is another example of the interchange of the forms of matter.

Electron capture is a process in which one of the inner-orbital electrons is captured by the nucleus, as illustrated by the process
\[
\overbrace{\text { Inner-orbital electron }}^{201}{ }_{80}^{201} \mathrm{Hg}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{0}^{0} \gamma
\]

This reaction would have been of great interest to the alchemists, but unfortunately it does not occur at a rate that would make it a practical means for changing mercury to gold. Gamma rays are always produced along with electron capture to release excess energy. The various types of radioactive decay are summarized in Table 19.2.
 successive decays such that it became the original nuclide? Which decays could account for this? Provide an example.

TABLE 19.2 | Various Types of Radioactive Processes Showing the Changes That Take Place in the Nuclides
\begin{tabular}{|c|c|c|c|c|}
\hline Process & Change in \(A\) & Change in \(Z\) & Change in Neutron/Proton Ratio & Example \\
\hline \(\beta\)-particle (electron) production & 0 & +1 & Decrease & \({ }_{89}^{227} \mathrm{Ac} \longrightarrow{ }_{90}^{227} \mathrm{Th}+{ }_{-1}^{0} \mathrm{e}\) \\
\hline Positron production & 0 & -1 & Increase & \({ }_{7}^{13} \mathrm{~N} \longrightarrow{ }_{6}^{13} \mathrm{C}+{ }_{1}^{0} \mathrm{e}\) \\
\hline Electron capture & 0 & -1 & Increase & \({ }_{33}^{73} \mathrm{As}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{32}^{73} \mathrm{Ge}\) \\
\hline \(\alpha\)-particle production & -4 & -2 & Increase & \({ }_{84}^{210} \mathrm{Po} \longrightarrow{ }_{82}^{206} \mathrm{~Pb}+{ }_{2}^{4} \mathrm{He}\) \\
\hline \(\gamma\)-ray production & 0 & 0 & - & Excited nucleus \(\longrightarrow\) ground-state nucleus \(+{ }_{0}^{0} \gamma\) \\
\hline Spontaneous fission & - & - & - & \({ }_{98}^{254} \mathrm{Cf} \longrightarrow\) lighter nuclides + neutrons \\
\hline
\end{tabular}

\section*{INTERACTIVE EXAMPLE 19.1 Nuclear Equations I}

Write balanced equations for each of the following processes.
a. \({ }_{6}^{11} \mathrm{C}\) produces a positron.
b. \({ }_{83}^{214} \mathrm{Bi}\) produces a \(\beta\) particle.
c. \({ }_{93}^{237} \mathrm{~Np}\) produces an \(\alpha\) particle.

SOLUTION a. We must find the product nuclide represented by \({ }_{Z}^{A} \mathrm{X}\) in the following equation:
\[
\underset{\substack{11 \\ C}}{\substack{\uparrow \\ \text { Positron }}}{ }^{0} \mathrm{e}+{ }_{Z}^{A} \mathrm{X}
\]

We can find the identity of \({ }_{Z}^{A} \mathrm{X}\) by recognizing that the total of the \(Z\) and \(A\) values must be the same on both sides of the equation. Thus for \(X, Z\) must be \(6-1=5\) and \(A\) must be \(11-0=11\). Therefore, \({ }_{Z}^{A} X\) is \({ }_{5}^{11} B\). (The fact that \(Z\) is 5 tells us that the nuclide is boron.) Thus the balanced equation is
\[
{ }_{6}^{11} \mathrm{C} \longrightarrow{ }_{1}^{0} \mathrm{e}+{ }_{5}^{11} \mathrm{~B}
\]
b. Knowing that a \(\beta\) particle is represented by \({ }_{-1}^{0} \mathrm{e}\) and that \(Z\) and \(A\) are conserved, we can write
\[
{ }_{83}^{214} \mathrm{Bi} \longrightarrow{ }_{-1}^{0} \mathrm{e}+{ }_{84}^{214} \mathrm{X}
\]
so \({ }_{Z}^{A} \mathrm{X}\) must be \({ }_{84}^{214} \mathrm{Po}\).
c. Since an \(\alpha\) particle is represented by \({ }_{2}^{4} \mathrm{He}\), the balanced equation must be
\[
{ }_{93}^{237} \mathrm{~Np} \longrightarrow{ }_{2}^{4} \mathrm{He}+{ }_{91}^{233} \mathrm{~Pa}
\]

See Exercises 19.15, 19.18, and 19.19

\section*{INTERACTVE EXAMPLE 19.2 Nuclear Equations II}

In each of the following nuclear reactions, supply the missing particle.
a. \({ }_{79}^{195} \mathrm{Au}+? \rightarrow{ }_{78}^{195} \mathrm{Pt}\)
b. \({ }_{19}^{38} \mathrm{~K} \rightarrow{ }_{18}^{38} \mathrm{Ar}+\) ?

SOLUTION
a. Since \(A\) does not change and \(Z\) decreases by 1 , the missing particle must be an electron:
\[
{ }_{79}^{195} \mathrm{Au}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{78}^{195} \mathrm{Pt}
\]

This is an example of electron capture.
b. To conserve \(Z\) and \(A\), the missing particle must be a positron:
\[
{ }_{19}^{38} \mathrm{~K} \longrightarrow{ }_{18}^{38} \mathrm{Ar}+{ }_{1}^{0} \mathrm{e}
\]

Thus potassium- 38 decays by positron production.

\section*{See Exercises 19.16, 19.17, and 19.20}

Often a radioactive nucleus cannot reach a stable state through a single decay process. In such a case, a decay series occurs until a stable nuclide is formed. A wellknown example is the decay series that starts with \({ }_{92}^{238} \mathrm{U}\) and ends with \({ }_{82}^{206} \mathrm{~Pb}\), as shown in Fig. 19.2. Similar series exist for \({ }_{92}^{235} \mathrm{U}\) :
\[
{ }_{92}^{235} \mathrm{U} \xrightarrow[\text { Series of }]{ }{ }_{82}^{207} \mathrm{~Pb}
\]
and for \({ }_{90}^{232} \mathrm{Th}\) :
\[
{ }_{90}^{232} \mathrm{Th} \xrightarrow[\text { decays }]{\text { Series of }}{ }_{82}^{208} \mathrm{~Pb}
\]

FIGURE 19.2 The decay series from \({ }_{92}^{238} \mathrm{U}\) to \({ }_{82}^{206} \mathrm{~Pb}\). Each nuclide in the series except \({ }_{82}^{206} \mathrm{~Pb}\) is radioactive, and the successive transformations (shown by the arrows) continue until \({ }_{82}^{238} \mathrm{~Pb}\) is finally formed. The horizontal red arrows indicate \(\beta\)-particle production ( \(Z\) increases by 1 and \(A\) is unchanged). The diagonal blue arrows signify \(\alpha\)-particle production (both \(A\) and \(Z\) decrease).

\subsection*{19.2 The Kinetics of Radioactive Decay}

In a sample containing radioactive nuclides of a given type, each nuclide has a certain probability of undergoing decay. Suppose that a sample of 1000 atoms of a certain nuclide produces 10 decay events per hour. This means that over the span of an hour, 1 out of every 100 nuclides will decay. Given that this probability of decay is characteristic for this type of nuclide, we could predict that a 2000 -atom sample would give 20 decay events per hour. Thus, for radioactive nuclides, the rate of decay, which is the negative of the change in the number of nuclides per unit time
\[
\left(-\frac{\Delta N}{\Delta t}\right)
\]

A
False-colored scintigram of normal pelvis obtained following the intravenous injection of a tracer marked with the radio isotope technetium-99m.
is directly proportional to the number of nuclides \(N\) in a given sample:
\[
\text { Rate }=-\frac{\Delta N}{\Delta t} \propto N
\]

The negative sign is included because the number of nuclides is decreasing. We now insert a proportionality constant \(k\) to give
\[
\text { Rate }=-\frac{\Delta N}{\Delta t}=k N
\]

This is the rate law for a first-order process, as we saw in Chapter 12. As shown in Section 12.4, the integrated first-order rate law is
\[
\ln \left(\frac{N}{N_{0}}\right)=-k t
\]
where \(N_{0}\) represents the original number of nuclides (at \(t=0\) ) and \(N\) represents the number remaining at time \(t\).

\section*{Half-Life}

The half-life \(\left(t_{1 / 2}\right)\) of a radioactive sample is defined as the time required for the number of nuclides to reach half the original value \(\left(N_{0} / 2\right)\). We can use this definition in connection with the integrated first-order rate law (as we did in Section 12.4) to produce the following expression for \(t_{1 / 2}\) :
\[
t_{1 / 2}=\frac{\ln (2)}{k}=\frac{0.693}{k}
\]

Thus, if the half-life of a radioactive nuclide is known, the rate constant can be easily calculated, and vice versa.

\section*{INTERACTIVE EXAMPLE 19.3}

\section*{SOLUTION}

The harmful effects of radiation will be discussed in Section 19.7.

FIGURE 19.3 The decay of a \(10.0-\mathrm{g}\) sample of strontium-90 over time. Note that the half-life is a constant 28.9 years.

\section*{Kinetics of Nuclear Decay I}

Technetium-99m is used to form pictures of internal organs in the body and is often used to assess heart damage. The \(m\) for this nuclide indicates an excited nuclear state that decays to the ground state by gamma emission. The rate constant for decay of \({ }_{43}^{99 \mathrm{~m}} \mathrm{Tc}\) is known to be \(1.16 \times 10^{-1} / \mathrm{h}\). What is the half-life of this nuclide?
The half-life can be calculated from the expression
\[
\begin{aligned}
t_{1 / 2} & =\frac{0.693}{k}=\frac{0.693}{1.16 \times 10^{-1} / \mathrm{h}} \\
& =5.98 \mathrm{~h}
\end{aligned}
\]

Thus it will take 5.98 h for a given sample of technetium-99m to decrease to half the original number of nuclides.

\section*{See Exercise 19.31}

As we saw in Section 12.4, the half-life for a first-order process is constant. This is shown for the \(\beta\)-particle decay of strontium-90 in Fig. 19.3; it takes 28.9 years for each halving of the amount of \({ }_{38}^{90} \mathrm{Sr}\). Contamination of the environment with \({ }_{38}^{90} \mathrm{Sr}\) poses serious health hazards because of the similar chemistry of strontium and calcium (both are in Group 2A). Strontium-90 in grass and hay is incorporated into cow's milk along with calcium and is then passed on to humans, where it lodges in the bones. Because of its relatively long half-life, it persists for years in humans, causing radiation damage that may lead to cancer.

\section*{EXAMPLE 19.4 Kinetics of Nuclear Decay II}

The half-life of molybdenum-99 is 66.0 h . How much of a \(1.000-\mathrm{mg}\) sample of \({ }_{42}^{99} \mathrm{Mo}\) is left after 330 h ?

The easiest way to solve this problem is to recognize that 330 h represents five half-lives for \({ }_{42}^{99} \mathrm{Mo}\) :
\[
330=5 \times 66.0
\]

We can sketch the change that occurs, as is shown in Fig. 19.4. Thus, after 330 h , 0.031 mg \({ }_{42}^{99}\) Mo remains.

See Exercises 19.33 and 19.34

The half-lives of radioactive nuclides vary over a tremendous range. For example, \({ }_{60}^{144} \mathrm{Nd}\) has a half-life of \(2.3 \times 10^{15}\) years, while \({ }_{84}^{214} \mathrm{Po}\) has a half-life of \(2 \times 10^{-4} \mathrm{sec}\) ond. To give you some perspective on this, the half-lives of the nuclides in the \({ }_{92}^{238} \mathrm{U}\) decay series are given in Table 19.3.

FIGURE 19.4 The change in the amount of \({ }_{42}^{99} \mathrm{Mo}\) with time ( \(t_{1 / 2}=66 \mathrm{~h}\) ).

TABLE 19.3 | The Half-Lives of Nuclides in the \({ }_{92}^{238} \mathrm{U}\) Decay Series
\begin{tabular}{|c|c|c|}
\hline Nuclide & Particle Produced & Half-Life \\

\hline \multicolumn{3}{|l|}{\(\downarrow\)} \\
\hline Lead-206 ( \({ }_{82}{ }_{2}^{206} \mathrm{~Pb}\) ) & - & Stable \\
\hline
\end{tabular}

\subsection*{19.3 Nuclear Transformations}

In 1919 Lord Rutherford observed the first nuclear transformation, the change of one element into another. He found that by bombarding \({ }_{7}^{14} \mathrm{~N}\) with \(\alpha\) particles, the nuclide \({ }_{8}^{17} \mathrm{O}\) could be produced:
\[
{ }_{7}^{14} \mathrm{~N}+{ }_{2}^{4} \mathrm{He} \longrightarrow{ }_{8}^{17} \mathrm{O}+{ }_{1}^{1} \mathrm{H}
\]

Fourteen years later, Irene Curie and her husband Frederick Joliot observed a similar transformation from aluminum to phosphorus:
\[
{ }_{13}^{27} \mathrm{Al}+{ }_{2}^{4} \mathrm{He} \longrightarrow{ }_{15}^{30} \mathrm{P}+{ }_{0}^{1} \mathrm{n}
\]
where \({ }_{0}^{1} \mathrm{n}\) represents a neutron.
Over the years, many other nuclear transformations have been achieved, mostly using particle accelerators, which, as the name reveals, are devices used to give particles very high velocities. Because of the electrostatic repulsion between the target nucleus and a positive ion, accelerators are needed when positive ions are used as bombarding particles. The particle, accelerated to a very high velocity, can overcome the repulsion and penetrate the target nucleus, thus effecting the transformation. A schematic diagram of one type of particle accelerator, the cyclotron, is shown in Fig. 19.5. The ion is introduced at the center of the cyclotron and is accelerated in an expanding spiral path by use of alternating electric fields in the presence of a magnetic field. The linear accelerator illustrated in Fig. 19.6 uses changing electric fields to achieve high velocities on a linear pathway.

In addition to positive ions, neutrons are often used as bombarding particles to effect nuclear transformations. Because neutrons are uncharged and thus not repelled electrostatically by a target nucleus, they are readily absorbed by many nuclei, leading to new nuclides. The most common source of neutrons for this purpose is a fission reactor (see Section 19.6).

A
A cyclotron at TRIUMF, Canada's national laboratory of particle and nuclear physics.

FIGURE 19.5 A schematic diagram of a cyclotron. The ion is introduced in the center and is pulled back and forth between the hollow D-shaped electrodes by constant reversals of the electric field. Magnets above and below these electrodes produce a spiral path that expands as the particle velocity increases. When the particle has sufficient speed, it exits the accelerator and is directed at the target nucleus.

FIGURE 19.6 Schematic diagram of a linear accelerator, which uses a changing electric field to accelerate a positive ion along a linear path. As the ion leaves the source, the odd-numbered tubes are negatively charged, and the even-numbered tubes are positively charged. The positive ion is thus attracted into tube 1. As the ion leaves tube 1 , the tube polarities are reversed. Now tube 1 is positive, repelling the positive ion, and tube 2 is negative, attracting the positive ion. This process continues, eventually producing high particle velocity.

\section*{CHEMICAL CDNNECTIDNS}

\section*{Tennessine}

\(T_{p}^{\text {nem }}\)he discovery of element 117 (Ts) provides an excellent illustration of the importance of teamwork in modern scientific activities. Although element 117 was prepared in Dubna, Russia, the target nuclides were prepared at Oak Ridge National Laboratory (ORNL) in Tennessee, and data analysis on the discovery was carried out at Lawrence Livermore Laboratory in California.

The birth of element 117 started at ORNL where a 250 -day irradiation
experiment produced 22 mg of berkelium-249, which has a 320-day half-life. This process was followed by a 90-day effort to separate and purify the berkelium, after which the berkelium was sent to the Joint Institute for Nuclear Research (JINR) in Dubna, Russia. JINR has an accelerator beam that enabled calcium- 48 to be directed at the berkelium-249 target. This 150-day process resulted in the production of six atoms of element 117 by the following nuclear reactions:
\[
\begin{gathered}
{ }_{20}^{48} \mathrm{Ca}+{ }_{97}^{249} \mathrm{Bk} \rightarrow{ }_{117}^{297} \mathrm{Ts}^{*} \rightarrow{ }_{117}^{294} \mathrm{Ts}+3{ }_{0}^{1} \mathrm{n} \\
\text { (1 atom produced) }
\end{gathered}
\]
\[
{ }_{20}^{48} \mathrm{Ca}+{ }_{97}^{249} \mathrm{Bk} \rightarrow{ }_{117}^{297} \mathrm{Ts}^{*} \rightarrow{ }_{117}^{293} \mathrm{Ts}+4_{0}^{1} \mathrm{n}
\]
(5 atoms produced)
The periodic table shows Ts as the heaviest element in the halogen family. However, because only six atoms of Ts were produced and they existed for only about 0.01 second, no evidence is available at present of the chemical behavior of Ts.

\section*{A}

The Large Haldron Collider at CERN is the world's largest and most powerful particle accelerator.

TABLE 19.4 | Syntheses of Some of the Transuranium Elements

\hline Seaborgium
\[
(Z=106)
\] & \({ }_{98}^{249} \mathrm{Cf}+{ }_{8}^{18} \mathrm{O} \longrightarrow{ }_{106}^{263} \mathrm{Sg}+4{ }_{0}^{1} \mathrm{n}\) & \\
\hline
\end{tabular}

By using neutron and positive-ion bombardment, scientists have been able to extend the periodic table. Prior to 1940, the heaviest known element was uranium \((Z=92)\), but in 1940, neptunium \((Z=93)\) was produced by neutron bombardment of \({ }_{92}^{238} \mathrm{U}\). The process initially gives \({ }_{92}^{239} \mathrm{U}\), which decays to \({ }_{93}^{239} \mathrm{~Np}\) by \(\beta\)-particle production:
\[
{ }_{92}^{238} \mathrm{U}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{92}^{239} \mathrm{U} \xrightarrow[t_{12}=23 \text { min }]{ }{ }_{92}^{238} \mathrm{~Np}+{ }_{-1}^{0} \mathrm{e}
\]

In the years since 1940, the elements with atomic numbers greater than 92 , called the transuranium elements,* have been synthesized. Many of these elements have very short half-lives, as shown in Table 19.4. As a result, only a few atoms of some have ever been formed. This, of course, makes the chemical characterization of these elements extremely difficult.

\subsection*{19.4 Detection and Uses of Radioactivity}

Although various instruments measure radioactivity levels, the most familiar of them is the Geiger-Müller counter, or Geiger counter (Fig. 19.7). This instrument takes advantage of the fact that the high-energy particles from radioactive decay processes

FIGURE 19.7 A schematic representation of a Geiger-Müller counter. The high-energy radioactive particle enters the window and ionizes argon atoms along its path. The resulting ions and electrons produce a momentary current pulse, which is amplified and counted.

\footnotetext{

}

\(\Delta\)
Paleontologist examining Triceratops horn in preparation for carbon-14 dating.

Radioactive nuclides are often called radionuclides. Carbon dating is based on the radionuclide \({ }_{6}^{14} \mathrm{C}\).

The \({ }_{6}^{14} \mathrm{C} /{ }_{6}^{12} \mathrm{C}\) ratio is the basis for carbon-14 dating.

A
Dr. Thomas Swetnam, a dendrochronologist at the University of Arizona in Tucson.
produce ions when they travel through matter. The probe of the Geiger counter is filled with argon gas, which can be ionized by a rapidly moving particle. This reaction is demonstrated by the equation:
\[
\operatorname{Ar}(g) \xrightarrow[\text { particle }]{\text { High }} \mathrm{Ar}^{+}(g)+\mathrm{e}^{-}
\]

Normally, a sample of argon gas will not conduct a current when an electrical potential is applied. However, the formation of ions and electrons produced by the passage of the high-energy particle allows a momentary current to flow. Electronic devices detect this current flow, and the number of these events can be counted. Thus the decay rate of the radioactive sample can be determined.

Another instrument often used to detect levels of radioactivity is a scintillation counter, which takes advantage of the fact that certain substances, such as zinc sulfide, give off light when they are struck by high-energy radiation. A photocell senses the flashes of light that occur as the radiation strikes and thus measures the number of decay events per unit of time.

\section*{Dating by Radioactivity}

Archaeologists, geologists, and others involved in reconstructing the ancient history of the earth rely heavily on radioactivity to provide accurate dates for artifacts and rocks. A method that has been very important for dating ancient articles made from wood or cloth is radiocarbon dating, or carbon-14 dating, a technique originated in the 1940s by Willard Libby, an American chemist who received a Nobel Prize for his efforts in this field.

Radiocarbon dating is based on the radioactivity of the nuclide \({ }_{6}^{14} \mathrm{C}\), which decays via \(\beta\)-particle production:
\[
{ }_{6}^{14} \mathrm{C} \longrightarrow{ }_{-1}^{0} \mathrm{e}+{ }_{7}^{14} \mathrm{~N}
\]

Carbon-14 is continuously produced in the atmosphere when high-energy neutrons from space collide with nitrogen-14:
\[
{ }_{7}^{14} \mathrm{~N}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{6}^{14} \mathrm{C}+{ }_{1}^{1} \mathrm{H}
\]

Thus carbon-14 is continuously produced by this process, and it continuously decomposes through \(\beta\)-particle production. Over the years, the rates for these two processes have become equal, and like a participant in a chemical reaction at equilibrium, the amount of \({ }_{6}^{14} \mathrm{C}\) that is present in the atmosphere remains approximately constant.

Carbon-14 can be used to date wood and cloth artifacts because the \({ }_{6}^{14} \mathrm{C}\), along with the other carbon isotopes in the atmosphere, reacts with oxygen to form carbon dioxide. A living plant consumes carbon dioxide in the photosynthesis process and incorporates the carbon, including \({ }_{6}^{14} \mathrm{C}\), into its molecules. As long as the plant lives, the \({ }_{6}^{14} \mathrm{C} /{ }_{6}^{12} \mathrm{C}\) ratio in its molecules remains the same as in the atmosphere because of the continuous uptake of carbon. However, as soon as a tree is cut to make a wooden bowl or a flax plant is harvested to make linen, the \({ }_{6}^{14} \mathrm{C} /{ }_{6}^{12} \mathrm{C}\) ratio begins to decrease because of the radioactive decay of \({ }_{6}^{14} \mathrm{C}\) (the \({ }_{6}^{12} \mathrm{C}\) nuclide is stable). Since the half-life of \({ }_{6}^{14} \mathrm{C}\) is 5730 years, a wooden bowl found in an archaeological dig showing a \({ }_{6}^{14} \mathrm{C} /{ }_{6}^{12} \mathrm{C}\) ratio that is half that found in currently living trees is approximately 5730 years old. This reasoning assumes that the current \({ }_{6}^{14} \mathrm{C} /{ }_{6}^{12} \mathrm{C}\) ratio is the same as that found in ancient times.

Dendrochronologists, scientists who date trees from annual growth rings, have used data collected from long-lived species of trees, such as bristlecone pines and sequoias, to show that the \({ }_{6}^{14} \mathrm{C}\) content of the atmosphere has changed significantly over the ages. These data have been used to derive correction factors that allow very accurate dates to be determined from the observed \({ }_{6}^{14} \mathrm{C} /{ }_{6}^{12} \mathrm{C}\) ratio in an artifact, especially for artifacts 10,000 years old or younger. Recent measurements of uranium-to-thorium ratios in
ancient coral indicate that dates in the 20,000- to 30,000-year range may have errors as large as 3000 years. As a result, efforts are now being made to recalibrate the \({ }_{6}^{14} \mathrm{C}\) dates over this period.

\section*{INTERACTIVE EXAMPLE 19.5}

\section*{\({ }^{14} \mathrm{C}\) Dating}

The remnants of an ancient fire in a cave in Africa showed a \({ }_{6}^{14} \mathrm{C}\) decay rate of 3.1 counts per minute per gram of carbon. Assuming that the decay rate of \({ }_{6}^{14} \mathrm{C}\) in freshly cut wood (corrected for changes in the \({ }_{6}^{14} \mathrm{C}\) content of the atmosphere) is 13.6 counts per minute per gram of carbon, calculate the age of the remnants. The half-life of \({ }_{6}^{14} \mathrm{C}\) is 5730 years.

\section*{SOLUTION}

The key to solving this problem is to realize that the decay rates given are directly proportional to the number of \({ }_{6}^{14} \mathrm{C}\) nuclides present. Radioactive decay follows first-order kinetics:
\[
\text { Rate }=k N
\]

Thus
\[
\left.\begin{array}{rl}
\frac{3.1 \text { counts } / \mathrm{min} \cdot \mathrm{~g}}{13.6 \text { counts } / \mathrm{min} \cdot \mathrm{~g}} & =\frac{\text { rate at time } t}{\text { rate at time } 0}=\frac{k N}{k N_{0}} \\
& \begin{array}{c}
\text { Number of nuclides } \\
\text { Number of nuclides } \\
\text { present at time } 0
\end{array} \\
N_{0}
\end{array}\right)
\]

We can now use the integrated first-order rate law:
where
\[
\ln \left(\frac{N}{N_{0}}\right)=-k t
\]
\[
k=\frac{0.693}{t_{1 / 2}}=\frac{0.693}{5730 \text { years }}
\]
to solve for \(t\), the time elapsed since the campfire:
\[
\ln \left(\frac{N}{N_{0}}\right)=\ln (0.23)=-\left(\frac{0.693}{5730 \text { years }}\right) t
\]
- Solving this equation gives \(t=12,000\) years; the campfire in the cave occurred about 12,000 years ago.

\section*{See Exercises 19.43 and 19.44}

One drawback of radiocarbon dating is that a fairly large piece of the object (from a half to several grams) must be burned to form carbon dioxide, which is then analyzed for radioactivity. Another method for counting \({ }_{6}^{14} \mathrm{C}\) nuclides avoids destruction of a significant portion of a valuable artifact. This technique, requiring only about \(10^{-3} \mathrm{~g}\), uses a mass spectrometer (see Chapter 3), in which the carbon atoms are ionized and accelerated through a magnetic field that deflects their path. Because of their different masses, the various ions are deflected by different amounts and can be counted separately. This allows a very accurate determination of the \({ }_{6}^{14} \mathrm{C} /{ }_{6}^{12} \mathrm{C}\) ratio in the sample.

In their attempts to establish the geologic history of the earth, geologists have made extensive use of radioactivity. For example, since \({ }_{92}^{238} \mathrm{U}\) decays to the stable \({ }_{82}^{206} \mathrm{~Pb}\)
nuclide, the ratio of \({ }_{82}^{206} \mathrm{~Pb}\) to \({ }_{92}^{238} \mathrm{U}\) in a rock can, under favorable circumstances, be used to estimate the age of the rock. The radioactive nuclide \({ }_{71}^{176} \mathrm{Lu}\), which decays to \({ }_{72}^{176} \mathrm{Hf}\), has a half-life of 37 billion years (only 186 nuclides out of 10 trillion decay each year!). Thus this nuclide can be used to date very old rocks. With this technique, scientists have estimated that the earth's crust formed 4.3 billion years ago.

\section*{INTERACTIVE EXAMPLE 19.6 Dating by Radioactivity}

A rock containing \({ }_{92}^{238} \mathrm{U}\) and \({ }_{82}^{206} \mathrm{~Pb}\) was examined to determine its approximate age. Analysis showed the ratio of \({ }_{82}^{206} \mathrm{~Pb}\) atoms to \({ }_{92}^{238} \mathrm{U}\) atoms to be 0.115 . Assuming that no lead was originally present, that all the \({ }_{82}^{206} \mathrm{~Pb}\) formed over the years has remained in the rock, and that the number of nuclides in intermediate stages of decay between \({ }_{92}^{238} \mathrm{U}\) and \({ }_{82}^{206} \mathrm{~Pb}\) is negligible, calculate the age of the rock. The half-life of \({ }_{92}^{238} \mathrm{U}\) is \(4.5 \times 10^{9}\) years.

SOLUTION

Because the half-life of \({ }_{92}^{238} \mathrm{U}\) is very long compared with those of the other members of the decay series (see Table 19.3) to reach \({ }_{82}^{206} \mathrm{~Pb}\), the number of nuclides present in intermediate stages of decay is negligible. That is, once a \({ }_{92}^{238} \mathrm{U}\) nuclide starts to decay, it reaches \({ }_{82}^{206} \mathrm{~Pb}\) relatively fast.

This problem can be solved using the integrated first-order rate law:
\[
\ln \left(\frac{N}{N_{0}}\right)=-k t=-\left(\frac{0.693}{4.5 \times 10^{9} \text { years }}\right) t
\]
where \(N / N_{0}\) represents the ratio of \({ }_{92}^{238} \mathrm{U}\) atoms now found in the rock to the number present when the rock was formed. We are assuming that each \({ }_{82}^{206} \mathrm{~Pb}\) nuclide present must have come from decay of a \({ }_{92}^{238} \mathrm{U}\) atom:
\[
{ }_{92}^{238} \mathrm{U} \longrightarrow{ }_{82}^{206} \mathrm{~Pb}
\]

Thus

Think carefully about what this means. For every \(1115{ }_{92}^{238} \mathrm{U}\) atoms originally present in the rock, 115 have been changed to \({ }_{82}^{206} \mathrm{~Pb}\) and 1000 remain as \({ }_{92}^{238} \mathrm{U}\). Thus
\[
\begin{aligned}
\frac{N}{N_{0}} & =\frac{{ }_{92}^{238} \mathrm{U}}{\underbrace{23{ }_{92}^{\mathrm{U}} \mathrm{U}}_{\substack{238 \\
202 \\
92 \\
\mathrm{U} \text { originally present }}}}=\frac{1000}{1115}=0.8969 \\
\ln \left(\frac{N}{N_{0}}\right) & =\ln (0.8969)=-\left(\frac{0.693}{4.5 \times 10^{9} \text { years }}\right) t \\
\square t & =7.1 \times 10^{8} \text { years }
\end{aligned}
\]

This is the approximate age of the rock. It was formed sometime in the Cambrian period.

\section*{Medical Applications of Radioactivity}

Although the rapid advances of the medical sciences in recent decades are due to many causes, one of the most important has been the discovery and use of radiotracers, radioactive nuclides that can be introduced into organisms in food or drugs and whose pathways can be traced by monitoring their radioactivity. For example, the incorporation of nuclides such as \({ }_{6}^{14} \mathrm{C}\) and \({ }_{15}^{32} \mathrm{P}\) into nutrients has produced important information about metabolic pathways.

A pellet containing radioactive \({ }^{1331}\).

FIGURE 19.8 After consumption of \(\mathrm{Na}^{1311}\), the patient's thyroid is scanned for radioactivity levels to determine the efficiency of iodine absorption. (left) A normal thyroid. (right) An enlarged thyroid.

TABLE 19.5 \| Some Radioactive Nuclides, with Half-Lives and Medical Applications as Radiotracers
\begin{tabular}{|l|ll|}
\hline Nuclide & Half-Life & Area of the Body Studied \\
\hline\({ }^{131} \mathrm{I}\) & 8.0 days & Thyroid \\
\hline\({ }^{59} \mathrm{Fe}\) & 44.5 days & Red blood cells \\
\hline\({ }^{99} \mathrm{Mo}\) & 66 hours & Metabolism \\
\hline\({ }^{32 \mathrm{P}}\) & 14.3 days & Eyes, liver, tumors \\
\hline\({ }^{51} \mathrm{Cr}\) & 27.7 days & Red blood cells \\
\hline\({ }^{87} \mathrm{Sr}\) & 2.8 hours & Bones \\
\hline\({ }^{99 \mathrm{~m} T \mathrm{Tc}}\) & 6.0 hours & Heart, bones, liver, and lungs \\
\hline\({ }^{133} \mathrm{Xe}\) & 5.2 days & Lungs \\
\hline\({ }^{24} \mathrm{Na}\) & 15.0 hours & Circulatory system \\
\hline
\end{tabular}

Iodine-131 has proved very useful in the diagnosis and treatment of illnesses of the thyroid gland. Patients drink a solution containing small amounts of \(\mathrm{Na}^{131} \mathrm{I}\), and the uptake of the iodine by the thyroid gland is monitored with a scanner (Fig. 19.8).

Thallium-201 can be used to assess the damage to the heart muscle in a person who has suffered a heart attack, because thallium is concentrated in healthy muscle tissue. Technetium- 99 m is also taken up by normal heart tissue and is used for damage assessment in a similar way.

Radiotracers provide sensitive and noninvasive methods for learning about biological systems, for detection of disease, for monitoring the action and effectiveness of drugs, and for early detection of pregnancy, and their usefulness should continue to grow. Some useful radiotracers are listed in Table 19.5.

\subsection*{19.5 Thermodynamic Stability of the Nucleus}

We can determine the thermodynamic stability of a nucleus by calculating the change in potential energy that would occur if that nucleus were formed from its constituent protons and neutrons. For example, let's consider the hypothetical process of forming a \({ }_{8}^{16} \mathrm{O}\) nucleus from eight neutrons and eight protons:
\[
8{ }_{0}^{1} \mathrm{n}+8{ }_{1}^{1} \mathrm{H} \longrightarrow{ }_{8}^{16} \mathrm{O}
\]

The energy changes associated with normal chemical reactions are small enough that the corresponding mass changes are not detectable.

The energy change associated with this process can be calculated by comparing the sum of the masses of eight protons and eight neutrons with that of the oxygen nucleus:
\[
\begin{aligned}
& \text { Mass of } \left.\left(8{ }_{0}^{1} \mathrm{n}+8{ }_{1}^{1} \mathrm{H}\right)=\underset{\text { Mass of }{ }_{\mathrm{C}}^{1} \mathrm{n}}{8\left(1.67493 \times 10^{-24} \mathrm{~g}\right)}+\underset{\uparrow}{\uparrow} \underset{\text { Mass of }{ }_{1}^{1} \mathrm{H}}{8(67262} \times 10^{-24} \mathrm{~g}\right) \\
& =2.67804 \times 10^{-23} \mathrm{~g} \\
& \text { Mass of }{ }_{8}^{16} \mathrm{O} \text { nucleus }=2.65535 \times 10^{-23} \mathrm{~g}
\end{aligned}
\]

The difference in mass for one nucleus is
\[
\text { Mass of }{ }_{8}^{16} \mathrm{O}-\text { mass of }\left(8{ }_{0}^{1} \mathrm{n}+8{ }_{1}^{1} \mathrm{H}\right)=-2.269 \times 10^{-25} \mathrm{~g}
\]

The difference in mass for formation of 1 mole of \({ }_{8}^{16} \mathrm{O}\) nuclei is therefore
\[
\left(-2.269 \times 10^{-25} \mathrm{~g} / \text { nucleus }\right)\left(6.022 \times 10^{23} \text { nuclei } / \mathrm{mol}\right)=-0.1366 \mathrm{~g} / \mathrm{mol}
\]

Thus 0.1366 g of mass would be lost if 1 mole of oxygen- 16 were formed from protons and neutrons. What is the reason for this difference in mass, and how can this information be used to calculate the energy change that accompanies this process?

The answers to these questions can be found in the work of Albert Einstein. As we discussed in Section 7.2, Einstein's theory of relativity showed that energy should be considered a form of matter. His famous equation
\[
E=m c^{2}
\]
where \(c\) is the speed of light, gives the relationship between a quantity of energy and its mass. When a system gains or loses energy, it also gains or loses a quantity of mass, given by \(E / c^{2}\). Thus the mass of a nucleus is less than that of its component nucleons because the process is so exothermic.

Einstein's equation in the form
\[
\text { Energy change }=\Delta E=\Delta m c^{2}
\]
where \(\Delta m\) is the change in mass, or the mass defect, can be used to calculate \(\Delta E\) for the hypothetical formation of a nucleus from its component nucleons.

\section*{INTERACTIVE EXAMPLE 19.7 Nuclear Binding Energy I}

Calculate the change in energy if 1 mole of \({ }_{8}^{16} \mathrm{O}\) nuclei was formed from neutrons and protons.
SOLUTION We have already calculated that 0.1366 g of mass would be lost in the hypothetical process of assembling 1 mole of \({ }_{8}^{16} \mathrm{O}\) nuclei from the component nucleons. We can calculate the change in energy for this process from
\[
\Delta E=\Delta m c^{2}
\]
where
\[
c=3.00 \times 10^{8} \mathrm{~m} / \mathrm{s} \quad \text { and } \quad \Delta m=-0.1366 \mathrm{~g} / \mathrm{mol}=-1.366 \times 10^{-4} \mathrm{~kg} / \mathrm{mol}
\]

Thus
\[
\Delta E=\left(-1.366 \times 10^{-4} \mathrm{~kg} / \mathrm{mol}\right)\left(3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)^{2}=-1.23 \times 10^{13} \mathrm{~J} / \mathrm{mol}
\]

The negative sign for the \(\Delta E\) value indicates that the process is exothermic. Energy, and thus mass, is lost from the system.

The energy changes observed for nuclear processes are extremely large compared with those observed for chemical and physical changes. Thus nuclear processes constitute a potentially valuable energy resource.

The thermodynamic stability of a particular nucleus is normally represented as energy released per nucleon. To illustrate how this quantity is obtained, we will continue to consider \({ }_{8}^{16} \mathrm{O}\). First, we calculate \(\Delta E\) per nucleus by dividing the molar value from Example 19.7 by Avogadro's number:
\[
\Delta E \text { per }{ }_{8}^{16} \mathrm{O} \text { nucleus }=\frac{-1.23 \times 10^{13} \mathrm{~J} / \mathrm{mol}}{6.022 \times 10^{23} \text { nuclei } / \mathrm{mol}}=-2.04 \times 10^{-11} \mathrm{~J} / \text { nucleus }
\]

In terms of a more convenient energy unit, a million electronvolts ( MeV ), where
\[
\begin{aligned}
1 \mathrm{MeV} & =1.60 \times 10^{-13} \mathrm{~J} \\
\Delta E \text { per }{ }_{8}^{16} \mathrm{O} \text { nucleus } & =\left(-2.04 \times 10^{-11} \mathrm{~J} / \text { nucleus }\right)\left(\frac{1 \mathrm{MeV}}{1.60 \times 10^{-13} \mathrm{~J}}\right) \\
& =-1.28 \times 10^{2} \mathrm{MeV} / \text { nucleus }
\end{aligned}
\]

Next, we can calculate the value of \(\Delta E\) per nucleon by dividing by \(A\), the sum of neutrons and protons:
\[
\begin{aligned}
\Delta E \text { per nucleon for }{ }_{8}^{16} \mathrm{O} & =\frac{-1.28 \times 10^{2} \mathrm{MeV} / \text { nucleus }}{16 \text { nucleons/nucleus }} \\
& =-7.98 \mathrm{MeV} / \text { nucleon }
\end{aligned}
\]

This means that 7.98 MeV of energy per nucleon would be released if \({ }_{8}^{16} \mathrm{O}\) were formed from neutrons and protons. The energy required to decompose this nucleus into its components has the same numeric value but a positive sign (since energy is required). This is called the binding energy per nucleon for \({ }_{8}^{16} \mathrm{O}\).

The values of the binding energy per nucleon for the various nuclides are shown in Fig. 19.9. Note that the most stable nuclei (those requiring the largest energy per nucleon to decompose the nucleus) occur at the top of the curve. The most stable nucleus known is \({ }_{26}^{56} \mathrm{Fe}\), which has a binding energy per nucleon of 8.79 MeV .

FIGURE 19.9 The binding energy per nucleon as a function of mass number. The most stable nuclei are at the top of the curve. The most stable nucleus is \({ }_{26}^{56} \mathrm{Fe}\).

\section*{INTERACTIVE EXAMPLE 19.8 Nuclear Binding Energy II}

Calculate the binding energy per nucleon for the \({ }_{2}^{4} \mathrm{He}\) nucleus (atomic masses: \({ }_{2}^{4} \mathrm{He}=\) \(4.0026 \mathrm{amu} ;{ }_{1}^{1} \mathrm{H}=1.0078 \mathrm{amu}\) ).

SOLUTION First, we must calculate the mass defect \((\Delta m)\) for \({ }_{2}^{4} \mathrm{He}\). Since atomic masses (which include the electrons) are given, we must decide how to account for the electron mass:
\[
\begin{gathered}
4.0026=\text { mass of }{ }_{2}^{4} \mathrm{He} \text { atom }=\operatorname{mass} \text { of }{ }_{2}^{4} \mathrm{He} \text { nucleus }+\underset{\nearrow}{2} m_{\mathrm{e}} \\
1.0078=\text { mass of }{ }_{1}^{1} \mathrm{H} \text { atom }=\text { mass of }{ }_{1}^{1} \mathrm{H} \text { nucleus }+m_{\mathrm{e}}
\end{gathered}
\]

Thus, since \(\mathrm{a}{ }_{2}^{4} \mathrm{He}\) nucleus is "synthesized" from two protons and two neutrons, we see that
\[
\begin{aligned}
\Delta m & =\underbrace{4.0026-2 m_{\mathrm{e}} \mathrm{e}}_{\begin{array}{c}
\text { Mass of }{ }_{2}^{4} \mathrm{He} \\
\text { nucleus }
\end{array}})-[\underbrace{(\underbrace{1.0078-m_{e}}_{\substack{\text { Mass of } \\
\text { neutron }}})}_{\begin{array}{c}
\text { Mass of } \mid \mathrm{H} \\
\text { nucleus (proton) }
\end{array}}+2(\underbrace{1.0087)}] \\
& =4.0026-2 m_{\mathrm{e}}-2(1.0078)+2 m_{\mathrm{e}}-2(1.0087) \\
& =4.0026-2(1.0078)-2(1.0087) \\
& =-0.0304 \mathrm{u}
\end{aligned}
\]

Note that in this case the electron mass cancels out in taking the difference. This will always happen in this type of calculation if the atomic masses are used both for the nuclide of interest and for \({ }_{1}^{1} \mathrm{H}\). Thus 0.0304 of mass is lost per \({ }_{2}^{4} \mathrm{He}\) nucleus formed.

The corresponding energy change can be calculated from
\[
\Delta E=\Delta m c^{2}
\]
where
\[
\begin{aligned}
& \Delta m=-0.0304 \frac{\mathrm{u}}{\text { nucleus }}=\left(-0.0304 \frac{\mathrm{u}}{\text { nucleus }}\right)\left(1.66 \times 10^{-27} \frac{\mathrm{~kg}}{\mathrm{u}}\right) \\
& =-5.04 \times 10^{-29} \frac{\mathrm{~kg}}{\text { nucleus }} \\
& c=3.00 \times 10^{8} \mathrm{~m} / \mathrm{s} \\
& \Delta E=\left(-5.04 \times 10^{-29} \frac{\mathrm{~kg}}{\text { nucleus }}\right)\left(3.00 \times 10^{8} \frac{\mathrm{~m}}{\mathrm{~s}}\right)^{2} \\
& =-4.54 \times 10^{-12} \mathrm{~J} / \text { nucleus }
\end{aligned}
\]
and

Thus

This means that \(4.54 \times 10^{-12} \mathrm{~J}\) of energy is released per nucleus formed and that \(4.54 \times 10^{-12} \mathrm{~J}\) would be required to decompose the nucleus into the constituent neutrons and protons. Thus the binding energy (BE) per nucleon is
\[
\begin{aligned}
\mathrm{BE} \text { per nucleon } & =\frac{4.54 \times 10^{-12} \mathrm{~J} / \text { nucleus }}{4 \text { nucleons } / \text { nucleus }} \\
& =1.14 \times 10^{-12} \mathrm{~J} / \text { nucleon } \\
& =\left(1.14 \times 10^{-12} \frac{\mathrm{~J}}{\text { nucleon }}\right)\left(\frac{1 \mathrm{MeV}}{1.60 \times 10^{-13} \mathrm{~J}}\right) \\
& =7.13 \mathrm{MeV} / \text { nucleon }
\end{aligned}
\]
19.6 Nuclear Fission and Nuclear Fusion
The graph shown in Fig. 19.9 has very important implications for the use of nuclear processes as sources of energy. Recall that energy is released, that is, \(\Delta E\) is negative, when a process goes from a less stable to a more stable state. The higher a nuclide is on the curve, the more stable it is. This means that two types of nuclear processes will be exothermic (Fig. 19.10):
1. Combining two light nuclei to form a heavier, more stable nucleus. This process is called fusion.
2. Splitting a heavy nucleus into two nuclei with smaller mass numbers. This process is called fission.

Because of the large binding energies involved in holding the nucleus together, both of these processes involve energy changes more than a million times larger than those associated with chemical reactions.

\section*{Nuclear Fission}

Nuclear fission was discovered in the late 1930s when \({ }_{92}^{235} \mathrm{U}\) nuclides bombarded with neutrons were observed to split into two lighter elements:
\[
{ }_{0}^{1} \mathrm{n}+{ }_{92}^{235} \mathrm{U} \longrightarrow{ }_{56}^{141} \mathrm{Ba}+{ }_{36}^{92} \mathrm{Kr}+3{ }_{0}^{1} \mathrm{n}
\]

This process, shown schematically in Fig. 19.11, releases \(3.5 \times 10^{-11} \mathrm{~J}\) of energy per event, which translates to \(2.1 \times 10^{13} \mathrm{~J}\) per mole of \({ }_{92}^{235} \mathrm{U}\). Compare this figure with that for the combustion of methane, which releases only \(8.0 \times 10^{5} \mathrm{~J}\) of energy per mole. The fission of \({ }_{92}^{235} \mathrm{U}\) produces about 26 million times more energy than the combustion of methane.

The process shown in Fig. 19.11 is only one of the many fission reactions that \({ }_{92}^{235} \mathrm{U}\) can undergo. Another is
\[
{ }_{0}^{1} \mathrm{n}+{ }_{92}^{235} \mathrm{U} \longrightarrow{ }_{52}^{137} \mathrm{Te}+{ }_{40}^{97} \mathrm{Zr}+2{ }_{0}^{1} \mathrm{n}
\]

In fact, over 200 different isotopes of 35 different elements have been observed among the fission products of \({ }_{92}^{235} \mathrm{U}\).

In addition to the product nuclides, neutrons are produced in the fission reactions of \({ }_{92}^{235} \mathrm{U}\). This makes it possible to have a self-sustaining fission process-a chain reaction (Fig. 19.12). For the fission process to be self-sustaining, at least one neutron from each fission event must go on to split another nucleus. If, on average, less than one neutron causes another fission event, the process dies out and the reaction is said

FIGURE 19.10 Both fission and fusion produce more stable nuclides and are thus exothermic.

FIGURE 19.11 On capturing a neutron, the \({ }_{92}^{235} \mathrm{U}\) nucleus undergoes fission to produce two lighter nuclides, free neutrons (typically three), and a large amount of energy.

FIGURE 19.12 Representation of a fission process in which each event produces two neutrons, which can go on to split other nuclei, leading to a selfsustaining chain reaction.

FIGURE 19.13 If the mass of fissionable material is too small, most of the neutrons escape before causing another fission event, and the process dies out.

to be subcritical. If exactly one neutron from each fission event causes another fission event, the process sustains itself at the same level and is said to be critical. If more than one neutron from each fission event causes another fission event, the process rapidly escalates and the heat buildup causes a violent explosion. This situation is described as supercritical.

To achieve the critical state, a certain mass of fissionable material, called the critical mass, is needed. If the sample is too small, too many neutrons escape before they have a chance to cause a fission event, and the process stops. This is illustrated in Fig. 19.13.

During World War II, an intense research effort called the Manhattan Project was carried out by the United States to build a bomb based on the principles of nuclear fission. This program produced the fission bombs that were used with devastating effects

on the cities of Hiroshima and Nagasaki in 1945. Basically, a fission bomb operates by suddenly combining subcritical masses of fissionable material to form a supercritical mass, thereby producing an explosion of incredible intensity.

\section*{Nuclear Reactors}

Because of the tremendous energies involved, it seemed desirable to develop the fission process as an energy source to produce electricity. To accomplish this, reactors were designed in which controlled fission can occur. The resulting energy is used to heat water to produce steam to run turbine generators, in much the same way that a coal-burning power plant generates energy. A schematic diagram of a nuclear power plant is shown in Fig. 19.14.

In the reactor core, shown in Fig. 19.15, uranium that has been enriched to approximately \(3 \%{ }_{92}^{235} \mathrm{U}\) (natural uranium contains only \(0.7 \%{ }_{92}^{235} \mathrm{U}\) ) is housed in cylinders. A moderator surrounds the cylinders to slow down the neutrons so that the uranium fuel can capture them more efficiently. Control rods, composed of substances that absorb neutrons, are used to regulate the power level of the reactor. The reactor is designed so that should a malfunction occur, the control rods are automatically inserted into the core to stop the reaction. A liquid (usually water) is circulated through the core to extract the heat generated by the energy of fission; the energy can then be passed on via a heat exchanger to water in the turbine system.

Although the concentration of \({ }_{92}^{235} \mathrm{U}\) in the fuel elements is not great enough to allow a supercritical mass to develop in the core, a failure of the cooling system can lead to temperatures high enough to melt the core. As a result, the building housing the core must be designed to contain the core even if meltdown occurs. A great deal of controversy now exists about the efficiency of the safety systems in nuclear power plants. Accidents such as the one at the Three Mile Island facility in Pennsylvania in 1979 and in Chernobyl,* Ukraine, in 1986 have led to questions about the wisdom of continuing to build fission-based power plants.
*See C. A. Atwood, "Chernobyl—What happened?" J. Chem. Educ. 65 (1988): 1037.

FIGURE 19.14 A schematic diagram of a nuclear power plant.

FIGURE 19.15 A schematic of a reactor core. The position of the control rods determines the level of energy production by regulating the amount of fission taking place.

\(\Delta\)
Uranium oxide (refined uranium).

FIGURE 19.16 A plot of energy versus the separation distance for two \({ }_{1}^{2} \mathrm{H}\) nuclei. The nuclei must have sufficient velocities to get over the electrostatic repulsion "hill" and get close enough for the nuclear binding forces to become effective, thus "fusing" the particles into a new nucleus and releasing large quantities of energy. The binding force is at least 100 times the electrostatic repulsion.

\section*{Breeder Reactors}

One potential problem facing the nuclear power industry is the supply of \({ }_{92}^{235} \mathrm{U}\). Some scientists have suggested that we have nearly depleted those uranium deposits rich enough in \({ }_{92}^{235} \mathrm{U}\) to make production of fissionable fuel economically feasible. Because of this possibility, breeder reactors have been developed, in which fissionable fuel is actually produced while the reactor runs. In the breeder reactors now being studied, the major component of natural uranium, nonfissionable \({ }_{92}^{238} \mathrm{U}\), is changed to fissionable \({ }_{94}^{239} \mathrm{Pu}\). The reaction involves absorption of a neutron, followed by production of two \(\beta\) particles:
\[
\begin{aligned}
{ }_{0}^{1} \mathrm{n}+{ }_{92}^{238} \mathrm{U} & \longrightarrow{ }_{92}^{239} \mathrm{U} \\
{ }_{92}^{239} \mathrm{U} & \longrightarrow{ }_{93}^{239} \mathrm{~Np}+{ }_{-1}^{0} \mathrm{e} \\
{ }_{93}^{239} \mathrm{~Np} & \longrightarrow{ }_{94}^{239} \mathrm{Pu}+{ }_{-1}^{0} \mathrm{e}
\end{aligned}
\]

As the reactor runs and \({ }_{92}^{235} \mathrm{U}\) is split, some of the excess neutrons are absorbed by \({ }_{92}^{238} \mathrm{U}\) to produce \({ }_{94}^{239} \mathrm{Pu}\). The \({ }_{94}^{239} \mathrm{Pu}\) is then separated out and used to fuel another reactor. Such a reactor thus "breeds" nuclear fuel as it operates.

Although breeder reactors are now used in France, the United States is proceeding slowly with their development because of their controversial nature. One problem involves the hazards in handling plutonium, which flames on contact with air and is very toxic.

\section*{Fusion}

Large quantities of energy are also produced by the fusion of two light nuclei. In fact, stars produce their energy through nuclear fusion. Our sun, which presently consists of \(73 \%\) hydrogen, \(26 \%\) helium, and \(1 \%\) other elements, gives off vast quantities of energy from the fusion of protons to form helium:
\[
\begin{aligned}
&{ }_{1}^{1} \mathrm{H}+{ }_{1}^{1} \mathrm{H} \longrightarrow{ }_{1}^{2} \mathrm{H}+{ }_{1}^{0} \mathrm{e} \\
&{ }_{1}^{1} \mathrm{H}+{ }_{1}^{2} \mathrm{H} \longrightarrow{ }_{2}^{3} \mathrm{He} \\
&{ }_{2}^{3} \mathrm{He}+{ }_{2}^{3} \mathrm{He} \longrightarrow{ }_{2}^{4} \mathrm{He}+2{ }_{1}^{1} \mathrm{H} \\
&{ }_{2}^{3} \mathrm{He}+{ }_{1}^{1} \mathrm{H} \longrightarrow{ }_{2}^{4} \mathrm{He}+{ }_{1}^{0} \mathrm{e}
\end{aligned}
\]

Intense research is under way to develop a feasible fusion process because of the ready availability of many light nuclides (deuterium, \({ }_{1}^{2} \mathrm{H}\), in seawater, for example) that can serve as fuel in fusion reactors. The major stumbling block is that high temperatures are required to initiate fusion. The forces that bind nucleons together to form a nucleus are effective only at very small distances \(\left(\sim 10^{-13} \mathrm{~cm}\right)\). Thus, for two protons to bind together and thereby release energy, they must get very close together. But protons, because they are identically charged, repel each other electrostatically. This means that to get two protons (or two deuterons) close enough to bind together (the nuclear binding force is not electrostatic), they must be "shot" at each other at speeds high enough to overcome the electrostatic repulsion.

The electrostatic repulsion forces between two \({ }_{1}^{2} \mathrm{H}\) nuclei are so great that a temperature of \(4 \times 10^{7} \mathrm{~K}\) is required to give them velocities large enough to cause them to collide with sufficient energy that the nuclear forces can bind the particles together and thus release the binding energy. This situation is represented in Fig. 19.16.

Currently, scientists are studying two types of systems to produce the extremely high temperatures required: high-powered lasers and heating by electric currents. At present, many technical problems remain to be solved, and it is not clear which method will prove more useful or when fusion might become a practical energy source. However, there is still hope that fusion will be a major energy source sometime in the future.
 of energy, but they also can be dangerous. What if Congress decided to outlaw all processes that involve fission? How would that change our society?

\subsection*{19.7 Effects of Radiation}

The ozone layer is discussed in Section 20.11.

Everyone knows that being hit by a train is very serious. The problem is the energy transfer involved. In fact, any source of energy is potentially harmful to organisms. Energy transferred to cells can break chemical bonds and cause malfunctioning of the cell systems. This fact is behind the concern about the ozone layer in the earth's upper atmosphere, which screens out high-energy ultraviolet radiation from the sun. Radioactive elements, which are sources of high-energy particles, are also potentially hazardous, although the effects are usually quite subtle. The reason for the subtlety of radiation damage is that even though high-energy particles are involved, the quantity of energy actually deposited in tissues per event is quite small. However, the resulting damage is no less real, although the effects may not be apparent for years.

Radiation damage to organisms can be classified as somatic or genetic damage. Somatic damage is damage to the organism itself, resulting in sickness or death. The effects may appear almost immediately if a massive dose of radiation is received; for smaller doses, damage may appear years later, usually in the form of cancer. Genetic damage is damage to the genetic machinery, which produces malfunctions in the offspring of the organism.

The biological effects of a particular source of radiation depend on several factors:
1. The energy of the radiation. The higher the energy content of the radiation, the more damage it can cause. Radiation doses are measured in rads (which is short for radiation \(a\) bsorbed \(d\) ose), where 1 rad corresponds to \(10^{-2} \mathrm{~J}\) of energy deposited per kilogram of tissue.
2. The penetrating ability of the radiation. The particles and rays produced in radioactive processes vary in their abilities to penetrate human tissue: \(\gamma\) rays are highly penetrating, \(\beta\) particles can penetrate approximately 1 cm , and \(\alpha\) particles are stopped by the skin.
3. The ionizing ability of the radiation. Extraction of electrons from biomolecules to form ions is particularly detrimental to their functions. The ionizing ability of radiation varies dramatically. For example, \(\gamma\) rays penetrate very deeply but cause only occasional ionization. On the other hand, \(\alpha\) particles, although not very penetrating, are very effective at causing ionization and produce a dense trail of damage. Thus ingestion of an \(\alpha\)-particle producer, such as plutonium, is particularly damaging.
4. The chemical properties of the radiation source. When a radioactive nuclide is ingested into the body, its effectiveness in causing damage depends on its residence time. For example, \({ }_{36}^{85} \mathrm{Kr}\) and \({ }_{38}^{90} \mathrm{Sr}\) are both \(\beta\)-particle producers. However, since krypton is chemically inert, it passes through the body quickly and does not have much time to do damage. Strontium, being chemically similar to calcium, can collect in bones, where it may cause leukemia and bone cancer.

\section*{TABLE 19.6 | Effects of Short-Term Exposures to Radiation}
\begin{tabular}{cl}
\hline Dose (rem) & Clinical Effect \\
\hline \(0-25\) & Nondetectable \\
\hline \(25-50\) & Temporary decrease in white blood cell counts \\
\hline \(100-200\) & Strong decrease in white blood cell counts \\
\hline 500 & Death of half the exposed population within 30 days after exposure \\
\hline
\end{tabular}

Because of the differences in the behavior of the particles and rays produced by radioactive decay, both the energy dose of the radiation and its effectiveness in causing biological damage must be taken into account. The rem (which is short for roentgen equivalent for \(m\) an) is defined as follows:
\[
\text { Number of rems }=\text { (number of rads) } \times \text { RBE }
\]
where RBE represents the relative effectiveness of the radiation in causing biological damage.

Table 19.6 shows the physical effects of short-term exposure to various doses of radiation, and Table 19.7 gives the sources and amounts of radiation exposure for a typical person in the United States. Note that natural sources contribute about twice as much as human activities to the total exposure. However, although the nuclear industry contributes only a small percentage of the total exposure, the major controversy associated with nuclear power plants is the potential for radiation hazards. These arise mainly from two sources: accidents allowing the release of radioactive materials and improper disposal of the radioactive products in spent fuel elements. The radioactive products of the fission of \({ }_{92}^{235} \mathrm{U}\), although only a small percentage of the total products, have half-lives of several hundred years and remain dangerous for a long time. Various schemes have been advanced for the disposal of these wastes. The one that seems to hold the most promise is the incorporation of the wastes into ceramic blocks and the burial of these blocks in geologically stable formations. At present, however, no disposal method has been accepted, and nuclear wastes continue to accumulate in temporary storage facilities.

Even if a satisfactory method for permanent disposal of nuclear wastes is found, there will continue to be concern about the effects of exposure to low levels of radiation. Exposure is inevitable from natural sources such as cosmic rays and radioactive minerals, and many people are also exposed to low levels of radiation from reactors, radioactive tracers, or diagnostic X rays. Currently, we have little reliable information on the long-term effects of low-level exposure to radiation.

Two models of radiation damage, illustrated in Fig. 19.17, have been proposed: the linear model and the threshold model. The linear model postulates that damage from

FIGURE 19.17 The two models for radiation damage. In the linear model, even a small dosage causes a proportional risk. In the threshold model, risk begins only after a certain dosage.
radiation is proportional to the dose, even at low levels of exposure. Thus any exposure is dangerous. The threshold model, on the other hand, assumes that no significant damage occurs below a certain exposure, called the threshold exposure. Note that if the linear model is correct, radiation exposure should be limited to a bare minimum (ideally at the natural levels). If the threshold model is correct, a certain level of radiation exposure beyond natural levels can be tolerated. Most scientists feel that since there is little evidence available to evaluate these models, it is safest to assume that the linear hypothesis is correct and to minimize radiation exposure.

\section*{Nuclear energy production}
> Fusion: the process of combining two light nuclei to form a heavier, more stable nucleus
> Fission: the process of splitting a heavy nucleus into two lighter, more stable nuclei
> Current nuclear power reactors use controlled fission to produce energy

\section*{Radiation damage}
> Radiation can cause direct (somatic) damage to a living organism or genetic damage to the organism's offspring
> The biological effects of radiation depend on the energy, the penetrating ability, the ionizing ability of the radiation, and the chemical properties of the nuclide producing the radiation

\section*{Review Questions Answers to the Review Questions can be found on the Student website (accessible from wwww.cengagebrain.com).}
1. Define or illustrate the following terms:
a. thermodynamic stability
b. kinetic stability
c. radioactive decay
d. beta-particle production
e. alpha-particle production
f. positron production
g. electron capture
h. gamma-ray emissions

In radioactive decay processes, \(A\) and \(Z\) are conserved. What does this mean?
2. Figure 19.1 illustrates the zone of stability. What is the zone of stability? Stable light nuclides have about equal numbers of neutrons and protons. What happens to the neutron-to-proton ratio for stable nuclides as the number of protons increases? Nuclides that are not already in the zone of stability undergo radioactive processes to get to the zone of stability. If a nuclide has too many neutrons, which process(es) can the nuclide undergo to become more stable? Answer the same question for a nuclide having too many protons.
3. All radioactive decay processes follow first-order kinetics. What does this mean? What happens to the rate of radioactive decay as the number of nuclides is halved? Write the first-order rate law and the integrated firstorder rate law. Define the terms in each equation. What is the half-life equation for radioactive decay processes? How does the half-life depend on how many nuclides are present? Are the half-life and rate constant \(k\) directly related or inversely related?
4. What is a nuclear transformation? How do you balance nuclear transformation reactions? Particle accelerators are used to perform nuclear transformations. What is a particle accelerator?
5. What is a Geiger counter, and how does it work? What is a scintillation counter, and how does it work? Radiotracers are used in the medical sciences to learn about metabolic pathways. What are radiotracers? Explain why \({ }^{14} \mathrm{C}\) and \({ }^{32} \mathrm{P}\) radioactive nuclides would be very helpful in learning about metabolic pathways. Why is iodine-131 useful for diagnosis of diseases of the thyroid? How could you use a radioactive nuclide to demonstrate that chemical equilibrium is a dynamic process?
6. Explain the theory behind carbon-14 dating. What assumptions must be made and what problems arise when using carbon- 14 dating?

The decay of uranium-238 to lead-206 is also used to estimate the age of objects. Specifically, \({ }^{206} \mathrm{~Pb} /{ }^{238} \mathrm{U}\) ratios allow dating of rocks. Why is the \({ }^{238} \mathrm{U}\) decay to \({ }^{206} \mathrm{~Pb}\) useful for dating rocks but useless for dating objects 10,000 years old or younger? Similarly, why is carbon-14 dating useful for dating objects 10,000 years old or younger but useless for dating rocks?
7. Define mass defect and binding energy. How do you determine the mass defect for a nuclide? How do you convert the mass defect into the binding energy for a nuclide? Iron- 56 has the largest binding energy per nucleon among all known nuclides. Is this good or bad for iron-56? Explain.
8. Define fission and fusion. How does the energy associated with fission or fusion processes compare to the energy changes associated with chemical reactions? Fusion processes are more likely to occur for lighter elements, whereas fission processes are more likely to occur for heavier elements. Why? (Hint: Refer to Fig. 19.10.) The major stumbling block for turning fusion reactions into a feasible source of power is the high temperature required to initiate a fusion reaction. Why are elevated temperatures necessary to initiate fusion reactions but not fission reactions?
9. The fission of uranium- 235 is used exclusively in nuclear power plants located in the United States. There are many different fission reactions of uranium-235, but all the fission reactions are self-sustaining chain reactions. Explain. Differentiate between the terms critical,
subcritical, and supercritical. What is the critical mass? How does a nuclear power plant produce electricity? What are the purposes of the moderator and the control rods in a fission reactor? What are some problems associated with nuclear reactors? What are breeder reactors? What are some problems associated with breeder reactors?
10. The biological effects of a particular source of radiation depend on several factors. List some of these factors. Even though \({ }^{85} \mathrm{Kr}\) and \({ }^{90} \mathrm{Sr}\) are both \(\beta\)-particle emitters, the dangers associated with the decay of \({ }^{90} \mathrm{Sr}\) are much greater than those linked to \({ }^{85} \mathrm{Kr}\). Why? Although \(\gamma\) rays are far more penetrating than \(\alpha\) particles, the latter are more likely to cause damage to an organism. Why? Which type of radiation is more effective at promoting the ionization of biomolecules?

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Resource Site.

\section*{Questions}
1. When nuclei undergo nuclear transformations, \(\gamma\) rays of characteristic frequencies are observed. How does this fact, along with other information in the chapter on nuclear stability, suggest that a quantum mechanical model may apply to the nucleus?
2. What type of radioactive decay must occur for each of the following nuclear processes?
a. Process 1
b. Process 2
c. Process 3

3. Do radiotracers generally have long or short half-lives? Explain.
4. There is a trend in the United States toward using coal-fired power plants to generate electricity rather than building new nuclear fission power plants. Is the use of coal-fired power plants without risk? Make a list of the risks to society from the use of each type of power plant.
5. Which type of radioactive decay has the net effect of changing a neutron into a proton? Which type of decay has the net effect of turning a proton into a neutron?
6. Consider the following graph of binding energy per nucleon as a function of mass number.

a. What does this graph tell us about the relative half-lives of the nuclides? Explain your answer.
b. Which nuclide shown is the most thermodynamically stable? Which is the least thermodynamically stable?
c. What does this graph tell us about which nuclides undergo fusion and which undergo fission to become more stable? Support your answer.
7. What are transuranium elements and how are they synthesized?
8. Scientists have estimated that the earth's crust was formed 4.3 billion years ago. The radioactive nuclide \({ }^{176} \mathrm{Lu}\), which decays to \({ }^{176} \mathrm{Hf}\), was used to estimate this age. The half-life of \({ }^{176} \mathrm{Lu}\) is 37 billion years. How are ratios of \({ }^{176} \mathrm{Lu}\) to \({ }^{176} \mathrm{Hf}\) utilized to date very old rocks?
9. Why are the observed energy changes for nuclear processes so much larger than the energy changes for chemical and physical processes?
10. Natural uranium is mostly nonfissionable \({ }^{238} \mathrm{U}\); it contains only about \(0.7 \%\) of fissionable \({ }^{235} \mathrm{U}\). For uranium to be useful as a nuclear fuel, the relative amount of \({ }^{235} \mathrm{U}\) must be increased to about \(3 \%\). This is accomplished through a gas diffusion process. In the diffusion process, natural uranium reacts with fluorine to form a mixture of \({ }^{238} \mathrm{UF}_{6}(g)\) and \({ }^{235} \mathrm{UF}_{6}(g)\). The fluoride mixture is then enriched through a multistage diffusion process to produce a \(3 \%{ }^{235} \mathrm{U}\) nuclear fuel. The diffusion process utilizes Graham's law of effusion (see Chapter 5, Section 5.7). Explain how Graham's law of effusion allows natural uranium to be enriched by the gaseous diffusion process.
11. Much of the research on controlled fusion focuses on the problem of how to contain the reacting material. Magnetic fields appear to be the most promising mode of containment. Why is containment such a problem? Why must one resort to magnetic fields for containment?
12. Describe the relative penetrating powers of alpha, beta, and gamma radiation.
13. Explain the difference between somatic damage from radiation and genetic damage. Which type causes immediate damage to the exposed individual?
14. A recent study concluded that any amount of radiation exposure can cause biological damage. Explain the differences between the two models of radiation damage, the linear model and the threshold model.

\section*{Exercises}

In this section similar exercises are paired.

\section*{Radioactive Decay and Nuclear Transformations}
15. Write an equation describing the radioactive decay of each of the following nuclides. (The particle produced is shown in parentheses, except for electron capture, where an electron is a reactant.)
a. \({ }_{1}^{3} \mathrm{H}(\beta)\)
b. \({ }_{3}^{8} \mathrm{Li}(\beta\) followed by \(\alpha)\)
c. \({ }_{4}^{7} \mathrm{Be}\) (electron capture)
d. \({ }_{5}^{8} \mathrm{~B}\) (positron)
16. In each of the following radioactive decay processes, supply the missing particle.
a. \({ }^{60} \mathrm{Co} \rightarrow{ }^{60} \mathrm{Ni}+\) ?
b. \({ }^{97} \mathrm{Tc}+? \rightarrow{ }^{97} \mathrm{Mo}\)
c. \({ }^{99} \mathrm{Tc} \rightarrow{ }^{99} \mathrm{Ru}+\) ?
d. \({ }^{239} \mathrm{Pu} \rightarrow{ }^{235} \mathrm{U}+\) ?
-17. Supply the missing particle, and state the type of decay for each of the following nuclear processes.
a.

b.

18. Write balanced equations for each of the processes described below.
a. Chromium-51, which targets the spleen and is used as a tracer in studies of red blood cells, decays by electron capture.
b. Iodine-131, used to treat hyperactive thyroid glands, decays by producing a \(\beta\) particle.
c. Phosphorus-32, which accumulates in the liver, decays by \(\beta\)-particle production.
19. Write an equation describing the radioactive decay of each of the following nuclides. (The particle produced is shown in parentheses, except for electron capture, where an electron is a reactant.)
a. \({ }^{68} \mathrm{Ga}\) (electron capture)
b. \({ }^{62} \mathrm{Cu}\) (positron)
c. \({ }^{212} \operatorname{Fr}(\alpha)\)
d. \({ }^{129} \mathrm{Sb}(\beta)\)
20. In each of the following radioactive decay processes, supply the missing particle.
a. \({ }^{73} \mathrm{Ga} \rightarrow{ }^{73} \mathrm{Ge}+\) ?
b. \({ }^{192} \mathrm{Pt} \rightarrow{ }^{188} \mathrm{Os}+\) ?
c. \({ }^{205} \mathrm{Bi} \rightarrow{ }^{205} \mathrm{~Pb}+\) ?
d. \({ }^{241} \mathrm{Cm}+? \rightarrow{ }^{241} \mathrm{Am}\)
-21. Uranium-235 undergoes a series of \(\alpha\)-particle and \(\beta\)-particle productions to end up as lead-207. How many \(\alpha\) particles and \(\beta\) particles are produced in the complete decay series?
22. The radioactive isotope \({ }^{242} \mathrm{Cm}\) decays by a series of \(\alpha\)-particle and \(\beta\)-particle productions, taking \({ }^{242} \mathrm{Cm}\) through many transformations to end up as \({ }^{206} \mathrm{~Pb}\). In the complete decay series, how many \(\alpha\) and \(\beta\) particles are produced?
-23. One type of commercial smoke detector contains a minute amount of radioactive americium-241 ( \({ }^{241} \mathrm{Am}\) ), which decays by \(\alpha\)-particle production. The \(\alpha\) particles ionize molecules in the air, allowing it to conduct an electric current. When smoke particles enter, the conductivity of the air is changed and the alarm buzzes.
a. Write the equation for the decay of \({ }_{95}^{241} \mathrm{Am}\) by \(\alpha\)-particle production.
b. The complete decay of \({ }^{241} \mathrm{Am}\) involves successively \(\alpha, \alpha\), \(\beta, \alpha, \alpha, \beta, \alpha, \alpha, \alpha, \beta, \alpha\), and \(\beta\) production. What is the final stable nucleus produced in this decay series?
c. Identify the 11 intermediate nuclides.
24. Thorium-232 is known to undergo a progressive decay series until it reaches stability at lead-208. For each step of the series indicated in the table below, which nuclear particle is emitted?
\begin{tabular}{|c|}
\hline Parent Nuclide \\
\hline Th-232 \\
\hline Ra-228 \\
\hline Ac-228 \\
\hline Th-228 \\
\hline Ra-224 \\
\hline Rn-220 \\
\hline Po-216 \\
\hline Pb-212 \\
\hline Bi-212 \\
\hline Po-212 \\
\hline Pb-208 \\
\hline
\end{tabular}
-25 . The stable isotopes of boron are boron-10 and boron-11. Four radioactive isotopes with mass numbers \(8,9,12\), and 13 are also known. Predict possible modes of radioactive decay for the four radioactive isotopes of boron.
26. The only stable isotope of fluorine is fluorine-19. Predict possible modes of decay for fluorine-21, fluorine-18, and fluorine-17.
-27. In 1994 it was proposed (and eventually accepted) that element 106 be named seaborgium, Sg , in honor of Glenn T. Seaborg, discoverer of the transuranium elements.
a. \({ }^{263} \mathrm{Sg}\) was produced by the bombardment of \({ }^{249} \mathrm{Cf}\) with a beam of \({ }^{18} \mathrm{O}\) nuclei. Complete and balance an equation for this reaction.
b. \({ }^{263} \operatorname{Sg}\) decays by \(\alpha\) emission. What is the other product resulting from the \(\alpha\) decay of \({ }^{263} \mathrm{Sg}\) ?
28. Many elements have been synthesized by bombarding relatively heavy atoms with high-energy particles in particle accelerators. Complete the following nuclear equations, which have been used to synthesize elements.
a. \(\qquad\) \(+{ }_{2}^{4} \mathrm{He} \rightarrow{ }_{97}^{243} \mathrm{Bk}+{ }_{0}^{1} \mathrm{n}\)
b. \({ }_{92}^{238} \mathrm{U}+{ }_{6}^{12} \mathrm{C} \rightarrow-+6{ }_{0}^{1} \mathrm{n}\)
c. \({ }_{98}^{249} \mathrm{Cf}+\longrightarrow{ }_{105}^{260} \mathrm{Db}+4{ }_{0}^{1} \mathrm{n}\)
d. \({ }_{98}^{249} \mathrm{Cf}+{ }_{5}^{10} \mathrm{~B} \rightarrow{ }_{103}^{257} \mathrm{Lr}+\)
\[

\section*{Kinetics of Radioactive Decay}
29. What is the rate of decay from 1.00 mol of radioactive nuclides having the following half-lives: 12,000 years? 12 hours? 12 seconds?
30. The curie \((\mathrm{Ci})\) is a commonly used unit for measuring nuclear radioactivity: 1 curie of radiation is equal to \(3.7 \times 10^{10}\) decay events per second (the number of decay events from 1 g of radium in 1 second).
a. What is the activity in Ci of \(120 \mathrm{~g} \mathrm{~K}_{3}{ }^{32} \mathrm{PO}_{4}\left(t_{1 / 2}\right.\) for \({ }^{32} \mathrm{P}=14.3\) days)? Assume the atomic mass of \({ }^{32} \mathrm{P}\) is 32.0 u .
b. What is the activity in mCi (millicuries) of 1.0 mol of plutonium-239 ( \(t_{1 / 2}=24,000\) years \()\) ?
-31. The rate constant for a certain radioactive nuclide is \(1.0 \times 10^{-3} \mathrm{~h}^{-1}\). What is the half-life of this nuclide?
32. Americium- 241 is widely used in smoke detectors. The radiation released by this element ionizes particles that are then detected by a charged-particle collector. The half-life of \({ }^{241} \mathrm{Am}\) is 433 years, and it decays by emitting \(\alpha\) particles. How many \(\alpha\) particles are emitted each second by a \(5.00-\mathrm{g}\) sample of \({ }^{241} \mathrm{Am}\) ?
-33. The number of radioactive nuclides in a sample decays from \(1.00 \times 10^{20}\) to \(2.50 \times 10^{19}\) in 10.0 minutes. What is the halflife of this radioactive species?
34. Krypton consists of several radioactive isotopes, some of which are listed in the following table.
\begin{tabular}{ll} 
& Half-Life \\
\hline\({ }^{73} \mathrm{Kr}\) & 27 s \\
\hline\({ }^{74} \mathrm{Kr}\) & 11.5 min \\
\hline\({ }^{76} \mathrm{Kr}\) & 14.8 h \\
\hline\({ }^{81} \mathrm{Kr}\) & \(2.1 \times 10^{5} \mathrm{yr}\) \\
\hline
\end{tabular}

Which of these isotopes is most stable, and which isotope is "hottest"? How long does it take for \(87.5 \%\) of each isotope to decay?
\({ }^{35}\). A chemist wishing to do an experiment requiring \({ }^{47} \mathrm{Ca}^{2+}\) (halflife \(=4.5\) days) needs \(5.0 \mu \mathrm{~g}\) of the nuclide. What mass of \({ }^{47} \mathrm{CaCO}_{3}\) must be ordered if it takes 48 h for delivery from the supplier? Assume that the atomic mass of \({ }^{47} \mathrm{Ca}\) is 47.0 u .
36. Radioactive copper-64 decays with a half-life of 12.8 days.
a. What is the value of \(k\) in \(\mathrm{s}^{-1}\) ?
b. A sample contains \(28.0 \mathrm{mg}{ }^{64} \mathrm{Cu}\). How many decay events will be produced in the first second? Assume the atomic mass of \({ }^{64} \mathrm{Cu}\) is 64.0 u .
c. A chemist obtains a fresh sample of \({ }^{64} \mathrm{Cu}\) and measures its radioactivity. She then determines that to do an experiment, the radioactivity cannot fall below \(25 \%\) of the initial measured value. How long does she have to do the experiment?
-37. The first atomic explosion was detonated in the desert north of Alamogordo, New Mexico, on July 16, 1945. What percentage of the strontium- \(90\left(t_{1 / 2}=28.9\right.\) years \()\) originally produced by that explosion still remains as of July 16, 2017?
38. Iodine-131 is used in the diagnosis and treatment of thyroid disease and has a half-life of 8.0 days. If a patient with thyroid disease consumes a sample of \(\mathrm{Na}^{131} \mathrm{I}\) containing \(10 . \mu \mathrm{g}{ }^{131} \mathrm{I}\), how long will it take for the amount of \({ }^{131} \mathrm{I}\) to decrease to \(1 / 100\) of the original amount?
-39. Technetium- 99 has been used as a radiographic agent in bone scans ( \({ }_{43}^{99} \mathrm{Tc}\) is absorbed by bones). If \({ }_{43}^{99} \mathrm{Tc}\) has a half-life of 6.0 hours, what fraction of an administered dose of \(100 . \mu \mathrm{g}\) \({ }_{43}^{99} \mathrm{Tc}\) remains in a patient's body after 2.0 days?
40. Phosphorus-32 is a commonly used radioactive nuclide in biochemical research, particularly in studies of nucleic acids. The half-life of phosphorus-32 is 14.3 days. What mass of phosphorus- 32 is left from an original sample of 175 mg \(\mathrm{Na}_{3}{ }^{32} \mathrm{PO}_{4}\) after 35.0 days? Assume the atomic mass of \({ }^{32} \mathrm{P}\) is 32.0 u .
41. The bromine- 82 nucleus has a half-life of \(1.0 \times 10^{3} \mathrm{~min}\). If you wanted \(1.0 \mathrm{~g}{ }^{82} \mathrm{Br}\) and the delivery time was 3.0 days, what mass of NaBr should you order (assuming all of the Br in the NaBr was \({ }^{82} \mathrm{Br}\) )?
-42. Fresh rainwater or surface water contains enough tritium \(\left({ }_{1}^{3} \mathrm{H}\right)\) to show 5.5 decay events per minute per 100. g water. Tritium has a half-life of 12.3 years. You are asked to check a vintage wine that is claimed to have been produced in 1946. How many decay events per minute should you expect to observe in 100. g of that wine?
-43. A living plant contains approximately the same fraction of carbon-14 as in atmospheric carbon dioxide. Assuming that the observed rate of decay of carbon-14 from a living plant is 13.6 counts per minute per gram of carbon, how many counts per minute per gram of carbon will be measured from a 15,000 -year-old sample? Will radiocarbon dating work well for small samples of 10 mg or less? (For \({ }^{14} \mathrm{C}, t_{1 / 2}=5730\) years.)
44. Assume a constant \({ }^{14} \mathrm{C} /{ }^{12} \mathrm{C}\) ratio of 13.6 counts per minute per gram of living matter. A sample of a petrified tree was found to give 1.2 counts per minute per gram. How old is the tree? (For \({ }^{14} \mathrm{C}, t_{1 / 2}=5730\) years.)
45. A rock contains \(0.688 \mathrm{mg}{ }^{206} \mathrm{~Pb}\) for every \(1.000 \mathrm{mg}{ }^{238} \mathrm{U}\) present. Assuming that no lead was originally present, that all the \({ }^{206} \mathrm{~Pb}\) formed over the years has remained in the rock, and that the number of nuclides in intermediate stages of decay between \({ }^{238} \mathrm{U}\) and \({ }^{206} \mathrm{~Pb}\) is negligible, calculate the age of the rock. (For \({ }^{238} \mathrm{U}, t_{1 / 2}=4.5 \times 10^{9}\) years.)
46. The mass ratios of \({ }^{40} \mathrm{Ar}\) to \({ }^{40} \mathrm{~K}\) also can be used to date geologic materials. Potassium- 40 decays by two processes:
\[
\begin{aligned}
& { }_{19}^{40} \mathrm{~K}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{18}^{40} \mathrm{Ar}(10.7 \%)
\end{aligned} t_{1 / 2}=1.27 \times 10^{9} \text { years }
\]
a. Why are \({ }^{40} \mathrm{Ar} /{ }^{40} \mathrm{~K}\) ratios used to date materials rather than \({ }^{40} \mathrm{Ca} /{ }^{40} \mathrm{~K}\) ratios?
b. What assumptions must be made using this technique?
c. A sedimentary rock has an \({ }^{40} \mathrm{Ar} /{ }^{40} \mathrm{~K}\) ratio of 0.95 . Calculate the age of the rock.
d. How will the measured age of a rock compare to the actual age if some \({ }^{40} \mathrm{Ar}\) escaped from the sample?

\section*{Energy Changes in Nuclear Reactions}
47. The sun radiates \(3.9 \times 10^{23} \mathrm{~J}\) of energy into space every second. What is the rate at which mass is lost from the sun?
48. The earth receives \(1.8 \times 10^{14} \mathrm{~kJ} / \mathrm{s}\) of solar energy. What mass of solar material is converted to energy over a \(24-\mathrm{h}\) period to provide the daily amount of solar energy to the earth? What mass of coal would have to be burned to provide the same amount of energy? (Coal releases 32 kJ of energy per gram when burned.)
-49. Many transuranium elements, such as plutonium-232, have very short half-lives. (For \({ }^{232} \mathrm{Pu}\), the half-life is 36 minutes.) However, some, like protactinium- 231 (half-life \(=3.34 \times 10^{4}\) years), have relatively long half-lives. Use the masses given in the following table to calculate the change in energy when 1 mole of \({ }^{232} \mathrm{Pu}\) nuclei and 1 mole of \({ }^{231} \mathrm{~Pa}\) nuclei are each formed from their respective number of protons and neutrons.
\begin{tabular}{|lc|}
\hline Atom or Particle & Atomic Mass \\
\hline Neutron & \(1.67493 \times 10^{-24} \mathrm{~g}\) \\
\hline Proton & \(1.67262 \times 10^{-24} \mathrm{~g}\) \\
\hline Electron & \(9.10939 \times 10^{-28} \mathrm{~g}\) \\
\hline\({ }^{232} \mathrm{Pu}\) & \(3.85285 \times 10^{-22} \mathrm{~g}\) \\
\hline\({ }^{231} \mathrm{~Pa}\) & \(3.83616 \times 10^{-22} \mathrm{~g}\) \\
\hline
\end{tabular}
(Since the masses of \({ }^{232} \mathrm{Pu}\) and \({ }^{231} \mathrm{~Pa}\) are atomic masses, they each include the mass of the electrons present. The mass of the nucleus will be the atomic mass minus the mass of the electrons.)
50. The most stable nucleus in terms of binding energy per nucleon is \({ }^{56} \mathrm{Fe}\). If the atomic mass of \({ }^{56} \mathrm{Fe}\) is 55.9349 u , calculate the binding energy per nucleon for \({ }^{56} \mathrm{Fe}\).
51. Calculate the binding energy in \(\mathrm{J} /\) nucleon for carbon- 12 (atomic mass \(=12.0000 \mathrm{u}\) ) and uranium- 235 (atomic mass \(=\) \(235.0439 \mathrm{u})\). The atomic mass of \({ }_{1}^{1} \mathrm{H}\) is 1.00782 u and the mass of a neutron is 1.00866 u . The most stable nucleus known is \({ }^{56} \mathrm{Fe}\) (see Exercise 50). Would the binding energy per nucleon for \({ }^{56} \mathrm{Fe}\) be larger or smaller than that of \({ }^{12} \mathrm{C}\) or \({ }^{235} \mathrm{U}\) ? Explain.
52. Calculate the binding energy for \({ }_{1}^{2} \mathrm{H}\) and \({ }_{1}^{3} \mathrm{H}\). The atomic masses are \({ }_{1}^{2} \mathrm{H}, 2.01410 \mathrm{u}\); and \({ }_{1}^{3} \mathrm{H}, 3.01605 \mathrm{u}\).
-53. The binding energy for lithium-6 is \(3.086 \times 10^{12} \mathrm{~J} / \mathrm{mol}\). Calculate the atomic mass of \({ }^{6} \mathrm{Li}\).
54. The binding energy per nucleon for magnesium- 27 is \(1.326 \times 10^{-12} \mathrm{~J} /\) nucleon. Calculate the atomic mass of \({ }^{27} \mathrm{Mg}\).
-55. Calculate the amount of energy released per gram of hydrogen nuclei reacted for the following reaction. The atomic masses are \({ }_{1}^{1} \mathrm{H}, 1.00782 \mathrm{u} ;{ }_{1}^{2} \mathrm{H}, 2.01410 \mathrm{u}\); and an electron, \(5.4858 \times 10^{-4} \mathrm{u}\). (Hint: Think carefully about how to account for the electron mass.)
\[
{ }_{1}^{1} \mathrm{H}+{ }_{1}^{1} \mathrm{H} \longrightarrow{ }_{1}^{2} \mathrm{H}+{ }_{+1}^{0} \mathrm{e}
\]
56. The easiest fusion reaction to initiate is
\[
{ }_{1}^{2} \mathrm{H}+{ }_{1}^{3} \mathrm{H} \longrightarrow{ }_{2}^{4} \mathrm{He}+{ }_{0}^{1} \mathrm{n}
\]

Calculate the energy released per \({ }_{2}^{4} \mathrm{He}\) nucleus produced and per mole of \({ }_{2}^{4} \mathrm{He}\) produced. The atomic masses are \({ }_{1}^{2} \mathrm{H}\), \(2.01410 \mathrm{u} ;{ }_{1}^{3} \mathrm{H}, 3.01605 \mathrm{u}\); and \({ }_{2}^{4} \mathrm{He}, 4.00260 \mathrm{u}\). The masses of the electron and neutron are \(5.4858 \times 10^{-4} u\) and \(1.00866 u\), respectively.

\section*{Detection, Uses, and Health Effects of Radiation}

The typical response of a Geiger-Müller tube is shown below. Explain the shape of this curve.

Disintegrations/s from sample
58. When using a Geiger-Müller counter to measure radioactivity, it is necessary to maintain the same geometrical orientation between the sample and the Geiger-Müller tube to compare different measurements. Why?
\({ }^{59}\). Consider the following reaction to produce methyl acetate:

When this reaction is carried out with \(\mathrm{CH}_{3} \mathrm{OH}\) containing oxygen-18, the water produced does not contain oxygen-18. Explain.
60. A chemist studied the reaction mechanism for the reaction
\[
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
\]
by reacting \(\mathrm{N}^{16} \mathrm{O}\) with \({ }^{18} \mathrm{O}_{2}\). If the reaction mechanism is
\[
\begin{aligned}
\mathrm{NO}+\mathrm{O}_{2} & \longmapsto \mathrm{NO}_{3} \text { (fast equilibrium) } \\
\mathrm{NO}_{3}+\mathrm{NO} & \longrightarrow 2 \mathrm{NO}_{2} \text { (slow) }
\end{aligned}
\]
what distribution of \({ }^{18} \mathrm{O}\) would you expect in the \(\mathrm{NO}_{2}\) ? Assume that N is the central atom in \(\mathrm{NO}_{3}\), assume only \(\mathrm{N}^{16} \mathrm{O}^{18} \mathrm{O}_{2}\) forms, and assume stoichiometric amounts of reactants are combined.
61. Uranium- 235 undergoes many different fission reactions. For one such reaction, when \({ }^{235} \mathrm{U}\) is struck with a neutron, \({ }^{144} \mathrm{Ce}\) and \({ }^{90} \mathrm{Sr}\) are produced along with some neutrons and electrons. How many neutrons and \(\beta\)-particles are produced in this fission reaction?
62. Breeder reactors are used to convert the nonfissionable nuclide \({ }_{92}^{238} \mathrm{U}\) to a fissionable product. Neutron capture of the \({ }_{92}^{238} \mathrm{U}\) is followed by two successive beta decays. What is the final fissionable product?
-63. Which do you think would be the greater health hazard: the release of a radioactive nuclide of Sr or a radioactive nuclide of Xe into the environment? Assume the amount of radioactivity is the same in each case. Explain your answer on the basis of the chemical properties of Sr and Xe . Why are the chemical properties of a radioactive substance important in assessing its potential health hazards?
64. Consider the following information:
i. The layer of dead skin on our bodies is sufficient to protect us from most \(\alpha\)-particle radiation.
ii. Plutonium is an \(\alpha\)-particle producer.
iii. The chemistry of \(\mathrm{Pu}^{4+}\) is similar to that of \(\mathrm{Fe}^{3+}\).
iv. Pu oxidizes readily to \(\mathrm{Pu}^{4+}\).

Why is plutonium one of the most toxic substances known?

\section*{Additional Exercises}
65. Predict whether each of the following nuclides is stable or unstable (radioactive). If the nuclide is unstable, predict the type of radioactivity you would expect it to exhibit.
a. \({ }_{19}^{45} \mathrm{~K}\)
b. \({ }_{26}^{56} \mathrm{Fe}\)
c. \({ }_{11}^{20} \mathrm{Na}\)
d. \({ }_{81}^{194} \mathrm{Tl}\)
66. Each of the following isotopes has been used medically for the purpose indicated. Suggest reasons why the particular element might have been chosen for this purpose.
a. cobalt-57, for study of the body's use of vitamin \(B_{12}\)
b. calcium-47, for study of bone metabolism
c. iron-59, for study of red blood cell function
67. In the bismuth-214 natural decay series, Bi-214 initially undergoes \(\beta\) decay, the resulting daughter emits an \(\alpha\) particle, and the succeeding daughters emit a \(\beta\) and a \(\beta\) particle in that order. Determine the product of each step in the Bi-214 decay series.
68. The curie \((\mathrm{Ci})\) is a commonly used unit for measuring nuclear radioactivity: 1 curie of radiation is equal to \(3.7 \times 10^{10}\) decay events per second (the number of decay events from 1 g radium in 1 s ).
a. What mass of \(\mathrm{Na}_{2}{ }^{38} \mathrm{SO}_{4}\) has an activity of 10.0 mCi ?

Sulfur- 38 has an atomic mass of 38.0 u and a half-life of 2.87 h .
b. How long does it take for \(99.99 \%\) of a sample of sulfur- 38 to decay?
69. The mass percent of carbon in a typical human is \(18 \%\), and the mass percent of \({ }^{14} \mathrm{C}\) in natural carbon is \(1.6 \times 10^{-10} \%\). Assuming a \(180-\mathrm{lb}\) person, how many decay events per second occur in this person due exclusively to the \(\beta\)-particle decay of \({ }^{14} \mathrm{C}\) (for \({ }^{14} \mathrm{C}, t_{1 / 2}=5730\) years)?
70. At a flea market, you've found a very interesting painting done in the style of Rembrandt's "dark period" (1642-1672). You suspect that you really do not have a genuine Rembrandt, but you take it to the local university for testing. Living wood shows a carbon-14 activity of 15.3 counts per minute per gram. Your painting showed a carbon-14 activity of 15.1 counts per minute per gram. Could it be a genuine Rembrandt?
71. Define "third-life" in a similar way to "half-life", and determine the "third-life" for a nuclide that has a half-life of 31.4 years.
72. A proposed system for storing nuclear wastes involves storing the radioactive material in caves or deep mine shafts. One of the most toxic nuclides that must be disposed of is plutonium-239, which is produced in breeder reactors and has a half-life of 24,100 years. A suitable storage place must be geologically stable long enough for the activity of plutonium-239 to decrease to \(0.1 \%\) of its original value. How long is this for plutonium-239?
73. During World War II, tritium \(\left({ }^{3} \mathrm{H}\right)\) was a component of fluorescent watch dials and hands. Assume you have such a watch that was made in January 1944. If \(17 \%\) or more of the original tritium was needed to read the dial in dark places, until what year could you read the time at night? (For \({ }^{3} \mathrm{H}, t_{1 / 2}=12.3 \mathrm{yr}\).)
74. A positron and an electron can annihilate each other on colliding, producing energy as photons:
\[
{ }_{-1}^{0} \mathrm{e}+{ }_{+1}^{0} \mathrm{e} \longrightarrow 2{ }_{0}^{0} \gamma
\]

Assuming that both \(\gamma\) rays have the same energy, calculate the wavelength of the electromagnetic radiation produced.
75. A small atomic bomb releases energy equivalent to the detonation of 20,000 tons of TNT; a ton of TNT releases \(4 \times 10^{9} \mathrm{~J}\) of energy when exploded. Using \(2 \times 10^{13} \mathrm{~J} / \mathrm{mol}\) as the energy released by fission of \({ }^{235} \mathrm{U}\), approximately what mass of \({ }^{235} \mathrm{U}\) undergoes fission in this atomic bomb?
76. During the research that led to production of the two atomic bombs used against Japan in World War II, different mechanisms for obtaining a supercritical mass of fissionable material were investigated. In one type of bomb, a "gun" shot one piece of fissionable material into a cavity containing another piece of fissionable material. In the second type of bomb, the fissionable material was surrounded with a high explosive that, when detonated, compressed the fissionable material into a smaller volume. Discuss what is meant by critical mass, and explain why the ability to achieve a critical mass is essential to sustaining a nuclear reaction.
77. Using the kinetic molecular theory (see Section 5.6), calculate the root mean square velocity and the average kinetic energy of \({ }_{1}^{2} \mathrm{H}\) nuclei at a temperature of \(4 \times 10^{7} \mathrm{~K}\). (See Exercise 56 for the appropriate mass values.)
78. Consider the following reaction, which can take place in particle accelerators:
\[
{ }_{1}^{1} \mathrm{H}+{ }_{0}^{1} \mathrm{n} \longrightarrow 2{ }_{1}^{1} \mathrm{H}+{ }_{0}^{1} \mathrm{n}+{ }_{-1}^{1} \mathrm{H}
\]

Calculate the energy change for this reaction. Is energy released or absorbed? What is a possible source for this energy?
79. Photosynthesis in plants can be represented by the following overall equation:
\[
6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \xrightarrow{\text { Light }} C_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g)
\]

Algae grown in water containing some \({ }^{18} \mathrm{O}\) (in \(\mathrm{H}_{2}{ }^{18} \mathrm{O}\) ) evolve oxygen gas with the same isotopic composition as the oxygen in the water. When algae growing in water containing only \({ }^{16} \mathrm{O}\) were furnished carbon dioxide containing \({ }^{18} \mathrm{O}\), no \({ }^{18} \mathrm{O}\) was found to be evolved from the oxygen gas produced. What conclusions about photosynthesis can be drawn from these experiments?
80. Strontium-90 and radon- 222 both pose serious health risks. \({ }^{90} \mathrm{Sr}\) decays by \(\beta\)-particle production and has a relatively long half-life ( 28.9 years). Radon-222 decays by \(\alpha\)-particle production and has a relatively short half-life ( 3.82 days). Explain why each decay process poses health risks.

\section*{ChemWork Problems}

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
81. Complete the following table with the nuclear particle that is produced in each nuclear reaction.
\begin{tabular}{|c|c|c|}
\hline Initial Nuclide & Product Nuclide & Particle Produced \\
\hline \({ }_{94}^{239} \mathrm{Pu}\) & \({ }_{92}^{235} \mathrm{U}\) & \\
\hline \({ }_{82}^{214} \mathrm{~Pb}\) & \({ }_{83}^{214} \mathrm{Bi}\) & \\
\hline \({ }_{27}^{60} \mathrm{Co}\) & \({ }_{28}^{60} \mathrm{Ni}\) & \\
\hline \({ }_{43}^{99} \mathrm{C}\) & \({ }_{44}^{99} \mathrm{Ru}\) & \\
\hline \({ }_{93}^{239} \mathrm{~Np}\) & \({ }_{94}^{239} \mathrm{Pu}\) & \\
\hline
\end{tabular}
82. A certain radioactive nuclide has a half-life of 3.00 hours.
a. Calculate the rate constant in \(\mathrm{s}^{-1}\) for this nuclide.
b. Calculate the decay rate in decays/s for 1.000 mole of this nuclide.
83. Cobalt-60 is commonly used as a source of \(\beta\) particles. How long does it take for \(87.5 \%\) of a sample of cobalt- 60 to decay (the half-life is 5.26 years)?
84. Rubidium- 87 decays by \(\beta\)-particle production to strontium- 87 with a half-life of \(4.7 \times 10^{10}\) years. What is the age of a rock sample that contains \(109.7 \mu \mathrm{~g}\) of \({ }^{87} \mathrm{Rb}\) and \(3.1 \mu \mathrm{~g}\) of \({ }^{87} \mathrm{Sr}\) ? Assume that no \({ }^{87} \mathrm{Sr}\) was present when the rock was formed. The atomic masses for \({ }^{87} \mathrm{Rb}\) and \({ }^{87} \mathrm{Sr}\) are 86.90919 u and 86.90888 u, respectively.
85. Given the following information:

Mass of proton \(=1.00728 \mathrm{u}\)
Mass of neutron \(=1.00866 \mathrm{u}\)
Mass of electron \(=5.486 \times 10^{-4} \mathrm{u}\)
Speed of light \(=2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}\)
Calculate the nuclear binding energy of \({ }_{12}^{24} \mathrm{Mg}\), which has an atomic mass of 23.9850 u .
86. Which of the following statement(s) is(are) true?
a. A radioactive nuclide that decays from \(2.00 \times 10^{21}\) atoms to \(5.0 \times 10^{20}\) atoms in 16 minutes has a half-life of 8.0 minutes.
b. Nuclides with large \(Z\) values are observed to be \(\alpha\)-particle producers.
c. As \(Z\) increases, nuclides need a greater proton-to-neutron ratio for stability.
d. Those "light" nuclides that have twice as many neutrons as protons are expected to be stable.

\section*{Challenge Problems}
87. Naturally occurring uranium is composed mostly of \({ }^{238} \mathrm{U}\) and \({ }^{235} \mathrm{U}\), with relative abundances of \(99.28 \%\) and \(0.72 \%\), respectively. The half-life for \({ }^{238} \mathrm{U}\) is \(4.5 \times 10^{9}\) years, and the halflife for \({ }^{235} \mathrm{U}\) is \(7.1 \times 10^{8}\) years. Assuming that the earth was formed 4.5 billion years ago, calculate the relative abundances of the \({ }^{238} \mathrm{U}\) and \({ }^{235} \mathrm{U}\) isotopes when the earth was formed.
88. The curie \((\mathrm{Ci})\) is a commonly used unit for measuring nuclear radioactivity: 1 curie of radiation is equal to \(3.7 \times 10^{10}\) decay events per second (the number of decay events from 1 g radium in 1 s ). A \(1.7-\mathrm{mL}\) sample of water containing tritium was injected into a \(150-\mathrm{lb}\) person. The total activity of radiation injected was 86.5 mCi . After some time to allow the tritium activity to equally distribute throughout the body, a sample of blood plasma containing 2.0 mL water at an activity of \(3.6 \mu \mathrm{Ci}\) was removed. From these data, calculate the mass percent of water in this \(150-\mathrm{lb}\) person.
89. A \(0.10-\mathrm{cm}^{3}\) sample of a solution containing a radioactive nuclide \(\left(5.0 \times 10^{3}\right.\) counts per minute per milliliter) is injected into a rat. Several minutes later \(1.0 \mathrm{~cm}^{3}\) of blood is removed. The blood shows 48 counts per minute of radioactivity. Calculate the volume of blood in the rat. What assumptions must be made in performing this calculation?
90. Zirconium is one of the few metals that retains its structural integrity upon exposure to radiation. The fuel rods in most nuclear reactors therefore are often made of zirconium. Answer the following questions about the redox properties of zirconium based on the half-reaction
\(\mathrm{ZrO}_{2} \cdot \mathrm{H}_{2} \mathrm{O}+\mathrm{H}_{2} \mathrm{O}+4 \mathrm{e}^{-} \longrightarrow \mathrm{Zr}+4 \mathrm{OH}^{-} \quad \mathscr{E} \circ=-2.36 \mathrm{~V}\)
a. Is zirconium metal capable of reducing water to form hydrogen gas at standard conditions?
b. Write a balanced equation for the reduction of water by zirconium.
c. Calculate \(\mathscr{E}^{\circ}, \Delta G^{\circ}\), and \(K\) for the reduction of water by zirconium metal.
d. The reduction of water by zirconium occurred during the accidents at Three Mile Island in 1979. The hydrogen produced was successfully vented and no chemical explosion occurred. If \(1.00 \times 10^{3} \mathrm{~kg} \mathrm{Zr}\) reacts, what mass of \(\mathrm{H}_{2}\) is produced? What volume of \(\mathrm{H}_{2}\) at 1.0 atm and \(1000 .{ }^{\circ} \mathrm{C}\) is produced?
e. At Chernobyl in 1986, hydrogen was produced by the reaction of superheated steam with the graphite reactor core:
\[
\mathrm{C}(s)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{CO}(g)+\mathrm{H}_{2}(g)
\]

It was not possible to prevent a chemical explosion at Chernobyl. In light of this, do you think it was a correct decision to vent the hydrogen and other radioactive gases into the atmosphere at Three Mile Island? Explain.
91. In addition to the process described in the text, a second process called the carbon-nitrogen cycle occurs in the sun:
\[
\begin{aligned}
& { }_{1}^{1} \mathrm{H}+{ }_{6}^{12} \mathrm{C} \longrightarrow{ }_{7}^{13} \mathrm{~N}+{ }_{0}^{0} \gamma \\
& { }_{7}^{13} \mathrm{~N} \longrightarrow{ }_{6}^{13} \mathrm{C}+{ }_{+1}^{0} \mathrm{e} \\
& { }_{1}^{1} \mathrm{H}+{ }_{6}^{13} \mathrm{C} \longrightarrow{ }_{7}^{14} \mathrm{~N}+{ }_{0}^{0} \gamma \\
& { }_{1}^{1} \mathrm{H}+{ }_{7}^{14} \mathrm{~N} \longrightarrow{ }_{8}^{15} \mathrm{O}+{ }_{0}^{0} \gamma \\
& { }_{8}^{15} \mathrm{O} \longrightarrow{ }_{7}^{15} \mathrm{~N}+{ }_{+1}^{0} \mathrm{e} \\
& { }_{1}^{1} \mathrm{H}+{ }_{7}^{15} \mathrm{~N} \longrightarrow{ }_{6}^{12} \mathrm{C}+{ }_{2}^{4} \mathrm{He}+{ }_{0}^{0} \gamma \\
& \text { Overall } \\
& \text { reaction } \mathrm{C}{ }_{1}^{1} \mathrm{H} \longrightarrow{ }_{2}^{4} \mathrm{He}+2+{ }_{1}^{0} \mathrm{e}
\end{aligned}
\]
a. What is the catalyst in this process?
b. What nucleons are intermediates?
c. How much energy is released per mole of hydrogen nuclei in the overall reaction? (The atomic masses of \({ }_{1}^{1} \mathrm{H}\) and \({ }_{2}^{4} \mathrm{He}\) are 1.00782 u and 4.00260 u , respectively.)
92. The most significant source of natural radiation is radon-222. \({ }^{222} \mathrm{Rn}\), a decay product of \({ }^{238} \mathrm{U}\), is continuously generated in the earth's crust, allowing gaseous Rn to seep into the basements of buildings. Because \({ }^{222} \mathrm{Rn}\) is an \(\alpha\)-particle producer with a relatively short half-life of 3.82 days, it can cause biological damage when inhaled.
a. How many \(\alpha\) particles and \(\beta\) particles are produced when \({ }^{238} \mathrm{U}\) decays to \({ }^{222} \mathrm{Rn}\) ? What nuclei are produced when \({ }^{222} \mathrm{Rn}\) decays?
b. Radon is a noble gas so one would expect it to pass through the body quickly. Why is there a concern over inhaling \({ }^{222} \mathrm{Rn}\) ?
c. Another problem associated with \({ }^{222} \mathrm{Rn}\) is that the decay of \({ }^{222} \mathrm{Rn}\) produces a more potent \(\alpha\)-particle producer \(\left(t_{1 / 2}=3.11 \mathrm{~min}\right)\) that is a solid. What is the identity of the solid? Give the balanced equation of this species decaying by \(\alpha\)-particle production. Why is the solid a more potent \(\alpha\)-particle producer?
d. The U.S. Environmental Protection Agency (EPA) recommends that \({ }^{222} \mathrm{Rn}\) levels not exceed 4 pCi per liter of air ( \(1 \mathrm{Ci}=1\) curie \(=3.7 \times 10^{10}\) decay events per second; \(1 \mathrm{pCi}=1 \times 10^{-12} \mathrm{Ci}\) ). Convert 4.0 pCi per liter of air into concentrations units of \({ }^{222} \mathrm{Rn}\) atoms per liter of air and moles of \({ }^{222} \mathrm{Rn}\) per liter of air.
93. To determine the \(K_{\text {sp }}\) value of \(\mathrm{Hg}_{2} \mathrm{I}_{2}\), a chemist obtained a solid sample of \(\mathrm{Hg}_{2} \mathrm{I}_{2}\) in which some of the iodine is present as radioactive \({ }^{131} \mathrm{I}\). The count rate of the \(\mathrm{Hg}_{2} \mathrm{I}_{2}\) sample is \(5.0 \times 10^{11}\) counts per minute per mole of \(I\). An excess amount of \(\mathrm{Hg}_{2} \mathrm{I}_{2}(s)\) is placed into some water, and the solid is allowed to come to equilibrium with its respective ions. A \(150.0-\mathrm{mL}\) sample of the saturated solution is withdrawn and the radioactivity measured at 33 counts per minute. From this information, calculate the \(K_{\text {sp }}\) value for \(\mathrm{Hg}_{2} \mathrm{I}_{2}\).
\[
\mathrm{Hg}_{2} \mathrm{I}_{2}(s) \rightleftharpoons \mathrm{Hg}_{2}^{2+}(a q)+2 \mathrm{I}^{-}(a q) \quad K_{\mathrm{sp}}=\left[\mathrm{Hg}_{2}^{2+}\right]\left[\mathrm{I}^{-}\right]^{2}
\]
94. Estimate the temperature needed to achieve the fusion of deuterium to make an \(\alpha\) particle. The energy required can be estimated from Coulomb's law [use the form \(E=9.0 \times 10^{9}\) \(\left(Q_{1} Q_{2} / r\right)\), using \(Q=1.6 \times 10^{-19} \mathrm{C}\) for a proton, and \(r=2 \times\) \(10^{-15} \mathrm{~m}\) for the helium nucleus; the unit for the proportionality constant in Coloumb's law is \(\mathrm{J} \cdot \mathrm{m} / \mathrm{C}^{2}\) ].

\section*{Integrative Problems}

These problems require the integration of multiple concepts to find the solutions.
95. A reported synthesis of the transuranium element bohrium (Bh) involved the bombardment of berkelium-249 with neon22 to produce bohrium-267. Write a nuclear reaction for this synthesis. The half-life of bohrium-267 is 15.0 seconds. If 199 atoms of bohrium- 267 could be synthesized, how much time would elapse before only 11 atoms of bohrium- 267 remain? What is the expected electron configuration of elemental bohrium?
96. Radioactive cobalt-60 is used to study defects in vitamin \(B_{12}\) absorption because cobalt is the metallic atom at the center of the vitamin \(\mathrm{B}_{12}\) molecule. The nuclear synthesis of this cobalt isotope involves a three-step process. The overall reaction is iron-58 reacting with two neutrons to produce cobalt-60 along with the emission of another particle. What particle is emitted in this nuclear synthesis? What is the binding energy in J per nucleon for the cobalt-60 nucleus (atomic masses: \({ }^{60} \mathrm{Co}=\) \(\left.59.9338 \mathrm{u} ;{ }^{1} \mathrm{H}=1.00782 \mathrm{u}\right)\) ? What is the de Broglie wavelength of the emitted particle if it has a velocity equal to \(0.90 c\), where \(c\) is the speed of light?

A magnified crystal of bismuth. (© mitzy/Shutterstock.com)

Oxyacids and Oxyanions
20.14 The Group 8A Elements

S o far in this book we have covered the major principles and explored the most important models of chemistry. In particular, we have seen that the chemical properties of the elements can be explained very successfully by the quantum mechanical model of the atom. In fact, the most convincing evidence of that model's validity is its ability to relate the observed periodic properties of the elements to the number of valence electrons in their atoms.

We have learned many properties of the elements and their compounds, but we have not discussed extensively the relationship between the chemical properties of a specific element and its position on the periodic table. In this chapter we will explore the chemical similarities and differences among the elements in the several groups of the periodic table and will try to interpret these data using the wave mechanical model of the atom. In the process we will illustrate a great variety of chemical properties and further demonstrate the practical importance of chemistry.

\subsection*{20.1 A Survey of the Representative Elements}

The traditional form of the periodic table is shown in Fig. 20.1. Recall that the representative elements, whose chemical properties are determined by the valence-level \(s\) and \(p\) electrons, are designated Groups 1 A through 8A. The transition metals, in the center of the table, result from the filling of \(d\) orbitals. The elements that correspond to the filling of the \(4 f\) and \(5 f\) orbitals are listed separately as the lanthanides and actinides, respectively.

The heavy black line in Fig. 20.1 separates the metals from the nonmetals. Some elements just on either side of this line, such as silicon and germanium, exhibit both metallic and nonmetallic properties. These elements are often called metalloids, or semimetals. The fundamental chemical difference between metals and nonmetals is that metals tend to lose their valence electrons to form cations, which usually have the valence electron configuration of the noble gas from the preceding period. On the other hand, nonmetals tend to gain electrons to form anions that exhibit the electron configuration of the noble gas in the same period. Metallic character is observed to increase in going down a given group, which is consistent with the trends in ionization energy, electron affinity, and electronegativity discussed earlier (see Sections 7.12 and 8.2).

\section*{Atomic Size and Group Anomalies}

Although the chemical properties of the members of a group have many similarities, there are also important differences. The most dramatic differences usually occur between the first and second member. For example, hydrogen in Group 1A is a nonmetal, whereas lithium is a very active metal. This extreme difference results primarily from the very large difference in the atomic radii of hydrogen and lithium, as shown in Fig. 20.2. Since the small hydrogen atom has a much greater attraction for electrons than do the larger members of Group 1A, it forms covalent bonds with nonmetals. In contrast, the other members of Group 1A lose their valence electrons to nonmetals to form \(1+\) cations in ionic compounds.

The effect of size is also evident in other groups. For example, the oxides of the metals in Group 2A are all quite basic except for the first member of the series; beryllium oxide ( BeO ) is amphoteric. The basicity of an oxide depends on its ionic character. Ionic oxides contain the \(\mathrm{O}^{2-}\) ion, which reacts with water to form two \(\mathrm{OH}^{-}\)ions. All the oxides of the Group 2A metals are highly ionic except for beryllium oxide, which has considerable covalent character. The small \(\mathrm{Be}^{2+}\) ion can effectively polarize the electron "cloud" of the \(\mathrm{O}^{2-}\) ion, thereby producing significant electron sharing. We see the same pattern in Group 3A, where only the small boron atom behaves as a

FIGURE 20.1 The periodic table. The elements in the A groups are the representative elements. The elements shown in yellow are called transition metals. The heavy black line approximately separates the nonmetals from the metals.
nonmetal, or sometimes as a semimetal, whereas aluminum and the other members are active metals.

In Group 4A the effect of size is reflected in the dramatic differences between the chemical properties of carbon and silicon. The chemistry of carbon is dominated by molecules containing chains of \(\mathrm{C}-\mathrm{C}\) bonds, but silicon compounds mainly contain \(\mathrm{Si}-\mathrm{O}\) bonds rather than Si - Si bonds. Silicon does form compounds with chains of \(\mathrm{Si}-\mathrm{Si}\) bonds, but these compounds are much more reactive than the corresponding carbon compounds. The reasons for the difference in reactivity between the carbon and silicon compounds are quite complex but are likely related to the differences in the sizes of the carbon and silicon atoms.

Carbon and silicon also differ markedly in their abilities to form \(\pi\) bonds. As we discussed in Section 9.1, carbon dioxide is composed of discrete \(\mathrm{CO}_{2}\) molecules with the Lewis structure
\[
\because \mathrm{O}=\mathrm{C}=\dot{\mathrm{O}}
\]
where the carbon and oxygen atoms achieve the \([\mathrm{Ne}]\) configuration by forming \(\pi\) bonds. In contrast, the structure of silica (empirical formula \(\mathrm{SiO}_{2}\) ) is based on \(\mathrm{SiO}_{4}\) tetrahedra with \(\mathrm{Si}-\mathrm{O}-\mathrm{Si}\) bridges, as shown in Fig. 20.3. The silicon \(3 p\) valence

FIGURE 20.2 Some atomic radii (in picometers).

FIGURE 20.3 The structure of quartz, which has the empirical formula \(\mathrm{SiO}_{2}\). Note that the structure is based on interlocking \(\mathrm{SiO}_{4}\) tetrahedra (shown below the arrow), in which each oxygen atom is shared by two silicon atoms.
orbitals do not overlap very effectively with the smaller oxygen \(2 p\) orbitals to form \(\pi\) bonds; therefore, discrete \(\mathrm{SiO}_{2}\) molecules with the Lewis structure
\[
\because \dot{\mathrm{O}}=\mathrm{Si}=\dot{\mathrm{O}}
\]
are not stable. Instead, the silicon atoms achieve a noble gas configuration by forming four \(\mathrm{Si}-\mathrm{O}\) single bonds.

The importance of \(\pi\) bonding for the relatively small elements of the second period also explains the different elemental forms of the members of Groups 5A and 6A. For example, elemental nitrogen exists as very stable \(\mathrm{N}_{2}\) molecules with the Lewis structure : \(\mathrm{N} \equiv \mathrm{N}\) :. Elemental phosphorus forms larger aggregates of atoms, the simplest being the tetrahedral \(\mathrm{P}_{4}\) molecules found in white phosphorus (see Fig. 20.18). Like silicon atoms, the relatively large phosphorus atoms do not form strong \(\pi\) bonds but prefer to achieve a noble gas configuration by forming single bonds to several other phosphorus atoms. In contrast, its very strong \(\pi\) bonds make the \(\mathrm{N}_{2}\) molecule the most stable form of elemental nitrogen. Similarly, in Group 6A the most stable form of elemental oxygen is the \(\mathrm{O}_{2}\) molecule with a double bond. However, the larger sulfur atom forms bigger aggregates, such as the cyclic \(\mathrm{S}_{8}\) molecule (see Fig. 20.22), which contain only single bonds.

The relatively large change in size in going from the first to the second member of a group also has important consequences for the Group 7A elements. For example,

Carbon is the cheapest and most readily available industrial reducing agent for metallic ions.
fluorine has a smaller electron affinity than chlorine. This violation of the expected trend can be attributed to the fact that the small size of the fluorine \(2 p\) orbitals causes unusually large electron-electron repulsions. The relative weakness of the bond in the \(\mathrm{F}_{2}\) molecule can be explained in terms of the repulsions among the lone pairs, shown in the Lewis structure:
\[
\ddot{\mathrm{F}}-\ddot{\mathrm{F}}:
\]

The small size of the fluorine atoms allows close approach of the lone pairs, which leads to much greater repulsions than those found in the \(\mathrm{Cl}_{2}\) molecule with its much larger atoms.

Thus the relatively large increase in atomic radius in going from the first to the second member of a group causes the first element to exhibit properties quite different from the others.

\section*{Abundance and Preparation}

Table 20.1 shows the distribution of elements in the earth's crust, oceans, and atmosphere. The major element is, of course, oxygen, which is found in the atmosphere as \(\mathrm{O}_{2}\), in the oceans as \(\mathrm{H}_{2} \mathrm{O}\), and in the earth's crust primarily in silicate and carbonate minerals. The second most abundant element, silicon, is found throughout the earth's crust in the silica and silicate minerals that form the basis of most sand, rocks, and soil. The most abundant metals, aluminum and iron, are found in ores, in which they are combined with nonmetals, most commonly oxygen. One notable fact revealed by Table 20.1 is the small incidence of most transition metals. Since many of these relatively rare elements are assuming increasing importance in our high-technology society, it is possible that the control of transition metal ores may ultimately have more significance in world politics than will control of petroleum supplies.

The distribution of elements in living materials is very different from that found in the earth's crust. Table 20.2 shows the distribution of elements in the human body. Oxygen, carbon, hydrogen, and nitrogen form the basis for all biologically important molecules. The other elements, even though they are found in relatively small amounts, are often crucial for life. For example, zinc is found in over 150 different biomolecules in the human body.

Only about one-fourth of the elements occur naturally in the free state. Most are found in a combined state. The process of obtaining a metal from its ore is called metallurgy. Since the metals in ores are found in the form of cations, the chemistry of metallurgy always involves reduction of the ions to the elemental metal (with an oxidation state of zero). A variety of reducing agents can be used, but carbon is the usual choice because of its wide availability and relatively low cost.

TABLE 20.1 | Distribution (Mass Percent) of the 18 Most Abundant Elements in the Earth's Crust, Oceans, and Atmosphere
\begin{tabular}{|lclllll|}
\hline Element & Mass Percent & Element & Mass Percent & Element & Mass Percent \\

\end{tabular}

Electrolysis is often used to reduce the most active metals. In Chapter 18 we considered the electrolytic production of aluminum metal. The alkali metals are also produced by electrolysis, usually of their molten halide salts.

The preparation of nonmetals varies widely. Elemental nitrogen and oxygen are usually obtained from the liquefaction of air, which is based on the principle that a gas cools as it expands. After each expansion, part of the cooler gas is compressed, whereas the rest is used to carry away the heat of the compression. The compressed gas is then allowed to expand again. This cycle is repeated many times. Eventually, the remaining gas becomes cold enough to form the liquid state. Because liquid nitrogen and liquid oxygen have different boiling points, they can be separated by the distillation of liquid air. Both substances are important industrial chemicals, with nitrogen ranking second in terms of amount manufactured in the United States (approximately 60 billion pounds per year) and oxygen ranking third (over 40 billion pounds per year). Hydrogen can be obtained from the electrolysis of water, but more commonly it is obtained from the decomposition of the methane in natural gas. Sulfur is found underground in its elemental form and is recovered by the Frasch process (see Section 20.12). The halogens are obtained by oxidation of the anions from halide salts (see Section 20.13).

\subsection*{20.2 The Group 1A Elements}

Several properties of the alkali metals are given in Table 7.8.

FIGURE 20.4 Lepidolite is composed of mainly lithium, aluminum, silicon, and oxygen, but it also contains significant amounts of rubidium and cesium.

The Group 1A elements with their \(n s^{1}\) valence electron configurations are all very active metals (they lose their valence electrons very readily), except for hydrogen, which behaves as a nonmetal. We will discuss the chemistry of hydrogen in the next section. Many of the properties of the alkali metals have been given previously (see Section 7.13). The sources and methods of preparation of pure alkali metals are given in Table 20.3. The ionization energies, standard reduction potentials, ionic radii, and melting points for the alkali metals are listed in Table 20.4.

In Section 7.13 we saw that the alkali metals all react vigorously with water to release hydrogen gas:
\[
2 \mathrm{M}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{M}^{+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
\]

We will reconsider this process briefly because it illustrates several important concepts. From the ionization energies, we might expect lithium to be the weakest of the alkali metals as a reducing agent in water. However, the standard reduction potentials indicate that it is the strongest. This reversal results mainly from the very large energy of hydration of the small \(\mathrm{Li}^{+}\)ion. Because of its relatively high charge density, the \(\mathrm{Li}^{+}\) ion very effectively attracts water molecules. A large quantity of energy is released in the process, favoring the formation of the \(\mathrm{Li}^{+}\)ion and making lithium a strong reducing agent in aqueous solution.

We also saw in Section 7.13 that lithium, although it is the strongest reducing agent, reacts more slowly with water than sodium or potassium. From the discussions in Chapters 12 and 17, we know that the equilibrium position for a reaction (in this case indicated by the \(\mathscr{E}^{\circ}\) values) is controlled by thermodynamic factors but that the rate of a reaction is controlled by kinetic factors. There is no direct connection between these factors. Lithium reacts more slowly with water than sodium or potassium because as a solid lithium has a higher melting point than either of the other elements. Since lithium

\hline
\end{tabular}
does not become molten from the heat of reaction with water as sodium and potassium do, it has a smaller area of contact with the water.

Table 20.5 summarizes some important reactions of the alkali metals.
The alkali metal ions are very important for the proper functioning of biological systems such as nerves and muscles; \(\mathrm{Na}^{+}\)and \(\mathrm{K}^{+}\)ions are present in all body cells and fluids. In human blood plasma, the concentrations are
\[
\left[\mathrm{Na}^{+}\right] \approx 0.15 M \quad \text { and } \quad\left[\mathrm{K}^{+}\right] \approx 0.005 M
\]

In the fluids inside the cells, the concentrations are reversed:
\[
\left[\mathrm{Na}^{+}\right] \approx 0.005 \mathrm{M} \quad \text { and } \quad\left[\mathrm{K}^{+}\right] \approx 0.16 M
\]

Since the concentrations are so different inside and outside the cells, an elaborate mechanism involving selective ligands is needed to transport \(\mathrm{Na}^{+}\)and \(\mathrm{K}^{+}\)ions through the cell membranes.

\subsection*{20.3 The Chemistry of Hydrogen}

Under ordinary conditions of temperature and pressure, hydrogen is a colorless, odorless gas composed of \(\mathrm{H}_{2}\) molecules. Because of its low molar mass and nonpolarity, hydrogen has a very low boiling point \(\left(-253^{\circ} \mathrm{C}\right)\) and melting point \(\left(-260^{\circ} \mathrm{C}\right)\). Hydrogen gas is highly flammable; mixtures of air containing from \(18 \%\) to \(60 \%\) hydrogen by volume are explosive. In a common lecture demonstration, hydrogen and oxygen gases are bubbled into soapy water. The resulting bubbles are then ignited with a candle on a long stick, producing a loud explosion.

The major industrial source of hydrogen gas is the reaction of methane with water at high temperatures \(\left(800-1000^{\circ} \mathrm{C}\right)\) and pressures \((10-50 \mathrm{~atm})\) in the presence of a metallic catalyst (often nickel):
\[
\mathrm{CH}_{4}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \xrightarrow[\text { Catalyst }]{\text { Heat, pressure }} \mathrm{CO}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g})
\]

Large quantities of hydrogen are also formed as a by-product of gasoline production, when hydrocarbons with high molecular masses are broken down (or cracked) to produce smaller molecules more suitable for use as a motor fuel.

Very pure hydrogen can be produced by the electrolysis of water (see Section 18.7), but this method currently is not economically feasible for large-scale production because of the relatively high cost of electricity.

The major industrial use of hydrogen is in the production of ammonia by the Haber process. Large quantities of hydrogen are also used for hydrogenating unsaturated
(left) Hydrogen gas being used to blow soap bubbles. (right) As the bubbles float upward, they are lighted by using a candle on a long stick. The orange flame results from the heat of the reaction between hydrogen and oxygen, which excites sodium atoms in the soap bubbles.

vegetable oils (those containing carbon-carbon double bonds) to produce solid shortenings that are saturated (containing carbon-carbon single bonds):

The catalysis of this process was discussed in Section 12.8.
Chemically, hydrogen behaves as a typical nonmetal, forming covalent compounds with other nonmetals and forming salts with very active metals. Binary compounds containing hydrogen are called hydrides, of which there are three classes. The ionic (or saltlike) hydrides are formed when hydrogen combines with the most active metals, those from Groups 1 A and 2A. Examples are LiH and \(\mathrm{CaH}_{2}\), which can best be characterized as containing hydride ions \(\left(\mathrm{H}^{-}\right)\)and metal cations. Because the presence of two electrons in the small \(1 s\) orbital produces large electron-electron repulsions and because the nucleus has only a \(1+\) charge, the hydride ion is a strong reducing agent. For example, when ionic hydrides are placed in water, a violent reaction takes place. This reaction results in the formation of hydrogen gas, as seen in the equation
\[
\mathrm{LiH}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{Li}^{+}(a q)+\mathrm{OH}^{-}(a q)
\]

Covalent hydrides are formed when hydrogen combines with other nonmetals. We have encountered many of these compounds already: \(\mathrm{HCl}, \mathrm{CH}_{4}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{O}\), and so on. The most important covalent hydride is water. The polarity of the \(\mathrm{H}_{2} \mathrm{O}\) molecule leads to many of water's unusual properties. Water has a much higher boiling point than is expected from its molar mass. It has a large heat of vaporization and a large heat capacity, both of which make it a very useful coolant. Water has a higher density as a liquid than as a solid because of the open structure of ice, which results from maximizing the hydrogen bonding (Fig. 20.5). Because water is an excellent solvent for ionic and polar substances, it provides an effective medium for life processes. In fact, water is one of the few covalent hydrides that is nontoxic to organisms.

The third class of hydrides is the metallic, or interstitial, hydrides, which are formed when transition metal crystals are treated with hydrogen gas. The hydrogen molecules dissociate at the metal's surface, and the small hydrogen atoms migrate into the crystal structure to occupy holes, or interstices. These metal-hydrogen mixtures are more like solid solutions than true compounds. Palladium can absorb about 900 times its own volume of hydrogen gas. In fact, hydrogen can be purified by placing it

FIGURE 20.5 The structure of ice, showing the hydrogen bonding.

See Section 6.6 for a discussion of the feasibility of using hydrogen gas as a fuel.

Ice
under slight pressure in a vessel containing a thin wall of palladium. The hydrogen diffuses into and through the metal wall, leaving the impurities behind.

Although hydrogen can react with transition metals to form compounds such as \(\mathrm{UH}_{3}\) and \(\mathrm{FeH}_{6}\), most of the interstitial hydrides have variable compositions (often called nonstoichiometric compositions) with formulas such as \(\mathrm{LaH}_{2.76}\) and \(\mathrm{VH}_{0.56}\). The compositions of the nonstoichiometric hydrides vary with the length of exposure of the metal to hydrogen gas.

When interstitial hydrides are heated, much of the absorbed hydrogen is lost as hydrogen gas. Because of this behavior, these materials offer possibilities for storing hydrogen for use as a portable fuel. The internal combustion engines in current automobiles can burn hydrogen gas with little modification, but storage of enough hydrogen to provide an acceptable mileage range remains a problem. One possible solution might be to use a fuel tank containing a porous solid that includes a transition metal. The hydrogen gas could be pumped into the solid to form the interstitial hydride. The hydrogen gas could then be released when the engine requires additional energy. This system is now being tested by several automobile companies.

\subsection*{20.4 The Group 2A Elements}

The Group 2A elements (with the valence electron configuration \(n s^{2}\) ) are very reactive, losing their two valence electrons to form ionic compounds that contain \(\mathrm{M}^{2+}\) cations. These elements are commonly called the alkaline earth metals because of the basicity of their oxides:
\[
\mathrm{MO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{M}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
\]

Only the amphoteric beryllium oxide ( BeO ) also shows some acidic properties, such as dissolving in aqueous solutions containing hydroxide ions:
\[
\mathrm{BeO}(s)+2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Be}(\mathrm{OH})_{4}{ }^{2-}(a q)
\]

The more active alkaline earth metals react with water as the alkali metals do, producing hydrogen gas:
\[
\mathrm{M}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{M}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
\]

Calcium, strontium, and barium react vigorously at \(25^{\circ} \mathrm{C}\). The less easily oxidized beryllium and magnesium show no observable reaction with water at \(25^{\circ} \mathrm{C}\), although magnesium reacts with boiling water. Table 20.6 summarizes various properties, sources, and methods of preparation of the alkaline earth metals.

\section*{-}

Calcium metal reacting with water to form bubbles of hydrogen gas.

The alkaline earth metals have great practical importance. Calcium and magnesium ions are essential for human life. Calcium is found primarily in the structural minerals composing bones and teeth. Magnesium (as the \(\mathrm{Mg}^{2+}\) ion) plays a vital role in metabolism and in muscle functions. Because magnesium metal has a relatively low density and displays moderate strength, it is a useful structural material, especially if alloyed with aluminum.

Table 20.7 summarizes some important reactions involving the alkaline earth metals.

Relatively large concentrations of \(\mathrm{Ca}^{2+}\) and \(\mathrm{Mg}^{2+}\) ions are often found in natural water supplies. These ions in this so-called hard water interfere with the action of detergents and form precipitates with soap. In Section 7.6 we saw that \(\mathrm{Ca}^{2+}\) is often removed by precipitation as \(\mathrm{CaCO}_{3}\) in large-scale water softening. In individual homes \(\mathrm{Ca}^{2+}, \mathrm{Mg}^{2+}\), and other cations are removed by ion exchange. An ion-exchange resin consists of large molecules (polymers) that have many ionic sites. A cation-exchange resin is represented schematically in Fig. 20.6(a), showing \(\mathrm{Na}^{+}\)ions bound ionically to the \(\mathrm{SO}_{3}^{-}\)groups that are covalently attached to the resin polymer. When hard water is passed over the resin, \(\mathrm{Ca}^{2+}\) and \(\mathrm{Mg}^{2+}\) bind to the resin in place of \(\mathrm{Na}^{+}\), which is released into the solution [Fig. 20.6(b)]. Replacing \(\mathrm{Mg}^{2+}\) and \(\mathrm{Ca}^{2+}\) by \(\mathrm{Na}^{+}\)[Fig. 20.6(c)] "softens" the water because the sodium salts of soap are soluble.

\subsection*{20.5 The Group 3A Elements}

The Group 3A elements (valence electron configuration \(n s^{2} n p^{1}\) ) generally show the increase in metallic character in going down the group that is characteristic of the representative elements. Some physical properties, sources, and methods of preparation of the Group 3A elements are summarized in Table 20.8.

Boron is a typical nonmetal, and most of its compounds are covalent. The most interesting compounds of boron are the covalent hydrides called boranes. We might expect \(\mathrm{BH}_{3}\) to be the simplest hydride, since boron has three valence electrons to share with three hydrogen atoms. However, this compound is unstable, and the simplest known member of the series is diborane \(\left(\mathrm{B}_{2} \mathrm{H}_{6}\right)\), with the structure shown in Fig. 20.7(a). In this molecule the terminal \(\mathrm{B}-\mathrm{H}\) bonds are normal covalent bonds, each involving one electron pair. The bridging bonds are three-center bonds similar to those in solid \(\mathrm{BeH}_{2}\). Another interesting borane contains the square pyramidal \(\mathrm{B}_{5} \mathrm{H}_{9}\) molecule [Fig. 20.7(b)], which has four three-center bonds situated around the base of the

FIGURE 20.7 (a) The structure of \(\mathrm{B}_{2} \mathrm{H}_{6}\) with its two three-center \(\mathrm{B}-\mathrm{H}-\mathrm{B}\) bridging bonds and four "normal" \(\mathrm{B}-\mathrm{H}\) bonds. (b) The structure of \(\mathrm{B}_{5} \mathrm{H}_{9}\). There are five "normal" B - H bonds to terminal hydrogens and four three-center bridging bonds around the base.

\hline
\end{tabular}
pyramid. Because the boranes are extremely electron-deficient, they are highly reactive. The boranes react very exothermically with oxygen and were once evaluated as potential fuels for rockets in the U.S. space program.

Aluminum, the most abundant metal on earth, has metallic physical properties, such as high thermal and electrical conductivities and a lustrous appearance; however, its bonds to nonmetals are significantly covalent. This covalency is responsible for the amphoteric nature of \(\mathrm{Al}_{2} \mathrm{O}_{3}\), which dissolves in acidic or basic solution, and for the acidity of \(\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) (see Section 14.8):
\[
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q) \rightleftharpoons \mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}{ }^{2+}(a q)+\mathrm{H}^{+}(a q)
\]

One especially interesting property of gallium is its unusually low melting point of \(29.8^{\circ} \mathrm{C}\), which is in contrast to the \(660^{\circ} \mathrm{C}\) melting point of aluminum. Also, since gallium's boiling point is about \(2400^{\circ} \mathrm{C}\), it has the largest liquid range of any metal. This makes it useful for thermometers, especially to measure high temperatures. Gallium, like water, expands when it freezes. The chemistry of gallium is quite similar to that of aluminum. For example, \(\mathrm{Ga}_{2} \mathrm{O}_{3}\) is amphoteric.

The chemistry of indium is similar to that of aluminum and gallium except that compounds containing the \(1+\) ion are known, such as InCl and \(\mathrm{In}_{2} \mathrm{O}\), in addition to those with the more common \(3+\) ion. The chemistry of thallium is completely metallic.

Table 20.9 summarizes some important reactions of the Group 3A elements.

\subsection*{20.6 The Group 4A Elements}

Group 4A (with the valence electron configuration \(n s^{2} n p^{2}\) ) contains two of the most important elements on earth: carbon, the fundamental constituent of the molecules necessary for life, and silicon, which forms the basis of the geological world. The change from nonmetallic to metallic properties seen in Group 3A is also apparent in going down Group 4A from carbon, a typical nonmetal, to silicon and germanium, usually considered semimetals, to the metals tin and lead. Table 20.10 summarizes some physical properties, sources, and methods of preparation of the elements in this group.

All the Group 4A elements can form four covalent bonds to nonmetals-for example, \(\mathrm{CH}_{4}, \mathrm{SiF}_{4}, \mathrm{GeBr}_{4}, \mathrm{SnCl}_{4}\), and \(\mathrm{PbCl}_{4}\). In each of these tetrahedral molecules, the central atom is described as \(s p^{3}\) hybridized by the localized electron model.

We have seen that carbon also differs markedly from the other members of Group 4A in its ability to form \(\pi\) bonds. This accounts for the completely different structures and properties of \(\mathrm{CO}_{2}\) and \(\mathrm{SiO}_{2}\). Note from Table 20.11 that \(\mathrm{C}-\mathrm{C}\) bonds and \(\mathrm{Si}-\mathrm{O}\) bonds are stronger than \(\mathrm{Si}-\mathrm{Si}\) bonds. This partly explains why the chemistry of carbon is dominated by \(\mathrm{C}-\mathrm{C}\) bonds, whereas that of silicon is dominated by \(\mathrm{Si}-\mathrm{O}\) bonds.

\hline
\end{tabular}

Carbon occurs in the allotropic forms graphite, diamond, and fullerenes, whose structures were given in Section 10.5. The most important chemistry of carbon is organic chemistry, which is described in detail in Chapter 22.

Silicon, the second most abundant element in the earth's crust, is a semimetal found widely distributed in silica and silicates (see Section 10.5). About \(85 \%\) of the earth's crust is composed of these substances. Although silicon is found in some steel and aluminum alloys, its major use is in semiconductors for electronic devices (see Chapter 10).

Germanium, a relatively rare element, is a semimetal used mainly in the manufacture of semiconductors for transistors and similar electronic devices.

Tin is a soft, silvery metal that can be rolled into thin sheets (tin foil) and has been used for centuries in various alloys such as bronze ( \(20 \% \mathrm{Sn}\) and \(80 \% \mathrm{Cu}\) ), solder ( \(33 \%\) Sn and \(67 \% \mathrm{~Pb})\), and pewter \((85 \% \mathrm{Sn}, 7 \% \mathrm{Cu}, 6 \% \mathrm{Bi}\), and \(2 \% \mathrm{Sb})\). Tin exists as three allotropes: white tin, stable at normal temperatures; gray tin, stable at temperatures below \(13.2^{\circ} \mathrm{C}\); and brittle tin, found at temperatures above \(161^{\circ} \mathrm{C}\). When tin is exposed to low temperatures, it gradually changes to powdery gray tin and crumbles away; this is known as tin disease.

Currently, tin is used mainly as a protective coating for steel, especially for cans used as food containers. The thin layer of tin, applied electrolytically, forms a protective oxide coating that prevents further corrosion.

Lead is easily obtained from its ore, galena ( PbS ). Because lead melts at such a low temperature, it may have been the first pure metal obtained from its ore. We know that lead was used as early as 3000 b.c. by the Egyptians. It was later used by the Romans to make eating utensils, glazes on pottery, and even intricate plumbing systems. The Romans also prepared a sweetener called sapa by boiling down grape juice in leadlined vessels. The sweetness of this syrup was partly caused by the formation of lead(II) acetate (formerly called sugar of lead), a very sweet-tasting compound. The problem with these practices is that lead is very toxic. In fact, the Romans had so much contact with lead that it may have contributed to the demise of their civilization. Analysis of bones from that era shows significant levels of lead.

Although lead poisoning has been known since at least the second century b.c., lead continues to be a problem. For example, many children have been exposed to lead by eating chips of lead-based paint. Because of this problem, lead-based paints are no longer used for children's furniture, and many states have banned lead-based paint for interior use. Lead poisoning can also occur when acidic foods and drinks leach the lead from lead-glazed pottery dishes that were improperly fired and when liquor is stored in leaded crystal decanters, producing toxic levels of lead in the drink in a relatively short time. In addition, the widespread use of tetraethyl lead

\section*{CHEMICAL CDNNECTIDNS}

\section*{Beethoven: Hair Is the Story}
udwig van Beethoven, arguably the -greatest composer who ever lived, led a troubled life fraught with sickness, deafness, and personality aberrations. Now we may know the source of these difficulties: lead poisoning. Scientists have recently reached this conclusion through analysis of Beethoven's hair. When Beethoven died in 1827 at age 56 , many mourners took samples of the great man's hair. In fact, it was said at the time that he was practically bald by the time he was buried. The hair that was recently analyzed consisted of 582 strands- 3 to 6 inches long-bought for the Center of Beethoven Studies for \$7300 in 1994 from Sotheby's auction house in London.

According to William Walsh of the Health Research Institute (HRI) in suburban Chicago, Beethoven's hair showed a lead concentration 100 times the normal levels. The scientists concluded that Beethoven's exposure to
lead came as an adult, possibly from the mineral water he drank and swam in when he visited spas.

The lead poisoning may well explain Beethoven's volatile temper-the composer was subject to towering rages and sometimes had the look of a wild animal. In rare cases lead poisoning has been known to cause deafness, but the researchers remain unsure if this problem led to Beethoven's hearing loss.

According to Walsh, the scientists at HRI were originally looking for mercury, a common treatment for syphilis in the early nineteenth century, in Beethoven's hair. The absence of mercury supports the consensus of scholars that Beethoven did not have this disease. Not surprisingly, Beethoven himself wanted to know what made him so ill. In a letter to his brothers in 1802, he
asked them to have doctors find the cause of his frequent abdominal pain after his death.

Portrait of Beethoven by Josef Karl Stieler.
\(\left[\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{~Pb}\right]\) as an antiknock agent in gasoline has increased the lead levels in our environment. Concern about the effects of this lead pollution has caused the U.S. government to require the gradual replacement of the lead in gasoline with other antiknock agents. The largest commercial use of lead (over one million tons annually) is for electrodes in the lead storage batteries used in automobiles (see Section 18.5).

\subsection*{20.7 The Group 5A Elements}

FIGURE 20.8 The pyramidal shape of the Group 5A MX \({ }_{3}\) molecules.

The Group 5A elements (with the valence electron configuration \(n s^{2} n p^{3}\) ), which are prepared as shown in Table 20.13, exhibit remarkably varied chemical properties. As usual, metallic character increases going down the group, as is apparent from the electronegativity values (Table 20.13). Nitrogen and phosphorus are nonmetals that can gain three electrons to form 3- anions in salts with active metals; examples are magnesium nitride \(\left(\mathrm{Mg}_{3} \mathrm{~N}_{2}\right)\) and beryllium phosphide \(\left(\mathrm{Be}_{3} \mathrm{P}_{2}\right)\). The chemistry of these two important elements is discussed in the next two sections.

Bismuth and antimony tend to be metallic, readily losing electrons to form cations. Although these elements have five valence electrons, so much energy is required to remove all five that no ionic compounds containing \(\mathrm{Bi}^{5+}\) or \(\mathrm{Sb}^{5+}\) ions are known.

The Group 5A elements can form molecules or ions that involve three, five, or six covalent bonds to the Group 5A atom. Examples involving three single bonds are \(\mathrm{NH}_{3}\), \(\mathrm{PH}_{3}, \mathrm{NF}_{3}\), and \(\mathrm{AsCl}_{3}\). Each of these molecules has a lone pair of electrons (and thus can behave as a Lewis base) and a pyramidal shape as predicted by the VSEPR model (Fig. 20.8).

All the Group 5A elements except nitrogen can form molecules with five covalent bonds (of general formula \(\mathrm{MX}_{5}\) ). Nitrogen cannot form such molecules because of its small size. The \(\mathrm{MX}_{5}\) molecules have a trigonal bipyramidal shape (Fig. 20.9) as predicted by the VSEPR model, and the central atom can be described as \(d s p^{3}\) hybridized.

Although the \(\mathrm{MX}_{5}\) molecules have a trigonal bipyramidal structure in the gas phase, the solids of many of these compounds contain a \(1: 1\) mixture of the ions \(\mathrm{MX}_{4}{ }^{+}\)and \(\mathrm{MX}_{6}{ }^{-}\)(Fig. 20.10). The \(\mathrm{MX}_{4}{ }^{+}\)cation is tetrahedral (the atom represented by M is \(s p^{3}\) hybridized), and the \(\mathrm{MX}_{6}{ }^{-}\)anion is octahedral (the atom represented by M is \(d^{2} s p^{3}\)

FIGURE 20.9 The trigonal bipyramidal shape of the \(\mathrm{MX}_{5}\) molecules.

FIGURE 20.10 The structures of the tetrahedral \(\mathrm{MX}_{4}{ }^{+}\) and the octahedral \(\mathrm{MX}_{6}{ }^{-}\)ions.

\end{tabular}
hybridized). Examples are \(\mathrm{PCl}_{5}\) (which in the solid state contains \(\mathrm{PCl}_{4}{ }^{+}\)and \(\mathrm{PCl}_{6}{ }^{-}\)) and \(\mathrm{AsF}_{3} \mathrm{Cl}_{2}\) (which in the solid state contains \(\mathrm{AsCl}_{4}{ }^{+}\)and \(\mathrm{AsF}_{6}{ }^{-}\)).

As discussed in Section 20.1, the ability of the Group 5A elements to form \(\pi\) bonds decreases dramatically after nitrogen. This explains why elemental nitrogen exists as \(\mathrm{N}_{2}\) molecules containing two \(\pi\) bonds, whereas the other elements in the group exist as larger aggregates containing single bonds. For example, in the gas phase the elements phosphorus, arsenic, and antimony consist of \(\mathrm{P}_{4}, \mathrm{As}_{4}\), and \(\mathrm{Sb}_{4}\) molecules, respectively.

\subsection*{20.8 The Chemistry of Nitrogen}

At the earth's surface virtually all elemental nitrogen exists as the \(\mathrm{N}_{2}\) molecule with its very strong triple bond ( \(941 \mathrm{~kJ} / \mathrm{mol}\) ). Because of this large bond strength, the \(\mathrm{N}_{2}\) molecule is so unreactive that it can coexist with most other elements under normal conditions without undergoing any appreciable reaction. This property makes nitrogen gas very useful as a medium for experiments involving substances that react with oxygen or water. Such experiments can be done using an inert atmosphere box of the type shown in Fig. 20.11.

The strength of the triple bond in the \(\mathrm{N}_{2}\) molecule is important both thermodynamically and kinetically. Thermodynamically, the great stability of the \(\mathrm{N} \equiv \mathrm{N}\) bond means that most binary compounds containing nitrogen decompose exothermically to the elements, for example:
\[
\begin{aligned}
\mathrm{N}_{2} \mathrm{O}(g) \longrightarrow \mathrm{N}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) & \Delta H^{\circ}=-82 \mathrm{~kJ} \\
\mathrm{NO}(g) \longrightarrow \frac{1}{2} \mathrm{~N}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) & \Delta H^{\circ}=-90 \mathrm{~kJ} \\
\mathrm{NO}_{2}(g) \longrightarrow \frac{1}{2} \mathrm{~N}_{2}(g)+\mathrm{O}_{2}(g) & \Delta H^{\circ}=-34 \mathrm{~kJ} \\
\mathrm{~N}_{2} \mathrm{H}_{4}(g) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2}(g) & \Delta H^{\circ}=-95 \mathrm{~kJ} \\
\mathrm{NH}_{3}(g) \longrightarrow \frac{1}{2} \mathrm{~N}_{2}(g)+\frac{3}{2} \mathrm{H}_{2}(g) & \Delta H^{\circ}=+46 \mathrm{~kJ}
\end{aligned}
\]

Of these compounds, only ammonia is thermodynamically more stable than its component elements. That is, only for ammonia is energy required to decompose the molecule to its elements. For the remaining molecules, energy is released when decomposition to the elements occurs, as a result of the great stability of \(\mathrm{N}_{2}\).

The importance of the thermodynamic stability of \(\mathrm{N}_{2}\) can be clearly seen in the power of nitrogen-based explosives, such as nitroglycerin \(\left(\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{~N}_{3} \mathrm{O}_{9}\right)\), which has the following skeletal structure:

FIGURE 20.11 An inert atmosphere box used when working with oxygen- or water-sensitive materials. The box is filled with an inert gas such as nitrogen, and work is done through the ports fitted with large rubber gloves.

FIGURE 20.12 A schematic diagram of the Haber process for the manufacture of ammonia.

When ignited or subjected to sudden impact, nitroglycerin decomposes very rapidly and exothermically:
\[
4 \mathrm{C}_{3} \mathrm{H}_{5} \mathrm{~N}_{3} \mathrm{O}_{9}(l) \longrightarrow 6 \mathrm{~N}_{2}(g)+12 \mathrm{CO}_{2}(g)+10 \mathrm{H}_{2} \mathrm{O}(g)+\mathrm{O}_{2}(g)+\text { energy }
\]

An explosion occurs; that is, large volumes of gas are produced in a fast, highly exothermic reaction. Note that 4 moles of liquid nitroglycerin produce \(29(6+12+10+1)\) moles of gaseous products. This alone produces a large increase in volume. However, also note that the products, which include \(\mathrm{N}_{2}\), are very stable molecules with strong bonds. Their formation is therefore accompanied by the release of large quantities of energy as heat, which increases the gaseous volume. The hot, rapidly expanding gases produce a pressure surge and damaging shock wave.

Most high explosives are organic compounds that, like nitroglycerin, contain nitro \(\left(-\mathrm{NO}_{2}\right)\) groups and produce nitrogen and other gases as products. Another example is trinitrotoluene (TNT), a solid at normal temperatures, which decomposes as follows:
\[
2 \mathrm{C}_{7} \mathrm{H}_{5} \mathrm{~N}_{3} \mathrm{O}_{6}(s) \longrightarrow 12 \mathrm{CO}(g)+5 \mathrm{H}_{2}(g)+3 \mathrm{~N}_{2}(g)+2 \mathrm{C}(s)+\text { energy }
\]

Note that 2 moles of solid TNT produce 20 moles of gaseous products plus energy.
The effect of bond strength on the kinetics of reactions involving the \(\mathrm{N}_{2}\) molecule is illustrated by the synthesis of ammonia from nitrogen and hydrogen, a reaction we have discussed many times before. Because a large quantity of energy is required to disrupt the \(\mathrm{N} \equiv \mathrm{N}\) bond, the ammonia synthesis reaction occurs at a negligible rate at room temperature, even though the equilibrium constant is very large ( \(K \approx 10^{8}\) ). Of course, the most direct way to increase the rate of a reaction is to raise the temperature. However, since this reaction is very exothermic,
\[
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g) \quad \Delta H^{\circ}=-92 \mathrm{~kJ}
\]
the value of \(K\) decreases significantly with a temperature increase (at \(500^{\circ} \mathrm{C}, K \approx 10^{-2}\) ).
Obviously, the kinetics and the thermodynamics of this reaction are in opposition. A compromise must be reached, involving high pressure to force the equilibrium to the right and high temperature to produce a reasonable rate. The Haber process for manufacturing ammonia represents such a compromise (Fig. 20.12). The process is carried out at a pressure of about 250 atm and a temperature of approximately \(400^{\circ} \mathrm{C}\). Even higher temperatures would be required if a catalyst consisting of a solid iron oxide mixed with small amounts of potassium oxide and aluminum oxide were not used to facilitate the reaction.

Nitrogen is essential to living systems. The problem with nitrogen is not one of supply-we are surrounded by it-but rather one of changing it from the inert \(\mathrm{N}_{2}\) molecule to a form usable by plants and animals. The process of transforming \(\mathrm{N}_{2}\) to other nitrogen-containing compounds is called nitrogen fixation. The Haber process is one example of nitrogen fixation. The ammonia produced can be applied to the soil as a fertilizer, since plants can readily use the nitrogen in ammonia to make the nitrogencontaining biomolecules essential for their growth.

Nitrogen fixation also results from the high-temperature combustion process in automobile engines. The nitrogen in the air is drawn into the engine and reacts at a significant rate with oxygen to form nitric oxide ( NO ), which further reacts with oxygen from the air to form nitrogen dioxide \(\left(\mathrm{NO}_{2}\right)\). This nitrogen dioxide, which contributes to photochemical smog in many urban areas (see Section 12.8), reacts with moisture in the air and eventually reaches the soil to form nitrate salts, which are plant nutrients.

Nitrogen fixation also occurs naturally. For example, lightning provides the energy to disrupt \(\mathrm{N}_{2}\) and \(\mathrm{O}_{2}\) molecules in the air, producing highly reactive nitrogen and oxygen atoms. These atoms in turn attack other \(\mathrm{N}_{2}\) and \(\mathrm{O}_{2}\) molecules to form nitrogen oxides that eventually become nitrates. Although lightning has traditionally been credited with forming about \(10 \%\) of the total fixed nitrogen, recent studies indicate that lightning may account for as much as half of the fixed nitrogen available on earth. Another natural nitrogen fixation process involves bacteria that reside in the root

A
Nodules on the roots of pea plants contain nitrogen-fixing bacteria.

FIGURE 20.14 The molecular structure of hydrazine \(\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)\). This arrangement minimizes the repulsion between the lone pairs on the nitrogen atoms by placing them on opposite sides.

FIGURE 20.13 The nitrogen cycle. To be used by plants and animals, nitrogen must be converted from \(\mathrm{N}_{2}\) to nitrogen-containing compounds, such as nitrates, ammonia, and proteins. The nitrogen is returned to the atmosphere by natural decay processes.
nodules of plants such as beans, peas, and alfalfa. These nitrogen-fixing bacteria readily allow the conversion of nitrogen to ammonia and to other nitrogen-containing compounds useful to plants. The efficiency of these bacteria is intriguing: They produce ammonia at soil temperatures and 1 atm pressure, whereas the Haber process requires severe conditions of \(400^{\circ} \mathrm{C}\) and 250 atm . For obvious reasons, researchers are studying these bacteria intensively.

When plants and animals die and decompose, the elements they consist of are returned to the environment. In the case of nitrogen, the return of the element to the atmosphere as nitrogen gas, called denitrification, is carried out by bacteria that change nitrates to nitrogen. The complex nitrogen cycle is summarized in Fig. 20.13. It has been estimated that as much as 10 million tons more nitrogen per year is currently being fixed by natural and human processes than is being returned to the atmosphere. This fixed nitrogen is accumulating in soil, lakes, rivers, and oceans, where it promotes the growth of algae and other undesirable organisms.

\section*{Nitrogen Hydrides}

By far the most important hydride of nitrogen is ammonia. A toxic, colorless gas with a pungent odor, ammonia is manufactured in huge quantities (approximately 40 billion pounds per year), mainly for use in fertilizers.

The pyramidal ammonia molecule has a lone pair of electrons on its nitrogen atom (see Fig. 20.8) and polar N - H bonds. This structure leads to a high degree of intermolecular interaction by hydrogen bonding in the liquid state, thereby producing an unusually high boiling point \(\left(-33.4^{\circ} \mathrm{C}\right)\) for a substance with such a low molar mass. Note, however, that the hydrogen bonding in liquid ammonia is clearly not as important as that in liquid water, which has about the same molar mass but a much higher boiling point. The water molecule has two polar bonds involving hydrogen and two lone pairs-the right combination for optimum hydrogen bonding-in contrast to the one lone pair and three polar bonds of the ammonia molecule.

As we saw in Chapter 14, ammonia behaves as a base, reacting with acids to produce ammonium salts. For example,
\[
\mathrm{NH}_{3}(g)+\mathrm{HCl}(g) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(s)
\]

A second nitrogen hydride of major importance is hydrazine \(\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)\). The Lewis structure of hydrazine

indicates that each nitrogen atom should be \(s p^{3}\) hybridized with bond angles close to \(109.5^{\circ}\) (the tetrahedral angle), since the nitrogen atom is surrounded by four electron pairs. The observed structure with bond angles of \(112^{\circ}\) (Fig. 20.14) agrees reasonably

A
Blowing agents-such as hydrazine, which forms nitrogen gas on decomposition-are used to produce porous plastics like these polystyrene products.
well with these predictions. Hydrazine, a colorless liquid with an ammoniacal odor, freezes at \(2^{\circ} \mathrm{C}\) and boils at \(113.5^{\circ} \mathrm{C}\). This boiling point is quite high for a compound with a molar mass of 32 ; this suggests that considerable hydrogen bonding occurs among the polar hydrazine molecules.

Hydrazine is a powerful reducing agent and has been widely used as a rocket propellant. For example, its reaction with oxygen is highly exothermic:
\[
\mathrm{N}_{2} \mathrm{H}_{4}(l)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g) \quad \Delta H^{\circ}=-622 \mathrm{~kJ}
\]

Since hydrazine also reacts vigorously with the halogens, fluorine is often used instead of oxygen as the oxidizer in rocket engines. Substituted hydrazines, where one or more of the hydrogen atoms are replaced by other groups, are also useful rocket fuels. For example, monomethylhydrazine,

is used with the oxidizer dinitrogen tetroxide \(\left(\mathrm{N}_{2} \mathrm{O}_{4}\right)\) to power the U.S. space shuttle orbiter. The reaction is
\[
5 \mathrm{~N}_{2} \mathrm{O}_{4}(l)+4 \mathrm{~N}_{2} \mathrm{H}_{3}\left(\mathrm{CH}_{3}\right)(l) \longrightarrow 12 \mathrm{H}_{2} \mathrm{O}(g)+9 \mathrm{~N}_{2}(g)+4 \mathrm{CO}_{2}(g)
\]

Because of the large number of gaseous molecules produced and the exothermic nature of this reaction, a very high thrust per mass of fuel is achieved. The reaction is also self-starting-it begins immediately when the fuels are mixed-which is a useful property for rocket engines that must be started and stopped frequently.

The use of hydrazine as a rocket propellant is a rather specialized application. The main industrial use of hydrazine is as a "blowing" agent in the manufacture of plastics. Hydrazine decomposes to form nitrogen gas, which causes foaming in the liquid plastic and results in a porous texture. Another major use of hydrazine is in the production of agricultural pesticides. Of the many hundreds of hydrazine derivatives (substituted hydrazines) that have been tested, 40 are used as fungicides, herbicides, insecticides, or plant growth regulators.

\section*{Nitrogen Oxides}

Nitrogen forms a series of oxides in which its oxidation state ranges from +1 to +5 , as shown in Table 20.14.

Dinitrogen monoxide \(\left(\mathrm{N}_{2} \mathrm{O}\right)\), more commonly called nitrous oxide or laughing gas, has an inebriating effect and has been used as a mild anesthetic by dentists. Because of its high solubility in fats, nitrous oxide is widely used as a propellant in aerosol cans of whipped cream. It is dissolved in the liquid inside the can at high pressure and forms bubbles that produce foaming as the liquid is released from the can. A significant amount of \(\mathrm{N}_{2} \mathrm{O}\) exists in the atmosphere, mostly produced by soil microorganisms, and its concentration appears to be gradually increasing. Because it can strongly absorb infrared radiation, nitrous oxide plays a small but probably significant role in controlling the earth's temperature in the same way that atmospheric carbon dioxide and water vapor do (see the discussion of the greenhouse effect in Section 6.5). Some scientists fear that the rapid decrease of tropical rain forests resulting from the development of countries such as Brazil will significantly affect the rate of production of \(\mathrm{N}_{2} \mathrm{O}\) by soil organisms and thus will have important effects on the earth's temperature.

Nitrogen monoxide (NO), commonly called nitric oxide, has been found to be an important regulator in biological systems. Nitric oxide is a colorless gas under normal conditions and can be produced in the laboratory by reacting \(6 M\) nitric acid with copper metal:
\[
8 \mathrm{H}^{+}(a q)+2 \mathrm{NO}_{3}^{-}(a q)+3 \mathrm{Cu}(s) \longrightarrow 3 \mathrm{Cu}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{NO}(g)
\]

When this reaction is carried out in the air, the nitric oxide is immediately oxidized by \(\mathrm{O}_{2}\) to reddish brown nitrogen dioxide \(\left(\mathrm{NO}_{2}\right)\).

A
A copper penny reacts with nitric acid to produce NO gas, which is immediately oxidized in air to give reddish brown \(\mathrm{NO}_{2}\).

TABLE 20.14 | Some Common Nitrogen Compounds
\begin{tabular}{|c|c|c|c|}
\hline Oxidation State of Nitrogen & Compound & Formula & Lewis Structure* \\
\hline -3 & Ammonia & \(\mathrm{NH}_{3}\) &  \\
\hline -2 & Hydrazine & \(\mathrm{N}_{2} \mathrm{H}_{4}\) &  \\
\hline -1 & Hydroxylamine & \[
\mathrm{NH}_{2} \mathrm{OH}
\] &  \\
\hline 0 & Nitrogen & \(\mathrm{N}_{2}\) & \(: \mathrm{N} \equiv \mathrm{N}\) : \\
\hline +1 & Dinitrogen monoxide (nitrous oxide) & \(\mathrm{N}_{2} \mathrm{O}\) & \(\therefore \mathrm{N}=\mathrm{N}=\dot{\mathrm{O}}\) \\
\hline +2 & Nitrogen monoxide (nitric oxide) & NO & \(\mathrm{N}=\mathrm{O}\) \\
\hline +3 & Dinitrogen trioxide & \(\mathrm{N}_{2} \mathrm{O}_{3}\) &  \\
\hline +4 & Nitrogen dioxide & \(\mathrm{NO}_{2}\) & \(: \ddot{\mathrm{O}}-\dot{\mathrm{N}}=\dot{\mathrm{O}}\) \\
\hline +5 & Nitric acid & \(\mathrm{HNO}_{3}\) &  \\
\hline
\end{tabular}
*In some cases additional resonance structures are needed to fully describe the electron distribution.

Since the NO molecule has an odd number of electrons, it is most conveniently described in terms of the molecular orbital model. The molecular orbital energy-level diagram is shown in Fig. 20.15. Note that the NO molecule should be paramagnetic and have a bond order of 2.5 , predictions that are supported by experimental observations. Since the NO molecule has one high-energy electron, it is not surprising that it can be rather easily oxidized to form \(\mathrm{NO}^{+}\), the nitrosyl ion. Because an antibonding electron is removed in going from NO to \(\mathrm{NO}^{+}\), the resulting ion should have a stronger bond (the predicted bond order is 3 ) than the molecule. This is borne out by experiment. The bond lengths and bond energies for nitric oxide and the nitrosyl ion are shown in Table 20.15.

Nitric oxide is thermodynamically unstable and decomposes to nitrous oxide and nitrogen dioxide:
\[
3 \mathrm{NO}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}(g)+\mathrm{NO}_{2}(g)
\]

Nitrogen dioxide \(\left(\mathrm{NO}_{2}\right)\), which is also an odd-electron molecule, has a V-shaped structure. The reddish brown, paramagnetic \(\mathrm{NO}_{2}\) molecule readily dimerizes to form dinitrogen tetroxide,
\[
2 \mathrm{NO}_{2}(g) \rightleftharpoons \mathrm{N}_{2} \mathrm{O}_{4}(g)
\]
which is diamagnetic and colorless. The value of the equilibrium constant is approximately 1 for this process at \(55^{\circ} \mathrm{C}\), and since the dimerization is exothermic, \(K\) decreases as the temperature increases.

FIGURE 20.15 The molecular orbital energy-level diagram for nitric oxide (NO). The bond order is 2.5 , or \((8-3) / 2\).

FIGURE 20.16 The Ostwald process.

The least common of the nitrogen oxides are dinitrogen trioxide \(\left(\mathrm{N}_{2} \mathrm{O}_{3}\right)\), a blue liquid that readily dissociates to gaseous nitric oxide and nitrogen dioxide, and dinitrogen pentoxide \(\left(\mathrm{N}_{2} \mathrm{O}_{5}\right)\), which under normal conditions is a solid that is best viewed as a mixture of \(\mathrm{NO}_{2}{ }^{+}\)and \(\mathrm{NO}_{3}{ }^{-}\)ions. Although \(\mathrm{N}_{2} \mathrm{O}_{5}\) molecules can exist in the gas phase, they readily dissociate to nitrogen dioxide and oxygen:
\[
2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \rightleftharpoons 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
\]

This reaction follows first-order kinetics, as discussed in Section 12.4.

\section*{Oxyacids of Nitrogen}

Nitric acid is an important industrial chemical (approximately 8 million tons produced annually) used in the manufacture of many products, such as nitrogen-based explosives and ammonium nitrate for use as a fertilizer.

Nitric acid is produced commercially by the oxidation of ammonia in the Ostwald process (Fig. 20.16). In the first step of this process, ammonia is oxidized to nitric oxide:
\[
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g) \quad \Delta H^{\circ}=-905 \mathrm{~kJ}
\]

Although this reaction is highly exothermic, it is very slow at \(25^{\circ} \mathrm{C}\). A side reaction occurs between nitric oxide and ammonia:
\[
4 \mathrm{NH}_{3}(g)+6 \mathrm{NO}(g) \longrightarrow 5 \mathrm{~N}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
\]
which is particularly undesirable because it traps the nitrogen in the very unreactive \(\mathrm{N}_{2}\) molecules. The desired reaction can be accelerated and the effects of the competing reaction can be minimized if the ammonia oxidation is carried out by using a catalyst of a platinum-rhodium alloy heated to \(900^{\circ} \mathrm{C}\). Under these conditions, there is a \(97 \%\) conversion of the ammonia to nitric oxide.

In the second step, nitric oxide is reacted with oxygen to produce nitrogen dioxide:
\[
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g) \quad \Delta H^{\circ}=-113 \mathrm{~kJ}
\]

This oxidation reaction has a rate that decreases with increasing temperature. Because of this very unusual behavior, the reaction is carried out at approximately \(25^{\circ} \mathrm{C}\) and is kept at this temperature by cooling with water.

The third step in the Ostwald process is the absorption of nitrogen dioxide by water:
\[
3 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{HNO}_{3}(a q)+\mathrm{NO}(g) \quad \Delta H^{\circ}=-139 \mathrm{~kJ}
\]

\section*{CHEMICAL CONNECTIONS}

\section*{Nitrous Oxide: Laughing Gas That Propels Whipped Cream and Cars}

Na
itrous oxide \(\left(\mathrm{N}_{2} \mathrm{O}\right)\), more properly called dinitrogen monoxide, is a compound with many interesting uses. It was discovered in 1772 by Joseph Priestley (who is also given credit for discovering oxygen gas), and its intoxicating effects were noted almost immediately. In 1798, the 20-year-old Humphry Davy became director of the Pneumatic Institute, which was set up to investigate the medical effects of various gases. Davy tested the effects of \(\mathrm{N}_{2} \mathrm{O}\) on himself, reporting that after inhaling 16 quarts of the gas in 7 minutes, he became "absolutely intoxicated."

Over the next century "laughing gas," as nitrous oxide became known, was developed as an anesthetic, particularly for dental procedures. Nitrous oxide is still used as an anesthetic, although it has been primarily replaced by more modern drugs.

One major use of nitrous oxide today is as the propellant in cans of "instant" whipped cream. The high solubility of \(\mathrm{N}_{2} \mathrm{O}\) in the whipped cream mixture makes it an excellent candidate for pressurizing the cans of whipping cream.

Another current use of nitrous oxide is to produce "instant horsepower" for street racers. Because the reaction of
\(\mathrm{N}_{2} \mathrm{O}\) with \(\mathrm{O}_{2}\) to form NO actually absorbs heat, this reaction has a cooling effect when placed in the fuel mixture in an automobile engine. This cooling effect lowers combustion temperatures, thus allowing the fuelair mixture to be significantly more dense (the density of a gas is inversely proportional to temperature). The effect can produce a burst of additional power in excess of 200 horsepower. Because engines are not designed to run steadily at such high power levels, the nitrous oxide is injected from a tank when extra power is desired.

An azeotrope is a solution that, like a pure liquid, distills at a constant temperature without a change in composition.

FIGURE 20.17 (a) The molecular structure of \(\mathrm{HNO}_{3}\). (b) The resonance structures of \(\mathrm{HNO}_{3}\).

-a

that forms pale yellow nitrite \(\left(\mathrm{NO}_{2}{ }^{-}\right)\)salts. In contrast to nitrates, which are often used as explosives, nitrites are quite stable even at high temperatures.
The gaseous NO produced in the reaction is recycled so that it can be oxidized to \(\mathrm{NO}_{2}\). The aqueous nitric acid from this process is about \(50 \% \mathrm{HNO}_{3}\) by mass, which can be increased to \(68 \%\) by distillation to remove some of the water. The maximum concentration attainable by this method is \(68 \%\) because nitric acid and water form an azeotrope at this concentration. The solution can be further concentrated to \(95 \% \mathrm{HNO}_{3}\) by treatment with concentrated sulfuric acid, which strongly absorbs water; \(\mathrm{H}_{2} \mathrm{SO}_{4}\) is often used as a dehydrating (water-removing) agent.

Nitric acid is a colorless, fuming liquid ( \(\mathrm{bp}=83^{\circ} \mathrm{C}\) ) with a pungent odor; it decomposes in sunlight by the following reaction:
\[
4 \mathrm{HNO}_{3}(l) \xrightarrow{h \nu} 4 \mathrm{NO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
\]

As a result, nitric acid turns yellow as it ages because of the dissolved nitrogen dioxide. The common laboratory reagent called concentrated nitric acid is \(15.9 \mathrm{M} \mathrm{HO}_{3}\) ( \(70.4 \% \mathrm{HNO}_{3}\) by mass) and is a very strong oxidizing agent. The resonance structures and molecular structure of \(\mathrm{HNO}_{3}\) are shown in Fig. 20.17. Note that the hydrogen is bound to an oxygen atom rather than to nitrogen as the formula might suggest.

Nitrous acid \(\left(\mathrm{HNO}_{2}\right)\) is a weak acid,
\[
\mathrm{HNO}_{2}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{NO}_{2}^{-}(a q) \quad K_{\mathrm{a}}=4.0 \times 10^{-4}
\]

\subsection*{20.9 The Chemistry of Phosphorus}

\section*{A}

White phosphorus reacts vigorously with the oxygen in air and must be stored under water. Red phosphorus is stable in air.

The terminal oxygens are the nonbridging oxygen atoms.

Although phosphorus lies directly below nitrogen in Group 5A of the periodic table, its chemical properties are significantly different from those of nitrogen. The differences arise mainly from four factors: nitrogen's ability to form much stronger \(\pi\) bonds, the greater electronegativity of nitrogen, the larger size of phosphorus atoms, and the potential availability of empty valence \(d\) orbitals on phosphorus.

The chemical differences between nitrogen and phosphorus are apparent in their elemental forms. In contrast to the diatomic form of elemental nitrogen, which is stabilized by strong \(\pi\) bonds, there are several solid forms of phosphorus that all contain aggregates of atoms. White phosphorus, which contains discrete tetrahedral \(\mathrm{P}_{4}\) molecules [Fig. 20.18(a)], is very reactive; it bursts into flames on contact with air (it is said to be pyrophoric). Consequently, white phosphorus is commonly stored under water. White phosphorus is quite toxic; the \(\mathrm{P}_{4}\) molecules are very damaging to tissue, particularly the cartilage and bones of the nose and jaw. The much less reactive forms, called black phosphorus and red phosphorus, are network solids (see Section 10.5). Black phosphorus has a regular crystalline structure [Fig. 20.18(b)], but red phosphorus is amorphous and is thought to consist of chains of \(\mathrm{P}_{4}\) units [Fig. 20.18(c)]. Red phosphorus can be obtained by heating white phosphorus in the absence of air at 1 atm . Black phosphorus is obtained from either white or red phosphorus by heating at high pressures.

Even though phosphorus has a lower electronegativity than nitrogen, it will form phosphides (ionic substances containing the \(\mathrm{P}^{3-}\) anion) such as \(\mathrm{Na}_{3} \mathrm{P}\) and \(\mathrm{Ca}_{3} \mathrm{P}_{2}\). Phosphide salts react vigorously with water to produce phosphine \(\left(\mathrm{PH}_{3}\right)\), a toxic, colorless gas:
\[
2 \mathrm{Na}_{3} \mathrm{P}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{PH}_{3}(g)+6 \mathrm{Na}^{+}(a q)+6 \mathrm{OH}^{-}(a q)
\]

Phosphine is analogous to ammonia, although it is a much weaker base ( \(K_{\mathrm{b}} \approx 10^{-26}\) ) and is much less soluble in water.

Phosphine has the Lewis structure

and a pyramidal molecular structure, as we would predict from the VSEPR model. However, it has bond angles of \(94^{\circ}\) rather than \(107^{\circ}\), as found in the ammonia molecule. The reasons for this are complex; therefore, we will simply regard phosphine as an exception to the simple version of the VSEPR model that we use.

\section*{Phosphorus Oxides and Oxyacids}

Phosphorus reacts with oxygen to form oxides in which its oxidation states are +5 and +3 . The oxide \(\mathrm{P}_{4} \mathrm{O}_{6}\) is formed when elemental phosphorus is burned in a limited supply of oxygen, and \(\mathrm{P}_{4} \mathrm{O}_{10}\) is produced when the oxygen is in excess. Picture these oxides (shown in Fig. 20.19) as being constructed by adding oxygen atoms to the fundamental \(\mathrm{P}_{4}\) structure. The intermediate states, \(\mathrm{P}_{4} \mathrm{O}_{7}, \mathrm{P}_{4} \mathrm{O}_{8}\), and \(\mathrm{P}_{4} \mathrm{O}_{9}\), which contain one, two, and three terminal oxygen atoms, respectively, are also known.

-a

-b

-

FIGURE 20.19 The structures of \(\mathrm{P}_{4} \mathrm{O}_{6}\) and \(\mathrm{P}_{4} \mathrm{O}_{10}\).

FIGURE 20.20 (a) The structure of phosphorous acid \(\left(\mathrm{H}_{3} \mathrm{PO}_{3}\right)\). (b) The structure of hypophosphorous acid \(\left(\mathrm{H}_{3} \mathrm{PO}_{2}\right)\).

Tetraphosphorus decoxide \(\left(\mathrm{P}_{4} \mathrm{O}_{10}\right)\), which was formerly represented as \(\mathrm{P}_{2} \mathrm{O}_{5}\) and called phosphorus pentoxide, has a great affinity for water and thus is a powerful dehydrating agent. For example, it can be used to convert \(\mathrm{HNO}_{3}\) and \(\mathrm{H}_{2} \mathrm{SO}_{4}\) to their parent oxides, \(\mathrm{N}_{2} \mathrm{O}_{5}\) and \(\mathrm{SO}_{3}\), respectively.

When tetraphosphorus decoxide dissolves in water, phosphoric acid \(\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)\), also called orthophosphoric acid, is produced:
\[
\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{4}(a q)
\]

Pure phosphoric acid is a white solid that melts at \(42^{\circ} \mathrm{C}\). Aqueous phosphoric acid is a much weaker acid ( \(K_{\mathrm{a}_{1}} \approx 10^{-2}\) ) than nitric acid or sulfuric acid and is a poor oxidizing agent.

When the oxide \(\mathrm{P}_{4} \mathrm{O}_{6}\) is placed in water, phosphorous acid \(\left(\mathrm{H}_{3} \mathrm{PO}_{3}\right)\) is formed [Fig. 20.20(a)]. Although the formula suggests a triprotic acid, phosphorous acid is a diprotic acid. The hydrogen atom bonded directly to the phosphorus atom is not acidic in aqueous solution; only those hydrogen atoms bonded to the oxygen atoms in \(\mathrm{H}_{3} \mathrm{PO}_{3}\) can be released as protons.

A third oxyacid of phosphorus is hypophosphorous acid \(\left(\mathrm{H}_{3} \mathrm{PO}_{2}\right)\) [Fig. 20.20(b)], which is a monoprotic acid.

\section*{Phosphorus in Fertilizers}

Phosphorus is essential for plant growth. Although most soil contains large amounts of phosphorus, it is often present in insoluble minerals, making it inaccessible to the plants. Soluble phosphate fertilizers are manufactured by treating phosphate rock with sulfuric acid to make superphosphate of lime, a mixture of \(\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}\) and \(\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{PO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}\). If phosphate rock is treated with phosphoric acid, \(\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{PO}_{4}\right)_{2}\), known as triple phosphate, is produced. The reaction of ammonia with phosphoric acid gives ammonium dihydrogen phosphate \(\left(\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}\right)\), a very efficient fertilizer that furnishes both phosphorus and nitrogen.

\hline Polonium & 2.0 & 230 & Pitchblende & \\
\hline
\end{tabular}

\subsection*{20.10 The Group 6A Elements}

Although in Group 6A (Table 20.16) there is the usual tendency for metallic properties to increase going down the group, none of the Group 6A elements behaves as a typical metal. The most common chemical behavior of a Group 6A element involves reacting with a metal to achieve a noble gas electron configuration by adding two electrons to become a \(2-\) anion in ionic compounds. In fact, for most metals, the oxides and sulfides constitute the most common minerals.

The Group 6A elements can form covalent bonds with other nonmetals. For example, they combine with hydrogen to form a series of covalent hydrides of the general formula \(\mathrm{H}_{2} \mathrm{X}\). Those members of the group that have valence \(d\) orbitals available (all

A
Walnuts contain trace amounts of selenium. except oxygen) commonly form molecules in which they are surrounded by more than eight electrons. Examples are \(\mathrm{SF}_{4}, \mathrm{SF}_{6}, \mathrm{TeI}_{4}\), and \(\mathrm{SeBr}_{4}\).

The two heaviest members of Group 6A can lose electrons to form cations. Although they do not lose all six valence electrons because of the high energies that would be required, tellurium and polonium appear to exhibit some chemistry involving their 4+ cations. However, the chemistry of these Group 6A cations is much more limited than that of the Group 5A elements bismuth and antimony.

In recent years there has been a growing interest in the chemistry of selenium, an element found throughout the environment in trace amounts. Selenium's toxicity has long been known, but some medical studies have shown an inverse relationship between the incidence of cancer and the selenium levels in soil. It has been suggested that the greater dietary intake of selenium by people living in areas with relatively high selenium levels somehow furnishes protection from cancer. These studies are only preliminary, but selenium is definitely known to be physiologically important (it is involved in the activity of vitamin E and certain enzymes). Selenium (as well as tellurium) is also a semiconductor and therefore finds some application in the electronics industry.

Polonium was discovered in 1898 by Marie and Pierre Curie in their search for the sources of radioactivity in pitchblende. Polonium has 27 isotopes and is highly toxic and very radioactive. It has been suggested that the isotope \({ }^{210} \mathrm{Po}\), a natural contaminant of tobacco and an \(\alpha\)-particle producer (see Section 19.1), might be at least partly responsible for the incidence of cancer in smokers.

\subsection*{20.11 The Chemistry of Oxygen}

It is hard to overstate the importance of oxygen, the most abundant element in and near the earth's crust. Oxygen is present in the atmosphere as oxygen gas and ozone; in soil and rocks in oxide, silicate, and carbonate minerals; in the oceans in water; and in our bodies in water and a myriad of other molecules. In addition, most of the energy we

\(\Delta\)
Young Hoon Oh on Mt Everest uses supplemental oxygen to survive in the rarified air at this high elevation.

Scientists have become concerned that Freons and nitrogen dioxide are promoting the destruction of the ozone layer (see Section 12.8).
need to live and run our civilization comes from the exothermic reactions of oxygen with carbon-containing molecules.

The most common elemental form of oxygen \(\left(\mathrm{O}_{2}\right)\) constitutes \(21 \%\) of the volume of the earth's atmosphere. Since nitrogen has a lower boiling point than oxygen, nitrogen can be boiled away from liquid air, leaving oxygen and small amounts of argon, another component of air. Liquid oxygen is a pale blue liquid that freezes at \(-219^{\circ} \mathrm{C}\) and boils at \(-183^{\circ} \mathrm{C}\). The paramagnetism of the \(\mathrm{O}_{2}\) molecule can be demonstrated by pouring liquid oxygen between the poles of a strong magnet, where it "sticks" until it boils away (see Fig. 9.39). The paramagnetism of the \(\mathrm{O}_{2}\) molecule can be accounted for by the molecular orbital model (Fig. 9.38), which also explains its bond strength.

The other form of elemental oxygen is ozone \(\left(\mathrm{O}_{3}\right)\), a molecule that can be represented by the resonance structures

The bond angle in the \(\mathrm{O}_{3}\) molecule is \(117^{\circ}\), in reasonable agreement with the prediction of the VSEPR model (three effective pairs require a trigonal planar arrangement). That the bond angle is slightly less than \(120^{\circ}\) can be explained by concluding that more space is required for the lone pair than for the bonding pairs.

Ozone can be prepared by passing an electrical discharge through pure oxygen gas. The electrical energy disrupts the bonds in some \(\mathrm{O}_{2}\) molecules, thereby producing oxygen atoms, which react with other \(\mathrm{O}_{2}\) molecules to form \(\mathrm{O}_{3}\). Ozone is much less stable than oxygen at \(25^{\circ} \mathrm{C}\) and 1 atm . For example, \(K \approx 10^{-56}\) for the equilibrium
\[
3 \mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{O}_{3}(\mathrm{~g})
\]

A pale blue, highly toxic gas, ozone is a much more powerful oxidizing agent than oxygen. The strong oxidizing power of ozone makes it useful for killing bacteria in swimming pools, hot tubs, and aquariums. It is also increasingly being used in municipal water treatment and for washing produce after it comes out of the fields. One of the main advantages of using ozone for water purification is that it does not leave potentially toxic residues behind. On the other hand, chlorine, which is widely used for water purification, leaves residues of chloro compounds, such as chloroform \(\left(\mathrm{CHCl}_{3}\right)\), which may cause cancer after long-term exposure. Although ozone effectively kills the bacteria in water, one problem with ozonolysis is that the water supply is not protected against recontamination, since virtually no ozone remains after the initial treatment. In contrast, for chlorination, significant residual chlorine remains after treatment.

The oxidizing ability of ozone can be detrimental, especially when it is present in the pollution from automobile exhausts (see Section 5.10).

Ozone exists naturally in the upper atmosphere of the earth. The ozone layer is especially important because it absorbs ultraviolet light and thus acts as a screen to prevent this radiation, which can cause skin cancer, from penetrating to the earth's surface. When an ozone molecule absorbs this energy, it splits into an oxygen molecule and an oxygen atom:
\[
\mathrm{O}_{3} \xrightarrow{h \nu} \mathrm{O}_{2}+\mathrm{O}
\]

If the oxygen molecule and atom collide, they will not stay together as ozone unless a "third body," such as a nitrogen molecule, is present to help absorb the energy released by bond formation. The third body absorbs this energy as kinetic energy; its temperature is increased. Therefore, the energy originally absorbed as ultraviolet radiation is eventually changed to thermal energy. Thus the ozone prevents the harmful highenergy ultraviolet light from reaching the earth.

FIGURE 20.21 The Frasch method for recovering sulfur from underground deposits.

\subsection*{20.12 The Chemistry of Sulfur}

A
The mineral cinnabar

A
Sulfur obtained from underground deposits by the Frasch process.

Sulfur is found in nature both in large deposits of the free element and in widely distributed ores, such as galena \((\mathrm{PbS})\), cinnabar \((\mathrm{HgS})\), pyrite \(\left(\mathrm{FeS}_{2}\right)\), gypsum \(\left(\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}\right)\), epsomite \(\left(\mathrm{MgSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}\right)\), and glauberite \(\left(\mathrm{Na}_{2} \mathrm{SO}_{4} \cdot \mathrm{CaSO}_{4}\right)\).

About \(60 \%\) of the sulfur produced in the United States comes from the underground deposits of elemental sulfur found in Texas and Louisiana. This sulfur is recovered by using the Frasch process developed by Herman Frasch in the 1890s. Superheated water is pumped into the deposit to melt the sulfur \(\left(\mathrm{mp}=113^{\circ} \mathrm{C}\right)\), which is then forced to the surface by air pressure (Fig. 20.21). The remaining \(40 \%\) of sulfur produced in the United States either is a by-product of the purification of fossil fuels before combustion to prevent pollution or comes from the sulfur dioxide \(\left(\mathrm{SO}_{2}\right)\) scrubbed from the exhaust gases when sulfur-containing fuels are burned.

In contrast to oxygen, elemental sulfur exists as \(S_{2}\) molecules only in the gas phase at high temperatures. Because sulfur atoms form much stronger \(\sigma\) bonds than \(\pi\) bonds, \(\mathrm{S}_{2}\) is less stable at \(25^{\circ} \mathrm{C}\) than larger aggregates such as \(\mathrm{S}_{6}\) and \(\mathrm{S}_{8}\) rings and \(\mathrm{S}_{n}\) chains (Fig. 20.22). The most stable form of sulfur at \(25^{\circ} \mathrm{C}\) and 1 atm is called rhombic sulfur [Fig. 20.23(a)], which contains stacked \(\mathrm{S}_{8}\) rings. If rhombic sulfur is melted and heated to \(120^{\circ} \mathrm{C}\), it forms monoclinic sulfur as it slowly cools [Fig. 20.23(b)]. The monoclinic form also contains \(S_{8}\) rings, but the rings are stacked differently than in rhombic sulfur.

FIGURE 20.22 (a) The \(\mathrm{S}_{8}\) molecule. (b) Chains of sulfur atoms in viscous liquid sulfur. The chains may contain as many as 10,000 atoms.

FIGURE 20.23 (a) Crystals of rhombic sulfur. (b) Crystals of monoclinic sulfur.

The scrubbing of sulfur dioxide from exhaust gases was discussed in Section 5.10.

\section*{Sulfur Oxides}

From its position below oxygen in the periodic table, we might expect the simplest stable oxide of sulfur to have the formula SO. However, sulfur monoxide, which can be produced in small amounts when gaseous sulfur dioxide \(\left(\mathrm{SO}_{2}\right)\) is subjected to an electrical discharge, is very unstable. The difference in the stabilities of the \(\mathrm{O}_{2}\) and SO molecules probably reflects the much stronger \(\pi\) bonding between oxygen atoms than between a sulfur and an oxygen atom.

Sulfur burns in air with a bright blue flame to give sulfur dioxide \(\left(\mathrm{SO}_{2}\right)\), a colorless gas with a pungent odor, which condenses to a liquid at \(-10^{\circ} \mathrm{C}\) and 1 atm . Sulfur dioxide is a V-shaped molecule, which is a very effective antibacterial agent often used to preserve stored fruit.

Sulfur dioxide reacts with oxygen to produce sulfur trioxide \(\left(\mathrm{SO}_{3}\right)\) :
\[
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)
\]

However, this reaction is very slow in the absence of a catalyst. One of the mysteries during early research on air pollution was how the sulfur dioxide produced from the combustion of sulfur-containing fuels is so rapidly converted to sulfur trioxide in the atmosphere. It is now known that dust and other particles can act as heterogeneous catalysts for this process (see Section 12.8).

\section*{Oxyacids of Sulfur}

Sulfur dioxide dissolves in water to form an acidic solution. The reaction is often represented as
\[
\mathrm{SO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{3}(a q)
\]
where \(\mathrm{H}_{2} \mathrm{SO}_{3}\) is called sulfurous acid. However, very little \(\mathrm{H}_{2} \mathrm{SO}_{3}\) actually exists in the solution. The major form of sulfur dioxide in water is \(\mathrm{SO}_{2}\), and the acid dissociation equilibria are best represented as
\[
\begin{aligned}
\mathrm{SO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{HSO}_{3}^{-}(a q) & K_{\mathrm{a}_{1}}=1.5 \times 10^{-2} \\
\mathrm{HSO}_{3}{ }^{-}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{SO}_{3}^{2-}(a q) & K_{\mathrm{a}_{2}}=1.0 \times 10^{-7}
\end{aligned}
\]

This situation is analogous to the behavior of carbon dioxide in water (see Section 14.7). Although \(\mathrm{H}_{2} \mathrm{SO}_{3}\) cannot be isolated, salts of \(\mathrm{SO}_{3}{ }^{2-}\) (sulfites) and \(\mathrm{HSO}_{3}{ }^{-}\)(hydrogen sulfites) are well known.

FIGURE 20.24 The reaction of \(\mathrm{H}_{2} \mathrm{SO}_{4}\) with sucrose (left) to produce a blackened column of carbon (right).

\subsection*{20.13}

\(\Delta\)
Samples of chlorine gas, liquid bromine, and solid iodine.

Sulfur trioxide reacts violently with water to produce the diprotic acid sulfuric acid:
\[
\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)
\]

Manufactured in greater amounts than any other chemical, sulfuric acid is usually produced by the contact process. About \(60 \%\) of the sulfuric acid manufactured in the United States is used to produce fertilizers from phosphate rock. The other \(40 \%\) is used in lead storage batteries, in petroleum refining, in steel manufacturing, and for various other purposes in the chemical industry.

Because sulfuric acid has a high affinity for water, it is often used as a dehydrating agent. Gases that do not react with sulfuric acid, such as oxygen, nitrogen, and carbon dioxide, are often dried by bubbling them through concentrated solutions of the acid. Sulfuric acid is such a powerful dehydrating agent that it will remove hydrogen and oxygen from a substance in a \(2: 1\) ratio even when the substance contains no molecular water. For example, concentrated sulfuric acid reacts vigorously with common table sugar (sucrose), leaving a charred mass of carbon (Fig. 20.24):
\[
\underset{\text { Sucrose }}{\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(s)+11 \mathrm{H}_{2} \mathrm{SO}_{4}(\text { conc }) \longrightarrow 12 \mathrm{C}(s)+11 \mathrm{H}_{2} \mathrm{SO}_{4} \cdot \mathrm{H}_{2} \mathrm{O}(l)}
\]

\section*{The Group 7A Elements}

In our coverage of the representative elements we have progressed from the groups of metallic elements (Groups 1A and 2A), through groups in which the lighter members are nonmetals and the heavier members are metals (Groups 3A, 4A, and 5A), to a group containing all nonmetals (Group 6A—although some might prefer to call polonium a metal). The Group 7A elements, the halogens (with the valence electron configuration \(n s^{2} n p^{5}\) ), are all nonmetals whose properties generally vary smoothly going down the group. The only notable exceptions are the unexpectedly low value for the electron affinity of fluorine and the unexpectedly small bond energy of the \(F_{2}\) molecule (see Section 20.1). Table 20.17 summarizes the trends in some physical properties of the halogens.

Because of their high reactivities, the halogens are not found as free elements in nature. Instead, they are found as halide ions \(\left(\mathrm{X}^{-}\right)\)in various minerals and in seawater (Table 20.18).

Although astatine is a member of Group 7A, its chemistry is of no practical importance because all its known isotopes are radioactive. The longest-lived isotope, \({ }^{210} \mathrm{At}\), has a half-life of only 8.3 hours.

The halogens, particularly fluorine, have very high electronegativity values (see Table 20.17). They tend to form polar covalent bonds with other nonmetals and ionic bonds with metals in their lower oxidation states. When a metal ion is in a higher oxidation state, such as +3 or +4 , the metal-halogen bonds are polar and covalent. For example, \(\mathrm{TiCl}_{4}\) and \(\mathrm{SnCl}_{4}\) are both covalent compounds that are liquids under normal conditions.

A
A candle burning in an atmosphere of \(\mathrm{Cl}_{2}(\mathrm{~g})\). The exothermic reaction, which involves breaking C-C and \(\mathrm{C}-\mathrm{H}\) bonds in the wax and forming C-Cl bonds in their places, produces enough heat to make the gases in the region incandescent (a flame results).

FIGURE 20.25 The hydrogen bonding among HF molecules in liquid hydrogen fluoride.

\section*{Hydrogen Halides}

The hydrogen halides can be prepared by a reaction of the elements
\[
\mathrm{H}_{2}(g)+\mathrm{X}_{2}(g) \longrightarrow 2 \mathrm{HX}(g)
\]

This reaction occurs with explosive vigor when fluorine and hydrogen are mixed. On the other hand, hydrogen and chlorine can coexist with little apparent reaction for relatively long periods in the dark. However, ultraviolet light causes an explosively fast reaction, and this is the basis of a popular lecture demonstration, the "hydrogenchlorine cannon." Bromine and iodine also react with hydrogen, but more slowly.

Some physical properties of the hydrogen halides are listed in Table 20.19. Note the very high boiling point for hydrogen fluoride, which results from extensive hydrogen bonding among the very polar HF molecules (Fig. 20.25). Fluoride ion has such a high affinity for protons that in concentrated aqueous solutions of hydrogen fluoride, the ion [F---H---F] \({ }^{-}\)exists, in which an \(\mathrm{H}^{+}\)ion is centered between two \(\mathrm{F}^{-}\)ions.

When dissolved in water, the hydrogen halides behave as acids, and all except hydrogen fluoride are completely dissociated. Because water is a much stronger base than the \(\mathrm{Cl}^{-}, \mathrm{Br}^{-}\), or \(\mathrm{I}^{-}\)ion, the acid strengths of \(\mathrm{HCl}, \mathrm{HBr}\), and HI cannot be differentiated in water. However, in a less basic solvent, such as glacial (pure) acetic acid, the acids show different strengths:

To see why hydrogen fluoride is the only weak acid in water among the HX molecules, let's consider the dissociation equilibrium,
\[
\mathrm{HX}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{X}^{-}(a q) \quad \text { where } \quad K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{X}^{-}\right]}{[\mathrm{HX}]}
\]

TABLE 20.19 \| Some Physical Properties of the Hydrogen Halides
\begin{tabular}{lccc|}
\hline \(\mathbf{H X}\) & Melting Point \(\left({ }^{\circ} \mathrm{C}\right)\) & Boiling Point \(\left({ }^{\circ} \mathrm{C}\right)\) & \(\mathrm{H}-\mathrm{X}\) Bond Energy (kJ/mol) \\
\hline HF & -83 & 20 & 565 \\
\hline HCl & -114 & -85 & 427 \\
\hline HBr & -87 & -67 & 363 \\
\hline HI & -51 & -35 & 295 \\
\hline
\end{tabular}

\section*{TABLE 20.20 | The Enthalpies and Entropies of Hydration for the Halide Ions}
\begin{tabular}{|c|c|c|}
\hline \multirow[b]{2}{*}{\(\mathrm{X}^{-}\)} & \multicolumn{2}{|l|}{\(\mathrm{X}^{-}(\mathrm{g}) \xrightarrow{\mathrm{H}, \mathrm{O}} \mathrm{X}^{-}(\mathrm{aq})\)} \\
\hline & \[
\underset{(\mathrm{kJ} / \mathrm{mol})}{\Delta \boldsymbol{H}^{\circ}}
\] & \[
\underset{(\mathrm{J} / \mathrm{K} \mathrm{~mol})}{ }
\] \\
\hline \(\mathrm{F}^{-}\) & -510 & -159 \\
\hline \(\mathrm{Cl}^{-}\) & -366 & -96 \\
\hline \(\mathrm{Br}^{-}\) & -334 & -81 \\
\hline \(\mathrm{I}^{-}\) & -291 & -64 \\
\hline
\end{tabular}

Hydration becomes more exothermic as the charge density of an ion increases. Thus, for ions of a given charge, the smallest is most strongly hydrated.

When \(\mathrm{H}_{2} \mathrm{O}\) molecules cluster around an ion, an ordering effect occurs; thus \(\Delta S^{\circ}\) hyd is negative.

\section*{Stomach acid is 0.1 M HCl}
from a thermodynamic point of view. Recall that acid strength is reflected by the magnitude of \(K_{\mathrm{a}}\)-a small \(K_{\mathrm{a}}\) value means a weak acid. Also recall that the value of an equilibrium constant is related to the standard free energy change for the reaction,
\[
\Delta G^{\circ}=-R T \ln (K)
\]

As \(\Delta G^{\circ}\) becomes more negative, \(K\) becomes larger; a decrease in free energy favors a given reaction. As we saw in Chapter 17, free energy depends on enthalpy, entropy, and temperature. For a process at constant temperature,
\[
\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}
\]

Thus, to explain the various acid strengths of the hydrogen halides, we must focus on the factors that determine \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) for the acid dissociation reaction.

What energy terms are important in determining \(\Delta H^{\circ}\) for the dissociation of HX in water? (Keep in mind that large, positive contributions to the value of \(\Delta H^{\circ}\) will tend to make \(\Delta G^{\circ}\) more highly positive, \(K_{\mathrm{a}}\) smaller, and the acid weaker.) One important factor is certainly the \(\mathrm{H}-\mathrm{X}\) bond strength. Note from Table 20.19 that the \(\mathrm{H}-\mathrm{F}\) bond is much stronger than the other \(\mathrm{H}-\mathrm{X}\) bonds. This factor tends to make HF a weaker acid than the others.

Another important contribution to \(\Delta H^{\circ}\) is the enthalpy of hydration (see Section 11.2) of \(\mathrm{X}^{-}\)(Table 20.20). As we would expect, the smallest of the halide ions, \(\mathrm{F}^{-}\), has the most negative value-its hydration is the most exothermic. This term favors the dissociation of HF into its ions more so than it does for the other HX molecules.

So far we have two conflicting factors: The large HF bond energy tends to make HF a weaker acid than the other hydrogen halides, but the enthalpy of hydration favors the dissociation of HF more than that of the others. When we compare data for HF and HCl , the difference in bond energy ( \(138 \mathrm{~kJ} / \mathrm{mol}\) ) is slightly smaller than the difference in the enthalpies of hydration for the anions ( \(144 \mathrm{~kJ} / \mathrm{mol}\) ). If these were the only important factors, HF should be a stronger acid than HCl because the large enthalpy of hydration of \(\mathrm{F}^{-}\)more than compensates for the large HF bond strength.

As it turns out, the deciding factor appears to be entropy. Note from Table 20.20 that the entropy of hydration for \(\mathrm{F}^{-}\)is much more negative than the entropy of hydration for the other halides because of the high degree of ordering that occurs as the water molecules associate with the small \(\mathrm{F}^{-}\)ion. Remember that a negative change in entropy is unfavorable. Thus, although the enthalpy of hydration favors dissociation of HF, the entropy of hydration strongly opposes it.

When all these factors are taken into account, \(\Delta G^{\circ}\) for the dissociation of HF in water is positive; that is, \(K_{\mathrm{a}}\) is small. In contrast, \(\Delta G^{\circ}\) for dissociation of the other HX molecules in water is negative ( \(K_{\mathrm{a}}\) is large). This example illustrates the complexity of the processes that occur in aqueous solutions and the importance of entropy effects in that medium.

In practical terms, hydrochloric acid is the most important of the hydrohalic acids, the aqueous solutions of the hydrogen halides. About 3 million tons of hydrochloric acid are produced annually for use in cleaning steel before galvanizing and in the manufacture of many other chemicals.

Hydrofluoric acid is used to etch glass by reacting with the silica in glass to form the volatile gas \(\mathrm{SiF}_{4}\) :
\[
\mathrm{SiO}_{2}(s)+4 \mathrm{HF}(a q) \longrightarrow \mathrm{SiF}_{4}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
\]

\section*{Oxyacids and Oxyanions}

All the halogens except fluorine combine with various numbers of oxygen atoms to form a series of oxyacids, as shown in Table 20.21. The strengths of these acids vary in direct proportion to the number of oxygen atoms attached to the halogen, with the acid strength increasing as more oxygens are added.

\section*{TABLE 20.21 | The Known Oxyacids of the Halogens}
\begin{tabular}{|cccccccl|}
\hline \begin{tabular}{c}

\hline & & & & & \\
\hline
\end{tabular}
*Iodine also forms \(\mathrm{H}_{4} \mathrm{I}_{2} \mathrm{O}_{9}\) (mesodiperiodic acid) and \(\mathrm{H}_{5} \mathrm{IO}_{6}\) (paraperiodic acid).
\({ }^{\dagger} \mathrm{HOF}\) oxidation state is best represented as -1 .
\({ }^{\ddagger}\) Compound is unknown.

The name for \(\mathrm{OF}_{2}\) is oxygen difluoride rather than difluorine oxide because fluorine has a higher electronegativity than oxygen and thus is named as the anion.

FIGURE 20.26 The structures of the oxychloro anions.

The only member of the chlorine series that has been obtained in the pure state is perchloric acid \(\left(\mathrm{HOClO}_{3}\right)\), a strong acid and a powerful oxidizing agent. Because perchloric acid reacts explosively with many organic materials, it must be handled with great caution. The other oxyacids of chlorine are known only in solution, although salts containing their anions are well known (Fig. 20.26).

Hypochlorous acid \((\mathrm{HOCl})\) is formed when chlorine gas is dissolved in cold water:
\[
\mathrm{Cl}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HOCl}(a q)+\mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q)
\]

Note that in this reaction chlorine is both oxidized (from 0 in \(\mathrm{Cl}_{2}\) to +1 in HOCl ) and reduced (from 0 in \(\mathrm{Cl}_{2}\) to -1 in \(\mathrm{Cl}^{-}\)). Such a reaction, in which a given element is both oxidized and reduced, is called a disproportionation reaction. Hypochlorous acid and its salts are strong oxidizing agents; their solutions are widely used as household bleaches and disinfectants.

Chlorate salts, such as \(\mathrm{KClO}_{3}\), are also strong oxidizing agents and are used as weed killers and as oxidizers in fireworks (see Chapter 7) and explosives.

Fluorine forms only one oxyacid, hypofluorous acid (HOF), but it forms at least two oxides. When fluorine gas is bubbled into a dilute solution of sodium hydroxide, the compound oxygen difluoride \(\left(\mathrm{OF}_{2}\right)\) is formed:
\[
4 \mathrm{~F}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 6 \mathrm{HF}(a q)+\mathrm{OF}_{2}(g)+\mathrm{O}_{2}(g)
\]

Oxygen difluoride is a pale yellow gas \(\left(\mathrm{bp}=-145^{\circ} \mathrm{C}\right)\) that is a strong oxidizing agent. The oxide dioxygen difluoride \(\left(\mathrm{O}_{2} \mathrm{~F}_{2}\right)\) is an orange solid that can be prepared by an electric discharge in an equimolar mixture of fluorine and oxygen gases:
\[
\mathrm{F}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \xrightarrow{\substack{\text { Electric } \\ \text { discharge }}} \mathrm{O}_{2} \mathrm{~F}_{2}(s)
\]

Hypochlorite ion, \(\mathrm{OCl}^{-}\)

Perchlorate ion, \(\mathrm{ClO}_{4}^{-}\)

\subsection*{20.14 The Group 8A Elements}

\(\Delta\)
A French neon signmaker.

The Group 8A elements, the noble gases, are characterized by filled \(s\) and \(p\) valence orbitals (electron configurations of \(2 s^{2}\) for helium and \(n s^{2} n p^{6}\) for the others). Because of their completed valence shells, these elements are very unreactive. In fact, no noble gas compounds were known prior to 1962. Selected properties of the Group 8A elements are summarized in Table 20.22.

Helium was identified by its characteristic emission spectrum as a component of the sun before it was found on earth. The major sources of helium on earth are natural gas deposits, where helium was formed from the \(\alpha\)-particle decay of radioactive elements. The \(\alpha\) particle is a helium nucleus that can easily pick up electrons from the environment to form a helium atom. Although helium forms no compounds, it is an important substance that is used as a coolant, as a pressurizing gas for rocket fuels, as a diluent in the gases used for deep-sea diving and spaceship atmospheres, and as the gas in lighter-than-air airships (blimps).

Like helium, neon forms no compounds, but it is a very useful element. For example, neon is widely used in luminescent lighting (neon signs). Argon, which recently has been shown to form chemical bonds under special circumstances, is used to provide the noncorrosive atmosphere in incandescent light bulbs, which prolongs the life of the tungsten filament.

Krypton and xenon have been observed to form many stable chemical compounds. The first of these was prepared in 1962 by Neil Bartlett (1932-2008), an English chemist who made an ionic compound that he thought had the formula \(\mathrm{XePtF}_{6}\). Subsequent studies indicated that the compound might be better represented as \(\mathrm{XeFPtF}_{6}\) and contains the \(\mathrm{XeF}^{+}\)and \(\mathrm{PtF}_{6}{ }^{-}\)ions.

Less than a year after Bartlett's report, a group at Argonne National Laboratory near Chicago prepared xenon tetrafluoride by reacting xenon and fluorine gases in a nickel reaction vessel at \(400^{\circ} \mathrm{C}\) and 6 atm :
\[
\mathrm{Xe}(g)+2 \mathrm{~F}_{2}(g) \longrightarrow \mathrm{XeF}_{4}(s)
\]

Xenon tetrafluoride forms stable colorless crystals. Two other xenon fluorides, \(\mathrm{XeF}_{2}\) and \(\mathrm{XeF}_{6}\), were synthesized by the group at Argonne, and a highly explosive xenon oxide \(\left(\mathrm{XeO}_{3}\right)\) was also found. The xenon fluorides react with water to form hydrogen fluoride and oxycompounds. For example:
\[
\begin{aligned}
\mathrm{XeF}_{6}(s)+3 \mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow \mathrm{XeO}_{3}(a q)+6 \mathrm{HF}(a q) \\
\mathrm{XeF}_{6}(s)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow \mathrm{XeOF}_{4}(a q)+2 \mathrm{HF}(a q)
\end{aligned}
\]

In the past 35 years, other xenon compounds have been prepared. Examples are \(\mathrm{XeO}_{4}\) (explosive), \(\mathrm{XeOF}_{4}, \mathrm{XeOF}_{2}\), and \(\mathrm{XeO}_{3} \mathrm{~F}_{2}\). These compounds contain discrete molecules with covalent bonds between the xenon atom and the other atoms. A few compounds of krypton, such as \(\mathrm{KrF}_{2}\) and \(\mathrm{KrF}_{4}\), have also been observed. The structures of several known xenon compounds are shown in Fig. 20.27. Radon also has been shown to form compounds similar to those of xenon and krypton.

\section*{Representative elements}
> Chemical properties are determined by their \(s\) and \(p\) valence-electron configurations
) Metallic character increases going down the group
> The properties of the first element in a group usually differ most from the properties of the other elements in the group due to a significant difference in size
> In Group 1A, hydrogen is a nonmetal and the other members of the group are active metals
> The first member of a group forms the strongest \(\pi\) bonds, causing nitrogen and oxygen to exist as \(\mathrm{N}_{2}\) and \(\mathrm{O}_{2}\) molecules

\section*{Elemental abundances on earth}
> Oxygen is the most abundant element, followed by silicon
) The most abundant metals are aluminum and iron, which are found as ores

\section*{Group 1A elements (alkali metals)}
) Have valence configuration \(n s^{1}\)
> Except for hydrogen, readily lose one electron to form \(\mathrm{M}^{+}\)ions in their compounds with nonmetals
> React vigorously with water to form \(\mathrm{M}^{+}\)and \(\mathrm{OH}^{-}\)ions and hydrogen gas
> Form a series of oxides of the types \(\mathrm{M}_{2} \mathrm{O}\) (oxide), \(\mathrm{M}_{2} \mathrm{O}_{2}\) (peroxide), and \(\mathrm{MO}_{2}\) (superoxide) > Not all metals form all types of oxide compounds
> Hydrogen forms covalent compounds with nonmetals
) With very active metals, hydrogen forms hydrides that contain the \(\mathrm{H}^{-}\)ion

\section*{Group 2A (alkaline earth metals)}
> Have valence configuration \(n s^{2}\)
> React less violently with water than alkali metals
> The heavier alkaline earth metals form nitrides and hydrides
> Hard water contains \(\mathrm{Ca}^{2+}\) and \(\mathrm{Mg}^{2+}\) ions
> Form precipitates with soap
, Usually removed by ion-exchange resins that replace the \(\mathrm{Ca}^{2+}\) and \(\mathrm{Mg}^{2+}\) ions with \(\mathrm{Na}^{+}\)

hydrochloric acid
hydrohalic acids disproportionation reaction

Section 20.14
noble gases

Group 3A
) Have valence configuration \(n s^{2} n p^{1}\)
> Show increasing metallic character going down the group
> Boron is a nonmetal that forms many types of covalent compounds, including boranes, which are highly electron-deficient and thus are very reactive
) The metals aluminum, gallium, and indium show some covalent tendencies

\section*{Group 4A}
) Have valence configuration \(n s^{2} n p^{2}\)
> Lighter members are nonmetals; heavier members are metals
> All group members can form covalent bonds to nonmetals
> Carbon forms a huge variety of compounds, most of which are classified as organic compounds

\section*{Group 5A}
> Elements show a wide variety of chemical properties
) Nitrogen and phosphorus are nonmetals
) Antimony and bismuth tend to be metallic, although no ionic compounds containing \(\mathrm{Sb}^{5+}\) and \(\mathrm{Bi}^{5+}\) are known; the compounds containing \(\mathrm{Sb}(\mathrm{V})\) and \(\mathrm{Bi}(\mathrm{V})\) are molecular rather than ionic
> All group members except N form molecules with five covalent bonds
> The ability to form \(\pi\) bonds decreases dramatically after N
> Chemistry of nitrogen
> Most nitrogen-containing compounds decompose exothermically, forming the very stable \(\mathrm{N}_{2}\) molecule, which explains the power of nitrogen-based explosives
> The nitrogen cycle, which consists of a series of steps, shows how nitrogen is cycled in the natural environment
> Nitrogen fixation changes the \(\mathrm{N}_{2}\) in air into compounds useful to plants
) The Haber process is a synthetic method of nitrogen fixation
> In the natural world, nitrogen fixation occurs through nitrogen-fixing bacteria in the root nodules of certain plants and through lightning in the atmosphere
> Ammonia is the most important hydride of nitrogen > Contains pyramidal \(\mathrm{NH}_{3}\) molecules ) Widely used as a fertilizer
) Hydrazine \(\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)\) is a powerful reducing agent
> Nitrogen forms a series of oxides including \(\mathrm{N}_{2} \mathrm{O}\), \(\mathrm{NO}, \mathrm{NO}_{2}\), and \(\mathrm{N}_{2} \mathrm{O}_{5}\)
> Nitric acid \(\left(\mathrm{HNO}_{3}\right)\) is a very important strong acid manufactured by the Ostwald process
> Chemistry of phosphorus
> Exists in three elemental forms: white (contains \(\mathrm{P}_{4}\) molecules), red, and black
) Phosphine \(\left(\mathrm{PH}_{3}\right)\) has bond angles close to 90 degrees
> Phosphorus forms oxides including \(\mathrm{P}_{4} \mathrm{O}_{6}\) and \(\mathrm{P}_{4} \mathrm{O}_{10}\) (which dissolves in water to form phosphoric acid, \(\mathrm{H}_{3} \mathrm{PO}_{4}\) )

\section*{Group 6A}
) Metallic character increases going down the group but no element behaves as a typical metal
) The lighter members tend to gain two electrons to form \(\mathrm{X}^{2-}\) ions in compounds with metals
> Chemistry of oxygen
, Elemental forms are \(\mathrm{O}_{2}\) and \(\mathrm{O}_{3}\)
> Oxygen forms a wide variety of oxides
> \(\mathrm{O}_{2}\) and especially \(\mathrm{O}_{3}\) are powerful oxidizing agents
> Chemistry of sulfur
, The elemental forms are called rhombic and monoclinic sulfur, both of which contain \(\mathrm{S}_{8}\) molecules
) The most important oxides are \(\mathrm{SO}_{2}\) (which forms \(\mathrm{H}_{2} \mathrm{SO}_{3}\) in water) and \(\mathrm{SO}_{3}\) (which forms \(\mathrm{H}_{2} \mathrm{SO}_{4}\) in water)
> Sulfur forms a wide variety of compounds in which it shows the oxidation states \(+6,+4\), \(+2,0\), and -2

\section*{Group 7A (halogens)}
) All nonmetals
> Form hydrides of the type HX that behave as strong acids in water except for HF, which is a weak acid
> The oxyacids of the halogens become stronger as more oxygen atoms are present

\section*{Group 8A (noble gases)}
) All elements are monatomic gases and are generally very unreactive
> The heavier elements form compounds with electronegative elements such as fluorine and oxygen

\section*{Review Questions Answers to the Review Questions can be found on the Student website (accessible from wwww.cengagebrain.com).}
1. What are the two most abundant elements by mass in the earth's crust, oceans, and atmosphere? Does this make sense? Why? What are the four most abundant elements by mass in the human body? Does this make sense? Why?
2. What evidence supports putting hydrogen in Group 1A of the periodic table? In some periodic tables hydrogen is listed separately from any of the groups. In what ways is hydrogen unlike a typical Group 1A element? What is the valence electron configuration for the alkali metals? List some common properties of alkali metals. How are the pure metals prepared? Predict the formulas of the compounds formed when an alkali metal reacts with \(\mathrm{F}_{2}, \mathrm{~S}, \mathrm{P}_{4}, \mathrm{H}_{2}\), and \(\mathrm{H}_{2} \mathrm{O}\).
3. What is the valence electron configuration for alkaline earth metals? List some common properties of alkaline earth metals. How are alkaline earth metals prepared? Predict the formulas of the compounds formed when an alkaline earth metal reacts with \(\mathrm{F}_{2}, \mathrm{O}_{2}, \mathrm{~S}, \mathrm{~N}_{2}, \mathrm{H}_{2}\), and \(\mathrm{H}_{2} \mathrm{O}\).
4. What is the valence electron configuration for the Group 3A elements? How does metallic character change as one goes down this group? How are boron and aluminum different? Predict the formulas of the compounds formed when aluminum reacts with \(\mathrm{F}_{2}, \mathrm{O}_{2}\), S , and \(\mathrm{N}_{2}\).
5. What is the valence electron configuration for Group 4A elements? Group 4A contains two of the most important elements on earth. What are they, and why are they so important? How does metallic character change as one goes down Group 4A? What are the three allotropic forms of carbon? List some properties of germanium, tin, and lead. Predict the formulas of the compounds formed when Ge reacts with \(\mathrm{F}_{2}\) and \(\mathrm{O}_{2}\).
6. What is the valence electron configuration for Group 5A elements? Metallic character increases when going down a group. Give some examples illustrating how Bi and Sb have metallic characteristics not associated with \(\mathrm{N}, \mathrm{P}\), and As. Elemental nitrogen exists as \(\mathrm{N}_{2}\), whereas in the gas phase the elements phosphorus, arsenic, and antimony consist of \(\mathrm{P}_{4}, \mathrm{As}_{4}\), and \(\mathrm{Sb}_{4}\) molecules, respectively. Give a possible reason for this difference between \(\mathrm{N}_{2}\) and the other Group 5A elements. White phosphorus is much more reactive than black or red phosphorus. Explain.
7. Table 20.14 lists some common nitrogen compounds having oxidation states ranging from -3 to +5 . Rationalize this spread in oxidation states. For each substance listed in Table 20.14, list some of its special properties. Ammonia forms hydrogen-bonding intermolecular forces resulting in an unusually high boiling point for a substance with the small size of \(\mathrm{NH}_{3}\). Can hydrazine \(\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)\) also form hydrogen-bonding interactions? How is phosphine's \(\left(\mathrm{PH}_{3}\right)\) structure different from that of ammonia?
8. What is the valence electron configuration of Group 6A elements? What are some property differences between oxygen and polonium? What are the Lewis structures for the two allotropic forms of oxygen? What is the molecular structure and the bond angle in ozone? The most stable form of solid sulfur is the rhombic form; however, a solid form called monoclinic sulfur can also form. What is the difference between rhombic and monoclinic sulfur? Explain why \(\mathrm{O}_{2}\) is much more stable than \(\mathrm{S}_{2}\) or SO. When \(\mathrm{SO}_{2}(g)\) or \(\mathrm{SO}_{3}(g)\) reacts with water, an acidic solution forms. Explain. What are the molecular structures and bond angles in \(\mathrm{SO}_{2}\) and \(\mathrm{SO}_{3}\) ? \(\mathrm{H}_{2} \mathrm{SO}_{4}\) is a powerful dehydrating agent: What does this mean?
9. What is the valence electron configuration of the halogens? Why do the boiling points and melting points of the halogens increase steadily from \(\mathrm{F}_{2}\) to \(\mathrm{I}_{2}\) ? Give two reasons why \(F_{2}\) is the most reactive of the halogens. Explain why the boiling point of HF is much higher than the boiling points of \(\mathrm{HCl}, \mathrm{HBr}\), and HI . In nature, the halogens are generally found as halide ions in various minerals and seawater. What is a halide ion, and why are halide salts so stable? The oxidation states of the halogens vary from -1 to +7 . Identify compounds of chlorine that have \(-1,+1,+3,+5\), and +7 oxidation states.
10. What special property of the noble gases makes them unreactive? The boiling points and melting points of the noble gases increase steadily from He to Xe. Explain. The noble gases were among the last elements discovered; their existence was not predicted by Mendeleev when he published his first periodic table. Explain. In chemistry textbooks written before 1962, the noble gases were referred to as the inert gases. Why do we no longer use this term? For the structures of the xenon compounds in Fig. 20.27, give the bond angles exhibited and the hybridization of the central atom in each compound.

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

\section*{Questions}
1. Although the earth was formed from the same interstellar material as the sun, there is little elemental hydrogen \(\left(\mathrm{H}_{2}\right)\) in the earth's atmosphere. Explain.
2. List two major industrial uses of hydrogen.
3. Calcium and magnesium are essential for human life. Explain their importance.
4. Diagonal relationships in the periodic table exist as well as the vertical relationships. For example, Be and Al are similar in some of their properties as are B and Si. Rationalize why these diagonal relationships hold for properties such as size, ionization energy, and electron affinity.
5. Atomic size seems to play an important role in explaining some of the differences between the first element in a group and the subsequent group elements. Explain.
6. Silicon carbide ( SiC ) is an extremely hard substance. Propose a structure for SiC .
7. In most compounds, the solid phase is denser than the liquid phase. Why isn't this true for water?
8. What is nitrogen fixation? Give some examples of nitrogen fixation.
9. All the Group 1A and 2A metals are produced by electrolysis of molten salts. Why?
10. Why are the \(\operatorname{tin}(I V)\) halides more volatile than the \(\operatorname{tin}\) (II) halides?
11. What trade-offs must be made between kinetics and thermodynamics in the Haber process for the production of ammonia? How did the discovery of an appropriate catalyst make the process feasible?
12. What structural features do the molecules \(\mathrm{P}_{4}, \mathrm{P}_{4} \mathrm{O}_{6}\), and \(\mathrm{P}_{4} \mathrm{O}_{10}\) have in common?
13. What are boranes? Why were they once considered as potential fuels for rockets?
14. There are three known xenon fluoride covalent compounds: \(\mathrm{XeF}_{2}, \mathrm{XeF}_{4}\), and \(\mathrm{XeF}_{6}\). In general, the xenon fluoride compounds must be stored in an inert atmosphere, free of oxygen and water. Why is this the case?

\section*{Exercises}

In this section similar exercises are paired.

\section*{Group 1A Elements}
-15. Hydrogen is produced commercially by the reaction of methane with steam:
\[
\mathrm{CH}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{CO}(g)+3 \mathrm{H}_{2}(g)
\]
a. Calculate \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) for this reaction (use the data in Appendix 4).
b. What temperatures will favor product formation at standard conditions? Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
16. The major industrial use of hydrogen is in the production of ammonia by the Haber process:
\[
3 \mathrm{H}_{2}(g)+\mathrm{N}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
\]
a. Using data from Appendix 4, calculate \(\Delta H^{\circ}, \Delta S^{\circ}\), and \(\Delta G^{\circ}\) for the Haber process reaction.
b. Is the reaction spontaneous at standard conditions?
c. At what temperatures is the reaction spontaneous at standard conditions? Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
-17. Write balanced equations describing the reaction of lithium metal with each of the following: \(\mathrm{O}_{2}, \mathrm{~S}, \mathrm{Cl}_{2}, \mathrm{P}_{4}, \mathrm{H}_{2}, \mathrm{H}_{2} \mathrm{O}\), and HCl .
18. The electrolysis of aqueous sodium chloride (brine) is an important industrial process for the production of chlorine and sodium hydroxide. In fact, this process is the second largest consumer of electricity in the United States, after the production of aluminum. Write a balanced equation for the electrolysis of aqueous sodium chloride (hydrogen gas is also produced).
-19. Refer to Table 20.5 and give examples of the three types of alkali metal oxides that form. How do they differ?
20. Label the following hydrides as ionic, covalent, or interstitial and support your answer. Note: The light blue atoms are hydrogen atoms.

21. Many lithium salts are hygroscopic (absorb water), but the corresponding salts of the other alkali metals are not. Why are lithium salts different from the others?
22. What will be the atomic number of the next alkali metal to be discovered? How would you expect the physical properties of the next alkali metal to compare with the properties of the other alkali metals summarized in Table 20.4?

\section*{Group 2A Elements}
-23. One harmful effect of acid rain is the deterioration of structures and statues made of marble or limestone, both of which are essentially calcium carbonate. The reaction of calcium carbonate with sulfuric acid yields carbon dioxide, water, and calcium sulfate. Because calcium sulfate is marginally soluble in water, part of the object is washed away by the rain. Write a balanced chemical equation for the reaction of sulfuric acid with calcium carbonate.
24. Write balanced equations describing the reaction of Sr with each of the following: \(\mathrm{O}_{2}, \mathrm{~S}, \mathrm{Cl}_{2}, \mathrm{P}_{4}, \mathrm{H}_{2}, \mathrm{H}_{2} \mathrm{O}\), and HCl .
25. What mass of barium is produced when molten \(\mathrm{BaCl}_{2}\) is electrolyzed by a current of \(2.50 \times 10^{5} \mathrm{~A}\) for 6.00 h ?
26. Electrolysis of an alkaline earth metal chloride using a current of 5.00 A for 748 seconds deposits 0.471 g of metal at an electrode. Is the metal deposited at the cathode or the anode of the electrolytic cell? What is produced at the other electrode? What is the identity of the alkaline earth metal?
27. Beryllium shows some covalent characteristics in some of its compounds, unlike the other alkaline earth compounds. Give a possible explanation for this phenomenon.
28. What ions are found in hard water? What happens when water is "softened"?
-29. Slaked lime, \(\mathrm{Ca}(\mathrm{OH})_{2}\), is used to soften hard water by removing calcium ions from hard water through the reaction
\[
\begin{gathered}
\mathrm{Ca}(\mathrm{OH})_{2}(a q)+\mathrm{Ca}^{2+}(a q)+2 \mathrm{HCO}_{3}^{-}(a q) \rightarrow \\
2 \mathrm{CaCO}_{3}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)
\end{gathered}
\]

Although \(\mathrm{CaCO}_{3}(s)\) is considered insoluble, some of it does dissolve in aqueous solutions. Calculate the molar solubility of \(\mathrm{CaCO}_{3}\) in water \(\left(K_{\text {sp }}=8.7 \times 10^{-9}\right)\).
30. The United States Public Health Service (USPHS) recommends the fluoridation of water as a means for preventing tooth decay. The recommended concentration is \(1 \mathrm{mg} \mathrm{F}^{-} / \mathrm{L}\). The presence of calcium ions in hard water can precipitate the added fluoride. What is the maximum molarity of calcium ions in hard water if the fluoride concentration is at the USPHS recommended level? ( \(K_{\text {sp }}\) for \(\mathrm{CaF}_{2}=4.0 \times 10^{-11}\).)

\section*{Group 3A Elements}
-31. Consider element \(113, \mathrm{Nh}\). What is the expected electron configuration for Nh ? What oxidation states would be exhibited by Nh in its compounds?
32. Thallium and indium form +1 and +3 oxidation states when in compounds. Predict the formulas of the possible compounds between thallium and oxygen and between indium and chlorine. Name the compounds.
-33. Boron hydrides were once evaluated for possible use as rocket fuels. Complete and balance the following equation for the combustion of diborane.
\[
\mathrm{B}_{2} \mathrm{H}_{6}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{B}(\mathrm{OH})_{3}(s)
\]
34. Elemental boron is produced by reduction of boron oxide with magnesium to give boron and magnesium oxide. Write a balanced equation for this reaction.
-35. Write equations describing the reactions of Ga with each of the following: \(\mathrm{F}_{2}, \mathrm{O}_{2}, \mathrm{~S}\), and HCl .
36. Write a balanced equation describing the reaction of aluminum metal with concentrated aqueous sodium hydroxide.
\(-37 . \mathrm{Al}_{2} \mathrm{O}_{3}\) is amphoteric. What does this mean?
38. What are three-centered bonds?

\section*{Group 4A Elements}
-39. Discuss the importance of the \(\mathrm{C}-\mathrm{C}\) and \(\mathrm{Si}-\mathrm{Si}\) bond strengths and of \(\pi\) bonding to the properties of carbon and silicon.
40. Besides the central atom, what are the differences between \(\mathrm{CO}_{2}\) and \(\mathrm{SiO}_{2}\) ?
41. The following illustration shows the orbitals used to form the bonds in carbon dioxide.

Each color represents a different orbital. Label each orbital, draw the Lewis structure for carbon dioxide, and explain how the localized electron model describes the bonding in \(\mathrm{CO}_{2}\).
42. In addition to \(\mathrm{CO}_{2}\), two additional stable oxides of carbon form. The space-filling models for \(\mathrm{CO}_{2}\) and the other two stable oxides are:

What are the formulas for the two additional stable oxides of carbon? Explain the bonding in each of these two forms using the localized electron model.
-43. Silicon is produced for the chemical and electronics industries by the following reactions. Give the balanced equation for each reaction.
a. \(\mathrm{SiO}_{2}(s)+\mathrm{C}(s) \longrightarrow \mathrm{Si}(s)+\mathrm{CO}(g)\)
b. Silicon tetrachloride is reacted with very pure magnesium, producing silicon and magnesium chloride.
c. \(\mathrm{Na}_{2} \mathrm{SiF}_{6}(s)+\mathrm{Na}(s) \longrightarrow \mathrm{Si}(s)+\mathrm{NaF}(s)\)
44. Write equations describing the reactions of Sn with each of the following: \(\mathrm{Cl}_{2}, \mathrm{O}_{2}\), and HCl .
45. The compound \(\mathrm{Pb}_{3} \mathrm{O}_{4}\) (red lead) contains a mixture of lead(II) and lead(IV) oxidation states. What is the mole ratio of lead(II) to lead(IV) in \(\mathrm{Pb}_{3} \mathrm{O}_{4}\) ?
46. Tin forms compounds in the +2 and +4 oxidation states. Therefore, when tin reacts with fluorine, two products are possible. Write balanced equations for the production of the two tin halide compounds and name them.

\section*{Group 5A Elements}
. The oxyanion of nitrogen in which it has the highest oxidation state is the nitrate ion \(\left(\mathrm{NO}_{3}{ }^{-}\right)\). The corresponding oxyanion of phosphorus is \(\mathrm{PO}_{4}{ }^{3-}\). The \(\mathrm{NO}_{4}{ }^{3-}\) ion is known but not very stable. The \(\mathrm{PO}_{3}{ }^{-}\)ion is not known. Account for these differences in terms of the bonding in the four anions.
48. In each of the following pairs of substances, one is stable and known, and the other is unstable. For each pair, choose the stable substance, and explain why the other is unstable.
a. \(\mathrm{NF}_{5}\) or \(\mathrm{PF}_{5}\)
b. \(\mathrm{AsF}_{5}\) or \(\mathrm{AsI}_{5}\)
c. \(\mathrm{NF}_{3}\) or \(\mathrm{NBr}_{3}\)
49. Write balanced equations for the reactions described in Table 20.13 for the production of Bi and Sb .
50. Arsenic reacts with oxygen to form oxides that react with water in a manner analogous to that of the phosphorus oxides. Write balanced chemical equations describing the reaction of arsenic with oxygen and the reaction of the resulting oxide with water.
51. The Group 5A elements can form molecules or ions that involve three, five, or six covalent bonds; \(\mathrm{NH}_{3}, \mathrm{AsCl}_{5}\), and \(\mathrm{PF}_{6}{ }^{-}\)are examples. Draw the Lewis structure for each of these substances, and predict the molecular structure and hybridization for each. Why doesn't \(\mathrm{NF}_{5}\) or \(\mathrm{NCl}_{6}{ }^{-}\)form?
\({ }^{5}\) 52. Compare the Lewis structures with the molecular orbital view of the bonding in \(\mathrm{NO}, \mathrm{NO}^{+}\), and \(\mathrm{NO}^{-}\). Account for any discrepancies between the two models.
53. Many oxides of nitrogen have positive values for the standard free energy of formation. Using NO as an example, explain why this is the case.
54. Using data from Appendix 4 calculate \(\Delta H^{\circ}, \Delta S^{\circ}\), and \(\Delta G^{\circ}\) for the reaction
\[
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)
\]

Why does NO form in an automobile engine but then does not readily decompose back to \(\mathrm{N}_{2}\) and \(\mathrm{O}_{2}\) in the atmosphere?
55. In many natural waters, nitrogen and phosphorus are the least abundant nutrients available for plant life. Some waters that become polluted from agricultural runoff or municipal sewage become infested with algae. The algae flourish, and fish life dies off as a result. Describe how these events are chemically related.
56. Phosphate buffers are important in regulating the pH of intracellular fluids. If the concentration ratio of \(\mathrm{H}_{2} \mathrm{PO}_{4}^{-} / \mathrm{HPO}_{4}{ }^{2-}\) in a sample of intracellular fluid is \(1.1: 1\), what is the pH of this sample of intracullular fluid?
\[
\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q) \rightleftharpoons \mathrm{HPO}_{4}^{2-}(a q)+\mathrm{H}^{+}(a q) \quad K_{\mathrm{a}}=6.2 \times 10^{-8}
\]

Phosphoric acid \(\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)\) is a triprotic acid, phosphorous acid \(\left(\mathrm{H}_{3} \mathrm{PO}_{3}\right)\) is a diprotic acid, and hypophosphorous acid \(\left(\mathrm{H}_{3} \mathrm{PO}_{2}\right)\) is a monoprotic acid. Explain this phenomenon.
\({ }^{5}\) 58. Trisodium phosphate (TSP) is an effective grease remover. Like many cleaners, TSP acts as a base in water. Write a balanced equation to account for this basic behavior.

\section*{Group 6A Elements}

Use bond energies to estimate the maximum wavelength of light that will cause the reaction
\[
\mathrm{O}_{3} \xrightarrow{h \nu} \mathrm{O}_{2}+\mathrm{O}
\]
60. The xerographic (dry writing) process was invented in 1938 by C. Carlson. In xerography, an image is produced on a photoconductor by exposing it to light. Selenium is commonly used, since its conductivity increases three orders of magnitude upon exposure to light in the range from 400 to 500 nm . What color light should be used to cause selenium to become conductive? (See Figure 7.2.)
-61. Write a balanced equation describing the reduction of \(\mathrm{H}_{2} \mathrm{SeO}_{4}\) by \(\mathrm{SO}_{2}\) to produce selenium.
62. Complete and balance each of the following reactions.
a. the reaction between sulfur dioxide gas and oxygen gas
b. the reaction between sulfur trioxide gas and water
c. the reaction between concentrated sulfuric acid and sucrose \(\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)\)
63. Ozone is desirable in the upper atmosphere but undesirable in the lower atmosphere. A dictionary states that ozone has the scent of a spring thunderstorm. How can these seemingly conflicting statements be reconciled in terms of the chemical properties of ozone?
64. Ozone is a possible replacement for chlorine in municipal water purification. Unlike chlorine, virtually no ozone remains after treatment. This has good and bad consequences. Explain.
65. How can the paramagnetism of \(\mathrm{O}_{2}\) be explained using the molecular orbital model?
66. Describe the bonding in \(\mathrm{SO}_{2}\) and \(\mathrm{SO}_{3}\) using the localized electron model (hybrid orbital theory). How would the molecular orbital model describe the \(\pi\) bonding in these two compounds?

\section*{Group 7A Elements}
-67. Write the Lewis structure for \(\mathrm{O}_{2} \mathrm{~F}_{2}\). Predict the bond angles and hybridization of the two central oxygen atoms. Assign oxidation states and formal charges to the atoms in \(\mathrm{O}_{2} \mathrm{~F}_{2}\). The compound \(\mathrm{O}_{2} \mathrm{~F}_{2}\) is a vigorous and potent oxidizing and fluorinating agent. Are oxidation states or formal charges more useful in accounting for these properties of \(\mathrm{O}_{2} \mathrm{~F}_{2}\) ?
68. Give the Lewis structure, molecular structure, and hybridization of the oxygen atom for \(\mathrm{OF}_{2}\). Would you expect \(\mathrm{OF}_{2}\) to be a strong oxidizing agent like \(\mathrm{O}_{2} \mathrm{~F}_{2}\) discussed in Exercise 67?
-69. Fluorine reacts with sulfur to form several different covalent compounds. Three of these compounds are \(\mathrm{SF}_{2}, \mathrm{SF}_{4}\), and \(\mathrm{SF}_{6}\). Draw the Lewis structures for these compounds, and predict the molecular structures (including bond angles). Would you expect \(\mathrm{OF}_{4}\) to be a stable compound?
70. Predict some possible compounds that could form between chlorine and selenium. (Hint: See Exercise 69.)
-71. How does the oxyacid strength of the halogens vary as the number of oxygens in the formula increases?
72. Explain why HF is a weak acid, whereas \(\mathrm{HCl}, \mathrm{HBr}\), and HI are all strong acids.

\section*{Group 8A Elements}
-73. The xenon halides and oxides are isoelectronic with many other compounds and ions containing halogens. Give a molecule or ion in which iodine is the central atom that is isoelectronic with each of the following.
a. xenon tetroxide
d. xenon tetrafluoride
b. xenon trioxide
e. xenon hexafluoride
c. xenon difluoride
74. For each of the following, write the Lewis structure(s), predict the molecular structure (including bond angles), and give the expected hybridization of the central atom.
a. \(\mathrm{KrF}_{2}\)
b. \(\mathrm{KrF}_{4}\)
c. \(\mathrm{XeO}_{2} \mathrm{~F}_{2}\)
d. \(\mathrm{XeO}_{2} \mathrm{~F}_{4}\)

Although He is the second most abundant element in the universe, it is very rare on the earth. Why?
76. Argon gas is inert, so it poses no serious health risks. However, if significant amounts of radon are inhaled into the lungs, lung cancer is a possible result. Explain the health risk differences between argon gas and radon gas.
77. There is evidence that radon reacts with fluorine to form compounds similar to those formed by xenon and fluorine. Predict the formulas of these \(\mathrm{RnF}_{x}\) compounds.
78. For the \(\mathrm{RnF}_{x}\) compounds you predicted in Exercise 77, give the molecular structure (including bond angles).

\section*{Additional Exercises}
79. Hydrazine \(\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)\) is used as a fuel in liquid-fueled rockets. When hydrazine reacts with oxygen gas, nitrogen gas and water vapor are produced. Write a balanced equation and use bond energies from Table 8.5 to estimate \(\Delta H\) for this reaction.
80. The inert-pair effect is sometimes used to explain the tendency of heavier members of Group 3A to exhibit +1 and +3 oxidation states. What does the inert-pair effect reference? (Hint: Consider the valence electron configuration for Group 3A elements.)
81. How could you determine experimentally whether the compound \(\mathrm{Ga}_{2} \mathrm{Cl}_{4}\) contains two gallium(II) ions or one gallium(I) and one gallium(III) ion? (Hint: Consider the electron configurations of the three possible ions.)
82. The resistivity (a measure of electrical resistance) of graphite is \((0.4\) to 5.0\() \times 10^{-4} \mathrm{ohm} \cdot \mathrm{cm}\) in the basal plane. (The basal plane is the plane of the six-membered rings of carbon atoms.) The resistivity is 0.2 to \(1.0 \mathrm{ohm} \cdot \mathrm{cm}\) along the axis perpendicular to the plane. The resistivity of diamond is \(10^{14}\) to \(10^{16} \mathrm{ohm} \cdot \mathrm{cm}\) and is independent of direction. How can you account for this behavior in terms of the structures of graphite and diamond?
83. When sodium reacts with hydrogen gas, sodium hydride is produced. Is sodium hydride an ionic or a covalent compound? When sodium hydride reacts with water, the equation is:
\[
\mathrm{NaH}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
\]

Show that this reaction can be considered both an oxidationreduction reaction and an acid-base reaction.
84. EDTA is used as a complexing agent in chemical analysis. Solutions of EDTA, usually containing the disodium salt \(\mathrm{Na}_{2} \mathrm{H}_{2}\) EDTA, are also used to treat heavy metal poisoning. The equilibrium constant for the following reaction is \(6.7 \times 10^{21}\) :

Calculate \(\left[\mathrm{Pb}^{2+}\right]\) at equilibrium in a solution originally 0.0050 M in \(\mathrm{Pb}^{2+}, 0.075 \mathrm{M}\) in \(\mathrm{H}_{2} \mathrm{EDTA}^{2-}\), and buffered at \(\mathrm{pH}=7.00\).
85. Photogray lenses contain small embedded crystals of solid silver chloride. Silver chloride is light-sensitive because of the reaction
\[
\mathrm{AgCl}(s) \xrightarrow{h l} \mathrm{Ag}(s)+\mathrm{Cl}
\]

Small particles of metallic silver cause the lenses to darken. In the lenses this process is reversible. When the light is removed, the reverse reaction occurs. However, when pure white silver chloride is exposed to sunlight it darkens; the reverse reaction does not occur in the dark.
a. How do you explain this difference?
b. Photogray lenses do become permanently dark in time.

How do you account for this?
86. Hydrazine is somewhat toxic. Use the following half-reactions to explain why household bleach (highly alkaline solutions of sodium hypochlorite) should not be mixed with household ammonia or glass cleansers that contain ammonia.
\(\mathrm{ClO}^{-}+\mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{OH}^{-}+\mathrm{Cl}^{-} \quad \mathscr{E}{ }^{\circ}=0.90 \mathrm{~V}\)
\(\mathrm{N}_{2} \mathrm{H}_{4}+2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{NH}_{3}+2 \mathrm{OH}^{-} \mathscr{E}^{\circ}=-0.10 \mathrm{~V}\)
87. The compound with the formula \(\mathrm{TII}_{3}\) is a black solid. Given the following standard reduction potentials,
\(\mathrm{Tl}^{3+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Tl}^{+}\)
\(\mathscr{C}^{\circ}=1.25 \mathrm{~V}\)
\(\mathrm{I}_{3}^{-}+2 \mathrm{e}^{-} \longrightarrow 3 \mathrm{I}^{-}\)
\[
\mathscr{E} \circ=0.55 \mathrm{~V}
\]
would you formulate this compound as thallium(III) iodide or thallium(I) triiodide?
88. Draw Lewis structures for the \(\mathrm{AsCl}_{4}{ }^{+}\)and \(\mathrm{AsCl}_{6}{ }^{-}\)ions. What type of reaction (acid-base, oxidation-reduction, or the like) is the following?
\[
2 \mathrm{AsCl}_{5}(g) \longrightarrow \mathrm{AsCl}_{4} \mathrm{AsCl}_{6}(s)
\]
89. There are two forms of solid sulfur: rhombic and monoclinic. The stable form of sulfur at \(25^{\circ} \mathrm{C}\) is the rhombic form. Upon heating, the rhombic form converts to the monoclinic form, which is the stable form of sulfur at high temperatures. Consider the process:
\[
\mathrm{S}_{\text {rhombic }}(s) \longrightarrow \mathrm{S}_{\text {monoclinic }}(s)
\]

Predict the signs of \(\Delta H\) and \(\Delta S\) for this process. Which form of sulfur has the more ordered structure (has the smaller positional probability)?
90. In large doses, selenium is toxic. However, in moderate intake, selenium is a physiologically important element. How is selenium physiologically important?
91. In the 1950s and 1960s, several nations conducted tests of nuclear warheads in the atmosphere. It was customary, following each test, to monitor the concentration of strontium- 90 (a radioactive isotope of strontium) in milk. Why would strontium-90 tend to accumulate in milk?
92. What is a disproportionation reaction? Use the following reduction potentials
\(\begin{array}{ll}\mathrm{ClO}_{3}{ }^{-}+3 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{HClO}_{2}+\mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ}=1.21 \mathrm{~V} \\ \mathrm{HClO}_{2}+2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{HClO}+\mathrm{H}_{2} \mathrm{O} & \mathscr{E}^{\circ}=1.65 \mathrm{~V}\end{array}\) to predict whether \(\mathrm{HClO}_{2}\) will disproportionate.
93. Sulfur forms a wide variety of compounds in which it has +6 , \(+4,+2,0\), and -2 oxidation states. Give examples of sulfur compounds having each of these oxidation states.
94. Halogens form a variety of covalent compounds with each other. For example, chlorine and fluorine form the compounds \(\mathrm{ClF}, \mathrm{ClF}_{3}\), and \(\mathrm{ClF}_{5}\). Predict the molecular structure (including bond angles) for each of these three compounds. Would you expect \(\mathrm{FCl}_{3}\) to be a stable compound? Explain.

\section*{ChemWork Problems}

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
95. Hydrogen gas is being considered as a fuel for automobiles. There are many chemical means for producing hydrogen gas from water. One of these reactions is
\[
\mathrm{C}(s)+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{CO}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g})
\]

In this case the form of carbon used is graphite.
a. Calculate \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) for this reaction using data from Appendix 4.
b. At what temperatures is this reaction spontaneous? Assume \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature.
96. Molten \(\mathrm{CaCl}_{2}\) is electrolyzed for 8.00 h to produce \(\mathrm{Ca}(s)\) and \(\mathrm{Cl}_{2}(g)\).
a. What current is needed to produce 5.52 kg of calcium metal?
b. If 5.52 kg calcium metal is produced, what mass (in kg ) of \(\mathrm{Cl}_{2}\) is produced?
97. Calculate the solubility of \(\operatorname{Mg}(\mathrm{OH})_{2}\left(K_{\text {sp }}=8.9 \times 10^{-12}\right)\) in an aqueous solution buffered at \(\mathrm{pH}=9.42\).
98. Which of the following statement(s) is(are) true?
a. The alkali metals are found in the earth's crust in the form of pure elements.
b. Gallium has one of the highest melting points known for metals.
c. When calcium metal reacts with water, one of the products is \(\mathrm{H}_{2}(g)\).
d. When \(\mathrm{AlCl}_{3}\) is dissolved in water, it produces an acidic solution.
e. Lithium reacts in the presence of excess oxygen gas to form lithium superoxide.
99. What is the hybridization of the underlined nitrogen atom in each of the following molecules or ions?
a. \(\mathrm{NO}^{+}\)
b. \(\mathrm{N}_{2} \mathrm{O}_{3}\left(\mathrm{O}_{2} \mathrm{NNO}\right)\)
c. \(\mathrm{NO}_{2}^{-}\)
d. \(\underline{N}_{2}\)
100. Nitrous oxide \(\left(\mathrm{N}_{2} \mathrm{O}\right)\) can be produced by thermal decomposition of ammonium nitrate:
\[
\mathrm{NH}_{4} \mathrm{NO}_{3}(s) \xrightarrow{\text { heat }} \mathrm{N}_{2} \mathrm{O}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
\]

What volume of \(\mathrm{N}_{2} \mathrm{O}(g)\) collected over water at a total pressure of 94.0 kPa and \(22^{\circ} \mathrm{C}\) can be produced from thermal decomposition of \(8.68 \mathrm{~g} \mathrm{NH}_{4} \mathrm{NO}_{3}\) ? The vapor pressure of water at \(22^{\circ} \mathrm{C}\) is 21 torr.
101. What is the hybridization of the central atom in each of the following molecules?
a. \(\mathrm{SF}_{6}\)
b. \(\mathrm{ClF}_{3}\)
c. \(\mathrm{GeCl}_{4}\)
d. \(\mathrm{XeF}_{4}\)
102. What is the molecular structure for each of the following molecules or ions?
a. \(\mathrm{OCl}_{2}\)
b. \(\mathrm{ClO}_{4}^{-}\)
c. \(\mathrm{ICl}_{5}\)
d. \(\mathrm{PF}_{6}{ }^{-}\)
103. The atmosphere contains \(9.0 \times 10^{-6} \% \mathrm{Xe}\) by volume at 1.0 atm and \(25^{\circ} \mathrm{C}\).
a. Calculate the mass of Xe in a room 7.26 m by 8.80 m by 5.67 m .
b. A typical person takes in about 2 L of air during a breath. How many Xe atoms are inhaled in each breath?
104. Which of following statement(s) is(are) true?
a. Phosphoric acid is a stronger acid than nitric acid.
b. The noble gas with the lowest boiling point is helium.
c. Sulfur is found as the free element in the earth's crust.
d. One of the atoms in Teflon is fluorine.
e. The \(P_{4}\) molecule has a square planar structure.

\section*{Challenge Problems}
105. Suppose 10.00 g of an alkaline earth metal reacts with 10.0 L water to produce 6.10 L hydrogen gas at 1.00 atm and \(25^{\circ} \mathrm{C}\). Identify the metal and determine the pH of the solution.
106. From the information on the temperature stability of white and gray tin given in this chapter, which form would you expect to have the more ordered structure (have the smaller positional probability)?
107. Lead forms compounds in the +2 and +4 oxidation states. All lead(II) halides are known (and are known to be ionic). Only \(\mathrm{PbF}_{4}\) and \(\mathrm{PbCl}_{4}\) are known among the possible lead(IV) halides. Presumably lead(IV) oxidizes bromide and iodide ions, producing the lead(II) halide and the free halogen:
\[
\mathrm{PbX}_{4} \longrightarrow \mathrm{PbX}_{2}+\mathrm{X}_{2}
\]

Suppose 25.00 g of a lead(IV) halide reacts to form 16.12 g of a lead(II) halide and the free halogen. Identify the halogen.
108. Many structures of phosphorus-containing compounds are drawn with some \(\mathrm{P}=\mathrm{O}\) bonds. These bonds are not the typical \(\pi\) bonds we've considered, which involve the overlap of two \(p\) orbitals. Instead, they result from the overlap of a \(d\) orbital on the phosphorus atom with a \(p\) orbital on oxygen. This type of \(\pi\) bonding is sometimes used as an explanation for why \(\mathrm{H}_{3} \mathrm{PO}_{3}\) has the first structure below rather than the second:

Draw a picture showing how a \(d\) orbital and a \(p\) orbital overlap to form a \(\pi\) bond.
109. Use bond energies (see Table 8.5) to show that the preferred products for the decomposition of \(\mathrm{N}_{2} \mathrm{O}_{3}\) are \(\mathrm{NO}_{2}\) and NO rather than \(\mathrm{O}_{2}\) and \(\mathrm{N}_{2} \mathrm{O}\). (The \(\mathrm{N}-\mathrm{O}\) single bond energy is \(201 \mathrm{~kJ} / \mathrm{mol}\).) (Hint: Consider the reaction kinetics.)
110. A proposed two-step mechanism for the destruction of ozone in the upper atmosphere is

a. What is the overall balanced equation for the ozone destruction reaction?
b. Which species is a catalyst?
c. Which species is an intermediate?
d. What is the rate law derived from this mechanism if the first step in the mechanism is slow and the second step is fast?
e. One of the concerns about the use of Freons is that they will migrate to the upper atmosphere, where chlorine atoms can be generated by the reaction
\[
\underset{\text { Freon-12 }}{\mathrm{CCl}_{2} \mathrm{~F}_{2}} \xrightarrow{h \nu} \mathrm{CF}_{2} \mathrm{Cl}+\mathrm{Cl}
\]

Chlorine atoms also can act as a catalyst for the destruction of ozone. The first step of a proposed mechanism for chlorinecatalyzed ozone destruction is
\[
\mathrm{Cl}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{ClO}(g)+\mathrm{O}_{2}(g) \quad \text { Slow }
\]

Assuming a two-step mechanism, propose the second step in the mechanism and give the overall balanced equation.
111. You travel to a distant, cold planet where the ammonia flows like water. In fact, the inhabitants of this planet use ammonia (an abundant liquid on their planet) much as earthlings use water. Ammonia is also similar to water in that it is amphoteric and undergoes autoionization. The \(K\) value for the autoionization of ammonia is \(1.8 \times 10^{-12}\) at the standard temperature of the planet. What is the pH of ammonia at this temperature?
112. Nitrogen gas reacts with hydrogen gas to form ammonia gas \(\left(\mathrm{NH}_{3}\right)\). Consider the following illustration representing the original reaction mixture in a 15.0 L container (the numbers of each molecule shown are relative numbers):

Assume this reaction mixture goes to completion. The piston apparatus allows the container volume to change in order to keep the pressure constant at 1.00 atm . Assume ideal behavior and constant temperature.
a. What is the partial pressure of ammonia in the container when the reaction is complete?
b. What is the mole fraction of ammonia in the container when the reaction is complete?
c. What is the volume of the container when the reaction is complete?
113. A cylinder fitted with a movable piston initially contains 2.00 moles of \(\mathrm{O}_{2}(g)\) and an unknown amount of \(\mathrm{SO}_{2}(g)\). The oxygen is known to be in excess. The density of the mixture is \(0.8000 \mathrm{~g} / \mathrm{L}\) at some \(T\) and \(P\). After the reaction has gone to completion, forming \(\mathrm{SO}_{3}(g)\), the density of the resulting gaseous mixture is \(0.8471 \mathrm{~g} / \mathrm{L}\) at the same \(T\) and \(P\). Calculate the mass of \(\mathrm{SO}_{3}\) formed in the reaction.
114. Sodium tripolyphosphate \(\left(\mathrm{Na}_{5} \mathrm{P}_{3} \mathrm{O}_{10}\right)\) is used in many synthetic detergents. Its major effect is to soften the water by complexing \(\mathrm{Mg}^{2+}\) and \(\mathrm{Ca}^{2+}\) ions. It also increases the efficiency of surfactants, or wetting agents, that lower a liquid's surface tension. The \(\mathrm{p} K\) value for the formation of \(\mathrm{MgP}_{3} \mathrm{O}_{10}{ }^{3-}\) is -8.60 . The reaction is
\[
\mathrm{Mg}^{2+}(a q)+\mathrm{P}_{3} \mathrm{O}_{10}{ }^{5-}(a q) \rightleftharpoons \mathrm{MgP}_{3} \mathrm{O}_{10}{ }^{3-}(a q)
\]

Calculate the concentration of \(\mathrm{Mg}^{2+}\) in a solution that was originally \(50 . \mathrm{ppm} \mathrm{Mg}^{2+}\) ( \(50 . \mathrm{mg} / \mathrm{L}\) of solution) after \(40 . \mathrm{g}\) of \(\mathrm{Na}_{5} \mathrm{P}_{3} \mathrm{O}_{10}\) is added to 1.0 L of the solution.
115. Provide a reasonable estimate for the number of atoms in a 150-lb adult human. Use the information given in Table 20.2.

\section*{Integrative Problems}

These problems require the integration of multiple concepts to find the solutions.
116. The heaviest member of the alkaline earth metals is radium ( Ra ), a naturally radioactive element discovered by Pierre and Marie Curie in 1898. Radium was initially isolated from the uranium ore pitchblende, in which it is present as approximately 1.0 g per 7.0 metric tons of pitchblende. How many atoms of radium can be isolated from \(1.75 \times 10^{8} \mathrm{~g}\) pitchblende ( 1 metric ton \(=1000 \mathrm{~kg}\) )? One of the early uses of radium was as an additive to paint so that watch dials coated with this paint would glow in the dark. The longest-lived isotope of radium has a half-life of \(1.60 \times 10^{3}\) years. If an antique watch, manufactured in 1925, contains 15.0 mg radium, how many atoms of radium will remain in 2025?
117. Indium(III) phosphide is a semiconducting material that has been frequently used in lasers, light-emitting diodes (LED), and fiber-optic devices. This material can be synthesized at 900. K according to the following reaction:
\[
\mathrm{In}\left(\mathrm{CH}_{3}\right)_{3}(g)+\mathrm{PH}_{3}(g) \longrightarrow \operatorname{InP}(s)+3 \mathrm{CH}_{4}(g)
\]
a. If \(2.56 \mathrm{~L} \operatorname{In}\left(\mathrm{CH}_{3}\right)_{3}\) at 2.00 atm is allowed to react with \(1.38 \mathrm{~L} \mathrm{PH}_{3}\) at 3.00 atm , what mass of \(\operatorname{InP}(s)\) will be produced assuming the reaction has an \(87 \%\) yield?
b. When an electric current is passed through an optoelectronic device containing InP, the light emitted has an energy of \(2.03 \times 10^{-19} \mathrm{~J}\). What is the wavelength of this light and is it visible to the human eye?
c. The semiconducting properties of InP can be altered by doping. If a small number of phosphorus atoms are replaced by atoms with an electron configuration of \([\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{4}\), is this n-type or p-type doping?
118. Although nitrogen trifluoride \(\left(\mathrm{NF}_{3}\right)\) is a thermally stable compound, nitrogen triiodide \(\left(\mathrm{NI}_{3}\right)\) is known to be a highly explosive material. \(\mathrm{NI}_{3}\) can be synthesized according to the equation
\[
\mathrm{BN}(s)+3 \mathrm{IF}(g) \longrightarrow \mathrm{BF}_{3}(g)+\mathrm{NI}_{3}(g)
\]
a. What is the enthalpy of formation for \(\mathrm{NI}_{3}(s)\) given the enthalpy of reaction \((-307 \mathrm{~kJ})\) and the enthalpies of formation for \(\mathrm{BN}(s)(-254 \mathrm{~kJ} / \mathrm{mol}), \operatorname{IF}(\mathrm{g})(-96 \mathrm{~kJ} / \mathrm{mol})\), and \(\mathrm{BF}_{3}(\mathrm{~g})(-1136 \mathrm{~kJ} / \mathrm{mol})\) ?
b. It is reported that when the synthesis of \(\mathrm{NI}_{3}\) is conducted using 4 moles of IF for every 1 mole of BN , one of the by-products isolated is \(\left[\mathrm{IF}_{2}\right]^{+}\left[\mathrm{BF}_{4}\right]^{-}\). What are the molecular geometries of the species in this by-product? What are the hybridizations of the central atoms in each species in the by-product?
119. While selenic acid has the formula \(\mathrm{H}_{2} \mathrm{SeO}_{4}\) and thus is directly related to sulfuric acid, telluric acid is best visualized as \(\mathrm{H}_{6} \mathrm{TeO}_{6}\) or \(\mathrm{Te}(\mathrm{OH})_{6}\).
a. What is the oxidation state of tellurium in \(\mathrm{Te}(\mathrm{OH})_{6}\) ?
b. Despite its structural differences with sulfuric and selenic acid, telluric acid is a diprotic acid with \(\mathrm{p} K_{\mathrm{a}_{1}}=7.68\) and \(\mathrm{p} K_{\mathrm{a}_{2}}=11.29\). Telluric acid can be prepared by hydrolysis of tellurium hexafluoride according to the equation
\[
\mathrm{TeF}_{6}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Te}(\mathrm{OH})_{6}(a q)+6 \mathrm{HF}(a q)
\]

Tellurium hexafluoride can be prepared by the reaction of elemental tellurium with fluorine gas:
\[
\mathrm{Te}(s)+3 \mathrm{~F}_{2}(g) \longrightarrow \mathrm{TeF}_{6}(g)
\]

If a cubic block of tellurium (density \(=6.240 \mathrm{~g} / \mathrm{cm}^{3}\) ) measuring 0.545 cm on edge is allowed to react with 2.34 L fluorine gas at 1.06 atm and \(25^{\circ} \mathrm{C}\), what is the pH of a solution of \(\mathrm{Te}(\mathrm{OH})_{6}\) formed by dissolving the isolated \(\mathrm{TeF}_{6}(g)\) in 115 mL solution? Assume \(100 \%\) yield in all reactions.

\section*{Marathon Problems}

These problems are designed to incorporate several concepts and techniques into one situation.
120. Captain Kirk has set a trap for the Klingons who are threatening an innocent planet. He has sent small groups of fighter rockets to sites that are invisible to Klingon radar and put a decoy in the open. He calls this the "fishhook" strategy. Mr. Spock has sent a coded message to the chemists on the fighters to tell the ships what to do next. The outline of the message is

\(\overline{(7)}-\frac{}{(8)} \overline{(9)} \overline{(10)} \overline{(11)} \overline{(12)} \overline{(10)} \overline{(11)}\)

Fill in the blanks of the message using the following clues.
(1) Symbol of the halogen whose hydride has the second highest boiling point in the series of HX compounds that are hydrogen halides.
(2) Symbol of the halogen that is the only hydrogen halide, HX, that is a weak acid in aqueous solution.
(3) Symbol of the element whose existence on the sun was known before its existence on earth was discovered.
(4) The Group 5A element in Table 20.13 that should have the most metallic character.
(5) Symbol of the Group 6A element that, like selenium, is a semiconductor.
(6) Symbol for the element known in rhombic and monoclinic forms.
(7) Symbol for the element that exists as diatomic molecules in a yellow-green gas when not combined with another element.
(8) Symbol for the most abundant element in and near the earth's crust.
(9) Symbol for the element that seems to give some protection against cancer when a diet rich in this element is consumed.
(10) Symbol for the smallest noble gas that forms compounds with fluorine having the general formula \(\mathrm{AF}_{2}\) and \(\mathrm{AF}_{4}\) (reverse the symbol and split the letters as shown).
(11) Symbol for the toxic element that, like phosphorus and antimony, forms tetrameric molecules when uncombined with other elements (split the letters of the symbol as shown).
(12) Symbol for the element that occurs as an inert component of air but is a very prominent part of fertilizers and explosives.
121. Use the symbols of the elements described in the following clues to fill in the blanks that spell out the name of a famous American scientist. Although this scientist was better known as a physicist than as a chemist, the Philadelphia institute that bears his name does include a biochemistry research facility.
\[
\overline{(1)} \overline{(2)} \overline{(3)}-\overline{(4)}-\overline{(5)} \overline{(6)}-\overline{(7)}
\]
(1) The oxide of this alkaline earth metal is amphoteric.
(2) The element that makes up approximately \(3.0 \%\) by mass of the human body.
(3) The element having a \(7 s^{1}\) valence electron configuration.
(4) This element is the alkali metal with the least negative standard reduction potential. Write its symbol in reverse order.
(5) The alkali metal whose ion is more concentrated in intracellular fluids as compared with blood plasma.
(6) This is the only alkali metal that reacts directly with nitrogen to make a binary compound with formula \(\mathrm{M}_{3} \mathrm{~N}\).
(7) This element is the first in Group 3A for which the +1 oxidation state is exhibited in stable compounds. Use only the second letter of its symbol.

The brilliant color of rubies results from trace concentrations of \(\mathrm{Cr}^{3+}\) ions. (© Stanislav Rishnyak/Alamy)

Hydrometallurgy
The Metallurgy of Iron
Production of Steel
Heat Treatment of Steel ransition metals have many uses in our society. Iron is used for steel; copper for electrical wiring and water pipes; titanium for paint; silver for photographic paper; manganese, chromium, vanadium, and cobalt as additives to steel; platinum for industrial and automotive catalysts; and so on.

One indication of the importance of transition metals is the great concern shown by the U.S. government for continuing the supply of these elements. In recent years the United States has been a net importer of about 60 "strategic and critical" minerals, including cobalt, manganese, platinum, palladium, and chromium. All these metals play a vital role in the U.S. economy and defense, and approximately \(90 \%\) of the required amounts must be imported (Table 21.1).

In addition to being important in industry, transition metal ions play a vital role in living organisms. For example, complexes of iron provide for the transport and storage of oxygen, molybdenum and iron compounds are catalysts in nitrogen fixation, zinc is found in more than 150 biomolecules in humans, copper and iron play a crucial role in the respiratory cycle, and cobalt is found in essential biomolecules such as vitamin \(B_{12}\).

In this chapter we will explore the general properties of transition metals, paying particular attention to the bonding, structure, and properties of the complex ions of these metals.

\subsection*{21.1 The Transition Metals: A Survey}

\section*{General Properties}

One striking characteristic of the representative elements is that their chemistry changes markedly across a given period as the number of valence electrons changes. The chemical similarities occur mainly within the vertical groups. In contrast, the transition metals show great similarities within a given period as well as within a given vertical group. This difference occurs because the last electrons added for transition metals are inner electrons: \(d\) electrons for the \(d\)-block transition metals and \(f\) electrons for the lanthanides and actinides. These inner \(d\) and \(f\) electrons cannot participate as easily in bonding as can the valence \(s\) and \(p\) electrons. Thus the chemistry of the transition elements is not affected as greatly by the gradual change in the number of electrons as is the chemistry of the representative elements.

Group designations are traditionally given on the periodic table for the \(d\)-block transition metals (Fig. 21.1). However, these designations do not relate as directly to the chemical behavior of these elements as they do for the representative elements (the A groups), so we will not use them.

\section*{TABLE 21.1 \| Some Transition Metals Important to the U.S. Economy and Defense}
\begin{tabular}{lll} 
& Uses & \begin{tabular}{c} 
Percentage \\
Imported
\end{tabular} \\
\hline Metal & \begin{tabular}{l}

magnets, catalysts, drill bits
\end{tabular} & \(\sim 93 \%\) \\
\hline Manganese & Steelmaking & \(\sim 97 \%\) \\
\hline Platinum and palladium & Catalysts & \(\sim 87 \%\) \\
\hline
\end{tabular}

FIGURE 21.1 The position of the transition elements on the periodic table. The \(d\)-block elements correspond to filling the \(3 d, 4 d, 5 d\), or \(6 d\) orbitals. The inner transition metals correspond to filling the \(4 f\) (lanthanides) or \(5 f\) (actinides) orbitals.

As a class, the transition metals behave as typical metals, possessing metallic luster and relatively high electrical and thermal conductivities. Silver is the best conductor of heat and electric current. However, copper is a close second, which explains copper's wide use in the electrical systems of homes and factories.

Despite their many similarities, the transition metals do vary considerably in certain properties. For example, tungsten has a melting point of \(3400^{\circ} \mathrm{C}\) and is used for filaments in light bulbs; mercury is a liquid at \(25^{\circ} \mathrm{C}\). Some transition metals such as iron and titanium are hard and strong and make very useful structural materials; others such as copper, gold, and silver are relatively soft. The chemical reactivity of the transition metals also varies significantly. Some react readily with oxygen to form oxides. Of these metals, some, such as chromium, nickel, and cobalt, form oxides that adhere tightly to the metallic surface, protecting the metal from further oxidation. Others, such as iron, form oxides that scale off, constantly exposing new metal to the corrosion process. On the other hand, the noble metals-primarily gold, silver, platinum, and palladium-do not readily form oxides.

In forming ionic compounds with nonmetals, the transition metals exhibit several typical characteristics:

More than one oxidation state is often found. For example, iron combines with chlorine to form \(\mathrm{FeCl}_{2}\) and \(\mathrm{FeCl}_{3}\).

The cations are often complex ions, species where the transition metal ion is surrounded by a certain number of ligands (molecules or ions that behave as Lewis bases). For example, the compound \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}\) contains the \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}\) cation and \(\mathrm{Cl}^{-}\)anions.

Most compounds are colored, because the transition metal ion in the complex ion can absorb visible light of specific wavelengths.

Many compounds are paramagnetic (they contain unpaired electrons).
In this chapter we will concentrate on the first-row transition metals (scandium through zinc) because they are representative of the other transition series and because they have great practical significance. Some important properties of these elements are summarized in Table 21.2 and are discussed in the next section.

\section*{Electron Configurations}

The electron configurations of the first-row transition metals were discussed in Section 7.11. The \(3 d\) orbitals begin to fill after the \(4 s\) orbital is complete, that is, after calcium ( \([\mathrm{Ar}] 4 s^{2}\) ). The first transition metal, scandium, has one electron in the \(3 d\) orbitals; the

(clockwise from upper left) Calcite stalactites colored by traces of iron. Quartz is often colored by the presence of transition metals such as \(\mathrm{Mn}, \mathrm{Fe}\), and Ni. Wulfenite contains \(\mathrm{PbMoO}_{4}\). Rhodochrosite is a mineral containing \(\mathrm{MnCO}_{3}\).

TABLE 21.2 | Selected Properties of the First-Row Transition Metals
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|}
\hline & Scandium & Titanium & Vanadium & Chromium & Manganese & Iron & Cobalt & Nickel & Copper & Zinc \\

Chromium has the electron configuration [Ar]4s'3d \({ }^{5}\)

A set of orbitals with the same energy is said to be degenerate.

Copper has the electron configuration [Ar]4s \({ }^{13} d^{10}\).

In transition metal ions, the 3d orbitals are lower in energy than the 4 s orbitals.
second, titanium, has two; and the third, vanadium, has three. We would expect chromium, the fourth transition metal, to have the electron configuration [Ar] \(4 s^{2} 3 d^{4}\). However, the actual configuration is \([\mathrm{Ar}] 4 s^{1} 3 d^{5}\), which shows a half-filled \(4 s\) orbital and a half-filled set of \(3 d\) orbitals (one electron in each of the five \(3 d\) orbitals). It is tempting to say that the configuration results because half-filled "shells" are especially stable. Although there are some reasons to think that this explanation might be valid, it is an oversimplification. For instance, tungsten, which is in the same vertical group as chromium, has the configuration \([\mathrm{Xe}] 6 s^{2} 4 f^{14} 5 d^{4}\), where half-filled \(s\) and \(d\) shells are not found. There are several similar cases.

Basically, the chromium configuration occurs because the energies of the \(3 d\) and \(4 s\) orbitals are very similar for the first-row transition elements. We saw in Section 7.11 that when electrons are placed in a set of degenerate orbitals, they first occupy each orbital singly to minimize electron repulsions. Since the \(4 s\) and \(3 d\) orbitals are virtually degenerate in the chromium atom, we would expect the configuration
\[
4 s \uparrow \quad 3 d \uparrow \uparrow \uparrow \uparrow \uparrow
\]
rather than
\[
4 s \uparrow \downarrow \quad 3 d \uparrow \uparrow \uparrow \uparrow-
\]
since the second arrangement has greater electron-electron repulsions and thus a higher energy.

The only other unexpected configuration among the first-row transition metals is that of copper, which is \([\mathrm{Ar}] 4 s^{1} 3 d^{10}\) rather than the expected \([\mathrm{Ar}] 4 s^{2} 3 d^{9}\).

In contrast to the neutral transition metals, where the \(3 d\) and \(4 s\) orbitals have very similar energies, the energy of the 3d orbitals in transition metal ions is significantly less than that of the \(4 s\) orbital. This means that the electrons remaining after the ion is formed occupy the \(3 d\) orbitals, since they are lower in energy. First-row transition metal ions do not have \(4 s\) electrons. For example, manganese has the configuration [ Ar\(] 4 s^{2} 3 d^{5}\), while that of \(\mathrm{Mn}^{2+}\) is \([\mathrm{Ar}] 3 d^{5}\). The neutral titanium atom has the configuration \([\mathrm{Ar}] 4 s^{2} 3 d^{2}\), while that of \(\mathrm{Ti}^{3+}\) is \([\mathrm{Ar}] 3 d^{1}\).

FIGURE 21.2 Plots of the first (red dots) and third (blue dots) ionization energies for the first-row transition metals.

\section*{Oxidation States and Ionization Energies}

The transition metals can form a variety of ions by losing one or more electrons. The common oxidation states of these elements are shown in Table 21.2. Note that for the first five metals the maximum possible oxidation state corresponds to the loss of all the \(4 s\) and \(3 d\) electrons. For example, the maximum oxidation state of chromium \(\left([\operatorname{Ar}] 4 s^{1} 3 d^{5}\right)\) is +6 . Toward the right end of the period, the maximum oxidation states are not observed; in fact, the \(2+\) ions are the most common. The higher oxidation states are not seen for these metals because the \(3 d\) orbitals become lower in energy as the nuclear charge increases, and the electrons become increasingly difficult to remove. From Table 21.2 we see that ionization energy increases gradually going from left to right across the period. However, the third ionization energy (when an electron is removed from a \(3 d\) orbital) increases faster than the first ionization energy, clear evidence of the significant decrease in the energy of the \(3 d\) orbitals going across the period (Fig. 21.2).

\section*{Standard Reduction Potentials}

When a metal acts as a reducing agent, the half-reaction is
\[
\mathrm{M} \longrightarrow \mathrm{M}^{n+}+n \mathrm{e}^{-}
\]

This is the reverse of the conventional listing for half-reactions in tables. Thus, to rank the transition metals in order of reducing ability, it is most convenient to reverse the reactions and the signs given in Table 21.2. The metal with the most positive potential is then the best reducing agent. The transition metals are listed in order of reducing ability in Table 21.3.

Since \(\mathscr{E}^{\circ}\) is zero for the process
\[
2 \mathrm{H}^{+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}
\]
all the metals except copper can reduce \(\mathrm{H}^{+}\)ions to hydrogen gas in \(1 M\) aqueous solutions of strong acid:
\[
\mathrm{M}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{M}^{2+}(a q)
\]

As Table 21.3 shows, the reducing abilities of the first-row transition metals generally decrease going from left to right across the period. Only chromium and zinc do not follow this trend.

FIGURE 21.3 Atomic radii of the \(3 d, 4 d\), and \(5 d\) transition series.

Niobium was originally called columbium and is still occasionally referred to by that name.

\section*{The 4d and 5d Transition Series}

In comparing the \(3 d, 4 d\), and \(5 d\) transition series, it is instructive to consider the atomic radii of these elements (Fig. 21.3). Note that there is a general, although not regular, decrease in size going from left to right for each of the series. Also note that although there is a significant increase in radius in going from the \(3 d\) to the \(4 d\) metals, the \(4 d\) and \(5 d\) metals are remarkably similar in size. This latter phenomenon is the result of the lanthanide contraction. In the lanthanide series, consisting of the elements between lanthanum and hafnium (see Fig. 21.1), electrons are filling the \(4 f\) orbitals. Since the \(4 f\) orbitals are buried in the interior of these atoms, the additional electrons do not add to the atomic size. In fact, the increasing nuclear charge (remember that a proton is added to the nucleus for each electron) causes the radii of the lanthanide elements to decrease significantly going from left to right. This lanthanide contraction just offsets the normal increase in size due to going from one principal quantum level to another. Thus the \(5 d\) elements, instead of being significantly larger than the \(4 d\) elements, are almost identical to them in size. This leads to a great similarity in the chemistry of the \(4 d\) and \(5 d\) elements in a given vertical group. For example, the chemical properties of hafnium and zirconium are remarkably similar, and they always occur together in nature. Their separation, which is probably more difficult than the separation of any other pair of elements, often requires fractional distillation of their compounds.

In general, the differences between the \(4 d\) and \(5 d\) elements in a group increase gradually going from left to right. For example, niobium and tantalum are also quite similar, but less so than zirconium and hafnium.

Although generally less well known than the \(3 d\) elements, the \(4 d\) and \(5 d\) transition metals have certain very useful properties. For example, zirconium and zirconium oxide \(\left(\mathrm{ZrO}_{2}\right)\) have great resistance to high temperatures and are used, along with niobium and molybdenum alloys, for space vehicle parts that are exposed to high temperatures during re-entry into the earth's atmosphere. Niobium and molybdenum are also important alloying materials for certain types of steel. Tantalum, which has a high resistance to attack by body fluids, is often used for replacement of bones. The platinum group metals-ruthenium, osmium, rhodium, iridium, palladium, and platinum—are all quite similar and are widely used as catalysts for many types of industrial processes.

\subsection*{21.2 The First-Row Transition Metals}

We have seen that the transition metals are similar in many ways but also show important differences. We will now explore some of the specific properties of each of the \(3 d\) transition metals.

Scandium is a rare element that exists in compounds mainly in the +3 oxidation state-for example, in \(\mathrm{ScCl}_{3}, \mathrm{Sc}_{2} \mathrm{O}_{3}\), and \(\mathrm{Sc}_{2}\left(\mathrm{SO}_{4}\right)_{3}\). The chemistry of scandium

\(\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) is purple in solution.

The manufacture of sulfuric acid was discussed at the end of Chapter 3.

The most common oxidation state for vanadium is +5 .

\hline+2 & \(\mathrm{~V}^{2+}(a q)\) (violet) \\
\hline
\end{tabular}
strongly resembles that of the lanthanides, with most of its compounds being colorless and diamagnetic. This is not surprising; as we will see in Section 21.6, the color and magnetism of transition metal compounds usually arise from the \(d\) electrons on the metal ion, and \(\mathrm{Sc}^{3+}\) has no \(d\) electrons. Scandium metal, which can be prepared by electrolysis of molten \(\mathrm{ScCl}_{3}\), is not widely used because of its rarity, but it is found in some electronic devices, such as high-intensity lamps.

Titanium is widely distributed in the earth's crust ( \(0.6 \%\) by mass). Because of its relatively low density and high strength, titanium is an excellent structural material, especially in jet engines, where light weight and stability at high temperatures are required. Nearly 5000 kg of titanium alloys is used in each engine of a Boeing 747 jetliner. In addition, the resistance of titanium to chemical attack makes it a useful material for pipes, pumps, and reaction vessels in the chemical industry.

The most familiar compound of titanium is no doubt responsible for the white color of this paper. Titanium dioxide, or more correctly, titanium \((I V)\) oxide \(\left(\mathrm{TiO}_{2}\right)\), is a highly opaque substance used as the white pigment in paper, paint, linoleum, plastics, synthetic fibers, whitewall tires, and cosmetics (sunscreens, for example). Over one million tons is used annually in these and other products. Titanium(IV) oxide is widely dispersed in nature, but the main ores are rutile (impure \(\mathrm{TiO}_{2}\) ) and ilmenite \(\left(\mathrm{FeTiO}_{3}\right)\). Rutile is processed by treatment with chlorine to form volatile \(\mathrm{TiCl}_{4}\), which is separated from the impurities and burned to form \(\mathrm{TiO}_{2}\) :
\[
\mathrm{TiCl}_{4}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{TiO}_{2}(s)+2 \mathrm{Cl}_{2}(g)
\]

Ilmenite is treated with sulfuric acid to form a soluble sulfate:
\[
\mathrm{FeTiO}_{3}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{Fe}^{2+}(a q)+\mathrm{TiO}^{2+}(a q)+2 \mathrm{SO}_{4}{ }^{2-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
\]

When this aqueous mixture is allowed to stand, under vacuum, solid \(\mathrm{FeSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}\) forms first and is removed. The mixture is then heated, and the insoluble titanium(IV) oxide hydrate \(\left(\mathrm{TiO}_{2} \cdot \mathrm{H}_{2} \mathrm{O}\right)\) forms. The water of hydration is driven off by heating to form pure \(\mathrm{TiO}_{2}\) :
\[
\mathrm{TiO}_{2} \cdot \mathrm{H}_{2} \mathrm{O}(s) \xrightarrow{\text { Heat }} \mathrm{TiO}_{2}(s)+\mathrm{H}_{2} \mathrm{O}(g)
\]

In its compounds, titanium is most often found in the +4 oxidation state. Examples are \(\mathrm{TiO}_{2}\) and \(\mathrm{TiCl}_{4}\), the latter a colorless liquid ( \(\mathrm{bp}=137^{\circ} \mathrm{C}\) ) that fumes in moist air to produce \(\mathrm{TiO}_{2}\) :
\[
\mathrm{TiCl}_{4}(l)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{TiO}_{2}(s)+4 \mathrm{HCl}(g)
\]

Titanium(III) compounds can be produced by reduction of the +4 state. In aqueous solution, \(\mathrm{Ti}^{3+}\) exists as the purple \(\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) ion, which is slowly oxidized to titanium(IV) by air. Titanium(II) is not stable in aqueous solution but does exist in the solid state in compounds such as TiO and the dihalides of general formula \(\mathrm{TiX}_{2}\).

Vanadium is widely spread throughout the earth's crust ( \(0.02 \%\) by mass). It is used mostly in alloys with other metals such as iron ( \(80 \%\) of vanadium is used in steel) and titanium. Vanadium \((\mathrm{V})\) oxide \(\left(\mathrm{V}_{2} \mathrm{O}_{5}\right)\) is used as an industrial catalyst in the production of materials such as sulfuric acid.

Pure vanadium can be obtained from the electrolytic reduction of fused salts, such as \(\mathrm{VCl}_{2}\), to produce a metal similar to titanium that is steel gray, hard, and corrosion resistant. Often the pure element is not required for alloying. For example, ferrovanadium, produced by the reduction of a mixture of \(\mathrm{V}_{2} \mathrm{O}_{5}\) and \(\mathrm{Fe}_{2} \mathrm{O}_{3}\) with aluminum, is added to iron to form vanadium steel, a hard steel used for engine parts and axles.

The principal oxidation state of vanadium is +5 , found in compounds such as the orange \(\mathrm{V}_{2} \mathrm{O}_{5}\left(\mathrm{mp}=650^{\circ} \mathrm{C}\right)\) and the colorless \(\mathrm{VF}_{5}\left(\mathrm{mp}=19.5^{\circ} \mathrm{C}\right)\). The oxidation states from +5 to +2 all exist in aqueous solution (Table 21.4). The higher oxidation states, +5 and +4 , do not exist as hydrated ions of the type \(\mathrm{V}^{n+}(a q)\) because the highly charged ion causes the attached water molecules to be very acidic. The \(\mathrm{H}^{+}\)ions are lost to give the oxycations \(\mathrm{VO}_{2}{ }^{+}\)and \(\mathrm{VO}^{2+}\). The hydrated \(\mathrm{V}^{3+}\) and \(\mathrm{V}^{2+}\) ions are easily oxidized and thus can function as reducing agents in aqueous solution.

\section*{CHEMICAL CONNECTIONS}

\section*{Titanium Dioxide—Miracle Coating}

Titanium dioxide, more properly called titanium(IV) oxide, is a very important material. Approximately 1.5 million tons of the substance is produced each year in the United States for use as a pigment in paper and paints and as a component of sunscreens.

Scientists, however, have found a different use for \(\mathrm{TiO}_{2}\). When surfaces are coated with titanium dioxide, they become resistant to dirt and bacteria. For example, the Pilkington Glass Company makes glass coated with \(\mathrm{TiO}_{2}\) that cleans itself. All the glass needs is sun and rain to keep itself clean. The selfcleaning action arises from two effects. First, the coating of \(\mathrm{TiO}_{2}\) acts as a catalyst in the presence of ultraviolet (UV)
light to break down carbon-based pollutants to carbon dioxide and water. Second, because \(\mathrm{TiO}_{2}\) reduces surface tension, rainwater "sheets" instead of forming droplets on the glass, thereby washing away the grime on the surface of the glass. Although this self-cleaning glass is bad news for window washers, it could save millions of dollars in maintenance costs for owners of commercial buildings.

Because the \(\mathrm{TiO}_{2}\)-treated glass requires UV light for its action, it does not work well for interior surfaces where UV light is present only in small amounts. However, a team of Japanese researchers has found that if the \(\mathrm{TiO}_{2}\) coating is doped with nitrogen atoms, it will catalyze the breakdown of dirt in
the presence of visible light as well as UV light. Studies also show that this N -doped \(\mathrm{TiO}_{2}\) surface coating kills many types of bacteria in the presence of visible or ultraviolet light. This discovery could lead to products such as self-sterilizing bathroom tiles, counters, and toilets. In addition, because the \(\mathrm{TiO}_{2}\) on the surface of glass has such a strong attraction for water molecules (greatly lowering the surface tension), water does not bead up to form droplets. Just as this effect produces sheeting action on exterior glass, so it prevents interior windows and mirrors from "fogging up."

Titanium dioxide, a cheap and plentiful material, may prove to be worth its weight in gold as a surface coating.

\section*{TABLE 21.5 | Typical Chromium Compounds}
\begin{tabular}{|cl|}
\hline \begin{tabular}{c} 
Oxidation \\
State of \\
Chromium
\end{tabular} & \begin{tabular}{l} 
Examples of \\
Compounds \\
(X = halogen)
\end{tabular} \\
\hline+2 & \(\mathrm{CrX}_{2}\) \\
\hline+3 & \(\mathrm{CrX}_{3}\) \\
\hline & \(\mathrm{Cr}_{2} \mathrm{O}_{3}\) (green) \\
\hline & \(\mathrm{Cr}^{(\mathrm{OH})_{3} \text { (blue-green) }}\) \\
\hline+6 & \(\mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}\) (orange) \\
\hline & \(\mathrm{Na}_{2} \mathrm{CrO}_{4}\) (yellow) \\
\hline & \(\mathrm{CrO}_{3}\) (red) \\
\hline
\end{tabular}

Although chromium is relatively rare, it is a very important industrial material. The chief ore of chromium is chromite \(\left(\mathrm{FeCr}_{2} \mathrm{O}_{4}\right)\), which can be reduced by carbon to give ferrochrome,
\[
\mathrm{FeCr}_{2} \mathrm{O}_{4}(s)+4 \mathrm{C}(s) \longrightarrow \underbrace{\mathrm{Fe}(s)+2 \mathrm{Cr}(s)}_{\text {Ferrochrome }}+4 \mathrm{CO}(g)
\]
which can be added directly to iron in the steelmaking process. Chromium metal, which is often used to plate steel, is hard and brittle and maintains a bright surface by developing a tough invisible oxide coating.

Chromium commonly forms compounds in which it has the oxidation state +2 , +3 , or +6 , as shown in Table 21.5. The \(\mathrm{Cr}^{2+}\) (chromous) ion is a powerful reducing agent in aqueous solution. In fact, traces of \(\mathrm{O}_{2}\) in other gases can be removed by bubbling through a \(\mathrm{Cr}^{2+}\) solution:
\[
4 \mathrm{Cr}^{2+}(a q)+\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q) \longrightarrow 4 \mathrm{Cr}^{3+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
\]

The chromium(VI) species are excellent oxidizing agents, especially in acidic solution, where chromium(VI) as the dichromate ion \(\left(\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}\right)\) is reduced to the \(\mathrm{Cr}^{3+}\) ion:
\[
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+14 \mathrm{H}^{+}(a q)+6 \mathrm{e}^{-} \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l) \quad \mathscr{E} \circ=1.33 \mathrm{~V}
\]

The oxidizing ability of the dichromate ion is strongly pH -dependent, increasing as \(\left[\mathrm{H}^{+}\right]\)increases, as predicted by Le Châtelier's principle. In basic solution, chromium(VI) exists as the chromate ion, a much less powerful oxidizing agent:
\[
\mathrm{CrO}_{4}{ }^{2-}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Cr}(\mathrm{OH})_{3}(s)+5 \mathrm{OH}^{-}(a q) \quad \mathscr{E}^{\circ}=-0.13 \mathrm{~V}
\]

The structures of the \(\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}\) and \(\mathrm{CrO}_{4}{ }^{2-}\) ions are shown in Fig. 21.4.

FIGURE 21.4 The structures of the chromium \((\mathrm{VI})\) anions: \((\mathbf{a}) \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}\), which exists in acidic solution, and (b) \(\mathrm{CrO}_{4}{ }^{2-}\), which exists in basic solution.

\hline & MnS (salmon) \\
\hline & \(\mathrm{MnSO}_{4}\) (reddish) \\
\hline+4 & \begin{tabular}{l}
\(\mathrm{MnCl}_{2}\) (pink) \\
\(\mathrm{MnO}_{2}\) (dark \\
\hline+7
\end{tabular} \\
\hline
\end{tabular}

Red chromium(VI) oxide \(\left(\mathrm{CrO}_{3}\right)\) dissolves in water to give a strongly acidic, redorange solution:
\[
2 \mathrm{CrO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{H}^{+}(a q)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)
\]

It is possible to precipitate bright orange dichromate salts, such as \(\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}\), from these solutions. When made basic, the solution turns yellow, and chromate salts such as \(\mathrm{Na}_{2} \mathrm{CrO}_{4}\) can be obtained. A mixture of chromium(VI) oxide and concentrated sulfuric acid, commonly called cleaning solution, is a powerful oxidizing medium that can remove organic materials from analytical glassware, yielding a very clean surface.

Manganese is relatively abundant ( \(0.1 \%\) of the earth's crust), although no significant sources are found in the United States. The most common use of manganese is in the production of an especially hard steel used for rock crushers, bank vaults, and armor plate. One interesting source of manganese is from manganese nodules found on the ocean floor. These roughly spherical "rocks" contain mixtures of manganese and iron oxides as well as smaller amounts of other metals such as cobalt, nickel, and copper. Apparently, the nodules were formed at least partly by the action of marine organisms. Because of the abundance of these nodules, there is much interest in developing economical methods for their recovery and processing.

Manganese can exist in all oxidation states from +2 to +7 , although +2 and +7 are the most common. Manganese(II) forms an extensive series of salts with all the common anions. In aqueous solution \(\mathrm{Mn}^{2+}\) forms \(\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\), which has a light pink color. Manganese(VII) is found in the intensely purple permanganate ion \(\left(\mathrm{MnO}_{4}^{-}\right)\). Widely used as an analytical reagent in acidic solution, the \(\mathrm{MnO}_{4}^{-}\)ion behaves as a strong oxidizing agent, with the manganese becoming \(\mathrm{Mn}^{2+}\) :
\[
\mathrm{MnO}_{4}^{-}(a q)+8 \mathrm{H}^{+}(a q)+5 \mathrm{e}^{-} \longrightarrow \mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l) \quad \mathscr{E}^{\circ}=1.51 \mathrm{~V}
\]

Several typical compounds of manganese are shown in Table 21.6.
Iron is the most abundant heavy metal ( \(4.7 \%\) of the earth's crust) and the most important to our civilization. It is a white, lustrous, not particularly hard metal that is very reactive toward oxidizing agents. For example, in moist air it is rapidly oxidized by oxygen to form rust, a mixture of iron oxides.

The chemistry of iron involves mainly its +2 and +3 oxidation states. Typical compounds are listed in Table 21.7. In aqueous solutions iron(II) salts are generally light green because of the presence of \(\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\). Although the \(\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) ion is colorless, aqueous solutions of iron(III) salts are usually yellow to brown in color due to the presence of \(\mathrm{Fe}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}{ }^{2+}\), which results from the acidity of \(\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) \(\left(K_{\mathrm{a}}=6 \times 10^{-3}\right)\) :
\[
\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q) \rightleftharpoons \mathrm{Fe}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}{ }^{2+}(a q)+\mathrm{H}^{+}(a q)
\]

Although cobalt is relatively rare, it is found in ores such as smaltite \(\left(\mathrm{CoAs}_{2}\right)\) and cobaltite (CoAsS) in large enough concentrations to make its production economically feasible. Cobalt is a hard, bluish white metal mainly used in alloys such as stainless steel and stellite, an alloy of iron, copper, and tungsten that is used in surgical instruments.

The chemistry of cobalt involves mainly its +2 and +3 oxidation states, although compounds containing cobalt in the \(0,+1\), or +4 oxidation state are known. Aqueous solutions of cobalt(II) salts contain the \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\) ion, which has a characteristic rose color. Cobalt forms a wide variety of coordination compounds, many of which will be discussed in later sections of this chapter. Some typical cobalt compounds are listed in Table 21.8.

Nickel, which ranks twenty-fourth in elemental abundance in the earth's crust, is found in ores, where it is combined mainly with arsenic, antimony, and sulfur. Nickel metal, a silvery white substance with high electrical and thermal conductivities, is quite resistant to corrosion and is often used for plating more active metals. Nickel is also widely used in the production of alloys such as steel.

Nickel in compounds is almost exclusively in the +2 oxidation state. Aqueous solutions of nickel(II) salts contain the \(\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\) ion, which has a characteristic emerald green color. Coordination compounds of nickel(II) will be discussed later in this chapter. Some typical nickel compounds are listed in Table 21.9.

Copper, widely distributed in nature in ores containing sulfides, arsenides, chlorides, and carbonates, is valued for its high electrical conductivity and its resistance to corrosion. It is widely used for plumbing, and \(50 \%\) of all copper produced annually is used for electrical applications. Copper is a major constituent in several well-known alloys (Table 21.10).

Although copper is not highly reactive (it will not reduce \(\mathrm{H}^{+}\)to \(\mathrm{H}_{2}\), for example), the reddish metal does slowly corrode in air, producing the characteristic green patina consisting of basic copper sulfate
\[
3 \mathrm{Cu}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{SO}_{2}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{Cu}_{3}(\mathrm{OH})_{4} \mathrm{SO}_{4}(s)
\]
and other similar compounds.
The chemistry of copper principally involves the +2 oxidation state, but many compounds containing copper(I) are also known. Aqueous solutions of copper(II) salts are a characteristic bright blue color due to the presence of the \(\mathrm{Cu}_{\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+} \text { ion. Table }}\) 21.11 lists some typical copper compounds.

Although trace amounts of copper are essential for life, copper in large amounts is quite toxic; copper salts are used to kill bacteria, fungi, and algae. For example, paints containing copper are used on ship hulls to prevent fouling by marine organisms.

Widely dispersed in the earth's crust, zinc is refined mainly from sphalerite (ZnS), which often occurs with galena ( PbS ). Zinc is a white, lustrous, very active metal that behaves as an excellent reducing agent and tarnishes rapidly. About \(90 \%\) of the zinc produced is used for galvanizing steel. Zinc forms colorless salts in the +2 oxidation state.

\subsection*{21.3 Coordination Compounds}

Transition metal ions characteristically form coordination compounds, which are usually colored and often paramagnetic. A coordination compound typically consists of a complex ion, a transition metal ion with its attached ligands (see Section 15.8), and counterions, anions or cations as needed to produce a compound with no net charge. The substance \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}\) is a typical coordination compound. The brackets indicate the composition of the complex ion, in this case \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}^{2+}\), and the two \(\mathrm{Cl}^{-}\)counterions are shown outside the brackets. Note that in this compound one \(\mathrm{Cl}^{-}\) acts as a ligand along with the five \(\mathrm{NH}_{3}\) molecules. In the solid state this compound consists of the large \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}^{2+}\) cations and twice as many \(\mathrm{Cl}^{-}\)anions, all packed together as efficiently as possible. When dissolved in water, the solid behaves like any ionic solid; the cations and anions are assumed to separate and move about independently:
\[
\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q)
\]

Coordination compounds have been known since about 1700, but their true nature was not understood until the 1890s when a young Swiss chemist named Alfred Werner (1866-1919) proposed that transition metal ions have two types of valence (combining ability). One type of valence, which Werner called the secondary valence, refers to the ability of a metal ion to bind to Lewis bases (ligands) to form complex ions. The other type, the primary valence, refers to the ability of the metal ion to form ionic bonds with oppositely charged ions. Thus Werner explained that the compound, originally written as \(\mathrm{CoCl}_{3} \cdot 5 \mathrm{NH}_{3}\), was really \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}\), where the \(\mathrm{Co}^{3+}\) ion has a primary valence of 3 , satisfied by the three \(\mathrm{Cl}^{-}\)ions, and a secondary valence of 6 , satisfied by the six ligands (five \(\mathrm{NH}_{3}\) and one \(\mathrm{Cl}^{-}\)). We now call the primary valence the oxidation state and the secondary valence the coordination number, which reflects the number of bonds formed between the metal ion and the ligands in the complex ion.

\section*{Coordination Number}

The number of bonds formed by metal ions to ligands in complex ions varies from two to eight depending on the size, charge, and electron configuration of the transition metal ion. As shown in Table 21.12, 6 is the most common coordination number, followed closely by 4 , with a few metal ions showing a coordination number of 2 . Many metal ions show more than one coordination number, and there is really no simple way to predict what the coordination number will be in a particular case. The typical geometries for the various common coordination numbers are shown in Fig. 21.5. Note that six ligands produce an octahedral arrangement around the metal ion. Four ligands can form either a tetrahedral or a square planar arrangement, and two ligands give a linear structure.

FIGURE 21.6 (a) The bidentate ligand ethylenediamine can bond to the metal ion through the lone pair on each nitrogen atom, thus forming two coordinate covalent bonds. (b) Ammonia is a monodentate ligand.

FIGURE 21.7 The coordination of EDTA with a \(2+\) metal ion.

\section*{Ligands}

A ligand is a neutral molecule or ion having a lone electron pair that can be used to form a bond to a metal ion. The formation of a metal-ligand bond therefore can be described as the interaction between a Lewis base (the ligand) and a Lewis acid (the metal ion). The resulting bond is often called a coordinate covalent bond.

A ligand that can form one bond to a metal ion is called a monodentate ligand, or a unidentate ligand (from root words meaning "one tooth"). Examples of unidentate ligands are shown in Table 21.13.

Some ligands have more than one atom with a lone electron pair that can be used to bond to a metal ion. Such ligands are said to be chelating ligands, or chelates (from the Greek word chele for "claw"). A ligand that can form two bonds to a metal ion is called a bidentate ligand. A very common bidentate ligand is ethylenediamine (abbreviated en), which is shown coordinating to a metal ion in Fig. 21.6(a). Note the relationship between this ligand and the unidentate ligand ammonia [Fig. 21.6(b)]. Oxalate, another typical bidentate ligand, is shown in Table 21.13.

Ligands that can form more than two bonds to a metal ion are called polydentate ligands. Some ligands can form as many as six bonds to a metal ion. The best-known example is ethylenediaminetetraacetate (abbreviated EDTA), which is shown in Table 21.13. This ligand virtually surrounds the metal ion (Fig. 21.7), coordinating through six atoms (a hexadentate ligand). As might be expected from the large number of coordination sites, EDTA forms very stable complex ions with most metal ions and is used as a "scavenger" to remove toxic heavy metals such as lead from the human body. It is also used as a reagent to analyze solutions for their metal ion content. EDTA is found

\end{tabular}
in countless consumer products, such as soda, beer, salad dressings, bar soaps, and most cleaners. In these products EDTA ties up trace metal ions that would otherwise catalyze decomposition and produce unwanted precipitates.

Some even more complicated ligands are found in biological systems, where metal ions play crucial roles in catalyzing reactions, transferring electrons, and transporting and storing oxygen. A discussion of these complex ligands will follow in Section 21.7.

\section*{Nomenclature}

In Werner's lifetime, no system was used to name coordination compounds. Names of the compounds were commonly based on colors and names of discoverers. As the field expanded and more coordination compounds were identified, an orderly system of nomenclature became necessary. A simplified version of this system is summarized by the following rules.

\section*{Rules for Naming Coordination Compounds}
" As with any ionic compound, the cation is named before the anion.
» In naming a complex ion, the ligands are named before the metal ion.
» In naming ligands, an o is added to the root name of an anion. For example, the halides as ligands are called fluoro, chloro, bromo, and iodo; hydroxide is hydroxo; cyanide is cyano; and so on. For a neutral ligand, the name of the molecule is used, with the exception of \(\mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{CO}\), and NO , as illustrated in Table 21.14.
» The prefixes mono-, di-, tri-, tetra-, penta-, and hexa- are used to denote the number of simple ligands. The prefixes bis-, tris-, tetrakis-, and so on are also used, especially for more complicated ligands or ones that already contain di-, tri-, and so on.
" The oxidation state of the central metal ion is designated by a Roman numeral in parentheses.
» When more than one type of ligand is present, they are named alphabetically.* Prefixes do not affect the order.
» If the complex ion has a negative charge, the suffix -ate is added to the name of the metal. Sometimes the Latin name is used to identify the metal (Table 21.15).

The application of these rules is shown in Example 21.1.

TABLE 21.15 | Latin Names Used for Some Metal lons in Anionic Complex Ions
\begin{tabular}{ll} 
Metal & Name in an Anionic Complex \\
\hline Iron & Ferrate \\
\hline Copper & Cuprate \\
\hline Lead & Plumbate \\
\hline Silver & Argentate \\
\hline Gold & Aurate \\
\hline Tin & Stannate \\
\hline
\end{tabular}

\footnotetext{
*In an older system the negatively charged ligands were named first, then neutral ligands, with positively charged ligands named last. We will follow the newer convention in this text.
}

\section*{INTERACTIVE EXAMPLE 21.1 Naming Coordination Compounds I}

Give the systematic name for each of the following coordination compounds.
a. \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}\)
b. \(\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}\)
c. \(\left[\mathrm{Fe}(\mathrm{en})_{2}\left(\mathrm{NO}_{2}\right)_{2}\right]_{2} \mathrm{SO}_{4}\)

\section*{SOLUTION}

-
An aqueous solution of \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl} 2_{2}\).
a. To determine the oxidation state of the metal ion, we examine the charges of all ligands and counterions. The ammonia molecules are neutral and each of the chloride ions has a \(1-\) charge, so the cobalt ion must have a \(3+\) charge to produce a neutral compound. Thus cobalt has the oxidation state +3 , and we use cobalt(III) in the name.

The ligands include one \(\mathrm{Cl}^{-}\)ion and five \(\mathrm{NH}_{3}\) molecules. The chloride ion is designated as chloro, and each ammonia molecule is designated as ammine. The prefix penta- indicates that there are five \(\mathrm{NH}_{3}\) ligands present. The name of the complex cation is therefore pentaamminechlorocobalt(III). Note that the ligands are named alphabetically, disregarding the prefix. Since the counterions are chloride ions, the compound is named as a chloride salt:

b. First, we determine the oxidation state of the iron by considering the other charged species. The compound contains three \(\mathrm{K}^{+}\)ions and six \(\mathrm{CN}^{-}\)ions. Therefore, the iron must carry a charge of \(3+\), giving a total of six positive charges to balance the six negative charges. The complex ion present is thus \(\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}\). The cyanide ligands are each designated cyano, and the prefix hexa-indicates that six are present. Since the complex ion is an anion, we use the Latin name ferrate. The oxidation state is indicated by (III) at the end of the name. The anion name is therefore hexacyanoferrate(III). The cations are \(\mathrm{K}^{+}\)ions, which are simply named potassium. Putting this together gives the name

\section*{Potassium hexacyanoferrate(III) \\ }
(The common name of this compound is potassium ferricyanide.)
c. We first determine the oxidation state of the iron by looking at the other charged species: four \(\mathrm{NO}_{2}{ }^{-}\)ions and one \(\mathrm{SO}_{4}{ }^{2-}\) ion. The ethylenediamine is neutral. Thus the two iron ions must carry a total positive charge of 6 to balance the six negative charges. This means that each iron has a +3 oxidation state and is designated as iron(III).

Since the name ethylenediamine already contains di, we use bis- instead of \(d i\) - to indicate the two en ligands. The name for \(\mathrm{NO}_{2}{ }^{-}\)as a ligand is nitro, and the prefix \(d i\) - indicates the presence of two \(\mathrm{NO}_{2}^{-}\)ligands. Since the anion is sulfate, the compound's name is
\[
\underbrace{\text { Bis(ethylenediamine)dinitroiron(III) }}_{\text {Cation }} \underbrace{\text { sulfate }}_{\text {Anion }}
\]

Because the complex ion is a cation, the Latin name for iron is not used.

\section*{INTERACTIVE EXAMPLE 21.2 Naming Coordination Compounds II}

SOLUTION a. Triammine signifies three ammonia ligands, and bromo indicates one bromide ion as a ligand. The oxidation state of platinum is +2 , as indicated by the Roman numeral II. Thus the complex ion is \(\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Br}\right]^{+}\). One chloride ion is needed to balance the \(1+\) charge of this cation. The formula of the compound is \(\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Br}\right] \mathrm{Cl}\). Note that brackets enclose the complex ion.
b. The complex ion contains six fluoride ligands attached to a \(\mathrm{Co}^{3+}\) ion to give \(\mathrm{CoF}_{6}{ }^{3-}\). Note that the -ate ending indicates that the complex ion is an anion. The cations are \(\mathrm{K}^{+}\)ions, and three are required to balance the \(3-\) charge on the complex ion. Thus the formula is \(\mathrm{K}_{3}\left[\mathrm{CoF}_{6}\right]\).

\section*{See Exercises 21.39 and 21.40}

\subsection*{21.4 Isomerism}

When two or more species have the same formula but different properties, they are said to be isomers. Although isomers contain exactly the same types and numbers of atoms, the arrangements of the atoms differ, and this leads to different properties. We will consider two main types of isomerism: structural isomerism, where the isomers contain the same atoms but one or more bonds differ, and stereoisomerism, where all the bonds in the isomers are the same but the spatial arrangements of the atoms are different. Each of these classes also has subclasses (Fig. 21.8), which we will now consider.

\section*{Structural Isomerism}

The first type of structural isomerism we will consider is coordination isomerism, in which the composition of the complex ion varies. For example, \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{SO}_{4}\right] \mathrm{Br}\) and \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Br}\right] \mathrm{SO}_{4}\) are coordination isomers. In the first case, \(\mathrm{SO}_{4}{ }^{2-}\) is coordinated to \(\mathrm{Cr}^{3+}\), and \(\mathrm{Br}^{-}\)is the counterion; in the second case, the roles of these ions are reversed.

FIGURE 21.8 Some classes of isomers.

a

b
FIGURE 21.9 As a ligand, \(\mathrm{NO}_{2}^{-}\)can bond to a metal ion (a) through a lone pair on the nitrogen atom or (b) through a lone pair on one of the oxygen atoms.

-b
FIGURE 21.10 (a) The cis isomer of \(\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\) (yellow). (b) The trans isomer of \(\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\) (pale yellow).

Another example of coordination isomerism is the \(\left[\mathrm{Co}(\mathrm{en})_{3}\right]\left[\mathrm{Cr}(\mathrm{ox})_{3}\right]\) and \(\left[\mathrm{Cr}(\mathrm{en})_{3}\right]\) \(\left[\mathrm{Co}(\mathrm{ox})_{3}\right]\) pair, where ox represents the oxalate ion, a bidentate ligand shown in Table 21.13.

In a second type of structural isomerism, linkage isomerism, the composition of the complex ion is the same, but the point of attachment of at least one of the ligands differs. Two ligands that can attach to metal ions in different ways are thiocyanate \(\left(\mathrm{SCN}^{-}\right)\), which can bond through lone electron pairs on the nitrogen or the sulfur atom, and the nitrite ion \(\left(\mathrm{NO}_{2}^{-}\right)\), which can bond through lone electron pairs on the nitrogen or the oxygen atom. For example, the following two compounds are linkage isomers:
\[
\begin{gathered}
\left.\qquad \mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{NO}_{2}\right) \mathrm{Cl}\right] \mathrm{Cl} \\
\text { Tetraamminechloronitrocobalt(III) chloride } \\
\text { (yellow) } \\
{\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4}(\mathrm{ONO}) \mathrm{Cl}\right] \mathrm{Cl}} \\
\text { Tetraamminechloronitritocobalt(III) chloride }
\end{gathered}
\]

In the first case, the \(\mathrm{NO}_{2}{ }^{-}\)ligand is called nitro and is attached to \(\mathrm{Co}^{3+}\) through the nitrogen atom; in the second case, the \(\mathrm{NO}_{2}{ }^{-}\)ligand is called nitrito and is attached to \(\mathrm{Co}^{3+}\) through an oxygen atom (Fig. 21.9).

\section*{Stereoisomerism}

Stereoisomers have the same bonds but different spatial arrangements of the atoms. One type, geometrical isomerism, or cis-trans isomerism, occurs when atoms or groups of atoms can assume different positions around a rigid ring or bond. An important example is the compound \(\operatorname{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\), which has a square planar structure. The two possible arrangements of the ligands are shown in Fig. 21.10. In the trans isomer, the ammonia molecules are across (trans) from each other. In the cis isomer, the ammonia molecules are next (cis) to each other.

Geometrical isomerism also occurs in octahedral complex ions. For example, the compound \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}\) has cis and trans isomers (Fig. 21.11).

A second type of stereoisomerism is called optical isomerism because the isomers have opposite effects on plane-polarized light. When light is emitted from a source

a

FIGURE 21.11 (a) The trans isomer of \(\left.\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}\right]_{2}\right]^{+}\). The chloride ligands are directly across from each other. (b) The cis isomer of \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}\). The chloride ligands in this case share an edge of the octahedron. Because of their different structures, the trans isomer of \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}\right]_{2} \mathrm{Cl}\) is green and the cis isomer is violet.

FIGURE 21.12 Unpolarized light consists of waves vibrating in many different planes (indicated by the arrows). The polarizing filter blocks all waves except those vibrating in a given plane.

such as a glowing filament, the oscillating electric fields of the photons in the beam are oriented randomly, as shown in Fig. 21.12. If this light is passed through a polarizer, only the photons with electric fields oscillating in a single plane remain, constituting plane-polarized light.

In 1815, a French physicist, Jean Biot (1774-1862), showed that certain crystals could rotate the plane of polarization of light. Later it was found that solutions of certain compounds could do the same thing (Fig. 21.13). Louis Pasteur (1822-1895) was the first to understand this behavior. In 1848 he noted that solid sodium ammonium tartrate \(\left(\mathrm{NaNH}_{4} \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{4}\right)\) existed as a mixture of two types of crystals, which he painstakingly separated with tweezers. Separate solutions of these two types of crystals rotated plane-polarized light in exactly opposite directions. This led to a connection between optical activity and molecular structure.

We now realize that optical activity is exhibited by molecules that have nonsuperimposable mirror images. Your hands are nonsuperimposable mirror images (Fig. 21.15). The two hands are related like an object and its mirror image; one hand cannot be turned to make it identical to the other. Many molecules show this same feature, such as the complex ion \(\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}\) shown in Fig. 21.16. Objects that have nonsuperimposable mirror images are said to be chiral (from the Greek word cheir, meaning "hand").

The isomers of \(\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}\) (Fig. 21.17) are nonsuperimposable mirror images called enantiomers, which rotate plane-polarized light in opposite directions and are thus optical isomers. The isomer that rotates the plane of light to the right (when viewed down the beam of oncoming light) is said to be dextrorotatory, designated by \(d\). The isomer that rotates the plane of light to the left is levorotatory ( \(l\) ). An equal

FIGURE 21.13 The rotation of the plane of polarized light by an optically active substance. The angle of rotation is called theta \((\theta)\).

\section*{CHEMICAL CONNECTIONS}

\section*{The Importance of Being cis}

s
ome of the most important advancements of science are the results of accidental discoveries-for example, penicillin, Teflon, and the sugar substitutes cyclamate and aspartame. Another important chance discovery occurred in 1964, when a group of scientists using platinum electrodes to apply an electric field to a colony of E. coli bacteria noticed that the bacteria failed to divide but continued to grow, forming long, fibrous cells. Further study revealed that cell division was inhibited by small concentrations of
cis- \(-\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\) and cis- \(\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{4}\) formed electrolytically in the solution.

Cancerous cells multiply very rapidly because cell division is uncontrolled. Thus these and similar platinum complexes were evaluated as antitumor agents, which inhibit the division of cancer cells. The results showed that cis- \(\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl} 2\) was active against a wide variety of tumors, including testicular and ovarian tumors, which are very resistant to treatment by more traditional methods. However, although the cis complex showed significant
antitumor activity, the corresponding trans complex had no effect on tumors. This shows the importance of isomerism in biological systems. When drugs are synthesized, great care must be taken to obtain the correct isomer.

Although cis- \(\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\) has proven to be a valuable drug, unfortunately it has some troublesome side effects, the most serious being kidney damage. As a result, the search continues for even more effective antitumor agents. Promising candidates are shown in Fig. 21.14. Note that they are all cis complexes.

FIGURE 21.14 Some cis complexes of platinum and palladium that show significant antitumor activity. It is thought that the cis complexes work by losing two adjacent ligands and forming coordinate covalent bonds to adjacent bases on a DNA molecule.

FIGURE 21.15 A human hand exhibits a nonsuperimposable mirror image. Note that the mirror image of the right hand (while identical to the left hand) cannot be turned in any way to make it identical to (superimposable on) the actual right hand.

FIGURE 21.16 Isomers I and II of Co(en) \(3^{3+}\) are mirror images (the image of I is identical to II) that cannot be superimposed. That is, there is no way that I can be turned in space so that it is the same as II.

mixture of the \(d\) and \(l\) forms in solution, called a racemic mixture, does not rotate the plane of the polarized light at all because the two opposite effects cancel each other.

Geometrical isomers are not necessarily optical isomers. For instance, the trans isomer of \(\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}\)shown in Fig. 21.17 is identical to its mirror image. Since this isomer is superimposable on its mirror image, it does not exhibit optical isomerism and is not chiral. On the other hand, cis-[Co(en) \(\left.)_{2} \mathrm{Cl}_{2}\right]^{+}\)is not superimposable on its mirror image; a pair of enantiomers exists for this complex ion (the cis isomer is chiral).

Most important biomolecules are chiral, and their reactions are highly structure dependent. For example, a drug can have a particular effect because its molecules can

a

b

FIGURE 21.17 (a) The trans isomer of \(\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}{ }^{+}\)and its mirror image are identical (superimposable).
(b) The cis isomer of \(\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}{ }^{+}\)and its mirror image are not superimposable and are thus a pair of optical isomers.
bind to chiral molecules in the body. To bind correctly, however, the correct optical isomer of the drug must be administered. Just as the right hand of one person requires the right hand of another to perform a handshake, a given isomer in the body requires a specific isomer of the drug to bind together. Because of this, the syntheses of drugs, which are usually very complicated molecules, must be carried out in a way that produces the correct "handedness," a requirement that greatly adds to the synthetic difficulties.

\section*{EXAMPLE 21.3 Geometrical and Optical Isomerism}

Does the complex ion \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right) \mathrm{Br}(\mathrm{en})_{2}\right]^{2+}\) exhibit geometrical isomerism? Does it exhibit optical isomerism?

SOLUTION The complex ion exhibits geometrical isomerism because the ethylenediamine ligands can be across from or next to each other:

The cis isomer of the complex ion also exhibits optical isomerism because its mirror images

cannot be turned in any way to make them superimposable. Thus these mirror-image isomers of the cis complex are shown to be enantiomers that will rotate plane-polarized light in opposite directions.

\subsection*{21.5 Bonding in Complex lons: The Localized Electron Model}

In Chapters 8 and 9 we considered the localized electron model, a very useful model for describing the bonding in molecules. Recall that a central feature of this model is the formation of hybrid atomic orbitals that are used to share electron pairs to form \(\sigma\) bonds between atoms. This same model can be used to account for the bonding in complex ions, but there are two important points to keep in mind:
1. The VSEPR model for predicting structure generally does not work for complex ions. However, we can safely assume that a complex ion with a coordination number of 6 will have an octahedral arrangement of ligands, and complexes with

FIGURE 21.18 A set of six \(d^{2} s p^{3}\) hybrid orbitals on \(\mathrm{Co}^{3+}\) can accept an electron pair from each of six \(\mathrm{NH}_{3}\) ligands to form the \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}^{3+}\) ion.

Tetrahedral ligand arrangement; \(s p^{3}\) hybridization

Square planar ligand arrangement; \(d s p^{2}\) hybridization

Linear ligand arrangement; \(s p\) hybridization

FIGURE 21.19 The hybrid orbitals required for tetrahedral, square planar, and linear complex ions. The metal ion hybrid orbitals are empty, and the metal ion bonds to the ligands by accepting lone pairs.

two ligands will be linear. On the other hand, complex ions with a coordination number of 4 can be either tetrahedral or square planar, and there is no completely reliable way to predict which will occur in a particular case.
2. The interaction between a metal ion and a ligand can be viewed as a Lewis acidbase reaction with the ligand donating a lone pair of electrons to an empty orbital of the metal ion to form a coordinate covalent bond:

Empty metal ion hybrid atomic orbital

Lone pair on the ligand in a hybrid atomic orbital

Coordinate covalent bond

The hybrid orbitals used by the metal ion depend on the number and arrangement of the ligands. For example, accommodating the lone pairs from the six ammonia molecules in the octahedral \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}\) ion requires a set of six empty hybrid atomic orbitals in an octahedral arrangement. As we discussed in Section 9.1, an octahedral set of orbitals is formed by the hybridization of two \(d\), one \(s\), and three \(p\) orbitals to give a set of six \(d^{2} s p^{3}\) orbitals (Fig. 21.18).

The hybrid orbitals required on a metal ion in a four-coordinate complex depend on whether the structure is tetrahedral or square planar. For a tetrahedral arrangement of ligands, an \(s p^{3}\) hybrid set is required (Fig. 21.19). For example, in the tetrahedral \(\mathrm{CoCl}_{4}{ }^{2-}\) ion, the \(\mathrm{Co}^{2+}\) can be described as \(s p^{3}\) hybridized. A square planar arrangement of ligands requires a \(d s p^{2}\) hybrid orbital set on the metal ion (Fig. 21.19). For example, in the square planar \(\mathrm{Ni}(\mathrm{CN})_{4}{ }^{2-}\) ion, the \(\mathrm{Ni}^{2+}\) is described as \(d s p^{2}\) hybridized.

A linear complex requires two hybrid orbitals 180 degrees from each other. This arrangement is given by an \(s p\) hybrid set (see Fig. 21.19). Thus, in the linear \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\) ion, the \(\mathrm{Ag}^{+}\)can be described as \(s p\) hybridized.

Although the localized electron model can account in a general way for metalligand bonds, it is rarely used today because it cannot readily account for important properties of complex ions, such as magnetism and color. Thus we will not pursue the model any further.

\subsection*{21.6 The Crystal Field Model}

The main reason the localized electron model cannot fully account for the properties of complex ions is that it gives no information about how the energies of the \(d\) orbitals are affected by complex ion formation. This is critical because, as we will see, the color and magnetism of complex ions result from changes in the energies of the metal ion \(d\) orbitals caused by the metal-ligand interactions.

The crystal field model focuses on the energies of the \(d\) orbitals. In fact, this model is not so much a bonding model as it is an attempt to account for the colors and magnetic properties of complex ions. In its simplest form, the crystal field model assumes that the ligands can be approximated by negative point charges and that metal-ligand bonding is entirely ionic.

\section*{Octahedral Complexes}

We will illustrate the fundamental principles of the crystal field model by applying it to an octahedral complex. Figure 21.20 shows the orientation of the \(3 d\) orbitals relative to an octahedral arrangement of point-charge ligands. The important thing to note is that two of the orbitals, \(d_{z^{2}}\) and \(d_{x^{2}-y^{2}}\), point their lobes directly at the point-charge ligands and three of the orbitals, \(d_{x z}, d_{y z}\), and \(d_{x y}\), point their lobes between the point charges.

To understand the effect of this difference, we need to consider which type of orbital is lower in energy. Because the negative point-charge ligands repel negatively charged electrons, the electrons will first fill the \(d\) orbitals farthest from the ligands to minimize repulsions. In other words, the \(d_{x z}, d_{y z}\), and \(d_{x y}\) orbitals (known as the \(t_{2 \mathrm{~g}}\) set) are at a lower energy in the octahedral complex than are the \(d_{z^{2}}\) and \(d_{x^{2}-y^{2}}\) orbitals (the \(e_{\mathrm{g}}\) set). This is shown in Fig. 21.21. The negative point-charge ligands increase the energies of all the \(d\) orbitals. However, the orbitals that point at the ligands are raised in energy more than those that point between the ligands.

It is this splitting of the \(3 \boldsymbol{d}\) orbital energies (symbolized by \(\Delta\) ) that explains the color and magnetism of complex ions of the first-row transition metal ions. For

FIGURE 21.20 An octahedral arrangement of point-charge ligands and the orientation of the 3d orbitals.

FIGURE 21.21 The energies of the \(3 d\) orbitals for a metal ion in an octahedral complex. The \(3 d\) orbitals are degenerate (all have the same energy) in the free metal ion. In the octahedral complex the orbitals are split into two sets as shown. The difference in energy between the two sets is designated as \(\Delta\) (delta).

FIGURE 21.22 Possible electron arrangements in the split 3d orbitals in an octahedral complex of \(\mathrm{Co}^{3+}\) (electron configuration \(3 d^{6}\) ). (a) In a strong field (large \(\Delta\) value), the electrons fill the \(t_{2 g}\) set first, giving a diamagnetic complex. (b) In a weak field (small \(\Delta\) value), the electrons occupy all five orbitals before any pairing occurs.

example, in an octahedral complex of \(\mathrm{Co}^{3+}\) (a metal ion with six \(3 d\) electrons), there are two possible ways to place the electrons in the split \(3 d\) orbitals (Fig. 21.22). If the splitting produced by the ligands is very large, a situation called the strong-field case, the electrons will pair in the lower-energy \(t_{2 g}\) orbitals. This gives a diamagnetic complex in which all the electrons are paired. On the other hand, if the splitting is small (the weak-field case), the electrons will occupy all five orbitals before pairing occurs. In this case the complex has four unpaired electrons and is paramagnetic.

The crystal field model allows us to account for the differences in the magnetic properties of \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}\) and \(\mathrm{CoF}_{6}{ }^{3-}\). The \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}\) ion is known to be diamagnetic and thus corresponds to the strong-field case, also called the low-spin case, since it yields the minimum number of unpaired electrons. In contrast, the \(\mathrm{CoF}_{6}{ }^{3-}\) ion, which is known to have four unpaired electrons, corresponds to the weak-field case, also known as the high-spin case, since it gives the maximum number of unpaired electrons.

> What if you are told the number of unpaired electrons for a coordinate covalent ion and are asked to tell if the ligand produced a strong or weak field? Give an example of a coordinate covalent ion for which you could decide if it produced a strong or weak field and one for which you couldn't, and explain your answers.

\section*{INTERACTIVE EXAMPLE 21.4 Crystal Field Model I}

The \(\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}\) ion is known to have one unpaired electron. Does the \(\mathrm{CN}^{-}\)ligand produce a strong or weak field?

\section*{SOLUTION}

Since the ligand is \(\mathrm{CN}^{-}\)and the overall complex ion charge is \(3-\), the metal ion must be \(\mathrm{Fe}^{3+}\), which has a \(3 d^{5}\) electron configuration. The two possible arrangements of the five electrons in the \(d\) orbitals split by the octahedrally arranged ligands are

The strong-field case gives one unpaired electron, which agrees with the experimental observation. The \(\mathrm{CN}^{-}\)ion is a strong-field ligand toward the \(\mathrm{Fe}^{3+}\) ion.

See Exercises 21.55 and 21.56

From studies of many octahedral complexes, we can arrange ligands in order of their ability to produce \(d\)-orbital splitting. A partial listing of ligands in this spectrochemical series is

The ligands are arranged in order of decreasing \(\Delta\) values toward a given metal ion.
It also has been observed that the magnitude of \(\Delta\) for a given ligand increases as the charge on the metal ion increases. For example, \(\mathrm{NH}_{3}\) is a weak-field ligand toward \(\mathrm{Co}^{2+}\) but acts as a strong-field ligand toward \(\mathrm{Co}^{3+}\). This makes sense; as the metal ion charge increases, the ligands will be drawn closer to the metal ion because of the increased charge density. As the ligands move closer, they cause greater splitting of the \(d\) orbitals and produce a larger \(\Delta\) value.

\section*{INTERACTIVE EXAMPLE 21.5}

\section*{SOLUTION}

\section*{Crystal Field Model II}

Predict the number of unpaired electrons in the complex ion \(\mathrm{Cr}(\mathrm{CN})_{6}{ }^{4-}\).
The net charge of \(4-\) means that the metal ion present must be \(\mathrm{Cr}^{2+}(-6+2=-4)\), which has a \(3 d^{4}\) electron configuration. Since \(\mathrm{CN}^{-}\)is a strong-field ligand (see the spectrochemical series), the correct crystal field diagram for \(\mathrm{Cr}(\mathrm{CN})_{6}{ }^{4-}\) is

The complex ion will have two unpaired electrons. Note that the \(\mathrm{CN}^{-}\)ligand produces such a large splitting that all four electrons will occupy the \(t_{2 g}\) set even though two of the electrons must be paired in the same orbital.

\section*{See Exeraises 21.57 and 21.58}

We have seen how the crystal field model can account for the magnetic properties of octahedral complexes. The same model also can explain the colors of these complex ions. For example, \(\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\), an octahedral complex of \(\mathrm{Ti}^{3+}\), which has a \(3 d^{1}\) electron configuration, is violet because it absorbs light in the middle of the visible region of the spectrum (Fig. 21.23). When a substance absorbs certain wavelengths of light in the visible region, the color of the substance is determined by the wavelengths of visible light that remain. We say that the substance exhibits the color complementary to those absorbed. The \(\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) ion is violet because it absorbs light in the yellow-green region, thus letting red light and blue light pass, which gives the observed violet color. This is shown schematically in Fig. 21.24. Table 21.16 shows the general relationship between the wavelengths of visible light absorbed and the approximate color observed.

FIGURE 21.23 The visible spectrum.

\section*{CHEMICAL CDNNECTIDNS}

\section*{Transition Metal Ions Lend Color to Gems}

The beautiful pure color of gems, so valued by cultures everywhere, arises from trace transition metal ion impurities in minerals that would otherwise be colorless. For example, the stunning red of a ruby, the most valuable of all gemstones, is caused by \(\mathrm{Cr}^{3+}\) ions, which replace about \(1 \%\) of the \(\mathrm{Al}^{3+}\) ions in the mineral corundum, which is a form of aluminum oxide \(\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)\) that is nearly as hard as diamond. In the corundum structure the \(\mathrm{Cr}^{3+}\) ions are surrounded by six oxide ions at the vertices of an octahedron. This leads to the characteristic octahedral splitting of chromium's \(3 d\) orbitals, such that the \(\mathrm{Cr}^{3+}\) ions absorb strongly in the blue-violet and yellow-green regions of the visible spectrum but transmit red light to give the characteristic ruby color. (On the other hand, if some of the \(\mathrm{Al}^{3+}\) ions in the corundum are replaced by a mixture of \(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}\), and \(\mathrm{Ti}^{4+}\) ions, the gem is a sapphire with its brilliant blue color; or if some of the \(\mathrm{Al}^{3+}\) ions are replaced by \(\mathrm{Fe}^{3+}\) ions, the stone is a yellow topaz.)

Emeralds are derived from the mineral beryl, a beryllium aluminum silicate (empirical formula \(3 \mathrm{BeO} \cdot \mathrm{Al}_{2} \mathrm{O}_{3}\) - \(6 \mathrm{SiO}_{2}\) ). When some of the \(\mathrm{Al}^{3+}\) ions in beryl are replaced by \(\mathrm{Cr}^{3+}\) ions, the characteristic green color of emerald
results. In this environment the splitting of the \(\mathrm{Cr}^{3+} 3 d\) orbitals causes it to strongly absorb yellow and blue-violet light and to transmit green light.

A gem closely related to ruby and emerald is alexandrite, named after Alexander II of Russia. This gem is based on the mineral chrysoberyl, a beryllium aluminate with the empirical formula \(\mathrm{BeO} \cdot \mathrm{Al}_{2} \mathrm{O}_{3}\) in which approximately \(1 \%\) of the \(\mathrm{Al}^{3+}\) ions are replaced by \(\mathrm{Cr}^{3+}\) ions. In the chrysoberyl environment \(\mathrm{Cr}^{3+}\) absorbs strongly in the yellow region of the spectrum. Alexandrite has the interesting property of changing colors depending on the light source. When the first alexandrite stone was discovered deep in a mine in the Russian Ural Mountains in 1831, it appeared to be a deep red color in the firelight of the miners' lamps. However, when the stone was brought to the surface, its color was blue. This seemingly magical color change occurs because the firelight of a miner's helmet is rich in the yellow and red wavelengths of the visible spectrum but does not contain much blue. Absorption of the yellow by the stone produces a reddish color. However, daylight has much more intensity in the blue region than firelight. Thus the extra blue in the light transmitted by
the stone gives it bluish color in daylight.

Once the structure of a natural gem is known, it is usually not very difficult to make the gem artificially. For example, rubies and sapphires are made on a large scale by fusing \(\mathrm{Al}(\mathrm{OH})_{3}\) with the appropriate transition metal salts at approximately \(1200^{\circ} \mathrm{C}\) to make the "doped" corundum. With these techniques gems of astonishing size can be manufactured: Rubies as large as 10 lb and sapphires up to 100 lb have been synthesized. Smaller synthetic stones produced for jewelry are virtually identical to the corresponding natural stones, and it takes great skill for a gemologist to tell the difference.

Alexandrite, a gem closely related to ruby and emerald.

FIGURE 21.24 (a) When white light shines on a filter that absorbs in the yellow-green region, the emerging light is violet. (b) Because the complex ion \(\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) absorbs yellow-green light, a solution of it is violet.

FIGURE 21.25 The complex ion \(\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}\) can absorb visible light in the yellow-green region to transfer the lone \(d\) electron from the \(t_{2 g}\) to the \(e_{g}\) set.

\hline\(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}\) & Purple \\
\hline\(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}\) & Violet \\
\hline
\end{tabular}

A
Solutions of \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}\) (left) and \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}^{2} \mathrm{Cl}_{2}\right.\) (right).

TABLE 21.16 | Approximate Relationship of Wavelength of Visible Light Absorbed to Color Observed
\begin{tabular}{|l|l|}
\hline Absorbed Wavelength in nm (Color) & Observed Color \\
\hline 400 (violet) & Greenish yellow \\
\hline 450 (blue) & Yellow \\
\hline 490 (blue-green) & Red \\
\hline 570 (yellow-green) & Violet \\
\hline 580 (yellow) & Dark blue \\
\hline 600 (orange) & Blue \\
\hline 650 (red) & Green \\
\hline
\end{tabular}

The reason that the \(\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) ion absorbs a specific wavelength of visible light can be traced to the transfer of the lone \(d\) electron between the split \(d\) orbitals, as shown in Fig. 21.25. A given photon of light can be absorbed by a molecule only if the wavelength of the light provides exactly the energy needed by the molecule. In other words, the wavelength absorbed is determined by the relationship
\[
\Delta E=\frac{h c}{\lambda}
\]
where \(\Delta E\) represents the energy spacing in the molecule (we have used simply \(\Delta\) in this chapter) and \(\lambda\) represents the wavelength of light needed. Because the \(d\)-orbital splitting in most octahedral complexes corresponds to the energies of photons in the visible region, octahedral complex ions are usually colored.

Since the ligands coordinated to a given metal ion determine the size of the \(d\)-orbital splitting, the color changes as the ligands are changed. This occurs because a change in \(\Delta\) means a change in the wavelength of light needed to transfer electrons between the \(t_{2 g}\) and \(e_{g}\) orbitals. Several octahedral complexes of \(\mathrm{Cr}^{3+}\) and their colors are listed in Table 21.17.

\section*{Other Coordination Geometries}

Using the same principles developed for octahedral complexes, we will now consider complexes with other geometries. For example, Fig. 21.26 shows a tetrahedral arrangement of point charges in relation to the \(3 d\) orbitals of a metal ion. There are two important facts to note:
1. None of the \(3 d\) orbitals "point at the ligands" in the tetrahedral arrangement, as the \(d_{x^{2}-y^{2}}\) and \(d_{z^{2}}\) orbitals do in the octahedral case. Thus the tetrahedrally arranged ligands do not differentiate the \(d\) orbitals as much in the tetrahedral case as in the octahedral case. That is, the difference in energy between the split \(d\) orbitals will

FIGURE 21.26 (a) Tetrahedral and octahedral arrangements of ligands shown inscribed in cubes. Note that in the two types of arrangements, the point charges occupy opposite parts of the cube; the octahedral point charges are at the centers of the cube faces, and the tetrahedral point charges occupy opposite corners of the cube. (b) The orientations of the \(3 d\) orbitals relative to the tetrahedral set of point charges.

-b
be significantly less in tetrahedral complexes. Although we will not derive it here, the tetrahedral splitting is \(\frac{4}{9}\) that of the octahedral splitting for a given ligand and metal ion:
\[
\Delta_{\mathrm{tet}}=\frac{4}{9} \Delta_{\mathrm{oct}}
\]
2. Although not exactly pointing at the ligands, the \(d_{\mathrm{xy}}, d_{\mathrm{xz}}\), and \(d_{\mathrm{yz}}\) orbitals are closer to the point charges than are the \(d_{z^{2}}\) and \(d_{x^{2}-y^{2}}\) orbitals. This means that the tetrahedral \(d\)-orbital splitting will be opposite to that for the octahedral arrangement. The two arrangements are contrasted in Fig. 21.27. Because the \(d\)-orbital splitting is relatively small for the tetrahedral case, the weak-field case (high-spin case) always applies. There are no known ligands powerful enough to produce the strong-field case in a tetrahedral complex.

\section*{INTERACTIVE EXAMPLE 21.6 Crystal Field Model III}

SOLUTION The complex ion contains \(\mathrm{Co}^{2+}\), which has a \(3 d^{7}\) electron configuration. The splitting of the \(d\) orbitals will be small, since this is a tetrahedral complex, giving the high-spin case with three unpaired electrons.
\[
\left.\boldsymbol{E} \begin{array}{ccc}
\frac{\uparrow}{d_{x y}} & \frac{\uparrow}{d_{x z}} & \uparrow \\
\frac{\uparrow \downarrow}{\frac{\downarrow \downarrow}{d_{z^{2}}}} \frac{\uparrow \downarrow}{d_{x^{2}-y^{2}}}
\end{array}\right\} \begin{gathered}
\text { Small } \\
\Delta
\end{gathered}
\]

FIGURE 21.27 The crystal field diagrams for octahedral and tetrahedral complexes. The relative energies of the sets of \(d\) orbitals are reversed. For a given type of ligand, the splitting is much larger for the octahedral complex ( \(\Delta_{\text {oct }}>\Delta_{\text {tet }}\) ) because in this arrangement the \(d_{z^{2}}\) and \(d_{x^{2}-y^{2}}\) orbitals point their lobes directly at the point charges and are thus relatively high in energy.

FIGURE 21.28 (a) The crystal field diagram for a square planar complex oriented in the \(x y\) plane with ligands along the \(x\) and \(y\) axes. The position of the \(d_{z^{2}}\) orbital is higher than those of the \(d_{x z}\) and \(d_{y z}\) orbitals because of the "doughnut" of electron density in the xy plane. The actual position of \(d_{z^{2}}\) is somewhat uncertain and varies in different square planar complexes. (b) The crystal field diagram for a linear complex where the ligands lie along the \(z\) axis.

The crystal field model also applies to square planar and linear complexes. The crystal field diagrams for these cases are shown in Fig. 21.28. The ranking of orbitals in these diagrams can be explained by considering the relative orientations of the point charges and the orbitals. The diagram in Fig. 21.27 for the octahedral arrangement can be used to obtain these orientations. We can obtain the square planar complex by removing the two point charges along the \(z\) axis. This will greatly lower the energy of \(d_{z^{2}}\), leaving only \(d_{x^{2}-y^{2}}\), which points at the four remaining ligands as the highestenergy orbital. We can obtain the linear complex from the octahedral arrangement by leaving the two ligands along the \(z\) axis and removing the four in the \(x y\) plane. This means that only the \(d_{z^{2}}\) points at the ligands and is highest in energy.

Figure 21.28(a) shows a crystal field diagram for a square planar complex oriented in the \(x y\) plane. What if you oriented the complex in the \(x z\) plane? Sketch the crystal field diagram and contrast it with Fig. 21.28(a).

\subsection*{21.7 The Biological Importance of Coordination Complexes}

The ability of metal ions to coordinate with and release ligands and to easily undergo oxidation and reduction makes them ideal for use in biological systems. For example, metal ion complexes are used in humans for the transport and storage of oxygen, as electron-transfer agents, as catalysts, and as drugs. Most of the first-row transition metals are essential for human health, as summarized in Table 21.18. We will concentrate on iron's role in biological systems, since several of its coordination complexes have been studied extensively.

\section*{TABLE 21.18 | The First-Row Transition Metals and Their Biological Significance}
\begin{tabular}{ll}
\hline First-Row Transition Metal & Biological Function(s) \\
\hline Scandium & None known. \\
\hline Titanium & None known. \\
\hline Vanadium & None known in humans. \\
\hline Chromium & Assists insulin in the control of blood sugar; may also be involved in the control of cholesterol. \\
\hline Manganese & Necessary for a number of enzymatic reactions. \\
\hline Iron & Component of hemoglobin and myoglobin; involved in the electron-transport chain. \\
\hline Cobalt & Component of vitamin \(\mathrm{B}_{12}\), which is essential for the metabolism of carbohydrates, fats, and proteins. \\
\hline Nickel & Component of the enzymes urease and hydrogenase. \\
\hline Copper & \begin{tabular}{l} 
Component of several enzymes; assists in iron storage; involved in the production of color pigments of \\
hair, skin, and eyes.
\end{tabular} \\
\hline Zinc & Component of insulin and many enzymes. \\
\hline
\end{tabular}

A protein is a large molecule assembled from amino acids, which have the general structure in which \(R\) represents various groups.

Iron plays a central role in almost all living cells. In mammals, the principal source of energy comes from the oxidation of carbohydrates, proteins, and fats. Although oxygen is the oxidizing agent for these processes, it does not react directly with these
molecules. Instead, the electrons from the breakdown of these nutrients are passed oxygen is the oxidizing agent for these processes, it does not react directly with these
molecules. Instead, the electrons from the breakdown of these nutrients are passed along a complex chain of molecules, called the respiratory chain, eventually reaching the \(\mathrm{O}_{2}\) molecule. The principal electron-transfer molecules in the respiratory chain are iron-containing species called cytochromes, consisting of two main parts: an iron complex called a heme and a protein. The structure of the heme complex is shown in Fig. 21.29. Note that it contains an iron ion (it can be either \(\mathrm{Fe}^{2+}\) or \(\mathrm{Fe}^{3+}\) ) coordinated

FIGURE 21.29 The heme complex, in which an \(\mathrm{Fe}^{2+}\) ion is coordinated to four nitrogen atoms of a planar porphyrin ligand.

FIGURE 21.30 Chlorophyll is a porphyrin complex of \(\mathrm{Mg}^{2+}\). There are two similar forms of chlorophyll, one of which is shown here.

FIGURE 21.31 A representation of the myoglobin molecule. The \(\mathrm{Fe}^{2+}\) ion is coordinated to four nitrogen atoms in the porphyrin of the heme (represented by the disk in the figure) and on nitrogen from the protein chain. This leaves a sixth coordination position (indicated by the W) available for an oxygen molecule.
to a rather complicated planar ligand called a porphyrin. As a class, porphyrins all contain the same central ring structure but have different substituent groups at the edges of the rings. The various porphyrin molecules act as tetradentate ligands for many metal ions, including iron, cobalt, and magnesium. In fact, chlorophyll, a substance essential to the process of photosynthesis, is a magnesium-porphyrin complex of the type shown in Fig. 21.30.

In addition to participating in the transfer of electrons from nutrients to oxygen, iron plays a principal role in the transport and storage of oxygen in mammalian blood and tissues. Oxygen is stored in a molecule called myoglobin, which consists of a heme complex and a protein in a structure very similar to that of the cytochromes. In myoglobin, the \(\mathrm{Fe}^{2+}\) ion is coordinated to four nitrogen atoms of the porphyrin ring and to a nitrogen atom of the protein chain, as shown in Fig. 21.31. Since \(\mathrm{Fe}^{2+}\) is normally six-coordinate, this leaves one position open for attachment of an \(\mathrm{O}_{2}\) molecule.

One especially interesting feature of myoglobin is that it involves an \(\mathrm{O}_{2}\) molecule attaching directly to \(\mathrm{Fe}^{2+}\). However, if gaseous \(\mathrm{O}_{2}\) is bubbled into an aqueous solution containing heme, the \(\mathrm{Fe}^{2+}\) is immediately oxidized to \(\mathrm{Fe}^{3+}\). This oxidation of the \(\mathrm{Fe}^{2+}\)

in heme does not happen in myoglobin. This fact is of crucial importance because \(\mathrm{Fe}^{3+}\) does not form a coordinate covalent bond with \(\mathrm{O}_{2}\), and myoglobin would not function if the bound \(\mathrm{Fe}^{2+}\) could be oxidized. Since the \(\mathrm{Fe}^{2+}\) in the "bare" heme complex can be oxidized, it must be the protein that somehow prevents the oxidation. How? Based on much research, the answer seems to be that the oxidation of \(\mathrm{Fe}^{2+}\) to \(\mathrm{Fe}^{3+}\) involves an oxygen bridge between two iron ions (the circles indicate the ligands):

The bulky protein around the heme group in myoglobin prevents two molecules from getting close enough to form the oxygen bridge, and so oxidation of the \(\mathrm{Fe}^{2+}\) is prevented.

The transport of \(\mathrm{O}_{2}\) in the blood is carried out by hemoglobin, a molecule consisting of four myoglobin-like units, as shown in Fig. 21.32. Each hemoglobin can therefore bind four \(\mathrm{O}_{2}\) molecules to form a bright red diamagnetic complex. The diamagnetism occurs because oxygen is a strong-field ligand toward \(\mathrm{Fe}^{2+}\), which has a \(3 d^{6}\) electron configuration. When the oxygen molecule is released, water molecules occupy the sixth coordination position around each \(\mathrm{Fe}^{2+}\), giving a bluish paramagnetic complex \(\left(\mathrm{H}_{2} \mathrm{O}\right.\) is a weak-field ligand toward \(\left.\mathrm{Fe}^{2+}\right)\) that gives venous blood its characteristic bluish tint.

Hemoglobin dramatically demonstrates how sensitive the function of a biomolecule is to its structure. In certain people, in the synthesis of the proteins needed for hemoglobin, an improper amino acid is inserted into the protein in two places. This may not seem very serious, since there are several hundred amino acids present. However, because the incorrect amino acid has a nonpolar substituent instead of the polar one found on the proper amino acid, the hemoglobin drastically changes its shape. The

FIGURE 21.33 A normal red blood cell (left) and a sickle cell (right), both highly magnified.

Sherpa and Balti porters are acclimatized to high elevations such as those around the K2 mountain peak in Pakistan.
red blood cells are then sickle-shaped rather than disk-shaped, as shown in Fig. 21.33. The misshapen cells can aggregate, causing clogging of tiny capillaries. This condition, known as sickle cell anemia, is the subject of intense research.

Our knowledge of the workings of hemoglobin allows us to understand the effects of high altitudes on humans. The reaction between hemoglobin and oxygen can be represented by the following equilibrium:

At high altitudes, where the oxygen content of the air is lower, the position of this equilibrium will shift to the left, according to Le Châtelier's principle. Because less oxyhemoglobin is formed, fatigue, dizziness, and even a serious illness called highaltitude sickness can result. One way to combat this problem is to use supplemental oxygen, as most high-altitude mountain climbers do. However, this is impractical for people who live at high elevations. In fact, the human body adapts to the lower oxygen concentrations by making more hemoglobin, causing the equilibrium to shift back to the right. Someone moving from Chicago to Boulder, Colorado ( 5300 feet), would notice the effects of the new altitude for a couple of weeks, but as the hemoglobin level increased, the effects would disappear. This change is called high-altitude acclimatization, which explains why athletes who want to compete at high elevations should practice there for several weeks prior to the event.

Our understanding of the biological role of iron also allows us to explain the toxicities of substances such as carbon monoxide and the cyanide ion. Both CO and \(\mathrm{CN}^{-}\)are very good ligands toward iron and so can interfere with the normal workings of the iron complexes in the body. For example, carbon monoxide has about 200 times the affinity for the \(\mathrm{Fe}^{2+}\) in hemoglobin as oxygen does. The resulting stable complex, carboxyhemoglobin, prevents the normal uptake of \(\mathrm{O}_{2}\), thus depriving the body of needed oxygen. Asphyxiation can result if enough carbon monoxide is present in the air. The mechanism for the toxicity of the cyanide ion is somewhat different. Cyanide coordinates strongly to cytochrome oxidase, an iron-containing cytochrome enzyme that catalyzes the oxidation-reduction reactions of certain cytochromes. The coordinated cyanide thus prevents the electron-transfer process and rapid death results. Because of its behavior, cyanide is called a respiratory inhibitor.

\subsection*{21.8 Metallurgy and Iron and Steel Production}

A
Pouring molten metal in a steel mill.

In the preceding section we saw the importance of iron in biological systems. Of course, iron is also very important in many other ways in our world. In this section we will discuss the isolation of metals from their natural sources and the formulation of metals into useful materials, with special emphasis on the role of iron.

Metals are very important for structural applications, electrical wires, cooking utensils, tools, decorative items, and many other purposes. However, because the main chemical characteristic of a metal is its ability to give up electrons, almost all metals in nature are found in ores, combined with nonmetals such as oxygen, sulfur, and the halogens. To recover and use these metals, we must separate them from their ores and reduce the metal ions. Then, because most metals are unsuitable for use in the pure state, we must form alloys that have the desired properties. The process of separating a metal from its ore and preparing it for use is known as metallurgy. The steps in this process are typically
1. Mining
2. Pretreatment of the ore
3. Reduction to the free metal
4. Purification of the metal (refining)
5. Alloying

An ore can be viewed as a mixture containing minerals (relatively pure metal compounds) and gangue (sand, clay, and rock). Some typical minerals are listed in Table 21.19. Although silicate minerals are the most common in the earth's crust, they are typically very hard and difficult to process, making metal extraction relatively expensive. Therefore, other ores are used when available.

TABLE 21.19 \| Common Minerals Found in Ores
\begin{tabular}{|c|c|}
\hline Anion & Examples \\
\hline None (free metal) & Au, Ag, Pt, Pd, Rh, Ir, Ru \\
\hline Oxide & \begin{tabular}{l}
\(\mathrm{Fe}_{2} \mathrm{O}_{3}\) (hematite) \\
\(\mathrm{Fe}_{3} \mathrm{O}_{4}\) (magnetite) \\
\(\mathrm{Al}_{2} \mathrm{O}_{3}\) (bauxite) \\
\(\mathrm{SnO}_{2}\) (cassiterite)
\end{tabular} \\
\hline Sulfide & \begin{tabular}{l}
PbS (galena) \\
ZnS (sphalerite) \\
\(\mathrm{FeS}_{2}\) (pyrite) \\
HgS (cinnabar) \\
\(\mathrm{Cu}_{2} \mathrm{~S}\) (chalcocite)
\end{tabular} \\
\hline Chloride & \begin{tabular}{l}
NaCl (rock salt) \\
KCl (sylvite) \\
\(\mathrm{KCl} \cdot \mathrm{MgCl}_{2}\) (carnalite)
\end{tabular} \\
\hline Carbonate & \[
\begin{aligned}
& \mathrm{FeCO}_{3} \text { (siderite) } \\
& \mathrm{CaCO}_{3} \text { (limestone) } \\
& \mathrm{MgCO}_{3} \text { (magnesite) } \\
& \mathrm{MgCO}_{3} \cdot \mathrm{CaCO}_{3} \text { (dolomite) }
\end{aligned}
\] \\
\hline Sulfate & \[
\begin{aligned}
& \mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O} \text { (gypsum) } \\
& \mathrm{BaSO}_{4} \text { (barite) }
\end{aligned}
\] \\
\hline Silicate & \(\mathrm{Be}_{3} \mathrm{Al}_{2} \mathrm{Si}_{6} \mathrm{O}_{18}\) (beryl) \(\mathrm{Al}_{2}\left(\mathrm{Si}_{2} \mathrm{O}_{8}\right)(\mathrm{OH})_{4}\) (kaolinite) \(\mathrm{LiAl}\left(\mathrm{SiO}_{3}\right)_{2}\) (spodumene) \\
\hline
\end{tabular}

FIGURE 21.34 A schematic diagram of a cyclone separator. The ore is pulverized and blown into the separator. The more dense mineral particles are thrown toward the walls by centrifugal force and fall down the funnel. The lighter particles (gangue) tend to stay closer to the center and are drawn out through the top by the stream of air.

FIGURE 21.35 A schematic representation of zone refining.

After mining, an ore must be treated to remove the gangue and to concentrate the mineral. The ore is first pulverized and then processed in a variety of devices, including cyclone separators (Fig. 21.34), inclined vibrating tables, and flotation tanks.

In the flotation process, the crushed ore is fed into a tank containing a water-oildetergent mixture. Because of the difference in the surface characteristics of the mineral particles and the silicate rock particles, the oil wets the mineral particles. A stream of air blown through the mixture causes tiny bubbles to form on the oil-covered pieces, which then float to the surface, where they can be skimmed off.

After the mineral has been concentrated, it is often chemically altered in preparation for the reduction step. For example, nonoxide minerals are often converted to oxides before reduction. Carbonates and hydroxides can be converted by simple heating:
\[
\begin{aligned}
\mathrm{CaCO}_{3}(s) & \xrightarrow{\text { Heat }} \mathrm{CaO}(s)+\mathrm{CO}_{2}(g) \\
\mathrm{Mg}(\mathrm{OH})_{2}(s) & \xrightarrow{\text { Heat }} \mathrm{MgO}(s)+\mathrm{H}_{2} \mathrm{O}(g)
\end{aligned}
\]

Sulfide minerals can be converted to oxides by heating in air at temperatures below their melting points, a process called roasting:
\[
2 \mathrm{ZnS}(s)+3 \mathrm{O}_{2}(g) \xrightarrow{\text { Heat }} 2 \mathrm{ZnO}(s)+2 \mathrm{SO}_{2}(g)
\]

As we have seen earlier, sulfur dioxide causes severe problems if released into the atmosphere, and modern roasting operations collect this gas and use it in the manufacture of sulfuric acid.

The method chosen to reduce the metal ion to the free metal, a process called smelting, depends on the affinity of the metal ion for electrons. Some metals are good enough oxidizing agents that the free metal is produced in the roasting process. For example, the roasting reaction for cinnabar is
\[
\mathrm{HgS}(s)+\mathrm{O}_{2}(g) \xrightarrow{\text { Heat }} \mathrm{Hg}(l)+\mathrm{SO}_{2}(g)
\]
where the \(\mathrm{Hg}^{2+}\) is reduced by electrons donated by the \(\mathrm{S}^{2-}\) ion, which is then further oxidized by \(\mathrm{O}_{2}\) to form \(\mathrm{SO}_{2}\).

The roasting of a more active metal produces the metal oxide, which must be reduced to obtain the free metal. The most common reducing agents are coke (impure carbon), carbon monoxide, and hydrogen. The following are some common examples of the reduction process:
\[
\begin{aligned}
\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+3 \mathrm{CO}(g) & \xrightarrow{\text { Heat }} 2 \mathrm{Fe}(l)+3 \mathrm{CO}_{2}(g) \\
\mathrm{WO}_{3}(s)+3 \mathrm{H}_{2}(g) & \xrightarrow{\text { Heat }} \mathrm{W}(l)+3 \mathrm{H}_{2} \mathrm{O}(g) \\
\mathrm{ZnO}(s)+\mathrm{C}(s) & \xrightarrow{\text { Heat }} \mathrm{Zn}(l)+\mathrm{CO}(g)
\end{aligned}
\]

The most active metals, such as aluminum and the alkali metals, must be reduced electrolytically, usually from molten salts (see Section 18.8).

The metal obtained in the reduction step is invariably impure and must be refined. The methods of refining include electrolytic refining (see Section 18.8), oxidation of impurities (as for iron, see below), and distillation of low-boiling metals such as mercury and zinc. One process used when highly pure metals are needed is zone refining. In this process a bar of the impure metal travels through a heater (Fig. 21.35), which

causes melting and recrystallizing of the metal as the bar cools. Purification of the metal occurs because as the crystal re-forms, the metal ions are likely to fit much better in the crystal lattice than are the atoms of impurities. Thus the impurities tend to be excluded and carried to the end of the bar. Several repetitions of this process give a very pure metal bar.

\section*{Hydrometallurgy}

The metallurgical processes we have considered so far are usually called pyrometallurgy (pyro means "at high temperatures"). These traditional methods require large quantities of energy and have two other serious problems: atmospheric pollution (mainly by sulfur dioxide) and relatively high costs that make treatment of low-grade ores economically unfeasible.

In the past hundred years, a different process, hydrometallurgy (hydro means "water"), has been used to extract metals from ores by use of aqueous chemical solutions, a process called leaching. The first two uses of hydrometallurgy were for the extraction of gold from low-grade ores and for the production of aluminum oxide, or alumina, from bauxite, an aluminum-bearing ore.

Gold is sometimes found in ores in the elemental state, but it usually occurs in relatively small concentrations. A process called cyanidation treats the crushed ore with an aqueous cyanide solution in the presence of air to dissolve the gold by forming the complex ion \(\mathrm{Au}(\mathrm{CN})_{2}{ }^{-}\):
\[
4 \mathrm{Au}(s)+8 \mathrm{CN}^{-}(a q)+\mathrm{O}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{Au}(\mathrm{CN})_{2}^{-}(a q)+4 \mathrm{OH}^{-}(a q)
\]

Pure gold is then recovered by reaction of the solution of \(\mathrm{Au}(\mathrm{CN})_{2}{ }^{-}\)with zinc powder to reduce \(\mathrm{Au}^{+}\)to Au :
\[
2 \mathrm{Au}(\mathrm{CN})_{2}{ }^{-}(a q)+\mathrm{Zn}(s) \longrightarrow 2 \mathrm{Au}(s)+\mathrm{Zn}(\mathrm{CN})_{4}{ }^{2-}(a q)
\]

The extraction of alumina from bauxite (the Bayer process) leaches the ore with sodium hydroxide at high temperatures and pressures to dissolve the amphoteric aluminum oxide:
\[
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+2 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{AlO}_{2}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
\]

This process leaves behind solid impurities such as \(\mathrm{SiO}_{2}, \mathrm{Fe}_{2} \mathrm{O}_{3}\), and \(\mathrm{TiO}_{2}\), which are not appreciably soluble in basic solution. After the solid impurities are removed, the pH of the solution is lowered, causing the pure aluminum oxide to re-form. It is then electrolyzed to produce aluminum metal (see Section 18.8).

As illustrated by these processes, hydrometallurgy involves two distinct steps: selective leaching of a given metal ion from the ore and recovery of the metal ion from the solution by selective precipitation as an ionic compound.

The leaching agent can simply be water if the metal-containing compound is a water-soluble chloride or sulfate. However, most commonly, the metal is present in a water-insoluble substance that must somehow be dissolved. The leaching agents used in such cases are usually aqueous solutions containing acids, bases, oxidizing agents, salts, or some combination of these. Often the dissolving process involves the formation of complex ions. For example, when an ore containing water-insoluble lead sulfate is treated with an aqueous sodium chloride solution, the soluble complex ion \(\mathrm{PbCl}_{4}{ }^{2-}\) is formed:
\[
\mathrm{PbSO}_{4}(s)+4 \mathrm{Na}^{+}(a q)+4 \mathrm{Cl}^{-}(a q) \longrightarrow 4 \mathrm{Na}^{+}(a q)+\mathrm{PbCl}_{4}^{2-}(a q)+\mathrm{SO}_{4}^{2-}(a q)
\]

Formation of a complex ion also occurs in the cyanidation process for the recovery of gold. However, since the gold is present in the ore as particles of metal, it must first be oxidized by oxygen to produce \(\mathrm{Au}^{+}\), which then reacts with \(\mathrm{CN}^{-}\)to form the soluble \(\mathrm{Au}(\mathrm{CN})_{2}{ }^{-}\)species. Thus, in this case, the leaching process involves a combination of oxidation and complexation.

TABLE 21.20 | Examples of Methods for Recovery of Metal lons from Leaching Solutions
\begin{tabular}{|c|c|}
\hline Method & Examples \\
\hline Precipitation of a salt & \(\mathrm{Cu}^{2+}(a q)+\mathrm{S}^{2-}(a q) \longrightarrow \mathrm{CuS}(\mathrm{s})\) \\
\hline \[
\text { Reduction }\left\{\begin{array}{l}
\text { Chemical } \\
\text { Electrolytic }
\end{array}\right.
\] & \[
\begin{aligned}
& \mathrm{Cu}^{+}(a q)+\mathrm{HCN}(a q) \longrightarrow \mathrm{CuCN}(s)+\mathrm{H}^{+}(a q) \\
& \mathrm{Au}^{+}(a q)+\mathrm{Fe}^{2+}(a q) \longrightarrow \mathrm{Au}(s)+\mathrm{Fe}^{3+}(a q) \\
& \mathrm{Cu}^{2+}(a q)+\mathrm{Fe}(s) \longrightarrow \mathrm{Cu}(s)+\mathrm{Fe}^{2+}(a q) \\
& \mathrm{Ni}^{2+}(a q)+\mathrm{H}_{2}(g) \longrightarrow \mathrm{Ni}(s)+2 \mathrm{H}^{+}(a q) \\
& \mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s) \\
& \mathrm{Al}^{++}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al}(s)
\end{aligned}
\] \\
\hline Reduction plus precipitation & \[
\begin{aligned}
& 2 \mathrm{Cu}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q)+ \mathrm{H}_{2} \mathrm{SO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}() \longrightarrow \\
& 2 \mathrm{CuCl}(s)+3 \mathrm{H}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q)
\end{aligned}
\] \\
\hline
\end{tabular}

Sometimes just oxidation is used. For example, insoluble zinc sulfide can be converted to soluble zinc sulfate by pulverizing the ore and suspending it in water to form a slurry through which oxygen is bubbled:
\[
\mathrm{ZnS}(s)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q)
\]

One advantage of hydrometallurgy over the traditional processes is that sometimes the leaching agent can be pumped directly into the ore deposits in the earth. For example, aqueous sodium carbonate \(\left(\mathrm{Na}_{2} \mathrm{CO}_{3}\right)\) can be injected into uranium-bearing ores to form water-soluble complex carbonate ions.

Recovering the metal ions from the leaching solution involves forming an insoluble solid containing the metal ion to be recovered. This step may involve addition of an anion to form an insoluble salt, reduction to the solid metal, or a combination of reduction and precipitation of a salt. Examples of these processes are shown in Table 21.20. Because of its suitability for treating low-grade ores economically and without significant pollution, hydrometallurgy is becoming more popular for recovering many important metals such as copper, nickel, zinc, and uranium.

\section*{The Metallurgy of Iron}

Iron is present in the earth's crust in many types of minerals. Iron pyrite \(\left(\mathrm{FeS}_{2}\right)\) is widely distributed but is not suitable for production of metallic iron and steel because it is almost impossible to remove the last traces of sulfur. The presence of sulfur makes the resulting steel too brittle to be useful. Siderite \(\left(\mathrm{FeCO}_{3}\right)\) is a valuable iron mineral that can be converted to iron oxide by heating. The iron oxide minerals are hematite \(\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)\), the more abundant, and magnetite \(\left(\mathrm{Fe}_{3} \mathrm{O}_{4}\right.\), really \(\left.\mathrm{FeO} \cdot \mathrm{Fe}_{2} \mathrm{O}_{3}\right)\). Taconite ores contain iron oxides mixed with silicates and are more difficult to process than the others. However, taconite ores are being increasingly used as the more desirable ores are consumed.

To concentrate the iron in iron ores, advantage is taken of the natural magnetism of \(\mathrm{Fe}_{3} \mathrm{O}_{4}\) (hence its name, magnetite). The \(\mathrm{Fe}_{3} \mathrm{O}_{4}\) particles can be separated from the gangue by magnets. The ores that are not magnetic are often converted to \(\mathrm{Fe}_{3} \mathrm{O}_{4}\); hematite is partially reduced to magnetite, while siderite is first converted to FeO thermally, then oxidized to \(\mathrm{Fe}_{2} \mathrm{O}_{3}\), and then reduced to \(\mathrm{Fe}_{3} \mathrm{O}_{4}\) :
\[
\begin{aligned}
\mathrm{FeCO}_{3}(s) & \xrightarrow{\text { Heat }} \mathrm{FeO}(s)+\mathrm{CO}_{2}(g) \\
4 \mathrm{FeO}(s)+\mathrm{O}_{2}(g) & \longrightarrow 2 \mathrm{Fe}_{2} \mathrm{O}_{3}(s) \\
3 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+\mathrm{C}(s) & \longrightarrow 2 \mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{CO}(g)
\end{aligned}
\]

Sometimes the nonmagnetic ores are concentrated by flotation processes.

FIGURE 21.36 The blast furnace used in the production of iron.

The most commonly used reduction process for iron takes place in the blast furnace (Fig. 21.36). The raw materials required are concentrated iron ore, coke, and limestone (which serves as a flux to trap impurities). The furnace, which is approximately 25 feet in diameter, is charged from the top with a mixture of iron ore, coke, and limestone. A very strong blast \((\sim 350 \mathrm{mi} / \mathrm{h})\) of hot air is injected at the bottom, where the oxygen reacts with the carbon in the coke to form carbon monoxide, the reducing agent for the iron. The temperature of the charge increases as it travels down the furnace, with reduction of the iron to iron metal occurring in steps:
\[
\begin{aligned}
3 \mathrm{Fe}_{2} \mathrm{O}_{3}+\mathrm{CO} & \longrightarrow 2 \mathrm{Fe}_{3} \mathrm{O}_{4}+\mathrm{CO}_{2} \\
\mathrm{Fe}_{3} \mathrm{O}_{4}+\mathrm{CO} & \longrightarrow 3 \mathrm{FeO}+\mathrm{CO}_{2} \\
\mathrm{FeO}+\mathrm{CO} & \longrightarrow \mathrm{Fe}+\mathrm{CO}_{2}
\end{aligned}
\]

Iron can reduce carbon dioxide,
\[
\mathrm{Fe}+\mathrm{CO}_{2} \longrightarrow \mathrm{FeO}+\mathrm{CO}
\]
so complete reduction of the iron occurs only if the carbon dioxide is destroyed by adding excess coke:
\[
\mathrm{CO}_{2}+\mathrm{C} \longrightarrow 2 \mathrm{CO}
\]

The limestone \(\left(\mathrm{CaCO}_{3}\right)\) in the charge loses carbon dioxide, or calcines, in the hot furnace and combines with silica and other impurities to form slag, which is mostly molten calcium silicate, \(\mathrm{CaSiO}_{3}\),
\[
\mathrm{CaO}+\mathrm{SiO}_{2} \longrightarrow \mathrm{CaSiO}_{3}
\]
and alumina \(\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)\). The slag floats on the molten iron and is skimmed off. The gas that escapes from the top of the furnace contains carbon monoxide, which is combined with air to form carbon dioxide. The energy released in this exothermic reaction is collected in a heat exchanger and used in heating the furnace.

The iron collected from the blast furnace, called pig iron, is quite impure. It contains \(\sim 90 \%\) iron, \(\sim 5 \%\) carbon, \(\sim 2 \%\) manganese, \(\sim 1 \%\) silicon, \(\sim 0.3 \%\) phosphorus,
and \(\sim 0.04 \%\) sulfur (from impurities in the coke). The production of 1 ton of pig iron requires approximately 1.7 tons of iron ore, 0.5 ton of coke, 0.25 ton of limestone, and 2 tons of air.

Iron oxide also can be reduced in a direct reduction furnace, which operates at much lower temperatures \(\left(1300-2000^{\circ} \mathrm{F}\right)\) than a blast furnace and produces a solid "sponge iron" rather than molten iron. Because of the milder reaction conditions, the direct reduction furnace requires a higher grade of iron ore (with fewer impurities) than that used in a blast furnace. The iron from the direct reduction furnace is called DRI (directly reduced iron) and contains \(\sim 95 \%\) iron, with the balance mainly silica and alumina.

\section*{Production of Steel}

Steel is an alloy and can be classified as carbon steel, which contains up to about \(1.5 \%\) carbon, or alloy steel, which contains carbon plus other metals such as \(\mathrm{Cr}, \mathrm{Co}, \mathrm{Mn}\), and Mo. The wide range of mechanical properties associated with steel is determined by its chemical composition and by the heat treatment of the final product.

The production of iron from its ore is fundamentally a reduction process, but the conversion of iron to steel is basically an oxidation process in which unwanted impurities are eliminated. Oxidation is carried out in various ways, but the two most common are the open hearth process and the basic oxygen process.

In the oxidation reactions of steelmaking, the manganese, phosphorus, and silicon in the impure iron react with oxygen to form oxides, which in turn react with appropriate fluxes to form slag. Sulfur enters the slag primarily as sulfides, and excess carbon forms carbon monoxide or carbon dioxide. The flux chosen depends on the major impurities present. If manganese is the chief impurity, an acidic flux of silica is used:
\[
\mathrm{MnO}(s)+\mathrm{SiO}_{2}(s) \xrightarrow{\text { Heat }} \mathrm{MnSiO}_{3}(l)
\]

If the main impurity is silicon or phosphorus, a basic flux, usually lime \((\mathrm{CaO})\) or magnesia ( MgO ) , is needed to give reactions such as
\[
\begin{gathered}
\mathrm{SiO}_{2}(s)+\mathrm{MgO}(s) \xrightarrow{\text { Heat }} \mathrm{MgSiO}_{3}(l) \\
\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{CaO}(s) \xrightarrow{\text { Heat }} 2 \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(l)
\end{gathered}
\]

Whether an acidic or a basic slag will be needed is a factor that must be considered when a furnace is constructed so that its refractory linings will be compatible with the slag. Silica bricks would deteriorate quickly in the presence of basic slag, and magnesia or lime bricks would dissolve in acid slag.

The open hearth process (Fig. 21.37) uses a dishlike container that holds 100 to 200 tons of molten iron. An external heat source is required to keep the iron molten, and a concave roof over the container reflects heat back toward the iron surface. A blast of air or oxygen is passed over the surface of the iron to react with impurities. Silicon

FIGURE 21.37 A schematic diagram of the open hearth process for steelmaking. The checker chambers contain bricks that absorb heat from gases passing over the molten charge. The flow of air and gases is reversed periodically.

FIGURE 21.38 The basic oxygen process for steelmaking.

Refer to Section 10.3 for a review of packing and crystal lattices.
and manganese are oxidized first and enter the slag, followed by oxidation of carbon to carbon monoxide, which causes agitation and foaming of the molten bath. The exothermic oxidation of carbon raises the temperature of the bath, causing the limestone flux to calcine:
\[
\mathrm{CaCO}_{3} \xrightarrow{\text { Heat }} \mathrm{CaO}+\mathrm{CO}_{2}
\]

The resulting lime floats to the top of the molten mixture (an event called the lime boil), where it combines with phosphates, sulfates, and silicates. Next comes the refining process, which involves continued oxidation of carbon and other impurities. Because the melting point increases as the carbon content decreases, the bath temperatures must be increased during this phase of the operation. If the carbon content falls below that desired in the final product, coke or pig iron may be added.

The final composition of the steel is "fine-tuned" after the charge is poured. For example, aluminum is sometimes added at this stage to remove trace amounts of oxygen via the reaction
\[
4 \mathrm{Al}+3 \mathrm{O}_{2} \longrightarrow 2 \mathrm{Al}_{2} \mathrm{O}_{3}
\]

Alloying metals such as vanadium, chromium, titanium, manganese, and nickel are also added to give the steel the properties needed for a specific application.

The processing of a batch of steel by the open hearth process is quite slow, taking up to 8 hours. The basic oxygen process is much faster. Molten pig iron and scrap iron are placed in a barrel-shaped container (Fig. 21.38) that can hold as much as 300 tons of material. A high-pressure blast of oxygen is directed at the surface of the molten iron, oxidizing impurities in a manner very similar to that used in the open hearth process. Fluxes are added after the oxygen blow begins. One advantage of this process is that the exothermic oxidation reactions proceed so rapidly that they produce enough heat to raise the temperature nearly to the boiling point of iron without an external heat source. Also, at these high temperatures only about an hour is needed to complete the oxidation processes.

The electric arc method, which was once used only for small batches of specialty steels, is being utilized more and more in the steel industry. In this process an electric arc between carbon electrodes is used to melt the charge. This means that no fuelborne impurities are added to the steel, since no fuel is needed. Also, higher temperatures are possible than in the open hearth or basic oxygen processes, and this leads to more effective removal of sulfur and phosphorus impurities. Oxygen is added in this process so that the oxide impurities in the steel can be controlled effectively.

\section*{Heat Treatment of Steel}

One way of producing the desired physical properties in steel is by controlling the chemical composition (Table 21.21). Another method for tailoring the properties of steel involves heat treatment. Pure iron exists in two different crystalline forms, depending on the temperature. At any temperature below \(912^{\circ} \mathrm{C}\), iron has a bodycentered cubic structure and is called \(\alpha\)-iron. Between \(912^{\circ} \mathrm{C}\) and \(1394^{\circ} \mathrm{C}\), iron has a face-centered cubic structure called austentite, or \(\gamma\)-iron. At \(1394^{\circ} \mathrm{C}\), iron changes to \(\delta\)-iron, a body-centered cubic structure identical to \(\alpha\)-iron.

When iron is alloyed with carbon, which fits into holes among the iron atoms to form the interstitial alloy carbon steel, the situation becomes even more complex. For example, the temperature at which \(\alpha\)-iron changes to austentite is lowered by about \(200^{\circ} \mathrm{C}\). Also, at high temperatures iron and carbon react by an endothermic reversible reaction to form an iron carbide called cementite:
\[
3 \mathrm{Fe}+\mathrm{C}+\underset{\text { (Heat) }}{\text { energy }} \rightleftharpoons \underset{\text { Cementite }}{\rightleftharpoons} \mathrm{Fe}_{3} \mathrm{C}
\]

By Le Châtelier's principle, we can predict that cementite will become more stable relative to iron and carbon as the temperature is increased. This is the observed result.

TABLE 21.21 | Percent Composition and Uses of Various Types of Steel
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|}
\hline Type of Steel & Carbon & \% Manganese & \% Phosphorus & \[
\begin{gathered}
\% \\
\text { Sulfur }
\end{gathered}
\] & \% Silicon & \% Nickel & \% Chromium & \% Other & Uses \\
\hline Plain carbon & \(\leq 1.35\) & \(\leq 1.65\) & \(\leq 0.04\) & \(\leq 0.05\) & \(\leq 0.60\) & - & - & - & Sheet steel, tools \\
\hline Highstrength (low-alloy) & \(\leq 0.25\) & \(\leq 1.65\) & \(\leq 0.04\) & \(\leq 0.05\) & 0.15-0.9 & 0.4-1 & 0.3-1.3 & \[
\begin{aligned}
& \mathrm{Cu}(0.2-0.6) \\
& \mathrm{Sb}(0.01-0.08) \\
& \mathrm{V}(0.01-0.08)
\end{aligned}
\] & Transportation equipment, structural beams \\
\hline Alloy & \(\leq 1.00\) & \(\leq 3.50\) & \(\leq 0.04\) & \(\leq 0.05\) & 0.15-2.0 & 0.25-10.0 & 0.25-4.0 & \[
\begin{aligned}
& \text { Mo (0.08-4.0) } \\
& \text { V (0-0.2) } \\
& \text { W (0-18) } \\
& \text { Co (0-5) }
\end{aligned}
\] & Automobile and aircraft engine parts \\
\hline Stainless & 0.03-1.2 & 1.0-10 & 0.04-0.06 & \(\leq 0.03\) & 1-3 & 1-22 & 4.0-27 & - & Engine parts, steam turbine parts, kitchen utensils \\
\hline Silicon & - & - & - & - & 0.5-5.0 & - & - & - & Electric motors and transformers \\
\hline
\end{tabular}

Thus steel is really a mixture of iron metal in one of its crystal forms, carbon, and cementite. The proportions of these components are very important in determining the physical properties of steel.

When steel is heated to temperatures in the region of \(1000^{\circ} \mathrm{C}\), much of the carbon is converted to cementite. If the steel is then allowed to cool slowly, the equilibrium shown above shifts to the left, and small crystals of carbon precipitate, giving a steel that is relatively ductile. If the cooling is very rapid, the equilibrium does not have time to adjust. The cementite is trapped, and the steel has a high cementite content, making it quite brittle. The proportions of carbon crystals and cementite can be "fine-tuned" to give the desired properties by heating to intermediate temperatures followed by rapid cooling, a process called tempering. The rate of heating and cooling determines not only the amounts of cementite present but also the size of its crystals and the form of crystalline iron present.

\section*{For Review}

\section*{Key terms}

Section 21.1
complex ion
first-row transition metals
lanthanide contraction
lanthanide series
Section 21.3
coordination compound counterion
oxidation state
coordination number
ligand
coordinate covalent bond

\section*{First-row transition metals (scandium-zinc)}
) All have one or more electrons in the \(4 s\) orbital and various numbers of \(3 d\) electrons
) All exhibit metallic properties
) A particular element often shows more than one oxidation state in its compounds
> Most compounds are colored, and many are paramagnetic
> Most commonly form coordination compounds containing a complex ion involving ligands (Lewis bases) attached to a central transition metal ion
> The number of attached ligands (called the coordination number) can vary from 2 to 8 , with 4 and 6 being most common
) Many transition metal ions have major biological importance in molecules such as enzymes and those that transport and store oxygen
) Chelating ligands form more than one bond to the transition metal ion

\section*{Key terms}
monodentate (unidentate) ligand
chelating ligand (chelate)
bidentate ligand
Section 21.4
isomers
structural isomerism stereoisomerism coordination isomerism linkage isomerism geometrical (cis-trans) isomerism
trans isomer
cis isomer
optical isomerism
chiral
enantiomers
Section 21.6
crystal field model
\(d\)-orbital splitting
strong-field (low-spin) case
weak-field (high-spin) case spectrochemical series

Section 21.7
cytochromes
heme
porphyrin
myoglobin
hemoglobin
carboxyhemoglobin
Section 21.8
metallurgy
minerals
gangue
flotation process
roasting
smelting
zone refining
pyrometallurgy
hydrometallurgy
leaching
cyanidation
blast furnace
slag
pig iron
direct reduction furnace
carbon steel
alloy steel
open hearth process
basic oxygen process
electric arc method
tempering

\section*{Isomerism}
> Isomers: two or more compounds with the same formula but different properties
) Coordination isomerism: the composition of the coordination sphere varies
) Linkage isomerism: the point of attachment of one or more ligands varies
) Stereoisomerism: isomers have identical bonds but different spatial arrangements
) Geometric isomerism: ligands assume different relative positions in the coordination sphere; examples are cis and trans isomers
> Optical isomerism: molecules with nonsuperimposable mirror images rotate planepolarized light in opposite directions

\section*{Spectral and magnetic properties}
> Usually explained in terms of the crystal field model
> Model assumes the ligands are point charges that split the energies of the \(3 d\) orbitals
> Color and magnetism are explained in terms of how the \(3 d\) electrons occupy the split \(3 d\) energy levels
> Strong-field case: relatively large orbital splitting
> Weak-field case: relatively small orbital splitting

\section*{Metallurgy}
> The processes connected with separating a metal from its ore
> The minerals in ores are often converted to oxides (roasting) before being reduced to the metal (smelting)
) The metallurgy of iron: most common method for reduction uses a blast furnace; process involves iron ore, coke, and limestone
> Impure product ( \(\sim 90 \%\) iron) is called pig iron
> Steel is manufactured by oxidizing the impurities in pig iron

\section*{Review Questions Answers to the Review Questions can be found on the Student website (accessible from wwww.cengagebrain.com).}
1. What two first-row transition metals have unexpected electron configurations? A statement in the text says that first-row transition metal ions do not have \(4 s\) electrons. Why not? Why do transition metal ions often have several oxidation states, whereas representative metals generally have only one?
2. Define each of the following terms:
a. coordination compound
b. complex ion
c. counterions
d. coordination number
e. ligand
f. chelate
g. bidentate

How would transition metal ions be classified using the Lewis definition of acids and bases? What must a ligand have to bond to a metal? What do we mean when we say that a bond is a "coordinate covalent bond"?
3. When a metal ion has a coordination number of 2,4 , or 6, what are the observed geometries and associated bond angles? For each of the following, give the correct formulas for the complex ions.
a. linear \(\mathrm{Ag}^{+}\)complex ions having \(\mathrm{CN}^{-}\)ligands
b. tetrahedral \(\mathrm{Cu}^{+}\)complex ions having \(\mathrm{H}_{2} \mathrm{O}\) ligands
c. tetrahedral \(\mathrm{Mn}^{2+}\) complex ions having oxalate ligands
d. square planar \(\mathrm{Pt}^{2+}\) complex ions having \(\mathrm{NH}_{3}\) ligands
e. octahedral \(\mathrm{Fe}^{3+}\) complex ions having EDTA ligands
f. octahedral \(\mathrm{Co}^{2+}\) complex ions having \(\mathrm{Cl}^{-}\)ligands
g. octahedral \(\mathrm{Cr}^{3+}\) complex ions having ethylenediamine ligands
What is the electron configuration for the metal ion in each of the complex ions in \(\mathrm{a}-\mathrm{g}\) ?
4. What is wrong with the following formula-name combinations? Give the correct names for each.
a. \(\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{Cl}_{2}\) copperammine chloride
b. \(\left[\mathrm{Ni}(\mathrm{en})_{2}\right] \mathrm{SO}_{4}\) bis(ethylenediamine)nickel(IV) sulfate
c. \(\mathrm{K}\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Cl}_{4}\right]\) potassium tetrachlorodiaquachromium(III)
d. \(\mathrm{Na}_{4}\left[\mathrm{Co}(\mathrm{CN})_{4} \mathrm{C}_{2} \mathrm{O}_{4}\right]\) tetrasodium tetracyanooxalatocobaltate(II)
5. Define each of the following and give examples of each.
a. isomer
b. structural isomer
c. stereoisomer
d. coordination isomer
e. linkage isomer
f. geometrical isomer
g. optical isomer

Consider the cis and trans forms of the octahedral complex \(\mathrm{Cr}(\mathrm{en})_{2} \mathrm{Cl}_{2}\). Are both of these isomers optically active? Explain.

Another way to determine whether a substance is optically active is to look for a plane of symmetry in the molecule. If a substance has a plane of symmetry, then it will not exhibit optical activity (the mirror image will be superimposable). Show the plane of symmetry in the trans isomer and prove to yourself that the cis isomer does not have a plane of symmetry.
6. What is the major focus of the crystal field model? Why are the \(d\) orbitals split into two sets for an octahedral complex? What are the two sets of orbitals?

Define each of the following.
a. weak-field ligand
b. strong-field ligand
c. low-spin complex
d. high-spin complex

Why is \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}\) diamagnetic whereas \(\mathrm{CoF}_{6}{ }^{3-}\) is paramagnetic? Some octahedral complex ions have the same \(d\)-orbital splitting diagrams whether they are highspin or low-spin. For which of the following is this true?
a. \(\mathrm{V}^{3+}\)
b. \(\mathrm{Ni}^{2+}\)
c. \(\mathrm{Ru}^{2+}\)
7. The crystal field model predicts magnetic properties of complex ions and explains the colors of these complex ions. How? Solutions of \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}\) are yellow, but \(\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}\) does not absorb yellow light. Why? What color light is absorbed by \(\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}\) ? What is the spectrochemical series, and how can the study of light absorbed by various complex ions be used to develop this series? Would you expect \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}\) to absorb light of a longer or shorter wavelength than \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}\) ? Explain.
8. Why do tetrahedral complex ions have a different crystal field diagram than octahedral complex ions? What is the tetrahedral crystal field diagram? Why are virtually all tetrahedral complex ions "high spin"?

Explain the crystal field diagram for square planar complex ions and for linear complex ions.
9. Review Table 21.18, which lists some important biological functions associated with different first-row transition metals. The transport of \(\mathrm{O}_{2}\) in the blood is carried out by hemoglobin. Briefly explain how hemoglobin transports \(\mathrm{O}_{2}\) in the blood.
10. Define and give an example of each of the following.
a. roasting
b. smelting
c. flotation
d. leaching
e. gangue

What are the advantages and disadvantages of hydrometallurgy? Describe the process by which a metal is purified by zone refining.

\section*{Active Learning Questions}

\section*{These questions are designed to be used by groups of students in class.}
1. You isolate a compound with the formula \(\mathrm{PtCl}_{4} \cdot 2 \mathrm{KCl}\). From electrical conductance tests of an aqueous solution of the compound, you find that three ions per formula unit are present, and you also notice that addition of \(\mathrm{AgNO}_{3}\) does not cause a precipitate. Give the formula for this compound that shows the complex ion present. Explain your findings. Name this compound.
2. Both \(\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\) and \(\mathrm{Ni}(\mathrm{SCN})_{4}{ }^{2-}\) have four ligands. The first is paramagnetic, and the second is diamagnetic. Are the complex ions tetrahedral or square planar? Explain.
3. Which is more likely to be paramagnetic, \(\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}\) or \(\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\) ? Explain.
4. A metal ion in a high-spin octahedral complex has two more unpaired electrons than the same ion does in a low-spin octahedral complex. Name some possible metal ions for which this would be true.
A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

\section*{Questions}
5. What is the lanthanide contraction? How does the lanthanide contraction affect the properties of the \(4 d\) and \(5 d\) transition metals?
6. Four different octahedral chromium coordination compounds exist that all have the same oxidation state for chromium and have \(\mathrm{H}_{2} \mathrm{O}\) and \(\mathrm{Cl}^{-}\)as the ligands and counterions. When 1 mole of each of the four compounds is dissolved in water, how many moles of silver chloride will precipitate upon addition of excess \(\mathrm{AgNO}_{3}\) ?
7. Figure 21.17 shows that the cis isomer of \(\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}{ }^{+}\)is optically active while the trans isomer is not optically active. Is the same true for \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}{ }^{+}\)? Explain.
8. A certain first-row transition metal ion forms many different colored solutions. When four coordination compounds of this metal, each having the same coordination number, are dissolved in water, the colors of the solutions are red, yellow, green, and blue. Further experiments reveal that two of the complex ions are paramagnetic with four unpaired electrons and the other two are diamagnetic. What can be deduced from this information about the four coordination compounds?
9. Oxalic acid is often used to remove rust stains. What properties of oxalic acid allow it to do this?
10. For the following crystal field diagrams, label each as low spin, high spin, or cannot tell. Explain your answers.
(a)

(b)

(c)

11. \(\mathrm{CoCl}_{4}{ }^{2-}\) forms a tetrahedral complex ion and \(\mathrm{Co}(\mathrm{CN})_{6}{ }^{3-}\) forms an octahedral complex ion. What is wrong about the following statements concerning each complex ion and the \(d\) orbital splitting diagrams?
a. \(\mathrm{CoCl}_{4}{ }^{2-}\) is an example of a strong-field case having two unpaired electrons.
b. Because \(\mathrm{CN}^{-}\)is a weak-field ligand, \(\mathrm{Co}(\mathrm{CN})_{6}{ }^{3-}\) will be a low-spin case having four unpaired electrons.
12. The compound \(\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6} \mathrm{Cl}_{2}\) is green, whereas \(\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6} \mathrm{Cl}_{2}\) is violet. Predict the predominant color of light absorbed by each compound. Which compound absorbs light with the shorter wavelength? Predict in which compound \(\Delta\) is greater and whether \(\mathrm{H}_{2} \mathrm{O}\) or \(\mathrm{NH}_{3}\) is the stronger field ligand. Do your conclusions agree with the spectrochemical series?
13. When concentrated hydrochloric acid is added to a red solution containing the \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\) complex ion, the solution turns blue as the tetrahedral \(\mathrm{CoCl}_{4}{ }^{2-}\) complex ion forms. Explain this color change.
14. Tetrahedral complexes of \(\mathrm{Co}^{2+}\) are quite common. Use a \(d\)-orbital splitting diagram to rationalize the stability of \(\mathrm{Co}^{2+}\) tetrahedral complex ions.
15. Which of the following ligands are capable of linkage isomerism? Explain your answer.
\[
\mathrm{SCN}^{-}, \mathrm{N}_{3}^{-}, \mathrm{NO}_{2}^{-}, \mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}, \mathrm{OCN}^{-}, \mathrm{I}^{-}
\]
16. Compounds of copper(II) are generally colored, but compounds of copper(I) are not. Explain. Would you expect \(\mathrm{Cd}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\) to be colored? Explain.
17. Compounds of \(\mathrm{Sc}^{3+}\) are not colored, but those of \(\mathrm{Ti}^{3+}\) and \(\mathrm{V}^{3+}\) are. Why?
18. What is the maximum number of unpaired \(d\) electrons that an octahedral transition metal complex ion can have? Predict a compound that would have this number of unpaired electrons.
19. Nickel can be purified by producing the volatile compound nickel tetracarbonyl. Nickel is the only metal that reacts with carbon monoxide at room temperature. Assuming this compound is overall neutral, what is the oxidation state of Ni in the compound? Deduce the formula of the compound.
20. Almost all metals in nature are found as ionic compounds in ores instead of being in the pure state. Why? What must be done to a sample of ore to obtain a metal substance that has desirable properties?
21. What causes high-altitude sickness, and what is high-altitude acclimatization?
22. Why are \(\mathrm{CN}^{-}\)and CO toxic to humans?

\section*{Exercises}

In this section similar exercises are paired.

\section*{Transition Metals and Coordination Compounds}
23. Write electron configurations for the following transition metals.
a. Sc
b. Ru
c. Ir
d. Mn
24. Write electron configurations for the following transition metal ions.
a. \(\mathrm{Sc}^{3+}\)
b. \(\mathrm{Ru}^{2+}, \mathrm{Ru}^{3+}\)
c. \(\mathrm{Ir}^{+}, \mathrm{Ir}^{3+}\)
d. \(\mathrm{Mn}^{2+}\)
\(\Gamma^{25}\). Write electron configurations for the following transition metals and their ions.
a. \(\mathrm{Co}, \mathrm{Co}^{2+}, \mathrm{Co}^{3+}\)
b. \(\mathrm{Pt}, \mathrm{Pt}^{2+}, \mathrm{Pt}^{4+}\)
c. \(\mathrm{Fe}, \mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}\)
26. Write electron configurations for each of the following.
a. \(\mathrm{Cr}, \mathrm{Cr}^{2+}, \mathrm{Cr}^{3+}\)
b. \(\mathrm{Cu}, \mathrm{Cu}^{+}, \mathrm{Cu}^{2+}\)
c. \(\mathrm{V}, \mathrm{V}^{2+}, \mathrm{V}^{3+}\)
27. What is the electron configuration for the transition metal ion in each of the following compounds?
a. \(\mathrm{K}_{3}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]\)
b. \(\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right] \mathrm{Cl}\)
c. \(\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{Br}_{2}\)
d. \(\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\left(\mathrm{NO}_{2}\right)_{2}\right] \mathrm{I}\)
28. What is the electron configuration for the transition metal ion(s) in each of the following compounds?
a. \(\left(\mathrm{NH}_{4}\right)_{2}\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Cl}_{4}\right]\)
b. \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{2}\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)_{2}\right] \mathrm{I}_{2}\)
c. \(\mathrm{Na}_{2}\left[\mathrm{TaF}_{7}\right]\)
d. \(\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{I}_{2}\right]\left[\mathrm{PtI}_{4}\right]\)

Pt forms +2 and +4 oxidation states in compounds.
Molybdenum is obtained as a by-product of copper mining or is mined directly (primary deposits are in the Rocky Mountains in Colorado). In both cases it is obtained as \(\mathrm{MoS}_{2}\), which is then converted to \(\mathrm{MoO}_{3}\). The \(\mathrm{MoO}_{3}\) can be used directly in the production of stainless steel for high-speed tools (which accounts for about \(85 \%\) of the molybdenum used). Molybdenum can be purified by dissolving \(\mathrm{MoO}_{3}\) in aqueous ammonia and crystallizing ammonium molybdate. Depending on conditions, either \(\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Mo}_{2} \mathrm{O}_{7}\) or \(\left(\mathrm{NH}_{4}\right)_{6} \mathrm{Mo}_{7} \mathrm{O}_{24} \cdot 4 \mathrm{H}_{2} \mathrm{O}\) is obtained.
a. Give names for \(\mathrm{MoS}_{2}\) and \(\mathrm{MoO}_{3}\).
b. What is the oxidation state of Mo in each of the compounds mentioned above?
30. Titanium dioxide, the most widely used white pigment, occurs naturally but is often colored by the presence of impurities. The chloride process is often used in purifying rutile, a mineral form of titanium dioxide.
a. Show that the unit cell for rutile, shown below, conforms to the formula \(\mathrm{TiO}_{2}\). (Hint: Recall the discussion in Sections 10.4 and 10.7.)

b. The reactions for the chloride process are
\[
\begin{aligned}
& 2 \mathrm{TiO}_{2}(s)+3 \mathrm{C}(s)+4 \mathrm{Cl}_{2}(g) \\
& \xrightarrow{950^{\circ} \mathrm{C}} 2 \mathrm{TiCl}_{4}(g)+\mathrm{CO}_{2}(g)+2 \mathrm{CO}(g) \\
& \mathrm{TiCl}_{4}(g)+\mathrm{O}_{2}(g) \xrightarrow{1000-1400^{\circ} \mathrm{C}} \mathrm{TiO}_{2}(s)+2 \mathrm{Cl}_{2}(g)
\end{aligned}
\]

Assign oxidation states to the elements in both reactions. Which elements are being reduced, and which are being oxidized? Identify the oxidizing agent and the reducing agent in each reaction.
-31. When \(6 M\) ammonia is added gradually to aqueous copper(II) nitrate, a white precipitate forms. The precipitate dissolves as more 6 M ammonia is added. Write balanced equations to explain these observations. [Hint: \(\mathrm{Cu}^{2+}\) reacts with \(\mathrm{NH}_{3}\) to form \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\).]
32. When an aqueous solution of KCN is added to a solution containing \(\mathrm{Ni}^{2+}\) ions, a precipitate forms, which redissolves on addition of more KCN solution. Write reactions describing what happens in this solution. [Hint: \(\mathrm{CN}^{-}\)is a BrønstedLowry base ( \(K_{\mathrm{b}} \approx 10^{-5}\) ) and a Lewis base.]
-33. Consider aqueous solutions of the following coordination compounds: \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}_{3}\right],\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}, \mathrm{Na}_{3}\left[\mathrm{CrCl}_{6}\right]\). If silver nitrate is added to each solution, in which will a precipitate form? Explain.
34. A coordination compound of cobalt(III) contains four ammonia molecules, one sulfate ion, and one chloride ion. Addition of aqueous \(\mathrm{BaCl}_{2}\) solution to an aqueous solution of the compound gives no precipitate. Addition of aqueous \(\mathrm{AgNO}_{3}\) to an aqueous solution of the compound produces a white precipitate. Propose a structure for this coordination compound.
-35. Name the following complex ions:

b. \(\left[\begin{array}{c}\mathrm{Cl} \\ \vdots \\ \mathrm{NH}_{3} \mathrm{~N}_{3}\end{array}\right]+\)

36. Name the following complex ions.
a. \(\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}^{2+}\)
b. \(\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}\)
c. \(\mathrm{Mn}\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)_{3}{ }^{2+}\)
d. \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{NO}_{2}{ }^{2+}\)
e. \(\mathrm{Ni}(\mathrm{CN})_{4}{ }^{2-}\)
f. \(\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}{ }^{+}\)
g. \(\mathrm{Fe}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}{ }^{3-}\)
h. \(\mathrm{Co}(\mathrm{SCN})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{+}\)
-37. Name the following coordination compounds.
a. \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{2}\)
b. \(\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{I}_{3}\)
c. \(\mathrm{K}_{2}\left[\mathrm{PtCl}_{4}\right]\)
d. \(\mathrm{K}_{4}\left[\mathrm{PtCl}_{6}\right]\)
e. \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}\)
f. \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{3}\left(\mathrm{NO}_{2}\right)_{3}\right]\)
38. Name the following coordination compounds.
a. \(\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{Br}\right] \mathrm{Br}_{2}\)
b. \(\mathrm{Na}_{3}\left[\mathrm{Co}(\mathrm{CN})_{6}\right]\)
c. \(\left[\mathrm{Fe}\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)_{2}\left(\mathrm{NO}_{2}\right)_{2}\right] \mathrm{Cl}\)
d. \(\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{I}_{2}\right]\left[\mathrm{PtI}_{4}\right]\)
-39 . Give formulas for the following.
a. potassium tetrachlorocobaltate(II)
b. aquatricarbonylplatinum(II) bromide
c. sodium dicyanobis(oxalato)ferrate(III)
d. triamminechloroethylenediaminechromium(III) iodide
40. Give formulas for the following complex ions.
a. tetrachloroferrate(III) ion
b. pentaammineaquaruthenium(III) ion
c. tetracarbonyldihydroxochromium(III) ion
d. amminetrichloroplatinate(II) ion
-41. Draw geometrical isomers of each of the following complex ions.
a. \(\mathrm{Co}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}^{-}\)
b. \(\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{I}_{2}{ }^{2+}\)
c. \(\mathrm{Ir}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}_{3}\)
d. \(\mathrm{Cr}(\mathrm{en})\left(\mathrm{NH}_{3}\right)_{2} \mathrm{I}_{2}{ }^{+}\)
42. Draw structures of each of the following.
a. cis-dichloroethylenediamineplatinum(II)
b. trans-dichlorobis(ethylenediamine)cobalt(II)
c. cis-tetraamminechloronitrocobalt(III) ion
d. trans-tetraamminechloronitritocobalt(III) ion
e. trans-diaquabis(ethylenediamine)copper(II) ion
43. The carbonate ion \(\left(\mathrm{CO}_{3}{ }^{2-}\right)\) can act as either a monodentate or a bidentate ligand. Draw a picture of \(\mathrm{CO}_{3}{ }^{2-}\) coordinating to a metal ion as a monodentate and as a bidentate ligand. The carbonate ion can also act as a bridge between two metal ions. Draw a picture of a \(\mathrm{CO}_{3}{ }^{2-}\) ion bridging between two metal ions.
44. Amino acids can act as ligands toward transition metal ions. The simplest amino acid is glycine \(\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{H}\right)\). Draw a structure of the glycinate anion \(\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CO}_{2}^{-}\right)\)acting as a bidentate ligand. Draw the structural isomers of the square planar complex \(\mathrm{Cu}\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CO}_{2}\right)_{2}\).
-45. How many bonds could each of the following chelating ligands form with a metal ion?
a. acetylacetone \((\mathrm{acacH})\), a common ligand in organometallic catalysts:

b. diethylenetriamine, used in a variety of industrial processes:
\[
\mathrm{NH}_{2}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{NH}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{NH}_{2}
\]
c. salen, a common ligand for chiral organometallic catalysts:

d. porphine, often used in supermolecular chemistry as well as catalysis; biologically, porphine is the basis for many different types of porphyrin-containing proteins, including heme proteins:

46. BAL is a chelating agent used in treating heavy metal poisoning. It acts as a bidentate ligand. What type of linkage isomers are possible when BAL coordinates to a metal ion?

-47. Draw all geometrical and linkage isomers of \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{NO}_{2}\right)_{2}\).
48. Draw all geometrical and linkage isomers of square planar \(\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2}(\mathrm{SCN})_{2}\).
49. Acetylacetone, abbreviated acacH, is a bidentate ligand. It loses a proton and coordinates as \(\mathrm{acac}^{-}\), as shown below, where M is a transition metal:

Which of the following complexes are optically active: cis\(\mathrm{Cr}(\mathrm{acac})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\), trans \(-\mathrm{Cr}(\mathrm{acac})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\), and \(\mathrm{Cr}(\mathrm{acac})_{3}\) ?
50. Draw all geometrical isomers of \(\mathrm{Pt}(\mathrm{CN})_{2} \mathrm{Br}_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\). Which of these isomers has an optical isomer? Draw the various optical isomers.

\section*{Bonding, Color, and Magnetism in Coordination Compounds}
51. Match the crystal field diagrams given below with the following complex ions.
\(\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}^{2+}\)
\(\underset{\text { (assume strong field) }}{\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Br}_{2}{ }^{+}}\)
\(\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\)
(assume weak field)

52. Match the crystal field diagrams given below with the following complex ions.
\(\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-} \quad \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\)

(a)

(b)

53. Draw the \(d\)-orbital splitting diagrams for the octahedral complex ions of each of the following.
a. \(\mathrm{Fe}^{2+}\) (high and low spin)
b. \(\mathrm{Fe}^{3+}\) (high spin)
c. \(\mathrm{Ni}^{2+}\)
54. Draw the \(d\)-orbital splitting diagrams for the octahedral complex ions of each of the following.
a. \(\mathrm{Zn}^{2+}\)
b. \(\mathrm{Co}^{2+}\) (high and low spin)
c. \(\mathrm{Ti}^{3+}\)
-55. The \(\mathrm{CrF}_{6}{ }^{4-}\) ion is known to have four unpaired electrons. Does the \(\mathrm{F}^{-}\)ligand produce a strong or weak field?
56. The \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}\) ion is diamagnetic, but \(\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\) is paramagnetic. Explain.
57. How many unpaired electrons are in the following complex ions?
a. \(\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}\) (low-spin case)
b. \(\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\)
c. \(\mathrm{V}(\mathrm{en})_{3}{ }^{3+}\)
58. The complex ion \(\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}\) is paramagnetic with one unpaired electron. The complex ion \(\mathrm{Fe}(\mathrm{SCN})_{6}{ }^{3-}\) has five unpaired electrons. Where does \(\mathrm{SCN}^{-}\)lie in the spectrochemical series relative to \(\mathrm{CN}^{-}\)?
9. Rank the following complex ions in order of increasing wavelength of light absorbed.
\[
\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }_{6}^{3+}, \mathrm{Co}(\mathrm{CN})_{6}{ }^{3-}, \mathrm{CoI}_{6}{ }^{3-}, \mathrm{Co}(\mathrm{en})_{3}{ }^{3+}
\]
60. The complex ion \(\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\) has an absorption maximum at around 800 nm . When four ammonias replace water, \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}{ }^{2+}\), the absorption maximum shifts to around 600 nm . What do these results signify in terms of the relative field splittings of \(\mathrm{NH}_{3}\) and \(\mathrm{H}_{2} \mathrm{O}\) ? Explain.
\({ }^{61}\). The following test tubes each contain a different chromium complex ion.

For each complex ion, predict the predominant color of light absorbed. If the complex ions are \(\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}, \mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\), and \(\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Cl}_{2}{ }^{+}\), what is the identity of the complex ion in each test tube? (Hint: Reference the spectrochemical series.)
62. Consider the complex ions \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}, \mathrm{Co}(\mathrm{CN})_{6}{ }^{3-}\), and \(\mathrm{CoF}_{6}{ }^{3-}\). The wavelengths of absorbed electromagnetic radiation for these compounds (in no specific order) are 770 nm , 440 nm , and 290 nm . Match the complex ion to the wavelength of absorbed electromagnetic radiation.
63. The wavelength of absorbed electromagnetic radiation for \(\mathrm{CoBr}_{4}{ }^{2-}\) is \(3.4 \times 10^{-6} \mathrm{~m}\). Will the complex ion \(\mathrm{CoBr}_{6}{ }^{4-}\) absorb electromagnetic radiation having a wavelength longer or shorter than \(3.4 \times 10^{-6} \mathrm{~m}\) ? Explain.
64. The complex ion \(\mathrm{NiCl}_{4}{ }^{2-}\) has two unpaired electrons, whereas \(\mathrm{Ni}(\mathrm{CN})_{4}{ }^{2-}\) is diamagnetic. Propose structures for these two complex ions.
65. How many unpaired electrons are present in the tetrahedral ion \(\mathrm{FeCl}_{4}{ }^{-}\)?
66. The complex ion \(\mathrm{PdCl}_{4}{ }^{2-}\) is diamagnetic. Propose a structure for \(\mathrm{PdCl}_{4}{ }^{2-}\).

\section*{Metallurgy}
67. A blast furnace is used to reduce iron oxides to elemental iron. The reducing agent for this reduction process is carbon monoxide.
a. Given the following data:
\[
\begin{array}{|cl}
\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+3 \mathrm{CO}(g) \longrightarrow 2 \mathrm{Fe}(s)+3 \mathrm{CO}_{2}(g) & \Delta H^{\circ}=-23 \mathrm{~kJ} \\
3 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+\mathrm{CO}(g) \longrightarrow 2 \mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{CO}_{2}(g) & \Delta H^{\circ}=-39 \mathrm{~kJ} \\
\mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{CO}(g) \longrightarrow 3 \mathrm{FeO}(s)+\mathrm{CO}_{2}(g) & \Delta H^{\circ}=18 \mathrm{~kJ} \\
\text { determine } \Delta H^{\circ} \text { for the reaction } & \\
\mathrm{FeO}(s)+\mathrm{CO}(g) \longrightarrow \mathrm{Fe}(s)+\mathrm{CO}_{2}(g) &
\end{array}
\]
b. The \(\mathrm{CO}_{2}\) produced in a blast furnace during the reduction process actually can oxidize iron into FeO . To eliminate this reaction, excess coke is added to convert \(\mathrm{CO}_{2}\) into CO by the reaction
\[
\mathrm{CO}_{2}(g)+\mathrm{C}(s) \longrightarrow 2 \mathrm{CO}(g)
\]

Using data from Appendix 4, determine \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) for this reaction. Assuming \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) do not depend on temperature, at what temperatures is the conversion reaction of \(\mathrm{CO}_{2}\) into CO spontaneous at standard conditions?
68. Use the data in Appendix 4 for the following.
a. Calculate \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) for the reaction
\[
3 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+\mathrm{CO}(g) \longrightarrow 2 \mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{CO}_{2}(g)
\]
that occurs in a blast furnace.
b. Assume that \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) are independent of temperature. Calculate \(\Delta G^{\circ}\) at \(800 .{ }^{\circ} \mathrm{C}\) for this reaction.
-69. Iron is present in the earth's crust in many types of minerals. The iron oxide minerals are hematite \(\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)\) and magnetite \(\left(\mathrm{Fe}_{3} \mathrm{O}_{4}\right)\). What is the oxidation state of iron in each mineral? The iron ions in magnetite are a mixture of \(\mathrm{Fe}^{2+}\) and \(\mathrm{Fe}^{3+}\) ions. What is the ratio of \(\mathrm{Fe}^{3+}\) to \(\mathrm{Fe}^{2+}\) ions in magnetite? The formula for magnetite is often written as \(\mathrm{FeO} \cdot \mathrm{Fe}_{2} \mathrm{O}_{3}\). Does this make sense? Explain.
70. What roles do kinetics and thermodynamics play in the effect that the following reaction has on the properties of steel?
\[
3 \mathrm{Fe}+\mathrm{C} \rightleftharpoons \mathrm{Fe}_{3} \mathrm{C}
\]
[71. Silver is sometimes found in nature as large nuggets; more often it is found mixed with other metals and their ores. Cyanide ion is often used to extract the silver by the following reaction that occurs in basic solution:
\[
\mathrm{Ag}(s)+\mathrm{CN}^{-}(a q)+\mathrm{O}_{2}(g) \xrightarrow{\text { Basic }} \mathrm{Ag}(\mathrm{CN})_{2}^{-}(a q)
\]

Balance this equation by using the half-reaction method.
72. One of the classic methods for the determination of the manganese content in steel involves converting all the manganese to the deeply colored permanganate ion and then measuring the absorption of light. The steel is first dissolved in nitric acid, producing the manganese(II) ion and nitrogen dioxide gas. This solution is then reacted with an acidic solution containing periodate ion; the products are the permanganate and iodate ions. Write balanced chemical equations for both of these steps.

\section*{Additional Exercises}
73. When aqueous KI is added gradually to mercury(II) nitrate, an orange precipitate forms. Continued addition of KI causes the precipitate to dissolve. Write balanced equations to explain these observations. (Hint: \(\mathrm{Hg}^{2+}\) reacts with \(\mathrm{I}^{-}\)to form \(\mathrm{HgI}_{4}{ }^{2-}\).) Would you expect \(\mathrm{HgI}_{4}{ }^{2-}\) to form colored solutions? Explain.
74. The following statements discuss some coordination compounds. For each coordination compound, give the complex ion and the counterions, the electron configuration of the transition metal, and the geometry of the complex ion.
a. \(\mathrm{CoCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}\) is a compound used in novelty devices that predict rain.
b. During the developing process of black-and-white film, silver bromide is removed from photographic film by the fixer. The major component of the fixer is sodium thiosulfate. The equation for the reaction is:
\[
\operatorname{AgBr}(s)+2 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}(a q) \longrightarrow \mathrm{Na}_{3}\left[\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}\right](a q)+\mathrm{NaBr}(a q)
\]
c. In the production of printed circuit boards for the electronics industry, a thin layer of copper is laminated onto an insulating plastic board. Next, a circuit pattern made of a chemically resistant polymer is printed on the board. The unwanted copper is removed by chemical etching, and the protective polymer is finally removed by solvents. One etching reaction is:
\[
\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}(a q)+4 \mathrm{NH}_{3}(a q)+\mathrm{Cu}(s) \underset{2 \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}(a q)}{\longrightarrow}
\]

Assume these copper complex ions have tetrahedral geometry.
75. Acetylacetone (see Exercise 45, part a), abbreviated acacH, is a bidentate ligand. It loses a proton and coordinates as acac \({ }^{-}\), as shown below:

Acetylacetone reacts with an ethanol solution containing a salt of europium to give a compound that is \(40.1 \% \mathrm{C}\) and \(4.71 \% \mathrm{H}\) by mass. Combustion of 0.286 g of the compound gives \(0.112 \mathrm{~g} \mathrm{Eu}_{2} \mathrm{O}_{3}\). Assuming the compound contains only C, H, O , and Eu , determine the formula of the compound formed from the reaction of acetylacetone and the europium salt. (Assume that the compound contains one europium ion.)
76. The compound cisplatin, \(\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\), has been studied extensively as an antitumor agent. The reaction for the synthesis of cisplatin is:
\(\mathrm{K}_{2} \mathrm{PtCl}_{4}(a q)+2 \mathrm{NH}_{3}(a q) \longrightarrow \mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}(s)+2 \mathrm{KCl}(a q)\)
Write the electron configuration for platinum ion in cisplatin. Most \(d^{8}\) transition metal ions exhibit square planar geometry. With this and the name in mind, draw the structure of cisplatin.
77. Use standard reduction potentials to calculate \(\mathscr{E}^{\circ}, \Delta G^{\circ}\), and \(K\) (at 298 K ) for the reaction that is used in production of gold:
\[
2 \mathrm{Au}(\mathrm{CN})_{2}{ }^{-}(a q)+\mathrm{Zn}(s) \longrightarrow 2 \mathrm{Au}(s)+\mathrm{Zn}(\mathrm{CN})_{4}{ }^{2-}(a q)
\]

The relevant half-reactions are
\[
\begin{aligned}
\mathrm{Au}(\mathrm{CN})_{2}^{-}+\mathrm{e}^{-} \longrightarrow \mathrm{Au}+2 \mathrm{CN}^{-} & \mathscr{E}^{\circ}=-0.60 \mathrm{~V} \\
\mathrm{Zn}(\mathrm{CN})_{4}{ }^{2-}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Zn}+4 \mathrm{CN}^{-} & \mathscr{E}^{\circ}=-1.26 \mathrm{~V}
\end{aligned}
\]
78. Until the discoveries of Alfred Werner, it was thought that carbon had to be present in a compound for it to be optically active. Werner prepared the following compound containing \(\mathrm{OH}^{-}\)ions as bridging groups and separated the optical isomers.
a. Draw structures of the two optically active isomers of this compound.
b. What are the oxidation states of the cobalt ions?
c. How many unpaired electrons are present if the complex is the low-spin case?

79. Draw all the geometrical isomers of \(\mathrm{Cr}(\mathrm{en})\left(\mathrm{NH}_{3}\right)_{2} \mathrm{BrCl}^{+}\). Which of these isomers also have an optical isomer? Draw the various isomers.
80. A compound related to acetylacetone is 1,1,1-trifluoroacetylacetone (abbreviated Htfa ):

Htfa forms complexes in a manner similar to acetylacetone. (See Exercise 49.) Both \(\mathrm{Be}^{2+}\) and \(\mathrm{Cu}^{2+}\) form complexes with \(\mathrm{tfa}^{-}\)having the formula \(\mathrm{M}(\mathrm{tfa})_{2}\). Two isomers are formed for each metal complex.
a. The \(\mathrm{Be}^{2+}\) complexes are tetrahedral. Draw the two isomers of \(\operatorname{Be}(\mathrm{tfa})_{2}\). What type of isomerism is exhibited by \(\mathrm{Be}(\mathrm{tfa})_{2}\) ?
b. The \(\mathrm{Cu}^{2+}\) complexes are square planar. Draw the two isomers of \(\mathrm{Cu}(\mathrm{tfa})_{2}\). What type of isomerism is exhibited by \(\mathrm{Cu}(\mathrm{tfa})_{2}\) ?
81. Would it be better to use octahedral \(\mathrm{Ni}^{2+}\) complexes or octahedral \(\mathrm{Cr}^{2+}\) complexes to determine whether a given ligand is a strong-field or weak-field ligand by measuring the number of unpaired electrons? How else could the relative ligand field strengths be determined?
82. Name the following coordination compounds.
a. \(\mathrm{Na}_{4}\left[\mathrm{Ni}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}\right]\)
b. \(\mathrm{K}_{2}\left[\mathrm{CoCl}_{4}\right]\)
c. \(\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{SO}_{4}\)
d. \(\left[\mathrm{Co}(\mathrm{en})_{2}(\mathrm{SCN}) \mathrm{Cl}\right] \mathrm{Cl}\)
83. Give formulas for the following.
a. hexakis(pyridine)cobalt(III) chloride
b. pentaammineiodochromium(III) iodide
c. tris(ethylenediamine)nickel(II) bromide
d. potassium tetracyanonickelate(II)
e. tetraamminedichloroplatinum(IV) tetrachloroplatinate(II)
84. The complex ion \(\mathrm{Ru}(\mathrm{phen}) 3_{3}{ }^{2+}\) has been used as a probe for the structure of DNA. (Phen is a bidentate ligand.)
a. What type of isomerism is found in \(\mathrm{Ru}(\text { phen })_{3}{ }^{2+}\) ?
b. \(\mathrm{Ru}(\mathrm{phen})_{3}{ }^{2+}\) is diamagnetic (as are all complex ions of \(\mathrm{Ru}^{2+}\) ). Draw the crystal field diagram for the \(d\) orbitals in this complex ion.

Phen \(=1,10\)-phenanthroline \(=\)

85. Consider aqueous solutions of the following coordination compounds: \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6} \mathrm{I}_{3}, \mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{I}_{4}, \mathrm{Na}_{2} \mathrm{PtI}_{6}\), and \(\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{I}_{3}\). If aqueous \(\mathrm{AgNO}_{3}\) is added to separate beakers containing solutions of each coordination compound, how many moles of AgI will precipitate per mole of transition metal present? Assume that each transition metal ion forms an octahedral complex.
86. The equilibrium constant \(K_{\mathrm{a}}\) for the reaction
\[
\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \underset{\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}(\mathrm{OH})^{2+}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)}{\rightleftharpoons}
\]
is \(1.0 \times 10^{-5}\).
a. Calculate the pH of a 0.10 M solution of \(\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{Cl}_{3}\).
b. Will a 1.0 M solution of cobalt(II) nitrate have a higher or lower pH than a 1.0 M solution of cobalt(III) nitrate? Explain.
c. \(\mathrm{Co}^{3+}\) complex ions are generally low-spin cases, whereas \(\mathrm{Co}^{2+}\) complex ions are generally high-spin cases. Explain. If this is the situation, how many unpaired electrons are present in \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) and \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\) ?
87. Carbon monoxide is toxic because it binds more strongly to iron in hemoglobin \((\mathrm{Hb})\) than does \(\mathrm{O}_{2}\). Consider the following reactions and approximate standard free energy changes:
\[
\begin{aligned}
\mathrm{Hb}+\mathrm{O}_{2} & \longrightarrow \mathrm{HbO}_{2} \\
\mathrm{Hb}+\mathrm{CO} & \Delta G^{\circ}=-70 \mathrm{~kJ} \\
\mathrm{HbCO} & \Delta G^{\circ}=-80 \mathrm{~kJ}
\end{aligned}
\]

Using these data, estimate the equilibrium constant value at \(25^{\circ} \mathrm{C}\) for the following reaction:
\[
\mathrm{HbO}_{2}(a q)+\mathrm{CO}(g) \rightleftharpoons \mathrm{HbCO}(a q)+\mathrm{O}_{2}(g)
\]
88. For the process
\(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}^{2+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}^{+}(a q)+\mathrm{NH}_{3}(a q)\)
what would be the expected ratio of cis to trans isomers in the product?

\section*{ChemWork Problems}

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student

\section*{would get from an instructor.}
89. In which of the following is(are) the electron configuration(s) correct for the species indicated?
a. \(\mathrm{Cu} \quad[\mathrm{Ar}] 4 s^{2} 3 d^{9}\)
b. \(\mathrm{Fe}^{3+} \quad[\mathrm{Ar}] 3 d^{5}\)
c. Co \([\mathrm{Ar}] 4 s^{2} 3 d^{7}\)
d. \(\mathrm{La} \quad[\mathrm{Ar}] 6 s^{2} 4 f^{1}\)
e. \(\mathrm{Pt}^{2+} \quad[\mathrm{Xe}] 4 f^{4} 5 d^{8}\)
90. Which of the following molecules exhibit(s) optical isomerism?
a. cis- \(\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\)
b. trans- \(\mathrm{Ni}(\mathrm{en})_{2} \mathrm{Br}_{2}\) (en is ethylenediamine)
c. cis- \(\mathrm{Ni}(\mathrm{en})_{2} \mathrm{Br}_{2}\) (en is ethylenediamine)

91. Which of the following ions is(are) expected to form colored octahedral aqueous complex ions?
a. \(\mathrm{Zn}^{2+}\)
b. \(\mathrm{Cu}^{2+}\)
c. \(\mathrm{Mn}^{3+}\)
d. \(\mathrm{Ti}^{4+}\)
92. The following table indicates the number of unpaired electrons in the crystal field diagrams for some complexes. Complete the table by classifying each species as weak field, strong field, or insufficient information.
\begin{tabular}{lcl} 
Species & \begin{tabular}{c} 
Unpaired \\
Electrons
\end{tabular} & Classification \\
\hline \(\mathrm{Fe}(\mathrm{CNS})_{6}{ }^{4-}\) & 0 & \\
\hline \(\mathrm{CoCl} 4_{4}{ }^{2-}\) & 3 & \\
\hline \(\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) & 5 & \\
\hline \(\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}\) & 0 & \\
\hline
\end{tabular}
93. Which of the following crystal field diagram(s) is(are) correct for the complex given?
a. \(\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\) (tetrahedral)
\[
\begin{gathered}
-\uparrow-4 \downarrow \\
-\uparrow \downarrow-\uparrow \downarrow
\end{gathered}
\]
b. \(\mathrm{Mn}(\mathrm{CN})_{6}{ }^{3-}\) (strong field)

c. \(\mathrm{Ni}(\mathrm{CN})_{4}{ }^{2-}\) (square planar, diamagnetic)

94. Which of the following statement(s) is(are) true?
a. The coordination number of a metal ion in an octahedral complex ion is 8 .
b. All tetrahedral complex ions are low-spin.
c. The formula for triaquatriamminechromium(III) sulfate is \(\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\left(\mathrm{NH}_{3}\right)_{3}\right]_{2}\left(\mathrm{SO}_{4}\right)_{3}\).
d. The electron configuration of \(\mathrm{Hf}^{2+}\) is \([\mathrm{Xe}] 4 f^{12} 6 s^{2}\).
e. Hemoglobin contains \(\mathrm{Fe}^{3+}\).

\section*{Challenge Problems}
95. Consider the following complex ion, where A and B represent ligands.

The complex is known to be diamagnetic. Do A and B produce very similar or very different crystal fields? Explain.
96. Consider the pseudo-octahedral complex ion of \(\mathrm{Cr}^{3+}\), where A and B represent ligands.

Ligand A produces a stronger crystal field than ligand B. Draw an appropriate crystal field diagram for this complex ion (assume the A ligands are on the \(z\)-axis).
97. Consider the following data:
\[
\begin{aligned}
\mathrm{Co}^{3+}+\mathrm{e}^{-} \longrightarrow \mathrm{Co}^{2+} & \mathscr{E} \circ & =1.82 \mathrm{~V} \\
\mathrm{Co}^{2+}+3 \mathrm{en} \longrightarrow \mathrm{Co}(\mathrm{en})_{3}^{2+} & K & =1.5 \times 10^{12} \\
\mathrm{Co}^{3+}+3 \mathrm{en} \longrightarrow \mathrm{Co}(\mathrm{en})_{3}{ }^{3+} & K & =2.0 \times 10^{47}
\end{aligned}
\]
where en \(=\) ethylenediamine.
a. Calculate \(\mathscr{E}^{\circ}\) for the half-reaction
\[
\mathrm{Co}(\mathrm{en})_{3}{ }^{3+}+\mathrm{e}^{-} \longrightarrow \mathrm{Co}(\mathrm{en})_{3}{ }^{2+}
\]
b. Based on your answer to part a, which is the stronger oxidizing agent, \(\mathrm{Co}^{3+}\) or \(\mathrm{Co}(\mathrm{en})_{3}{ }^{3+}\) ?
c. Use the crystal field model to rationalize the result in part b.
98. Henry Taube, 1983 Nobel Prize winner in chemistry, has studied the mechanisms of the oxidation-reduction reactions of transition metal complexes. In one experiment he and his students studied the following reaction:
\[
\begin{aligned}
\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}(a q) & +\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}^{2+}(a q) \\
& \mathrm{Cr}(\mathrm{III}) \text { complexes }+\mathrm{Co}(\mathrm{II}) \text { complexes }
\end{aligned}
\]

Chromium(III) and cobalt(III) complexes are substitutionally inert (no exchange of ligands) under conditions of the experiment. Chromium(II) and cobalt(II) complexes can exchange ligands very rapidly. One of the products of the reaction is \(\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{Cl}^{2+}\). Is this consistent with the reaction proceeding through formation of \(\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{Cr}-\mathrm{Cl}-\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5}\) as an intermediate? Explain.
99. Chelating ligands often form more stable complex ions than the corresponding monodentate ligands with the same donor atoms. For example,
\[
\begin{aligned}
\mathrm{Ni}^{2+}(a q)+6 \mathrm{NH}_{3}(a q) & \rightleftharpoons \mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}(a q) & & K=3.2 \times 10^{8} \\
\mathrm{Ni}^{2+}(a q)+3 \mathrm{en}(a q) & \rightleftharpoons \mathrm{Ni}(\mathrm{en})_{3}{ }^{2+}(a q) & & K=1.6 \times 10^{18} \\
\mathrm{Ni}^{2+}(a q)+\operatorname{penten}(a q) & \rightleftharpoons \mathrm{Ni}(\text { penten })^{2+}(a q) & & K=2.0 \times 10^{19}
\end{aligned}
\]
where en is ethylenediamine and penten is

This increased stability is called the chelate effect. Based on bond energies, would you expect the enthalpy changes for the above reactions to be very different? What is the order (from least favorable to most favorable) of the entropy changes for the above reactions? How do the values of the formation constants correlate with \(\Delta S^{\circ}\) ? How can this be used to explain the chelate effect?
100. Qualitatively draw the crystal field splitting of the \(d\) orbitals in a trigonal planar complex ion. (Let the \(z\) axis be perpendicular to the plane of the complex.)
101. Qualitatively draw the crystal field splitting for a trigonal bipyramidal complex ion. (Let the \(z\) axis be perpendicular to the trigonal plane.)
102. Sketch a \(d\)-orbital energy diagram for the following.
a. a linear complex ion with ligands on the \(x\) axis
b. a linear complex ion with ligands on the \(y\) axis
103. Sketch and explain the most likely crystal field diagram for the following complex ion:

Note: The \(\mathrm{CN}^{-}\)ligand produces a much stronger crystal field than \(\mathrm{NH}_{3}\). Assume the \(\mathrm{NH}_{3}\) ligands lie on the \(z\) axis.
104. Ethylenediaminetetraacetate (EDTA \({ }^{4-}\) ) is used as a complexing agent in chemical analysis with the structure shown in Fig. 21.7. Solutions of EDTA \({ }^{4-}\) are used to treat heavy metal poisoning by removing the heavy metal in the form of a soluble complex ion. The complex ion virtually prevents the heavy metal ions from reacting with biochemical systems. The reaction of EDTA \({ }^{4-}\) with \(\mathrm{Pb}^{2+}\) is
\[
\begin{aligned}
\mathrm{Pb}^{2+}(a q)+\operatorname{EDTA}^{4-}(a q) \rightleftharpoons \operatorname{PbEDTA}^{2-}(a q) & \\
& K=1.1 \times 10^{18}
\end{aligned}
\]

Consider a solution with 0.010 mol of \(\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}\) added to 1.0 L of an aqueous solution buffered at \(\mathrm{pH}=13.00\) and containing \(0.050 \mathrm{M} \mathrm{a}_{4} \mathrm{EDTA}\). Does \(\mathrm{Pb}(\mathrm{OH})_{2}\) precipitate from this solution? \(\left[K_{\text {sp }}\right.\) for \(\mathrm{Pb}(\mathrm{OH})_{2}=1.2 \times 10^{-15}\).]
105. Will 0.10 mol of AgBr completely dissolve in 1.0 L of \(3.0 \mathrm{M} \mathrm{H}_{3}\) ? The \(K_{\text {sp }}\) value for \(\operatorname{AgBr}(s)\) is \(5.0 \times 10^{-13}\), and the overall formation constant for the complex ion \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)is \(1.7 \times 10^{7}\), that is,
\(\mathrm{Ag}^{+}(a q)+2 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}(a q) \quad K=1.7 \times 10^{7}\)

\section*{Integrative Problems}

These problems require the integration of multiple concepts to find the solutions.
106. The ferrate ion, \(\mathrm{FeO}_{4}{ }^{2-}\), is such a powerful oxidizing agent that in acidic solution, aqueous ammonia is reduced to elemental nitrogen along with the formation of the iron(III) ion.
a. What is the oxidation state of iron in \(\mathrm{FeO}_{4}{ }^{2-}\), and what is the electron configuration of iron in this polyatomic ion?
b. If 25.0 mL of a \(0.243 \mathrm{M} \mathrm{FeO}_{4}{ }^{2-}\) solution is allowed to react with 55.0 mL of 1.45 M aqueous ammonia, what volume of nitrogen gas can form at \(25^{\circ} \mathrm{C}\) and 1.50 atm ?
107. Ammonia and potassium iodide solutions are added to an aqueous solution of \(\mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}\). A solid is isolated (compound A ), and the following data are collected:
i. When 0.105 g of compound A was strongly heated in excess \(\mathrm{O}_{2}, 0.0203 \mathrm{~g} \mathrm{CrO}_{3}\) was formed.
ii. In a second experiment it took 32.93 mL of 0.100 M HCl to titrate completely the \(\mathrm{NH}_{3}\) present in 0.341 g compound A .
iii. Compound A was found to contain \(73.53 \%\) iodine by mass.
iv. The freezing point of water was lowered by \(0.64^{\circ} \mathrm{C}\) when 0.601 g compound A was dissolved in \(10.00 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}\left(K_{\mathrm{f}}=\right.\) \(\left.1.86^{\circ} \mathrm{C} \cdot \mathrm{kg} / \mathrm{mol}\right)\).
What is the formula of the compound? What is the structure of the complex ion present? (Hints: \(\mathrm{Cr}^{3+}\) is expected to be sixcoordinate, with \(\mathrm{NH}_{3}\) and possibly \(\mathrm{I}^{-}\)as ligands. The \(\mathrm{I}^{-}\)ions will be the counterions if needed.)
108. a. In the absorption spectrum of the complex ion \(\mathrm{Cr}(\mathrm{NCS})_{6}{ }^{3-}\), there is a band corresponding to the absorption of a photon of light with an energy of \(1.75 \times 10^{4} \mathrm{~cm}^{-1}\). Given \(1 \mathrm{~cm}^{-1}=1.986 \times 10^{-23} \mathrm{~J}\), what is the wavelength of this photon?
b. The \(\mathrm{Cr}-\mathrm{N}-\mathrm{C}\) bond angle in \(\mathrm{Cr}(\mathrm{NCS})_{6}{ }^{3-}\) is predicted to be \(180^{\circ}\). What is the hybridization of the N atom in the \(\mathrm{NCS}^{-}\) ligand when a Lewis acid-base reaction occurs between \(\mathrm{Cr}^{3+}\) and \(\mathrm{NCS}^{-}\)that would give a \(180^{\circ} \mathrm{Cr}-\mathrm{N}-\mathrm{C}\) bond angle? \(\mathrm{Cr}(\mathrm{NCS})_{6}{ }^{3-}\) undergoes substitution by ethylenediamine (en) according to the equation
\[
\mathrm{Cr}(\mathrm{NCS})_{6}{ }^{3-}+2 \mathrm{en} \longrightarrow \mathrm{Cr}(\mathrm{NCS})_{2}(\mathrm{en})_{2}{ }^{+}+4 \mathrm{NCS}^{-}
\]

Does \(\mathrm{Cr}(\mathrm{NCS})_{2}(\mathrm{en})_{2}{ }^{+}\)exhibit geometric isomerism? Does \(\mathrm{Cr}(\mathrm{NCS})_{2}(\mathrm{en})_{2}{ }^{+}\)exhibit optical isomerism?

\section*{Marathon Problem}

This problem is designed to incorporate several concepts and techniques into one situation.
109. There are three salts that contain complex ions of chromium and have the molecular formula \(\mathrm{CrCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}\). Treating 0.27 g of the first salt with a strong dehydrating agent resulted in a
mass loss of 0.036 g . Treating 270 mg of the second salt with the same dehydrating agent resulted in a mass loss of 18 mg . The third salt did not lose any mass when treated with the same dehydrating agent. Addition of excess aqueous silver nitrate to \(100.0-\mathrm{mL}\) portions of 0.100 M solutions of each salt resulted in the formation of different masses of silver chloride; one solution yielded 1430 mg AgCl ; another, 2870 mg AgCl ; the third, 4300 mg AgCl . Two of the salts are green and one is violet.

Suggest probable structural formulas for these salts, defending your answer on the basis of the preceding observations. State which salt is most likely to be violet. Would a study of the magnetic properties of the salts be helpful in determining the structural formulas? Explain.

\(T\)wo Group 4A elements, carbon and silicon, form the basis of most natural substances. Silicon, with its great affinity for oxygen, forms chains and rings containing \(\mathrm{Si}-\mathrm{O}-\mathrm{Si}\) bridges to produce the silica and silicates that form the basis for most rocks, sands, and soils. What silicon is to the geological world, carbon is to the biological world. Carbon has the unusual ability of bonding strongly to itself to form long chains or rings of carbon atoms. In addition, carbon forms strong bonds to other nonmetals such as hydrogen, nitrogen, oxygen, sulfur, and the halogens. Because of these bonding properties, there are a myriad of carbon compounds; several million are now known, and the number continues to grow rapidly. Among these many compounds are the biomolecules, those responsible for maintaining and reproducing life.

The study of carbon-containing compounds and their properties is called organic chemistry. Although a few compounds involving carbon, such as its oxides and carbonates, are considered to be inorganic substances, the vast majority are organic compounds that typically contain chains or rings of carbon atoms.

Originally, the distinction between inorganic and organic substances was based on whether a compound was produced by living systems. For example, until the early nineteenth century it was believed that organic compounds had some sort of "life force" and could be synthesized only by living organisms. This view was dispelled in 1828 when the German chemist Friedrich Wöhler (1800-1882) prepared urea from the inorganic salt ammonium cyanate by simple heating:

Ammonium cyanate
Urea
Urea is a component of urine, so it is clearly an organic material; yet here was clear evidence that it could be produced in the laboratory as well as by living things.

Organic chemistry plays a vital role in our quest to understand living systems. Beyond that, the synthetic fibers, plastics, artificial sweeteners, and drugs that are such an accepted part of modern life are products of industrial organic chemistry. In addition, the energy on which we rely so heavily to power our civilization is based mostly on the organic materials found in coal and petroleum.

Because organic chemistry is such a vast subject, we can provide only a brief introduction to it in this book. We will begin with the simplest class of organic compounds, the hydrocarbons, and then show how most other organic compounds can be considered to be derivatives of hydrocarbons.

\section*{22.1}

\section*{Alkanes: Saturated Hydrocarbons}

As the name indicates, hydrocarbons are compounds composed of carbon and hydrogen. Those compounds whose carbon-carbon bonds are all single bonds are said to be saturated, because each carbon is bound to four atoms, the maximum number. Hydrocarbons containing carbon-carbon multiple bonds are described as being unsaturated, since the carbon atoms involved in a multiple bond can react with additional atoms, as shown by the addition of hydrogen to ethylene:

Note that each carbon in ethylene is bonded to three atoms (one carbon and two hydrogens) but that each can bond to one additional atom if one bond of the carbon-carbon double bond is broken.

FIGURE 22.1 The C-H bonds in methane.

FIGURE 22.2 (a) The Lewis structure of ethane \(\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)\). (b) The molecular structure of ethane represented by spacefilling and ball-and-stick models.

The simplest member of the saturated hydrocarbons, which are also called the alkanes, is methane \(\left(\mathrm{CH}_{4}\right)\). As discussed in Section 9.1, methane has a tetrahedral structure and can be described in terms of a carbon atom using an \(s p^{3}\) hybrid set of orbitals to bond to the four hydrogen atoms (Fig. 22.1). The next alkane, the one containing two carbon atoms, is ethane \(\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)\), as shown in Fig. 22.2. Each carbon in ethane is surrounded by four atoms and thus adopts a tetrahedral arrangement and \(s p^{3}\) hybridization, as predicted by the localized electron model.

The next two members of the series are propane \(\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)\) and butane \(\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)\), shown in Fig. 22.3. Again, each carbon is bonded to four atoms and is described as \(s p^{3}\) hybridized.

Alkanes in which the carbon atoms form long "strings" or chains are called normal, straight-chain, or unbranched hydrocarbons. As can be seen from Fig. 22.3, the chains in normal alkanes are not really straight but zigzag, since the tetrahedral \(\mathrm{C}-\mathrm{C}-\mathrm{C}\) angle is \(109.5^{\circ}\). The normal alkanes can be represented by the structure

where \(n\) is an integer. Note that each member is obtained from the previous one by inserting a methylene \(\left(\mathrm{CH}_{2}\right)\) group. We can condense the structural formulas by omitting some of the \(\mathrm{C}-\mathrm{H}\) bonds. For example, the general formula for normal alkanes shown above can be condensed to
\[
\mathrm{CH}_{3}-\left(\mathrm{CH}_{2}\right)_{n} \mathrm{CH}_{3}
\]

The first ten normal alkanes and some of their properties are listed in Table 22.1. Note that all alkanes can be represented by the general formula \(\mathrm{C}_{n} \mathrm{H}_{2 n+2}\). For example,

FIGURE 22.3 The structures of (a) propane \(\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}\right)\) and (b) butane \(\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\right)\). Each angle shown in red is \(109.5^{\circ}\).

-b
nonane, which has nine carbon atoms, is represented by \(\mathrm{C}_{9} \mathrm{H}_{(2 \times 9)+2}\), or \(\mathrm{C}_{9} \mathrm{H}_{20}\). Also note from Table 22.1 that the melting points and boiling points increase as the molar masses increase, as we would expect.

\section*{Isomerism in Alkanes}

Butane and all succeeding members of the alkanes exhibit structural isomerism. Recall from Section 21.4 that structural isomerism occurs when two molecules have the same atoms but different bonds. For example, butane can exist as a straight-chain molecule (normal butane, or \(n\)-butane) or with a branched-chain structure (called isobutane), as shown in Fig. 22.4. Because of their different structures, these molecules exhibit different properties. For example, the boiling point of \(n\)-butane is \(-0.5^{\circ} \mathrm{C}\), whereas that of isobutane is \(-12^{\circ} \mathrm{C}\).

\section*{EXAMPLE 22.1 Structural Isomerism}

Draw the isomers of pentane.

\section*{SOLUTION Pentane \(\left(\mathrm{C}_{5} \mathrm{H}_{12}\right)\) has the following isomeric structures:}
1.

\(\mathrm{CH}_{3}-\mathrm{CH}_{2}-\underset{\text { n-Pentane }}{\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{CH}_{3}}\)
2.

3.

Note that the structures

which might appear to be other isomers, are actually identical to structure 2 .

See Exercise 22. 15

\section*{Nomenclature}

Because there are literally millions of organic compounds, it would be impossible to remember common names for all of them. We must have a systematic method for naming them. The following rules are used in naming alkanes.

\section*{Rules for Naming Alkanes}
1. The names of the alkanes beyond butane are obtained by adding the suffix -ane to the Greek root for the number of carbon atoms (pent-for five, hex- for six, and so on). For a branched hydrocarbon, the longest continuous chain of carbon atoms determines the root name for the hydrocarbon. For example, in the alkane

the longest chain contains six carbon atoms, and this compound is named as a hexane.
2. When alkane groups appear as substituents, they are named by dropping the -ane and adding -yl. For example, \(-\mathrm{CH}_{3}\) is obtained by removing a hydrogen from methane and is called methyl, \(-\mathrm{C}_{2} \mathrm{H}_{5}\) is called ethyl, \(-\mathrm{C}_{3} \mathrm{H}_{7}\) is called propyl, and so on. The compound above is therefore an ethylhexane (Table 22.2).
3. The positions of substituent groups are specified by numbering the longest chain of carbon atoms sequentially, starting at the end closest to the branching. For example, the compound

is called 3-methylhexane. Note that the top set of numbers is correct since the left end of the molecule is closest to the branching, and this gives the smallest number for the position of the substituent. Also, note that a hyphen is written between the number and the substituent name.
4. The location and name of each substituent are followed by the root alkane name. The substituents are listed in alphabetical order, and the prefixes di-, tri-, and so on, are used to indicate multiple, identical substituents.
*The bond with one end open shows the point of attachment of the substituent to the carbon chain.
\(\dagger\) For the butyl groups, sec-indicates attachment to the chain through a secondary carbon, a carbon atom attached to two other carbon atoms. The designation tert- signifies attachment through a tertiary carbon, a carbon attached to three other carbon atoms.
tert-Butyl

tert-Butyl
TABLE 22.2| The Most Common Alkyl Substituents and Their Names
\begin{tabular}{|c|c|}
\hline Structure* & Name \({ }^{\text { }}\) \\
\hline \(-\mathrm{CH}_{3}\) & Methyl \\
\hline \(-\mathrm{CH}_{2} \mathrm{CH}_{3}\) & Ethyl \\
\hline \(-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\) & Propyl \\
\hline \[
\stackrel{\mid}{\mathrm{CH}_{3} \mathrm{CHCH}_{3}}
\] & Isopropyl \\
\hline \(-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\) & Butyl \\
\hline \[
\stackrel{\mid}{\mathrm{CH}_{3} \mathrm{CHCH}_{2} \mathrm{CH}_{3}}
\] & sec-Butyl \\
\hline  & Isobutyl \\
\hline  & tert-Butyl \\
\hline
\end{tabular}

\section*{EXAMPLE 22.2 Isomerism and Nomenclature}

Draw the structural isomers for the alkane \(\mathrm{C}_{6} \mathrm{H}_{14}\) and give the systematic name for each one.

SOLUTION We will proceed systematically, starting with the longest chain and then rearranging the carbons to form the shorter, branched chains.

\section*{1. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\) \\ Hexane}

Note that although a structure such as

may look different it is still hexane, since the longest carbon chain has six atoms.
2. We now take one carbon out of the chain and make it a methyl substituent.

Since the longest chain consists of five carbons, this is a substituted pentane: 2-methylpentane. The 2 indicates the position of the methyl group on the chain. Note that if we numbered the chain from the right end, the methyl group would be on carbon 4. Because we want the smallest possible number, the numbering shown is correct.
3. The methyl substituent can also be on carbon 3 to give

Note that we have now exhausted all possibilities for placing a single methyl group on pentane.
4. Next, we can take two carbons out of the original six-member chain:

\section*{2,3-Dimethylbutane}

Since the longest chain now has four carbons, the root name is butane. Since there are two methyl groups, we use the prefix \(d i\). The numbers denote that the two methyl groups are positioned on the second and third carbons in the butane chain. Note that when two or more numbers are used, they are separated by a comma.
5. The two methyl groups can also be attached to the same carbon atom as shown here:

2,2-Dimethylbutane

We might also try ethyl-substituted butanes, such as

However, note that this is instead a pentane (3-methylpentane), since the longest chain has five carbon atoms. Thus it is not a new isomer. Trying to reduce the chain to three atoms provides no further isomers either. For example, the structure

is actually 2,2-dimethylbutane.
Thus there are only five distinct structural isomers of \(\mathrm{C}_{6} \mathrm{H}_{14}\) : hexane, 2-methylpentane, 3-methylpentane, 2,3-dimethylbutane, and 2,2-dimethylbutane.

\section*{INTERACTIVE EXAMPLE 2.3.3 Structures from Names}

Determine the structure for each of the following compounds.
a. 4-ethyl-3,5-dimethylnonane
b. 4-tert-butylheptane

SOLUTION a. The root name nonane signifies a nine-carbon chain. Thus we have

b. Heptane signifies a seven-carbon chain, and the tert-butyl group is

Thus we have

The \(h v\) above the arrow represents ultraviolet light.

\section*{Reactions of Alkanes}

Because they are saturated compounds and because the \(\mathrm{C}-\mathrm{C}\) and \(\mathrm{C}-\mathrm{H}\) bonds are relatively strong, the alkanes are fairly unreactive. For example, at \(25^{\circ} \mathrm{C}\) they do not react with acids, bases, or strong oxidizing agents. This chemical inertness makes them valuable as lubricating materials and as the backbone for structural materials such as plastics.

At a sufficiently high temperature alkanes do react vigorously and exothermically with oxygen, and these combustion reactions are the basis for their widespread use as fuels. For example, the reaction of butane with oxygen is
\[
2 \mathrm{C}_{4} \mathrm{H}_{10}(g)+13 \mathrm{O}_{2}(g) \longrightarrow 8 \mathrm{CO}_{2}(g)+10 \mathrm{H}_{2} \mathrm{O}(g)
\]

The alkanes can also undergo substitution reactions, primarily where halogen atoms replace hydrogen atoms. For example, methane can be successively chlorinated as follows:

Note that the products of the last two reactions have two names; the systematic name is given first, followed by the common name in parentheses. (This format will be used throughout this chapter for compounds that have common names.) Also, note that ultraviolet light \((h v)\) furnishes the energy to break the \(\mathrm{Cl}-\mathrm{Cl}\) bond to produce chlorine atoms:
\[
\mathrm{Cl}_{2} \longrightarrow \mathrm{Cl} \cdot+\mathrm{Cl} \cdot
\]

A chlorine atom has an unpaired electron, as indicated by the dot, which makes it very reactive and able to attack the \(\mathrm{C}-\mathrm{H}\) bond.

Substituted methanes with the general formula \(\mathrm{CF}_{x} \mathrm{Cl}_{4-x}\) containing both chlorine and fluorine as substituents are called chlorofluorocarbons (CFCs) and are also known as Freons. These substances are very unreactive and have been extensively used as coolant fluids in refrigerators and air conditioners. Unfortunately, their chemical inertness allows Freons to remain in the atmosphere so long that they eventually reach altitudes where they are a threat to the protective ozone layer (see Section 12.8), and the use of these compounds is being rapidly phased out.

FIGURE 22.5 (a) The molecular structure of cyclopropane \(\left(\mathrm{C}_{3} \mathrm{H}_{6}\right)\).
(b) The overlap of the \(s p^{3}\) orbitals that form the \(\mathrm{C}-\mathrm{C}\) bonds in cyclopropane.

FIGURE 22.6 The (a) chair and (b) boat forms of cyclohexane.

Alkanes can also undergo dehydrogenation reactions in which hydrogen atoms are removed and the product is an unsaturated hydrocarbon. For example, in the presence of chromium(III) oxide at high temperatures, ethane can be dehydrogenated, yielding ethylene:

\section*{Cyclic Alkanes}

Besides forming chains, carbon atoms also form rings. The simplest of the cyclic alkanes (general formula \(\mathrm{C}_{n} \mathrm{H}_{2 n}\) ) is cyclopropane \(\left(\mathrm{C}_{3} \mathrm{H}_{6}\right)\), shown in Fig. 22.5(a). Since the carbon atoms in cyclopropane form an equilateral triangle with \(60^{\circ}\) bond angles, their \(s p^{3}\) hybrid orbitals do not overlap head-on as in normal alkanes [Fig. 22.5(b)]. This results in unusually weak, or strained, \(\mathrm{C}-\mathrm{C}\) bonds; thus the cyclopropane molecule is much more reactive than straight-chain propane. The carbon atoms in cyclobutane \(\left(\mathrm{C}_{4} \mathrm{H}_{8}\right)\) form a square with \(88^{\circ}\) bond angles, and cyclobutane is also quite reactive.

The next two members of the series, cyclopentane \(\left(\mathrm{C}_{5} \mathrm{H}_{10}\right)\) and cyclohexane \(\left(\mathrm{C}_{6} \mathrm{H}_{12}\right)\), are quite stable, because their rings have bond angles very close to the tetrahedral angles, which allows the \(s p^{3}\) hybrid orbitals on adjacent carbon atoms to overlap headon and form normal \(\mathrm{C}-\mathrm{C}\) bonds, which are quite strong. To attain the tetrahedral angles, the cyclohexane ring must "pucker"-that is, become nonplanar. Cyclohexane can exist in two forms, the chair and the boat forms, as shown in Fig. 22.6. The two hydrogen atoms above the ring in the boat form are quite close to each other, and the resulting repulsion between these atoms causes the chair form to be preferred. At \(25^{\circ} \mathrm{C}\) more than \(99 \%\) of cyclohexane exists in the chair form.

For simplicity, the cyclic alkanes are often represented by the following structures:

Thus the structure \(\mathrm{CH}_{3}\) represents methylcyclopropane.

The nomenclature for cycloalkanes follows the same rules as for the other alkanes except that the root name is preceded by the prefix cyclo-. The ring is numbered to yield the smallest substituent numbers possible.

\section*{INTERACTIVE EXAMPLE 22.4 Naming Cyclic Alkanes}

Name each of the following cyclic alkanes.
a.

b.

\section*{SOLUTION}
a. The six-carbon cyclohexane ring is numbered as follows:

There is an isopropyl group at carbon 1 and a methyl group at carbon 3. The name is 1-isopropyl-3-methylcyclohexane, since the alkyl groups are named in alphabetical order.
b. This is a cyclobutane ring, which is numbered as follows:

The name is 1-ethyl-2-propylcyclobutane.

\subsection*{22.2 Alkenes and Alkynes}

Multiple carbon-carbon bonds result when hydrogen atoms are removed from alkanes. Hydrocarbons that contain at least one carbon-carbon double bond are called alkenes and have the general formula \(\mathrm{C}_{n} \mathrm{H}_{2 n}\). The simplest alkene \(\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)\), commonly known as ethylene, has the Lewis structure

As discussed in Section 9.1, each carbon in ethylene can be described as \(s p^{2}\) hybridized. The \(\mathrm{C}-\mathrm{C} \sigma\) bond is formed by sharing an electron pair between \(s p^{2}\) orbitals, and the \(\pi\) bond is formed by sharing a pair of electrons between \(p\) orbitals (Fig. 22.7).

The systematic nomenclature for alkenes is quite similar to that for alkanes.
1. The root hydrocarbon name ends in -ene rather than -ane. Thus the systematic name for \(\mathrm{C}_{2} \mathrm{H}_{4}\) is ethene and the name for \(\mathrm{C}_{3} \mathrm{H}_{6}\) is propene.
2. In alkenes containing more than three carbon atoms, the location of the double bond is indicated by the lowest-numbered carbon atom involved in the bond. Thus \(\mathrm{CH}_{2}=\mathrm{CHCH}_{2} \mathrm{CH}_{3}\) is called 1-butene, and \(\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CHCH}_{3}\) is called 2-butene.

FIGURE 22.7 The bonding in ethylene.

-a
-b

FIGURE 22.9 The two stereoisomers of 2-butene: (a) cis-2-butene and (b) trans-2-butene.

For cyclic alkenes, number through the double bond toward the substituent.

FIGURE 22.8 The bonding in ethane.

FIGURE 22.10 The bonding in acetylene.

Note from Fig. 22.7 that the \(p\) orbitals on the two carbon atoms in ethylene must be lined up (parallel) to allow formation of the \(\pi\) bond. This prevents rotation of the two \(\mathrm{CH}_{2}\) groups relative to each other at ordinary temperatures, in contrast to alkanes, where free rotation is possible (Fig. 22.8). The restricted rotation around doubly bonded carbon atoms means that alkenes exhibit cis-trans isomerism. For example, there are two stereoisomers of 2-butene (Fig. 22.9). Identical substituents on the same side of the double bond are designated cis and those on opposite sides are labeled trans.

Alkynes are unsaturated hydrocarbons containing at least one triple carbon-carbon bond. The simplest alkyne is \(\mathrm{C}_{2} \mathrm{H}_{2}\) (commonly called acetylene), which has the systematic name ethyne. As discussed in Section 9.1, the triple bond in acetylene can be described as one \(\sigma\) bond between two \(s p\) hybrid orbitals on the two carbon atoms and two \(\pi\) bonds involving two \(2 p\) orbitals on each carbon atom (Fig. 22.10).

The nomenclature for alkynes involves the use of -yne as a suffix to replace the -ane of the parent alkane. Thus the molecule \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{C} \equiv \mathrm{CCH}_{3}\) has the name 2-pentyne.

Like alkanes, unsaturated hydrocarbons can exist as ringed structures, for example,

\section*{INTERACTIVE EXAMPLE 22.5 Naming Alkenes and Alkynes}

Name each of the following molecules.
a.

b.

SOLUTION

A
A worker using an oxyacetylene torch.
a. The longest chain, which contains six carbon atoms, is numbered as follows:

Thus the hydrocarbon is a 2-hexene. Since the hydrogen atoms are located on opposite sides of the double bond, this molecule corresponds to the trans isomer. The name is trans-4-methyl-2-hexene.
b. The longest chain, consisting of seven carbon atoms, is numbered as shown (giving the triple bond the lowest possible number):

The hydrocarbon is a 3-heptyne. The full name is 5-ethyl-3-heptyne, where the position of the triple bond is indicated by the lower-numbered carbon atom involved in this bond.

See Exercises 22.27, 22.28, and 22.46

\section*{Reactions of Alkenes and Alkynes}

Because alkenes and alkynes are unsaturated, their most important reactions are addition reactions. In these reactions \(\pi\) bonds, which are weaker than the \(\mathrm{C}-\mathrm{C} \sigma\) bonds, are broken, and new \(\sigma\) bonds are formed to the atoms being added. For example, hydrogenation reactions involve the addition of hydrogen atoms:
\[
\underset{\text { 1-Propene }}{\mathrm{CH}_{2}} \mathrm{CHCH}_{3}+\mathrm{H}_{2} \xrightarrow[\text { Propane }]{\text { Catalyst }} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}
\]

For this reaction to proceed rapidly at normal temperatures, a catalyst of platinum, palladium, or nickel is used. The catalyst serves to help break the relatively strong \(\mathrm{H}-\mathrm{H}\) bond, as was discussed in Section 12.7. Hydrogenation of alkenes is an important industrial process, particularly in the manufacture of solid shortenings where unsaturated fats (fats containing double bonds), which are generally liquid, are converted to solid saturated fats.

\subsection*{22.3 Aromatic Hydrocarbons}

a

\section*{-}

FIGURE 22.11 (a) The structure of benzene, a planar ring system in which all bond angles are \(120^{\circ}\). (b) Two of the resonance structures of benzene. (c) The usual representation of benzene. The circle represents the electrons in the delocalized \(\pi\) system. All C-C bonds in benzene are equivalent.

Halogenation of unsaturated hydrocarbons involves addition of halogen atoms. For example,

Another important reaction involving certain unsaturated hydrocarbons is polymerization, a process in which many small molecules are joined together to form a large molecule. Polymerization will be discussed in Section 22.5.

A special class of cyclic unsaturated hydrocarbons is known as the aromatic hydrocarbons. The simplest of these is benzene \(\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)\), which has a planar ring structure, as shown in Fig. 22.11(a). In the localized electron model of the bonding in benzene, resonance structures of the type shown in Fig. 22.11(b) are used to account for the known equivalence of all the carbon-carbon bonds. But as we discussed in Section 9.5, the best description of the benzene molecule assumes that \(s p^{2}\) hybrid orbitals on each carbon are used to form the \(\mathrm{C}-\mathrm{C}\) and \(\mathrm{C}-\mathrm{H} \sigma\) bonds, while the remaining \(2 p\) orbital on each carbon is used to form \(\pi\) molecular orbitals. The delocalization of these \(\pi\) electrons is usually indicated by a circle inside the ring [Fig. 22.11(c)].

The delocalization of the \(\pi\) electrons makes the benzene ring behave quite differently from a typical unsaturated hydrocarbon. As we have seen previously, unsaturated hydrocarbons generally undergo rapid addition reactions. However, benzene does not. Instead, it undergoes substitution reactions in which hydrogen atoms are replaced by other atoms. For example,

Nitrobenzene

Toluene

In each case the substance shown over the arrow is needed to catalyze these substitution reactions.

Substitution reactions are characteristic of saturated hydrocarbons, and addition reactions are characteristic of unsaturated ones. The fact that benzene reacts more like a saturated hydrocarbon indicates the great stability of the delocalized \(\pi\) electron system.

1,2-Dibromobenzene (o-dibromobenzene)

3-Bromonitrobenzene ( \(m\)-bromonitrobenzene)

1,3-Dibromobenzene ( \(m\)-dibromobenzene)

3-Chlorotoluene ( \(m\)-chlorotoluene)

1,4-Dibromobenzene (p-dibromobenzene)

Phenyl group

Methylbenzene (toluene)

4-Chloro-2-phenylhexane

FIGURE 22.12 Some selected substituted benzenes and their names. Common names are given in parentheses.

The nomenclature of benzene derivatives is similar to the nomenclature for saturated ring systems. If there is more than one substituent present, numbers are used to indicate substituent positions. For example, the compound

is named 1,2-dichlorobenzene. Another nomenclature system uses the prefix ortho( \(o\)-) for two adjacent substituents, meta- ( \(m-\) ) for two substituents with one carbon between them, and para- ( \(p\)-) for two substituents opposite each other. When benzene is used as a substituent, it is called the phenyl group. Examples of some aromatic compounds are shown in Fig. 22.12.

Benzene is the simplest aromatic molecule. More complex aromatic systems can be viewed as consisting of a number of "fused" benzene rings. Some examples are given in Table 22.3.

TABLE 22.3 | More Complex Aromatic Systems

\subsection*{22.4 Hydrocarbon Derivatives}

The vast majority of organic molecules contain elements in addition to carbon and hydrogen. However, most of these substances can be viewed as hydrocarbon derivatives, molecules that are fundamentally hydrocarbons but that have additional atoms or groups of atoms called functional groups. The common functional groups are listed in Table 22.4. Because each functional group exhibits characteristic chemistry, we will consider the groups separately.

\section*{Alcohols}

A
Compounds containing aromatic rings are often used in dyes, such as these for sale in a market in Nepal.

Alcohols are characterized by the presence of the hydroxyl group ( -OH ). Some common alcohols are listed in Table 22.5. The systematic name for an alcohol is obtained by replacing the final \(-e\) of the parent hydrocarbon with -ol. The position of the -OH group is specified by a number (where necessary) chosen so that it is the smallest of the substituent numbers. Alcohols are classified according to the number of hydrocarbon fragments bonded to the carbon where the - OH group is attached (see below), where \(R, R^{\prime}\), and \(R^{\prime \prime}\) (which may be the same or different) represent hydrocarbon fragments.
\begin{tabular}{|c|c|c|c|}

TABLE 22.5 | Some Common Alcohols
\begin{tabular}{lll} 
Formula & Systematic Name & Common Name \\
\hline \(\mathrm{CH}_{3} \mathrm{OH}\) & Methanol & Methyl alcohol \\
\hline \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\) & Ethanol & Ethyl alcohol \\
\hline \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\) & 1-Propanol & \(n\)-Propyl alcohol \\
\hline \(\mathrm{CH}_{3} \mathrm{CHCH}_{3}\) & 2-Propanol & Isopropyl alcohol \\
OH & & \\
\hline
\end{tabular}

Alcohols usually have much higher boiling points than might be expected from their molar masses. For example, both methanol and ethane have a molar mass of 30, but the boiling point for methanol is \(65^{\circ} \mathrm{C}\) while that for ethane is \(-89^{\circ} \mathrm{C}\). This difference can be understood if we consider the types of intermolecular attractions that occur in these liquids. Ethane molecules are nonpolar and exhibit only weak London dispersion interactions. However, the polar - OH group of methanol produces extensive hydrogen bonding similar to that found in water (see Section 10.1), which results in the relatively high boiling point.

Although there are many important alcohols, the simplest ones, methanol and ethanol, have the greatest commercial value. Methanol, also known as wood alcohol because it was formerly obtained by heating wood in the absence of air, is prepared industrially (approximately 4 million tons annually in the United States) by the hydrogenation of carbon monoxide:
\[
\mathrm{CO}+2 \mathrm{H}_{2} \xrightarrow[\mathrm{ZnO} / \mathrm{Cr}_{2} \mathrm{O}_{3}]{400^{\circ}} \mathrm{CH}_{3} \mathrm{OH}
\]

Methanol is used as a starting material for the synthesis of acetic acid and for many types of adhesives, fibers, and plastics. It is also used (and such use may increase) as a motor fuel. Methanol is highly toxic to humans and can lead to blindness and death if ingested.

Ethanol is the alcohol found in beverages such as beer, wine, and whiskey; it is produced by the fermentation of glucose in corn, barley, grapes, and so on:
\[
\underset{\text { Glucose }}{\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}} \xrightarrow{\text { Yeast }} \underset{\text { Ethanol }}{2 \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}}+2 \mathrm{CO}_{2}
\]

The reaction is catalyzed by the enzymes found in yeast. This reaction can proceed only until the alcohol content reaches about \(13 \%\) (the percentage found in most wines), at which point the yeast can no longer survive. Beverages with higher alcohol content are made by distilling the fermentation mixture.

Ethanol, like methanol, can be burned in the internal combustion engines of automobiles and is now commonly added to gasoline to form gasohol (see Section 6.6). It is also used in industry as a solvent and for the preparation of acetic acid. One common method for the production of ethanol in the chemical industry is by reaction of water with ethylene:
\[
\mathrm{CH}_{2}=\mathrm{CH}_{2}+\mathrm{H}_{2} \mathrm{O} \xrightarrow[\text { Catalyst }]{\text { Acid }} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}
\]

Many polyhydroxyl (more than one - OH group) alcohols are known, the most important being 1,2-ethanediol (ethylene glycol),

a toxic substance that is the major constituent of most automobile antifreeze solutions.

The simplest aromatic compound with an attached -OH group is

which is commonly called phenol. While this compound looks like an alcohol, its properties are very different from alcohols. Most of the 1 million tons of phenol produced annually in the United States is used to make polymers for adhesives and plastics.

\section*{INTERACTIVE EXAMPLE 22.6}

\section*{Naming and Classifying Alcohols}

For each of the following alcohols, give the systematic name and specify whether the alcohol is primary, secondary, or tertiary.
a.

b. \(\mathrm{ClCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\)
c.

\section*{SOLUTION}
a. The chain is numbered as follows:

The compound is called 2-butanol, since the - OH group is located at the number 2 position of a four-carbon chain. Note that the carbon to which the - OH is attached also has \(-\mathrm{CH}_{3}\) and \(-\mathrm{CH}_{2} \mathrm{CH}_{3}\) groups attached:

Therefore, this is a secondary alcohol.
b. The chain is numbered as follows:

The name is 3-chloro-1-propanol. This is a primary alcohol:

One R group attached to the carbon with the -OH group
c. The chain is numbered as follows:

The name is 6-bromo-2-methyl-2-hexanol. This is a tertiary alcohol since the carbon where the -OH is attached also has three other R groups attached.

\section*{Aldehydes and Ketones}

\(\Delta\)
Cinnamaldehyde produces the characteristic odor of cinnamon.

Aldehydes and ketones contain the carbonyl group,

In ketones this group is bonded to two carbon atoms, as in acetone,

In aldehydes the carbonyl group is bonded to at least one hydrogen atom, as in formaldehyde,

or acetaldehyde,

The systematic name for an aldehyde is obtained from the parent alkane by removing the final \(-e\) and adding -al. For ketones the final \(-e\) is replaced by -one, and a number indicates the position of the carbonyl group where necessary. Examples of common aldehydes and ketones are shown in Fig. 22.13. Note that since the aldehyde functional group always occurs at the end of the carbon chain, the aldehyde carbon is assigned the number 1 when substituent positions are listed in the name.

Vanillin

Cinnamaldehyde

Butyraldehyde

FIGURE 22.13 Some common ketones and aldehydes. Note that since the aldehyde functional group always appears at the end of a carbon chain, the aldehyde carbon is assigned the number 1 when the compound is named.
\(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{COOH}\)
Butanoic acid

Benzoic acid

4-Bromopentanoic acid

Trichloroethanoic acid (trichloroacetic acid)

FIGURE 22.14
Some carboxylic acids.

Ketones often have useful solvent properties (acetone is found in nail polish remover, for example) and are frequently used in industry for this purpose. Aldehydes typically have strong odors. Vanillin is responsible for the pleasant odor in vanilla beans; cinnamaldehyde produces the characteristic odor of cinnamon. On the other hand, the unpleasant odor in rancid butter arises from the presence of butyraldehyde.

Aldehydes and ketones are most often produced commercially by the oxidation of alcohols. For example, oxidation of a primary alcohol yields the corresponding aldehyde:

Oxidation of a secondary alcohol results in a ketone:

\section*{Carboxylic Acids and Esters}

Carboxylic acids are characterized by the presence of the carboxyl group

that gives an acid of the general formula RCOOH. Typically, these molecules are weak acids in aqueous solution (see Section 14.5). Organic acids are named from the parent alkane by dropping the final \(-e\) and adding -oic. Thus \(\mathrm{CH}_{3} \mathrm{COOH}\), commonly called acetic acid, has the systematic name ethanoic acid, since the parent alkane is ethane. Other examples of carboxylic acids are shown in Fig. 22.14.

Many carboxylic acids are synthesized by oxidizing primary alcohols with a strong oxidizing agent. For example, ethanol can be oxidized to acetic acid by using potassium permanganate:

A carboxylic acid reacts with an alcohol to form an ester and a water molecule. For example, the reaction of acetic acid with ethanol produces ethyl acetate and water:

Esters often have a sweet, fruity odor that is in contrast to the often pungent odors of the parent carboxylic acids. For example, the odor of bananas is caused by \(n\)-amyl acetate,

and that of oranges is caused by \(n\)-octyl acetate,

The systematic name for an ester is formed by changing the -oic ending of the parent acid to -oate. The parent alcohol chain is named first with a \(-y l\) ending. For example, the systematic name for \(n\)-octyl acetate is \(n\)-octylethanoate (from ethanoic acid).

\(\Delta\)
Computer-generated space-filling model of acetylsalicylic acid (aspirin).

Primary amine

Secondary amine

Tertiary amine
FIGURE 22.15 The general formulas for primary, secondary, and tertiary amines. \(R, R^{\prime}\), and \(R^{\prime \prime}\) represent carbon-containing substituents.

A very important ester is formed from the reaction of salicylic acid and acetic acid:

The product is acetylsalicylic acid, commonly known as aspirin, which is used in huge quantities as an analgesic (painkiller).

\section*{Amines}

Amines are probably best viewed as derivatives of ammonia in which one or more \(\mathrm{N}-\mathrm{H}\) bonds are replaced by \(\mathrm{N}-\mathrm{C}\) bonds. The resulting amines are classified as primary if one \(\mathrm{N}-\mathrm{C}\) bond is present, secondary if two \(\mathrm{N}-\mathrm{C}\) bonds are present, and tertiary if all three \(\mathrm{N}-\mathrm{H}\) bonds in \(\mathrm{NH}_{3}\) have been replaced by \(\mathrm{N}-\mathrm{C}\) bonds (Fig. 22.15). Examples of some common amines are given in Table 22.6.

Common names are often used for simple amines; the systematic nomenclature for more complex molecules uses the name amino- for the \(-\mathrm{NH}_{2}\) functional group. For example, the molecule

is named 2-aminobutane.
Many amines have unpleasant "fishlike" odors. For example, the odors associated with decaying animal and human tissues are caused by amines such as putrescine \(\left(\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)\) and cadaverine \(\left(\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)\).

Aromatic amines are used primarily to make dyes. Since many of them are carcinogenic, they must be handled with great care.

TABLE 22.6 \| Some Common Amines

\subsection*{22.5 Polymers}

Polymers are large, usually chainlike molecules that are built from small molecules called monomers. Polymers form the basis for synthetic fibers, rubbers, and plastics and have played a leading role in the revolution that has been brought about in daily life by chemistry. It has been estimated that about \(50 \%\) of the industrial chemists in the United States work in some area of polymer chemistry, a fact that illustrates just how important polymers are to our economy and standard of living.

\section*{The Development and Properties of Polymers}

The development of the polymer industry provides a striking example of the importance of serendipity in the progress of science. Many discoveries in polymer chemistry arose from accidental observations that scientists followed up.

The age of plastics might be traced to a day in 1846 when Christian Schoenbein, a chemistry professor at the University of Basel in Switzerland, spilled a flask containing nitric and sulfuric acids. In his hurry to clean up the spill, he grabbed his wife's cotton apron, which he then rinsed out and hung up in front of a hot stove to dry. Instead of drying, the apron flared and burned.

Very interested in this event, Schoenbein repeated the reaction under more controlled conditions and found that the new material, which he correctly concluded to be nitrated cellulose, had some surprising properties. As he had experienced, the nitrated cellulose is extremely flammable and, under certain circumstances, highly explosive. In addition, he found that it could be molded at moderate temperatures to give objects that were, upon cooling, tough but elastic. Predictably, the explosive nature of the substance was initially of more interest than its other properties, and cellulose nitrate rapidly became the basis for smokeless gunpowder. Although Schoenbein's discovery cannot be described as a truly synthetic polymer (because he simply found a way to modify the natural polymer cellulose), it formed the basis for a large number of industries that grew up to produce photographic films, artificial fibers, and molded objects of all types.

The first synthetic polymers were produced as by-products of various organic reactions and were regarded as unwanted contaminants. Thus the first preparations of many of the polymers now regarded as essential to our modern lifestyle were thrown away in disgust. One chemist who refused to be defeated by the "tarry" products obtained when he reacted phenol with formaldehyde was the Belgian-American chemist Leo H. Baekeland (1863-1944). Baekeland's work resulted in the first completely synthetic plastic (called Bakelite), a substance that when molded to a certain shape under high pressure and temperature cannot be softened again or dissolved. Bakelite is a thermoset polymer. In contrast, cellulose nitrate is a thermoplastic polymer; that is, it can be remelted after it has been molded.

The discovery of Bakelite in 1907 spawned a large plastics industry, producing telephones, billiard balls, and insulators for electrical devices. During the early days of polymer chemistry, there was a great deal of controversy over the nature of these materials. Although the German chemist Hermann Staudinger speculated in 1920 that polymers were very large molecules held together by strong chemical bonds, most chemists of the time assumed that these materials were much like colloids, in which small molecules are aggregated into large units by forces weaker than chemical bonds.

One chemist who contributed greatly to the understanding of polymers as giant molecules was Wallace H. Carothers of the DuPont Chemical Company. Among his accomplishments was the preparation of nylon. The nylon story further illustrates the importance of serendipity in scientific research. When nylon is first prepared, the resulting product is a sticky material with little structural integrity. Because of this, it was initially put aside as having no apparently useful characteristics. However, Julian Hill, a chemist in the Carothers research group, one day put a small ball of this nylon

\section*{CHEMICAL CDNNECTIDNS}

\section*{Wallace Hume Carothers}

W/allace H. Carothers, a brilliant organic chemist who was principally responsible for the development of nylon and the first synthetic rubber (Neoprene), was born in 1896 in Burlington, lowa. As a youth, Carothers was fascinated by tools and mechanical devices and spent many hours experimenting. In 1915 he entered Tarkio College in Missouri. Carothers so excelled in chemistry that even before his graduation, he was made a chemistry instructor.

Carothers eventually moved to the University of Illinois at UrbanaChampaign, where he was appointed to the faculty when he completed his Ph.D. in organic chemistry in 1924. He moved to Harvard University in 1926, and then to DuPont in 1928 to participate in a new program in
fundamental research. At DuPont, Carothers headed the organic chemistry division, and during his ten years there played a prominent role in laying the foundations of polymer chemistry.

By the age of 33 , Carothers had become a world-famous chemist whose advice was sought by almost everyone working in polymers. He was the first industrial chemist to be elected to the prestigious National Academy of Sciences.

Carothers was an avid reader of poetry and a lover of classical music. Unfortunately, he also suffered from severe bouts of depression that finally led to his suicide in 1937 in a Philadelphia hotel room, where he drank a cyanide solution. He was 41 years old. Despite the brevity of his career,

Wallace H. Carothers.

Carothers was truly one of the finest American chemists of all time. His great intellect, his love of chemistry, and his insistence on perfection produced his special genius.

A
Magnified nylon fibers.

\footnotetext{
Charles Goodyear tried for many years to change natural rubber into a useful product. In 1839 he accidentally dropped some rubber containing sulfur on a hot stove. Noting that the rubber did not melt as expected, Goodyear pursued this lead and developed vulcanization.
}
on the end of a stirring rod and drew it away from the remaining sticky mass, forming a string. He noticed the silky appearance and strength of this thread and realized that nylon could be drawn into useful fibers.

The reason for this behavior of nylon is now understood. When nylon is first formed, the individual polymer chains are oriented randomly, like cooked spaghetti, and the substance is highly amorphous. However, when drawn out into a thread, the chains tend to line up (the nylon becomes more crystalline), which leads to increased hydrogen bonding between adjacent chains. This increase in crystallinity, along with the resulting increase in hydrogen-bonding interactions, leads to strong fibers and thus to a highly useful material. Commercially, nylon is produced by forcing the raw material through a spinneret, a plate containing small holes, which forces the polymer chains to line up.

Another property that adds strength to polymers is crosslinking, the existence of covalent bonds between adjacent chains. The structure of Bakelite is highly crosslinked, which accounts for the strength and toughness of this polymer. Another example of crosslinking occurs in the manufacture of rubber. Raw natural rubber consists of chains of the type

and is a soft, sticky material unsuitable for tires. However, in 1839 Charles Goodyear (1800-1860), an American chemist, accidentally found that if sulfur is added to rubber

\section*{CHEMICAL CONNECTIONS}

\section*{Super-Slippery Slope}

O
ne of the most amazing characteristics of insects is their ability to cling to almost any surface, whether it is vertical or upside down. However, the walls of the Nepenthes pitcher plant are so slippery that any insect that lands on those walls slips to its death in the digestive juices at the bottom of the "pitcher." One can envision this type of slippery surface being useful in human activities, such as in pipes for handling biomedical fluids and fuels.

Slippery surfaces also could be useful in repelling ice inside freezers or on ship hulls used in polar regions.

Joanna Aizenberg and her colleagues at Harvard University have designed a synthetic system that mimics the slippery pitcher plant surface. Their omniphobic (repels virtually all liquids) surface, which they call SLIPS, is prepared from a porous network of Teflon nanofibers that is infused with a special oil-and-water fluid. It is the layer
of fluid on the surface of the Teflon "sponge" that makes SLIPS so slippery. Another advantage of SLIPS is its selfhealing property. If any damage occurs to the surface, more fluid flows from the interior to heal cracks or dents. The surface can be maintained indefinitely because a reservoir of fluid sustains the fluid.

SLIPS is a great example of how useful it can be to mimic nature's problem-solving skills.
and the resulting mixture is heated (a process called vulcanization), the resulting rubber is still elastic (reversibly stretchable) but is much stronger. This change in character occurs because sulfur atoms become bonded between carbon atoms on different chains. These sulfur atoms form bridges between the polymer chains, thus linking the chains together.

\section*{Types of Polymers}

The simplest and one of the best-known polymers is polyethylene, which is constructed from ethylene monomers:

where \(n\) represents a large number (usually several thousand). Polyethylene is a tough, flexible plastic used for piping, bottles, electrical insulation, packaging films, garbage bags, and many other purposes. Its properties can be varied by using substituted ethylene monomers. For example, when tetrafluoroethylene is the monomer, the polymer Teflon is obtained:

The discovery of Teflon, a very important substituted polyethylene, is another illustration of the role of chance in chemical research. In 1938 a DuPont chemist named Roy Plunkett was studying the chemistry of gaseous tetrafluoroethylene. He synthesized about 100 pounds of the chemical and stored it in steel cylinders. When one of the cylinders failed to produce tetrafluoroethylene gas when the valve was opened, the cylinder was cut open to reveal a white powder. This powder turned out to be a polymer of tetrafluoroethylene, which was eventually developed into Teflon. Because of the resistance of the strong \(\mathrm{C}-\mathrm{F}\) bonds to chemical attack, Teflon is an inert, tough, and nonflammable material widely used for electrical insulation, nonstick coatings on cooking utensils, and bearings for low-temperature applications.

TABLE 22.7 | Some Common Synthetic Polymers and Their Monomers and Applications
\begin{tabular}{|c|c|c|c|c|}
\hline \multicolumn{2}{|r|}{Monomer} & \multicolumn{3}{|c|}{Polymer} \\
\hline Name & Formula & Name & Formula & Uses \\
\hline Ethylene & \(\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2}\) & Polyethylene & \(-\left(\mathrm{CH}_{2}-\mathrm{CH}_{2}\right)_{n}\) & Plastic piping, bottles, electrical insulation, toys \\
\hline Propylene &  & Polypropylene &  & Film for packaging, carpets, lab wares, toys \\
\hline Vinyl chloride &  & Polyvinyl chloride (PVC) &  & Piping, siding, floor tile, clothing, toys \\
\hline Acrylonitrile &  & Polyacrylonitrile (PAN) &  & Carpets, fabrics \\
\hline Tetrafluoroethylene & \(\mathrm{F}_{2} \mathrm{C}=\mathrm{CF}_{2}\) & Teflon & \(-\left(\mathrm{CF}_{2}-\mathrm{CF}_{2}\right)_{n}\) & Cooking utensils, electrical insulation, bearings \\
\hline Styrene &  & Polystyrene &  & Containers, thermal insulation, toys \\
\hline Butadiene &  & Polybutadiene & \(-\left(\mathrm{CH}_{2} \mathrm{CH}=\mathrm{CHCH}_{2}\right)_{n}\) & Tire tread, coating resin \\
\hline Butadiene and styrene & (See above.) & Styrenebutadiene rubber &  & Synthetic rubber \\
\hline
\end{tabular}

Other polyethylene-type polymers are made from monomers containing chloro, methyl, cyano, and phenyl substituents, as summarized in Table 22.7. In each case the double carbon-carbon bond in the substituted ethylene monomer becomes a single bond in the polymer. The different substituents lead to a wide variety of properties.

The polyethylene polymers illustrate one of the major types of polymerization reactions, called addition polymerization, in which the monomers simply "add together" to produce the polymer. No other products are formed. The polymerization process is initiated by a free radical (a species with an unpaired electron) such as the hydroxyl radical (HO \(\cdot\) ). The free radical attacks and breaks the \(\pi\) bond of an ethylene molecule to form a new free radical,

FIGURE 22.16 The reaction to form nylon can be carried out at the interface of two immiscible liquid layers in a beaker. The bottom layer contains adipoyl chloride,

dissolved in \(\mathrm{CCl}_{4}\), and the top layer contains hexamethylenediamine,
\[
\mathrm{H}_{2} \mathrm{~N}-\left(\mathrm{CH}_{2}\right)_{6} \mathrm{NH}_{2}
\]
dissolved in water. A molecule of HCl is formed as each \(\mathrm{C}-\mathrm{N}\) bond forms.
which is then available to attack another ethylene molecule:

Repetition of this process thousands of times creates a long-chain polymer. Termination of the growth of the chain occurs when two radicals react to form a bond, a process that consumes two radicals without producing any others.

Another common type of polymerization is condensation polymerization, in which a small molecule, such as water, is formed for each extension of the polymer chain. The most familiar polymer produced by condensation is nylon. Nylon is a copolymer, since two different types of monomers combine to form the chain; a homopolymer is the result of polymerizing a single type of monomer. One common form of nylon is produced when hexamethylenediamine and adipic acid react by splitting out a water molecule to form a \(\mathrm{C}-\mathrm{N}\) bond:

Hexamethylenediamine
Adipic acid

The molecule formed, called a dimer (two monomers joined), can undergo further condensation reactions since it has an amino group at one end and a carboxyl group at the other. Thus both ends are free to react with another monomer. Repetition of this process leads to a long chain of the type

which is the basic structure of nylon. The reaction to form nylon occurs quite readily and is often used as a lecture demonstration (Fig. 22.16). The properties of nylon can be varied by changing the number of carbon atoms in the chain of the acid or amine monomer.

More than 1 million tons of nylon is produced annually in the United States for use in clothing, carpets, rope, and so on. Many other types of condensation polymers are also produced. For example, Dacron is a copolymer formed from the condensation reaction of ethylene glycol (a dialcohol) and p-terephthalic acid (a dicarboxylic acid):

psi is the abbreviation for pounds per square inch: \(15 \mathrm{psi} \approx 1 \mathrm{~atm}\).

Molecular weight (not molar mass) is the common terminology in the polymer industry.

The repeating unit of Dacron is

Note that this polymerization involves a carboxylic acid and an alcohol forming an ester group:

Thus Dacron is called a polyester. By itself or blended with cotton, Dacron is widely used in fibers for the manufacture of clothing.

\section*{Polymers Based on Ethylene}

A large section of the polymer industry involves the production of macromolecules from ethylene or substituted ethylenes. As discussed previously, ethylene molecules polymerize by addition after the double bond has been broken by some initiator:

This process continues by adding new ethylene molecules to eventually give polyethylene, a thermoplastic material.

There are two forms of polyethylene: low-density polyethylene (LDPE) and highdensity polyethylene (HDPE). The chains in LDPE contain many branches and thus do not pack as tightly as those in HDPE, which consist of mostly straight-chain molecules.

Traditionally, LDPE has been manufactured under conditions of high pressure ( \(\approx 20,000 \mathrm{psi}\) ) and high temperature \(\left(500^{\circ} \mathrm{C}\right)\). These severe reaction conditions require specially designed equipment, and for safety reasons the reaction usually has been run behind a reinforced concrete barrier. More recently, lower reaction pressures and temperatures have become possible through the use of catalysts. One catalytic system using triethylaluminum, \(\mathrm{Al}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3}\), and titanium(IV) chloride was developed by Karl Ziegler in Germany and Giulio Natta in Italy. Although this catalyst is very efficient, it catches fire on contact with air and must be handled very carefully. A safer catalytic system was developed at Phillips Petroleum Company. It uses a chromium(III) oxide \(\left(\mathrm{Cr}_{2} \mathrm{O}_{3}\right)\) and aluminosilicate catalyst and has mainly taken over in the United States. The product of the catalyzed reaction is highly linear (unbranched) and is often called linear low-density polyethylene. It is very similar to HDPE.

The major use of LDPE is in the manufacture of the tough, transparent film that is used in packaging so many consumer goods. Two-thirds of the approximately 10 billion pounds of LDPE produced annually in the United States are used for this purpose. The major use of HDPE is for blow-molded products, such as bottles for consumer products (Fig. 22.17).

The useful properties of polyethylene are due primarily to its high molecular weight (molar mass). Although the strengths of the interactions between specific points on the nonpolar chains are quite small, the chains are so long that these small attractions accumulate to a very significant value, so that the chains stick together very tenaciously. There is also a great deal of physical tangling of the lengthy chains. The combination of these interactions gives the polymer strength and toughness. However, a material like polyethylene can be melted and formed into a new shape (thermoplastic behavior), because in the melted state the molecules can readily flow past one another.

FIGURE 22.17 A major use of HDPE is for blow-molded objects such as bottles for soft drinks, shampoos, bleaches, and so on. (a) A tube composed of HDPE is inserted into the mold (die). (b) The die closes, sealing the bottom of the tube. (c) Compressed air is forced into the warm HDPE tube, which then expands to take the shape of the die. (d) The molded bottle is removed from the die.

Since a high molecular weight gives a polymer useful properties, one might think that the goal would be to produce polymers with chains as long as possible. However, this is not the case-polymers become much more difficult to process as the molecular weights increase. Most industrial operations require that the polymer flow through pipes as it is processed. But as the chain lengths increase, viscosity also increases. In practice, the upper limit of a polymer's molecular weight is set by the flow requirements of the manufacturing process. Thus the final product often reflects a compromise between the optimal properties for the application and those needed for ease of processing.

Although many polymer properties are greatly influenced by molecular weight, some other important properties are not. For example, chain length does not affect a polymer's resistance to chemical attack. Physical properties such as color, refractive index, hardness, density, and electrical conductivity are also not greatly influenced by molecular weight.

We have already seen that one way of altering the strength of a polymeric material is to vary the chain length. Another method for modifying polymer behavior involves varying the substituents. For example, if we use a monomer of the type

the properties of the resulting polymer depend on the identity of X . The simplest example is polypropylene, whose monomer is

and that has the form

The \(\mathrm{CH}_{3}\) groups can be arranged on the same side of the chain (called an isotactic chain) as shown above, can alternate (called a syndiotactic chain) as shown below,

or can be randomly distributed (called an atactic chain).

The chain arrangement has a significant effect on the polymer's properties. Most polypropylene is made using the Ziegler-Natta catalyst, \(\mathrm{Al}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3} \cdot \mathrm{TiCl}_{4}\), which produces highly isotactic chains that pack together quite closely. As a result, polypropylene is more crystalline, and therefore stronger and harder, than polyethylene. The major uses of polypropylene are for molded parts (40\%), fibers (35\%), and packaging films ( \(10 \%\) ). Polypropylene fibers are especially useful for athletic wear because they do not absorb water from perspiration, as cotton does. Rather, the moisture is drawn away from the skin to the surface of the polypropylene garment, where it can evaporate. The annual U.S. production of polypropylene is about 7 billion pounds.

Another related polymer, polystyrene, is constructed from the monomer styrene,

Pure polystyrene is too brittle for many uses, so most polystyrene-based polymers are actually copolymers of styrene and butadiene,

thus incorporating bits of butadiene rubber into the polystyrene matrix. The resulting polymer is very tough and is often used as a substitute for wood in furniture.

Another polystyrene-based product is acrylonitrile-butadiene-styrene (ABS), a tough, hard, and chemically resistant plastic used for pipes and for items such as radio housings, telephone cases, and golf club heads, for which shock resistance is an essential property. Originally, ABS was produced by copolymerization of the three monomers:

Acrylonitrile

Butadiene

It is now prepared by a special process called grafting, in which butadiene is polymerized first, and then the cyanide and phenyl substituents are added chemically.

Another high-volume polymer, polyvinyl chloride (PVC), is constructed from the monomer vinyl chloride,

\subsection*{22.6 Natural Polymers}

\section*{Proteins}

We have seen that many useful synthetic materials are polymers. Thus it should not be surprising that a great many natural materials are also polymers: starch, hair, silicate chains in soil and rocks, silk and cotton fibers, and the cellulose in woody plants, to name only a few.

-
The protein in muscles enables them to contract.

In this section we will consider a class of natural polymers, the proteins, which make up about \(15 \%\) of our bodies and have molecular weights (molar masses) that range from about 6000 to over \(1,000,000\) grams per mole. Proteins perform many functions in the human body. Fibrous proteins provide structural integrity and strength for many types of tissue and are the main components of muscle, hair, and cartilage. Other proteins, usually called globular proteins because of their roughly spherical shape, are the "worker" molecules of the body. These proteins transport and store oxygen and nutrients, act as catalysts for the thousands of reactions that make life possible, fight invasion by foreign objects, participate in the body's many regulatory systems, and transport electrons in the complex process of metabolizing nutrients.

The building blocks of all proteins are the \(\boldsymbol{\alpha}\)-amino acids, where R may represent \(\mathrm{H}, \mathrm{CH}_{3}\), or a more complex substituent. These molecules are called \(\alpha\)-amino acids because the amino group \(\left(-\mathrm{NH}_{2}\right)\) is always attached to the \(\alpha\)-carbon, the one next to the carboxyl group \(\left(-\mathrm{CO}_{2} \mathrm{H}\right)\). The 20 amino acids most commonly found in proteins are shown in Fig. 22.18.

Note from Fig. 22.18 that the amino acids are grouped into polar and nonpolar classes, determined by the R groups, or side chains. Nonpolar side chains contain mostly carbon and hydrogen atoms, whereas polar side chains contain large numbers of nitrogen and oxygen atoms. This difference is important, because polar side chains are hydrophilic (water-loving), but nonpolar side chains are hydrophobic (water-fearing), and this characteristic greatly affects the three-dimensional structure of the resulting protein.

The protein polymer is built by condensation reactions between amino acids. For example,

At the pH in biological fluids, the amino acids shown in Fig. 22.18 exist in a different form, with the proton of the - COOH group transferred to the \(-\mathrm{NH}_{2}\) group. For example, glycine would be in the form \(\mathrm{H}_{3}{ }^{+} \mathrm{NCH}_{2} \mathrm{COO}^{-}\).

The peptide linkage is also found in nylon (see Section 22.5).

The product shown before is called a dipeptide. This name is used because the structure

is called a peptide linkage by biochemists. (The same grouping is called an amide by organic chemists.) Additional condensation reactions lengthen the chain to produce a polypeptide, eventually yielding a protein.

You can imagine that with 20 amino acids, which can be assembled in any order, there is essentially an infinite variety possible in the construction of proteins. This flexibility allows an organism to tailor proteins for the many types of functions that must be carried out.

The order, or sequence, of amino acids in the protein chain is called the primary structure, conveniently indicated by using three-letter codes for the amino acids (see Fig. 22.18), where it is understood that the terminal carboxyl group is on the right and the terminal amino group is on the left. For example, one possible sequence for a tripeptide containing the amino acids lysine, alanine, and leucine is

which is represented in the shorthand notation by
lys-ala-leu

Note from Example 22.7 that there are six sequences possible for a polypeptide with three given amino acids. There are three possibilities for the first amino acid (any one of the three given amino acids), there are two possibilities for the second amino acid (one has already been accounted for), but there is only one possibility left for the third amino acid. Thus the number of sequences is \(3 \times 2 \times 1=6\). The product \(3 \times 2 \times 1\) is often written 3 ! (and is called 3 factorial). Similar reasoning shows that for a polypeptide with four amino acids, there are 4 !, or \(4 \times 3 \times 2 \times 1=24\), possible sequences.

\section*{INTERACTIVE EXAMPLE 22.7 Tripeptide Sequences}

Write the sequences of all possible tripeptides composed of the amino acids tyrosine, histidine, and cysteine.

SOLUTION There are six possible sequences:
\begin{tabular}{lll} 
tyr-his-cys & his-tyr-cys & cys-tyr-his \\
tyr-cys-his & his-cys-tyr & cys-his-tyr
\end{tabular}

See Exercise 22.95

\section*{INTERACTIVE EXAMPLE 22.8}

\section*{SOLUTION}

\section*{Polypeptide Sequences}

What number of possible sequences exists for a polypeptide composed of 20 different amino acids?

The answer is 20 !, or
\[
20 \times 19 \times 18 \times 17 \times 16 \times \cdots \times 5 \times 4 \times 3 \times 2 \times 1=2.43 \times 10^{18}
\]

See Exercise 22.96

A striking example of the importance of the primary structure of polypeptides can be seen in the differences between oxytocin and vasopressin. Both of these molecules are nine-unit polypeptides that differ by only two amino acids (Fig. 22.19), yet they perform completely different functions in the human body. Oxytocin is a hormone that triggers contraction of the uterus and milk secretion. Vasopressin raises blood pressure levels and regulates kidney function.

A second level of structure in proteins, beyond the sequence of amino acids, is the arrangement of the chain of the long molecule. The secondary structure is determined to a large extent by hydrogen bonding between lone pairs on an oxygen atom in the carbonyl group of an amino acid and a hydrogen atom attached to a nitrogen of another amino acid:

Such interactions can occur within the chain coils to form a spiral structure called an \(\boldsymbol{\alpha}\)-helix, as shown in Figs. 22.20 and 22.21. This type of secondary structure gives the protein elasticity (springiness) and is found in the fibrous proteins in wool, hair, and tendons. Hydrogen bonding can also occur between different protein chains, joining them together in an arrangement called a pleated sheet, as shown in Fig. 22.22. Silk contains this arrangement of proteins, making its fibers flexible yet very strong

FIGURE 22.19 The amino acid sequences in (a) oxytocin and (b) vasopressin. The differing amino acids are boxed.

FIGURE 22.20 Hydrogen bonding within a protein chain causes it to form a stable helical structure called the \(\alpha\)-helix. Only the main atoms in the helical backbone are shown here. The hydrogen bonds are not shown.

FIGURE 22.22 When hydrogen bonding occurs between protein chains rather than within them, a stable structure (the pleated sheet) results. This structure contains many protein chains and is found in natural fibers, such as silk, and in muscles.

FIGURE 22.21 Ball-and-stick model of a portion of a protein chain in the \(\alpha\)-helical arrangement, showing the hydrogen-bonding interactions.
and resistant to stretching. The pleated sheet is also found in muscle fibers. The hydrogen bonds in the \(\alpha\)-helical protein are called intrachain (within a given protein chain), and those in the pleated sheet are said to be interchain (between protein chains).

As you might imagine, a molecule as large as a protein has a great deal of flexibility and can assume a variety of overall shapes. The specific shape that a protein assumes depends on its function. For long, thin structures, such as hair, wool and silk fibers, and tendons, an elongated shape is required. This may involve an \(\alpha\)-helical secondary structure, as found in the protein \(\alpha\)-keratin in hair and wool or in the collagen found in

\footnotetext{
: Hydrogen bond
}

FIGURE 22.23 (a) Collagen, a protein found in tendons, consists of three protein chains (each with a helical structure) twisted together to form a superhelix. The result is a long, relatively narrow protein. (b) The pleated-sheet arrangement of many proteins bound together to form the elongated protein found in silk fibers.
tendons [Fig. 22.23(a)], or it may involve a pleated-sheet secondary structure, as found in silk [Fig. 22.23(b)]. Many of the proteins in the body having nonstructural functions are globular, such as myoglobin (see Fig. 21.31). Note that the secondary structure of myoglobin is basically \(\alpha\)-helical. However, in the areas where the chain bends to give the protein its compact globular structure, the \(\alpha\)-helix breaks down to give a secondary configuration known as the random-coil arrangement.

The overall shape of the protein, long and narrow or globular, is called its tertiary structure and is maintained by several different types of interactions: hydrogen bonding, dipole-dipole interactions, ionic bonds, covalent bonds, and London dispersion forces between nonpolar groups. These bonds, which represent all the bonding types discussed in this text, are summarized in Fig. 22.24.

The amino acid cysteine

plays a special role in stabilizing the tertiary structure of many proteins because the - SH groups on two cysteines can react in the presence of an oxidizing agent to form a \(\mathrm{S}-\mathrm{S}\) bond called a disulfide linkage:

A practical application of the chemistry of disulfide bonds is permanent waving of hair, as summarized in Fig. 22.25. The S-S linkages in the protein of hair are broken by treatment with a reducing agent. The hair is then set in curlers to change the tertiary protein structure to the desired shape. Then treatment with an oxidizing agent causes new \(S-S\) bonds to form, which allow the hair protein to retain the new structure.

The three-dimensional structure of a protein is crucial to its function. The process of breaking down this structure is called denaturation (Fig. 22.26). For example, the denaturation of egg proteins occurs when an egg is cooked. Any source of energy can cause denaturation of proteins and is thus potentially dangerous to living organisms. For example, ultraviolet and X-ray radiation or nuclear radioactivity can disrupt protein structure, which may lead to cancer or genetic damage. Protein damage is also caused by chemicals like benzene, trichloroethane, and 1,2-dibromoethane. The metals lead and mercury, which have a very high affinity for sulfur, cause protein denaturation by disrupting disulfide bonds between protein chains.

The tremendous flexibility in the various levels of protein structure allows the tailoring of proteins for a wide range of specific functions. Proteins are the "workhorse" molecules of living organisms.

What if you contracted a disease that prevents all hydrogen bonding in proteins? Could you live with such a condition?

\section*{Carbohydrates}

Carbohydrates form another class of biologically important molecules. They serve as a food source for most organisms and as a structural material for plants. Because many carbohydrates have the empirical formula \(\mathrm{CH}_{2} \mathrm{O}\), it was originally believed that these substances were hydrates of carbon, thus accounting for the name.

Most important carbohydrates, such as starch and cellulose, are polymers composed of monomers called monosaccharides, or simple sugars. The monosaccharides are polyhydroxy ketones and aldehydes. The most important contain five carbon atoms (pentoses) or six carbon atoms (hexoses). One important hexose is fructose, a sugar found in honey and fruit. Its structure is

where the asterisks indicate chiral carbon atoms. In Section 21.4 we saw that molecules with nonsuperimposable mirror images exhibit optical isomerism. A carbon atom with four different groups bonded to it in a tetrahedral arrangement always has a

FIGURE 22.27 When a tetrahedral carbon atom has four different substituents, there is no way that its mirror image can be superimposed. The lower two forms show other possible orientations of the molecule. Compare these with the mirror image and note that they cannot be superimposed.

FIGURE 22.28 The mirror image optical isomers of glyceraldehyde. Note that these mirror images cannot be superimposed.
nonsuperimposable mirror image (Fig. 22.27), which gives rise to a pair of optical isomers. For example, the simplest sugar, glyceraldehyde,

which has one chiral carbon, has two optical isomers, as shown in Fig. 22.28.
In fructose each of the three chiral carbon atoms satisfies the requirement of being surrounded by four different groups. This leads to a total of \(2^{3}\), or 8 , isomers that differ in their ability to rotate polarized light. The particular isomer whose structure is shown in Table 22.8 is called D-fructose. Generally, monosaccharides have one isomer that is more common in nature than the others. The most important pentoses and hexoses are shown in Table 22.8 .

\section*{CHEMICAL CONNECTIDNS}

\section*{Tanning in the Shade}

Among today's best-selling cosmetics are self-tanning lotions. Many light-skinned people want to look like they have just spent a vacation in the Caribbean, but they recognize the dangers of too much sun-it causes premature aging and may lead to skin cancer. Chemistry has come to the rescue in the form of lotions that produce an authentic-looking tan. All of these lotions have the same active ingredient: dihydroxyacetone (DHA). DHA, which has the structure

is a nontoxic, simple sugar that occurs as an intermediate in carbohydrate metabolism in higher-order plants and
animals. The DHA used in self-tanners is prepared by bacterial fermentation of glycerine,

The tanning effects of DHA were discovered by accident in the 1950s at Children's Hospital at the University of Cincinnati, where DHA was being used to treat children with glycogen storage disease. When the DHA was accidentally spilled on the skin, it produced brown spots.

The mechanism of the browning process involves the Maillard reaction, which was discovered by Louis-Camille

Maillard in 1912. In this process amino acids react with sugars to create brown or golden brown products. The same reaction is responsible for much of the browning that occurs during the manufacture and storage of foods. It is also the reason that beer is golden brown.

The browning of skin occurs in the stratum corneum-the outermost, dead layer-where the DHA reacts with free amino \(\left(-\mathrm{NH}_{2}\right)\) groups of the proteins found there.

DHA is present in most tanning lotions at concentrations between \(2 \%\) and \(5 \%\), although some products designed to give a deeper tan are more concentrated. Because the lotions themselves turn brown above pH 7 , the tanning lotions are buffered at pH 5 .

Thanks to these new products, tanning is now both safe and easy.

> Ingredients: Water, Aloe Vera Gel. Gycerin, Propylene Glycol, Polysorbate 20. Fragrance. Tocopheryl Aceatate (Vitamin E Acetate), Imidazolidinyl Urea, Dihydroxyacetone.

\section*{SOLUTION}

FIGURE 22.29 The cyclization of D-fructose.

\section*{Chiral Carbons in Carbohydrates}

Determine the number of chiral carbon atoms in the following pentose:

We must look for carbon atoms that have four different substituents. The top carbon has only three substituents and thus cannot be chiral. The three carbon atoms shown in blue each have four different groups attached to them:

Since the fifth carbon atom has only three types of substituents (it has two hydrogen atoms), it is not chiral.

Thus the three chiral carbon atoms in this pentose are those shown in blue:

Note that D-ribose and D-arabinose, shown in Table 22.8, are two of the eight isomers of this pentose.

\section*{See Exercises 2P. 104 and 22. 109 through 22. 114}

Although we have so far represented the monosaccharides as straight-chain molecules, they usually cyclize, or form a ring structure, in aqueous solution. Figure 22.29 shows this reaction for fructose. Note that a new bond is formed between the oxygen of the terminal hydroxyl group and the carbon of the ketone group. In the cyclic form fructose is a five-membered ring containing a \(\mathrm{C}-\mathrm{O}-\mathrm{C}\) bond. The same type of reaction can occur between a hydroxyl group and an aldehyde group, as shown for D-glucose in Fig. 22.30. In this case a six-membered ring is formed.

FIGURE 22.30 The cyclization of glucose. Two different rings are possible; they differ in the orientation of the hydroxy group and hydrogen on one carbon, as indicated. The two forms are designated \(\alpha\) and \(\beta\) and are shown here in two representations.

A
Bowl of sugar cubes.

FIGURE 22.31 Sucrose is a disaccharide formed from \(\alpha-\mathrm{D}\)-glucose and fructose.

\(\alpha\)

\(\alpha\)

More complex carbohydrates are formed by combining monosaccharides. For example, sucrose, common table sugar, is a disaccharide formed from glucose and fructose by elimination of water to form a \(\mathrm{C}-\mathrm{O}-\mathrm{C}\) bond between the rings, which is called a glycoside linkage (Fig. 22.31). When sucrose is consumed in food, the above reaction is reversed. An enzyme in saliva catalyzes the breakdown of this disaccharide.

Large polymers consisting of many monosaccharide units, called polysaccharides, can form when each ring forms two glycoside linkages, as shown in Fig. 22.32. Three of the most important of these polymers are starch, cellulose, and glycogen. All these substances are polymers of glucose, differing from each other in the nature of the glycoside linkage, the amount of branching, and molecular weight (molar mass).

Starch, a polymer of \(\alpha\)-D-glucose, consists of two parts: amylose, a straight-chain polymer of \(\alpha\)-glucose [see Fig. 22.32(a)], and amylopectin, a highly branched polymer of \(\alpha\)-glucose with a molecular weight that is 10 to 20 times that of amylose. Branching occurs when a third glycoside linkage attaches a branch to the main polymer chain.

FIGURE 22.32
(a) The polymer amylose is a major component of starch and is made up of \(\alpha\)-D-glucose monomers. (b) The polymer cellulose, which consists of \(\beta\)-Dglucose monomers.

Starch, the carbohydrate reservoir in plants, is the form in which glucose is stored by the plant for later use as cellular fuel. Glucose is stored in this high-molecularweight form because it results in less stress on the plant's internal structure by osmotic pressure. Recall from Section 11.6 that it is the concentration of solute molecules (or ions) that determines the osmotic pressure. Combining the individual glucose molecules into one large chain keeps the concentration of solute molecules relatively low, minimizing the osmotic pressure.

Cellulose, the major structural component of woody plants and natural fibers (such as cotton), is a polymer of \(\beta\)-D-glucose and has the structure shown in Fig. 22.32(b). Note that the \(\beta\)-glycoside linkages in cellulose give the glucose rings a different relative orientation than is found in starch. Although this difference may seem minor, it has very important consequences. The human digestive system contains \(\alpha\)-glycosidases, enzymes that can catalyze breakage of the \(\alpha\)-glycoside bonds in starch. These enzymes are not effective on the \(\beta\)-glycoside bonds of cellulose, presumably because the different structure results in a poor fit between the enzyme's active site and the carbohydrate. The enzymes necessary to cleave \(\beta\)-glycoside linkages, the \(\beta\)-glycosidases, are found in bacteria that exist in the digestive tracts of termites, cows, deer, and many other animals. Thus, unlike humans, these animals can derive nutrition from cellulose.

Glycogen, the main carbohydrate reservoir in animals, has a structure similar to that of amylopectin but with more branching. It is this branching that is thought to facilitate the rapid breakdown of glycogen into glucose when energy is required.

\section*{Nucleic Acids}

Life is possible only because each cell, when it divides, can transmit the vital information about how it works to the next generation. It has been known for a long time that this process involves the chromosomes in the nucleus of the cell. Only since 1953, however, have scientists understood the molecular basis of this intriguing cellular "talent."

The substance that stores and transmits the genetic information is a polymer called deoxyribonucleic acid (DNA), a huge molecule with a molecular weight as high as several billion grams per mole. Together with other similar nucleic acids called the ribonucleic acids (RNA), DNA is also responsible for the synthesis of the various proteins needed by the cell to carry out its life functions. The RNA molecules, which are found in the cytoplasm outside the nucleus, are much smaller than DNA polymers, with molecular weights of only 20,000 to 40,000 grams per mole.

FIGURE 22.34 The organic bases found in DNA and RNA.

The monomers of the nucleic acids, called nucleotides, are composed of three distinct parts:
1. a five-carbon sugar, deoxyribose in DNA and ribose in RNA (Fig. 22.33)
2. a nitrogen-containing organic base of the type shown in Fig. 22.34
3. a phosphoric acid molecule \(\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)\)

The base and the sugar combine as shown in Fig. 22.35(a) to form a unit that in turn reacts with phosphoric acid to create the nucleotide, which is an ester [Fig. 22.35(b)].

-b
FIGURE 22.35 (a) Adenosine is formed by the reaction of adenine with ribose. (b) The reaction of phosphoric acid with adenosine to form the ester adenosine 5 -phosphoric acid, a nucleotide. (At biological pH, the phosphoric acid would not be fully protonated as is shown here.)

FIGURE 22.36 A portion of a typical nucleic acid chain. Note that the backbone consists of sugar-phosphate esters.

The nucleotides become connected through condensation reactions that eliminate water to give a polymer of the type represented in Fig. 22.36; such a polymer can contain a billion units.

The key to DNA's functioning is its double-helical structure with complementary bases on the two strands. The bases form hydrogen bonds to each other, as shown in Fig. 22.37. Note that the structures of cytosine and guanine make them perfect partners for hydrogen bonding, and they are always found as pairs on the two strands of DNA. Thymine and adenine form similar hydrogen-bonding pairs.

There is much evidence to suggest that the two strands of DNA unwind during cell division and that new complementary strands are constructed on the unraveled strands (Fig. 22.38). Because the bases on the strands always pair in the same way-cytosine with guanine and thymine with adenine-each unraveled strand serves as a template for attaching the complementary bases (along with the rest of the nucleotide). This process results in two double-helix DNA structures that are identical to the original one. Each new double strand contains one strand from the original DNA double helix and one newly synthesized strand. This replication of DNA allows for the transmission of genetic information as the cells divide.

The other major function of DNA is protein synthesis. A given segment of the DNA, called a gene, contains the code for a specific protein. These codes transmit the primary structure of the protein (the sequence of amino acids) to the construction "machinery" of the cell. There is a specific code for each amino acid in the protein, which ensures that the correct amino acid will be inserted as the protein chain grows. A code consists of a set of three bases called a codon.

DNA stores the genetic information, while RNA molecules are responsible for transmitting this information to the ribosomes, where protein synthesis actually occurs. This complex process involves, first, the construction of a special RNA molecule

-b

c
FIGURE 22.37 (a) The DNA double helix contains two sugar-phosphate backbones, with the bases from the two strands hydrogen-bonded to each other. The complementarity of the (b) thymine-adenine and (c) cytosine-guanine pairs.

FIGURE 22.38 During cell division the original DNA double helix unwinds and new complementary strands are constructed on each original strand.

called messenger RNA (mRNA). The mRNA is built in the cell nucleus on the appropriate section of DNA (the gene); the double helix is "unzipped," and the complementarity of the bases is used in a process similar to that used in DNA replication. The mRNA then migrates into the cytoplasm of the cell where, with the assistance of the ribosomes, the protein is synthesized.

Small RNA fragments, called transfer RNA (tRNA), are tailored to find specific amino acids and then to attach them to the growing protein chain as dictated by the codons in the mRNA. Transfer RNA has a lower molecular weight than messenger RNA. It consists of a chain of 75 to 80 nucleotides, including the bases adenine, cytosine, guanine, and uracil, among others. The chain folds back onto itself in various places as the complementary bases along the chain form hydrogen bonds. The tRNA decodes the genetic message from the mRNA, using a complementary triplet of bases called an anticodon. The nature of the anticodon governs which amino acid will be brought to the protein under construction.

The protein is built in several steps. First, a tRNA molecule brings an amino acid to the mRNA [the anticodon of the tRNA must complement the codon of the mRNA (Fig. 22.39)]. Once this amino acid is in place, another tRNA moves to the second codon site of the mRNA with its specific amino acid. The two amino acids link via a peptide bond, and the tRNA on the first codon breaks away. The process is repeated down the chain, always matching the tRNA anticodon with the mRNA codon.

FIGURE 22.39 The mRNA molecule, constructed from a specific gene on the DNA, is used as the pattern to construct a given protein with the assistance of ribosomes. The tRNA molecules attach to specific amino acids and put them in place as called for by the codons on the mRNA.

\section*{For Review}

\section*{Key terms}
biomolecule organic chemistry

Section 22.1
hydrocarbons
saturated unsaturated
alkanes
normal (straight-chain or unbranched) hydrocarbons structural isomerism combustion reaction substitution reaction dehydrogenation reaction cyclic alkanes

\section*{Section 22.2}
alkenes

halogenation
polymerization
Section 22.3
aromatic hydrocarbons phenyl group

\section*{Hydrocarbons}
> Compounds composed of mostly carbon and hydrogen atoms that typically contain chains or rings of carbon atoms
> Alkanes
) Contain compounds with only \(\mathrm{C}-\mathrm{C}\) single bonds
) Can be represented by the formula \(\mathrm{C}_{n} \mathrm{H}_{2 n+2}\)
> Are said to be saturated because each carbon present is bonded to the maximum number of atoms (4)
) The carbon atoms are described as being \(s p^{3}\) hybridized
> Their structural isomerism involves the formation of branched chains
> React with \(\mathrm{O}_{2}\) to form \(\mathrm{CO}_{2}\) and \(\mathrm{H}_{2} \mathrm{O}\) (called a combustion reaction)
> Undergo substitution reactions
> Alkenes
) Contain one or more \(\mathrm{C}=\mathrm{C}\) double bonds
》 Simplest alkene is \(\mathrm{C}_{2} \mathrm{H}_{4}\) (ethylene), which is described as containing \(s p^{2}\) hybridized carbon atoms
> Restricted rotation about the \(\mathrm{C}=\mathrm{C}\) bonds in alkenes can lead to cis-trans isomerism
) Undergo addition reactions
> Alkynes
) Contain one or more \(\mathrm{C} \equiv \mathrm{C}\) triple bonds
> Simplest example is \(\mathrm{C}_{2} \mathrm{H}_{2}\) (acetylene), described as containing \(s p\)-hybridized carbon atoms
> Undergo addition reactions

> Aromatic hydrocarbons
) Contain rings of carbon atoms with delocalized \(\pi\) electrons
> Undergo substitution reactions rather than addition reactions

\section*{Hydrocarbon derivatives}
) Contain one or more functional groups
) Alcohols: contain the -OH group
) Aldehydes: contain a
, Ketones: contain the \(\mathrm{C}=\mathrm{O}\) group

\section*{Polymers}
) Large molecules formed from many small molecules (called monomers)
) Addition polymerization: monomers add together by a free radical mechanism
> Condensation polymerization: monomers connect by splitting out a small molecule, such as water

\section*{Proteins}
) A class of natural polymers with molar masses ranging from 600 to \(1,000,000\)
) Fibrous proteins form the structural basis of muscle, hair, and cartilage
> Globular proteins perform many biologic functions, including transport and storage of oxygen, catalysis of biologic reactions, and regulation of biological systems
> Building blocks of proteins (monomers) are \(\alpha\)-amino acids, which connect by a condensation reaction to form a peptide linkage
) Protein structure
> Primary: the order of amino acids in the chain
) Secondary: the arrangement of the protein chain
> \(\alpha\)-helix
> pleated sheet
> Tertiary structure: the overall shape of the protein

\section*{Carbohydrates}
> Contain carbon, hydrogen, and oxygen
) Serve as food sources for most organisms
> Monosaccharides are most commonly five-carbon and six-carbon polyhydroxy ketones and aldehydes
》 Monosaccharides combine to form more complex carbohydrates, such as sucrose, starch, and cellulose

\section*{Key terms}
disaccharide
glycoside linkage
starch
cellulose
glycogen
deoxyribonucleic acid (DNA)
ribonucleic acid (RNA)
nucleotides
protein synthesis
gene

messenger RNA (mRNA)
transfer RNA (tRNA)
anticodon

\section*{Genetic processes}
) When a cell divides, the genetic information is transmitted via deoxyribonucleic acid (DNA), which has a double helical structure
> During cell division, the double helix unravels and a new polymer forms along each strand of the original DNA
) The genetic code is carried by organic bases that hydrogen-bond to each other in specific pairs in the interior of the DNA double helix

\section*{Review Questions Answers to the Review Questions can be found on the Student website (accessible from wwww.cengagebrain.com).}
1. What is a hydrocarbon? What is the difference between a saturated hydrocarbon and an unsaturated hydrocarbon? Distinguish between normal and branched hydrocarbons. What is an alkane? What is a cyclic alkane? What are the two general formulas for alkanes? What is the hybridization of carbon atoms in alkanes? What are the bond angles in alkanes? Why are cyclopropane and cyclobutane so reactive?

The normal (unbranched) hydrocarbons are often referred to as straight-chain hydrocarbons. What does this name refer to? Does it mean that the carbon atoms in a straight-chain hydrocarbon really have a linear arrangement? Explain. In the shorthand notation for cyclic alkanes, the hydrogens are usually omitted. How do you determine the number of hydrogens bonded to each carbon in a ring structure?
2. What is an alkene? What is an alkyne? What are the general formulas for alkenes and alkynes, assuming one multiple bond in each? What are the bond angles in alkenes and alkynes? Describe the bonding in alkenes and alkynes using \(\mathrm{C}_{2} \mathrm{H}_{4}\) and \(\mathrm{C}_{2} \mathrm{H}_{2}\) as your examples. Why is there restricted rotation in alkenes and alkynes? Is the general formula for a cyclic alkene \(\mathrm{C}_{n} \mathrm{H}_{2 n}\) ? If not, what is the general formula, assuming one multiple bond?
3. What are aromatic hydrocarbons? Benzene exhibits resonance. Explain. What are the bond angles in benzene? Give a detailed description of the bonding in benzene. The \(\pi\) electrons in benzene are delocalized, while the \(\pi\) electrons in simple alkenes and alkynes are localized. Explain the difference.
4. Summarize the nomenclature rules for alkanes, alkenes, alkynes, and aromatic compounds. Correct the following false statements regarding nomenclature of hydrocarbons.
a. The root name for a hydrocarbon is based on the shortest continuous chain of carbon atoms.
b. The suffix used to name all hydrocarbons is -ane.
c. Substituent groups are numbered so as to give the largest numbers possible.
d. No number is required to indicate the positions of double or triple bonds in alkenes and alkynes.
e. Substituent groups get the lowest number possible in alkenes and alkynes.
f. The ortho- term in aromatic hydrocarbons indicates the presence of two substituent groups bonded to carbon- 1 and carbon- 3 in benzene.
5. What functional group distinguishes each of the following hydrocarbon derivatives?
a. halohydrocarbons
b. alcohols
c. ethers
d. aldehydes
e. ketones
f. carboxylic acids
g. esters
h. amines

Give examples of each functional group. What prefix or suffix is used to name each functional group? What are the bond angles in each? Describe the bonding in each functional group. What is the difference between a primary, secondary, and tertiary alcohol? For the functional groups in \(\mathrm{a}-\mathrm{h}\), when is a number required to indicate the position of the functional group? Carboxylic acids are often written as RCOOH. What does -COOH indicate and what does R indicate? Aldehydes are sometimes written as RCHO. What does - CHO indicate?
6. Distinguish between isomerism and resonance. Distinguish between structural and geometrical isomerism. When writing the various structural isomers, the most difficult task is identifying which are different isomers and which are identical to a previously written structurethat is, which are compounds that differ only by the rotation of a carbon single bond. How do you distinguish between structural isomers and those that are identical?

Alkenes and cycloalkanes are structural isomers of each other. Give an example of each using \(\mathrm{C}_{4} \mathrm{H}_{8}\). Another common feature of alkenes and cycloalkanes is that both have restricted rotation about one or more bonds in the compound, so both can exhibit cis-trans isomerism. What is required for an alkene or cycloalkane to exhibit cis-trans isomerism? Explain the difference between cis and trans isomers.

Alcohols and ethers are structural isomers of each other, as are aldehydes and ketones. Give an example of each to illustrate. Which functional group in Table 22.4 can be structural isomers of carboxylic acids?

What is optical isomerism? What do you look for to determine whether an organic compound exhibits optical isomerism? 1-Bromo-1-chloroethane is optically active whereas 1-bromo-2-chloroethane is not optically active. Explain.
7. What type of intermolecular forces do hydrocarbons exhibit? Explain why the boiling point of \(n\)-heptane is greater than that of \(n\)-butane. A general rule for a group of hydrocarbon isomers is that as the amount of branching increases, the boiling point decreases. Explain why this would be true.

The functional groups listed in Table 22.4 all exhibit London dispersion forces, but they also usually exhibit additional dipole-dipole forces. Explain why this is the case for each functional group. Although alcohols and ethers are structural isomers of each other, alcohols always boil at significantly higher temperatures than similar-size ethers. Explain. What would you expect when comparing the boiling points of similar-size carboxylic acids to esters? \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\), \(\mathrm{CH}_{3} \mathrm{CHO}\), and HCOOH all have about the same molar mass, but they boil at very different temperatures. Why? Place these compounds in order by increasing boiling point.
8. Distinguish between substitution and addition reactions. Give an example of each type of reaction. Alkanes and aromatics are fairly stable compounds. To make them react, a special catalyst must be present. What catalyst must be present when reacting \(\mathrm{Cl}_{2}\) with an alkane or with benzene? Adding \(\mathrm{Cl}_{2}\) to an alkene or alkyne does not require a special catalyst. Why are alkenes and alkynes more reactive than alkanes and aromatic compounds? All organic compounds can be combusted.

What is the other reactant in a combustion reaction, and what are the products, assuming the organic compound contains only \(\mathrm{C}, \mathrm{H}\), and perhaps O ?

The following are some other organic reactions covered in Section 22.4. Give an example to illustrate each type of reaction.
a. Adding \(\mathrm{H}_{2} \mathrm{O}\) to an alkene (in the presence of \(\mathrm{H}^{+}\)) yields an alcohol.
b. Primary alcohols are oxidized to aldehydes, which can be further oxidized to carboxylic acids.
c. Secondary alcohols are oxidized to ketones.
d. Reacting an alcohol with a carboxylic acid (in the presence of \(\mathrm{H}^{+}\)) produces an ester.
9. Define and give an example of each of the following.
a. addition polymer
b. condensation polymer
c. copolymer
d. homopolymer
e. polyester
f. polyamide

Distinguish between a thermoset polymer and a thermoplastic polymer. How do the physical properties of polymers depend on chain length and extent of chain branching? Explain how crosslinking agents are used to change the physical properties of polymers. Isotactic polypropylene makes stronger fibers than atactic polypropylene. Explain. In which polymer, polyethylene or polyvinyl chloride, would you expect to find the stronger intermolecular forces (assuming the average chain lengths are equal)?
10. Give the general formula for an amino acid. Some amino acids are labeled hydrophilic and some are labeled hydrophobic. What do these terms refer to? Aqueous solutions of amino acids are buffered solutions. Explain. Most of the amino acids in Fig. 22.18 are optically active. Explain. What is a peptide bond? Show how glycine, serine, and alanine react to form a tripeptide. What is a protein, and what are the monomers in proteins? Distinguish between the primary, secondary, and tertiary structures of a protein. Give examples of the types of forces that maintain each type of structure. Describe how denaturation affects the function of a protein.
11. What are carbohydrates, and what are the monomers in carbohydrates? The monosaccharides in Table 22.8 are all optically active. Explain. What is a disaccharide? Which monosaccharide units make up the disaccharide sucrose? What do you call the bond that forms between the monosaccharide units? What is the difference between starch, cellulose, and glycogen?
12. Describe the structural differences between DNA and RNA. The monomers in nucleic acids are called nucleotides. What are the three parts of a nucleotide? The compounds adenine, guanine, cytosine, and thymine are called the nucleic acid bases. What structural features in these compounds make them bases? DNA exhibits a double-helical structure. Explain. Describe how the complementary base pairing between the two individual

A blue question or exercise number indicates that the answer to that question or exercise appears at the back of this book and a solution appears in the Solutions Guide, as found on the Instructor Companion Site.

\section*{Questions}
1. Why can carbon form so many different compounds?
2. Give an example of a hydrocarbon that, in theory, exhibits each of the following bond angles: \(60^{\circ}, 90^{\circ}, 109.5^{\circ}, 120^{\circ}\), and \(180^{\circ}\).
3. A confused student was doing an isomer problem and listed the following six names as different structural isomers of \(\mathrm{C}_{7} \mathrm{H}_{16}\).
a. 1-sec-butylpropane
b. 4-methylhexane
c. 2-ethylpentane
d. 1-ethyl-1-methylbutane
e. 3-methylhexane
f. 4-ethylpentane

How many different structural isomers are actually present in these six names?
4. The following organic compounds cannot exist. Why?
a. 2-chloro-2-butyne
b. 2-methyl-2-propanone
c. 1,1-dimethylbenzene
d. 2-pentanal
e. 3-hexanoic acid
f. 5,5-dibromo-1-cyclobutanol
5. If you had a group of hydrocarbons, what structural features would you look at to rank the hydrocarbons in order of increasing boiling point?
6. Which of the functional groups in Table 22.4 can exhibit hydrogen bonding intermolecular forces? \(\mathrm{Can} \mathrm{CH}_{2} \mathrm{CF}_{2}\) exhibit hydrogen bonding? Explain.
7. A polypeptide is also called a polyamide. Nylon is also an example of a polyamide. What is a polyamide? Consider a polyhydrocarbon, a polyester, and a polyamide. Assuming average chain lengths are equal, which polymer would you expect to make the strongest fibers and which polymer would you expect to make the weakest fibers? Explain.
strands of DNA forms the overall double-helical structure. How is complementary base pairing involved in the replication of the DNA molecule during cell division? Describe how protein synthesis occurs. What is a codon, and what is a gene? The deletion of a single base from a DNA molecule can constitute a fatal mutation, whereas substitution of one base for another is often not as serious a mutation. Explain.
8. Give an example reaction that would yield the following products. Name the organic reactant and product in each reaction.
a. alkane
b. monohalogenated alkane
c. dihalogenated alkane
d. tetrahalogenated alkane
e. monohalogenated benzene
f. alkene
9. Give an example reaction that would yield the following products as major organic products. See Exercises 22.68 and 22.71 for some hints. For oxidation reactions, just write oxidation over the arrow and don't worry about the actual reagent.
a. primary alcohol
e. ketone
b. secondary alcohol
f. carboxylic acid
c. tertiary alcohol
g. ester
d. aldehyde
10. What is polystyrene? The following processes result in a stronger polystyrene polymer. Explain why in each case.
a. addition of catalyst to form syndiotactic polystyrene
b. addition of 1,3-butadiene and sulfur
c. producing long chains of polystyrene
d. addition of a catalyst to make linear polystyrene
11. Answer the following questions regarding the formation of polymers.
a. What structural features must be present in a monomer in order to form a homopolymer polyester?
b. What structural features must be present in the monomers in order to form a copolymer polyamide? (Hint: Nylon is an example of a polyamide. When the monomers link together to form nylon, an amide functional group results from each linkage.)
c. What structural features must be present in a monomer that can form both an addition polymer and a condensation polymer?
12. In Section 22.6 , three important classes of biologically important natural polymers are discussed. What are the three classes, what are the monomers used to form the polymers, and why are they biologically important?
13. Is the primary, secondary, or tertiary structure of a protein changed by denaturation?
14. What forces are responsible for the solubility of starch in water?

\section*{Exercises}

In this section similar exercises are paired.

\section*{Hydrocarbons}
15. Draw the five structural isomers of hexane \(\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)\).
16. Name the structural isomers in Exercise 15.
17. Draw all the structural isomers for \(\mathrm{C}_{8} \mathrm{H}_{18}\) that have the following root name (longest carbon chain). Name the structural isomers.
a. heptane
b. butane
18. Draw all the structural isomers for \(\mathrm{C}_{8} \mathrm{H}_{18}\) that have the following root name (longest carbon chain). Name the structural isomers.
a. hexane
b. pentane
-19. Draw a structural formula for each of the following compounds.
a. 2-methylpropane
b. 2-methylbutane
c. 2-methylpentane
d. 2-methylhexane
20. Draw a structural formula for each of the following compounds.
a. 2,2-dimethylheptane
c. 3,3-dimethylheptane
b. 2,3-dimethylheptane
d. 2,4-dimethylheptane
21. Draw the structural formula for each of the following.
a. 3-isobutylhexane
b. 2,2,4-trimethylpentane, also called isooctane. This substance is the reference ( 100 level) for octane ratings.
c. 2-tert-butylpentane
d. The names given in parts a and c are incorrect. Give the correct names for these hydrocarbons.
22. Draw the structure for 4-ethyl-2,3-diisopropylpentane. This name is incorrect. Give the correct systematic name.
23. Name each of the following.
a.

b.

c.

d.

24. Name each of the following cyclic alkanes, and indicate the formula of the compound.
a.

b.

c.

-25. Give two examples of saturated hydrocarbons. How many other atoms are bonded to each carbon in a saturated hydrocarbon?
26. Draw the structures for two examples of unsaturated hydrocarbons. What structural feature makes a hydrocarbon unsaturated?
27. Name each of the following alkenes.
a. \(\mathrm{CH}_{2}=\mathrm{CH}-\mathrm{CH}_{2}-\mathrm{CH}_{3}\)
b.

c.

28. Name each of the following alkenes or alkynes.
a.

b.

c.

-29 . Give the structure for each of the following.
a. 3-hexene
b. 2,4-heptadiene
c. 2-methyl-3-octene
30. Give the structure for each of the following.
a. 4-methyl-1-pentyne
b. 2,3,3-trimethyl-1-hexene
c. 3-ethyl-4-decene
[31. Give the structure of each of the following aromatic hydrocarbons.
a. o-ethyltoluene
c. m-diethylbenzene
b. p-di-tert-butylbenzene
d. 1-phenyl-2-butene
32. Cumene is the starting material for the industrial production of acetone and phenol. The structure of cumene is

Give the systematic name for cumene.
-33. Name each of the following.

b. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CCl}_{3}\)
c. \(\mathrm{CH}_{3}\)

d. \(\mathrm{CH}_{2} \mathrm{FCH}_{2} \mathrm{~F}\)
34. Name each of the following compounds.
a.

b.

c.

d.

e.

f.

g.

\section*{Isomerism}
-35. There is only one compound that is named 1,2-dichloroethane, but there are two distinct compounds that can be named 1,2-dichloroethene. Why?
36. Consider the following four structures.

(i)

(ii)

(iii)

(iv)
a. Which of these compounds would have the same physical properties (melting point, boiling point, density, and so on)?
b. Which of these compounds are trans isomers?
c. Which of these compound do not exhibit cis-trans isomerism?
37. Which of the compounds in Exercises 27 and 29 exhibit cistrans isomerism?
38. Which of the compounds in Exercises 28 and 30 exhibit cistrans isomerism?
-39. Draw all the structural isomers of \(\mathrm{C}_{5} \mathrm{H}_{10}\). Ignore any cyclic isomers.
40. Which of the structural isomers in Exercise 39 exhibit cistrans isomerism?
-41. Draw all the structural and geometrical (cis-trans) isomers of \(\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{Cl}\).
42. Draw all the structural and geometrical (cis-trans) isomers of bromochloropropene.
43. Draw all structural and geometrical (cis-trans) isomers of \(\mathrm{C}_{4} \mathrm{H}_{7} \mathrm{~F}\). Ignore any cyclic isomers.
44. Cis-trans isomerism is also possible in molecules with rings. Draw the cis and trans isomers of 1,2-dimethylcyclohexane. In Exercise 43, you drew all of the noncyclic structural and geometrical isomers of \(\mathrm{C}_{4} \mathrm{H}_{7} \mathrm{~F}\). Now draw the cyclic structural and geometrical isomers of \(\mathrm{C}_{4} \mathrm{H}_{7} \mathrm{~F}\).
-45. Draw the following.
a. cis-2-hexene
b. trans-2-butene
c. cis-2,3-dichloro-2-pentene
46. Name the following compounds.
a.

c.

47. Structural, geometrical, and optical isomers can be drawn having the formula \(\mathrm{C}_{6} \mathrm{H}_{12}\). Give examples to illustrate these types of isomerism for \(\mathrm{C}_{6} \mathrm{H}_{12}\).
48. Structural and optical isomers can be drawn having the formula \(\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{~F}\). Give examples to illustrate these types of isomerism for \(\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{~F}\). Why can't \(\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{~F}\) exhibit geometrical isomerism?
49. If one hydrogen in a hydrocarbon is replaced by a halogen atom, the number of isomers that exist for the substituted compound depends on the number of types of hydrogen in the original hydrocarbon. Thus there is only one form of chloroethane (all hydrogens in ethane are equivalent), but there are two isomers of propane that arise from the substitution of a methyl hydrogen or a methylene hydrogen. How many isomers can be obtained when one hydrogen in each of the compounds named below is replaced by a chlorine atom?
a. n-pentane
c. 2,4-dimethylpentane
b. 2-methylbutane
d. methylcyclobutane
50. There are three isomers of dichlorobenzene, one of which has now replaced naphthalene as the main constituent of mothballs.
a. Identify the ortho, the meta, and the para isomers of dichlorobenzene.
b. Predict the number of isomers for trichlorobenzene.
c. It turns out that the presence of one chlorine atom on a benzene ring will cause the next substituent to add ortho or para to the first chlorine atom on the benzene ring. What does this tell you about the synthesis of \(m\)-dichlorobenzene?
d. Which of the isomers of trichlorobenzene will be the hardest to prepare?

\section*{Functional Groups}

Identify each of the following compounds as a carboxylic acid, ester, ketone, aldehyde, or amine.
a. Anthraquinone, an important starting material in the manufacture of dyes:

b.

c.

d.

52. Identify the functional groups present in the following compounds.
a.

b. \(\mathrm{CH}_{3} \mathrm{O}\)

c.

-53. Mimosine is a natural product found in large quantities in the seeds and foliage of some legume plants and has been shown to cause inhibition of hair growth and hair loss in mice.

Mimosine, \(\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{2} \mathrm{O}_{4}\)
a. What functional groups are present in mimosine?
b. Give the hybridization of the eight carbon atoms in mimosine.
c. How many \(\sigma\) and \(\pi\) bonds are found in mimosine?
54. Minoxidil \(\left(\mathrm{C}_{9} \mathrm{H}_{15} \mathrm{~N}_{5} \mathrm{O}\right)\) is a compound produced by Pharmacia Company that has been approved as a treatment of some types of male pattern baldness.

a. Would minoxidil be more soluble in acidic or basic aqueous solution? Explain.
b. Give the hybridization of the five nitrogen atoms in minoxidil.
c. Give the hybridization of each of the nine carbon atoms in minoxidil.
d. Give approximate values of the bond angles marked \(a, b\), \(c, d\), and \(e\).
e. Including all the hydrogen atoms, how many \(\sigma\) bonds exist in minoxidil?
f. How many \(\pi\) bonds exist in minoxidil?
-55. For each of the following alcohols, give the systematic name and specify whether the alcohol is primary, secondary, or tertiary.
a.

b.

c.

56. Draw structural formulas for each of the following alcohols. Indicate whether the alcohol is primary, secondary, or tertiary.
a. 1-butanol
c. 2-methyl-1-butanol
b. 2-butanol
d. 2-methyl-2-butanol
-57. Name all of the alcohols that have the formula \(\mathrm{C}_{4} \mathrm{H}_{10} \mathrm{O}\). How many ethers have the formula \(\mathrm{C}_{4} \mathrm{H}_{10} \mathrm{O}\) ?
58. Name all the alcohols that have the formula \(\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}\). How many ethers have the formula \(\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}\) ?
59. Name all of the aldehydes and ketones that have the formula \(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\).
60. Name all the aldehydes and ketones that have the formula \(\mathrm{C}_{5} \mathrm{H}_{10} \mathrm{O}\).
-61. Name the following compounds.
a.

b.

c. \(\mathrm{CH}_{3}\)

62. Draw the structural formula for each of the following.
a. formaldehyde (methanal)
b. 4-heptanone
c. 3-chlorobutanal
d. 5,5-dimethyl-2-hexanone
63. Name the following compounds.
a.

b.

c. HCOOH
64. Draw a structural formula for each of the following.
a. 3-methylpentanoic acid
b. ethyl methanoate
c. methyl benzoate
d. 3-chloro-2,4-dimethylhexanoic acid
65. Which of the following statements is(are) false? Explain why the statement(s) is(are) false.

a. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{COCH}_{3}\) is a structural isomer of pentanoic acid.

b. \(\mathrm{HCCH}_{2} \mathrm{CH}_{2} \mathrm{CHCH}_{3}\) is a structural isomer of 2-methyl-3pentanone.
c. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\) is a structural isomer of 2-pentanol.
d. \(\mathrm{CH}_{2}=\mathrm{CHCHCH}_{3}\) is a structural isomer of 2-butenal. OH
e. Trimethylamine is a structural isomer of \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\).
66. Draw the isomer(s) specified. There may be more than one possible isomer for each part.
a. a cyclic compound that is an isomer of trans-2-butene
b. an ester that is an isomer of propanoic acid
c. a ketone that is an isomer of butanal
d. a secondary amine that is an isomer of butylamine
e. a tertiary amine that is an isomer of butylamine
f. an ether that is an isomer of 2-methyl-2-propanol
g. a secondary alcohol that is an isomer of 2-methyl-2-propanol

\section*{Reactions of Organic Compounds}
-67. Complete the following reactions.
a. \(\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CHCH}_{3}+\mathrm{H}_{2} \xrightarrow{\mathrm{Pt}}\)
b.

c.

68. Reagents such as \(\mathrm{HCl}, \mathrm{HBr}\), and \(\mathrm{HOH}\left(\mathrm{H}_{2} \mathrm{O}\right)\) can add across carbon-carbon double and triple bonds, with H forming a bond to one of the carbon atoms in the multiple bond and Cl , Br , or OH forming a bond to the other carbon atom in the multiple bond. In some cases, two products are possible. For the major organic product, the addition occurs so that the hydrogen atom in the reagent attaches to the carbon atom in the multiple bond that already has the greater number of hydrogen atoms bonded to it. With this rule in mind, draw the structure of the major product in each of the following reactions.
a. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}=\mathrm{CH}_{2}+\mathrm{H}_{2} \mathrm{O} \xrightarrow{\mathrm{H}^{+}}\)
b. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}=\mathrm{CH}_{2}+\mathrm{HBr} \longrightarrow\)
c. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{C} \equiv \mathrm{CH}+2 \mathrm{HBr} \longrightarrow\)
d.

69. When toluene \(\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}_{3}\right)\) reacts with chlorine gas in the presence of iron(III) catalyst, the product is a mixture of the ortho and para isomers of \(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{ClCH}_{3}\). However, when the reaction is light-catalyzed with no \(\mathrm{Fe}^{3+}\) catalyst present, the product is \(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}_{2} \mathrm{Cl}\). Explain.
70. Why is it preferable to produce chloroethane by the reaction of \(\mathrm{HCl}(g)\) with ethene than by the reaction of \(\mathrm{Cl}_{2}(g)\) with ethane? (See Exercise 68.)
-71. Using appropriate reactants, alcohols can be oxidized into aldehydes, ketones, and/or carboxylic acids. Primary alcohols can be oxidized into aldehydes, which can then be oxidized into carboxylic acids. Secondary alcohols can be oxidized into ketones, while tertiary alcohols do not undergo this type of oxidation. Give the structure of the product(s) resulting from the oxidation of each of the following alcohols.
a. 3-methyl-1-butanol
b. 3-methyl-2-butanol
c. 2-methyl-2-butanol
d.

e.

f.

72. Oxidation of an aldehyde yields a carboxylic acid:

Draw the structures for the products of the following oxidation reactions.
a. propanal \(\xrightarrow{[0 x x}\)
b. 2,3-dimethylpentanal \(\xrightarrow{\text { (0x) }}\)
c. 3-ethylbenzaldehyde \(\xrightarrow{+0 x}\)
-73. How would you synthesize each of the following?
a. 1,2-dibromopropane from propene
b. acetone (2-propanone) from an alcohol
c. tert-butyl alcohol (2-methyl-2-propanol) from an alkene (See Exercise 68.)
d. propanoic acid from an alcohol
74. What tests could you perform to distinguish between the following pairs of compounds?
a. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}, \quad \mathrm{CH}_{2}=\mathrm{CHCH}_{2} \mathrm{CH}_{3}\)
b.
\(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{COOH}\),

c.
\[
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH},
\]

d. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{NH}_{2}, \quad \mathrm{CH}_{3} \mathrm{OCH}_{3}\)
-75. How would you synthesize the following esters?
a. n-octylacetate
b. \(\stackrel{\stackrel{\mathrm{O}}{\|}}{\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{O}-\stackrel{\mathrm{CCH}}{2} \mathrm{CH}_{3}}\)
76. Complete the following reactions.
a. \(\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}+\mathrm{CH}_{3} \mathrm{OH} \rightarrow\)
b. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}+\mathrm{HCOOH} \rightarrow\)

\section*{Polymers}
77. Kel-F is a polymer with the structure

What is the monomer for Kel-F?
78. What monomer(s) must be used to produce the following polymers?
a. \(\left\{\underset{\mathrm{F}}{\mathrm{CH}}-\mathrm{CH}_{2}-\underset{\mathrm{F}}{\mathrm{CH}}-\mathrm{CH}_{2}-\underset{\mid}{\mathrm{CH}}-\mathrm{CH}_{2}-\right.\)
b.

c.

d.

e.

f.

(This polymer is Kodel, used to make fibers of stain-resistant carpeting.)
Classify these polymers as condensation or addition polymers. Which are copolymers?
79. "Super glue" contains methyl cyanoacrylate,

which readily polymerizes upon exposure to traces of water or alcohols on the surfaces to be bonded together. The polymer provides a strong bond between the two surfaces. Draw the structure of the polymer formed by methyl cyanoacrylate.
80. Isoprene is the repeating unit in natural rubber. The structure of isoprene is

a. Give a systematic name for isoprene.
b. When isoprene is polymerized, two polymers of the form

are possible. In natural rubber, the cis configuration is found. The polymer with the trans configuration about the double bond is called gutta percha and was once used in the manufacture of golf balls. Draw the structure of natural rubber and gutta percha showing three repeating units and the configuration about the carbon-carbon double bonds.
81. Kevlar, used in bulletproof vests, is made by the condensation copolymerization of the monomers

and

Draw the structure of a portion of the Kevlar chain.
82. The polyester formed from lactic acid,

is used for tissue implants and surgical sutures that will dissolve in the body. Draw the structure of a portion of this polymer.
83. Polyimides are polymers that are tough and stable at temperatures of up to \(400^{\circ} \mathrm{C}\). They are used as a protective coating on the quartz fibers used in fiber optics. What monomers were used to make the following polyimide?

84. The Amoco Chemical Company has successfully raced a car with a plastic engine. Many of the engine parts, including piston skirts, connecting rods, and valve-train components, were made of a polymer called Torlon:

What monomers are used to make this polymer?
85. Polystyrene can be made more rigid by copolymerizing styrene with divinylbenzene:

How does the divinylbenzene make the copolymer more rigid?
86. Polyesters containing double bonds are often crosslinked by reacting the polymer with styrene.
a. Draw the structure of the copolymer of
\[
\mathrm{HO}-\mathrm{CH}_{2} \mathrm{CH}_{2}-\mathrm{OH} \quad \text { and } \quad \mathrm{HO}_{2} \mathrm{C}-\mathrm{CH}=\mathrm{CH}-\mathrm{CO}_{2} \mathrm{H}
\]
b. Draw the structure of the crosslinked polymer (after the polyester has been reacted with styrene).
-87. Which of the following polymers would be stronger or more rigid? Explain your choices.
a. The copolymer of ethylene glycol and terephthalic acid or the copolymer of 1,2-diaminoethane and terephthalic acid (1,2-diaminoethane \(=\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\) )
b. The polymer of \(\mathrm{HO}-\left(\mathrm{CH}_{2}\right)_{6}-\mathrm{CO}_{2} \mathrm{H}\) or that of

c. Polyacetylene or polyethylene (The monomer in polyacetylene is ethyne.)
88. Poly(lauryl methacrylate) is used as an additive in motor oils to counter the loss of viscosity at high temperature. The structure is

The long hydrocarbon chain of poly(lauryl methacrylate) makes the polymer soluble in oil (a mixture of hydrocarbons with mostly 12 or more carbon atoms). At low temperatures the polymer is coiled into balls. At higher temperatures the balls uncoil and the polymer exists as long chains. Explain how this helps control the viscosity of oil.

\section*{Natural Polymers}
-89. Which of the amino acids in Fig. 22.18 contain the following functional groups in their R group?
a. alcohol
c. amine
b. carboxylic acid
d. amide
90. When pure crystalline amino acids are heated, decomposition generally occurs before the solid melts. Account for this observation. (Hint: Crystalline amino acids exist as \(\mathrm{H}_{3}{ }^{+}{ }^{+} \mathrm{CRHCOO}{ }^{-}\), called zwitterions.)
91. Aspartame, the artificial sweetener marketed under the name NutraSweet, is a methyl ester of a dipeptide:

a. What two amino acids are used to prepare aspartame?
b. There is concern that methanol may be produced by the decomposition of aspartame. From what portion of the molecule can methanol be produced? Write an equation for this reaction.
92. Glutathione, a tripeptide found in virtually all cells, functions as a reducing agent. The structure of glutathione is

What amino acids make up glutathione?
-93. Draw the structures of the two dipeptides that can be formed from serine and alanine.
94. Draw the structures of the tripeptides gly-ala-ser and ser-alagly. How many other tripeptides are possible using these three amino acids?
-95. Write the sequence of all possible tetrapeptides composed of the following amino acids.
a. two phenylalanines and two glycines
b. two phenylalanines, glycine, and alanine
96. How many different pentapeptides can be formed using five different amino acids?
-97. In general terms, what does the secondary structure of a protein represent? How is the secondary structure of a protein related to its function?
98. In general terms, what does the tertiary structure of a protein represent? Distinguish between the secondary and tertiary structures of a protein.
99. Give an example of amino acids that could give rise to the interactions pictured in Fig. 22.24 that maintain the tertiary structures of proteins.
100. What types of interactions can occur between the side chains of the following amino acids that would help maintain the tertiary structure of a protein?
a. cysteine and cysteine
c. glutamic acid and lysine
b. glutamine and serine
d. proline and leucine
-101. Oxygen is carried from the lungs to tissues by the protein hemoglobin in red blood cells. Sickle cell anemia is a disease resulting from abnormal hemoglobin molecules in which a valine is substituted for a single glutamic acid in normal hemoglobin. How might this substitution affect the structure of hemoglobin?
102. Over 100 different kinds of mutant hemoglobin molecules have been detected in humans. Unlike sickle cell anemia (see Exercise 101), not all of these mutations are as serious. In one nonlethal mutation, glutamine substitutes for a single glutamic acid in normal hemoglobin. Rationalize why this substitution is nonlethal.
-103. Draw cyclic structures for D-ribose and D-mannose.
104. Indicate the chiral carbon atoms found in the monosaccharides D-ribose and D-mannose.
-105. In addition to using numerical prefixes in the general names of sugars to indicate how many carbon atoms are present, we often use the prefixes keto- and aldo- to indicate whether the sugar is a ketone or an aldehyde. For example, the monosaccharide fructose is frequently called a ketohexose to emphasize that it contains six carbons as well as the ketone functional group. For each of the monosaccharides shown in Table 22.8 classify the sugars as aldohexoses, aldopentoses, ketohexoses, or ketopentoses.
106. Glucose can occur in three forms: two cyclic forms and one open-chain structure. In aqueous solution, only a tiny fraction of the glucose is in the open-chain form. Yet tests for the presence of glucose depend on reaction with the aldehyde group, which is found only in the open-chain form. Explain why these tests work.
-107. What are the structural differences between \(\alpha\) - and \(\beta\)-glucose? These two cyclic forms of glucose are the building blocks to form two different polymers. Explain.
108. Cows can digest cellulose, but humans can't. Why not?
-109. Which of the amino acids in Fig. 22.18 contain more than one chiral carbon atom? Draw the structures of these amino acids and indicate all chiral carbon atoms.
110. Why is glycine not optically active?
-111. Which of the noncyclic isomers of bromochloropropene are optically active?
112. Which of the noncyclic isomers of \(\mathrm{C}_{4} \mathrm{H}_{7} \mathrm{~F}\) are optically active?
-113. Aspartame, also known as NutraSweet, has the structure

How many chiral carbon atoms does aspartame have?
114. How many chiral carbon atoms does the following structure have?

115. Part of a certain DNA sequence is \(\mathrm{G}-\mathrm{G}-\mathrm{T}-\mathrm{C}-\mathrm{T}-\mathrm{A}-\mathrm{T}-\mathrm{A}-\mathrm{C}\). What is the complementary sequence?
116. The codons (words) in DNA (that specify which amino acid should be at a particular point in a protein) are three bases long. How many such three-letter words can be made from the four bases adenine, cytosine, guanine, and thymine?
-117. Which base will hydrogen-bond with uracil within an RNA molecule? Draw the structure of this base pair.
118. Tautomers are molecules that differ in the position of a hydrogen atom. A tautomeric form of thymine has the structure

If this tautomeric form, rather than the stable form of thymine, were present in a strand of DNA during replication, what would be the result?
-119. The base sequences in mRNA that code for certain amino acids are
Glu: GAA, GAG
Val: GUU, GUC, GUA, GUG
Met: AUG
Trp: UGG
Phe: UUU, UUC
Asp: GAU, GAC
These sequences are complementary to the sequences in DNA.
a. Give the corresponding sequences in DNA for the amino acids listed above.
b. Give a DNA sequence that would code for the peptide trp-glu-phe-met.
c. How many different DNA sequences can code for the tetrapeptide in part b ?
d. What is the peptide that is produced from the DNA sequence \(\mathrm{T}-\mathrm{A}-\mathrm{C}-\mathrm{C}-\mathrm{T}-\mathrm{G}-\mathrm{A}-\mathrm{A}-\mathrm{G}\) ?
e. What other DNA sequences would yield the same tripeptide as in part d?
120. The change of a single base in the DNA sequence for normal hemoglobin can encode for the abnormal hemoglobin giving rise to sickle cell anemia. Which base in the codon for glu in DNA is replaced to give the codon(s) for val? (See Exercises 101 and 119.)

\section*{Additional Exercises}
121. Draw the following incorrectly named compounds and name them correctly.
a. 2-ethyl-3-methyl-5-isopropylhexane
b. 2-ethyl-4-tert-butylpentane
c. 3-methyl-4-isopropylpentane
d. 2-ethyl-3-butyne
122. In the presence of light, chlorine can substitute for one (or more) of the hydrogens in an alkane. For the following reactions, draw the possible monochlorination products.
a. 2,2-dimethylpropane \(+\mathrm{Cl}_{2} \xrightarrow{h \nu}\)
b. 1,3-dimethylcyclobutane \(+\mathrm{Cl}_{2} \xrightarrow{h \nu}\)
c. 2,3-dimethylbutane \(+\mathrm{Cl}_{2} \xrightarrow{h \nu}\)
123. Polychlorinated dibenzo- \(p\)-dioxins (PCDDs) are highly toxic substances that are present in trace amounts as by-products of some chemical manufacturing processes. They have been implicated in a number of environmental incidents-for example, the chemical contamination at Love Canal and the herbicide spraying in Vietnam. The structure of dibenzo-pdioxin, along with the customary numbering convention, is

The most toxic PCDD is 2,3,7,8-tetrachloro-dibenzo-p-dioxin. Draw the structure of this compound. Also draw the structures of two other isomers containing four chlorine atoms.
124. Consider the reaction of propane with chlorine (and appropriate catalyst).
a. How many different monochloro products are possible? Name them.
b. How many different dichloro products are possible? Name them.
125. A common shorthand notation to draw organic structures is to use lines to represent \(\mathrm{C}-\mathrm{C}\) bonds. For example, the shorthand notation for the two structural isomers of the formula \(\mathrm{C}_{4} \mathrm{H}_{10}\) are:

At the end of each zigzag line is a carbon atom. The \(\mathrm{C}-\mathrm{H}\) bonds are omitted in such shorthand notation. Use line notation to illustrate the structural isomers of \(\mathrm{C}_{6} \mathrm{H}_{14}\).
126. Use shorthand line notation (see Exercise 125) to illustrate the structural isomers of \(\mathrm{C}_{7} \mathrm{H}_{16}\).
127. The two isomers having the formula \(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}\) boil at \(-23^{\circ} \mathrm{C}\) and \(78.5^{\circ} \mathrm{C}\). Draw the structure of the isomer that boils at \(-23^{\circ} \mathrm{C}\) and of the isomer that boils at \(78.5^{\circ} \mathrm{C}\).
128. Ignoring ring compounds, which isomer of \(\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O}_{2}\) should boil at the lowest temperature?
129. Explain why methyl alcohol is soluble in water in all proportions, while stearyl alcohol \(\left[\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{16} \mathrm{OH}\right]\) is a waxy solid that is not soluble in water.
130. Is octanoic acid more soluble in \(1 M \mathrm{HCl}, 1 M \mathrm{NaOH}\), or pure water? Explain. Drugs such as morphine \(\left(\mathrm{C}_{17} \mathrm{H}_{19} \mathrm{NO}_{3}\right)\) are often treated with strong acids. The most commonly used form of morphine is morphine hydrochloride \(\left(\mathrm{C}_{17} \mathrm{H}_{20} \mathrm{ClNO}_{3}\right)\). Why is morphine treated in this way? (Hint: Morphine is an amine.)
131. Consider the compounds butanoic acid, pentanal, \(n\)-hexane, and 1-pentanol. The boiling points of these compounds (in no
specific order) are \(69^{\circ} \mathrm{C}, 103^{\circ} \mathrm{C}, 137^{\circ} \mathrm{C}\), and \(164^{\circ} \mathrm{C}\). Match the boiling points to the correct compound.
132. A compound containing only carbon and hydrogen is \(85.63 \%\) C by mass. Reaction of this compound with \(\mathrm{H}_{2} \mathrm{O}\) produces a secondary alcohol as the major product and a primary alcohol as the minor product. (See Exercise 68.) If the molar mass of the hydrocarbon is between 50 and \(60 \mathrm{~g} / \mathrm{mol}\), name the compound.
133. Three different organic compounds have the formula \(\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}\). Only two of these isomers react with \(\mathrm{KMnO}_{4}\) (a strong oxidizing agent). What are the names of the products when these isomers react with excess \(\mathrm{KMnO}_{4}\) ?
134. Consider the following polymer:

Is this polymer a homopolymer or a copolymer, and is it formed by addition polymerization or condensation polymerization? What is(are) the monomer(s) for this polymer?
135. Nylon is named according to the number of C atoms between the N atoms in the chain. Nylon- 46 has 4 C atoms, then 6 C atoms, and this pattern repeats. Nylon- 6 always has 6 carbon atoms in a row. Speculate as to why nylon- 46 is stronger than nylon-6. (Hint: Consider the strengths of interchain forces.)
136. The polymer nitrile is a copolymer made from acrylonitrile and butadiene; it is used to make automotive hoses and gaskets. Draw the structure of nitrile. (Hint: See Table 22.7.)
137. Polyaramid is a term applied to polyamides containing aromatic groups. These polymers were originally made for use as tire cords but have since found many other uses.
a. Kevlar is used in bulletproof vests and many high-strength composites. The structure of Kevlar is

Which monomers are used to make Kevlar?
b. Nomex is a polyaramid used in fire-resistant clothing. It is a copolymer of

Draw the structure of the Nomex polymer. How do Kevlar and Nomex differ in their structures?
138. When acrylic polymers are burned, toxic fumes are produced. For example, in many airplane fires, more passenger deaths have been caused by breathing toxic fumes than by the fire itself. Using polyacrylonitrile as an example, what would you expect to be one of the most toxic, gaseous combustion products created in the reaction?
139. Ethylene oxide,

is an important industrial chemical. Although most ethers are unreactive, ethylene oxide is quite reactive. It resembles \(\mathrm{C}_{2} \mathrm{H}_{4}\) in its reactions in that addition reactions occur across the \(\mathrm{C}-\mathrm{O}\) bond in ethylene oxide.
a. Why is ethylene oxide so reactive? (Hint: Consider the bond angles in ethylene oxide as compared with those predicted by the VSEPR model.)
b. Ethylene oxide undergoes addition polymerization, forming a polymer used in many applications requiring a nonionic surfactant. Draw the structure of this polymer.
140. Another way of producing highly crosslinked polyesters is to use glycerol. Alkyd resins are a polymer of this type. The polymer forms very tough coatings when baked onto a surface and is used in paints for automobiles and large appliances. Draw the structure of the polymer formed from the condensation of

Explain how crosslinking occurs in this polymer.
141. Monosodium glutamate (MSG) is commonly used as a flavoring in foods. Draw the structure of MSG.
142. a. Use bond energies (see Table 8.5) to estimate \(\Delta H\) for the reaction of two molecules of glycine to form a peptide linkage.
b. Would you predict \(\Delta S\) to favor the formation of peptide linkages between two molecules of glycine?
c. Would you predict the formation of proteins to be a spontaneous process?
143. The reaction to form a phosphate-ester linkage between two nucleotides can be approximated as follows:

Would you predict the formation of a dinucleotide from two nucleotides to be a spontaneous process?
144. Considering your answers to Exercises 142 and 143, how can you justify the existence of proteins and nucleic acids in light of the second law of thermodynamics?
145. All amino acids have at least two functional groups with acidic or basic properties. In alanine, the carboxylic acid group has \(K_{\mathrm{a}}=4.5 \times 10^{-3}\) and the amino group has \(K_{\mathrm{b}}=7.4 \times 10^{-5}\). Three ions of alanine are possible when alanine is dissolved in water. Which of these ions would predominate in a solution with \(\left[\mathrm{H}^{+}\right]=1.0 \mathrm{M}\) ? In a solution with \(\left[\mathrm{OH}^{-}\right]=1.0 \mathrm{M}\) ?
146. The average molar mass of one base pair of nucleotides in DNA is approximately \(600 \mathrm{~g} / \mathrm{mol}\). The spacing between successive base pairs is about 0.34 nm , and a complete turn in the helical structure of DNA occurs about every 3.4 nm . If a DNA molecule has a molar mass of \(4.5 \times 10^{9} \mathrm{~g} / \mathrm{mol}\), approximately how many complete turns exist in the DNA \(\alpha\)-helix structure?
147. When heat is added to proteins, the hydrogen bonding in the secondary structure is disrupted. What are the algebraic signs of \(\Delta H\) and \(\Delta S\) for the denaturation process?
148. In glycine, the carboxylic acid group has \(K_{\mathrm{a}}=4.3 \times 10^{-3}\) and the amino group has \(K_{\mathrm{b}}=6.0 \times 10^{-5}\). Use these equilibrium constant values to calculate the equilibrium constants for the following.
a. \({ }^{+} \mathrm{H}_{3} \mathrm{NCH}_{2} \mathrm{CO}_{2}{ }^{-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CO}_{2}{ }^{-}+\mathrm{H}_{3} \mathrm{O}^{+}\)
b. \(\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CO}_{2}^{-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}+\mathrm{OH}^{-}\)
c. \({ }^{+} \mathrm{H}_{3} \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H} \rightleftharpoons 2 \mathrm{H}^{+}+\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CO}_{2}{ }^{-}\)

\section*{ChemWork Problems}

These multiconcept problems (and additional ones) are found interactively online with the same type of assistance a student would get from an instructor.
149. Name each of the following alkanes.
a. \(\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{CH}_{3}\)

150. Name each of the following alkanes.

151. Name each of the following cyclic alkanes.
a.

b.

c.

d.

152. Name each of the following alkenes and alkynes.
a.

b. C

d. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}-\mathrm{C} \equiv \mathrm{CH}\)

153. a. Name each of the following alcohols.
\[
\mathrm{HO}-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}
\]

b. Name each of the following alcohols, including the stereochemistry if cis-trans isomers are possible.

154. Name each of the following organic compounds.

b. \(\mathrm{CH}_{3} \mathrm{CHCH}_{2} \mathrm{CHCH}_{2} \stackrel{\mathrm{CH}}{\mathrm{CH}} \stackrel{\mathrm{CH}}{\mathrm{CH}}\)
c. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\)

e.

155. Esterification reactions are carried out in the presence of a strong acid such as \(\mathrm{H}_{2} \mathrm{SO}_{4}\). A carboxylic acid is warmed with an alcohol, and an ester and water are formed. You may have made a fruity-smelling ester in the lab when studying organic functional groups. Name the carboxylic acid that is necessary to complete the following esterification reaction.

156. Rank these organic compounds in terms of increasing water solubility (from least water soluble to most water soluble).

\section*{Challenge Problems}
157. Ethyl caprate is an ester used in the manufacture of wine bouquets. It is sometimes called "cognac essence." Combustion analysis of a sample of ethyl caprate shows it to be \(71.89 \%\) C, \(12.13 \%\) hydrogen, and \(15.98 \%\) O by mass. Hydrolysis (reaction with water) of the ester produces ethanol and a carboxylic acid. The molar mass of the carboxylic acid is \(172 \mathrm{~g} / \mathrm{mol}\), and the R group attached to the COOH group of the acid is a straight chain alkane. What is the structure of ethyl caprate?
158. Estimate \(\Delta H\) for the following reactions using bond energies given in Table 8.5.
\[
3 \mathrm{CH}_{2}=\mathrm{CH}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow 3 \mathrm{CH}_{3}-\mathrm{CH}_{3}(\mathrm{~g})
\]

The enthalpies of formation for \(\mathrm{C}_{6} \mathrm{H}_{6}(g)\) and \(\mathrm{C}_{6} \mathrm{H}_{12}(g)\) are 82.9 and \(-90.3 \mathrm{~kJ} / \mathrm{mol}\), respectively. Calculate \(\Delta H^{\circ}\) for the two reactions using standard enthalpies of formation from Appendix 4 . Account for any differences between the results obtained from the two methods.
159. The isoelectric point of an amino acid is the pH at which the molecule has no net charge. For glycine, that point would be the pH at which virtually all glycine molecules are in the form \({ }^{+} \mathrm{H}_{3} \mathrm{NCH}_{2} \mathrm{CO}_{2}{ }^{-}\). This form of glycine is amphoteric since it can act as both an acid and a base. If we assume that the principal equilibrium at the isoelectric point has the best acid reacting with the best base present, then the reaction is
\(2^{+} \mathrm{H}_{3} \mathrm{NCH}_{2} \mathrm{CO}_{2}^{-} \rightleftharpoons \mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CO}_{2}^{-}+{ }^{+} \mathrm{H}_{3} \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}\)
Assuming this reaction is the principal equilibrium, then the following relationship must hold true:
\[
\begin{equation*}
\left[\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CO}_{2}^{-}\right]=\left[{ }^{+} \mathrm{H}_{3} \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}\right] \tag{ii}
\end{equation*}
\]

Use this result and your answer to part c of Exercise 148 to calculate the pH at which equation (ii) is true. This pH will be the isoelectric point of glycine.
160. In 1994 chemists at Texas A \& M University reported the synthesis of a non-naturally occurring amino acid ( \(C \& E\) News, April 18, 1994, pp. 26-27):

a. To which naturally occurring amino acid is this compound most similar?
b. A tetrapeptide, phe-met-arg-phe- \(\mathrm{NH}_{2}\), is synthesized in the brains of rats addicted to morphine and heroin. (The
\(-\mathrm{NH}_{2}\) indicates that the peptide ends in \(-\stackrel{\|}{\mathrm{C}}-\mathrm{NH}_{2}\) instead of \(-\mathrm{CO}_{2} \mathrm{H}\).) The TAMU scientists synthesized a similar tetrapeptide, with the synthetic amino acid above replacing one of the original amino acids. Draw a structure for the tetrapeptide containing the synthetic amino acid.
c. Indicate the chiral carbon atoms in the synthetic amino acid.
161. The structure of tartaric acid is

a. Is the form of tartaric acid pictured below optically active? Explain.

(Note: The dashed lines show groups behind the plane of the page. The wedges show groups in front of the plane.)
b. Draw the optically active forms of tartaric acid.
162. Consider a sample of a hydrocarbon at 0.959 atm and 298 K . Upon combusting the entire sample in oxygen, you collect a mixture of gaseous carbon dioxide and water vapor at 1.51 atm and 375 K . This mixture has a density of \(1.391 \mathrm{~g} / \mathrm{L}\) and occupies a volume four times as large as that of the pure hydrocarbon. Determine the molecular formula of the hydrocarbon and name it.
163. Mycomycin, a naturally occurring antibiotic produced by the fungus Nocardia acidophilus, has the molecular formula \(\mathrm{C}_{13} \mathrm{H}_{10} \mathrm{O}_{2}\) and the systematic name \(3,5,7,8\)-tridecatetraene10,12 -diynoic acid. Draw the structure of mycomycin.
164. Sorbic acid is used to prevent mold and fungus growth in some food products, especially cheeses. The systematic name for sorbic acid is 2,4 -hexadienoic acid. Draw structures for the four geometrical isomers of sorbic acid.
165. Consider the following reactions. For parts b-d, see Exercise 68.
a. When \(\mathrm{C}_{5} \mathrm{H}_{12}\) is reacted with \(\mathrm{Cl}_{2}(g)\) in the presence of ultraviolet light, four different monochlorination products form. What is the structure of \(\mathrm{C}_{5} \mathrm{H}_{12}\) in this reaction?
b. When \(\mathrm{C}_{4} \mathrm{H}_{8}\) is reacted with \(\mathrm{H}_{2} \mathrm{O}\), a tertiary alcohol is produced as the major product. What is the structure of \(\mathrm{C}_{4} \mathrm{H}_{8}\) in this reaction?
c. When \(\mathrm{C}_{7} \mathrm{H}_{12}\) is reacted with HCl , 1-chloro-1-methylcyclohexane is produced as the major product. What are the two possible structures for \(\mathrm{C}_{7} \mathrm{H}_{12}\) in this reaction?
d. When a hydrocarbon is reacted with \(\mathrm{H}_{2} \mathrm{O}\) and the major product of this reaction is then oxidized, acetone (2-propanone) is produced. What is the structure of the hydrocarbon in this reaction?
e. When \(\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}\) is oxidized, a carboxylic acid is produced. What are the possible structures for \(\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}\) in this reaction?
166. Polycarbonates are a class of thermoplastic polymers that are used in the plastic lenses of eyeglasses and in the shells of bicycle helmets. A polycarbonate is made from the reaction of bisphenol \(\mathrm{A}(\mathrm{BPA})\) with phosgene \(\left(\mathrm{COCl}_{2}\right)\) :

Phenol \(\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right)\) is used to terminate the polymer (stop its growth).
a. Draw the structure of the polycarbonate chain formed from the above reaction.
b. Is this reaction a condensation or an addition polymerization?
167. A urethane linkage occurs when an alcohol adds across the carbon-nitrogen double bond in an isocyanate:

Polyurethanes (formed from the copolymerization of a diol with a diisocyanate) are used in foamed insulation and a variety of other construction materials. What is the structure of the polyurethane formed by the following reaction?

168. ABS plastic is a tough, hard plastic used in applications requiring shock resistance. The polymer consists of three monomer units: acrylonitrile \(\left(\mathrm{C}_{3} \mathrm{H}_{3} \mathrm{~N}\right)\), butadiene \(\left(\mathrm{C}_{4} \mathrm{H}_{6}\right)\), and styrene \(\left(\mathrm{C}_{8} \mathrm{H}_{8}\right)\).
a. Draw two repeating units of ABS plastic assuming that the three monomer units react in a \(1: 1: 1\) mole ratio and react in the same order as the monomers listed above.
b. A sample of ABS plastic contains \(8.80 \% \mathrm{~N}\) by mass. It took \(0.605 \mathrm{~g} \mathrm{Br}_{2}\) to react completely with a \(1.20-\mathrm{g}\) sample of ABS plastic. What is the percent by mass of acrylonitrile, butadiene, and styrene in this polymer sample?
c. ABS plastic does not react in a \(1: 1: 1\) mole ratio among the three monomer units. Using the results from part b, determine the relative numbers of the monomer units in this sample of ABS plastic.
169. Stretch a rubber band while holding it gently to your lips. Then slowly let it relax while still in contact with your lips.
a. What happens to the temperature of the rubber band on stretching?
b. Is the stretching an exothermic or endothermic process?
c. Explain the above result in terms of intermolecular forces.
d. What is the sign of \(\Delta S\) and \(\Delta G\) for stretching the rubber band?
e. Give the molecular explanation for the sign of \(\Delta S\) for stretching.
170. Alcohols are very useful starting materials for the production of many different compounds. The following conversions, starting with 1-butanol, can be carried out in two or more steps. Show the steps (reactants/catalysts) you would follow to carry out the conversions, drawing the formula for the organic product in each step. For each step, a major product must be produced. (See Exercise 68.) (Hint: In the presence of \(\mathrm{H}^{+}\), an alcohol is converted into an alkene and water. This is the exact reverse of the reaction of adding water to an alkene to form an alcohol.)
a. 1-butanol \(\longrightarrow\) butane
b. 1-butanol \(\longrightarrow\) 2-butanone
171. A chemical "breathalyzer" test works because ethanol in the breath is oxidized by the dichromate ion (orange) to form acetic acid and chromium(III) ion (green). The balanced reaction is
\[
\begin{array}{r}
3 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(a q)+2 \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+2 \mathrm{H}^{+}(a q) \longrightarrow \\
3 \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)+4 \mathrm{Cr}^{3+}(a q)+11 \mathrm{H}_{2} \mathrm{O}(l)
\end{array}
\]

You analyze a breathalyzer test in which \(4.2 \mathrm{mg} \mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}\) was reduced. Assuming the volume of the breath was 0.500 L at \(30 .{ }^{\circ} \mathrm{C}\) and \(750 . \mathrm{mm} \mathrm{Hg}\), what was the mole percent alcohol of the breath?
172. Estradiol is a female hormone with the following structure:

How many chiral carbon atoms are in estradiol?

\section*{Integrative Problems}

These problems require the integration of multiple concepts to find the solutions.
173. An organometallic compound is one containing at least one metal-carbon bond. An example of an organometallic species is \(\left(\mathrm{CH}_{3} \mathrm{CH}_{2}\right) \mathrm{MBr}\), which contains a metal-ethyl bond.
a. If \(\mathrm{M}^{2+}\) has the electron configuration \([\mathrm{Ar}] 3 d^{10}\), what is the percent by mass of M in \(\left(\mathrm{CH}_{3} \mathrm{CH}_{2}\right) \mathrm{MBr}\) ?
b. A reaction involving \(\left(\mathrm{CH}_{3} \mathrm{CH}_{2}\right) \mathrm{MBr}\) is the conversion of a ketone to an alcohol as illustrated here:

How does the hybridization of the starred carbon atom change, if at all, in going from reactants to products?
c. What is the systematic name of the product? (Hint: In this shorthand notation, all the \(\mathrm{C}-\mathrm{H}\) bonds have been eliminated and the lines represent \(\mathrm{C}-\mathrm{C}\) bonds, unless shown differently. As is typical of most organic compounds, each carbon atom has four bonds to it and the oxygen atoms have only two bonds.)
174. Helicenes are extended fused polyaromatic hydrocarbons that have a helical or screw-shaped structure.
a. A \(0.1450-\mathrm{g}\) sample of solid helicene is combusted in air to give \(0.5063 \mathrm{~g} \mathrm{CO}_{2}\). What is the empirical formula of this helicene?
b. If a \(0.0938-\mathrm{g}\) sample of this helicene is dissolved in 12.5 g of solvent to give a 0.0175 M solution, what is the molecular formula of this helicene?
c. What is the balanced reaction for the combustion of this helicene?

\section*{Marathon Problems}

These problems are designed to incorporate several concepts and techniques into one situation.
175. For each of the following, fill in the blank with the correct response. All of these fill-in-the-blank problems pertain to material covered in the sections on alkanes, alkenes and alkynes, aromatic hydrocarbons, and hydrocarbon derivatives.
a. The first "organic" compound to be synthesized in the laboratory, rather than being isolated from nature, was
\(\qquad\) which was prepared from \(\qquad\) -.
b. An organic compound whose carbon-carbon bonds are all single bonds is said to be
c. The general orientation of the four pairs of electrons around the carbon atoms in alkanes is \(\qquad\) _.
d. Alkanes in which the carbon atoms form a single unbranched chain are said to be \(\qquad\) alkanes.
e. Structural isomerism occurs when two molecules have the same number of each type of atom but exhibit different arrangements of the \(\qquad\) between those atoms.
f. The systematic names of all saturated hydrocarbons have the ending \(\qquad\) added to a root name that indicates the number of carbon atoms in the molecule.
g. For a branched hydrocarbon, the root name for the hydrocarbon comes from the number of carbon atoms in the __ continuous chain in the molecule.
h. The positions of substituents along the hydrocarbon framework of a molecule are indicated by the of the carbon atom to which the substituents are attached.
i. The major use of alkanes has been in \(\qquad\) reactions, as a source of heat and light.
j. With very reactive agents, such as the halogen elements, alkanes undergo \(\qquad\) reactions, whereby a new atom replaces one or more hydrogen atoms of the alkane.
k. Alkenes and alkynes are characterized by their ability to undergo rapid, complete \(\qquad\) reactions, by which other atoms attach themselves to the carbon atoms of the double or triple bond.
1. Unsaturated fats may be converted to saturated fats by the process of \(\qquad\) -.
\(\mathbf{m}\). Benzene is the parent member of the group of hydrocarbons called \(\qquad\) hydrocarbons.
n. An atom or group of atoms that imparts new and characteristic properties to an organic molecule is called a group.
o. A \(\qquad\) alcohol is one in which there is only one hydrocarbon group attached to the carbon atom holding the hydroxyl group.
p. The simplest alcohol, methanol, is prepared industrially by the hydrogenation of \(\qquad\) _.
q. Ethanol is commonly prepared by the \(\qquad\) of certain sugars by yeast.
r. Both aldehydes and ketones contain the \(\qquad\) group, but they differ in where this group occurs along the hydrocarbon chain.
s. Aldehydes and ketones can be prepared by \(\qquad\) of the corresponding alcohol.
t. Organic acids, which contain the \(\qquad\) group, are typically weak acids.
u. The typically sweet-smelling compounds called
\(\qquad\) result from the condensation reaction of an organic acid with an \(\qquad\)
176. Choose one of the following terms to match the description given in statements (1)-(17). All of the following pertain to proteins or carbohydrates.
a. aldohexose
h. disulfide
m. ketohexoses
b. saliva
i. globular
n. oxytocin
c. cellulose
j. glycogen
o. pleated sheet
d. \(\mathrm{CH}_{2} \mathrm{O}\)
e. cysteine
k. glycoside
p. polypeptide
q. primary structure
f. denaturation
1. hydrophobic
g. disaccharides
(1) polymer consisting of many amino acids
(2) linkage that forms between two cysteine species
(3) peptide hormone that triggers milk secretion
(4) proteins with roughly spherical shape
(5) sequence of amino acids in a protein
(6) silk protein secondary structure
(7) water-repelling amino acid side chain
(8) amino acid responsible for permanent wave in hair
(9) breakdown of a protein's tertiary and/or secondary structure
(10) animal polymer of glucose
(11) \(-\mathrm{C}-\mathrm{O}-\mathrm{C}-\) bond between rings in disaccharide sugars
(12) empirical formula leading to the name carbohydrate
(13) where enzymes catalyzing the breakdown of glycoside linkages are found
(14) six-carbon ketone sugars
(15) structural component of plants, polymer of glucose
(16) sugars consisting of two monomer units
(17) six-carbon aldehyde sugars
177. For each of the following, fill in the blank with the correct response(s). All of the following pertain to nucleic acids.
a. The substance in the nucleus of the cell that stores and transmits genetic information is DNA, which stands for
b. The basic repeating monomer units of DNA and RNA are called
c. The pentose deoxyribose is found in DNA, whereas
\(\qquad\) is found in RNA.
d. The basic linkage in DNA or RNA between the sugar molecule and phosphoric acid is a phosphate linkage.
e. The bases on opposite strands of DNA are said to be ___ to each other, which means the bases fit together specifically by hydrogen bonding to one another.
f. In a strand of normal DNA, the base \(\qquad\) is always found paired with the base adenine, whereas \(\qquad\) is always found paired with cytosine.
g. A given segment of the DNA molecule, which contains the molecular coding for a specific protein to be synthesized, is referred to as a \(\qquad\)
h. During protein synthesis, \(\qquad\) RNA molecules attach to and transport specific amino acids to the appropriate position on the pattern provided by \(\qquad\) RNA molecules.
i. The codes specified by \(\qquad\) are responsible for assembling the correct primary structure of proteins.

\section*{Appendix 1 Mathematical Procedures}

\section*{A1.1 Exponential Notation}

The numbers characteristic of scientific measurements are often very large or very small; thus it is convenient to express them using powers of 10 . For example, the number \(1,300,000\) can be expressed as \(1.3 \times 10^{6}\), which means multiply 1.3 by 10 six times, or
\[
1.3 \times 10^{6} \times 1.3 \times \underbrace{10 \times 10 \times 10 \times 10 \times 10 \times 10}_{10^{6}=1 \text { million }}
\]

Note that each multiplication by 10 moves the decimal point one place to the right:
\[
\begin{gathered}
1.3 \times 10=13 \\
13 \times 10=130 \\
130 \times 10=1300
\end{gathered}
\]

Thus the easiest way to interpret the notation \(1.3 \times 10^{6}\) is that it means move the decimal point in 1.3 to the right six times:
\[
1.3 \times 10^{6}=1 \underbrace{300000}_{123456} 00=1,300,000
\]

Using this notation, the number 1985 can be expressed as \(1.985 \times 10^{3}\). Note that the usual convention is to write the number that appears before the power of 10 as a number between 1 and 10 . To end up with the number 1.985, which is between 1 and 10, we had to move the decimal point three places to the left. To compensate for that, we must multiply by \(10^{3}\), which says that to get the intended number we start with 1.985 and move the decimal point three places to the right; that is:
\[
1.985 \times 10^{3}=1985
\]

Some other examples are given below.
\begin{tabular}{|cc|}
\hline Number & \begin{tabular}{c} 
Exponential \\
Notation
\end{tabular} \\
\hline 5.6 & \(5.6 \times 10^{0}\) or \(5.6 \times 1\) \\
\hline 39 & \(3.9 \times 10^{1}\) \\
\hline 943 & \(9.43 \times 10^{2}\) \\
\hline 1126 & \(1.126 \times 10^{3}\) \\
\hline
\end{tabular}

So far we have considered numbers greater than 1 . How do we represent a number such as 0.0034 in exponential notation? We start with a number between 1 and 10 and divide by the appropriate power of 10 :
\[
0.0034=\frac{3.4}{10 \times 10 \times 10}=\frac{3.4}{10^{3}}=3.4 \times 10^{-3}
\]

Division by 10 moves the decimal point one place to the left. Thus the number
\[
\text { 0. } \underbrace{0}_{7} \underbrace{0}_{6} \underbrace{0}_{4} \underbrace{0}_{2} \underbrace{0} 4
\]
can be written as \(1.4 \times 10^{-7}\).
To summarize, we can write any number in the form
\[
N \times 10^{ \pm n}
\]
where \(N\) is between 1 and 10 and the exponent \(n\) is an integer. If the sign preceding \(n\) is positive, it means the decimal point in \(N\) should be moved \(n\) places to the right. If a negative sign precedes \(n\), the decimal point in \(N\) should be moved \(n\) places to the left.

\section*{Multiplication and Division}

When two numbers expressed in exponential notation are multiplied, the initial numbers are multiplied and the exponents of 10 are added:
\[
\left(M \times 10^{m}\right)\left(N \times 10^{n}\right)=(M N) \times 10^{m+n}
\]

For example (to two significant figures, as required),
\[
\left(3.2 \times 10^{4}\right)\left(2.8 \times 10^{3}\right)=9.0 \times 10^{7}
\]

When the numbers are multiplied, if a result greater than 10 is obtained for the initial number, the decimal point is moved one place to the left and the exponent of 10 is increased by 1 :
\[
\begin{aligned}
\left(5.8 \times 10^{2}\right)\left(4.3 \times 10^{8}\right) & =24.9 \times 10^{10} \\
& =2.49 \times 10^{11} \\
& =2.5 \times 10^{11} \quad \text { (two significant figures) }
\end{aligned}
\]

Division of two numbers expressed in exponential notation involves normal division of the initial numbers and subtraction of the exponent of the divisor from that of the dividend. For example,
\[
\underbrace{\frac{4.8 \times 10^{8}}{2.1 \times 10^{3}}}=\frac{4.8}{2.1} \times 10^{(8-3)}=2.3 \times 10^{5}
\]

If the initial number resulting from the division is less than 1 , the decimal point is moved one place to the right and the exponent of 10 is decreased by 1 . For example,
\[
\begin{aligned}
\frac{6.4 \times 10^{3}}{8.3 \times 10^{5}}=\frac{6.4}{8.3} \times 10^{(3-5)} & =0.77 \times 10^{-2} \\
& =7.7 \times 10^{-3}
\end{aligned}
\]

\section*{Addition and Subtraction}

To add or subtract numbers expressed in exponential notation, the exponents of the numbers must be the same. For example, to add \(1.31 \times 10^{5}\) and \(4.2 \times 10^{4}\), we must rewrite one number so that the exponents of both are the same. The number \(1.31 \times 10^{5}\) can be written \(13.1 \times 10^{4}\), since moving the decimal point one place to the right can be compensated for by decreasing the exponent by 1 . Now we can add the numbers:
\[
\begin{array}{r}
13.1 \times 10^{4} \\
+4.2 \times 10^{4} \\
\hline 17.3 \times 10^{4}
\end{array}
\]

In correct exponential notation the result is expressed as \(1.73 \times 10^{5}\).
To perform addition or subtraction with numbers expressed in exponential notation, only the initial numbers are added or subtracted. The exponent of the result is the same as those of the numbers being added or subtracted. To subtract \(1.8 \times 10^{2}\) from \(8.99 \times 10^{3}\), we write
\[
\begin{array}{r}
8.99 \times 10^{3} \\
-0.18 \times 10^{3} \\
\hline 8.81 \times 10^{3}
\end{array}
\]

\section*{Powers and Roots}

When a number expressed in exponential notation is taken to some power, the initial number is taken to the appropriate power and the exponent of 10 is multiplied by that power:
\[
\left(N \times 10^{n}\right)^{m}=N^{m} \times 10^{m \cdot n}
\]

For example,*
\[
\begin{aligned}
\left(7.5 \times 10^{2}\right)^{3} & =7.5^{3} \times 10^{3 \cdot 2} \\
& =422 \times 10^{6} \\
& =4.22 \times 10^{8} \\
& =4.2 \times 10^{8} \quad \text { (two significant figures) }
\end{aligned}
\]

When a root is taken of a number expressed in exponential notation, the root of the initial number is taken and the exponent of 10 is divided by the number representing the root:
\[
\sqrt{N \times 10^{n}}=\left(n \times 10^{n}\right)^{1 / 2}=\sqrt{N} \times 10^{n / 2}
\]

For example,
\[
\begin{aligned}
\left(2.9 \times 10^{6}\right)^{1 / 2} & =\sqrt{2.9} \times 10^{6 / 2} \\
& =1.7 \times 10^{3}
\end{aligned}
\]

Because the exponent of the result must be an integer, we may sometimes have to change the form of the number so that the power divided by the root equals an integer. For example,
\[
\begin{aligned}
\sqrt{1.9 \times 10^{3}}=\left(1.9 \times 10^{3}\right)^{1 / 2} & =\left(0.19 \times 10^{4}\right)^{1 / 2} \\
& =\sqrt{0.19} \times 10^{2} \\
& =0.44 \times 10^{2} \\
& =4.4 \times 10^{1}
\end{aligned}
\]

In this case, we moved the decimal point one place to the left and increased the exponent from 3 to 4 to make \(n / 2\) an integer.

The same procedure is followed for roots other than square roots. For example,
\[
\begin{aligned}
\sqrt[3]{6.9 \times 10^{5}}=\left(6.9 \times 10^{5}\right)^{1 / 3} & =\left(0.69 \times 10^{6}\right)^{1 / 3} \\
& =\sqrt[3]{0.69} \times 10^{2} \\
& =0.88 \times 10^{2} \\
& =8.8 \times 10^{1}
\end{aligned}
\]
and
\[
\begin{aligned}
\sqrt[3]{4.6 \times 10^{10}}=\left(4.6 \times 10^{10}\right)^{1 / 3} & =\left(46 \times 10^{9}\right)^{1 / 3} \\
& =\sqrt[3]{46} \times 10^{3} \\
& =3.6 \times 10^{3}
\end{aligned}
\]

\footnotetext{
*Refer to the instruction booklet for your calculator for directions concerning how to take roots and powers of numbers.
}

\section*{A1.2 Logarithms}

A logarithm is an exponent. Any number \(N\) can be expressed as follows:
\[
N=10^{x}
\]

For example,
\[
\begin{aligned}
1000 & =10^{3} \\
100 & =10^{2} \\
10 & =10^{1} \\
1 & =10^{0}
\end{aligned}
\]

The common, or base 10 , logarithm of a number is the power to which 10 must be taken to yield the number. Thus, since \(1000=10^{3}\),
\[
\log 1000=3
\]

Similarly,
\[
\begin{aligned}
\log 100 & =2 \\
\log 10 & =1 \\
\log 1 & =0
\end{aligned}
\]

For a number between 10 and 100, the required exponent of 10 will be between 1 and 2. For example, \(65=10^{1.8129}\); that is, \(\log 65=1.8129\). For a number between 100 and 1000 , the exponent of 10 will be between 2 and 3 . For example, \(650=10^{2.8129}\) and \(\log 650=2.8129\).

A number \(N\) greater than 0 and less than 1 can be expressed as follows:
\[
N=10^{-x}=\frac{1}{10^{x}}
\]

For example,
\[
\begin{aligned}
0.001 & =\frac{1}{1000}=\frac{1}{10^{3}}=10^{-3} \\
0.01 & =\frac{1}{100}=\frac{1}{10^{2}}=10^{-2} \\
0.1 & =\frac{1}{10}=\frac{1}{10^{1}}=10^{-1}
\end{aligned}
\]

Thus
\[
\begin{aligned}
\log 0.001 & =-3 \\
\log 0.01 & =-2 \\
\log 0.1 & =-1
\end{aligned}
\]

Although common logs are often tabulated, the most convenient method for obtaining such logs is to use an electronic calculator. On most calculators the number is first entered and then the \(\log\) key is punched. The \(\log\) of the number then appears in the display.* Some examples are given below. You should reproduce these results on your calculator to be sure that you can find common logs correctly.
\begin{tabular}{|cc|}
\hline Number & Common Log \\
\hline 36 & 1.56 \\
\hline 1849 & 3.2669 \\
\hline 0.156 & -0.807 \\
\hline \(1.68 \times 10^{-5}\) & -4.775 \\
\hline
\end{tabular}

\footnotetext{
*Refer to the instruction booklet for your calculator for the exact sequence to obtain logarithms.
}

Note that the number of digits after the decimal point in a common log is equal to the number of significant figures in the original number.

Since logs are simply exponents, they are manipulated according to the rules for exponents. For example, if \(A=10^{x}\) and \(B=10^{y}\), then their product is
\[
A \cdot B=10^{x} \cdot 10^{y}=10^{x+y}
\]
and
\[
\log A B=x+y=\log A+\log B
\]

For division, we have
\[
\frac{A}{B}=\frac{10^{x}}{10^{y}}=10^{x-y}
\]
and
\[
\log \frac{A}{B}=x-y=\log A-\log B
\]

For a number raised to a power, we have
\[
A^{n}=\left(10^{x}\right)^{n}=10^{n x}
\]
and
\[
\log A^{n}=n x=n \log A
\]

It follows that
\[
\log \frac{1}{A^{n}}=\log A^{-n}=-n \log A
\]
or, for \(n=1\),
\[
\log \frac{1}{A}=-\log A
\]

When a common log is given, to find the number it represents, we must carry out the process of exponentiation. For example, if the \(\log\) is 2.673 , then \(N=10^{2.673}\). The process of exponentiation is also called taking the antilog, or the inverse logarithm. This operation is usually carried out on calculators in one of two ways. The majority of calculators require that the \(\log\) be entered first and then the keys INV and LOG pressed in succession. For example, to find \(N=10^{2.673}\) we enter 2.673 and then press INV and LOG. The number 471 will be displayed; that is, \(N=471\). Some calculators have a \(10^{x}\) key. In that case, the log is entered first and then the \(10^{x}\) key is pressed. Again, the number 471 will be displayed.

Natural logarithms, another type of logarithm, are based on the number 2.7183, which is referred to as \(e\). In this case, a number is represented as \(N=e^{x}=2.7183^{x}\). For example,
\[
\begin{gathered}
N=7.15=e^{x} \\
\ln 7.15=x=1.967
\end{gathered}
\]

To find the natural log of a number using a calculator, the number is entered and then the \(\ln\) key is pressed. Use the following examples to check your technique for finding natural logs with your calculator:
\begin{tabular}{|cc|}
\hline Number \(\left(e^{x}\right)\) & Natural Log \((x)\) \\
\hline 784 & 6.664 \\
\hline \(1.61 \times 10^{3}\) & 7.384 \\
\hline \(1.00 \times 10^{-7}\) & -16.118 \\
\hline 1.00 & 0 \\
\hline
\end{tabular}

FIGURE A. 1 Graph of the linear equation \(y=3 x+4\).

If a natural logarithm is given, to find the number it represents, exponentiation to the base \(e(2.7183)\) must be carried out. With many calculators this is done using a key marked \(e^{x}\) (the natural \(\log\) is entered, with the correct sign, and then the \(e^{x}\) key is pressed). The other common method for exponentiation to base \(e\) is to enter the natural \(\log\) and then press the INV and \(1 n\) keys in succession. The following examples will help you check your technique:
\begin{tabular}{|cc|}
\hline \(\ln N(x)\) & \(N\left(e^{x}\right)\) \\
\hline 3.256 & 25.9 \\
\hline-5.169 & \(5.69 \times 10^{-3}\) \\
\hline 13.112 & \(4.95 \times 10^{5}\) \\
\hline
\end{tabular}

Since natural logarithms are simply exponents, they are also manipulated according to the mathematical rules for exponents given earlier for common logs.

\section*{A1.3 Graphing Functions}

In interpreting the results of a scientific experiment, it is often useful to make a graph. If possible, the function to be graphed should be in a form that gives a straight line. The equation for a straight line (a linear equation) can be represented by the general form
\[
y=m x+b
\]
where \(y\) is the dependent variable, \(x\) is the independent variable, \(m\) is the slope, and \(b\) is the intercept with the \(y\) axis.

To illustrate the characteristics of a linear equation, the function \(y=3 x+4\) is plotted in Fig. A.1. For this equation \(m=3\) and \(b=4\). Note that the \(y\) intercept occurs when \(x=0\). In this case the intercept is 4 , as can be seen from the equation \((b=4)\).

The slope of a straight line is defined as the ratio of the rate of change in \(y\) to that in \(x\) :
\[
m=\text { slope }=\frac{\Delta y}{\Delta x}
\]

For the equation \(y=3 x+4, y\) changes three times as fast as \(x\) (since \(x\) has a coefficient of 3 ). Thus the slope in this case is 3 . This can be verified from the graph. For the triangle shown in Fig. A.1,
\[
\Delta y=34-10=24 \text { and } \Delta x=10-2=8
\]

TABLE A. 1 | Some Useful Linear Equations in Standard Form
\begin{tabular}{lllll}
\begin{tabular}{c} 
Equation \\
\((y=m x+b)\)
\end{tabular} & \begin{tabular}{c} 
What Is Plotted \\
\((\boldsymbol{y}\) vs. \(x)\)
\end{tabular} & \begin{tabular}{c} 
Slope \\
\((m)\)
\end{tabular} & \begin{tabular}{l} 
Intercept \((b)\)
\end{tabular} & \begin{tabular}{c} 
Section \\

\end{tabular} \\
{\([A]=-k t+[A]_{0}\)} & {\([A]\) vs. \(t\)} & \(-k\) & {\([A]_{0}\)} & 12.4 \\
\hline \(\ln [A]=-k t+\ln [A]_{0}\) & \(\ln [A]\) vs.t & \(-k\) & \(\ln [A]_{0}\) & 12.4 \\
\hline\(\frac{1}{[A]}=k t+\frac{1}{[A]_{0}}\) & \(\frac{1}{[A]}\) vs.t & \(k\) & \(\frac{1}{[A]_{0}}\) & 12.4 \\
\hline \(\ln P_{\text {vap }}=-\frac{\Delta H_{\text {vap }}}{R}\left(\frac{1}{T}\right)+C\) & \(\ln P_{\text {vap }}\) vs. \(\frac{1}{T}\) & \(\frac{-\Delta H_{\text {vap }}}{R}\) & \(C\) & 10.8 \\
\hline
\end{tabular}

FIGURE A. 2 Graph of \(\ln k\) versus \(1 / T\).

Thus
\[
\text { Slope }=\frac{\Delta y}{\Delta x}=\frac{24}{8}=3
\]

The preceding example illustrates a general method for obtaining the slope of a line from the graph of that line. Simply draw a triangle with one side parallel to the \(y\) axis and the other parallel to the \(x\) axis as shown in Fig. A.1. Then determine the lengths of the sides to give \(y\) and \(x\), respectively, and compute the ratio \(\Delta y / \Delta x\).

Sometimes an equation that is not in standard form can be changed to the form \(y=m x+b\) by rearrangement or mathematical manipulation. An example is the equation \(k=A e^{-E_{\mathrm{a}} / R T}\) described in Section 12.7 , where \(A, E_{\mathrm{a}}\), and \(R\) are constants; \(k\) is the dependent variable; and \(1 / T\) is the independent variable. This equation can be changed to standard form by taking the natural logarithm of both sides,
\[
\ln k=\ln A e^{-E_{\mathrm{a}} / R T}=\ln A+\ln e^{-E_{\mathrm{a}} / R T}=\ln A-\frac{E_{\mathrm{a}}}{R T}
\]
noting that the \(\log\) of a product is equal to the sum of the logs of the individual terms and that the natural \(\log\) of \(e^{-E_{\mathrm{a}} / R T}\) is simply the exponent \(-E_{\mathrm{a}} / R T\). Thus, in standard form, the equation \(k=A e^{-E_{2} / R T}\) is written
\[
\underbrace{\ln k}_{\uparrow}=\underbrace{-\frac{E_{\mathrm{a}}}{R}}_{\substack{\uparrow \\ m}} \underbrace{\text { 考 }}_{\substack{\left(\frac{1}{T}\right)}} \ln
\]

A plot of \(\ln k\) versus \(1 / T\) (Fig. A.2) gives a straight line with slope \(-E_{\mathrm{a}} / R\) and intercept \(\ln A\).

Other linear equations that are useful in the study of chemistry are listed in standard form in Table A.1.

\section*{A1.4 Solving Quadratic Equations}

A quadratic equation, a polynomial in which the highest power of \(x\) is 2 , can be written as
\[
a x^{2}+b x+c=0
\]

One method for finding the two values of \(x\) that satisfy a quadratic equation is to use the quadratic formula:
\[
x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a}
\]
where \(a, b\), and \(c\) are the coefficients of \(x^{2}, x\), and the constant, respectively. For example, in determining \(\left[\mathrm{H}^{+}\right]\)in a solution of \(1.0 \times 10^{-4} M\) acetic acid the following expression arises:
\[
1.8 \times 10^{-5}=\frac{x^{2}}{1.0 \times 10^{-4}-x}
\]
which yields
\[
x^{2}+\left(1.8 \times 10^{-5}\right) x-1.8 \times 10^{-9}=0
\]
where \(a=1, b=1.8 \times 10^{-5}\), and \(c=-1.8 \times 10^{-9}\). Using the quadratic formula, we have
\[
\begin{aligned}
x & =\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a} \\
& =\frac{-1.8 \times 10^{-5} \pm \sqrt{3.24 \times 10^{-10}-(4)(1)\left(-1.8 \times 10^{-9}\right)}}{2(1)} \\
& =\frac{-1.8 \times 10^{-5} \pm \sqrt{3.24 \times 10^{-10}+7.2 \times 10^{-9}}}{2} \\
& =\frac{-1.8 \times 10^{-5} \pm \sqrt{7.5 \times 10^{-9}}}{2} \\
& =\frac{-1.8 \times 10^{-5} \pm 8.7 \times 10^{-5}}{2}
\end{aligned}
\]

Thus
\[
x=\frac{6.9 \times 10^{-5}}{2}=3.5 \times 10^{-5}
\]
and
\[
x=\frac{-10.5 \times 10^{-5}}{2}=-5.2 \times 10^{-5}
\]

Note that there are two roots, as there always will be, for a polynomial in \(x^{2}\). In this case \(x\) represents a concentration of \(\mathrm{H}^{+}\)(see Section 14.3). Thus the positive root is the one that solves the problem, since a concentration cannot be a negative number.

A second method for solving quadratic equations is by successive approximations, a systematic method of trial and error. A value of \(x\) is guessed and substituted into the equation everywhere \(x\) (or \(x^{2}\) ) appears, except for one place. For example, for the equation
\[
x^{2}+\left(1.8 \times 10^{-5}\right) x-1.8 \times 10^{-9}=0
\]
we might guess \(x=2 \times 10^{-5}\). Substituting that value into the equation gives
\[
x^{2}+\left(1.8 \times 10^{-5}\right)\left(2 \times 10^{-5}\right)-1.8 \times 10^{-9}=0
\]
or
\[
x^{2}=1.8 \times 10^{-9}-3.6 \times 10^{-10}=1.4 \times 10^{-9}
\]

Thus
\[
x=3.7 \times 10^{-5}
\]

Note that the guessed value of \(x\left(2 \times 10^{5}\right)\) is not the same as the value of \(x\) that is calculated ( \(3.7 \times 10^{-5}\) ) after inserting the estimated value. This means that \(x=2 \times 10^{-5}\) is not the correct solution, and we must try another guess. We take the calculated value \(\left(3.7 \times 10^{-5}\right)\) as our next guess:
\[
\begin{gathered}
x^{2}+\left(1.8 \times 10^{-5}\right)\left(3.7 \times 10^{-5}\right)-1.8 \times 10^{-9}=0 \\
x^{2}=1.8 \times 10^{-9}-6.7 \times 10^{-10}=1.1 \times 10^{-9}
\end{gathered}
\]

Thus
\[
x=3.3 \times 10^{-5}
\]

Now we compare the two values of \(x\) again:
\[
\begin{array}{ll}
\text { Guessed: } & x=3.7 \times 10^{-5} \\
\text { Calculated: } & x=3.3 \times 10^{-5}
\end{array}
\]

These values are closer but not close enough. Next we try \(3.3 \times 10^{-5}\) as our guess:
\[
\begin{gathered}
x^{2}+\left(1.8 \times 10^{-5}\right)\left(3.3 \times 10^{-5}\right)-1.8 \times 10^{-9}=0 \\
x^{2}=1.8 \times 10^{-9}-5.9 \times 10^{-10}=1.2 \times 10^{-9}
\end{gathered}
\]

Thus
\[
x=3.5 \times 10^{-5}
\]

Again we compare:
\[
\begin{array}{ll}
\text { Guessed: } & x=3.3 \times 10^{-5} \\
\text { Calculated: } & x=3.5 \times 10^{-5}
\end{array}
\]

Next we guess \(x=3.5 \times 10^{-5}\) to give
\[
\begin{gathered}
x^{2}+\left(1.8 \times 10^{-5}\right)\left(3.5 \times 10^{-5}\right)-1.8 \times 10^{-9}=0 \\
x^{2}=1.8 \times 10^{-9}-6.3 \times 10^{-10}=1.2 \times 10^{-9}
\end{gathered}
\]

Thus
\[
x=3.5 \times 10^{-5}
\]

Now the guessed value and the calculated value are the same; we have found the correct solution. Note that this agrees with one of the roots found with the quadratic formula in the first method.

To further illustrate the method of successive approximations, we will solve Example 14.17 using this procedure. In solving for \(\left[\mathrm{H}^{+}\right]\)for \(0.010 M \mathrm{H}_{2} \mathrm{SO}_{4}\), we obtain the following expression:
\[
1.2 \times 10^{-2}=\frac{x(0.010+x)}{0.010-x}
\]
which can be rearranged to give
\[
x=\left(1.2 \times 10^{-2}\right)\left(\frac{0.010-x}{0.010+x}\right)
\]

We will guess a value for \(x\), substitute it into the right side of the equation, and then calculate a value for \(x\). In guessing a value for \(x\), we know it must be less than 0.010 , since a larger value will make the calculated value for \(x\) negative and the guessed and calculated values will never match. We start by guessing \(x=0.005\).

The results of the successive approximations are shown in the following table:
\begin{tabular}{|cll|}
\hline Trial & \begin{tabular}{c} 
Guessed \\
Value for \(\boldsymbol{x}\)
\end{tabular} & \begin{tabular}{c} 
Calculated \\
Value for \(\boldsymbol{x}\)
\end{tabular} \\
\hline 1 & 0.0050 & 0.0040 \\
\hline 2 & 0.0040 & 0.0051 \\
\hline 3 & 0.00450 & 0.00455 \\
\hline 4 & 0.00452 & 0.00453 \\
\hline
\end{tabular}

Note that the first guess was close to the actual value and that there was oscillation between 0.004 and 0.005 for the guessed and calculated values. For trial 3, an average of these values was used as the guess, and this led rapidly to the correct value ( 0.0045 to the correct number of significant figures). Also, note that it is useful to carry extra digits until the correct value is obtained. That value can then be rounded off to the correct number of significant figures.

The method of successive approximations is especially useful for solving polynomials containing \(x\) to a power of 3 or higher. The procedure is the same as for quadratic equations: Substitute a guessed value for \(x\) into the equation for every \(x\) term but one, and then solve for \(x\). Continue this process until the guessed and calculated values agree.

\section*{A1.5 Uncertainties in Measurements}

Like all the physical sciences, chemistry is based on the results of measurements. Every measurement has an inherent uncertainty, so if we are to use the results of measurements to reach conclusions, we must be able to estimate the sizes of these uncertainties.

For example, the specification for a commercial 500-mg acetaminophen (the active painkiller in Tylenol) tablet is that each batch of tablets must contain 450 to 550 mg of acetaminophen per tablet. Suppose that chemical analysis gave the following results for a batch of acetaminophen tablets: \(428 \mathrm{mg}, 479 \mathrm{mg}, 442 \mathrm{mg}\), and 435 mg . How can we use these results to decide if the batch of tablets meets the specification? Although the details of how to draw such conclusions from measured data are beyond the scope of this text, we will consider some aspects of how this is done. We will focus here on the types of experimental uncertainty, the expression of experimental results, and a simplified method for estimating experimental uncertainty when several types of measurement contribute to the final result.

\section*{Types of Experimental Error}

There are two types of experimental uncertainty (error). A variety of names are applied to these types of errors:
\[
\begin{aligned}
& \text { Precision } \longleftrightarrow \text { random error } \equiv \text { indeterminate error } \\
& \text { Accuracy } \longleftrightarrow \text { systematic error } \equiv \text { determinate error }
\end{aligned}
\]

The difference between the two types of error is well illustrated by the attempts to hit a target shown in Fig. 1.8 in Chapter 1.

Random error is associated with every measurement. To obtain the last significant figure for any measurement, we must always make an estimate. For example, we interpolate between the marks on a meter stick, a buret, or a balance. The precision of replicate measurements (repeated measurements of the same type) reflects the size of the random errors. Precision refers to the reproducibility of replicate measurements.

The accuracy of a measurement refers to how close it is to the true value. An inaccurate result occurs as a result of some flaw (systematic error) in the measurement: the presence of an interfering substance, incorrect calibration of an instrument, operator error, and so on. The goal of chemical analysis is to eliminate systematic error, but random errors can only be minimized. In practice, an experiment is almost always done to find an unknown value (the true value is not known-someone is trying to obtain that value by doing the experiment). In this case the precision of several replicate determinations is used to assess the accuracy of the result. The results of the replicate experiments are expressed as an average (which we assume is close to the true value) with an error limit that gives some indication of how close the average value may be to the true value. The error limit represents the uncertainty of the experimental result.

\section*{Expression of Experimental Results}

If we perform several measurements, such as for the analysis for acetaminophen in painkiller tablets, the results should express two things: the average of the measurements and the size of the uncertainty.

There are two common ways of expressing an average: the mean and the median. The mean \((\bar{x})\) is the arithmetic average of the results, or
\[
\text { Mean }=\bar{x}=\sum_{i=1}^{n} \frac{x_{i}}{n}=\frac{x_{1}+x_{2}+\cdots+x_{n}}{n}
\]
where \(\Sigma\) means take the sum of the values. The mean is equal to the sum of all the measurements divided by the number of measurements. For the acetaminophen results given previously, the mean is
\[
\bar{x}=\frac{428+479+442+435}{4}=446 \mathrm{mg}
\]

The median is the value that lies in the middle among the results. Half the measurements are above the median and half are below the median. For results of \(465 \mathrm{mg}, 485 \mathrm{mg}\), and 492 mg , the median is 485 mg . When there is an even number of results, the median is the average of the two middle results. For the acetaminophen results, the median is
\[
\frac{442+435}{2}=438 \mathrm{mg}
\]

There are several advantages to using the median. If a small number of measurements is made, one value can greatly affect the mean. Consider the results for the analysis of acetaminophen: \(428 \mathrm{mg}, 479 \mathrm{mg}, 442 \mathrm{mg}\), and 435 mg . The mean is 446 mg , which is larger than three of the four weights. The median is 438 mg , which lies near the three values that are relatively close to one another.

In addition to expressing an average value for a series of results, we must express the uncertainty. This usually means expressing either the precision of the measurements or the observed range of the measurements. The range of a series of measurements is defined by the smallest value and the largest value. For the analytical results on the acetaminophen tablets, the range is from 428 mg to 479 mg . Using this range, we can express the results by saying that the true value lies between 428 mg and 479 mg . That is, we can express the amount of acetaminophen in a typical tablet as \(446 \pm 33 \mathrm{mg}\), where the error limit is chosen to give the observed range (approximately).

The most common way to specify precision is by the standard deviation, \(s\), which for a small number of measurements is given by the formula
\[
s=\left[\frac{\sum_{i=1}^{n}\left(x_{\mathrm{i}}-\bar{x}\right)^{2}}{n-1}\right]^{1 / 2}
\]
where \(x_{i}\) is an individual result, \(\bar{x}\) is the average (either mean or median), and \(n\) is the total number of measurements. For the acetaminophen example, we have
\[
s=\left[\frac{(428-446)^{2}+(479-446)^{2}+(442-446)^{2}+(435-446)^{2}}{4-1}\right]^{1 / 2}=23
\]

Thus we can say the amount of acetaminophen in the typical tablet in the batch of tablets is 446 mg with a sample standard deviation of 23 mg . Statistically this means that any additional measurement has a \(68 \%\) probability ( 68 chances out of 100 ) of being between \(423 \mathrm{mg}(446-23)\) and \(469 \mathrm{mg}(446+23)\). Thus the standard deviation is a measure of the precision of a given type of determination.

The standard deviation gives us a means of describing the precision of a given type of determination using a series of replicate results. However, it is also useful to be able to estimate the precision of a procedure that involves several measurements by combining the precisions of the individual steps. That is, we want to answer the
following question: How do the uncertainties propagate when we combine the results of several different types of measurements? There are many ways to deal with the propagation of uncertainty. We will discuss only one simple method here.

\section*{A Simplified Method for Estimating Experimental Uncertainty}

To illustrate this method, we will consider the determination of the density of an irregularly shaped solid. In this determination we make three measurements. First, we measure the mass of the object on a balance. Next, we must obtain the volume of the solid. The easiest method for doing this is to partially fill a graduated cylinder with a liquid and record the volume. Then we add the solid and record the volume again. The difference in the measured volumes is the volume of the solid. We can then calculate the density of the solid from the equation
\[
D=\frac{M}{V_{2}-V_{1}}
\]
where \(M\) is the mass of the solid, \(V_{1}\) is the initial volume of liquid in the graduated cylinder, and \(V_{2}\) is the volume of liquid plus solid. Suppose we get the following results:
\[
\begin{aligned}
M & =23.06 \mathrm{~g} \\
V_{1} & =10.4 \mathrm{~mL} \\
V_{2} & =13.5 \mathrm{~mL}
\end{aligned}
\]

The calculated density is
\[
\frac{23.06 \mathrm{~g}}{13.5 \mathrm{~mL}-10.4 \mathrm{~mL}}=7.44 \mathrm{~g} / \mathrm{mL}
\]

Now suppose that the precision of the balance used is \(\pm 0.02 \mathrm{~g}\) and that the volume measurements are precise to \(\pm 0.05 \mathrm{~mL}\). How do we estimate the uncertainty of the density? We can do this by assuming a worst case. That is, we assume the largest uncertainties in all measurements, and see what combinations of measurements will give the largest and smallest possible results (the greatest range). Since the density is the mass divided by the volume, the largest value of the density will be that obtained using the largest possible mass and the smallest possible volume:
\[
\begin{gathered}
\text { Largest possible mass }=23.06+.02 \\
D_{\max }=\frac{23.08}{13.45-10.45}=7.69 \mathrm{~g} / \mathrm{mL} \\
\text { Smallest possible } V_{2} \quad \text { Largest possible } V_{1}
\end{gathered}
\]

The smallest value of the density is
\[
D_{\min }=\frac{23.04}{13.35-\underset{\nearrow}{~ S m a l l e s t ~ p o s s i b l e ~ m a s s ~}}=7.20 \mathrm{~g} / \mathrm{mL}
\]

Thus the calculated range is from 7.20 to 7.69 and the average of these values is 7.44. The error limit is the number that gives the high and low range values when added and subtracted from the average. Therefore, we can express the density as \(7.44 \pm 0.25 \mathrm{~g} / \mathrm{mL}\), which is the average value plus or minus the quantity that gives the range calculated by assuming the largest uncertainties.

Analysis of the propagation of uncertainties is useful in drawing qualitative conclusions from the analysis of measurements. For example, suppose that we obtained the preceding results for the density of an unknown alloy and we want to know if it is one of the following alloys:

Alloy A: \(D=7.58 \mathrm{~g} / \mathrm{mL}\)
Alloy B: \(D=7.42 \mathrm{~g} / \mathrm{mL}\)
Alloy C: \(D=8.56 \mathrm{~g} / \mathrm{mL}\)
We can safely conclude that the alloy is not C. But the values of the densities for alloys A and B are both within the inherent uncertainty of our method. To distinguish between \(A\) and \(B\), we need to improve the precision of our determination: The obvious choice is to improve the precision of the volume measurement.

The worst-case method is very useful in estimating uncertainties when the results of several measurements are combined to calculate a result. We assume the maximum uncertainty in each measurement and calculate the minimum and maximum possible result. These extreme values describe the range and thus the error limit.

\section*{Appandix e The Quantitative Kinetic Molecular Model}

FIGURE A. 3 An ideal gas particle in a cube whose sides are of length \(L\). The particle collides elastically with the walls in a random, straight-line motion.

We have seen that the kinetic molecular model successfully accounts for the properties of an ideal gas. This appendix will show in some detail how the postulates of the kinetic molecular model lead to an equation corresponding to the experimentally obtained ideal gas equation.

Recall that the particles of an ideal gas are assumed to be volumeless, to have no attraction for each other, and to produce pressure on their container by colliding with the container walls.

Suppose there are \(n\) moles of an ideal gas in a cubical container with sides each of length \(L\). Assume each gas particle has a mass \(m\) and that it is in rapid, random, straightline motion colliding with the walls, as shown in Fig. A.3. The collisions will be assumed to be elastic-no loss of kinetic energy occurs. We want to compute the force on the walls from the colliding gas particles and then, since pressure is force per unit area, to obtain an expression for the pressure of the gas.

Before we can derive the expression for the pressure of a gas, we must first discuss some characteristics of velocity. Each particle in the gas has a particular velocity \(u\) that can be divided into components \(u_{x}, u_{y}\), and \(u_{z}\), as shown in Fig. A.4. First, using \(u_{x}\) and \(u_{y}\) and the Pythagorean theorem, we can obtain \(u_{x y}\) as shown in Fig. A.4(c):
\[
\begin{aligned}
& \qquad u_{x y}^{2}=u_{x}^{2}+u_{y}^{2} \\
& \begin{array}{c}
\text { Hypotenuse of } \\
\text { Hight triangle }
\end{array} \\
& \text { Sides of } \\
& \text { right triangle }
\end{aligned}
\]

Then, constructing another triangle as shown in Fig. A.4(c), we find
or
\[
\begin{gathered}
u^{2}=u_{x y}^{2}+u_{z}^{2} \\
u^{2}=\overbrace{u_{x}^{2}+u_{y}^{2}}^{\uparrow}+u_{z}^{2}
\end{gathered}
\]

Now let's consider how an "average" gas particle moves. For example, how often does this particle strike the two walls of the box that are perpendicular to the \(x\) axis? It is important to realize that only the \(x\) component of the velocity affects the particle's impacts on these two walls, as shown in Fig. A.5(a). The larger the \(x\) component of the velocity, the faster the particle travels between these two walls, and the more impacts per unit of time it will make on these walls. Remember, the pressure of the gas is due to these collisions with the walls.

(c)
(c) In the xy plane,
\[
u_{x}^{2}+u_{y}^{2}=u_{x y}^{2}
\]
by the Pythagorean theorem. Since \(u_{x y}\) and \(u_{x}\) are also perpendicular,
\[
u^{2}=u_{x y}^{2}+u_{z}^{2}=u_{x}^{2}+u_{y}^{2}+u_{z}^{2}
\]

(a)

(b)

FIGURE A. 5 (a) Only the \(x\) component of the gas particle's velocity affects the frequency of impacts on the shaded walls, the walls that are perpendicular to the \(x\) axis.
(b) For an elastic collision, there is an exact reversal of the x component of the velocity and of the total velocity. The change in momentum (final - initial) is then
\[
-m u_{x}-m u_{x}=-2 m u_{x}
\]

The collision frequency (collisions per unit of time) with the two walls that are perpendicular to the \(x\) axis is given by
\[
\begin{aligned}
(\text { Collision frequency })_{x} & =\frac{\text { velocity in the } x \text { direction }}{\text { distance between the walls }} \\
& =\frac{u_{x}}{L}
\end{aligned}
\]

Next, what is the force of a collision? Force is defined as mass times acceleration (change in velocity per unit of time):
\[
F=m a=m\left(\frac{\Delta u}{\Delta t}\right)
\]
where \(F\) represents force, \(a\) represents acceleration, \(\Delta u\) represents a change in velocity, and \(\Delta t\) represents a given length of time.

Since we assume that the particle has constant mass, we can write
\[
F=\frac{m \Delta u}{\Delta t}=\frac{\Delta(m u)}{\Delta t}
\]

The quantity \(m u\) is the momentum of the particle (momentum is the product of mass and velocity), and the expression \(F=\Delta(m u) / \Delta t\) implies that force is the change in momentum per unit of time. When a particle hits a wall perpendicular to the \(x\) axis, as shown in Fig. A.5(b), an elastic collision results in an exact reversal of the \(x\) component of velocity. That is, the sign, or direction, of \(u_{x}\) reverses when the particle collides with one of the walls perpendicular to the \(x\) axis. Thus the final momentum is the negative, or opposite, of the initial momentum. Remember that an elastic collision means that there is no change in the magnitude of the velocity. The change in momentum in the \(x\) direction is then
\[
\text { Change in momentum } \begin{aligned}
\Delta\left(m u_{x}\right) & =\text { final momentum }- \text { initial momentum } \\
& =-m u_{x}-m u_{x} \\
& \text { Final } \\
& \text { momentum } \\
& \text { in } x \text { direction } \\
& \text { momentum } \\
& =-2 m u_{x}
\end{aligned}
\]

But we are interested in the force the gas particle exerts on the walls of the box. Since we know that every action produces an equal but opposite reaction, the change in momentum with respect to the wall on impact is \(-\left(-2 m u_{x}\right)\), or \(2 m u_{x}\).

Recall that since force is the change in momentum per unit of time,
\[
\text { Force }_{x}=\frac{\Delta\left(m u_{x}\right)}{\Delta t}
\]
for the walls perpendicular to the \(x\) axis.
This expression can be obtained by multiplying the change in momentum per impact by the number of impacts per unit of time:
\[
\begin{gathered}
\text { Force }_{x}=\left(2 m u_{x}\right)\left(\frac{u_{x}}{L}\right)=\text { change in momentum per unit of time } \\
\text { Change in momentum } \\
\begin{array}{c}
\pi \\
\text { per impact }
\end{array} \\
\text { Impacts per } \\
\text { unit of time }
\end{gathered}
\]

That is,
\[
\text { Force }_{x}=\frac{2 m u_{x}^{2}}{L}
\]

So far we have considered only the two walls of the box perpendicular to the \(x\) axis. We can assume that the force on the two walls perpendicular to the \(y\) axis is given by
\[
\text { Force }_{y}=\frac{2 m u_{y}^{2}}{L}
\]
and that on the two walls perpendicular to the \(z\) axis by
\[
\text { Force }_{z}=\frac{2 m u_{z}^{2}}{L}
\]

Since we have shown that
\[
u^{2}=u_{x}^{2}+u_{y}^{2}+u_{z}^{2}
\]
the total force on the box is
\[
\begin{aligned}
\text { Force }_{\text {TOTAL }} & =\text { force }_{x}+\text { force }_{y}+\text { force }_{z} \\
& =\frac{2 m u_{x}^{2}}{L}+\frac{2 m u_{y}^{2}}{L}+\frac{2 m u_{z}^{2}}{L} \\
& =\frac{2 m}{L}\left(u_{x}^{2}+u_{y}^{2}+u_{z}^{2}\right)=\frac{2 m}{L}\left(u^{2}\right)
\end{aligned}
\]

Now since we want the average force, we use the average of the square of the velocity \(\left(\overline{u^{2}}\right)\) to obtain
\[
\overline{\text { Force }}_{\text {TOTAL }}=\frac{2 m}{L}\left(\overline{u^{2}}\right)
\]

Next, we need to compute the pressure (force per unit of area)
\[
\begin{aligned}
& \text { Pressure due to "average" particle }=\frac{\overline{\text { force }}_{\text {TOTAL }}}{\operatorname{area}_{\mathrm{TOTAL}}} \\
&=\frac{\frac{2 m \overline{u^{2}}}{L}}{6 L^{2}}=\frac{m \overline{u^{2}}}{3 L^{3}} \\
& \begin{array}{ll}
\text { The } 6 \text { sides } \\
\text { of the cube }
\end{array} \quad \begin{array}{l}
\text { Area of } \\
\text { each side }
\end{array}
\end{aligned}
\]

Since the volume \(V\) of the cube is equal to \(L^{3}\), we can write
\[
\text { Pressure }=P=\frac{m \overline{u^{2}}}{3 V}
\]

So far we have considered the pressure on the walls due to a single, "average" particle. Of course, we want the pressure due to the entire gas sample. The number of particles in a given gas sample can be expressed as follows:
\[
\text { Number of gas particles }=n N_{\mathrm{A}}
\]
where \(n\) is the number of moles and \(N_{\mathrm{A}}\) is Avogadro's number.
The total pressure on the box due to \(n\) moles of a gas is therefore
\[
P=n N_{\mathrm{A}} \frac{m \overline{u^{2}}}{3 V}
\]

Next we want to express the pressure in terms of the kinetic energy of the gas molecules. Kinetic energy (the energy due to motion) is given by \(\frac{1}{2} m u^{2}\), where \(m\) is the mass and \(u\) is the velocity. Since we are using the average of the velocity squared \(\left(\overline{u^{2}}\right)\), and since \(m \overline{u^{2}}=2\left(\frac{1}{2} m \overline{u^{2}}\right)\), we have
\[
P=\left(\frac{2}{3}\right) \frac{n N_{\mathrm{A}}\left(\frac{1}{2} m \overline{u^{2}}\right)}{V}
\]
or
\[
\frac{P V}{n}=\left(\frac{2}{3}\right) N_{\mathrm{A}}\left(\frac{1}{2} m \overline{u^{2}}\right)
\]

Thus, based on the postulates of the kinetic molecular model, we have been able to derive an equation that has the same form as the ideal gas equation,
\[
\frac{P V}{n}=R T
\]

This agreement between experiment and theory supports the validity of the assumptions made in the kinetic molecular model about the behavior of gas particles, at least for the limiting case of an ideal gas.

Although volumetric and gravimetric analyses are still very commonly used, spectroscopy is the technique most often used for modern chemical analysis. Spectroscopy is the study of electromagnetic radiation emitted or absorbed by a given chemical species. Since the quantity of radiation absorbed or emitted can be related to the quantity of the absorbing or emitting species present, this technique can be used for quantitative analysis. There are many spectroscopic techniques, as electromagnetic radiation spans a wide range of energies to include X rays; ultraviolet, infrared, and visible light; and microwaves, to name a few of its familiar forms. We will consider here only one procedure, which is based on the absorption of visible light.

If a liquid is colored, it is because some component of the liquid absorbs visible light. In a solution the greater the concentration of the light-absorbing substance, the more light absorbed, and the more intense the color of the solution.

The quantity of light absorbed by a substance can be measured by a spectrophotometer, shown schematically in Fig. A.6. This instrument consists of a source that emits all wavelengths of light in the visible region (wavelengths of \(\sim 400\) to 700 nm ); a monochromator, which selects a given wavelength of light; a sample holder for the solution being measured; and a detector, which compares the intensity of incident light \(I_{0}\) to the intensity of light after it has passed through the sample \(I\). The ratio \(I / I_{0}\), called the transmittance, is a measure of the fraction of light that passes through the sample. The amount of light absorbed is given by the absorbance \(A\), where
\[
A=-\log \frac{I}{I_{0}}
\]

The absorbance can be expressed by the Beer-Lambert law:
\[
A=\epsilon l c
\]
where \(\epsilon\) is the molar absorptivity or the molar extinction coefficient (in \(\mathrm{L} / \mathrm{mol} \cdot \mathrm{cm}\) ), \(l\) is the distance the light travels through the solution (in cm ), and \(c\) is the concentration of the absorbing species (in mol/L). The Beer-Lambert law is the basis for using spectroscopy in quantitative analysis. If \(\epsilon\) and \(l\) are known, measuring \(A\) for a solution allows us to calculate the concentration of the absorbing species in the solution.

Suppose we have a pink solution containing an unknown concentration of \(\mathrm{Co}^{2}(a q)\) ions. A sample of this solution is placed in a spectrophotometer, and the absorbance is measured at a wavelength where \(\epsilon\) for \(\mathrm{Co}^{2+}(a q)\) is known to be \(12 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{cm}\). The absorbance \(A\) is found to be 0.60 . The width of the sample tube is 1.0 cm . We want to determine the concentration of \(\mathrm{Co}^{2+}(a q)\) in the solution. This problem can be solved by a straightforward application of the Beer-Lambert law,
\[
A=\epsilon l c
\]

FIGURE A. 6 A schematic diagram of a simple spectrophotometer. The source emits all wavelengths of visible light, which are dispersed using a prism or grating and then focused, one wavelength at a time, onto the sample. The detector compares the intensity of the incident light ( \(l_{0}\) ) to the intensity of the light after it has passed through the sample ( \(/\) ).
where
\[
\begin{aligned}
A & =0.60 \\
\epsilon & =\frac{12 \mathrm{~L}}{\mathrm{~mol} \cdot \mathrm{~cm}} \\
l & =\text { light path }=1.0 \mathrm{~cm}
\end{aligned}
\]

Solving for the concentration gives
\[
c=\frac{A}{\epsilon l}=\frac{0.06}{\left(12 \frac{\mathrm{~L}}{\mathrm{~mol} \cdot \mathrm{~cm}}\right)(1.0 \mathrm{~cm})}=5.0 \times 10^{-2} \mathrm{~mol} / \mathrm{L}
\]

To obtain the unknown concentration of an absorbing species from the measured absorbance, we must know the product \(\epsilon l\), since
\[
c=\frac{A}{\epsilon l}
\]

We can obtain the product \(\epsilon l\) by measuring the absorbance of a solution of known concentration, since
\[
\boldsymbol{\epsilon l}=\frac{A}{c} \stackrel{\text { Measured using a }}{\substack{\text { Mpectrophotometer } \\ \\ \text { the solution }}}
\]

However, a more accurate value of the product \(\epsilon l\) can be obtained by plotting \(A\) versus \(c\) for a series of solutions. Note that the equation \(A=\epsilon l c\) gives a straight line with slope \(\epsilon l\) when \(A\) is plotted against \(c\).

For example, consider the following typical spectroscopic analysis. A sample of steel from a bicycle frame is to be analyzed to determine its manganese content. The procedure involves weighing out a sample of the steel, dissolving it in strong acid, treating the resulting solution with a very strong oxidizing agent to convert all the manganese to permanganate ion \(\left(\mathrm{MnO}_{4}^{-}\right)\), and then using spectroscopy to determine the concentration of the intensely purple \(\mathrm{MnO}_{4}^{-}\)ions in the solution. To do this, however, the value of \(\epsilon l\) for \(\mathrm{MnO}_{4}{ }^{-}\)must be determined at an appropriate wavelength. The absorbance values for four solutions with known \(\mathrm{MnO}_{4}^{-}\)concentrations were measured to give the following data:
\begin{tabular}{|ccc|}
\hline Solution & \begin{tabular}{c} 
Concentration of \\
MnO \(_{4}-(\mathbf{m o l} / \mathrm{L})\)
\end{tabular} & Absorbance \\
\hline 1 & \(7.00 \times 10^{-5}\) & 0.175 \\
\hline 2 & \(1.00 \times 10^{-4}\) & 0.250 \\
\hline 3 & \(2.00 \times 10^{-4}\) & 0.500 \\
\hline 4 & \(3.50 \times 10^{-4}\) & 0.875 \\
\hline
\end{tabular}

A plot of absorbance versus concentration for the solutions of known concentration is shown in Fig. A.7. The slope of this line (change in \(A /\) change in \(c\) ) is \(2.48 \times 10^{3} \mathrm{~L} / \mathrm{mol}\). This quantity represents the product \(\epsilon l\).

A sample of the steel weighing 0.1523 g was dissolved and the unknown amount of manganese was converted to \(\mathrm{MnO}_{4}^{-}\)ions. Water was then added to give a solution with a final volume of 100.0 mL . A portion of this solution was placed in a spectrophotometer, and its absorbance was found to be 0.780 . Using these data, we want to calculate the percent manganese in the steel. The \(\mathrm{MnO}_{4}{ }^{-}\)ions from the manganese in

FIGURE A. 7 A plot of absorbance versus concentration of \(\mathrm{MnO}_{4}^{-}\)in a series of solutions of known concentration.

the dissolved steel sample show an absorbance of 0.780 . Using the Beer-Lambert law, we calculate the concentration of \(\mathrm{MnO}_{4}{ }^{-}\)in this solution:
\[
c=\frac{A}{\epsilon l}=\frac{0.780}{2.48 \times 10^{3} \mathrm{~L} / \mathrm{mol}} \times 3.15 \times 10^{-4} \mathrm{~mol} / \mathrm{L}
\]

There is a more direct way for finding \(c\). Using a graph such as that in Fig. A. 7 (often called a Beer's law plot), we can read the concentration that corresponds to \(A=0.780\). This interpolation is shown by dashed lines on the graph. By this method, \(c=3.15 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\), which agrees with the value obtained above.

Recall that the original \(0.1523-\mathrm{g}\) steel sample was dissolved, the manganese was converted to permanganate, and the volume was adjusted to 100.0 mL . We now know that \(\left[\mathrm{MnO}_{4}\right]\) in that solution is \(3.15 \times 10^{-4} \mathrm{M}\). Using this concentration, we can calculate the total number of moles of \(\mathrm{MnO}_{4}{ }^{-}\)in that solution:
\[
\begin{aligned}
\mathrm{molM} \mathrm{nO}_{4}^{-} & =100.0 \mathrm{~mL} \times \frac{1 \mathrm{~L}}{1000 \mathrm{~mL}} \times 3.15 \times 10^{-4} \frac{\mathrm{~mol}}{\mathrm{~L}} \\
& =3.15 \times 10^{-5} \mathrm{~mol}
\end{aligned}
\]

Since each mole of manganese in the original steel sample yields a mole of \(\mathrm{MnO}_{4}\), that is,
\[
1 \mathrm{~mol} \mathrm{Mn} \xrightarrow{\text { Oxidation }} 1 \mathrm{~mol} \mathrm{MnO}_{4}^{-}
\]
the original steel sample must have contained \(3.15 \times 10^{-5}\) mole of manganese. The mass of manganese present in the sample is
\[
3.15 \times 10^{-5} \mathrm{~mol} \mathrm{Mn} \times \frac{54.938 \mathrm{~g} \text { of } \mathrm{Mn}}{1 \mathrm{~mol} \mathrm{Mn}}=1.73 \times 10^{-3} \mathrm{~g} \text { of } \mathrm{Mn}
\]

Since the steel sample weighed 0.1523 g , the present manganese in the steel is
\[
\frac{1.73 \times 10^{-3} \mathrm{~g} \text { of } \mathrm{Mn}}{1.523 \times 10^{-1} \mathrm{~g} \text { of sample }} \times 100=1.14 \%
\]

This example illustrates a typical use of spectroscopy in quantitative analysis. The steps commonly involved are as follows:
1. Preparation of a calibration plot (a Beer's law plot) by measuring the absorbance values of a series of solutions with known concentrations
2. Measurement of the absorbance of the solution of unknown concentration
3. Use of the calibration plot to determine the unknown concentration

\section*{Molecular Spectroscopy: An Introduction}

Spectroscopy can be defined as the study of the interaction of electromagnetic radiation with matter. Spectroscopy provides a nondestructive and highly sensitive method for obtaining information about the identity, structure, and properties of substances. We have already discussed the emission spectrum of the hydrogen atom in Chapter 7 and the importance of the information it provides about hydrogen's quantized energy levels. Spectroscopy is also very useful for the study of molecules. Molecules can absorb electromagnetic radiation to furnish energy for many different processes, all which have quantized energy levels.

For example, a molecule can absorb or emit a photon and go from a lower electronic energy state to a higher electronic energy state or vice versa. This "electronic transition" can be described approximately as a change from one electronic arrangement to another. Typically, electronic transitions require photons in the ultraviolet (UV) or visible regions of the spectrum. One example of the use of this type of spectroscopy is illustrated by photoelectron spectroscopy (PES) discussed in Sections 7.12 and 9.3.

Molecules can also undergo vibrational energy transitions. For example, the atoms in a molecule vibrate around their equilibrium positions, giving rise to quantized vibrational energy levels. These spacings correspond to the energies of photons in the infrared (IR) region of the electromagnetic spectrum.

In addition, molecules can rotate, and the spacings of quantized rotational energy levels correspond to the energies of photons in the microwave region. In fact, it is the rotational excitation of the water molecules in food and the transfer of this energy to other molecules that form the basis of microwave cooking.

We will consider electronic spectroscopy and vibrational spectroscopy in more detail.

\section*{Electronic Spectroscopy}

The electronic spectrum of a molecule, which typically occurs in the ultraviolet (UV) or visible region of the electromagnetic spectrum, provides information about the spacings of electronic energy levels in the molecule. This allows us to better determine the electronic structure of a molecule. The electronic spectrum plots the quantity of radiation absorbed versus the wavelength of the radiation, showing peaks (maxima) at wavelengths where the photons have an energy that matches an energy gap in the molecule.

The majority of electronic transitions in molecules occurs in the UV region of the spectrum because the energy separations of electron states typically correspond to the energies of the photons in the UV region. However, some molecules have electronic energy separations that correspond to radiation in the visible region. One such class of compounds includes the coordination compounds that contain transitional metal ions. Thus, for example, dissolving copper(II) sulfate ions in water gives rise to a characteristic blue solution. Coordination compounds are discussed in Chapter 21. Another class of compounds that absorbs in the visible region of the spectrum involves molecules with long chains of carbon molecules that have alternating double bonds, such as carotene. The molecular structure of beta-carotene is given in Fig. A.8.

Substances with alternating double bonds are called conjugated molecules. It turns out that as the conjugated system gets longer, the electronic energies get closer together and the light absorbed corresponds to longer wavelengths.

White light consists of all of the colors of the rainbow (see Fig. 7.7), so when particular colors are absorbed by a given molecule, the substance appears colored. The color that results is the one given by the "sum" of the colors that remain unabsorbed. For example, carotene absorbs visible light in the violet and blue regions. It appears orange in color because the colors not absorbed "add up" to produce orange. In fact, carotene is the substance that gives carrots their bright orange color. The electronic
absorption spectrum of beta-carotene is shown in Fig. A.9.

Electronic spectroscopy also provides a sensitive and accurate method for determining the amount of absorbing species present in a sample (quantitative analysis). This technique is described in Appendix 3.

\section*{Vibrational Spectroscopy}

As we have seen, a molecule can be approximated as a collection of atoms held together by bonds. In describing the vibrations in a molecule, we can compare the bond between a given pair of atoms to a spring attached to two masses. As the atoms move apart in a vibrational motion, the bond-like a spring-provides a restoring force that pulls the atoms back toward each other. Vibrational transitions in molecules usually require energies that correspond to the IR region of the electromagnetic spectrum. The data are often represented in "wave numbers"; a wave number is the reciprocal of the wavelength (in centimeters) required to cause the vibrational transition.

A particular bonded pair of atoms has a characteristic vibrational frequency (wave number) that is relatively insensitive to its molecular environment. Thus, a signal that appears in the IR spectrum at that characteristic frequency provides good evidence that this particular atom pair is present in the molecule. For example, a \(\mathrm{C}-\mathrm{H}\) pair in a molecule will always show a vibrational signal at about \(3000 \mathrm{~cm}^{-1}\) (the range of wave numbers is actually \(2850-3300 \mathrm{~cm}^{-1}\) depending on the specific molecular environment). On the other hand, the \(\mathrm{O}-\mathrm{H}\) group in a molecule will show a vibrational bond at about \(3600 \mathrm{~cm}^{-1}\). Typical frequency ranges for the stretching motions of several common bonds are given in the table below.
\begin{tabular}{|l|}
\hline \multicolumn{1}{|c|}{ Bond } \\
\(\mathrm{C}-\mathrm{H}\)
\end{tabular} Frequency range \(\left(\mathrm{cm}^{-1}\right)\)

It turns out that several characteristic vibrational motions, called normal modes, are possible, not simply stretching motions. As an example, the normal modes of vibration for the \(\mathrm{SO}_{2}\) molecule are shown in Fig. A. 10 .

The IR spectrum of a molecule can be a great aid in identifying which atom groupings (that is, the types of bonds) are present in a molecule and thus can provide valuable information for identifying a specific molecule.

For example, consider methanol \(\left(\mathrm{CH}_{3} \mathrm{OH}\right)\), which has the following structure:

The IR spectrum of methanol is:

Notice that we can identify the bond present due to the stretching motions. The spectrum has other peaks due to different modes of vibration (such as those we saw with the \(\mathrm{SO}_{2}\) molecule) and hydrogen bonding between the molecules.

\section*{Answers to Selected Exercises}

The answers listed here are from the Complete Solutions Guide, in which rounding is carried out at each intermediate step in a calculation in order to show the correct number of significant figures for that step. Therefore, an answer given here may differ in the last digit from the result obtained by carrying extra digits throughout the entire calculation and rounding at the end (the procedure you should follow).

\section*{Chapter 1}
19. A law summarizes what happens, e.g., law of conservation of mass in a chemical reaction or the ideal gas law, \(P V=n R T\). A theory (model) is an attempt to explain why something happens. Dalton's atomic theory explains why mass is conserved in a chemical reaction. The kinetic molecular theory explains why pressure and volume are inversely related at constant temperature and moles of gas. 21. The fundamental steps are (1) making observations; (2) formulating hypotheses; (3) performing experiments to test the hypotheses. The key to the scientific method is performing experiments to test hypotheses. If after the test of time, the hypotheses seem to account satisfactorily for some aspect of natural behavior, then the set of tested hypotheses turns into a theory (model). However, scientists continue to perform experiments to refine or replace existing theories. 23. A qualitative observation expresses what makes something what it is; it does not involve a number; e.g., the air we breathe is a mixture of gases, ice is less dense than water, rotten milk stinks. The SI units are mass in grams, length in meters, and volume in the derived units of \(\mathrm{m}^{3}\). The assumed uncertainty in a number is \(\pm 1\) in the last significant figure of the number. The precision of an instrument is related to the number of significant figures associated with an experimental reading on that instrument. Different instruments for measuring mass, length, or volume have varying degrees of precision. Some instruments only give a few significant figures for a measurement while others will give more significant figures. 25. Significant figures are the digits we associate with a number. They contain all of the certain digits and the first uncertain digit (the first estimated digit). What follows is one thousand indicated to varying numbers of significant figures: 1000 or \(1 \times 10^{3}\) ( 1 S.F.); \(1.0 \times 10^{3}\left(2\right.\) S.F.); \(1.00 \times 10^{3}\) (3 S.F.); 1000 . or \(1.000 \times 10^{3}\) ( 4 S.F.). To perform the calculation, the addition/subtraction significant rule is applied to \(1.5-1.0\). The result of this is the one significant figure answer of 0.5 . Next, the multiplication/division rule is applied to \(0.5 / 0.50\). A one significant number divided by a two significant number yields an answer with one significant figure (answer \(=1\) ). 27. The slope of the \(T_{\mathrm{F}}\) vs. \(T_{\mathrm{C}}\) plot is \(1.8(=9 / 5)\) and the \(y\)-intercept is \(32^{\circ} \mathrm{F}\). The slope of \(T_{\mathrm{C}}\) vs. \(T_{\mathrm{K}}\) plot is 1 and the \(y\)-intercept is \(-273^{\circ} \mathrm{C}\). 29. The density of a gas is much smaller than the density of a solid or a liquid. The molecules in a solid and a liquid are very close together, whereas in the gas phase, the molecules are very far apart. 31. a. exact; b. inexact; c. exact; d. inexact 33. a. 3; b. 4; c. 4; d. 1; e. 7; f. 1; g. 3; h. 3 35. a. \(3.42 \times 10^{-4}\); b. \(1.034 \times 10^{4}\); c. \(1.7992 \times 10^{1}\); d. \(3.37 \times 10^{5} \quad 37.2 .85\) \(+0.280=3.13 \mathrm{~mL}\); the graduated cylinder on the left limits the precision of the total volume; it is the least precise measuring device between the two graduated cylinders. 39. a. 641.0; b. 1.327; c. 77.34; d. 3215; e. 0.420 41. a. 188.1 ; b. 12 ; c. \(4 \times 10^{-7}\); d. \(6.3 \times 10^{-26}\); e. 4.9 ; Uncertainty appears in the first decimal place. Since mass (orange) \(>\) mass (blue) and volume (orange) \(<\) volume (blue), the density of the orange block must be greater to account for the larger mass of the orange block. b. Which block is more dense cannot be determined. Since mass (orange) \(>\) mass (blue) and volume (orange) \(>\) volume (blue), the density of the orange block may or may not be larger than the blue block. If the blue block is more dense, then its density cannot be so large that the mass of the smaller blue block becomes larger than the orange block mass. \(\mathbf{c}\). The blue block is more dense. Since mass (blue) \(=\) mass (orange) and volume (blue) < volume (orange), the density of the blue block must be larger to equate the masses. d. The blue block is more dense. Since mass (blue) \(>\) mass (orange) and the volumes are equal, the density of the blue block must be larger to give the blue block the larger mass. \(\quad \mathbf{1 0 9 .} 8.5 \pm 0.5 \mathrm{~g} / \mathrm{cm}^{3}\) 111. \(3.648 \times 10^{4}\) cable lengths; \(6.671 \times 10^{6} \mathrm{~m} ; 3648\) nautical miles 113. Phosphorus would be a liquid. 115. a. False; sugar is generally considered to be the pure compound sucrose, \(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\). b. False; elements and compounds are pure substances. c. True; air is a mixture of mostly nitrogen and oxygen gases. d. False; gasoline has many additives, so it is a mixture. e. True; compounds are broken down to elements by chemical change. 117. In a subtraction, the result gets smaller, but the uncertainties add. If the two numbers are very close together, the uncertainty may be larger than the result. For example, let us assume we want to take the difference of the following two measured quantities, \(999,999 \pm 2\) and \(999,996 \pm 2\). The difference is \(3 \pm 4\). Because of the larger uncertainty, subtracting two similar numbers is bad practice. 119. a. \(2 \%\); b. \(2.2 \%\); c. \(0.2 \%\) 121. \(d_{\text {old }}=\) \(8.8 \mathrm{~g} / \mathrm{cm}^{3}, d_{\text {new }}=7.17 \mathrm{~g} / \mathrm{cm}^{3} ; d_{\text {new }} / d_{\text {old }}=\) mass \(_{\text {new }} /\) mass \(_{\text {old }}=0.81 ;\) The difference in mass is accounted for by the difference in the alloy used (if the assumptions are correct). 123. \(7.0 \% \quad \mathbf{1 2 5}\). a. One possibility is that rope B is not attached to anything and rope A and rope C are connected via a pair of pulleys and/or gears; \(\mathbf{b}\). Try to pull rope B out of the box. Measure the distance moved by C for a given movement of A . Hold either A or C firmly while pulling on the other rope. 127. \(\$ 160 . /\) person; \(3.20 \times 10^{3}\) nickels/person;
\(85.6 £ /\) person 129. \(200.0^{\circ} \mathrm{F}=93.33^{\circ} \mathrm{C} ;-100.0^{\circ} \mathrm{F}=-73.33^{\circ} \mathrm{C} ; 93.33^{\circ} \mathrm{C}\) \(=366.48 \mathrm{~K} ;-73.33^{\circ} \mathrm{C}=199.82 \mathrm{~K}\); difference of temperatures in \({ }^{\circ} \mathrm{C}=\) 166.66; difference of temperatures in \(\mathrm{K}=166.66\); No, there is not a difference of 300 degrees in \({ }^{\circ} \mathrm{C}\) or K .

\section*{Chapter 2}
19. A compound will always contain the same numbers (and types) of atoms. A given amount of hydrogen will react only with a specific amount of oxygen. Any excess oxygen will remain unreacted. 21. Law of conservation of mass: mass is neither created nor destroyed. The mass before a chemical reaction always equals the mass after a chemical reaction. Law of definite proportion: a given compound always contains exactly the same proportion of elements by mass. Water is always 1 g H for every 8 g oxygen. Law of multiple proportions: When two elements form a series of compounds, the ratios of the mass of the second element that combine with one gram of the first element can always be reduced to small whole numbers. For \(\mathrm{CO}_{2}\) and CO discussed in Section 2.2, the mass ratios of oxygen that react with 1 g of carbon in each compound are in a \(2: 1\) ratio. 23. J. J. Thomson's study of cathode-ray tubes led him to postulate the existence of negatively charged particles, which we now call electrons. Ernest Rutherford and his alpha bombardment of metal foil experiments led him to postulate the nuclear atoman atom with a tiny dense center of positive charge (the nucleus) with electrons moving about the nucleus at relatively large distances away; the distance is so large that an atom is mostly empty space. \(\mathbf{2 5}\). The number and arrangement of electrons in an atom determines how the atom will react with other atoms. The electrons determine the chemical properties of an atom. The number of neutrons present determine the isotope identity and the mass number. 27. 2; the ratio increases 29. Metallic character increases as one goes down a family and decreases from left to right across the periodic table. 31. In the paste, sodium chloride will dissolve to form separate \(\mathrm{Na}^{+}\) and \(\mathrm{Cl}^{-}\)ions. With the ions present and able to move about, electrical impulses will be conducted. 33. a. This represents ionic bonding, which is the electrostatic attraction between anions and cations. b. This represents covalent bonding, where electrons are shared between two atoms. This could be the space-filling model for \(\mathrm{H}_{2} \mathrm{O}\) or \(\mathrm{SF}_{2}\) or \(\mathrm{NO}_{2}\), etc. 35. Statements a and b are true. Element 118 is a noble gas and will be a nonmetal. For statement c, hydrogen has mostly nonmetallic properties. For statement d, a family of elements is also known as a group of elements. For statement e, two items are incorrect. When a metal reacts with a nonmetal, an ionic compound is produced and the formula of the compound would be \(\mathrm{AX}_{2}\) (since alkaline earth metals for +2 ions and halogens form -1 ions in ionic compounds). The correct statement would be: When alkaline earth metal, A, reacts with a halogen, \(X\), the formula of the ionic compound formed should be \(A X_{2}\). 37. \(\mathbf{a}\). The composition of a substance depends on the number of atoms of each element making up the compound (depends on the formula of the compound) and not on the composition of the mixture from which it was formed. b. Avogadro's hypothesis implies that volume ratios are equal to molecule ratios at constant temperature and pressure. \(\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) \rightarrow 2 \mathrm{HCl}(g)\); from the balanced equation, the volume of HCl produced will be twice the volume of \(\mathrm{H}_{2}\) (or \(\mathrm{Cl}_{2}\) ) reacted. 39. 299 g 41. The ratio of the masses of carbon that combine with 1 g of oxygen is \(\frac{0.751}{0.375}=\frac{2}{1}\). Note that this supports the law of multiple proportions because this carbon ratio is a small whole number. 43. For CO and \(\mathrm{CO}_{2}\), it is easiest to concentrate on the mass of oxygen that combines with 1 g of carbon. From the formulas (two oxygen atoms per carbon atom in \(\mathrm{CO}_{2}\) vs. one oxygen atom per carbon atom in CO ), \(\mathrm{CO}_{2}\) will have twice the mass of oxygen that combines per gram of carbon as compared to CO . For \(\mathrm{CO}_{2}\) and \(\mathrm{C}_{3} \mathrm{O}_{2}\), it is easiest to concentrate on the mass of carbon that combines with 1 g of oxygen. From the formulas (three carbon atoms per two oxygen atoms in \(\mathrm{C}_{3} \mathrm{O}_{2}\) vs. one carbon atom per two oxygen atoms in \(\mathrm{CO}_{2}\) ), \(\mathrm{C}_{3} \mathrm{O}_{2}\) will have three times the mass of carbon that combines per gram of oxygen as compared to \(\mathrm{CO}_{2}\). As expected, the mass ratios are whole numbers as predicted by the law of multiple proportions. 45. Mass is conserved in a chemical reaction because atoms are conserved. Chemical reactions involve the reorganization of atoms, so formulas change in a chemical reaction, but the number and types of atoms do not change. Because the atoms do not change in a chemical reac-
tion, mass must not change. In this equation we have two oxygen atoms and four hydrogen atoms both before and after the reaction occurs. 47. \(0,7.94\); \(\mathrm{Na}, 22.8 ; \mathrm{Mg}, 11.9 ; \mathrm{O}\) and Mg are incorrect by a factor of \(\approx 2\); correct formulas are \(\mathrm{H}_{2} \mathrm{O}, \mathrm{Na}_{2} \mathrm{O}\), and MgO . 49. Using \(r=5 \times 10^{-14} \mathrm{~cm}, d_{\text {nucleus }}=\) \(3 \times 10^{15} \mathrm{~g} / \mathrm{cm}^{3}\); using \(r=1 \times 10^{-8} \mathrm{~cm}, d_{\text {atom }}=0.4 \mathrm{~g} / \mathrm{cm}^{3} \quad \mathbf{5 1 .} 37\) 53. The law of multiple proportions does not involve looking at the ratio of the mass of one element with the total mass of the compounds. To illustrate the law of multiple proportions, we compare the mass of carbon that combines with 1.0 g of oxygen in each compound: compound 1: \(\frac{27.2 \mathrm{~g} \mathrm{C}}{72.8 \mathrm{~g} \mathrm{O}}=0.374 \mathrm{~g} \mathrm{C} / \mathrm{g} \mathrm{O}\); compound \(2: \frac{42.9 \mathrm{~g} \mathrm{C}}{57.1 \mathrm{~g} \mathrm{O}}=0.751 \mathrm{~g} \mathrm{C} / \mathrm{g} \mathrm{O}\); \(\frac{0.751}{0.374}=\frac{2}{1}\). Because the ratio is a small whole number, this supports the law of multiple proportions.

\section*{Chapter 3}
25. The atomic mass of any particular isotope is a relative mass to a specific standard. The standard is one atom of the carbon- 12 isotope weighing exactly \(12.000 \overline{0} \mathrm{u}\). One can determine from experiment how much heavier or lighter any specific isotope is than \({ }^{12} \mathrm{C}\). From this information, we assign an atomic mass value to that isotope. For example, experiment tells one that \({ }^{16} \mathrm{O}\) is about \(4 / 3\) heavier than \({ }^{12} \mathrm{C}\), so a mass of \(4 / 3(12.00)=16.00 \mathrm{u}\) is assigned to \({ }^{16} \mathrm{O}\). The atomic mass listed in the periodic table is also an average mass. Most elements in nature occur as a mixture of isotopes. The atomic mass of an element is the average mass of all the isotopes that make up a specific element, weighted by abundance. 27. Each person would have 90 trillion dollars. 29. Only in b are the empirical formulas the same for both compounds illustrated. In b, general formulas of \(\mathrm{X}_{2} \mathrm{Y}_{4}\) and \(\mathrm{XY}_{2}\) are illustrated, and both have \(\mathrm{XY}_{2}\) for an empirical formula. 31. The mass percent of a compound is a constant no matter what amount of substance is present. Compounds always have constant composition. 33. c 35. The theoretical yield is the stoichiometric amount of product that should form if the limiting reactant is completely consumed and the reaction has \(100 \%\) yield. 37. The information needed is mostly the coefficients in the balanced equation and the molar masses of the reactants and products. For percent yield, we would need the actual yield of the reaction and the amounts of reactants used.
a. mass of CB produced \(=1.00 \times 10^{4}\) molecules \(\mathrm{A}_{2} \mathrm{~B}_{2} \times\)
\[
\frac{1 \mathrm{~mol} \mathrm{~A}_{2} \mathrm{~B}_{2}}{6.022 \times 10^{23} \text { molecules } \mathrm{A}_{2} \mathrm{~B}_{2}} \times \frac{2 \mathrm{~mol} \mathrm{CB}}{1 \mathrm{~mol} \mathrm{~A}_{2} \mathrm{~B}_{2}} \times \frac{\text { molar mass of } \mathrm{CB}}{\mathrm{~mol} \mathrm{CB}}
\]
b. atoms of A produced \(=1.00 \times 10^{4}\) molecules \(\mathrm{A}_{2} \mathrm{~B}_{2} \times \frac{2 \text { atoms } \mathrm{A}}{1 \text { molecule } \mathrm{A}_{2} \mathrm{~B}_{2}}\) c. mol of C reacted \(=1.00 \times 10^{4}\) molecules \(\mathrm{A}_{2} \mathrm{~B}_{2} \times\)
\[
\frac{1 \mathrm{~mol} \mathrm{~A}_{2} \mathrm{~B}_{2}}{6.022 \times 10^{23} \text { molecules } \mathrm{A}_{2} \mathrm{~B}_{2}} \times \frac{2 \mathrm{~mol} \mathrm{C}}{1 \mathrm{~mol} \mathrm{~A}_{2} \mathrm{~B}_{2}}
\]
d. \(\%\) yield \(=\frac{\text { actual mass }}{\text { theoretical mass }} \times 100\); The theoretical mass of CB produced was calculated in part a. If the actual mass of CB produced is given, then the percent yield can be determined for the reaction using the percent yield equation. 39. \(207.2 \mathrm{u}, \mathrm{Pb}\) 41. 185 u 43. \(48 \%{ }^{151} \mathrm{Eu}\) and \(52 \%{ }^{153} \mathrm{Eu}\) 45. \section*{Chapter 4}
17. a. Polarity is a term applied to covalent compounds. Polar covalent compounds have an unequal sharing of electrons in bonds that results in an unequal charge distribution in the overall molecule. Polar molecules have a partial negative end and a partial positive end. These are not full charges as in ionic compounds, but are charges much less in magnitude. Water is a polar molecule and dissolves other polar solutes readily. The oxygen end of water (the partial negative end of the polar water molecule) aligns with the partial positive end of the polar solute while the hydrogens of water (the partial positive end of the polar water molecule) align with the partial negative end of the solute. These opposite charged attractions stabilize polar solutes in water. This process is called hydration. Nonpolar solutes do not have permanent partial negative and partial positive ends; nonpolar solutes are not stabilized in water and do not dissolve. b. KF is a soluble ionic compound so it is a strong electrolyte. \(\mathrm{KF}(a q)\) actually exists as separate hydrated \(\mathrm{K}^{+}\)ions and hydrated \(\mathrm{F}^{-}\)ions in solution: \(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\) is a polar covalent molecule that is a nonelectrolyte. \(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\) is hydrated as described in part a. c. RbCl is a soluble ionic compound so it exists as separate hydrated \(\mathrm{Rb}^{+}\)ions and hydrated \(\mathrm{Cl}^{-}\)ions in solution. AgCl is an insoluble ionic compound so the ions stay
together in solution and fall to the bottom of the container as a precipitate. d. \(\mathrm{HNO}_{3}\) is a strong acid and exists as separate hydrated \(\mathrm{H}^{+}\)ions and hydrated \(\mathrm{NO}_{3}{ }^{-}\)ions in solution. CO is a polar covalent molecule and is hydrated as explained in part a. 19. Only statement b is true. A concentrated solution can also contain a nonelectrolyte dissolved in water, e.g., concentrated sugar water. Acids are either strong or weak electrolytes. Some ionic compounds are not soluble in water, so they are not labeled as a specific type of electrolyte. 21. Bromides: \(\mathrm{NaBr}, \mathrm{KBr}\), and \(\mathrm{NH}_{4} \mathrm{Br}\) (and others) would be soluble and \(\mathrm{AgBr}, \mathrm{PbBr}_{2}\), and \(\mathrm{Hg}_{2} \mathrm{Br}_{2}\) would be insoluble. Sulfates: \(\mathrm{Na}_{2} \mathrm{SO}_{4}\), \(\mathrm{K}_{2} \mathrm{SO}_{4}\), and \(\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}\) (and others) would be soluble and \(\mathrm{BaSO}_{4}, \mathrm{CaSO}_{4}\), and \(\mathrm{PbSO}_{4}\) (or \(\mathrm{Hg}_{2} \mathrm{SO}_{4}\) ) would be insoluble. Hydroxides: \(\mathrm{NaOH}, \mathrm{KOH}\), and \(\mathrm{Ca}(\mathrm{OH})_{2}\) (and others) would be soluble and \(\mathrm{Al}(\mathrm{OH})_{3}, \mathrm{Fe}(\mathrm{OH})_{3}\), and \(\mathrm{Cu}(\mathrm{OH})_{2}\) (and others) would be insoluble. Phosphates: \(\mathrm{Na}_{3} \mathrm{PO}_{4}, \mathrm{~K}_{3} \mathrm{PO}_{4}\), and \(\left(\mathrm{NH}_{4}\right)_{3} \mathrm{PO}_{4}\) (and others) would be soluble and \(\mathrm{Ag}_{3} \mathrm{PO}_{4}, \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}\), and \(\mathrm{FePO}_{4}\) (and others) would be insoluble. Lead: \(\mathrm{PbCl}_{2}, \mathrm{PbBr}_{2}, \mathrm{PbI}_{2}, \mathrm{~Pb}(\mathrm{OH})_{2}, \mathrm{PbSO}_{4}\), and PbS (and others) would be insoluble. \(\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}\) would be a soluble \(\mathrm{Pb}^{2+}\) salt. 23. The Brønsted-Lowry definitions are best for our purposes. An acid is a proton donor and a base is a proton acceptor. A proton is an \(\mathrm{H}^{+}\)ion. Neutral hydrogen has 1 electron and 1 proton, so an \(\mathrm{H}^{+}\)ion is just a proton. An acidbase reaction is the transfer of an \(\mathrm{H}^{+}\)ion (a proton) from an acid to a base. 25. a. The species reduced is the element that gains electrons. The reducing agent causes reduction to occur by itself being oxidized. The reducing agent is generally listed as the entire formula of the compound/ion that contains the element oxidized. \(\mathbf{b}\). The species oxidized is the element that loses electrons. The oxidizing agent causes oxidation to occur by itself being reduced. The oxidizing agent is generally listed as the entire formula of the compound/ion that contains the element reduced. c. For simple binary ionic compounds, the actual charges on the ions are the oxidation states. For covalent compounds, nonzero oxidation states are imaginary charges the elements would have if they were held together by ionic bonds (assuming the bond is between two different nonmetals). Nonzero oxidation states for elements in covalent compounds are not actual charges. Oxidation states for covalent compounds are a bookkeeping method to keep track of electrons in a reaction.

c. For answers \(\mathrm{c}-\mathrm{i}\), we will describe what should be in each solution. For c, the drawing should have three times as many \(\mathrm{NO}_{3}{ }^{-}\)anions as \(\mathrm{Al}^{3+}\) cations. d. The drawing should have twice as many \(\mathrm{NH}_{4}{ }^{+}\)cations as \(\mathrm{SO}_{4}{ }^{2-}\) anions. e. The drawing should have equal numbers of \(\mathrm{Na}^{+}\)cations and \(\mathrm{OH}^{-}\)anions. f. The drawing should have equal numbers of \(\mathrm{Fe}^{2+}\) cations and \(\mathrm{SO}_{4}{ }^{2-}\) anions. g. The drawing should have equal numbers of \(\mathrm{K}^{+}\)cations and \(\mathrm{MnO}_{4}^{-}\)anions. h. The drawing should have equal numbers of \(\mathrm{H}^{+}\)cations and \(\mathrm{ClO}_{4}{ }^{-}\)anions. i. The drawing should have equal numbers of \(\mathrm{NH}_{4}^{+}\)cations and \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}\) anions. 29. \(\mathrm{CaCl}_{2}(s) \rightarrow \mathrm{Ca}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q) \quad\) 31. a. 0.2677 M ; b. 1.255 \(\times 10^{-3} M\); c. \(8.065 \times 10^{-3} M\) 33. a. \(M_{\mathrm{Ca}^{2+}}=1.00 M, M_{\mathrm{NO}_{3}}=2.00 \mathrm{M}\); b. \(M_{\mathrm{Na}^{+}}=4.0 \mathrm{M}, M_{\mathrm{SO}_{4^{-2}}}=2.0 \mathrm{M}\); c. \(M_{\mathrm{NH}_{4^{+}}}=M_{\mathrm{Cl}^{-}}=0.187 \mathrm{M}\); d. \(M_{\mathrm{K}^{+}}=\) \(0.0564 M, M_{\mathrm{PO}_{4}{ }^{3-}}=0.0188 \mathrm{M} \quad\) 35. 100.0 mL of \(0.30 \mathrm{M} \mathrm{AlCl}_{3} \quad 37.4 .00 \mathrm{~g}\) 39. \(0.0472 \mathrm{~g} \quad\) 41. a. Place 20.0 g NaOH in a 2-L volumetric flask; add water to dissolve the NaOH and fill to the mark. b. Add 500 . mL of the 1.00 M NaOH stock solution to a 2-L volumetric flask; fill to the mark with water. c. As in a, instead using \(38.8 \mathrm{~g} \mathrm{~K}_{2} \mathrm{CrO}_{4}\). d. As in b, instead using 114 mL of 1.75 M \(\mathrm{K}_{2} \mathrm{CrO}_{4}\) stock solution. 43. \(M_{\mathrm{NH}_{4}+}=0.272 M, M_{\mathrm{SO}_{4}{ }^{2-}}=0.136 \mathrm{M} \quad\) 45. 4.5 M 47. \(5.94 \times 10^{-8} M\) 49. \section*{Chapter 5}
23. higher than; 13.6 times taller; When the pressure of the column of liquid standing on the surface of the liquid is equal to the pressure exerted by air on the rest of the surface of the liquid, then the height of the column of liquid is a measure of atmospheric pressure. Because water is 13.6 times less dense than mercury, the column of water must be 13.6 times longer than that of mercury to match the force exerted by the columns of liquid standing on the surface. 25. The \(P\) versus \(1 / V\) plot is incorrect. The plot should be linear with positive slope and a \(y\)-intercept of zero. \(P V=k\) so \(P=k(1 / V)\), which is in the form of the straight-line equation \(y=m x+b\). 27. \(d=\) (molar mass) \(P / R T\); density is directly proportional to the molar mass of the gas. Helium, which has the smallest molar mass of all the noble gases, will have the smallest density. 29. At STP \((T=273.2 \mathrm{~K}\) and \(P=1.000 \mathrm{~atm})\), the volume of 1.000 mole of gas is:
\[
V=\frac{n R T}{P}=\frac{1.000 \mathrm{~mol} \times \frac{0.08206 \mathrm{~L} \mathrm{~atm}}{\mathrm{~K} \mathrm{~mol}} \times 273.2 \mathrm{~K}}{1.000 \mathrm{~atm}}=22.42 \mathrm{~L}
\]

The volume of 1.000 mole of any gas is 22.42 L , assuming the gas behaves ideally. Therefore, the molar volume of \(\mathrm{He}(g)\) and \(\mathrm{N}_{2}(g)\) at STP both equal \(22.42 \mathrm{~L} / \mathrm{mol}\). If the temperature increases to \(25.0^{\circ} \mathrm{C}(298.2 \mathrm{~K})\), the molar volume of a gas will be larger than \(22.42 \mathrm{~L} / \mathrm{mol}\) because volume and temperature are directly related at constant pressure. If 1.000 mole of a gas is collected over water at a total pressure of 1.000 atm , the partial pressure of the collected gas will be less than 1.000 atm because water vapor is present \(\left(P_{\text {total }}=P_{\text {gas }}+P_{\mathrm{H}_{2} \mathrm{O}}\right)\). At some partial pressure below 1.000 atm , the molar volume of a gas will be larger than \(22.42 \mathrm{~L} / \mathrm{mol}\) because volume and pressure are inversely related at constant temperature. 31. a. As temperature increases, the average kinetic energy will increase; \(\mathbf{b}\). As temperature increases, the average velocity of the gas molecules will increase; c. At constant temperature, the lighter the gas molecules (the smaller the molar mass), the faster the average velocity. 33. No; At any nonzero Kelvin temperature, there is a distribution of kinetic energies. Similarly, there is a distribution of velocities at any nonzero Kelvin temperature. 35. \(2 \mathrm{NH}_{3}(g) \rightarrow \mathrm{N}_{2}(g)+\) \(3 \mathrm{H}_{2}(g)\); At constant \(P\) and \(T\), volume is directly proportional to the moles of gas present. In the reaction, the moles of gas double as reactants are converted to products, so the volume of the container should double. At constant \(V\) and \(T, P\) is directly proportional to the moles of gas present. As the moles of gas double, the pressure will double. The partial pressure of \(\mathrm{N}_{2}\) will be \(1 / 2\) the initial pressure of \(\mathrm{NH}_{3}\) and the partial pressure of \(\mathrm{H}_{2}\) will be \(3 / 2\) the initial
pressure of \(\mathrm{NH}_{3}\). The partial pressure of \(\mathrm{H}_{2}\) will be three times the partial pressure of \(\mathrm{N}_{2}\). 37. \(\mathrm{CO}_{2}\) 39. From the plot, Ne appears to behave most ideally. 41. a. \(3.6 \times 10^{3} \mathrm{~mm} \mathrm{Hg} ;\) b. \(3.6 \times 10^{3}\) torr; c. \(4.9 \times 10^{5} \mathrm{~Pa} ; \mathbf{d} .71 \mathrm{psi}\) 43. 65 torr, \(8.7 \times 10^{3} \mathrm{~Pa}, 8.6 \times 10^{-2} \mathrm{~atm}\) 45. a. 642 torr, 0.845 atm ; \(8.56 \times 10^{4} \mathrm{~Pa} ;\) b. 975 torr; \(1.28 \mathrm{~atm} ; 1.30 \times 10^{5} \mathrm{~Pa}\); c. 517 torr; 850 . torr 47. 0.972 atm 49. \(8.01 \mathrm{~L} \quad\) 51. a. 14.0 L ; b. \(4.72 \times 10^{-2} \mathrm{~mol}\); c. 678 K ; d. 133 atm 53. \(88.9 \mathrm{~g} \mathrm{He} ; 44.8 \mathrm{~g} \mathrm{H}_{2}\) 55. 0.0449 mol 57. a. 69.6 K ; b. 32.3 atm 59. \(1.1 \times 10^{22}\) air particles 61. 1.27 mol 63. \(P_{\mathrm{B}}=2 P_{\mathrm{A}}\) 65. a. \(12.8 \mathrm{~atm} ;\) b. \(161 \mathrm{~K} ;\) c. 620 . The number of gas particles is constant, so at constant moles of gas, either a temperature change or a pressure change results in the smaller volume. If the temperature is constant, an increase in the external pressure would cause the volume to decrease. Gases are mostly empty space, so gases are easily compressible. If the pressure is constant, a decrease in temperature would cause the volume to decrease. As the temperature is lowered, the gas particles move with a slower average velocity and don't collide with the container walls as frequently and as forcefully. As a result, the internal pressure decreases. In order to keep the pressure constant, the volume of the container must decrease in order to increase the gas particle collisions per unit area.

133. \(0.772 \mathrm{~atm} \cdot \mathrm{~L}\); in Example 5.3, 1.0 mole of gas was present at \(0^{\circ} \mathrm{C}\). The moles of gas and/or the temperature must have been different for Boyle's data. 135. \(P_{\mathrm{He}}=582\) torr, \(P_{\mathrm{Xe}}=18\) torr 137. \(13.3 \%\) 139. 1490 141. 24 torr 143. \(4.1 \times 10^{6} \mathrm{~L}\) air; \(7.42 \times 10^{5} \mathrm{~L} \mathrm{H}_{2} \quad\) 145. \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N} ; \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}\) 147. \(\mathrm{C}_{12} \mathrm{H}_{21} \mathrm{NO} ; \mathrm{C}_{24} \mathrm{H}_{42} \mathrm{~N}_{2} \mathrm{O}_{2}\) 149. Processes b , c , and d will all result in a doubling of the pressure. Process \(b\) doubles the pressure because the absolute temperature is doubled (from 200. K to 400. K). Process c has the effect of halving the volume, which would double the pressure by Boyle's law. Process \(d\) doubles the pressure because the moles of gas are doubled ( \(28 \mathrm{~g} \mathrm{~N}_{2}\) is 1 mol of \(\mathrm{N}_{2}\) and \(32 \mathrm{~g} \mathrm{O}_{2}\) is 1 mol of \(\mathrm{O}_{2}\) ). Process a won't double the pressure because \(28 \mathrm{~g} \mathrm{O}_{2}\) is less than 1 mol of gas, and process e won't double the temperature since the absolute temperature is not doubled (goes from 303 K to 333 K ). 151. \(\Delta V=142 \mathrm{~L} \quad\) 153. \(51.4 \mathrm{~g} \quad\) 155. All the gases have the same average kinetic energy since they are all at the same temperature. The average velocity order from slowest to fastest is \(\mathrm{F}_{2}<\mathrm{N}_{2}<\mathrm{He}\). \(\mathbf{1 5 7 . 1 3 . 4 \%}\) \(\mathrm{CaO}, 86.6 \% \mathrm{BaO} \quad 159 . \mathrm{C}_{2} \mathrm{H}_{6} \quad\) 161. a. \(8.7 \times 10^{3} \mathrm{~L}\) air \(/ \mathrm{min} ;\) b. \(\chi_{\mathrm{CO}}=0.0017\), \(\chi_{\mathrm{CO}_{2}}=0.032, \chi_{\mathrm{O}_{2}}=0.13, \chi_{\mathrm{N}_{2}}=0.77, \chi_{\mathrm{H}_{2} \mathrm{O}}=0.067\) 163. a. \(1.01 \times 10^{4} \mathrm{~g}\); b. \(6.65 \times 10^{4} \mathrm{~g} ; \mathbf{c} .8 .7 \times 10^{3} \mathrm{~g} \quad \mathbf{1 6 5}\). a. Due to air's larger average molar mass, a given volume of air at a given set of conditions has a higher density than helium. We need to heat the air to greater than \(25^{\circ} \mathrm{C}\) to lower the air density (by driving air out of the hot-air balloon) until the density is the same as that for helium (at \(25^{\circ} \mathrm{C}\) and 1.00 atm ). b. \(2150 \mathrm{~K} \quad 167 . \mathrm{C}_{3} \mathrm{H}_{8}\) is the most likely identity. 169. row \(7 \quad\) 171. \(0.023 \mathrm{~mol} \quad 173.4 .8 \mathrm{~g} / \mathrm{L} ; \mathrm{UF}_{3}\) will effuse 1.02 times faster.

\section*{Chapter 6}
13. Path-dependent functions for a trip from Chicago to Denver are those quantities that depend on the route taken. One can fly directly from Chicago to Denver or one could fly from Chicago to Atlanta to Los Angeles and then to Denver. Some path-dependent quantities are miles traveled, fuel consumption of the airplane, time traveling, airplane snacks eaten, etc. State functions are path-independent; they only depend on the initial and final states. Some state functions for an airplane trip from Chicago to Denver would be longitude change, latitude change, elevation change, and overall time zone change. 15. Both \(q\) and \(w\) are negative. 17. a. 446 kJ released; b. 446 kJ released 19. exothermic, evolved

23. The zero points for \(\Delta H_{\mathrm{f}}^{\circ}\) values are elements in their standard state. All substances are measured in relationship to this zero point. 25. No matter how insulated your thermos bottle, some heat will always escape into the surroundings. If the temperature of the thermos bottle (the surroundings) is high, less heat initially will escape from the coffee (the system); as a result your coffee will stay hotter for a longer period of time. 27. Fossil fuels contain carbon; the incomplete combustion of fossil fuels produces \(\mathrm{CO}(g)\) instead of \(\mathrm{CO}_{2}(g)\). This occurs when the amount of oxygen reacting is not sufficient to convert all of the carbon in fossil fuels to \(\mathrm{CO}_{2}\). Carbon monoxide is a poisonous gas to humans. 29. 150 J 31. a. Potential energy is energy due to position. Initially, ball A has a higher potential energy than ball \(B\) because the position of ball \(A\) is higher than that of ball \(B\). In the final position, ball B has the higher position, so ball B has the higher potential energy. b. As ball A rolled down the hill, some of the potential energy lost by A was converted to random motion of the components of the hill (frictional heating). The remainder of the lost potential energy was added to \(B\) to initially increase its kinetic energy and then to increase its potential energy.
33. 16 kJ 35.70. \(\mathrm{J} \quad\) 37. 375 J heat transferred to the system \(\quad\) 39. -13.2 kJ 41. 11.0 L 43. \(q=30.9 \mathrm{~kJ}, w=-12.4 \mathrm{~kJ}, \Delta E=18.5 \mathrm{~kJ} \quad\) 45. This is an endothermic reaction, so heat must be absorbed to convert reactants into products. The high-temperature environment of internal combustion engines provides the heat. 47. a. endothermic; b. exothermic; c. exothermic; d. endothermic 49. a. 1650 kJ released; b. 826 kJ released; c. 7.39 kJ released; d. 34.4 kJ released \(\mathbf{5 1 .} 4400 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{8} \quad\) 53. When a liquid is converted into a gas, there is an increase in volume. The \(2.5 \mathrm{~kJ} / \mathrm{mol}\) quantity can be considered as the work done by the vaporization process in pushing back the atmosphere. 55. \(\mathrm{H}_{2} \mathrm{O}(l) ; 2.30 \times 10^{3} \mathrm{~J} ; \mathrm{Hg}(l) ; 140^{\circ} \mathrm{C}\) 57. \(\mathrm{Al}(s)\) 59. 311 K 61. \(23.7^{\circ} \mathrm{C} \quad 63.0 .25 \mathrm{~J} /{ }^{\circ} \mathrm{C} \cdot \mathrm{g} \quad 65 .-66 \mathrm{~kJ} / \mathrm{mol} \quad 67.170 \mathrm{~J} / \mathrm{g} ; 20 . \mathrm{kJ} / \mathrm{mol}\) 69. \(39.2^{\circ} \mathrm{C} \quad\) 71. \(-25 \mathrm{~kJ} / \mathrm{g} ;-2700 \mathrm{~kJ} / \mathrm{mol} \quad\) 73. a. \(31.5 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}\); b. \(-1.10 \times\) \(10^{3} \mathrm{~kJ} / \mathrm{mol}\) 75. \(-220.8 \mathrm{~kJ} \quad 77.1268 \mathrm{~kJ}\); No, because this reaction is very endothermic, it would not be a practical way of making ammonia due to the high energy costs. 79. \(-202.6 \mathrm{~kJ} \quad \mathbf{8 1} .-713 \mathrm{~kJ} \quad\) 83. For \(\mathrm{C}_{3} \mathrm{H}_{8}(g),-50.37 \mathrm{~kJ} / \mathrm{g}\) vs. \(-47.7 \mathrm{~kJ} / \mathrm{g}\) for octane. Because of the low boiling point of propane, there are extra safety hazards associated with storing the propane in high-pressure compressed gas tanks. \(\quad 99.1 .05 \times 10^{5} \mathrm{~L} \quad 101.4900 \mathrm{~g} \quad\) 103. a. \(2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightarrow 2 \mathrm{SO}_{3}(g)\); \(w>0 ;\) b. \(\mathrm{COCl}_{2}(g) \rightarrow \mathrm{CO}(g)+\mathrm{Cl}_{2}(g) ; w<0 ;\) c. \(\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightarrow 2 \mathrm{NO}(g) ;\) \(w=0\); Compare the sum of the coefficients of all the product gases in the balanced equation to the sum of the coefficients of all the reactant gases. When a balanced reaction has more moles of product gases than moles of reactant gases, then the reaction will expand in volume ( \(\Delta V\) is positive) and the system does work on the surroundings \((w<0)\). When a balanced reaction has a decrease in the moles of gas from reactants to products, then the reaction will contract in volume ( \(\Delta V\) is negative) and the surroundings does compression work on the system \((w>0)\). When there is no change in the moles of gas from reactants to products, then \(\Delta V=0\) and \(w=0\). 105. a. \(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(s)+12 \mathrm{O}_{2}(g) \rightarrow 12 \mathrm{CO}_{2}(g)+11 \mathrm{H}_{2} \mathrm{O}(l)\); b. \(-5630 \mathrm{~kJ} / \mathrm{mol}\) 107. 3.0 miles 109. 4.2 kJ heat released 111. The calculated \(\Delta H\) value will be less positive (smaller) than it should be. 113. \(25.91^{\circ} \mathrm{C}\) 115. \(\frac{1}{2} \mathrm{C}+\mathrm{F} \rightarrow \mathrm{A}+\mathrm{B}+\mathrm{D} ; 47.0 \mathrm{~kJ} \quad\) 117. a. 632 kJ ; b. \(\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g}) \quad 119.28 \mathrm{~g}\) 121. a. -361 kJ ; b. -199 kJ ; c. -227 kJ ; d. -112 kJ 123 . Work is done by the surroundings on the system when there is a compression. This will occur when the moles of gas decrease when going from reactants to products. This will occur for reactions a and c . The other reactions have an increase in the moles of gas as reactants are converted to products. In these reactions, the system does \(P V\) work on the surroundings. 125. \(3.97 \times 10^{3} \mathrm{~kJ}\) heat is released \(\quad 127.51 .5^{\circ} \mathrm{C} \quad\) 129. An element in its standard state has a standard enthalpy of formation equal to zero. At \(25^{\circ} \mathrm{C}\) and 1 atm , chlorine is found as \(\mathrm{Cl}_{2}(g)\) and hydrogen is found as \(\mathrm{H}_{2}(g)\). So these two elements ( \(a\) and \(b\) ) have enthalpies of formation equal to zero. The other two choices (c and d) do not have the elements in their standard state. The standard state for nitrogen is \(\mathrm{N}_{2}(g)\) and the standard state for chlorine is \(\mathrm{Cl}_{2}(g)\). 131. \(w=-2940 \mathrm{~J} ; \Delta E=27.8 \mathrm{~kJ} \quad\) 133. \(25 \mathrm{~m}^{2} \quad\) 135. \(1 \times 10^{4}\) steps 137. 56.9 kJ 139. \(q=\Delta H=-8.51 \mathrm{~kJ}, w=1.83 \mathrm{~kJ}, \Delta E=-6.68 \mathrm{~kJ}\) 141. 1.74 kJ 143.3 .3 cm

\section*{Chapter 7}
23. The equations relating the terms are \(v \lambda=c, E=h v\), and \(E=h c / \lambda\). From the equations, wavelength and frequency are inversely related, photon energy and frequency are directly related, and photon energy and wavelength are inversely related. The unit of 1 joule \((J)=1 \mathrm{~kg} \mathrm{~m}^{2} / \mathrm{s}^{2}\). This is why you must change mass units to kg when using the de Broglie equation. 25. The photoelectric effect refers to the phenomenon in which electrons are emitted from the surface of a metal when light strikes it. The light must have a certain minimum frequency (energy) in order to remove electrons from the surface of a metal. Light having a frequency below the minimum results in no electrons being emitted, whereas light at or higher than the minimum frequency does cause electrons to be emitted. For light having a frequency higher than the minimum frequency, the excess energy is transferred into kinetic energy for the
emitted electron. Albert Einstein explained the photoelectric effect by applying quantum theory. 27. Example 7.3 calculates the de Broglie wavelength of a ball and of an electron. The ball has a wave length on the order of \(10^{-34} \mathrm{~m}\). This is incredibly short and, as far as the wave-particle duality is concerned, the wave properties of large objects are insignificant. The electron, with its tiny mass, also has a short wavelength: on the order of \(10^{-10} \mathrm{~m}\). However, this wavelength is significant as it is on the same order as the spacing between atoms in a typical crystal. For very tiny objects like electrons, the wave properties are important. The wave properties must be considered, along with the particle properties, when hypothesizing about the electron motion in an atom. 29. The Bohr model was an important step in the development of the current quantum mechanical model of the atom. The idea that electrons can occupy only certain, allowed energy levels is illustrated nicely (and relatively easily). We talk about the Bohr model to present the idea of quantized energy levels. 31. When the \(p\) and \(d\) orbital functions are evaluated at various points in space, the results sometimes have positive values and sometimes have negative values. The term phase is often associated with the + and - signs. For example, a sine wave has alternating positive and negative phases. This is analogous to the positive and negative values (phases) in the \(p\) and \(d\) orbitals. 33. a. \(m_{\ell}\); b. \(n\); c. \(m_{\mathrm{s}}\); d. \(\ell\) 35. If one more electron is added to a half-filled subshell, electron-electron repulsions will increase because two electrons must now occupy the same atomic orbital. This may slightly decrease the stability of the atom. 37. The valence electrons are strongly attracted to the nucleus for elements with large ionization energies. One would expect these species to readily accept another electron and have very exothermic electron affinities. The noble gases are an exception; they have a large ionization energy but an endothermic electron affinity. Noble gases have a filled valence shell. The added electron must go into a higher \(n\) value atomic orbital, which would have a significantly higher energy. This is unfavorable. 39. For hydrogen and hydrogenlike (one electron) ions, all orbitals with the same value of \(n\) have the same energy. For polyatomic atoms/ions, the energy of the orbitals also depends on \(\ell\). Because there are more nondegenerate energy levels for polyatomic atoms/ ions as compared with hydrogen, there are many more possible electronic transitions resulting in more complicated line spectra. 41. Yes, the maximum number of unpaired electrons in any configuration corresponds to a minimum in electron-electron repulsions. 43. a. \(n\); b. \(n\) and \(\ell \quad\) 45. \(4.5 \times 10^{14} \mathrm{~s}^{-1}\) 47. \(3.0 \times 10^{10} \mathrm{~s}^{-1}, 2.0 \times 10^{-23} \mathrm{~J} /\) photon, \(12 \mathrm{~J} / \mathrm{mol} \quad 49.9 .4 \times 10^{14} \mathrm{~s}^{-1}\) to \(1.1 \times 10^{15} \mathrm{~s}^{-1} \quad\) 51. Wave a has the longer wavelength \(\left(4.0 \times 10^{-4} \mathrm{~m}\right)\). Wave b has the higher frequency \(\left(1.5 \times 10^{12} \mathrm{~s}^{-1}\right)\) and larger photon energy \((9.9 \times\) \(10^{-22} \mathrm{~J}\). Since both of these waves represent electromagnetic radiation, they both should travel at the same speed, \(c\), the speed of light. Both waves represent infrared radiation. \(\quad \mathbf{5 3 . 1 . 5 0} \times 10^{23}\) atoms \(\quad \mathbf{5 5 .} 427.7 \mathrm{~nm} \quad \mathbf{5 7 . 2 7 6} \mathrm{~nm}\) 59. a. \(2.4 \times 10^{-11} \mathrm{~m}\); b. \(3.4 \times 10^{-34} \mathrm{~m} \quad 61.1 .6 \times 10^{-27} \mathrm{~kg} \quad\) 63. a. 656.7 nm (visible); b. 486.4 nm (visible); c. 121.6 nm (ultraviolet)
65.

\end{tabular}

For boron, there are six possibilities for the \(2 p\) electron. For nitrogen, all the \(2 p\) electrons could have \(m_{s}=-\frac{1}{2}\). 103. \(1 \mathrm{~A}: 1, n s^{1}, \mathrm{Li}, 2 s^{1} ; 2 \mathrm{~A}: 2, n s^{2}, \mathrm{Ra}\), \(7 s^{2} ; 3 \mathrm{~A}: 3, n s^{2} n p^{1}, \mathrm{Ga}, 4 s^{2} 4 p^{1} ; 4 \mathrm{~A}: 4, n s^{2} n p^{2}, \mathrm{Si}, 3 s^{2} 3 p^{2} ; 5 \mathrm{~A}: 5, n s^{2} n p^{3}, \mathrm{Sb}\), \(5 s^{2} 5 p^{3} ; 6 \mathrm{~A}: 6, n s^{2} n p^{4}\), Po, \(6 s^{2} 6 p^{4} ; 7 \mathrm{~A}: 7, n s^{2} n p^{5}, \mathrm{Ts}, 7 s^{2} 7 p^{5} ; 8 \mathrm{~A}: 8, n s^{2} n p^{6}, \mathrm{Ne}\), \(2 s^{2} 2 p^{6} \quad\) 105. none; an excited state; energy released 107. C, O, Si, S, Ti, \(\mathrm{Ni}, \mathrm{Ge}, \mathrm{Se}\) 109. Li (1 unpaired electron), N (3 unpaired electrons), Ni ( 2 unpaired electrons), and Te ( 2 unpaired electrons) are all expected to be paramagnetic because they have unpaired electrons. 111. a. \(\mathrm{S}<\mathrm{Se}<\mathrm{Te}\); b. \(\mathrm{Br}<\mathrm{Ni}<\mathrm{K}\); c. \(\mathrm{F}<\mathrm{Si}<\mathrm{Ba}\) 113. a. \(\mathrm{Te}<\mathrm{Se}<\mathrm{S}\); b. \(\mathrm{K}<\mathrm{Ni}<\mathrm{Br}\); c. \(\mathrm{Ba}<\mathrm{Si}<\mathrm{F}\) 115. a. He ; b. Cl ; c. element 116 ; d. Si ; e. \(\mathrm{Na}^{+}\) 117. a. \([\mathrm{Rn}] 7 s^{2} 5 f^{14} 6 d^{4}\); b. W; c. \(\mathrm{SgO}_{3}\) and \(\mathrm{SgO}_{4}{ }^{2-}\) probably would form (similar to Cr ). 119. Se is an exception to the general ionization trend. There are extra electron-electron repulsions in Se because two electrons are in the same \(4 p\) orbital, resulting in a lower ionization energy than expected. 121. a. As we remove succeeding electrons, the electron being removed is closer to the nucleus, and there are fewer electrons left repelling it. The remaining electrons are more strongly attracted to the nucleus, and it takes more energy to remove these electrons. b. \(\mathrm{Al}: 1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{1}\). For \(\mathrm{I}_{4}\), we begin removing an electron with \(n=2\). For \(\mathrm{I}_{3}\), we remove an electron with \(n=3\) (the last valence electron). In going from \(n=3\) to \(n=2\), there is a big jump in ionization energy because the \(n=2\) electrons are closer to the nucleus on average than the \(n=3\) electrons. Since the \(n=2\) electrons are closer, on average, to the nucleus, they are held more tightly and require a much larger amount of energy to remove compared to the \(n=3\) electrons. In general, valence electrons are much easier to remove than inner-core electrons. 123. a. C, Br; b. N, Ar; c. C, Br 125. \(\mathrm{Al}(-44), \mathrm{Si}(-120), \mathrm{P}(-74)\), \(\mathrm{S}(-200.4), \mathrm{Cl}(-348.7)\); Based on the increasing nuclear charge, we would expect the electron affinity (EA) values to become more exothermic as we go from left to right in the period. Phosphorus is out of line. The reaction for the \(E A\) of \(P\) is
\[
\begin{gathered}
\mathrm{P}(g)+\mathrm{e}^{-} \rightarrow \mathrm{P}^{-}(g) \\
{[\mathrm{Ne}] 3 s^{2} 3 p^{3} \quad[\mathrm{Ne}] 3 s^{2} 3 p^{4}}
\end{gathered}
\]

The additional electron in \(\mathrm{P}^{-}\)will have to go into an orbital that already has one electron. There will be greater repulsions between the paired electrons in \(\mathrm{P}^{-}\), causing the EA of P to be less favorable than predicted based solely on attractions to the nucleus. 127. a. \(\mathrm{Se}<\mathrm{S} ; \mathbf{b} . \mathrm{I}<\mathrm{Br}<\mathrm{F}<\mathrm{Cl}\) 129. Electronelectron repulsions are much greater in \(\mathrm{O}^{-}\)than in \(\mathrm{S}^{-}\)because the electron goes into a smaller \(2 p\) orbital versus the larger \(3 p\) orbital in sulfur. This results in a more favorable (more exothermic) EA for sulfur. 131. a. \(\mathrm{Se}^{3+}(g)\) \(\rightarrow \mathrm{Se}^{4+}(g)+\mathrm{e}^{-}\); b. \(\mathrm{S}^{-}(g)+\mathrm{e}^{-} \rightarrow \mathrm{S}^{2-}(g) ;\) c. \(\mathrm{Fe}^{3+}(g)+\mathrm{e}^{-} \rightarrow \mathrm{Fe}^{2+}(g) ;\) d. \(\operatorname{Mg}(g) \rightarrow \mathrm{Mg}^{+}(g)+\mathrm{e}^{-}\)133. \(\mathrm{C}: 1 s^{2} 2 s^{2} 2 p^{2}\); in the ground state, carbon has three different orbitals that hold electrons. Each orbital will have a separate peak on the PES spectrum, so we should have three different peaks in the spectrum. The peak at the lowest binding energy corresponds to the peak with the easiest electrons to remove. This will be the \(2 p\) electrons. The peak at the highest energy corresponds to the \(1 s\) orbital electrons since they will have the largest binding energy. The area under each peak is directly related to the number of electrons in each orbital. Since all orbitals in carbon have two electrons, each peak area will be equal. This is shown on the PES spectrum for carbon: three peaks with equal area. 135. potassium peroxide, \(\mathrm{K}_{2} \mathrm{O}_{2} ; \mathrm{K}^{2+}\) unstable \(137.6 .582 \times 10^{14} \mathrm{~s}^{-1} ; 4.361 \times 10^{-19} \mathrm{~J} \quad\) 139. Yes; the ionization energy general trend decreases down a group and the atomic radius trend increases down a group. The data in Table 7.8 confirm both of these general trends. 141. No; lithium metal is very reactive. It will react somewhat violently with water, making it completely unsuitable for human consumption. Lithium has a small first ionization energy, so it is more likely that the lithium prescribed will be in the form of a soluble lithium salt (a soluble ionic compound with \(\mathrm{Li}^{+}\)as the cation). 143. a. \(6 \mathrm{Li}(s)+\mathrm{N}_{2}(g) \rightarrow\) \(2 \mathrm{Li}_{3} \mathrm{~N}(s) ;\) b. \(2 \mathrm{Rb}(s)+\mathrm{S}(s) \rightarrow \mathrm{Rb}_{2} \mathrm{~S}(s) \quad\) 145. a. 6; b. O, S, Se, and Te; c. \(\mathrm{K}_{2} \mathrm{X}\) would be the predicted formula, where X is the unknown nonmetal. d. smaller; e. smaller 147. 386 nm 149. 200 s 151. \(\lambda=4.104 \times\) \(10^{-5} \mathrm{~cm}\) so violet light is emitted. 153. a. true for H only; \(\mathbf{b}\). true for all atoms; c. true for all atoms \(\mathbf{1 5 5 .} 1 p: n=1, \ell=1\) is not possible; \(3 f: n=3\), \(\ell=3\) is not possible; \(2 d\) : \(n=2\), \(\ell=2\) is not possible. In all three incorrect cases, \(n=\ell\). The maximum value \(\ell\) can have is \(n-1\), not \(n\). 157. smallest size: O ; largest size: K ; smallest 1st ionization energy: K ; largest 1st ionization energy: \(N\) 159. Valence electrons are easier to remove than inner-core electrons. The large difference in energy between \(I_{2}\) and \(I_{3}\) indicates that this element has two valence electrons. The element is most likely an alkaline earth metal because alkaline earth metals have two valence electrons. 161. a. 146 kJ ; b. 407 kJ ; c. 1117 kJ ; d. 1524 kJ 163. \(251 \mathrm{~nm} \quad \mathbf{1 6 5 .} 15\) 167. The number of electrons with \(\ell=1\) is 15 . The number of electrons with \(m_{\ell}=0\) is 15 . The number of electrons with \(m_{\ell}=1\) is \(7 . \quad 169 . \mathbf{a}\). Te; b. Ge; c. \(F\) 171. a. true; b. false; cations are smaller than the parent atom; c. false; all ionization energies are endothermic; d. true; e. true; this is hard to predict because the general atomic radius trends go against each other when going from Li to Al. Figure 7.37 of the text was used to answer this question. 173. S 175. a. line \(\mathrm{A}, n=6\) to \(n=3\); line \(\mathrm{B}, n=5\) to \(n=3\); b. 121.6 nm 177. \(\mathrm{X}=\mathrm{C}, m=5 ; \mathrm{C}^{5+}\) is the ion. 179. For \(r=a_{0}\) and \(\theta=0^{\circ}, \psi^{2}=2.46\) \(\times 10^{28}\). For \(r=a_{0}\) and \(\theta=90^{\circ}, \psi^{2}=0\). As expected, the \(x y\) plane is a node for the \(2 p_{z}\) atomic orbital.

b. 2, 4, 12, and 20; c. There are many possibilities. One example of each formula is \(\mathrm{XY}=1+11, \mathrm{XY}_{2}=6+11, \mathrm{X}_{2} \mathrm{Y}=1+10, \mathrm{XY}_{3}=7+11\), and \(X_{2} Y_{3}=7+10\); d. 6; e. 0; f. 18 183. The ratios for \(\mathrm{Mg}, \mathrm{Si}, \mathrm{P}, \mathrm{Cl}\), and Ar are about the same. However, the ratios for \(\mathrm{Na}, \mathrm{Al}\), and S are higher. For Na , the second IE is extremely high because the electron is taken from \(n=2\) (the first electron is taken from \(n=3\) ). For Al , the first electron requires a bit less energy than expected by the trend due to the fact it is a \(3 p\) electron. For S , the first electron requires a bit less energy than expected by the trend due to electrons being paired in one of the \(p\) orbitals. \(\quad\) 185. \(\mathbf{a} . Z_{\text {eff }}=43.33\); \(\mathbf{b}\). Silver is element 47 , so \(Z=47\) for silver. Our calculated \(Z_{\text {eff }}\) value is less than 47 . Electrons in other orbitals can penetrate the \(1 s\) orbital. Thus a \(1 s\) electron can be slightly shielded from the nucleus, giving a \(Z_{\text {eff }}\) close to but less than \(Z\). 187. Solving for the molar mass of the element gives \(40.2 \mathrm{~g} / \mathrm{mol}\); this is calcium.
189. a. Fr: \([\mathrm{Rn}] 7 s^{1}, \mathrm{Fr}^{+}:[\mathrm{Rn}]=[\mathrm{Xe}] 6 s^{2} 4 f^{14} 5 d^{10} 6 p^{6}\); b. \(7.7 \times 10^{22} \mathrm{Fr}\) atoms; c. \(2.27790 \times 10^{-22} \mathrm{~g}\)

\section*{Chapter 8}
19. a. This diagram represents a polar covalent bond as in HCl . In a polar covalent bond, there is an electron-rich region (indicated by the red color) and an electron-poor region (indicated by the blue color). In HCl , the more electronegative Cl atom has a slightly greater ability to attract the bonding electrons, which in turn produces a dipole moment. b. This diagram represents an ionic bond as in NaCl . Here, the electronegativity differences between the Na and Cl are so great that the valence electron of sodium is transferred to the chlorine atom. This results in the formation of a cation, an anion, and an ionic bond. c. This diagram represents a pure covalent bond as in \(\mathrm{H}_{2}\). Both atoms attract the bonding electrons equally, so there is no bond dipole formed. This is illustrated in the electrostatic potential diagram as there is no one region that is red nor one region that is blue (there is no specific partial negative end and no specific partial positive end). 21. \(\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}\) and \(\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}\) are compounds with both ionic and covalent bonds. 23. Electronegativity increases left to right across the periodic table and decreases from top to bottom. Hydrogen has an electronegativity value between \(B\) and \(C\) in the second row, and identical to P in the third row. Going further down the periodic table, \(H\) has an electronegativity value between As and Se (row 4) and identical to Te (row 5). It is important to know where hydrogen fits into the electronegativity trend, especially for rows 2 and 3. If you know where H fits into the trend, then you can predict bond dipole directions for nonmetals bonded to hydrogen. 25. For ions, concentrate on the number of protons and the number of electrons present. The species whose nucleus holds the electrons most tightly will be smallest. For example, compare the size of an anion to the neutral atom. The anion has more electrons held by the same number of protons in the nucleus. These electrons will not be held as tightly, resulting in a bigger size for the anion as compared to the neutral atom. For isoelectronic ions, the same number of electrons are held by different numbers of protons in the various ions. The ion with the most protons holds the electrons tightest and has smallest size. 27. Fossil fuels contain a lot of carbon and hydrogen atoms. Combustion of fossil fuels (reaction with \(\mathrm{O}_{2}\) ) produces \(\mathrm{CO}_{2}\) and \(\mathrm{H}_{2} \mathrm{O}\). Both these compounds have very strong bonds. Because much stronger product bonds are formed than reactant bonds broken, combustion reactions are very exothermic.
29. \(\mathrm{C} \equiv \mathrm{O}\) :
\[
\text { Carbon: formal charge }=-1 ; \text { oxygen: formal charge }=+1
\]

Electronegativity predicts the opposite polarization with the partial negative end of the molecule around the more electronegative oxygen atom. The two opposing effects seem to partially cancel to give a much less polar molecule than expected.
31. a. \(\mathrm{C}<\mathrm{N}<\mathrm{O}\); b. \(\mathrm{Se}<\mathrm{S}<\mathrm{Cl}\); c. \(\mathrm{Sn}<\mathrm{Ge}<\mathrm{Si}\); d. \(\mathrm{Tl}<\mathrm{Ge}<\mathrm{S}\) 33. a. \(\mathrm{Ge}-\mathrm{F}\); b. \(\mathrm{P}-\mathrm{Cl}\); c. \(\mathrm{S}-\mathrm{F}\); d. \(\mathrm{Ti}-\mathrm{Cl}\) 35. Order of electronegativity from Fig. 8.3: a. \(\mathrm{C}(2.5)<\mathrm{N}(3.0)<\mathrm{O}(3.5)\), same; b. \(\mathrm{Se}(2.4)<\mathrm{S}(2.5)<\mathrm{Cl}\) (3.0), same; \(\mathbf{c} . \mathrm{Si}=\mathrm{Ge}=\mathrm{Sn}(1.8)\), different; d. \(\mathrm{Tl}(1.8)=\mathrm{Ge}(1.8)<\mathrm{S}(2.5)\), different. Most polar bonds using actual electronegativity values: \(\mathrm{a} . \mathrm{Si}-\mathrm{F}\) and \(\mathrm{Ge}-\mathrm{F}\) equal polarity ( \(\mathrm{Ge}-\mathrm{F}\) predicted); b. \(\mathrm{P}-\mathrm{Cl}\) (same as predicted); c. \(\mathrm{S}-\mathrm{F}\) (same as predicted); d. \(\mathrm{Ti}-\mathrm{Cl}\) (same as predicted) 37. Incorrect: b, d, e; b. \({ }^{\delta-} \mathrm{Cl}-\mathrm{I}^{\delta+}\); d. nonpolar bond so no dipole moment; e. \({ }^{\delta-} \mathrm{O}-\mathrm{P}^{\delta+}\) 39. a. ionic; b. covalent; c. polar covalent; d. ionic; e. polar covalent; f. covalent 41. \(\mathrm{F}-\mathrm{H}>\mathrm{O}-\mathrm{H}>\mathrm{N}-\mathrm{H}>\mathrm{C}-\mathrm{H}>\mathrm{P}-\mathrm{H} \quad\) 43. a. Has a permanent dipole; b. has no permanent dipole; c. has no permanent dipole; d. has a permanent dipole; e. has no permanent dipole; f. has no permanent dipole. 45. \(\mathrm{Al}^{3+}:[\mathrm{He}] 2 s^{2} 2 p^{6} ; \mathrm{Ba}^{2+}:[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{6} ; \mathrm{Se}^{2-}:[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{6} ; \mathrm{I}^{-}\): \([\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{6} \quad\) 47. a. \(\mathrm{Li}^{+}\)and \(\mathrm{N}^{3-}\) are the expected ions. The formula of the compound would be \(\mathrm{Li}_{3} \mathrm{~N}\) (lithium nitride). b. \(\mathrm{Ga}^{3+}\) and \(\mathrm{O}^{2-} ; \mathrm{Ga}_{2} \mathrm{O}_{3}\), gallium(III) oxide or gallium oxide; \(\mathbf{c} . \mathrm{Rb}^{+}\)and \(\mathrm{Cl}^{-} ; \mathrm{RbCl}\), rubidium chloride; d. \(\mathrm{Ba}^{2+}\) and \(\mathrm{S}^{2-}\); BaS, barium sulfide 49. a. \(\mathrm{Mg}^{2+}\) and \(\mathrm{Al}^{3+}: 1 s^{2} 2 s^{2} 2 p^{6} ; \mathrm{K}^{+}\): \(1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} ;\) b. \(\mathrm{N}^{3-}, \mathrm{O}^{2-}\), and \(\mathrm{F}^{-}: 1 s^{2} 2 s^{2} 2 p^{6} ; \mathrm{Te}^{2-}:[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{6}\) 51. a. \(\mathrm{Sc}^{3+}\); b. \(\mathrm{Te}^{2-}\); c. \(\mathrm{Ce}^{4+}, \mathrm{Ti}^{4+}\); d. \(\mathrm{Ba}^{2+}\) 53. a. \(\mathrm{F}^{-}, \mathrm{O}^{2-}\), or \(\mathrm{N}^{3-}\); b. \(\mathrm{Cl}^{-}\), \(\mathrm{S}^{2-}\), or \(\mathrm{P}^{3-}\); c. \(\mathrm{F}^{-}, \mathrm{O}^{2-}\), or \(\mathrm{N}^{3-}\); d. \(\mathrm{Br}^{-}, \mathrm{Se}^{2-}\), or \(\mathrm{As}^{3-} \quad\) 55. \(\mathrm{Se}^{2-}, \mathrm{Br}^{-}, \mathrm{Rb}^{+}\), \(\mathrm{Sr}^{2+}, \mathrm{Y}^{3+}\), and \(\mathrm{Zr}^{4+}\) are some ions that are isoelectronic with Kr . The size trend is
\[
\mathrm{Zr}^{4+}<\mathrm{Y}^{3+}<\mathrm{Sr}^{2+}<\mathrm{Rb}^{+}<\mathrm{Br}^{-}<\mathrm{Se}^{2-}
\]
57. a. \(\mathrm{Cu}>\mathrm{Cu}^{+}>\mathrm{Cu}^{2+}\); b. \(\mathrm{Pt}^{2+}>\mathrm{Pd}^{2+}>\mathrm{Ni}^{2+} ;\) c. \(\mathrm{O}^{2-}>\mathrm{O}^{-}>\mathrm{O} ;\) d. \(\mathrm{La}^{3+}\) \(>\mathrm{Eu}^{3+}>\mathrm{Gd}^{3+}>\mathrm{Yb}^{3+}\); e. \(\mathrm{Te}^{2-}>\mathrm{I}^{-}>\mathrm{Cs}^{+}>\mathrm{Ba}^{2+}>\mathrm{La}^{3+}\) 59. a. NaCl , \(\mathrm{Na}^{+}\)smaller than \(\mathrm{K}^{+} ;\)b. LiF, \(\mathrm{F}^{-}\)smaller than \(\mathrm{Cl}^{-} ;\)c. \(\mathrm{MgO}, \mathrm{O}^{2-}\) greater charge than \(\mathrm{OH}^{-} ;\)d. \(\mathrm{Fe}(\mathrm{OH})_{3}, \mathrm{Fe}^{3+}\) greater charge than \(\mathrm{Fe}^{2+} ;\) e. \(\mathrm{Na}_{2} \mathrm{O}, \mathrm{O}^{2-}\) greater charge than \(\mathrm{Cl}^{-} ; \mathbf{f}\). \(\mathrm{MgO}, \mathrm{Mg}^{2+}\) smaller than \(\mathrm{Ba}^{2+}\), and \(\mathrm{O}^{2-}\) smaller than \(\mathrm{S}^{2-}\). 61. \(-411 \mathrm{~kJ} / \mathrm{mol}\) 63. The lattice energy for \(\mathrm{Mg}^{2+} \mathrm{O}^{2-}\) will be much more exothermic than for \(\mathrm{Mg}^{+} \mathrm{O}^{-}\). \(65.161 \mathrm{~kJ} / \mathrm{mol} \quad \mathbf{6 7} . \mathrm{Ca}^{2+}\) has greater charge than \(\mathrm{Na}^{+}\), and \(\mathrm{Se}^{2-}\) is smaller than \(\mathrm{Te}^{2-}\). Charge differences affect lattice energy values more than size differences, and we expect the trend from most exothermic to least exothermic to be:
\[
\underset{(-2862)}{\mathrm{CaSe}}>\underset{(-2721)}{\mathrm{CaTe}}>\underset{(-2130)}{\mathrm{Na}_{2} \mathrm{Se}}>\underset{(-2095)}{\mathrm{Na}_{2} \mathrm{Te}}
\]
69. a. -183 kJ ; b. \(-109 \mathrm{~kJ} \quad\) 71. \(-42 \mathrm{~kJ} \quad\) 73. \(-1282 \mathrm{~kJ} \quad\) 75. -1228 kJ 77. \(485 \mathrm{~kJ} / \mathrm{mol}\) 79. a. Using standard enthalpies of formation, \(\Delta H^{\circ}=\) -184 kJ vs. -183 kJ from bond energies; b. Using standard enthalpies of formation, \(\Delta H=-92 \mathrm{~kJ}\) vs. -109 kJ from bond energies. Bond energies give a reasonably good estimate for \(\Delta H\), especially when all reactants and products are gases. 81. a. Using \(\mathrm{SF}_{4}\) data: \(D_{\mathrm{SF}}=342.5 \mathrm{~kJ} / \mathrm{mol}\). Using \(\mathrm{SF}_{6}\) data: \(D_{\mathrm{SF}}=327.0 \mathrm{~kJ} / \mathrm{mol}\). b. The S-F bond energy in the table is \(327 \mathrm{~kJ} / \mathrm{mol}\). The value in the table was based on the \(\mathrm{S}-\mathrm{F}\) bond in \(\mathrm{SF}_{6} . \mathrm{c} . \mathrm{S}(g)\) and \(\mathrm{F}(g)\) are not the most stable forms of the elements at \(25^{\circ} \mathrm{C}\). The most stable forms are \(\mathrm{S}_{8}(s)\) and \(\mathrm{F}_{2}(g) ; \Delta H_{\mathrm{f}}^{\circ}=0\) for these two species. \(83.158 .4 \mathrm{~kJ} / \mathrm{mol}\) vs. 160. \(\mathrm{kJ} / \mathrm{mol}\) in Table 8.5

\]

Row 3 and heavier nonmetals can have more than 8 electrons around them when they have to. Row 3 and heavier elements have empty \(d\) orbitals that are close in energy to valence \(s\) and \(p\) orbitals. These empty \(d\) orbitals can accept extra electrons.
93. a. \(\mathrm{NO}_{2}^{-}[\ddot{\mathrm{O}}=\ddot{\mathrm{N}}-\ddot{\mathrm{O}}: \cdot]^{-} \longleftrightarrow[: \ddot{\mathrm{O}}-\ddot{\mathrm{N}}=\ddot{\mathrm{O}}]^{-}\)

b. \(\mathrm{OCN}^{-}\)

95.

97. With resonance all carbon-carbon bonds are equivalent (we indicate this with a circle in the ring), giving three different structures:

Localized double bonds would give four unique structures.

101. Longest \(\rightarrow\) shortest \(\mathrm{C}-\mathrm{O}\) bond: \(\mathrm{CH}_{3} \mathrm{OH}>\mathrm{CO}_{3}{ }^{2-}>\mathrm{CO}_{2}>\mathrm{CO}\); weakest \(\rightarrow\) strongest \(\mathrm{C}-\mathrm{O}\) bond: \(\mathrm{CH}_{3} \mathrm{OH}<\mathrm{CO}_{3}{ }^{2-}<\mathrm{CO}_{2}<\mathrm{CO}\)
103.

The first Lewis structure obeys the octet rule but has a +1 formal charge on the most electronegative element there is, fluorine, and a negative formal charge on a much less electronegative element, boron. This is just the opposite of what we expect: negative formal charge on \(F\) and positive formal charge on \(B\). The other Lewis structure does not obey the octet rule for B but has a zero formal
charge on each element in \(\mathrm{BF}_{3}\). Since structures generally want to minimize formal charge, \(\mathrm{BF}_{3}\) with only single bonds is best from a formal charge point of view. 105. a-f and \(\mathbf{h}\) all have similar Lewis structures:

g. \(\mathrm{ClO}_{3}{ }^{-}\)

Formal charges: \(\mathbf{a} .+1 ;\) b. \(+2 ; \mathbf{c} .+3 ; \mathbf{d} .+1 ;\) e. \(+2 ; \mathbf{f} .+4 ;\) g. \(+2 ;\) h. +1
107.
\begin{tabular}{lrrrr} 
& \(: \ddot{\mathrm{F}}-\ddot{\mathrm{O}}-\ddot{\mathrm{O}}-\ddot{\mathrm{F}}:\) \\
Formal charge: & 0 & 0 & 0 & 0 \\
Oxidation number: & -1 & +1 & +1 & -1
\end{tabular}

Oxidation numbers are more useful. We are forced to assign +1 as the oxidation number for oxygen. Oxygen is very electronegative and +1 is not a stable oxidation state for this element.

129. Element E is a halogen \((\mathrm{F}, \mathrm{Cl}, \mathrm{Br}\), or I\()\); trigonal pyramid; \(<109.5^{\circ}\)
131.

Nonpolar
133. a. radius: \(\mathrm{N}^{+}<\mathrm{N}<\mathrm{N}^{-}\); I.E.: \(\mathrm{N}^{-}<\mathrm{N}<\mathrm{N}^{+}\); b. radius: \(\mathrm{Cl}^{+}<\mathrm{Cl}<\mathrm{Se}\) \(<\mathrm{Se}^{-}\); I.E.: \(\mathrm{Se}^{-}<\mathrm{Se}<\mathrm{Cl}<\mathrm{Cl}^{+}\); c. radius: \(\mathrm{Sr}^{2+}<\mathrm{Rb}^{+}<\mathrm{Br}^{-}\); I.E.: \(\mathrm{Br}^{-}<\mathrm{Rb}^{+}<\mathrm{Sr}^{2+}\); 135. a. 1549 kJ; b. 1390 . kJ c. 1312 kJ ; d. 1599 kJ 137. a. NaBr : In \(\mathrm{NaBr}_{2}\), the sodium ion would have a +2 charge assuming each bromine has a -1 charge. Sodium doesn't form stable \(\mathrm{Na}^{2+}\) compounds. b. \(\mathrm{ClO}_{4}^{-}\): \(\mathrm{ClO}_{4}\) has 31 valence electrons so it is impossible to satisfy the octet rule for all atoms in \(\mathrm{ClO}_{4}\). The extra electron from the -1 charge in \(\mathrm{ClO}_{4}{ }^{-}\)allows for complete octets for all atoms. c. \(\mathrm{XeO}_{4}\) : We can't draw a Lewis structure that obeys the octet rule for \(\mathrm{SO}_{4}\) ( 30 electrons), unlike \(\mathrm{XeO}_{4}\) ( 32 electrons). d. \(\mathrm{SeF}_{4}\) : Both compounds require the central atom to expand its octet. O is too small and doesn't have low-energy \(d\) orbitals to expand its octet (which is true for all row 2 elements). 139. a. Both have one or more \(180^{\circ}\) bond angles; both are made up entirely of Xe and Cl ; both have the individual bond dipoles arranged so they cancel each other (both are nonpolar); both have lone pairs on the central Xe atom; both have a central Xe atom that has more than 8 electrons around it. b. All have lone pairs on the central atom; all have a net dipole moment (all are polar). 141. -5681 kJ 143. Yes, each structure has the same number of effective pairs around the central atom. (We count a multiple bond as a single group of electrons.)
145.

The lone pair of electrons around Te exerts a stronger repulsion than the bonding pairs. The stronger repulsion pushes the four square planar F atoms away from the lone pair, reducing the bond angles between the axial F atom and the square planar \(F\) atoms. 147. a. nonpolar covalent; \(\mathbf{b}\). ionic; \(\mathbf{c}\). ionic; d. polar covalent; e. polar covalent; f. polar covalent; g. polar covalent; h. ionic 149. a. \(\mathrm{O}^{2-}>\mathrm{O}^{-}>\mathrm{O}\); b. \(\mathrm{Fe}^{2+}>\mathrm{Ni}^{2+}>\mathrm{Zn}^{2+}\); c. \(\mathrm{Cl}^{-}>\mathrm{K}^{+}\) \(>\mathrm{Ca}^{2+}\) 151. \(-303 \mathrm{~kJ} \quad\) 153. \(\mathrm{CO}_{2}\) : carbon dioxide, linear; \(\mathrm{NH}_{3}\) : ammonia (nitrogen trihydride), trigonal pyramid; \(\mathrm{SO}_{3}\) : sulfur trioxide, trigonal planar; \(\mathrm{H}_{2} \mathrm{O}\) : water (dihydrogen monoxide), V -shaped or bent; \(\mathrm{ClO}_{4}^{-}\): perchlorate ion, tetrahedral 155 . a. \(-5 \times 10^{-18} \mathrm{~J}\); b. \(-6 \times 10^{-18} \mathrm{~J} \quad 157.17 \mathrm{~kJ} / \mathrm{mol}\) 159. See Fig. 8.11 to see the data supporting MgO as an ionic compound. Note that the lattice energy is large enough to overcome all of the other pro-
cesses (removing 2 electrons from Mg , and so on). The bond energy for \(\mathrm{O}_{2}\) ( \(247 \mathrm{~kJ} / \mathrm{mol}\) ) and electron affinity ( \(737 \mathrm{~kJ} / \mathrm{mol}\) ) are the same when making CO. However, the energy needed to ionize carbon to form a \(\mathrm{C}^{2+}\) ion must be too large. Figure 7.32 shows that the first ionization energy for carbon is about \(350 \mathrm{~kJ} / \mathrm{mol}\) greater than the first IE for magnesium. If all other numbers were equal, the overall energy change would be \(250 \mathrm{~kJ} / \mathrm{mol}\) (see Fig. 8.11). It is not unreasonable to assume that the second ionization energy for carbon is more than \(250 \mathrm{~kJ} / \mathrm{mol}\) greater than the second ionization energy for magnesium. This would result in a positive \(\Delta \mathrm{H}\) value for the formation of CO as an ionic compound. One wouldn't expect CO to be ionic if the energetics were unfavorable. 161. As the halogen atoms get larger, it becomes more difficult to fit three halogen atoms around the small nitrogen atom, and the \(\mathrm{NX}_{3}\) molecule becomes less stable. 163. reaction i: -2636 kJ ; reaction ii: -3471 kJ ; reaction iii: -3543 kJ ; Reaction iii yields the most energy per kg ( \(-8085 \mathrm{~kJ} / \mathrm{kg}\) )
165.

We would expect \(120^{\circ}\) bond angles about the carbon atom labeled 1 and \(\sim 109.5^{\circ}\) bond angles about the nitrogen atom labeled 2 . The nitrogen bond angles should be slightly smaller than \(109.5^{\circ}\) due to the lone pair of electrons on nitrogen.
167. a. Two possible structures exist; each has a T-shaped molecular structure:

\(90^{\circ}\) bond angle between I atoms
\(180^{\circ}\) bond angle between I atoms
b. Three possible structures exist; each has a see-saw molecular structure:

\(90^{\circ}\) bond angle between O atoms

\(180^{\circ}\) bond angle
between O atoms

\(120^{\circ}\) bond angle
between O atoms
c. Three possible structures exist; each has a square pyramid molecular structure:

One F atom is \(180^{\circ}\) from lone pair.

Both F atoms are \(90^{\circ}\)
from lone pair and \(90^{\circ}\) from each other.

Both F atoms are \(90^{\circ}\)
from lone pair and \(180^{\circ}\) from each other.

Note: \(\mathrm{OH}, \mathrm{CH}, \mathrm{H}_{2} \mathrm{C}, \mathrm{CH}_{2}\), and \(\mathrm{CH}_{3}\) are short-hand notation. In this notation, single bonds to the various H atoms are assumed. Most of the bond angles in the molecule are predicted to be 109.5 degrees because most of the carbon atoms exhibit tetrahedral geometry. The exceptions are the two carbons with the *. These two carbons exhibit trigonal planar geometry and are predicted to have 120-degree bond angles. Because most of the carbon atoms exhibit tetrahedral geometry, the molecule is not planar. 171. X is iodine; square pyramid 173. \([\mathrm{Ar}] 4 s^{1} 3 d^{5}=\mathrm{Cr} ;[\mathrm{Ne}] 3 s^{2} 3 p^{3}=\mathrm{P}\); \([\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{3}=\mathrm{As}\); \([\mathrm{Ne}] 3 s^{2} 3 p^{5}=\mathrm{Cl} ; \mathrm{Cr}<\mathrm{As}<\mathrm{P}<\mathrm{Cl}\)

\section*{Chapter 9}
11. In hybrid orbital theory, some or all of the valence atomic orbitals of the central atom in a molecule are mixed together to form hybrid orbitals; these hybrid orbitals point to where the bonded atoms and lone pairs are oriented. The \(\sigma\) bonds are formed from the hybrid orbitals overlapping head to head with an appropriate orbital on the bonded atom. The \(\pi\) bonds in hybrid orbital theory are formed from unhybridized \(p\) atomic orbitals. The \(p\) orbitals overlap side to side to form the \(\pi\) bond where the \(\pi\) electrons occupy the space above and below a line joining the atoms \(\pi\) the internuclear axis). Assuming the \(z\)-axis is the internuclear axis, then the \(p_{z}\) atomic orbital will always be hybridized whether the hybridization is \(s p, s p^{2}, s p^{3}, d s p^{3}\) or \(d^{2} s p^{3}\). For \(s p\) hybridization, the \(p_{x}\) and \(p_{y}\) atomic orbitals are unhybridized; they are used to form two \(\pi\) bonds to the bonded atom(s). For \(s p^{2}\) hybridization, either the \(p_{x}\) or \(p_{y}\) atomic orbital is hybridized (along with the \(s\) and \(p_{z}\) orbitals); the other \(p\) orbital is used to form a \(\pi\) bond to a bonded atom. For \(s p^{3}\) hybridization, the \(s\) and all of the \(p\) orbitals are hybridized; no unhybridized \(p\) atomic orbitals are present, so typical \(\pi\) bonds do not form with \(s p^{3}\) hybridization. For \(d s p^{3}\) and \(d^{2} s p^{3}\) hybridization, we just mix in one or two \(d\) orbitals into the hybridization process. Which specific \(d\) orbitals are used is not important to our discussion. 13. We use \(d\) orbitals when we have to; i.e., we use \(d\) orbitals when the central atom on a molecule has more than eight electrons around it. The \(d\) orbitals are necessary to accommodate the electrons over eight. Row 2 elements never have more than eight electrons around them so they never hybridize \(d\) orbitals. We rationalize this by saying there are no \(d\) orbitals close in energy to the valence \(2 s\) and \(2 p\) orbitals ( \(2 d\) orbitals are forbidden energy levels). However, for row 3 and heavier elements, there are \(3 d, 4 d, 5 d\), etc. orbitals that will be close in energy to the valence \(s\) and \(p\) orbitals. It is row 3 and heavier nonmetals that hybridize \(d\) orbitals when they have to. For sulfur, the valence electrons are in \(3 s\) and \(3 p\) orbitals. Therefore, \(3 d\) orbitals are closest in energy and are available for hybridization. Arsenic would hybridize \(4 d\) orbitals to go with the valence \(4 s\) and \(4 p\) orbitals while iodine would hybridize \(5 d\) orbitals since the valence electrons are in \(n=5\).
15. \(\ddot{\mathrm{O}}=\mathrm{C}=\ddot{\mathrm{O}}\)

The darker green orbitals about carbon are \(s p\) hybrid orbitals. The lighter green orbitals about each oxygen are \(s p^{2}\) hybrid orbitals, and the gold orbitals about all of the atoms are unhybridized \(p\) atomic orbitals. In each double bond in \(\mathrm{CO}_{2}\), one \(\sigma\) and one \(\pi\) bond exists. The two carbon-oxygen \(\sigma\) bonds are formed from overlap of \(s p\) hybrid orbitals from carbon with a \(s p^{2}\) hybrid orbital from each oxygen. The two carbon-oxygen \(\pi\) bonds are formed from side-to-side overlap of the unhybridized \(p\) atomic orbitals from carbon with an unhybridized \(p\) atomic orbital from each oxygen. These two \(\pi\) bonds are oriented perpendicular to each other as illustrated in the figure. 17. Bonding and antibonding molecular orbitals are both solutions to the quantum mechanical treatment of the molecule. Bonding orbitals form when in-phase orbitals combine to give constructive interference. This results in enhanced electron probability located between the two nuclei. The end result is that a bonding MO is lower in energy than the atomic orbitals of which it is composed. Antibonding orbitals form when out-of-phase orbitals combine. The mismatched phases produce destructive interference leading to a node in the electron probability between the two nuclei. With electron distribution pushed to the outside, the energy of an antibonding orbital is higher than the energy of the atomic orbitals of which it is composed. 19. The localized electron model does not deal effectively with molecules containing unpaired electrons. We can draw all of the possible resonance structures for NO, but still not have a good feel for whether the bond in NO is weaker or stronger than the bond in \(\mathrm{NO}^{-}\). MO theory can handle odd electron species without any modifications. In addition, hybrid orbital theory does not predict that \(\mathrm{NO}^{-}\)is paramagnetic. The MO theory correctly makes this prediction.
21. \(\mathrm{H}_{2} \mathrm{O}\) :

\(\mathrm{H}_{2} \mathrm{O}\) has a tetrahedral arrangement of the electron pairs about the O atom that requires \(s p^{3}\) hybridization. Two of the \(s p^{3}\) hybrid orbitals are used to form bonds to the two hydrogen atoms, and the other two \(s p^{3}\) hybrid orbitals hold the two lone pairs on oxygen.
23. \(\mathrm{H}_{2} \mathrm{CO}\) :

The central carbon atom has a trigonal planar arrangement of the electron pairs that requires \(s p^{2}\) hybridization. Two of the \(s p^{2}\) hybrid orbitals are used to form the two bonds to hydrogen. The other \(s p^{2}\) hybrid orbital forms the \(\sigma\) bond to oxygen. The unchanged (unhybridized) \(p\) orbital on carbon is used to form the \(\pi\) bond between carbon and oxygen.
25. Ethane:

The carbon atoms are \(s p^{3}\) hybridized. The six \(\mathrm{C}-\mathrm{H}\) bonds are formed from the \(s p^{3}\) hybrid orbitals on C with the \(1 s\) atomic orbitals from the hydrogen atoms. The carbon-carbon bond is formed from an \(s p^{3}\) hybrid orbital on each C atom.

Ethanol:

The two C atoms and the O atom are all \(s p^{3}\) hybridized. All bonds are formed from these \(s p^{3}\) hybrid orbitals. The \(\mathrm{C}-\mathrm{H}\) and \(\mathrm{O}-\mathrm{H}\) bonds form from \(s p^{3}\) hybrid orbitals and the \(1 s\) atomic orbitals from the hydrogen atom. The \(\mathrm{C}-\mathrm{C}\) and \(\mathrm{C}-\mathrm{O}\) bonds are formed from \(s p^{3}\) hybrid orbitals on each atom. 27. [87] All are \(s p^{3}\) hybridized. [93] a. \(\mathrm{NO}_{2}{ }^{-}, s p^{2} ; \mathrm{NO}_{3}{ }^{-}, s p^{2} ; \mathrm{N}_{2} \mathrm{O}_{4}\), both N atoms are \(s p^{2}\) hybridized; b. All are \(s p\) hybridized. 29. All exhibit \(d s p^{3}\) hybridization. 31. The molecules in Exercise 119 all exhibit \(s p^{2}\) hybridization about the central atom; the molecules in Exercise 120 all exhibit \(s p^{3}\) hybridization about the central atom. 33. a. tetrahedral, \(109.5^{\circ}\), \(s p^{3}\), nonpolar

35. The \(\pi\) bond forces all six atoms into the same plane. 37. a. There are \(33 \sigma\) and \(9 \pi\) bonds. b. All C atoms are \(s p^{2}\) hybridized since all have a trigonal planar arrangement of the electrons. 39. Biacetyl:

All CCO angles are \(120^{\circ}\). The six atoms are not forced to lie in the same plane. \(11 \sigma\) and \(2 \pi\) bonds; Acetoin:

angle \(\mathrm{a}=120^{\circ}\), angle \(\mathrm{b}=109.5^{\circ}, 13 \sigma\) bonds and \(1 \pi\) bond

Note: \(\mathrm{NH}_{2}, \mathrm{CH}_{2}\), and \(\mathrm{CH}_{3}\) are shorthand for carbon atoms singly bonded to hydrogen atoms. b. In azodicarbonamide, the two carbon atoms are \(s p^{2}\) hybridized. The two nitrogen atoms with hydrogens attached are \(s p^{3}\) hybridized and the other two nitrogens are \(s p^{2}\) hybridized. In methyl cyanoacrylate, the \(\mathrm{CH}_{3}\) carbon is \(s p^{3}\) hybridized, the carbon with the triple bond is \(s p\) hybridized, and the other three carbons are \(s p^{2}\) hybridized. c. Azodicarbonamide contains
\(3 \pi\) bonds and methyl cyanoacrylate contains \(4 \pi\) bonds. d. \(a: \approx 109.5^{\circ}, b: 120^{\circ}\), \(c: \approx 120^{\circ}, d: 120^{\circ}, e: 180^{\circ}, f: 120^{\circ}, g: \approx 109.5^{\circ}, h: 120^{\circ}\) 43. To complete the Lewis structure, add lone pairs to complete octets for each atom. a. 6; b. 4; c. The center N in \(-\mathrm{N}=\mathrm{N}=\mathrm{N}\) group; d. \(33 \sigma\); e. \(5 \pi\); f. \(180^{\circ}\); g. \(\approx 109.5^{\circ}\); h. \(s p^{3}\) 45. a. The bonding molecular orbital is on the right and the antibonding molecular orbital is on the left. The bonding MO has the greatest electron probability between the nuclei, while the antibonding MO has greatest electron probability on either side of the nuclei. \(\mathbf{b}\). The bonding MO is lower in energy. Because the electrons in the bonding MO have the greatest probability of lying between the two nuclei, these electrons are attracted to two different nuclei, resulting in a lower energy. 47. a. \(\mathrm{H}_{2}^{+}, \mathrm{H}_{2}, \mathrm{H}_{2}{ }^{-}\); b. \(\mathrm{He}_{2}{ }^{2+}\) and \(\mathrm{He}_{2}{ }^{+}\)49. a. \(\left(\sigma_{2 s}\right)^{2}\); B.O. \(=1\); diamagnetic ( 0 unpaired electrons); b. \(\left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s}{ }^{*}\right)^{2}\left(\pi_{2 p}\right)^{4}\); B.O. \(=2\); diamagnetic (0 unpaired electrons); c. \(\left(\sigma_{3 s}\right)^{2}\) \(\left(\sigma_{3 s}\right)^{2}\left(\sigma_{3 p}\right)^{2}\left(\pi_{3 p}\right)^{4}\left(\pi_{3 p} *\right)^{2}\); B.O. \(=2\); paramagnetic (2 unpaired electrons) 51. \(\mathrm{N}_{2}{ }^{+}\)and \(\mathrm{N}_{2}{ }^{-}\)both have bond orders of 2.5. 53. The peroxide ion has a bond order of 1 and the superoxide ion has a bond order of 1.5 . The superoxide ion with the larger bond order should have the shorter (and stronger) bond. 55. a. \(\left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s} *\right)^{2}\left(\pi_{2 p}\right)^{4}\left(\sigma_{2 p}\right)^{2}\); B.O. \(=3\); diamagnetic; b. \(\left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s} *\right)^{2}\left(\pi_{2 p}\right)^{4}\) \(\left(\sigma_{2 p}\right)^{1}\); B.O. \(=2.5\); paramagnetic; c. \(\left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s}{ }^{*}\right)^{2}\left(\pi_{2 p}\right)^{4}\); B.O. \(=2\); diamagnetic; bond length: \(\mathrm{CO}<\mathrm{CO}^{+}<\mathrm{CO}^{2+}\); bond energy: \(\mathrm{CO}^{2+}<\mathrm{CO}^{+}<\mathrm{CO}\) 57. \(\mathrm{H}_{2}\); \(\mathrm{B}_{2} ; \mathrm{C}_{2}{ }^{2-}\)
59.

61. a. The electrons would be closer to F on the average. The F atom is more electronegative than the H atom, and the \(2 p\) orbital of F is lower in energy than the \(1 s\) orbital of H ; \(\mathbf{b}\). The bonding MO would have more fluorine \(2 p\) character because it is closer in energy to the fluorine \(2 p\) orbital; \(\mathbf{c}\). The antibonding MO would place more electron density closer to H and would have a greater contribution from the higher-energy hydrogen \(1 s\) atomic orbital. 63. \([: \mathrm{C} \equiv \mathrm{C}:]^{2-} s p\) hybrid orbitals form the \(\sigma\) bond and the two unhybridized \(p\) atomic orbitals from each carbon form the two \(\pi\) bonds.
\[
\text { MO: }\left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s} *\right)^{2}\left(\pi_{2 p}\right)^{4}\left(\sigma_{2 p}\right)^{2}, \text { B.O. }=(8-2) / 2=3
\]

Both give the same picture, a triple bond composed of a \(\sigma\) bond and two \(\pi\) bonds. Both predict the ion to be diamagnetic. Lewis structures deal well with diamagnetic (all electrons paired) species. The Lewis model cannot really predict magnetic properties. 65. \(\mathrm{O}_{3}\) and \(\mathrm{NO}_{2}{ }^{-}\)have identical Lewis structures, so we need to discuss only one of them. The Lewis structures for \(\mathrm{O}_{3}\) are

Localized electron model: The central oxygen atom is \(s p^{2}\) hybridized, which is used to form the two \(\sigma\) bonds and hold the lone pair of electrons. An unchanged (unhybridized) \(p\) atomic orbital forms the \(\pi\) bond with the neighboring oxygen atoms. The actual structure of \(\mathrm{O}_{3}\) is an average of the two resonance structures. Molecular orbital model: There are two localized \(\sigma\) bonds and a \(\pi\) bond that is delocalized over the entire surface of the molecule. The delocalized \(\pi\) bond results from overlap of a \(p\) atomic oribtal on each oxygen atom in \(\mathrm{O}_{3}\).
67. a. Trigonal pyramid; \(s p^{3}\)

b. Tetrahedral; \(s p^{3}\)

c. Square pyramid; \(d^{2} s p^{3}\)

d. T-shaped; \(d s p^{3}\)

e. Trigonal bipyramid; \(d s p^{3}\)

69. a. No, some atoms are attached differently; b. Structure 1: All N atoms are \(s p^{3}\) hybridized, all C atoms are \(s p^{2}\) hybridized; structure 2: All C and N atoms are \(s p^{2}\) hybridized; \(\mathbf{c}\). The first structure with the carbon-oxygen double bonds is slightly more stable.
71.

a. \(21 \sigma\) bonds; \(4 \pi\) bonds (The electrons in the \(3 \pi\) bonds in the ring are delocalized.) b. angles \(a, c\), and \(g: \approx 109.5^{\circ}\); angles \(b, d, e\), and \(f: \approx 120^{\circ}\); c. \(6 s p^{2}\) carbons; d. \(4 s p^{3}\) atoms; e. Yes, the \(\pi\) electrons in the ring are delocalized. The atoms in the ring are all \(s p^{2}\) hybridized. This leaves a \(p\) orbital perpendicular to the plane of the ring from each atom. Overlap of all six of these \(p\) orbitals results in a \(\pi\) molecular orbital system where the electrons are delocalized above and below the plane of the ring (similar to benzene in Fig. 9.47 of the text). \(\quad \mathbf{7 3} .267 \mathrm{~kJ} / \mathrm{mol}\); this amount of energy must be supplied to break the \(\pi\) bond.
75. a.

Trigonal planar, nonpolar, \(120^{\circ}, s p^{2}\)
b. \(\mathrm{N}_{2} \mathrm{~F}_{2}\)

V-shaped about both N atoms, \(\approx 120^{\circ}, s p^{2}\)
These are distinctly different molecules.

Trigonal planar about all C atoms, nonpolar, \(120^{\circ}, s p^{2}\)
77. a. The NNO structure is correct. From the Lewis structures we would predict both NNO and NON to be linear, but NON would be nonpolar. NNO is polar.

The central N is \(s p\) hybridized. We can probably ignore the third resonance structure on the basis of formal charge. c. \(s p\) hybrid orbitals on the center N overlap with atomic orbitals (or hybrid orbitals) on the other two atoms to form two \(\sigma\) bonds. The remaining \(p\) orbitals on the center N overlap with \(p\) orbitals on the other N to form two \(\pi\) bonds. 79. In \(\mathrm{O}_{2}\), an antibonding electron is removed, which will increase the bond order to \(2.5[=(8-3) / 2]\). The bond order increases as an electron is removed, so the bond strengthens. In \(\mathrm{N}_{2}\), a bonding electron is removed, which decreases the bond order to \(2.5=[(7-2) / 2]\). So the bond strength weakens as an electron is removed from \(\mathrm{N}_{2}\). 81. \(\mathrm{F}_{2}:\left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s}{ }^{*}\right)^{2}\left(\sigma_{2 p}\right)^{2}\left(\pi_{2 p}\right)^{4}\left(\pi_{2 p}{ }^{*}\right)^{4} ; \mathrm{F}_{2}\) should have a lower ionization energy than F . The electron removed from \(\mathrm{F}_{2}\) is in a \(\pi_{2 p} *\) antibonding molecular orbital, which is higher in energy than the \(2 p\) atomic orbitals from which the electron in atomic fluorine is removed. Since the electron removed from \(\mathrm{F}_{2}\) is higher in energy than the electron removed from F , it should be easier to remove an electron from \(F_{2}\) than from \(F\). 83. \(\pi\) molecular orbital
85.

All of these compounds are polar. In each compound, the bond dipoles do not cancel each other out, leading to a polar compound. \(\mathrm{SeO}_{2}\) is the only compound exhibiting \(\sim 120\)-degree bond angles. \(\mathrm{PCl}_{3}\) and \(\mathrm{PF}_{3}\) both have a tetrahedral arrangement of electron pairs, so these are the compounds that have central atoms that are \(s p^{3}\) hybridized. NNO and COS both have a linear molecular structure.

see-saw, \(d s p^{3}\)

tetrahedral, \(s p^{3}\)

Note: Similar to Exercise \(67 \mathrm{c}, \mathrm{d}\), and e, \(\mathrm{F}_{3} \mathrm{ClO}\) has one additional Lewis structure that is possible, and \(\mathrm{F}_{3} \mathrm{ClO}_{2}\) (below) has two additional Lewis structures that are possible. The predicted hybridization is unaffected.

89. A Lewis structure for this compound is:

All of the carbon atoms in the rings have a trigonal planar arrangement of electron pairs, so these five carbon atoms are \(s p^{2}\) hybridized. The other three carbon atoms are \(s p^{3}\) hybridized because they have a tetrahedral arrangement of electron pairs. The three nitrogen atoms that are bonded to a \(-\mathrm{CH}_{3}\) group all have the \(\mathrm{C}-\mathrm{N}\) bond formed from overlap of an \(s p^{3}\) hybrid orbital from carbon with an \(s p^{3}\) hybrid orbital from nitrogen. Note that each of these nitrogen atoms has a tetrahedral arrangement of electron pairs, hence they are \(s p^{3}\) hybridized. There are eight lone pairs of electrons, and the molecule has four \(\pi\) bonds (each double bond contains one \(\pi\) bond). 91. \(\mathrm{N}_{2}:\left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s}{ }^{*}\right)^{2}\left(\pi_{2 p}\right)^{4}\left(\sigma_{2 p}\right)^{2} ; \mathrm{N}_{2}^{+}:\left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s}\right)^{2}\left(\pi_{2 p}\right)^{4}\left(\sigma_{2 p}\right)^{1} ; \mathrm{N}_{2}{ }^{-}:\left(\sigma_{2 s}\right)^{2}\) \(\left(\sigma_{2 s}{ }^{*}\right)^{2}\left(\pi_{2 p}\right)^{4}\left(\sigma_{2 p}\right)^{2}\left(\pi_{2 p}{ }^{*}\right)^{1}\)
93.

6 C and N atoms exhibit \(120^{\circ}\) bond angles;
6 C and N atoms are \(s p^{3}\) hybridized;
0 C and N atoms are \(s p\) hybridized;
\(25 \sigma\) bonds and \(4 \pi\) bonds
95. a. \(\mathrm{NCN}^{2-}\) :

Favored by formal charge
Dicyandiamide:

Melamine:

b. \(\mathrm{NCN}^{2-}\) : C is \(s p\) hybridized. Each resonance structure predicts a different hybridization for the N atoms. For the remaining compounds, we will predict hybrids for the favored resonance structures only.

Melamine: N in \(\mathrm{NH}_{2}\) groups are all \(s p^{3}\) hybridized. Atoms in ring are all \(s p^{2}\) hybridized; c. \(\mathrm{NCN}^{2-}: 2 \sigma\) and \(2 \pi\) bonds; \(\mathrm{H}_{2} \mathrm{NCN}: 4 \sigma\) and \(2 \pi\) bonds; dicyandiamide: \(9 \sigma\) and \(3 \pi\) bonds; melamine: \(15 \sigma\) and \(3 \pi\) bonds; \(\mathbf{d}\). The \(\pi\)
system forces the ring to be planar just as the benzene ring is planar. e. The structure

best agrees with experiment because it has three different CN bonds. This structure is also favored on the basis of formal charge. 97. a. 25-nm light has sufficient energy to ionize N and \(\mathrm{N}_{2}\) and to break the triple bond in \(\mathrm{N}_{2}\). Thus, \(\mathrm{N}_{2}, \mathrm{~N}_{2}{ }^{+}, \mathrm{N}\), and \(\mathrm{N}^{+}\)will all be present, assuming excess \(\mathrm{N}_{2}\). b. 85.33 nm \(<\lambda \leq 127 \mathrm{~nm} ; \mathbf{c}\). The ionization energy of a substance is the energy it takes to completely remove an electron. \(\mathrm{N}_{2}:\left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s} *\right)^{2}\left(\pi_{2 p}\right)^{4}\left(\sigma_{2 p}\right)^{2}\); the electron removed from \(\mathrm{N}_{2}\) is in the \(\sigma_{2 p}\) molecular orbital, which is lower in energy than the \(2 p\) atomic orbital from which the electron in atomic nitrogen is removed. Since the electron removed from \(\mathrm{N}_{2}\) is lower in energy than the electron removed in N , then the ionization energy of \(\mathrm{N}_{2}\) is greater than the ionization energy of N. 99. Both reactions apparently involve only the breaking of the \(\mathrm{N}-\mathrm{Cl}\) bond. However, in the reaction \(\mathrm{ONCl} \rightarrow \mathrm{NO}+\mathrm{Cl}\) some energy is released in forming the stronger NO bond, lowering the value of \(\Delta H\). Therefore, the apparent \(\mathrm{N}-\mathrm{Cl}\) bond energy is artificially low for this reaction. The first reaction involves only the breaking of the \(\mathrm{N}-\mathrm{Cl}\) bond. 101. The ground state MO electron configuration for \(\mathrm{He}_{2}\) is \(\left(\sigma_{1 s}\right)^{2}\left(\sigma_{1 s}{ }^{*}\right)^{2}\) giving a bond order of 0 . Therefore, \(\mathrm{He}_{2}\) molecules are not predicted to be stable (and are not stable) in the lowest-energy ground state. However, in a high-energy environment, the electron(s) from the antibonding orbitals in \(\mathrm{He}_{2}\) can be promoted into higher-energy bonding orbitals, thus giving a nonzero bond order and a "reason" to form. For example, a possible excited-state MO electron configuration for \(\mathrm{He}_{2}\) would be \(\left(\sigma_{1 s}\right)^{2}\left(\sigma_{1 s}\right)^{1}\left(\sigma_{2 s}\right)^{1}\), giving a bond order of \((3-1) / 2=1\). Thus excited \(\mathrm{He}_{2}\) molecules can form, but they spontaneously break apart as the electron(s) fall back to the ground state, where the bond order equals zero. 103. The species with the smallest ionization energy has the highest energy electron. \(\mathrm{O}_{2}, \mathrm{~N}_{2}^{2-}, \mathrm{N}_{2}^{-}\), and \(\mathrm{O}_{2}{ }^{+}\)all have at least one electron in the highenergy \(\pi_{2 p}{ }^{*}\) orbitals. Because \(\mathrm{N}_{2}{ }^{2-}\) has the highest ratio of electrons to protons, the \(\pi_{2 p}\) * electrons are least attracted to the nuclei and easiest to remove, translating into the smallest ionization energy. 105. a. The CO bond is polar, with the negative end at the more electronegative oxygen atom. We would expect metal cations to be attracted to and to bond to the oxygen end of CO on the basis of electronegativity. \(\mathbf{b}\). The formal charge on C is -1 , and the formal charge on O is +1 . From formal charge, we would expect metal cations to bond to the carbon (with the negative formal charge). c. In molecular orbital theory, only orbitals with proper symmetry overlap to form bonding orbitals. The metals that form bonds to CO are usually transition metals, all of which have outer electrons in the \(d\) orbitals. The only molecular orbitals of CO that have proper symmetry to overlap with \(d\) orbitals are the \(\pi_{2 p}\) * orbitals, whose shape is similar to that of the \(d\) orbitals. Since the antibonding molecular orbitals have more carbon character, one would expect the bond to form through carbon. 107. a. \(\mathrm{Li}_{2}\) bond order \(=1 ; \mathrm{B}_{2}\) bond order \(=1 ;\) b. 4 electrons must be removed; c. \(4.5 \times 10^{5} \mathrm{~kJ} \quad \mathbf{1 0 9}\). T-shaped and \(d s p^{3}\) hybridized

\section*{Chapter 10}
15. Intermolecular forces are the forces between molecules that hold the substances together in the solid and liquid phases. Hydrogen bonding is a specific type of intermolecular force. In this figure, the dotted lines represent the hydrogen bonding interactions that hold individual \(\mathrm{H}_{2} \mathrm{O}\) molecules together in the solid and liquid phases (answer a is correct). The solid lines represent the \(\mathrm{O}-\mathrm{H}\) covalent bonds. 17. \(\mathrm{N}_{2}\) because it will have the weaker intermolecular forces. 19. Atoms have an approximately spherical shape. It is impossible to pack spheres together without some empty space between the spheres. 21. An alloy is a substance that contains a mixture of elements and has metallic properties. In a substitutional alloy, some of the host metal atoms are replaced by other metal atoms of similar size (e.g., in brass, pewter, plumber's solder). An interstitial alloy is formed when some of the interstices (holes) in the closest packed metal structure are occupied by smaller atoms (e.g., in carbon steels). 23. a. As intermolecular forces increase, the rate of evaporation
decreases. b. increase \(T\) : increase rate; c. increase surface area: increase rate 25. \(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l) \rightarrow \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(g)\) is an endothermic process. Heat is absorbed when liquid ethanol vaporizes; the internal heat from the body provides this heat, which results in the cooling of the body. 27. Sublimation will occur, allowing water to escape as \(\mathrm{H}_{2} \mathrm{O}(g)\). 29. The strength of intermolecular forces determines relative boiling points. The types of intermolecular forces for covalent compounds are London dispersion forces, dipole forces, and hydrogen bonding. Because the three compounds are assumed to have similar molar mass and shape, the strength of the London dispersion forces will be about equal among the three compounds. One of the compounds will be nonpolar so it only has London dispersion forces. The other two compounds will be polar so they have additional dipole forces and will boil at a higher temperature than the nonpolar compound. One of the polar compounds will have an H covalently bonded to either \(\mathrm{N}, \mathrm{O}\), or F . This gives rise to the strongest type of covalent intermolecular force, hydrogen bonding. This compound exhibiting hydrogen bonding will have the highest boiling point while the polar compound with no hydrogen bonding will boil at an intermediate temperature. 31. a. Both \(\mathrm{CO}_{2}\) and \(\mathrm{H}_{2} \mathrm{O}\) are molecular solids. Both have an ordered array of the individual molecules, with the molecular units occupying the lattice points. A difference within each solid lattice is the strength of the intermolecular forces. \(\mathrm{CO}_{2}\) is nonpolar and only exhibits London dispersion forces. \(\mathrm{H}_{2} \mathrm{O}\) exhibits the relatively strong hydrogen bonding interactions. The difference in strength is evidenced by the solid phase change that occurs at \(1 \mathrm{~atm} . \mathrm{CO}_{2}\) sublimes at a relatively low temperature of \(-78^{\circ} \mathrm{C}\). In sublimation, all of the intermolecular forces are broken. However, \(\mathrm{H}_{2} \mathrm{O}\) doesn't have a solid phase change until \(0^{\circ} \mathrm{C}\), and in this phase change from ice to water, only a fraction of the intermolecular forces are broken. The higher temperature and the fact that only a portion of the intermolecular forces are broken are attributed to the strength of the intermolecular forces in \(\mathrm{H}_{2} \mathrm{O}\) as compared to \(\mathrm{CO}_{2}\). Related to the intermolecular forces are the relative densities of the solid and liquid phases for these two compounds. \(\mathrm{CO}_{2}(s)\) is denser than \(\mathrm{CO}_{2}(l)\) while \(\mathrm{H}_{2} \mathrm{O}(s)\) is less dense than \(\mathrm{H}_{2} \mathrm{O}(l)\). For \(\mathrm{CO}_{2}(s)\) and for most solids, the molecules pack together as close as possible, which is why solids are usually more dense than the liquid phase. Water is an exception to this. Water molecules are particularly well suited to interact with each other because each molecule has two polar \(\mathrm{O}-\mathrm{H}\) bonds and two lone pairs on each oxygen. This can lead to the association of four hydrogen atoms with each oxygen: two by covalent bonds and two by dipoles. To keep this symmetric arrangement (which maximizes the hydrogen bonding interactions), the \(\mathrm{H}_{2} \mathrm{O}(s)\) molecules occupy positions that create empty space in the lattice. This translates into a smaller density for \(\mathrm{H}_{2} \mathrm{O}(s)\) (less mass per unit volume). b. Both NaCl and CsCl are ionic compounds with the anions at the lattice points of the unit cell and the cations occupying the empty spaces created by the anions (called holes). In NaCl , the \(\mathrm{Cl}^{-}\)anions occupy the lattice points of a face-centered unit cell with the \(\mathrm{Na}^{+}\)cations occupying the octahedral holes. Octahedral holes are the empty spaces created by six \(\mathrm{Cl}^{-}\)ions. CsCl has the \(\mathrm{Cl}^{-}\)ions at the lattice points of a simple cubic unit cell with the \(\mathrm{Cs}^{+}\)cations occupying the middle of the cube. 33. Chalk is composed of the ionic compound calcium carbonate \(\left(\mathrm{CaCO}_{3}\right)\). The electrostatic forces in ionic compounds are much stronger than the intermolecular forces in covalent compounds. Therefore, \(\mathrm{CaCO}_{3}\) should have a much higher boiling point than the covalent compounds found in motor oil and in \(\mathrm{H}_{2} \mathrm{O}\). Motor oil is composed of nonpolar \(\mathrm{C}-\mathrm{C}\) and \(\mathrm{C}-\mathrm{H}\) bonds. The intermolecular forces in motor oil are therefore London dispersion forces. We generally consider these forces to be weak. However, with compounds that have large molar masses, these London dispersion forces add up significantly and can overtake the relatively strong hydrogen bonding interactions in water. 35. In the \(\ln \left(P_{\text {vap }}\right)\) versus \(1 / T\) plot, the slope of the straight line is equal to \(-\Delta H_{\text {vap }} / R\). Because \(\Delta H_{\text {vap }}\) is always positive, the slope of the line will always be negative. 37. a. LD (London dispersion); b. dipole, LD; c. hydrogen bonding, LD; d. ionic; e. LD; f. dipole, \(\mathrm{LD} ;\) g. ionic 39. a. OCS ; b. \(\mathrm{SeO}_{2}\); c. \(\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\); d. \(\mathrm{H}_{2} \mathrm{CO}\); e. \(\mathrm{CH}_{3} \mathrm{OH}\) 41. a. The compound with the stronger intermolecular forces will boil at the higher temperature. Both HCl and Ar have about the same molar mass, so the London dispersion forces are approximately equivalent. However, HCl is a polar molecule leading to additional dipole forces that the
nonpolar Ar does not have. HCl has the stronger intermolecular forces, and it boils at the higher temperature. \(\mathbf{b}\). HF is capable of hydrogen bonding; HCl is not. \(\mathbf{c} . \mathrm{LiCl}\) is ionic, and HCl is a molecular solid with only dipole forces and London dispersion forces. Ionic forces are much stronger than the forces for molecular solids. d. \(n\)-Hexane is a larger molecule, so it has stronger London dispersion forces. 43. a. HBr has dipole forces in addition to LD forces; b. NaCl , stronger ionic forces; c. \(\mathrm{I}_{2}\), larger molecule so stronger LD forces; d. \(\mathrm{N}_{2}\), smallest nonpolar compound present, has weakest LD forces; e. \(\mathrm{CH}_{4}\), smallest nonpolar compound present, has weakest LD forces; f. HF, can form relatively strong hydrogen bonding interactions, unlike the other compounds; g. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\), unlike others, has relatively strong hydrogen bonding. 45. \(\mathrm{H}_{2} \mathrm{O}\) is attracted to glass while Hg is not. 47. The structure of \(\mathrm{H}_{2} \mathrm{O}_{2}\) produces greater hydrogen bonding than water. 49. 313 pm 51. \(0.704 \AA\) 53. \(1.54 \mathrm{~g} / \mathrm{cm}^{3} \quad \mathbf{5 5 . 1 7 4} \mathrm{pm} ; 11.6 \mathrm{~g} / \mathrm{cm}^{3} \quad\) 57. Ag \(\quad\) 59. edge, 328 pm ; radius, 142 pm 61. face-centered cubic unit cell 63. For a cubic closest packed structure, \(74.06 \%\) of the volume of each unit cell is occupied by atoms; in a simple cubic unit cell structure, \(52.36 \%\) is occupied. The cubic closest packed structure provides the more efficient means for packing atoms. 65. Doping silicon with phosphorus produces an n-type semiconductor. The phosphorus adds electrons at energies near the conduction band of silicon. Electrons do not need as much energy to move from filled to unfilled energy levels so conduction increases. Doping silicon with gallium produces a p-type semiconductor. Because gallium has fewer valence electrons than silicon, holes (unfilled energy levels) at energies in the previously filled molecular orbitals are created, which induces greater electron movement (greater conductivity). 67. p-type 69. \(5.0 \times 10^{2} \mathrm{~nm} \quad\) 71. \(\mathrm{NaCl}: 4 \mathrm{Na}^{+}, 4 \mathrm{Cl}^{-} ; \mathrm{CsCl}: 1 \mathrm{Cs}^{+}, 1 \mathrm{Cl}^{-}\); \(\mathrm{ZnS}: 4 \mathrm{Zn}^{2+}, 4 \mathrm{~S}^{2-} ; \mathrm{TiO}_{2}: 2 \mathrm{Ti}^{4+}, 4 \mathrm{O}^{2-}\) 73. \(\mathrm{CoF}_{2}\) 75. \(\mathrm{ZnAl}_{2} \mathrm{~S}_{4}\) 77. \(\mathrm{MF}_{2}\) 79. NaCl structure; \(r_{\mathrm{O}^{2-}}=1.49 \times 10^{-8} \mathrm{~cm} ; r_{\mathrm{Mg}^{2+}}=6.15 \times 10^{-9} \mathrm{~cm} \quad\) 81. The calculated distance between ion centers is 358 pm . Ionic radii give a distance of 350 pm . The distance calculated from the density is \(8 \mathrm{pm}(2.3 \%)\) greater than that calculated from the table of ionic radii. 83. a. \(\mathrm{CO}_{2}\) : molecular; b. \(\mathrm{SiO}_{2}\) : network; c. Si : atomic, network; d. \(\mathrm{CH}_{4}\) : molecular; e. Ru : atomic, metallic; f. \(\mathrm{I}_{2}\) : molecular; g. KBr: ionic; h. \(\mathrm{H}_{2} \mathrm{O}\) : molecular; i. NaOH : ionic; j. U: atomic, metallic; k. \(\mathrm{CaCO}_{3}\) : ionic; l. \(\mathrm{PH}_{3}\) : molecular 85. a. The unit cell consists of Ni at the cube corners and Ti at the body center or Ti at the cube corners and Ni at the body center. b. NiTi; c. Both have a coordination number of 8. 87. \(\mathrm{CaTiO}_{3}\); each structure has six oxygens around each Ti. 89. a. \(\mathrm{YBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{9}\); b. The structure of this superconductor material is based on the second perovskite structure. The \(\mathrm{YBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{9}\) structure is three of these cubic perovskite unit cells stacked on top of each other. The oxygens are in the same places, Cu takes the place of Ti , two Ca are replaced by two Ba , and one Ca is replaced by Y. c. \(\mathrm{YBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7} \quad 91 . \mathrm{Li}, 158 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{Mg}, 139 \mathrm{~kJ} / \mathrm{mol}\). Bonding is stronger in Li . \(\quad 93.89^{\circ} \mathrm{C} \quad 95.28 .6 \mathrm{~kJ} / \mathrm{mol}\)
97.

99. a. Much more energy is required to break the intermolecular forces when going from a liquid to a gas than is required to go from a solid to a liquid. Hence \(\Delta H_{\text {vap }}\) is much larger than \(\Delta H_{\text {fus }} ;\) b. \(113 \mathrm{~J} ;\) c. \(4220 \mathrm{~J} ;\) d. 4220 J released
101. \(1680 \mathrm{~kJ} \quad\) 103. \(1490 \mathrm{~g} \quad\) 105. A: solid; B: liquid; C: vapor; D: solid + vapor; E : solid + liquid + vapor (triple point); F: liquid + vapor; G: liquid + vapor (critical point); H: vapor; the first dashed line (at the lower temperature) is the normal freezing point, and the second dashed line is the normal boiling point. The solid phase is denser. 107. a. two; b. higher pressure triple point: graphite, diamond, and liquid; lower pressure triple point: graphite, liquid and vapor; \(\mathbf{c}\). It is converted to diamond (the more dense solid form); d. Diamond is more dense, which is why graphite can be converted to diamond by applying pressure. 109. Because the density of the liquid phase is greater than the density of the solid phase, the slope of the solid/liquid boundary line is negative (as in \(\mathrm{H}_{2} \mathrm{O}\) ). With a negative slope, the melting points increase with a decrease in pressure so the normal melting point of \(X\) should be greater than \(225^{\circ} \mathrm{C}\). 111. The covalent bonds within a molecule are much stronger than the intermolecular forces between molecules. Consider water, which exhibits a very strong type of dipole force called hydrogen bonding. When water boils at \(100^{\circ} \mathrm{C}\), hydrogen bonding intermolecular forces that hold the \(\mathrm{H}_{2} \mathrm{O}\) molecules together in the liquid phase are broken, resulting in \(\mathrm{H}_{2} \mathrm{O}(l)\) converting to \(\mathrm{H}_{2} \mathrm{O}(g)\). At \(100^{\circ} \mathrm{C}\), the covalent bonds within each water molecule are not broken; if they were to be broken, then \(\mathrm{H}_{2}(g)\) and \(\mathrm{O}_{2}(g)\) would be the produced. It takes a lot more energy than what is provided at \(100^{\circ} \mathrm{C}\) to break the covalent bonds within a water molecule; the intramolecular forces within a covalent compound are much stronger than the intermolecular forces between molecules. 113. As the physical properties indicate, the intermolecular forces are slightly stronger in \(\mathrm{D}_{2} \mathrm{O}\) than in \(\mathrm{H}_{2} \mathrm{O}\). 115. A: \(\mathrm{CH}_{4}\); B: \(\mathrm{SiH}_{4}\); C: \(\mathrm{NH}_{3}\) 117. 4.67 min 119. \(\mathrm{XeF}_{2}\) 121. \(\mathrm{B}_{2} \mathrm{H}_{6}\), molecular; \(\mathrm{SiO}_{2}\), network; CsI, ionic; W , metallic 123.57.8 torr 125. A mixture of \(\mathrm{H}_{2} \mathrm{O}(s)\) and \(\mathrm{H}_{2} \mathrm{O}(l)\) will be present at \(0^{\circ} \mathrm{C}\) when 215 kJ of heat are removed from the gas sample. 127. If we extend the liquid-vapor line of the water phase diagram to below the freezing point, we find that supercooled water will have a higher vapor pressure than ice at \(-10^{\circ} \mathrm{C}\) (see Fig. 10.44). To achieve equilibrium, there must be a constant vapor pressure. Over time, supercooled water will be transformed through the vapor into ice in an attempt to equilibrate the vapor pressure. Eventually there will only be ice at \(-10^{\circ} \mathrm{C}\) along with \(\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\) at the vapor pressure given by the solidvapor line in the phase diagram. 129. \(4.65 \mathrm{~kg} / \mathrm{h} \quad\) 131. \(\mathrm{CO}_{2}\) and \(\mathrm{XeF}_{4}\) are both nonpolar covalent compounds, so they only exhibit London dispersion forces. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\) and HF are covalent compounds that contain either an \(\mathrm{N}-\mathrm{H}, \mathrm{O}-\mathrm{H}\), or \(\mathrm{F}-\mathrm{H}\) bond, so they can form hydrogen bonding forces. \(\mathrm{SF}_{4}\) and \(\mathrm{ICl}_{5}\) are polar covalent compounds, so they can exhibit dipole-dipole forces. 133. a. False; the ionic forces in LiF are much stronger than the molecular intermolecular forces found in \(\mathrm{H}_{2} \mathrm{~S}\). b. True; HF is capable of H bonding; HBr is not. c. True; the larger \(\mathrm{Cl}_{2}\) molecule will have the stronger London dispersion forces. d. True; HCl is a polar compound while \(\mathrm{CCl}_{4}\) is a nonpolar compound. e. False; the ionic forces in MgO are much stronger than the molecular intermolecular forces found in \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\). 135. 4+ 137. a. 145.

Liquid (H-bonding)
and

Gas (no H-bonding)
The first structure with the - OH bond is capable of forming hydrogen bonding; the other structure is not. Therefore, the liquid (which has the stronger intermolecular forces) is the first structure, and the gas is the second structure. 147. The solids with high melting points \(\left(\mathrm{NaCl}, \mathrm{MgCl}_{2}, \mathrm{NaF}, \mathrm{MgF}_{2}, \mathrm{AlF}_{3}\right)\) are all ionic solids. \(\mathrm{SiCl}_{4}, \mathrm{SiF}_{4}, \mathrm{Cl}_{2}, \mathrm{~F}_{2}, \mathrm{PF}_{5}\), and \(\mathrm{SF}_{6}\) are nonpolar covalent molecules with LD forces. \(\mathrm{PCl}_{3}\) and \(\mathrm{SCl}_{2}\) are polar molecules with LD and dipole forces. In these 8 molecular substances the intermolecular forces are weak and the melting points low. \(\mathrm{AlCl}_{3}\) is intermediate. The melting point indicates there are stronger forces present than in the nonmetal halides, but not as strong as for an ionic solid. \(\mathrm{AlCl}_{3}\) illustrates a gradual transition from ionic to covalent bonding; from an ionic solid to discrete molecules. 149. \(\mathrm{TiO}_{1.182}\) or \(\mathrm{Ti}_{0.8462} \mathrm{O} ; 63.7 \% \mathrm{Ti}^{2+}, 36.3 \% \mathrm{Ti}^{3+}\) (a \(1.75: 1\) ion ratio) 151. \(6.58 \mathrm{~g} / \mathrm{cm}^{3}\)

As \(P\) is lowered, we go from \(a\) to \(b\) on the phase diagram. The water boils. The boiling of water is endothermic and the water is cooled \((b \rightarrow c)\), forming some ice. If the pump is left on, the ice will sublime until none is left. This is the basis of freeze drying.
155. The volume of the hole is \(\frac{4}{3} \pi[(\sqrt{3}-1) r]^{3} \quad\) 157. CdS; n-type
159. 253 torr; \(6.38 \times 10^{22}\) atoms

\section*{Chapter 11}
13. \(9.74 M \quad 15.160 \mathrm{~mL} \quad\) 17. \(4.5 M \quad\) 19. As the temperature increases, the gas molecules will have a greater average kinetic energy. A greater fraction of the gas molecules in solution will have kinetic energy greater than the attractive forces between the gas molecules and the solvent molecules. More gas molecules will escape to the vapor phase, and the solubility of the gas will decrease. 21. The levels of the liquids in each beaker will become constant when the concentration of solute is the same in both beakers. Because the solute is less volatile, the beaker on the right will have a larger volume when the concentrations become equal. There will be a larger net transfer of water molecules into the the right beaker than the net transfer of solute molecules to the left beaker. Eventually the rate that solute and \(\mathrm{H}_{2} \mathrm{O}\) leave and return to each beaker will become equal when the concentrations become equal. 23. No. For an ideal solution, \(\Delta H_{\text {soln }}=0\). 25. Normality is the number of equivalents per liter of solution. For an acid or a base, an equivalent is the mass of acid or base that can furnish 1 mole of protons (if an acid) or accept 1 mole of protons (if a base). A proton is an \(\mathrm{H}^{+}\)ion. Molarity is defined as the moles of solute per liter of solution. When the number of equivalents equals the number of moles of solute, then normality \(=\) molarity. This is true for acids that only have one acidic proton in them and for bases that accept only one proton per formula unit. Examples of acids where equivalents \(=\) moles solute are \(\mathrm{HCl}, \mathrm{HNO}_{3}, \mathrm{HF}\), and \(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\). Examples of bases where equivalents \(=\) moles solute are \(\mathrm{NaOH}, \mathrm{KOH}\), and \(\mathrm{NH}_{3}\). When equivalents \(\neq\) moles solute, then normality \(\neq\) molarity. This is true for acids that donate more than one proton \(\left(\mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{H}_{3} \mathrm{PO}_{4}, \mathrm{H}_{2} \mathrm{CO}_{3}\right.\), etc.) and for bases that react with more than one proton per formula unit \(\left[\mathrm{Ca}(\mathrm{OH})_{2}\right.\), \(\mathrm{Ba}(\mathrm{OH})_{2}, \mathrm{Sr}(\mathrm{OH})_{2}\), etc.]. 27. Only statement b is true. A substance freezes when the vapor pressures of the liquid and solid phases are the same. When a solute is added to water, the vapor pressure of the solution at \(0^{\circ} \mathrm{C}\) is less than the vapor pressure of the solid; the net result is for any ice present to convert to liquid in order to try to equalize the vapor pressures (which never can occur at \(0^{\circ} \mathrm{C}\). A lower temperature is needed to equalize the vapor pressures of water and ice, hence the freezing point is depressed. For statement a, the vapor pressure of a solution is directly related to the mole fraction of solvent (not solute) by Raoult's law. For statement c, colligative properties depend on the number of solute particles present and not on the identity of the solute. For statement d , the boiling point of water is increased because the sugar solute decreases the vapor pressure of the water; a higher temperature is required for the vapor pressure of the solution to equal the external pressure so boiling can occur. 29. Adding a solute to a solvent increases the boiling point and decreases the freezing point of the solvent. Thus, the solvent is a liquid over a wider range of temperatures when a solute is dissolved. 31. The vapor pressure, boiling point, and osmotic pressure will be the same between the two different solutions. 33. Isotonic solutions are those that have identical osmotic pressures. Crenation and hemolysis refer to phenomena that occur when red blood cells are bathed in solutions having a mismatch in osmotic pressure between the inside and the outside of the cell. When red blood cells are in a solution having a higher osmotic pressure than
that of the cells, the cells shrivel as there is a net transfer of water out of the cells. This is called crenation. Hemolysis occurs when the red blood cells are bathed in a solution having lower osmotic pressure than that inside the cell. Here, the cells rupture as there is a net transfer of water to inside the red blood cells. 35. \(1.9 \%\) 37. \(1.06 \mathrm{~g} / \mathrm{mL}\); 0.0180 mole fraction \(\mathrm{H}_{3} \mathrm{PO}_{4}\), 0.9820 mole fraction \(\mathrm{H}_{2} \mathrm{O} ; 0.981 \mathrm{~mol} / \mathrm{L} ; 1.02 \mathrm{~mol} / \mathrm{kg} \quad 39 . \mathrm{HCl}: 12 \mathrm{M}, 17 \mathrm{~m}\), \(0.23 ; \mathrm{HNO}_{3}: 16 \mathrm{M}, 37 \mathrm{~m}, 0.39 ; \mathrm{H}_{2} \mathrm{SO}_{4}: 18 \mathrm{M}, 200 \mathrm{~m}, 0.76 ; \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}: 17 \mathrm{M}\), \(2000 \mathrm{~m}, 0.96 ; \mathrm{NH}_{3}: 15 \mathrm{M}, 23 \mathrm{~m}, 0.29\) 41. \(35 \% ; 0.39 ; 7.3 \mathrm{~m} ; 3.1 \mathrm{M}\) 43. \(10.1 \%\) by mass; \(2.45 \mathrm{~mol} / \mathrm{kg}\) 45. \(23.9 \%\); \(1.6 \mathrm{~m}, 0.028,4.11 \mathrm{~N}\) 47. \(\mathrm{NaI}(s) \rightarrow \mathrm{Na}^{+}(a q)+\mathrm{I}^{-}(a q) \Delta H_{\text {soln }}=-8 \mathrm{~kJ} / \mathrm{mol} \quad\) 49. The attraction of water molecules for \(\mathrm{Al}^{3+}\) and \(\mathrm{OH}^{-}\)cannot overcome the larger lattice energy of \(\mathrm{Al}(\mathrm{OH})_{3}\). 51. a. \(\mathrm{CCl}_{4} ;\) b. \(\mathrm{H}_{2} \mathrm{O} ;\) c. \(\mathrm{H}_{2} \mathrm{O} ;\) d. \(\mathrm{CCl}_{4} ;\) e. \(\mathrm{H}_{2} \mathrm{O} ;\) f. \(\mathrm{H}_{2} \mathrm{O} ;\) g. \(\mathrm{CCl}_{4}\) 53. a. \(\mathrm{NH}_{3} ;\) b. \(\mathrm{CH}_{3} \mathrm{CN} ; \mathbf{c} . \mathrm{CH}_{3} \mathrm{COOH} \quad \mathbf{5 5}\). As the length of the hydrocarbon chain increases, the solubility decreases because the nonpolar hydrocarbon chain interacts poorly with the polar water molecules. 57. \(1.04 \times\) \(10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm} ; 1.14 \times 10^{-3} \mathrm{~mol} / \mathrm{L}\) 59. 136 torr 61. 0.918 63. a. 290 torr; b. 0.69 65. \(\chi_{\text {methanol }}=\chi_{\text {propanol }}=0.500 \quad\) 67. solution c 69. a. These two molecules are named acetone \(\left(\mathrm{CH}_{3} \mathrm{COCH}_{3}\right)\) and water. As discussed in Section 11.4 on nonideal solutions, acetone-water solutions exhibit negative deviations from Raoult's law. Acetone and water have the ability to hydrogen bond with each other, which gives the solution stronger intermolecular forces compared to the pure states of both solute and solvent. In the pure state, acetone cannot hydrogen bond with itself, so the middle diagram illustrating negative deviations from Raoult's law is the correct choice for acetone-water solutions. b. These two molecules are named ethanol \(\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)\) and water. Ethanol-water solutions show positive deviations from Raoult's law. Both substances can hydrogen bond in the pure state, and they can continue this in solution. However, the solute-solvent interactions are weaker for ethanol-water solutions due to the significant nonpolar part of ethanol \(\left(\mathrm{CH}_{3}-\mathrm{CH}_{2}\right.\) is the nonpolar part of ethanol). This nonpolar part of ethanol weakens the intermolecular forces in solution, so the first diagram illustrating positive deviations from Raoult's law is the correct choice for ethanol-water solutions. c. These two molecules are named heptane \(\left(\mathrm{C}_{7} \mathrm{H}_{16}\right)\) and hexane \(\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)\). Heptane and hexane are very similar nonpolar substances; both are composed entirely of nonpolar \(\mathrm{C}-\mathrm{C}\) bonds and relatively nonpolar \(\mathrm{C}-\mathrm{H}\) bonds, and both have a similar size and shape. Solutions of heptane and hexane should be ideal, so the third diagram illustrating no deviation from Raoult's law is the correct choice for heptane-hexane solutions. d. These two molecules are named heptane \(\left(\mathrm{C}_{7} \mathrm{H}_{16}\right)\) and water. The interactions between the nonpolar heptane molecules and the polar water molecules will certainly be weaker in solution compared to the pure solvent and pure solute interactions. This results in positive deviations from Raoult's law (the first diagram). 71. \(101.5^{\circ} \mathrm{C} \quad\) 73. \(14.8 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{3} \quad\) 75. \(T_{\mathrm{f}}=-29.9^{\circ} \mathrm{C}, T_{\mathrm{b}}=\) \(108.2^{\circ} \mathrm{C} \quad 77.6 .6 \times 10^{-2} \mathrm{~mol} / \mathrm{kg} ; 590 \mathrm{~g} / \mathrm{mol}(610 \mathrm{~g} / \mathrm{mol}\) if no rounding of numbers) 79. a. \(\Delta T=2.0 \times 10^{-50} \mathrm{C}, \pi=0.20\) torr; \(\mathbf{b}\). Osmotic pressure is better for determining the molar mass of large molecules. A temperature change of \(10^{-50} \mathrm{C}\) is very difficult to measure. A change in height of a column of mercury by 0.2 mm is not as hard to measure precisely. 81. \(2.51 \times 10^{5} \mathrm{~g} / \mathrm{mol} \quad\) 83. Dissolve 210 g sucrose in some water and dilute to 1.0 L in a volumetric flask. To get \(0.62 \pm 0.01 \mathrm{~mol} / \mathrm{L}\), we need \(212 \pm\) 3 g sucrose. 85. a. \(0.010 \mathrm{~m} \mathrm{Na}_{3} \mathrm{PO}_{4}\) and 0.020 m KCl ; b. 0.020 m HF ; c. \(0.020 \mathrm{~m} \mathrm{CaBr}_{2} \quad\) 87. a. \(T_{\mathrm{f}}=-13^{\circ} \mathrm{C} ; T_{\mathrm{b}}=103.5^{\circ} \mathrm{C}\); b. \(T_{\mathrm{f}}=-4.7^{\circ} \mathrm{C}\); \(T_{\mathrm{b}}=\) \(101.3^{\circ} \mathrm{C}\) 89. 1.67 91. a. \(T_{\mathrm{f}}=-0.28^{\circ} \mathrm{C} ; T_{\mathrm{b}}=100.077^{\circ} \mathrm{C}\); b. \(T_{\mathrm{f}}=\) \(-0.37^{\circ} \mathrm{C} ; T_{\mathrm{b}}=100.10^{\circ} \mathrm{C}\) 93. \(2.63(0.0225 \mathrm{~m}), 2.60(0.0910 \mathrm{~m}), 2.57\) \((0.278 \mathrm{~m}) ; i_{\text {average }}=2.60 \quad 95\). a. yes; \(\mathbf{b}\). no 97 . Benzoic acid is capable of hydrogen bonding, but a significant part of benzoic acid is the nonpolar benzene ring. In benzene, a hydrogen bonded dimer forms.

The dimer is relatively nonpolar and thus more soluble in benzene than in water. Because benzoic acid forms dimers in benzene, the effective solute particle concentration will be less than 1.0 molal. Therefore, the freezingpoint depression would be less than \(5.12^{\circ} \mathrm{C}\left(\Delta T_{\mathrm{f}}=K_{\mathrm{f}} m\right)\). 99. The main factor for stabilization seems to be electrostatic repulsion. The center of a colloid particle is surrounded by a layer of same charged ions, with oppo-
sitely charged ions forming another charged layer on the outside. Overall, there are equal numbers of charged and oppositely charged ions, so the colloidal particles are electrically neutral. However, since the outer layers are the same charge, the particles repel each other and do not easily aggregate for precipitation to occur. Heating increases the velocities of the colloidal particles. This causes the particles to collide with enough energy to break the ion barriers, allowing the colloids to aggregate and eventually precipitate out. Adding an electrolyte neutralizes the adsorbed ion layers, which allows colloidal particles to aggregate and then precipitate out. 101. No, the solution is not behaving ideally. If the solution were behaving ideally, the freezing point would be \(-1.9^{\circ} \mathrm{C}\). 103. a. Water boils when the vapor pressure equals the pressure above the water. In an open pan, \(P_{\mathrm{atm}} \approx 1.0 \mathrm{~atm}\). In a pressure cooker, \(P_{\text {inside }}>1.0 \mathrm{~atm}\) and water boils at a higher temperature. The higher the cooking temperature, the faster the cooking time. b. When water freezes from a solution, it freezes as pure water, leaving behind a more concentrated salt solution. c. On the \(\mathrm{CO}_{2}\) phase diagram, the triple point is above 1 atm and \(\mathrm{CO}_{2}(\mathrm{~g})\) is the stable phase at 1 atm and room temperature. \(\mathrm{CO}_{2}(l)\) can't exist at normal atmospheric pressures, which explains why dry ice sublimes rather than boils. In a fire extinguisher, \(P>1 \mathrm{~atm}\) and \(\mathrm{CO}_{2}(l)\) can exist. When \(\mathrm{CO}_{2}\) is released from the fire extinguisher, \(\mathrm{CO}_{2}(g)\) forms as predicted from the phase diagram. 105. 0.600 107. \(P_{\text {ideal }}=188.6\) torr; \(\chi_{\text {acetone }}=0.512, \chi_{\text {methanol }}=0.488\); the actual vapor pressure of the solution is smaller than the ideal vapor pressure, so this solution exhibits a negative deviation from Raoult's law. This occurs when solute-solvent attractions are stronger than for the pure substances. 109. \(776 \mathrm{~g} / \mathrm{mol}\) 111. \(\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O}_{3}\); \(151 \mathrm{~g} / \mathrm{mol}\) (exp.); \(152.10 \mathrm{~g} / \mathrm{mol}\) (calc.); \(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}_{6}\) 113. \(1.97 \% \mathrm{NaCl}\) 115. a. \(100.77^{\circ} \mathrm{C}\); b. 23.1 mm Hg ; c. Salt water has a solute concentration of \(2(0.60 M)=1.2 M\) ions. The solute concentration of salt water is much too high for this reverse osmosis unit to work. 139. a. \(26.6 \mathrm{~kJ} / \mathrm{mol}\); b. \(-657 \mathrm{~kJ} / \mathrm{mol}\) 141. \(i=3.00 ; \mathrm{CdCl}_{2}\)

\section*{Chapter 12}
11. One experimental method to determine rate laws is the method of initial rates. Several experiments are carried out using different initial concentrations of reactants, and the initial rate is determined for each experiment. The results are then compared to see how the initial rate depends on the initial concentrations. This allows the orders in the rate law to be determined. The value of the rate constant is determined from the experiments once the orders are known. The second experimental method utilizes the fact that the integrated rate laws can be put in the form of a straight-line equation. Concentration versus time data are collected for a reactant as a reaction is run. These data are then manipulated and plotted to see which manipulation gives a straight line. From the straight-line plot we get the order of the reactant, and the slope of the line is mathematically related to \(k\), the rate constant. 13. All of these choices would affect the rate of the reaction, but only band caffect
the rate by affecting the value of the rate constant \(k\). The value of the rate constant is dependent on temperature. It also depends on the activation energy. A catalyst will change the value of \(k\) because the activation energy changes. Increasing the concentration (partial pressure) of either \(\mathrm{O}_{2}\) or NO does not affect the value of \(k\), but it does increase the rate of the reaction because both concentrations appear in the rate law. 15. In a unimolecular reaction, a single reactant molecule decomposes to products. In a bimolecular reaction, two molecules collide to give products. The probability of the simultaneous collision of three molecules with enough energy and orientation is very small, making termolecular steps very unlikely. 17. When the rate doubles as the concentration quadruples, the order is \(1 / 2\). For a reactant that has an order of -1 , the rate will decrease by a factor of \(1 / 2\) when the concentrations are doubled. 19. Two reasons are: 1) the collision must involve enough energy to produce the reaction; i.e., the collision energy must equal or exceed the activation energy. 2) the relative orientation of the reactants must allow formation of any new bonds necessary to produce products. 21. Enzymes are very efficient catalysts. As is true for all catalysts, enzymes speed up a reaction by providing an alternative pathway for reactants to convert to products. This alternative pathway has a smaller activation energy and, hence, a faster rate. Also true is that catalysts are not used up in the overall chemical reaction. Once an enzyme comes in contact with the correct reagent, the chemical reaction quickly occurs, and the enzyme is then free to catalyze another reaction. Because of the efficiency of the reaction step, only a relatively small amount of enzyme is needed to catalyze a specific reaction, no matter how complex the reaction. 23. The rate of a reaction is independent of the enthalpy change for the reaction. The combustion of carbohydrates has a lower activation energy, which is why it is the faster process. 25. \(\mathrm{P}_{4}: 6.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s} ; \mathrm{H}_{2}: 3.6 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s} \quad\) 27. a. average rate of decomposition of \(\mathrm{H}_{2} \mathrm{O}_{2}=2.31 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}\), rate of production of \(\mathrm{O}_{2}=1.16 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s} ; \mathbf{b}\). average rate of decomposition of \(\mathrm{H}_{2} \mathrm{O}_{2}=\) \(1.16 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}\), rate of production of \(\mathrm{O}_{2}=5.80 \times 10^{-6} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}\) 29. a. \(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s}\); b. \(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s} ; \mathbf{c} . \mathrm{s}^{-1}\); d. \(\mathrm{L} / \mathrm{mol} \cdot \mathrm{s} ; \mathbf{e} . \mathrm{L}^{2} / \mathrm{mol}^{2} \cdot \mathrm{~s} \quad\) 31. a. rate \(=\) \(k[\mathrm{NO}]^{2}\left[\mathrm{Cl}_{2}\right]\); b. \(1.8 \times 10^{2} \mathrm{~L}^{2} / \mathrm{mol}^{2} \cdot \min \quad\) 33. a. rate \(=k[\mathrm{NOCl}]^{2}\); b. \(6.6 \times\) \(10^{-29} \mathrm{~cm}^{3} /\) molecules \(\cdot \mathrm{s} ; \mathbf{c} .4 .0 \times 10^{-8} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s} \quad\) 35. a. rate \(=k\left[\mathrm{I}^{-}\right]\left[\mathrm{OCl}^{-}\right]\); b. \(3.7 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}\); \(\mathbf{c} .0 .083 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s} \quad\) 37. a. first order in Hb and first order in CO ; b. rate \(=k[\mathrm{Hb}][\mathrm{CO}] ; \mathbf{c} .0 .280 \mathrm{~L} / \mu \mathrm{mol} \cdot \mathrm{s} ; \mathbf{d} .2 .26 \mu \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s} \quad\) 39. rate \(=k\left[\mathrm{H}_{2} \mathrm{O}_{2}\right] ; \ln \left[\mathrm{H}_{2} \mathrm{O}_{2}\right]=-k t+\ln \left[\mathrm{H}_{2} \mathrm{O}_{2}\right]_{0}\);

Rate \(=k\left[\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{Br}\right] ; \mathrm{C}_{4} \mathrm{H}_{9} \mathrm{Br}+2 \mathrm{H}_{2} \mathrm{O} \rightarrow \mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}+\mathrm{Br}^{-}+\mathrm{H}_{3} \mathrm{O}^{+}\); the intermediates are \(\mathrm{C}_{4} \mathrm{H}_{9}{ }^{+}\)and \(\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}_{2}{ }^{+}\). 65. The rate law is Rate \(=\) \(k[\mathrm{NO}]^{2}\left[\mathrm{Cl}_{2}\right]\). If we assume the first step is rate determining, we would expect the rate law to be Rate \(=k_{1}[\mathrm{NO}]\left[\mathrm{Cl}_{2}\right]\). This isn't correct. However, if we assume the second step to be rate determining, then Rate \(=k_{2}\left[\mathrm{NOCl}_{2}\right][\mathrm{NO}]\). To see if this agrees with experiment, we must substitute for the intermediate \(\mathrm{NOCl}_{2}\) concentration. Assuming a fast-equilibrium first step (rate reverse \(=\) rate forward):
\[
k_{-1}\left[\mathrm{NOCl}_{2}\right]=k_{1}[\mathrm{NO}]\left[\mathrm{Cl}_{2}\right],\left[\mathrm{NOCl}_{2}\right]=\frac{k_{1}}{k_{-1}}[\mathrm{NO}]\left[\mathrm{Cl}_{2}\right] ;
\]
substituting into the rate equation:
\[
\text { Rate }=\frac{k_{2} k_{1}}{k_{-1}}[\mathrm{NO}]^{2}\left[\mathrm{Cl}_{2}\right]=k[\mathrm{NO}]^{2}\left[\mathrm{Cl}_{2}\right] \text { where } k=\frac{k_{2} k_{1}}{k_{-1}}
\]

This is a possible mechanism with the second step the rate-determining step because the derived rate law agrees with the experimentally determined rate law.

69. \(341 \mathrm{~kJ} / \mathrm{mol}\) 71. The graph of \(\ln (k)\) versus \(1 / T\) is linear with slope \(=\) \(-E_{\mathrm{a}} / R=-1.2 \times 10^{4} \mathrm{~K} ; E_{\mathrm{a}}=1.0 \times 10^{2} \mathrm{~kJ} / \mathrm{mol} \quad 73.9 .5 \times 10^{-5} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}\) 75. \(51^{\circ} \mathrm{C} \quad\) 77. \(\mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{OH}^{-}(a q) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)\) should have the faster rate. \(\mathrm{H}_{3} \mathrm{O}^{+}\)and \(\mathrm{OH}^{-}\)will be electrostatically attracted to each other; \(\mathrm{Ce}^{4+}\) and \(\mathrm{Hg}_{2}{ }^{2+}\) will repel each other (so \(E_{\mathrm{a}}\) is much larger). 79. a. NO ; b. \(\mathrm{NO}_{2}\); c. 2.3 81. \(\mathrm{CH}_{2} \mathrm{D}-\mathrm{CH}_{2} \mathrm{D}\) should be the product. If the mechanism is possible, then the reaction must be \(\mathrm{C}_{2} \mathrm{H}_{4}+\mathrm{D}_{2} \rightarrow \mathrm{CH}_{2} \mathrm{DCH}_{2} \mathrm{D}\). If we got this product, then we could conclude that this is a possible mechanism. If we got some other product, e.g., \(\mathrm{CH}_{3} \mathrm{CHD}_{2}\), then we would conclude that the mechanism is wrong. Even though this mechanism correctly predicts the products of the reaction, we cannot say conclusively that this is the correct mechanism; we might be able to conceive of other mechanisms that would give the same product as our proposed one. 83. The rate depends on the number of reactant molecules adsorbed on the surface of the catalyst. This quantity is proportional to the concentration of reactant. However, when all the catalyst surface sites are occupied, the rate becomes independent of the concentration of reactant. \(\quad \mathbf{8 5} .215^{\circ} \mathrm{C} \quad \mathbf{8 7}\). a. 20 min ; b. 30 min ; c. \(15 \mathrm{~min} \quad \mathbf{8 9 .} 427 \mathrm{~s}\) 91. \(1.0 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}\) 93. a. second order; b. 20 s ; c. 190 s ; d. 847 s ; e. \(31 \mathrm{~kJ} / \mathrm{mol} . \quad 95.6 .58 \times 10^{-6} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s} \quad 97\). a. \(25 \mathrm{~kJ} / \mathrm{mol} ;\) b. 12 s ;
\begin{tabular}{ccc}
\(T\) & Interval & \(54-2\) (Intervals) \\
\hline \(21.0^{\circ} \mathrm{C}\) & 16.3 s & \(21^{\circ} \mathrm{C}\) \\

\(30.0^{\circ} \mathrm{C}\) & 12 s & \(30 .{ }^{\circ} \mathrm{C}\)
\end{tabular}

This rule of thumb gives excellent agreement to two significant figures. 99. \(12.5 \mathrm{~s} \quad\) 101. a. \(115 \mathrm{~L}^{3} / \mathrm{mol}^{3} \cdot \mathrm{~s} ;\) b. \(87.0 \mathrm{~s} ; \mathbf{c} .[\mathrm{A}]=1.27 \times 10^{-5} \mathrm{M},[\mathrm{B}]=\) 1.00 M 103. The reaction is first order with respect to both A and B ; rate \(=\) \(k[\mathrm{~A}][\mathrm{B}]\) where \(k=1.6 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s} . \quad \mathbf{1 0 5 . 3 5 . 4} \mathrm{s} \quad \mathbf{1 0 7}\). a. False; from the halflife expression for a zero-order reaction in Table 12.6 of the text, there is a direct relationship between concentration and the half-life value. As the reaction proceeds for a zero-order reaction, the half-life value will decrease because concentration decreases. b. True. c. False; from the half-life expression for a first-order reaction in Table 12.6, the half-life does not depend on concentration. d. True; the half-life for a second-order reaction increases with time because there is an inverse relationship between concentration and the half-life value. \(\quad \mathbf{1 0 9 .} 53.9 \mathrm{~kJ} / \mathrm{mol}\); the chirping rate will be about 45 chirps per minute at \(7.5^{\circ} \mathrm{C}\). 111. rate \(=\frac{k\left[\mathrm{I}^{-}\right]\left[\mathrm{OCl}^{-}\right]}{\left[\mathrm{OH}^{-}\right]} ; k=6.0 \times 10^{1} \mathrm{~s}^{-1}\) 113. a. first order with respect to both reactants; b. rate \(=k[\mathrm{NO}]\left[\mathrm{O}_{3}\right]\); c. \(k^{\prime}=1.8 \mathrm{~s}^{-1} ; k^{\prime \prime}=3.6 \mathrm{~s}^{-1}\); d. \(k=1.8 \times 10^{-14} \mathrm{~cm}^{3} /\) molecules \(\cdot \mathrm{s}\) 115. a. Rate \(=k_{3} \frac{k_{2}}{k_{-2}}\left(\frac{k_{1}}{k_{-1}}\right)^{1 / 2}[\mathrm{CO}]\left[\mathrm{Cl}_{2}\right]^{3 / 2}=k[\mathrm{CO}]\left[\mathrm{Cl}_{2}\right]^{3 / 2}\). b. Cl and COCl are intermediates. 117. a. For a three-step reaction with the first step limiting, the energy-level diagram could be

Reaction coordinate

Note that the heights of the second and third humps must be lower than the first-step activation energy. However, the height of the third hump could be higher than the second hump. One cannot determine this absolutely from the information in the problem.

c. \(\mathrm{F}_{2}\) was the limiting reactant. 119. a. \([\mathrm{B}] \gg[\mathrm{A}]\), so \([\mathrm{B}]\) can be considered constant over the experiments. This gives us a pseudo-order rate-law equation. b. Rate \(=k[\mathrm{~A}]^{2}[\mathrm{~B}], k=0.050 \mathrm{~L}^{2} / \mathrm{mol}^{2} \cdot \mathrm{~s}\). c. i. This mechanism gives the wrong stoichiometry, so it can't be correct. ii. Rate \(=k[\mathrm{E}][\mathrm{A}]\); \(k_{1}[\mathrm{~A}][\mathrm{B}]=k_{-1}[\mathrm{E}] ;[\mathrm{E}]=\frac{k_{1}[\mathrm{~A}][\mathrm{B}]}{k_{-1}} ;\) Rate \(=\frac{k k_{1}}{k_{-1}}[\mathrm{~A}]^{2}[\mathrm{~B}]\). This mechanism gives the correct stoichiometry and gives the correct rate law when it is derived from the mechanism. This is a possible mechanism for this reaction. iii. Rate \(=k[\mathrm{~A}]^{2}\). This mechanism gives the wrong derived rate law, so it can't be correct. Only mechanism ii is possible. 121. Rate \(=k[\mathrm{~A}][\mathrm{B}]^{2}\), \(k=1.4 \times 10^{-2} \mathrm{~L}^{2} / \mathrm{mol}^{2} \cdot \mathrm{~s} \quad\) 123. \(2.20 \times 10^{-5} \mathrm{~s}^{-1} ; 5.99 \times 10^{21}\) molecules 125. \(1.3 \times 10^{-5} \mathrm{~s}^{-1}\); 112 torr

\section*{Chapter 13}
13. No, equilibrium is a dynamic process. Both the forward and reverse reactions are occurring at equilibrium, just at equal rates. Thus the forward and reverse reactions will distribute \({ }^{14} \mathrm{C}\) atoms between CO and \(\mathrm{CO}_{2}\). 15. A large value for \(K(\mathrm{~K} \gg 1)\) indicates there are relatively large concentrations of product gases and/or solutes as compared with the concentrations of reactant gases and/or solutes at equilibrium. A reaction with a large \(K\) value is a good source of products. \(\mathbf{1 7 .} 4\) molecules \(\mathrm{H}_{2} \mathrm{O}, 2\) molecules \(\mathrm{CO}, 4\) molecules \(\mathrm{H}_{2}\), and 4 molecules \(\mathrm{CO}_{2}\) are present at equilibrium. 19. \(K\) and \(K_{\mathrm{p}}\) are equilibrium constants as determined by the law of mass action. For \(K\), the units used for concentrations are \(\mathrm{mol} / \mathrm{L}\), and for \(K_{\mathrm{p}}\), partial pressures in units of atm are used (generally). \(Q\) is called the reaction quotient. \(Q\) has the exact same form as \(K\) or \(K_{\mathrm{p}}\), but instead of equilibrium concentrations, initial concentrations are used to calculate the \(Q\) value. \(Q\) is of use when it is compared to the \(K\) value. When \(Q=K\) (or when \(Q_{\mathrm{p}}=K_{\mathrm{p}}\) ), the reaction is at equilibrium. When \(Q \neq K\), the reaction is not at equilibrium and one can determine what has to be the net change for the system to get to equilibrium. 21. We always try to make good assumptions that simplify the math. In some problems, we can set up the problem so that the net change, \(x\), that must occur to reach equilibrium is a small number. This comes in handy when you have expressions like \(0.12-x\) or \(0.727+2 x\). When \(x\) is small, we assume that it makes little difference when subtracted from or added to some relatively big number. When this is true, \(0.12-x \approx 0.12\) and \(0.727+2 x \approx 0.727\). If the assumption holds by the \(5 \%\) rule, then the assumption is assumed valid. The \(5 \%\) rule refers to \(x\) (or \(2 x\) or \(3 x\), etc.) that was assumed small compared to some number. If \(x\) (or \(2 x\) or \(3 x\), etc.) is less than \(5 \%\) of the number the assumption was made against, then the assumption will be assumed valid. If the \(5 \%\) rule fails to work, one can generally use a math procedure called the method of successive approximations to solve the quadratic or cubic equation. 23. There will be a net increase in the amount of \(\mathrm{N}_{2} \mathrm{O}\) present once equilibrium is reestablished. As \(\mathrm{N}_{2} \mathrm{O}(g)\) is added, the reaction will shift right to use up some of the added \(\mathrm{N}_{2} \mathrm{O}\). However, only some of the added \(\mathrm{N}_{2} \mathrm{O}\) will react, not all. The net effect is for the amount of \(\mathrm{N}_{2} \mathrm{O}\) to increase once equilibrium is reestablished. As far as the \(K\) value is concerned, as long as the temperature didn't change, \(K\) will remain a constant value.
25. a. \(K=\frac{[\mathrm{NO}]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{O}_{2}\right]} ; \quad\) b. \(K=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]} ; \quad\) c. \(K=\frac{\left[\mathrm{SiCl}_{4}\right]\left[\mathrm{H}_{2}\right]^{2}}{\left[\mathrm{SiH}_{4}\right]\left[\mathrm{Cl}_{2}\right]^{2}}\);

Assuming mol/L units for concentrations, \(K=8.16 \times 10^{47}\); b. 33.9 L 119. 0.63 121. 0.240 atm 123. a. \(2.33 \times 10^{-4}\); b. The argon gas will increase the volume of the container. This is because the container is a constantpressure system, and if the number of moles increases at constant \(T\) and \(P\), the volume must increase. An increase in volume will dilute the concentrations of all gaseous reactants and gaseous products. Because there are more moles of product gases than reactant gases ( 3 moles vs. 2 moles), the dilution will decrease the numerator of \(K\) more than the denominator will decrease. This causes \(Q<K\) and the reaction shifts right to get back to equilibrium. Because temperature was unchanged, the value of \(K\) will not change. \(K\) is a constant as long as temperature is constant. \(\quad \mathbf{1 2 5 .} 192 \mathrm{~g} ; 1.3 \mathrm{~atm} \quad \mathbf{1 2 7 .} 33\)

Acid
\end{tabular}

One of the \(\mathrm{NH}_{3}\) molecules acts as a base and accepts a proton to form \(\mathrm{NH}_{4}{ }^{+}\). The other \(\mathrm{NH}_{3}\) molecule acts as an acid and donates a proton to form \(\mathrm{NH}_{2}{ }^{-}\). \(\mathrm{NH}_{4}{ }^{+}\)is the conjugate acid of the \(\mathrm{NH}_{3}\) base. In the reverse reaction, \(\mathrm{NH}_{4}{ }^{+}\)
donates a proton. \(\mathrm{NH}_{2}{ }^{-}\)is the conjugate base of the \(\mathrm{NH}_{3}\) acid. In the reverse reaction, \(\mathrm{NH}_{2}{ }^{-}\)accepts a proton. Conjugate acid-base pairs differ only by an \(\mathrm{H}^{+}\)in the formula. 29. a. These would be 0.10 M solutions of strong acids like \(\mathrm{HCl}, \mathrm{HBr}, \mathrm{HI}, \mathrm{HNO}_{3}, \mathrm{H}_{2} \mathrm{SO}_{4}\), or \(\mathrm{HClO}_{4}\). b. These are salts of the conjugate acids of the bases in Table 14.3. These conjugate acids are all weak acids. Three examples would be 0.10 M solutions of \(\mathrm{NH}_{4} \mathrm{Cl}, \mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{NO}_{3}\), and \(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{Br}\). Note that the anions used to form these salts are conjugate bases of strong acids; this is because they have no acidic or basic properties in water (with the exception of \(\mathrm{HSO}_{4}^{-}\), which has weak acid properties). c. These would be 0.10 M solutions of strong bases like \(\mathrm{LiOH}, \mathrm{NaOH}, \mathrm{KOH}\), \(\mathrm{RbOH}, \mathrm{CsOH}, \mathrm{Ca}(\mathrm{OH})_{2}, \mathrm{Sr}(\mathrm{OH})_{2}\), and \(\mathrm{Ba}(\mathrm{OH})_{2}\). d. These are salts of the conjugate bases of the neutrally charged weak acids in Table 14.2. The conjugate bases of weak acids are weak bases themselves. Three examples would be 0.10 M solutions of \(\mathrm{NaClO}_{2}, \mathrm{KC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\), and \(\mathrm{CaF}_{2}\). The cations used to form these salts are \(\mathrm{Li}^{+}, \mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{Rb}^{+}, \mathrm{Cs}^{+}, \mathrm{Ca}^{2+}, \mathrm{Sr}^{2+}\), and \(\mathrm{Ba}^{2+}\) since these cations have no acidic or basic properties in water. Notice that these are the cations of the strong bases that you should memorize. e. There are two ways to make a neutral salt. The easiest way is to combine a conjugate base of a strong acid (except for \(\mathrm{HSO}_{4}{ }^{-}\)) with one of the cations from the strong bases. These ions have no acidic/basic properties in water so salts of these ions are neutral. Three examples would be 0.10 M solutions of \(\mathrm{NaCl}, \mathrm{KNO}_{3}\), and \(\mathrm{SrI}_{2}\). Another type of strong electrolyte that can produce neutral solutions are salts that contain an ion with weak acid properties combined with an ion of opposite charge having weak base properties. If the \(K_{\mathrm{a}}\) for the weak acid ion is equal to the \(K_{\mathrm{b}}\) for the weak base ion, then the salt will produce a neutral solution. The most common example of this type of salt is ammonium acetate, \(\mathrm{NH}_{4} \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\). For this salt, \(K_{\mathrm{a}}\) for \(\mathrm{NH}_{4}{ }^{+}=K_{\mathrm{b}}\) for \(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}=\) \(5.6 \times 10^{-10}\). This salt, at any concentration, produces a neutral solution.
31. a. \(\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{OH}^{-}(a q)\) or
\[
\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \quad K=K_{\mathrm{w}}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]
\]
b. \(\mathrm{HF}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{F}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)\) or

c. \(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+}(a q)+\mathrm{OH}^{-}(a q)\)
\[
K=K_{\mathrm{b}}=\frac{\left[\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right]}
\]
33. a. \(\mathrm{H}_{2} \mathrm{SO}_{3}\); b. \(\mathrm{HClO}_{3}\); c. \(\mathrm{H}_{3} \mathrm{PO}_{3}\); NaOH and KOH are ionic compounds composed of either \(\mathrm{Na}^{+}\)or \(\mathrm{K}^{+}\)cations and \(\mathrm{OH}^{-}\)anions. When soluble ionic compounds dissolve in water, they form the ions from which they are formed. The acids in this problem are all covalent compounds. When these acids dissolve in water, the covalent bond between oxygen and hydrogen breaks to form \(\mathrm{H}^{+}\)ions. 35. a. This expression holds true for solutions of monoprotic strong acids having a concentration greater than \(1.0 \times 10^{-6} M\). For example, \(0.10 M \mathrm{HCl}, 7.8 M \mathrm{HNO}_{3}\), and \(3.6 \times 10^{-4} M \mathrm{HClO}_{4}\) are solutions where this expression holds true. b. This expression holds true for solutions of weak acids where the two normal assumptions hold. The two assumptions are that the contribution of \(\mathrm{H}^{+}\)from water is negligible and that the acid is less than \(5 \%\) dissociated in water (from the assumption that \(x\) is small compared to some number). This expression will generally hold true for solutions of weak acids having a \(K_{\mathrm{a}}\) value less than \(1 \times 10^{-4}\), as long as there is a significant amount of weak acid present. Three example solutions are \(1.5 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\), 0.10 M HOCl , and 0.72 M HCN . c. This expression holds true for strong bases that donate \(2 \mathrm{OH}^{-}\)ions per formula unit. As long as the concentration of the base is above \(5 \times 10^{-7} M\), this expression will hold true. Three examples are \(5.0 \times 10^{-3} M \mathrm{Ca}(\mathrm{OH})_{2}, 2.1 \times 10^{-4} M \mathrm{Sr}(\mathrm{OH})_{2}\), and \(9.1 \times\) \(10^{-5} M \mathrm{Ba}(\mathrm{OH})_{2}\). d. This expression holds true for solutions of weak bases where the two normal assumptions hold. The assumptions are that the \(\mathrm{OH}^{-}\)contribution from water is negligible and that the base is less than \(5 \%\) ionized in water. For the \(5 \%\) rule to hold, you generally need bases with \(K_{\mathrm{b}}<1 \times 10^{-4}\) and concentrations of weak base greater than 0.10 M . Three examples are \(0.10 M \mathrm{NH}_{3}, 0.54 M \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}\), and \(1.1 M \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\). 37. One reason HF is a weak acid is that the \(\mathrm{H}-\mathrm{F}\) bond is unusually strong and thus, is difficult to break. This contributes to the reluctance of the HF molecules to dissociate in water. 39. a. \(\mathrm{HClO}_{4}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{ClO}_{4}{ }^{-}(a q)\) or \(\mathrm{HClO}_{4}(a q) \rightarrow \mathrm{H}^{+}(a q)+\mathrm{ClO}_{4}^{-}(a q)\); water is commonly omitted from \(K_{\mathrm{a}}\) reactions. b. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{H}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CO}_{2}^{-}(a q)\); c. \(\mathrm{NH}_{4}{ }^{+}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{NH}_{3}(a q)\) 41. a. \(\mathrm{H}_{2} \mathrm{O}\), base; \(\mathrm{H}_{2} \mathrm{CO}_{3}\), acid;

\section*{Chapter 15}
11. When an acid dissociates, ions are produced. A common ion is when one of the product ions in a particular equilibrium is added from an outside source. For a weak acid dissociating to its conjugate base and \(\mathrm{H}^{+}\), the common ion would be the conjugate base; this would be added by dissolving a soluble salt of the conjugate base into the acid solution. The presence of the conjugate base from an outside source shifts the equilibrium to the left so less acid dissociates. 13. The more weak acid and conjugate base present, the more \(\mathrm{H}^{+}\)and/or \(\mathrm{OH}^{-}\)that can be absorbed by the buffer without significant pH change. When the concentrations of weak acid and conjugate base are equal (so that \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\) ), the buffer system is equally efficient at absorbing either \(\mathrm{H}^{+}\)or \(\mathrm{OH}^{-}\). If the buffer is overloaded with weak acid or with conjugate base, then the buffer is not equally efficient at absorbing either \(\mathrm{H}^{+}\) or \(\mathrm{OH}^{-}\). 15. a. Let's call the acid HA, which is a weak acid. When HA is present in the beakers, it exists in the undissociated form, making it a weak acid. A strong acid would exist as separate \(\mathrm{H}^{+}\)and \(\mathrm{A}^{-}\)ions. b. beaker \(\mathrm{c} \rightarrow\) beaker \(\mathrm{a} \rightarrow\) beaker \(\mathrm{e} \rightarrow\) beaker \(\mathrm{b} \rightarrow\) beaker d c. \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\) when a buffer solution is present that has equal concentrations of the weak acid and conjugate base. This is beaker e. d. The equivalence point is when just enough \(\mathrm{OH}^{-}\)has been added to exactly react with all of the acid present initially. This is beaker b. e. Past the equivalence point, the pH is dictated by the concentration of excess \(\mathrm{OH}^{-}\)added from the strong base. We can ignore the amount of hydroxide added by the weak conjugate base that is also present. This is beaker d. 17. The three key points to emphasize in your sketch are the initial pH , the pH at the halfway point to equivalence, and the pH at the equivalence point. For the two weak bases titrated, \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}\) at the halfway point to equivalence ( 50.0 mL HCl added) because [weak base] \(=\) [conjugate acid] at this point. For the initial pH , the strong base has the highest pH (most basic), while the weakest base has the lowest pH (least basic). At the equivalence point, the strong base titration has \(\mathrm{pH}=7.0\). The weak bases titrated have acidic pHs at the equivalence point because the conjugate acids of the weak bases titrated are the major species present. The weakest base has the strongest conjugate acid so its pH will be lowest (most acidic) at the equivalence point.

19. At 50.0 mL of NaOH added, this is the first halfway point to equivalence where \(\mathrm{H}_{3} \mathrm{AsO}_{4}\) and \(\mathrm{H}_{2} \mathrm{AsO}_{4}^{-}\)are the major species present (along with \(\mathrm{H}_{2} \mathrm{O}\) ). At this point, we have a buffer solution in which \(\left[\mathrm{H}_{3} \mathrm{AsO}_{4}\right]=\left[\mathrm{H}_{2} \mathrm{AsO}_{4}^{-}\right]\)and \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}_{1}}=-\log \left(5.5 \times 10^{-3}\right)=2.26\). At 150.0 mL of NaOH added, this is the second halfway point to equivalence at which \(\mathrm{H}_{2} \mathrm{AsO}_{4}{ }^{-}\)and \(\mathrm{HAsO}_{4}{ }^{2-}\) are the major species present (along with \(\mathrm{H}_{2} \mathrm{O}\) ). At this point, we have a buffer solution in which \(\left[\mathrm{H}_{2} \mathrm{AsO}_{4}{ }^{-}\right]=\left[\mathrm{HAsO}_{4}{ }^{2-}\right]\) and \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}_{2}}=-\log (1.7 \times\) \(\left.10^{-7}\right)=6.77\). At the third halfway point to equivalence, \(\left[\mathrm{HAsO}_{4}{ }^{2-}\right]=\) [ \(\mathrm{AsO}_{4}{ }^{3-}\) ] and \(\mathrm{pH}=\mathrm{p} K_{\mathrm{a}_{3}}\). This third halfway point will be at 250.0 mL of NaOH added. 21. Only the third beaker represents a buffer solution. A weak acid and its conjugate base both must be present in large quantities in order to have a buffer solution. This is only the case in the third beaker. The first beaker represents a beaker full of strong acid that is \(100 \%\) dissociated. The second beaker represents a weak acid solution. In a weak acid solution, only a small fraction of the acid is dissociated. In this representation, \(1 / 10\) of the weak acid has dissociated. The only \(\mathrm{B}^{-}\)present in this beaker is from the dissociation of the weak acid. A buffer solution has \(\mathrm{B}^{-}\)added from another source. 23. When strong acid or strong base is added to a sodium bicarbonate/sodium carbonate buffer mixture, the strong acid/base is neutralized. The reaction goes to completion resulting in the strong acid/base being replaced with a weak acid/base. This results in a new buffer solution. The reactions are \(\mathrm{H}^{+}(a q)+\mathrm{CO}_{3}{ }^{2-}(a q) \rightarrow \mathrm{HCO}_{3}^{-}(a q) ; \mathrm{OH}^{-}(a q)+\mathrm{HCO}_{3}^{-}(a q) \rightarrow\) \(\mathrm{CO}_{3}{ }^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \quad\) 25. a. 2.96 ; b. 8.94 ; c. 7.00 ; d. \(4.89 \quad 27.1 .1 \%\) vs. 1.3 \(\times 10^{-2} \%\) dissociated; the presence of \(\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{2}{ }^{-}\)in solution 25 d greatly inhibits the dissociation of \(\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}\). This is called the common ion effect. 29. a. 1.70 ; b. 5.49 ; c. 1.70 ; d. 4.71 31. a. 4.29 ; b. 12.30 ; c. 12.30 ; d. 5.07 33. solution d ; solution d is a buffer solution that resists pH changes. \(\quad 35.3 .40\) 37. 3.48 ; 3.22 39. a. 5.14 ; b. 4.34 ; c. 5.14 ; d. \(4.34 \quad\) 41. \(4.37 \quad\) 43. a. 7.97 ; b. 8.73 ; both solutions have an initial \(\mathrm{pH}=8.77\). A best buffer has approximately equal concentrations of weak acid and conjugate base, so \(\mathrm{pH} \approx \mathrm{p} K_{\mathrm{a}}\) for a best buffer. The \(\mathrm{p} K_{\mathrm{a}}\) value for an \(\mathrm{H}_{3} \mathrm{PO}_{4} / \mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}\) buffer is \(-\log \left(7.5 \times 10^{-3}\right)=2.12\). A pH of 7.15 is too high for an \(\mathrm{H}_{3} \mathrm{PO}_{4} / \mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}\)buffer to be effective. At this high of a pH, there would be so little \(\mathrm{H}_{3} \mathrm{PO}_{4}\) present that we could hardly consider it a buffer; this solution would not be effective in resisting pH changes, especially when a strong base is added. 97. Removal of \(\mathrm{NaHCO}_{3}\left(\mathrm{HCO}_{3}^{-}\right)\)causes the buffer equilibrium to shift right to produce more \(\mathrm{H}^{+}\). This causes the blood to become more acidic, so pH decreases. Treatment involves the IV addition of \(\mathrm{HCO}_{3}{ }^{-}\). 99. a. \(1.8 \times 10^{9}\); b. \(5.6 \times 10^{4}\); c. \(1.0 \times 10^{14} \quad\) 101. \(4.4 \mathrm{~L} \quad\) 103. 65 mL 105. \(180 \mathrm{~g} / \mathrm{mol} ; 3.3 \times 10^{-4}\); assumed acetylsalicylic acid is a weak monoprotic acid. 107. \(0.210 M\) 109. \(1.74 \times 10^{-8}\) 111. 3.62 113. \(0.92 M\) 115. a. \section*{Chapter 16}
11. \(K_{\mathrm{sp}}\) values can only be compared to determine relative solubilities when the salts produce the same number of ions. Here, \(\mathrm{Ag}_{2} \mathrm{~S}\) and CuS do not produce the same number of ions when they dissolve, so each has a different mathematical relationship between the \(K_{\text {sp }}\) value and the molar solubility. To determine which salt has the larger molar solubility, you must do the actual calculations and compare the two molar solubility values. 13. i. This is the result when you have a salt that breaks up into two ions. Examples of these salts would be \(\mathrm{AgCl}, \mathrm{SrSO}_{4}, \mathrm{BaCrO}_{4}\), and \(\mathrm{ZnCO}_{3}\). ii. This is the result when you have a salt that breaks up into three ions, either two cations and one anion or one cation and two anions. Some examples are \(\mathrm{SrF}_{2}, \mathrm{Hg}_{2} \mathrm{I}_{2}\), and \(\mathrm{Ag}_{2} \mathrm{SO}_{4}\). iii. This is the result when you have a salt that breaks up into four ions, either three cations and one anion \(\left(\mathrm{Ag}_{3} \mathrm{PO}_{4}\right)\) or one cation and three
anions (ignoring the hydroxides, there are no examples of this type of salt in Table 16.1). iv. This is the result when you have a salt that breaks up into five ions, either three cations and two anions \(\left[\mathrm{Sr}_{3}\left(\mathrm{PO}_{4}\right)_{2}\right]\) or two cations and three anions (no examples of this type of salt are in Table 16.1). 15. For the \(K_{\text {sp }}\) reaction of a salt dissolving into its respective ions, the common ion would be if one of the ions in the salt was added from an outside source. When a common ion is present, the \(K_{\text {sp }}\) equilibrium shifts to the left resulting in less of the salt dissolving into its ions. 17. Some people would automatically think that an increase in temperature would increase the solubility of a salt. This is not always the case because some salts show a decrease in solubility as temperature increases. The two major methods used to increase solubility of a salt both involve removing one of the ions in the salt by reaction. If the salt has an ion with basic properties, adding \(\mathrm{H}^{+}\)will increase the solubility of the salt because the added \(\mathrm{H}^{+}\)will react with the basic ion, thus removing it from solution. More salt dissolves in order to make up for the lost ion. Some examples of salts with basic ions are \(\mathrm{AgF}, \mathrm{CaCO}_{3}\), and \(\mathrm{Al}(\mathrm{OH})_{3}\). The other way to remove an ion is to form a complex ion. For example, the \(\mathrm{Ag}^{+}\) ion in silver salts forms the complex ion \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)as ammonia is added. Silver salts increase their solubility as \(\mathrm{NH}_{3}\) is added because the \(\mathrm{Ag}^{+}\)ion is removed through complex ion formation. 19. For conjugate acid-base pairs, the weaker the acid, the stronger is the conjugate base. Because HX is a stronger acid (has a larger \(K_{\mathrm{a}}\) value) than \(\mathrm{HY}, \mathrm{Y}^{-}\)will be a stronger base than \(\mathrm{X}^{-}\). In acidic solution, \(\mathrm{Y}^{-}\)will have a greater affinity for the \(\mathrm{H}^{+}\)ions. Therefore, \(\operatorname{AgY}(s)\) will be more soluble in acidic solution because more \(\mathrm{Y}^{-}\) will be removed through reaction with \(\mathrm{H}^{+}\), which will cause more \(\mathrm{AgY}(s)\) to dissolve. 21. In \(2.0 M \mathrm{NH}_{3}\), the soluble complex ion \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\) forms, which increases the solubility of \(\mathrm{AgCl}(s)\). The reaction is \(\mathrm{AgCl}(s)+2 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}(a q)+\mathrm{Cl}^{-}(a q)\). In \(2.0 M \mathrm{NH}_{4} \mathrm{NO}_{3}\), \(\mathrm{NH}_{3}\) is only formed by the dissociation of the weak acid \(\mathrm{NH}_{4}{ }^{+}\). There is not enough \(\mathrm{NH}_{3}\) produced by this reaction to dissolve \(\mathrm{AgCl}(s)\) by the formation of the complex ion. 23. a. \(\mathrm{AgC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(s) \rightleftharpoons \mathrm{Ag}^{+}(a q)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}(a q)\); \(K_{\text {sp }}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right] ;\)b. \(\mathrm{Al}(\mathrm{OH})_{3}(s) \rightleftharpoons \mathrm{Al}^{3+}(a q)+3 \mathrm{OH}^{-}(a q) ; K_{\text {sp }}=\) \(\left[\mathrm{Al}^{3+}\right]\left[\mathrm{OH}^{-}\right]^{3} ;\) c. \(\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s) \rightleftharpoons 3 \mathrm{Ca}^{2+}(a q)+2 \mathrm{PO}_{4}{ }^{3-}(a q) ; K_{\text {sp }}=\) \(\left[\mathrm{Ca}^{2+}\right]^{3}\left[\mathrm{PO}_{4}{ }^{3-}\right]^{2} \quad\) 25. a. \(2.3 \times 10^{-9}\); b. \(8.20 \times 10^{-19} \quad\) 27. \(1.4 \times 10^{-8}\) 29. \(3.92 \times 10^{-5} \quad\) 31. a. \(1.6 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\); b. \(9.3 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\); c. \(6.5 \times\) \(10^{-7} \mathrm{~mol} / \mathrm{L} \quad 33.0 .89 \mathrm{~g} \quad 35.1 .1 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \quad 37.2 \times 10^{-11} \mathrm{~mol} / \mathrm{L}\) 39. a. \(\mathrm{CaF}_{2}\); b. \(\mathrm{FePO}_{4} \quad\) 41. a. \(4 \times 10^{-17} \mathrm{~mol} / \mathrm{L} ;\) b. \(4 \times 10^{-11} \mathrm{~mol} / \mathrm{L}\); c. \(4 \times\) \(10^{-29} \mathrm{~mol} / \mathrm{L}\) 43. a. \(1.4 \times 10^{-2} \mathrm{~mol} / \mathrm{L}\); b. \(1.2 \times 10^{-3} \mathrm{~mol} / \mathrm{L}\); c. \(3.9 \times\) \(10^{-3} \mathrm{~mol} / \mathrm{L} \quad 45.2 .3 \times 10^{-11} \mathrm{~mol} / \mathrm{L} \quad 47.3 .5 \times 10^{-10} \quad\) 49. If the anion in the salt can act as a base in water, then the solubility of the salt will increase as the solution becomes more acidic. Added \(\mathrm{H}^{+}\)will react with the base, forming the conjugate acid. As the basic anion is removed, more of the salt will dissolve to replenish the basic anion. The salts with basic anions are \(\mathrm{Ag}_{3} \mathrm{PO}_{4}, \mathrm{CaCO}_{3}, \mathrm{CdCO}_{3}\), and \(\mathrm{Sr}_{3}\left(\mathrm{PO}_{4}\right)_{2} . \mathrm{Hg}_{2} \mathrm{Cl}_{2}\) and \(\mathrm{PbI}_{2}\) do not have any pH dependence because \(\mathrm{Cl}^{-}\)and \(\mathrm{I}^{-}\)are terrible bases (the conjugate bases of strong acids).
\[
\begin{aligned}

67. \(1.0 \times 10^{42} \quad\) 69. \(\mathrm{Hg}^{2+}(a q)+2 \mathrm{I}^{-}(a q) \rightleftharpoons \mathrm{HgI}_{2}(s)\) (orange precipitate); \(\mathrm{HgI}_{2}(s)+2 \mathrm{I}^{-}(a q) \rightleftharpoons \mathrm{HgI}_{4}{ }^{2-}(a q)\) (soluble complex ion) \(\quad 71.3 .3 \times 10^{-32} \mathrm{M}\) 73. a. \(1.0 \times 10^{-3} \mathrm{M}\); b. \(2.0 \times 10^{-7} \mathrm{M}\); c. \(8.0 \times 10^{-15} \mathrm{M} \quad\) 75. a. \(1.2 \times 10^{-8}\) \(\mathrm{mol} / \mathrm{L} ;\) b. \(1.5 \times 10^{-4} \mathrm{~mol} / \mathrm{L} ; \mathbf{c}\). The presence of \(\mathrm{NH}_{3}\) increases the solubility of AgI. Added \(\mathrm{NH}_{3}\) removes \(\mathrm{Ag}^{+}\)from solution by forming the complex ion
 concentration. 77. \(4.7 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \quad\) 79. Test tube 1 : added \(\mathrm{Cl}^{-}\)reacts with \(\mathrm{Ag}^{+}\)to form the silver chloride precipitate. The net ionic equation is \(\mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) \rightarrow \mathrm{AgCl}(s)\). Test tube 2: added \(\mathrm{NH}_{3}\) reacts with \(\mathrm{Ag}^{+}\) ions to form the soluble complex ion \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\). As this complex ion forms, \(\mathrm{Ag}^{+}\)is removed from solution, which causes \(\mathrm{AgCl}(s)\) to dissolve. When enough \(\mathrm{NH}_{3}\) is added, then all of the silver chloride precipitate will dissolve. The equation is \(\mathrm{AgCl}(s)+2 \mathrm{NH}_{3}(a q) \rightarrow \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}(a q)+\mathrm{Cl}^{-}(a q)\). Test tube 3: added \(\mathrm{H}^{+}\)reacts with the weak base \(\mathrm{NH}_{3}\) to form \(\mathrm{NH}_{4}{ }^{+}\). As \(\mathrm{NH}_{3}\) is removed, \(\mathrm{Ag}^{+}\)ions are released to solution, which can then react with \(\mathrm{Cl}^{-}\)to re-form \(\mathrm{AgCl}(s)\). The equations are \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}(a q)+2 \mathrm{H}^{+}(a q) \rightarrow \mathrm{Ag}^{+}(a q)\) \(+2 \mathrm{NH}_{4}^{+}(a q)\) and \(\mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) \rightarrow \mathrm{AgCl}(s)\). 81. \(1.7 \mathrm{~g} \mathrm{AgCl} ; 5 \times\) \(10^{-9} \mathrm{~mol} / \mathrm{L}\) 83. \(2.7 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\); the solubility of hydroxyapatite will increase as a solution gets more acidic, since both phosphate and hydroxide can react with \(\mathrm{H}^{+} .6 \times 10^{-8} \mathrm{~mol} / \mathrm{L}\); the hydroxyapatite in the tooth enamel is converted to the less soluble fluorapatite by fluoride-treated water. The less soluble fluorapatite will then be more difficult to dissolve, making teeth less susceptible to decay. 85. Precipitation of \(\mathrm{Al}(\mathrm{OH})_{3}(s)\) will begin when \(\mathrm{pH}>3.7\). 87. \(7.0 \times 10^{-8} \quad\) 89. \(\mathrm{AgOH}, 10.15 ; \mathrm{Cd}(\mathrm{OH})_{2}, 9.34 ; \mathrm{Pb}(\mathrm{OH})_{2}\), 9.11 91. \(6.2 \times 10^{5} \quad\) 93. a. \(6.7 \times 10^{-6} \mathrm{~mol} / \mathrm{L}\); b. \(1.2 \times 10^{-13} \mathrm{~mol} / \mathrm{L}\); c. \(\mathrm{Pb}(\mathrm{OH})_{2}(s)\) will not form since \(Q<K_{\text {sp }}\). 95. a. \(1.6 \times 10^{-6}\); b. 0.056 \(\mathrm{mol} / \mathrm{L} \quad 97.7 .4 \times 10^{-4} \quad\) 99. \(1.1 \times 10^{-32} \quad\) 101. \(6.1 \times 10^{-6} \mathrm{~mol} / \mathrm{L}\) 103. \(1.08 \times 10^{-6} \mathrm{~mol} / \mathrm{L} \quad\) 105. a. \(0.33 \mathrm{~mol} / \mathrm{L}\); b. 0.33 M ; c. \(4.8 \times 10^{-3} \mathrm{M}\) 107. a. \(7.1 \times 10^{-7} \mathrm{~mol} / \mathrm{L}\); b. \(8.7 \times 10^{-3} \mathrm{~mol} / \mathrm{L}\); c. The presence of \(\mathrm{NH}_{3}\) increases the solubility of AgBr . Added \(\mathrm{NH}_{3}\) removes \(\mathrm{Ag}^{+}\)from solution by
 dissolve to replenish the \(\mathrm{Ag}^{+}\)concentration. d. 0.41 g AgBr ; e. Added \(\mathrm{HNO}_{3}\) will have no effect on the \(\operatorname{AgBr}(s)\) solubility in pure water. Neither \(\mathrm{H}^{+}\)nor \(\mathrm{NO}_{3}^{-}\)react with \(\mathrm{Ag}^{+}\)or \(\mathrm{Br}^{-}\)ions. \(\mathrm{Br}^{-}\)is the conjugate base of the strong acid HBr , so it is a terrible base. However, added \(\mathrm{HNO}_{3}\) will reduce the solubility of \(\operatorname{AgBr}(s)\) in the ammonia solution. \(\mathrm{NH}_{3}\) is a weak base \(\left(K_{\mathrm{b}}=1.8 \times 10^{-5}\right)\). Added \(\mathrm{H}^{+}\)will react with \(\mathrm{NH}_{3}\) to form \(\mathrm{NH}_{4}{ }^{+}\). As \(\mathrm{NH}_{3}\) is removed, a smaller amount of the \(\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}\)complex ion will form, resulting in a smaller amount of \(\operatorname{AgBr}(s)\) that will dissolve. \(\quad 109.5 .7 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \quad\) 111. 3 M 113. \(4.8 \times 10^{-11} M \quad \mathbf{1 1 5 .}\) a. \(5.8 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\); b. greater; \(\mathrm{F}^{-}\)is a weak base \(\left(K_{\mathrm{b}}=1.4 \times 10^{-11}\right)\), so some of the \(\mathrm{F}^{-}\)is removed by reaction with water. As \(\mathrm{F}^{-}\)is removed, more \(\mathrm{SrF}_{2}\) will dissolve; c. \(3.5 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \quad\) 117. \(\mathrm{pH}=\) \(0.70 ; 0.20 \mathrm{M} \mathrm{Ba}^{2+} ; 23 \mathrm{~g} \mathrm{BaSO}_{4}(s) \quad\) 119. Precipitation of \(\mathrm{CaF}_{2}(s)\) will begin when just over \(9.0 \times 10^{-6} \mathrm{~g} \mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}\) has been added.

\section*{Chapter 17}
11. Living organisms need an external source of energy to carry out these processes. For all processes combined, \(\Delta S_{\text {univ }}\) must be greater than zero (the 2nd law). 13. As any process occurs, \(\Delta S_{\text {univ }}\) will increase; \(\Delta S_{\text {univ }}\) cannot decrease. Time also goes in one direction, just as \(\Delta S_{\text {univ }}\) goes in one direction. 15. This reaction is kinetically slow but thermodynamically favorable \((\Delta \mathrm{G}<0)\). Thermodynamics only tells us if a reaction can occur. To answer the question will the reaction occur, one also needs to consider the kinetics (speed of reaction). The ultraviolet light provides the activation energy for this slow reaction to occur. 17. \(\Delta S_{\text {surr }}=-\Delta H / T\); heat flow \((\Delta H)\) into or out of the system dictates \(\Delta S_{\text {surr }}\). If heat flows into the surroundings, the random motions of the surroundings increase, and the entropy of the surroundings increases. The opposite is true when heat flows from the surroundings into the system (an endothermic reaction). Although the driving force described here really results from the change in entropy of the surroundings, it is often described in terms of energy. Nature tends to seek the lowest possible energy. 19. a. increases; b. no change; c. decreases 21. Note that these sub-
stances are not in the solid state but are in the aqueous state; water molecules are also present. There is an apparent increase in ordering when these ions are placed in water. The hydrating water molecules must be in a highly ordered state when surrounding these anions. 23. One can determine \(\Delta S^{\circ}\) and \(\Delta H^{\circ}\) for the reaction using the standard entropies and standard enthalpies of formation in Appendix 4, then use the equation \(\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}\). One can also use the standard free energies of formation in Appendix 4. And finally, one can use Hess's law to calculate \(\Delta G^{\circ}\). Here, reactions having known \(\Delta G^{\circ}\) values are manipulated to determine \(\Delta G^{\circ}\) for a different reaction. For temperatures other than \(25^{\circ} \mathrm{C}, \Delta G^{\circ}\) is estimated using the \(\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}\) equation. The assumptions made are that the \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) values determined from Appendix 4 data are temperature independent. We use the same \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) values as determined when \(T=25^{\circ} \mathrm{C}\), then plug in the new temperature in kelvins into the equation to estimate \(\Delta G^{\circ}\) at the new temperature. \(\mathbf{2 5}\). The light source for the first reaction is necessary for kinetic reasons. The first reaction is just too slow to occur unless a light source is available. The kinetics of a reaction are independent of the thermodynamics of a reaction. Even though the first reaction is more favorable thermodynamically (assuming standard conditions), it is unfavorable for kinetic reasons. The second reaction has a negative \(\Delta G^{\circ}\) value and is a fast reaction, so the second reaction occurs very quickly. When considering if a reaction will occur, thermodynamics and kinetics must both be considered. 27. Only statement e is true. 29. a, b, c 31. Possible arrangements for one molecule:

1 way

1 way

Both are equally probable.
Possible arrangements for two molecules:

1 way

2 ways
Most probable

Possible arrangement for three molecules:

33. We draw all of the possible arrangements of the two particles in the three levels.

taneous at standard concentrations and 298 K. c. \(T>630 \mathrm{~K}\) 69. \(\mathrm{CH}_{4}(g)+\) \(\mathrm{CO}_{2}(g) \rightarrow \mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}(l), \Delta H^{\circ}=-16 \mathrm{~kJ}, \Delta S^{\circ}=-240 . \mathrm{J} / \mathrm{K}, \Delta G^{\circ}=56 \mathrm{~kJ}\); \(\mathrm{CH}_{3} \mathrm{OH}(g)+\mathrm{CO}(g) \rightarrow \mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}(\mathrm{l}), \Delta H^{\circ}=-173 \mathrm{~kJ}, \Delta S^{\circ}=-278 \mathrm{~J} / \mathrm{K}\), \(\Delta G^{\circ}=-90 . \mathrm{kJ}\); the second reaction is preferred. It should be run at temperatures below \(622 \mathrm{~K} . \quad\) 71. -188 kJ 73. a. shifts right; b. no shift since the reaction is at equilibrium; c. shifts left 75. \(-198 \mathrm{~kJ} ; 5.07 \times 10^{34}\) 77. \(8.72 ; 0.0789\) 79. \(140 \mathrm{~kJ} \quad\) 81. a. \(2.22 \times 10^{5}\); b. \(94.3 \quad\) 83. \(-71 \mathrm{~kJ} / \mathrm{mol}\) 85. \(\Delta H^{\circ}=1.1 \times 10^{5} \mathrm{~J} / \mathrm{mol} ; \Delta S^{\circ}=330 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\); the major difference in the plot is the slope of the line. An endothermic process has a negative slope for the \(\ln (K)\) versus \(1 / T\) plot, whereas an exothermic process has a positive slope. 87. All have positive signs at \(25^{\circ} \mathrm{C}\). 89. \(447 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} \quad\) 91. \(\Delta S_{\text {univ }}\) must be positive. 93. a. \(\Delta H^{\circ}=-183 \mathrm{~kJ} ; \Delta S^{\circ}=-100 . \mathrm{J} / \mathrm{K} ; \Delta G^{\circ}=-153 \mathrm{~kJ}\); b. \(\Delta H^{\circ}=-177 \mathrm{~kJ} ; \Delta S^{\circ}=-129 \mathrm{~J} / \mathrm{K} ; \Delta G_{343}^{\circ}=-133 \mathrm{~kJ} ; \mathbf{c} . \Delta H^{\circ}=-1336 \mathrm{~kJ}\); \(\Delta S^{\circ}=88 \mathrm{~J} / \mathrm{K} ; \Delta G_{973}^{\circ}=-1422 \mathrm{~kJ} \quad \mathbf{9 5} .43 .7 \mathrm{~K} \quad 97.7 .0 \times 10^{-4} \quad 99.60\) 101. \(\Delta S\) is more favorable (less negative) for reaction 2 than for reaction 1 , resulting in \(K_{2}>K_{1}\). In reaction 1 , seven particles in solution form one particle. In reaction 2 , four particles form one, which results in a smaller decrease in positional probability than for reaction 1. 103. 725 K 105. A negative value for \(\Delta S^{\circ}\) indicates a process that has a decrease in positional probability. Processes b, c, and d all are expected to have negative values for \(\Delta S^{\circ}\). In these processes, the number of moles of gaseous molecules decreases as reactants are converted to products. Whenever this occurs, positional probability decreases. Processes a and e have positive \(\Delta S^{\circ}\) values. In process a, the number of gaseous molecules increase as reactants are converted to products, so positional probability increases. In process e, the liquid state has a larger positional probability compared to the solid state. 107. \(\Delta S^{\circ}=49 \mathrm{~J} / \mathrm{K} ; \Delta S_{\text {surr }}=-140 \mathrm{~J} / \mathrm{K} \quad 109.74 .4 \mathrm{~kJ} / \mathrm{mol} \quad\) 111. a. False; the moles of gaseous molecules decrease in this reaction, so \(\Delta S^{\circ}\) is negative (unfavorable). From the problem \(\Delta G^{\circ}\) is negative, which can only occur if \(\Delta H^{\circ}\) is negative (exothermic). \(\mathbf{b}\). True. c. False; heat is a product in this exothermic reaction. As heat is added (temperature increases), this reaction will shift left by Le Châtelier's principle. This results in a decrease in the value of \(K\). At equilibrium at the higher temperature, reactant concentrations will increase and the product concentration will decrease. Therefore, the ratio of \(\left[\mathrm{PCl}_{5}\right] /\left[\mathrm{PCl}_{3}\right]\) will decrease with an increase in temperature. d. False; when the signs of \(\Delta H^{\circ}\) and \(\Delta S^{\circ}\) are both negative, the reaction will only be spontaneous at temperatures below some value (at low temperatures) where the favorable \(\Delta H^{\circ}\) term dominates. e. True; when \(\Delta G^{\circ}<0, K\) must be greater than 1. 113. a. Vessel 1: At \(0^{\circ} \mathrm{C}\), this system is at equilibrium, so \(\Delta S_{\text {univ }}=0\) and \(\Delta S=\Delta S_{\text {surr }}\). Because the vessel is perfectly insulated, \(q=0\) so \(\Delta S_{\text {surr }}=0=\Delta S_{\text {sys }}\). b. Vessel 2: The presence of salt in water lowers the freezing point of water to a temperature below \(0^{\circ} \mathrm{C}\). In vessel 2 the conversion of ice into water will be spontaneous at \(0^{\circ} \mathrm{C}\), so \(\Delta S_{\text {univ }}>0\). Because the vessel is perfectly insulated, \(\Delta S_{\text {surr }}=0\). Therefore, \(\Delta S_{\text {sys }}\) must be positive \((\Delta S>0)\) in order for \(\Delta S_{\text {univ }}\) to be positive. \(\quad 115 . \Delta H^{\circ}=286 \mathrm{~kJ} ; \Delta G^{\circ}=326 \mathrm{~kJ}\); \(K=7.22 \times 10^{-58} ; P_{\mathrm{O}_{3}}=3.3 \times 10^{-41} \mathrm{~atm}\); this partial pressure represents one molecule of ozone per \(9.5 \times 10^{17} \mathrm{~L}\) of air. Equilibrium is probably not maintained under the conditions because the concentration of ozone is not large enough to maintain equilibrium

\section*{117. a.}
\(k_{\mathrm{f}}=A \exp \left(\frac{-E_{\mathrm{a}}}{R T}\right)\) and \(k_{\mathrm{r}}=A \exp \left(\frac{-\left(E_{\mathrm{a}}-\Delta G^{\circ}\right)}{R T}\right)\),
\(\frac{k_{\mathrm{f}}}{k_{\mathrm{r}}}=\exp \left(\frac{-E_{\mathrm{a}}}{R T}+\frac{\left(E_{\mathrm{a}}-\Delta G^{\circ}\right)}{R T}\right)=\exp \left(\frac{-\Delta G^{\circ}}{R T}\right)\)
From \(\Delta G^{\circ}=-R T \ln K, K\) also equals the same expression: \(K=\exp \left(\frac{-\Delta G^{\circ}}{R T}\right)\), so \(K=\frac{k_{\mathrm{f}}}{k_{\mathrm{r}}}\). b. A catalyst increases the value of the rate constant (increases rate) by lowering the activation energy. For the equilibrium constant \(K\) to remain constant, both \(k_{\mathrm{f}}\) and \(k_{\mathrm{r}}\) must increase by the same factor. Therefore, a catalyst must increase the rate of both the forward and the reverse reactions. 119. a. 0.333 ; b. \(P_{\mathrm{A}}=1.50 \mathrm{~atm} ; P_{\mathrm{B}}=0.50 \mathrm{~atm} ;\) c. \(\Delta G=\Delta G^{\circ}+\) \(R T \ln \left(P_{\mathrm{B}} / P_{\mathrm{A}}\right)=2722 \mathrm{~J}-2722 \mathrm{~J}=0 \quad\) 121. greater than 7.5 torr \(\quad \mathbf{1 2 3 .} 6 \mathrm{M}\) 125. \(61 \mathrm{~kJ} / \mathrm{mol} \quad \mathbf{1 2 7} .0 .14 \mathrm{~atm} \quad \mathbf{1 2 9}\). \(-4.1 \mathrm{~kJ} / \mathrm{mol}\)

Electrochemistry is the study of the interchange of chemical and electrical energy. A redox (oxidation-reduction) reaction is a reaction in which one or more electrons are transferred. In a galvanic cell, a spontaneous redox reaction occurs which produces an electric current. In an electrolytic cell, electricity is used to force a nonspontaneous redox reaction to occur. 25. Magnesium is an alkaline earth metal; Mg will oxidize to \(\mathrm{Mg}^{2+}\). The oxidation state of hydrogen in HCl is +1 . To be reduced, the oxidation state of H must decrease. The obvious choice for the hydrogen product is \(\mathrm{H}_{2}(g)\) where hydrogen has a zero oxidation state. The balanced reaction is: \(\mathrm{Mg}(s)+\) \(2 \mathrm{HCl}(a q) \rightarrow \mathrm{MgCl}_{2}(a q)+\mathrm{H}_{2}(g) . \mathrm{Mg}\) goes from the 0 to the +2 oxidation state by losing two electrons. Each H atom goes from the +1 to the 0 oxidation state by gaining one electron. Since there are two H atoms in the balanced equation, then a total of two electrons are gained by the H atoms. Hence, two electrons are transferred in the balanced reaction. When the electrons are transferred directly from Mg to \(\mathrm{H}^{+}\), no work is obtained. In order to harness this reaction to do useful work, we must control the flow of electrons through a wire. This is accomplished by making a galvanic cell, which separates the reduction reaction from the oxidation reaction in order to control the flow of electrons through a wire to produce a voltage. 27. An extensive property is one that depends on how many times the reaction occurs. The free energy change for a reaction depends on whether 1 mole of product is produced or 2 moles of product is produced or 1 million moles of product is produced. This is not the case for cell potentials, which do not depend on how many times the reaction occurs. The equation that relates \(\Delta G\) to \(E\) is \(\Delta G=-n F E\). It is the \(n\) term that converts the intensive property \(E\) into the extensive property \(\Delta G . n\) is the number of moles of electrons transferred in the balanced reaction that \(\Delta G\) is associated with. 29. A potential hazard when jump-starting a car is that the electrolysis of \(\mathrm{H}_{2} \mathrm{O}(l)\) can occur. When \(\mathrm{H}_{2} \mathrm{O}(l)\) is electrolyzed, the products are the explosive gas mixture of \(\mathrm{H}_{2}(g)\) and \(\mathrm{O}_{2}(g)\). A spark produced during jump-starting a car could ignite any \(\mathrm{H}_{2}(g)\) and \(\mathrm{O}_{2}(g)\) produced. Grounding the jumper cable far from the battery minimizes the risk of a spark nearby the battery where \(\mathrm{H}_{2}(g)\) and \(\mathrm{O}_{2}(g)\) could be collecting. 31. You need to know the identity of the metal so you know which molar mass to use. You need to know the oxidation state of metal ion in the salt so the moles of electrons transferred can be determined. And finally, you need to know the amount of current and the time the current was passed through the electrolytic cell. If you know these four quantities, then the mass of metal plated out can be calculated. 33. Only statement e is true. The attached metals that are more easily oxidized than iron are called sacrificial metals. For statement a, corrosion is a spontaneous process, like the ones harnessed to make galvanic cells. For statement b, corrosion of steel is the oxidation of iron coupled with the reduction of oxygen. For statement \(c\), cars rust more easily in high-moisture areas (the humid areas) because water is a reactant in the reduction half-reaction as well as providing a medium for ion migration (a salt bridge of sorts). For statement d, salting roads adds ions to the corrosion process, which increases the conductivity of the aqueous solution and, in turn, accelerates corrosion. 35. The reducing agent causes reduction to occur; it does this by containing the species that is oxidized. Oxidation occurs at the anode, so the reducing agent will be in the anode compartment. The oxidizing agent causes oxidation to occur; it does this by containing the species that is reduced. Reduction occurs at the cathode, so the oxidizing agent will be in the cathode compartment. Electron flow is always from the anode compartment to the cathode compartment. 37. See Fig. 18.3 of the text for a typical galvanic cell. The anode compartment
contains the oxidation half-reaction compounds/ions, and the cathode compartment contains the reduction half-reaction compounds/ions. The electrons flow from the anode to the cathode. For each of the following answers, all solutes are 1.0 M and all gases are at 1.0 atm . a. \(7 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{Cr}^{3+}(a q)+\) \(3 \mathrm{Cl}_{2}(g) \rightarrow \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+6 \mathrm{Cl}^{-}(a q)+14 \mathrm{H}^{+}(a q)\); cathode: Pt electrode; \(\mathrm{Cl}_{2}\) bubbled into solution, \(\mathrm{Cl}^{-}\)in solution; anode: Pt electrode; \(\mathrm{Cr}^{3+}, \mathrm{H}^{+}\), and \(\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}\) in solution; \(\mathbf{b}\). \(\mathrm{Cu}^{2+}(a q)+\mathrm{Mg}(s) \rightarrow \mathrm{Cu}(s)+\mathrm{Mg}^{2+}(a q)\); cathode: Cu electrode; \(\mathrm{Cu}^{2+}\) in solution; anode: Mg electrode; \(\mathrm{Mg}^{2+}\) in solution 39. a. 0.03 V ; b. 2.71 V 41. \section*{Chapter 19}
1. The characteristic frequencies of energies emitted in a nuclear reaction suggest that discrete energy levels exist in the nucleus. The extra stability of certain numbers of nucleons and the predominance of nuclei with even numbers of nucleons suggest that the nuclear structure might be described by using quantum numbers. 3. Radiotracers generally have short half-lives. The radioactivity from the radiotracers is monitored to study a specific area of the body. However, we don't want long-lived radioactivity in order to minimize potential damage to healthy tissue by the radioactivity. 5. \(\beta\)-particle production has the net effect of turning a neutron into a proton. Radioactive nuclei having too many neutrons typically undergo \(\beta\)-particle decay. Positron production has the net effect of turning a proton into a neutron. Nuclei having too many protons typically undergo positron decay. 7. The transuranium elements are the elements having more protons than uranium. They are synthesized by bombarding heavier nuclei with neutrons and positive ions in a particle accelerator. 9. \(\Delta E=\Delta m c^{2}\); The key difference is the mass change when going from reactants to products. In chemical reactions, the mass change is indiscernible. In nuclear processes, the mass change is discernible. It is the conversion of this discernible mass change into energy that results in the huge energies associated with nuclear processes. 11. The temperatures of fusion reactions are so high that all physical containers would be destroyed. At these high temperatures, most of the electrons are stripped from the atoms. A plasma of gaseous ions is formed that can be controlled by magnetic fields. 13. Somatic damage is immediate damage to the organism itself, resulting in sickness or death. Genetic damage is damage to the genetic material, which can be passed on to future generations. The organism will not feel immediate consequences from genetic damage, but its offspring may be damaged. 15. a. \({ }_{1}^{3} \mathrm{H} \rightarrow{ }_{2}^{3} \mathrm{He}+{ }_{-1}^{0} \mathrm{e} ; \mathbf{b} \cdot{ }_{3}^{8} \mathrm{Li} \rightarrow{ }_{4}^{8} \mathrm{Be}+{ }_{-1}^{0} \mathrm{e}\), \({ }_{4}^{8} \mathrm{Be} \rightarrow 2{ }_{2}^{4} \mathrm{He}\); overall reaction: \({ }_{3}^{8} \mathrm{Li} \rightarrow 2{ }_{2}^{4} \mathrm{He}+{ }_{-1}^{0} \mathrm{e}\); c. \({ }_{4}^{7} \mathrm{Be}+{ }_{-}^{0} \mathrm{e} \rightarrow{ }_{3}^{7} \mathrm{Li}\); d. \({ }_{5}^{8} \mathrm{~B} \rightarrow{ }_{4}^{8} \mathrm{Be}+{ }_{+1}^{0} \mathrm{e} \quad\) 17. a. \({ }_{90}^{234} \mathrm{Th}\); this is \(\alpha\)-particle production. b. \({ }_{-1}^{0} \mathrm{e}\); this is \(\beta\)-particle production. 19. a. \({ }_{31}^{68} \mathrm{Ga}+{ }_{-1}^{0} \mathrm{e} \rightarrow{ }_{30}^{68} \mathrm{Zn}\); b. \({ }_{29}^{62} \mathrm{Cu} \rightarrow{ }_{+1}^{0} \mathrm{e}+{ }_{28}^{62} \mathrm{Ni}\); c. \({ }_{87}^{212} \mathrm{Fr} \rightarrow{ }_{2}^{4} \mathrm{He}+{ }_{85}^{208} \mathrm{At}\); d. \({ }_{51}^{12} \mathrm{Sb} \rightarrow{ }_{-1}^{0} \mathrm{e}+{ }_{52}^{129} \mathrm{Te} \quad \mathbf{2 1 . 7} \alpha\) particles; \(4 \beta\) particles 23. a. \({ }_{95}^{241} \mathrm{Am} \rightarrow{ }_{2}^{4} \mathrm{He}+{ }_{93}^{237} \mathrm{~Np}\); b. \({ }_{83}^{209} \mathrm{Bi}\); c. The intermediate radionuclides are \({ }_{93}^{237} \mathrm{~Np},{ }_{91}^{233} \mathrm{~Pa},{ }_{92}^{233} \mathrm{U},{ }_{90}^{229} \mathrm{Th},{ }_{88}^{225} \mathrm{Ra},{ }_{89}^{225} \mathrm{Ac},{ }_{87}^{221} \mathrm{Fr},{ }_{85}^{217} \mathrm{At},{ }_{83}^{213} \mathrm{Bi},{ }_{84}^{213} \mathrm{Po}\), and \({ }_{82}^{209} \mathrm{~Pb}\). 25. \({ }^{8} \mathrm{~B}\) and \({ }^{9} \mathrm{~B}\) contain too many protons or too few neutrons. Electron capture and positron production are both possible decay mechanisms that increase the neutron-to-proton ratio. Alpha-particle production also increases the neutron-to-proton ratio, but it is not likely for these light nuclei. \({ }^{12} \mathrm{~B}\) and \({ }^{13} \mathrm{~B}\) contain too many neutrons or too few protons. Beta-particle production lowers the neutron-to-proton ratio, so we expect these to be beta-emitters. 27. a. \({ }_{98}^{249} \mathrm{Cf}+{ }_{8}^{18} \mathrm{O} \rightarrow{ }_{106}^{263} \mathrm{Sg}+4{ }_{0}^{1} \mathrm{n}\); b. \({ }_{104}^{259} \mathrm{Rf} \quad\) 29. For \(t_{1 / 2}=12,000\) years: \(1.1 \times 10^{12}\) decays \(/ \mathrm{s}\); for \(t_{1 / 2}=12 \mathrm{~h}: 9.6 \times 10^{18}\) decays \(/ \mathrm{s}\); for \(t_{1 / 2}=12 \mathrm{~s}\) : \(3.5 \times 10^{22}\) decays/s \(\quad 31.690\) hours \(\quad 33.5 .0 \mathrm{~min} \quad 35.15 \mu \mathrm{~g}{ }^{47} \mathrm{CaCO}_{3}\) should
be ordered at a minimum. 37. \(17.7 \%\) 39. The fraction that remains is 0.0041 , or \(0.41 \%\). \(\quad 41.26 \mathrm{~g} \quad \mathbf{4 3} .2 .3\) counts per minute per gram of C. No; for a \(10 .-\mathrm{mg} \mathrm{C}\) sample, it would take roughly 40 min to see a single disintegration. This is too long to wait, and the background radiation would probably be much greater than the \({ }^{14} \mathrm{C}\) activity. Thus \({ }^{14} \mathrm{C}\) dating is not practical for very small samples. \(\quad 45.3 .8 \times 10^{9} \mathrm{yr} \quad 47.4 .3 \times 10^{6} \mathrm{~kg} / \mathrm{s} \quad 49 .{ }^{232} \mathrm{Pu},-1.715 \times 10^{14} \mathrm{~J} / \mathrm{mol}\); \({ }^{231} \mathrm{~Pa},-1.714 \times 10^{14} \mathrm{~J} / \mathrm{mol} \quad 51 .{ }^{12} \mathrm{C}: 1.230 \times 10^{-12} \mathrm{~J} /\) nucleon; \({ }^{235} \mathrm{U}\) : \(1.2154 \times 10^{-12} \mathrm{~J} /\) nucleon; since \({ }^{56} \mathrm{Fe}\) is the most stable known nucleus, the binding energy per nucleon for \({ }^{56} \mathrm{Fe}\) would be larger than that of \({ }^{12} \mathrm{C}\) or \({ }^{235} \mathrm{U}\). (See Fig. 19.9 of the text.) \(\quad 53.6 .01513 \mathrm{u} \quad 55 .-2.0 \times 10^{10} \mathrm{~J} / \mathrm{g}\) of hydrogen nuclei 57. The Geiger-Müller tube has a certain response time. After the gas in the tube ionizes to produce a "count," some time must elapse for the gas to return to an electrically neutral state. The response of the tube levels off because, at high activities, radioactive particles are entering the tube faster than the tube can respond to them. 59. Water is produced in this reaction by removing an OH group from one substance and an H from the other substance. There are two ways to do this:

Because the water produced is not radioactive, methyl acetate forms by the first reaction, where all of the oxygen-18 ends up in methyl acetate. 61. 2 neutrons; \(4 \beta\) particles 63. Strontium. Xe is chemically unreactive and not readily incorporated into the body. Sr can be easily oxidized to \(\mathrm{Sr}^{2+}\). Strontium is in the same family as calcium and could be absorbed and concentrated in the body in a fashion similar to \(\mathrm{Ca}^{2+}\). The chemical properties determine where radioactive material may be concentrated in the body or how easily it may be excreted. 65. a. unstable; beta production; b. stable; c. unstable; positron production or electron capture; d. unstable, positron production, electron capture, or alpha production. 67. The products of the various steps are \({ }_{84}^{214} \mathrm{Po},{ }_{82}^{210} \mathrm{~Pb},{ }_{83}^{210} \mathrm{Bi}\), and \({ }_{84}^{210} \mathrm{Po}\). 69. 3800 decays/s 71. The third-life will be the time required for the number of nuclides to reach one-third of the original value \(\left(N_{0} / 3\right)\). The third-life of this nuclide is 49.8 years. \(\quad 73.1975 \quad \mathbf{7 5 . 9 0 0}\) g \({ }^{235} \mathrm{U} \quad 77.7 \times 10^{5} \mathrm{~m} / \mathrm{s} ; 8 \times 10^{-16} \mathrm{~J} /\) nuclei; 79. All evolved \(\mathrm{O}_{2}(g)\) comes from water. 81. The equations for the nuclear reactions are \({ }_{94}^{239} \mathrm{Pu} \rightarrow{ }_{92}^{235} \mathrm{U}+{ }_{2}^{4} \mathrm{He} ; \quad{ }_{82}^{214} \mathrm{~Pb} \rightarrow{ }_{83}^{214} \mathrm{Bi}+{ }_{-1}^{0} \mathrm{e}\); \({ }_{27}^{60} \mathrm{Co} \rightarrow{ }_{28}^{60} \mathrm{Ni}+{ }_{-1}^{0} \mathrm{e} ; \quad{ }_{43}^{99} \mathrm{Tc} \rightarrow{ }_{44}^{99} \mathrm{Ru}+{ }_{-1}^{0} \mathrm{e} ; \quad{ }_{93}^{239} \mathrm{~Np} \rightarrow{ }_{94}^{239} \mathrm{Pu}+{ }_{-1}^{0} \mathrm{e}\) \(\begin{array}{lll}\text { 83. } 15.8 \mathrm{yr} & 85.3 .177 \times 10^{-11} \mathrm{~J} & \mathbf{8 7} .77 \%\end{array}{ }^{238} \mathrm{U}\) and \(23 \%{ }^{235} \mathrm{U} \quad\) 89. Assuming that (1) the radionuclide is long lived enough that no significant decay occurs during the time of the experiment, and (2) the total activity is uniformly distributed only in the rat's blood, \(V=10\). mL. 91. a. \({ }_{6}^{12} \mathrm{C}\); b. \({ }^{13} \mathrm{~N},{ }^{13} \mathrm{C},{ }^{14} \mathrm{~N},{ }^{15} \mathrm{O}\), and \({ }^{15} \mathrm{~N}\); c. \(-5.950 \times 10^{11} \mathrm{~J} / \mathrm{mol}{ }^{1} \mathrm{H} \quad 93.4 .3 \times 10^{-29}\) 95. \({ }_{97}^{249} \mathrm{Bk}+{ }_{10}^{22} \mathrm{Ne} \rightarrow{ }_{107}^{267} \mathrm{Bh}+4{ }_{0}^{1} \mathrm{n} ; 62.7 \mathrm{~s} ;[\mathrm{Rn}] 7 s^{2} 5 f^{14} 6 d^{5}\)

\section*{Chapter 20}
1. The gravity of the earth cannot keep the light \(\mathrm{H}_{2}\) molecules in the atmosphere. 3. Calcium is found in the structural material that makes up bones and teeth. Magnesium plays a vital role in metabolism and in muscle function. 5. For Groups 1A-3A, the small size of H (as compared to Li ), Be (as compared to Mg ), and B (as compared to Al ) seems to be the reason why these elements have nonmetallic properties, while others in Groups 1A-3A are strictly metallic. The small size of \(\mathrm{H}, \mathrm{Be}\), and B also causes these species to polarize the electron cloud in nonmetals, thus forcing a sharing of electrons when bonding occurs. For Groups 4A-6A, a major difference between the first and second members of a group is the ability to form \(\pi\) bonds. The smaller elements form stable \(\pi\) bonds, while the larger elements do not exhibit good overlap between parallel \(p\) orbitals and, in turn, do not form strong \(\pi\) bonds. For Group 7A, the small size of F as compared to Cl is used to explain the low electron affinity of F and the weakness of the \(\mathrm{F}-\mathrm{F}\) bond. 7. In order to maximize hydrogen bonding interactions in the solid phase, ice is forced into an open structure. This open structure is why \(\mathrm{H}_{2} \mathrm{O}(s)\) is less dense than \(\mathrm{H}_{2} \mathrm{O}(l)\). 9. Group 1A and 2A metals are all easily oxidized. They must be produced in the absence of materials \(\left(\mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}\right)\) that are capable of oxidiz-
ing them. 11. The reaction \(\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)\) is exothermic. Thus, the value of the equilibrium constant \(K\) decreases as the temperature increases. Lower temperatures are favored for maximum yield of ammonia. However, at lower temperatures the rate is slow; without a catalyst the rate is too slow for the process to be feasible. The discovery of a catalyst increased the rate of reaction at a lower temperature favored by thermodynamics. 13. Boranes are covalent compounds produced between boron and hydrogen. The \(\mathrm{B}-\mathrm{H}\) bonds in boranes are relatively weak and are very reactive. When boranes are reacted with oxygen, the product bonds are much stronger than the reactant bonds. When this is the case, very exothermic reactions result, which are the bases for good rocket fuels. 15. a. \(\Delta H^{\circ}=207 \mathrm{~kJ}\), \(\Delta S^{\circ}=216 \mathrm{~J} / \mathrm{K}\); b. \(T>958 \mathrm{~K} \quad\) 17. \(4 \mathrm{Li}(s)+\mathrm{O}_{2}(g) \rightarrow 2 \mathrm{Li}_{2} \mathrm{O}(s) ; 2 \mathrm{Li}(s)+\) \(\mathrm{S}(s) \rightarrow \mathrm{Li}_{2} \mathrm{~S}(s) ; 2 \mathrm{Li}(s)+\mathrm{Cl}_{2}(g) \rightarrow 2 \mathrm{LiCl}(s) ; 12 \mathrm{Li}(s)+\mathrm{P}_{4}(s) \rightarrow 4 \mathrm{Li}_{3} \mathrm{P}(s) ;\) \(2 \mathrm{Li}(s)+\mathrm{H}_{2}(g) \rightarrow 2 \mathrm{LiH}(s) ; 2 \mathrm{Li}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \rightarrow 2 \mathrm{LiOH}(a q)+\mathrm{H}_{2}(g) ;\) \(2 \mathrm{Li}(s)+2 \mathrm{HCl}(a q) \rightarrow 2 \mathrm{LiCl}(a q)+\mathrm{H}_{2}(g) \quad\) 19. When lithium reacts with excess oxygen, \(\mathrm{Li}_{2} \mathrm{O}\) forms, which is composed of \(\mathrm{Li}^{+}\)and \(\mathrm{O}^{2-}\) ions. This is called an oxide salt. When sodium reacts with oxygen, \(\mathrm{Na}_{2} \mathrm{O}_{2}\) forms, which is composed of \(\mathrm{Na}^{+}\)and \(\mathrm{O}_{2}{ }^{2-}\) ions. This is called a peroxide salt. When potassium (or rubidium or cesium) reacts with oxygen, \(\mathrm{KO}_{2}\) forms, which is composed of \(\mathrm{K}^{+}\)and \(\mathrm{O}_{2}^{-}\)ions. For your information, this is called a superoxide salt. So the three types of alkali metal oxides that can form differ in the oxygen anion part of the formula \(\left(\mathrm{O}^{2-}\right.\) vs. \(\mathrm{O}_{2}{ }^{2-}\) vs. \(\left.\mathrm{O}_{2}{ }^{-}\right)\). Each of these anions have unique bonding arrangements and oxidation states. 21. The small size of the \(\mathrm{Li}^{+}\)cation results in a much greater attraction to water. The attraction to water is not so great for the other alkali metal ions. Thus lithium salts tend to absorb water. 23. \(\mathrm{CaCO}_{3}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \rightarrow\) \(\mathrm{CaSO}_{4}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g) \quad\) 25. \(3.84 \times 10^{6} \mathrm{~g} \mathrm{Ba} \quad\) 27. Beryllium has a small size and a large electronegativity as compared with the other alkaline earth metals. The electronegativity of Be is so high that it does not readily give up electrons to nonmetals, as is the case for the other alkaline earth metals. Instead, Be has significant covalent character in its bonds; it prefers to share valence electrons rather than give them up to form ionic bonds. 29. \(9.3 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \quad\) 31. \(\mathrm{Nh}:[\mathrm{Rn}] 7 s^{2} 5 f^{14} 6 d^{10} 7 p^{1}\); Nh falls below Tl in the periodic table. We would expect Nh , like Tl , to form +1 and +3 oxidation states in its compounds. 33. \(\mathrm{B}_{2} \mathrm{H}_{6}(g)+3 \mathrm{O}_{2}(g) \rightarrow 2 \mathrm{~B}(\mathrm{OH})_{3}(s)\) 35. \(2 \mathrm{Ga}(s)+3 \mathrm{~F}_{2}(g) \rightarrow 2 \mathrm{GaF}_{3}(s)\); \(4 \mathrm{Ga}(\mathrm{s})+3 \mathrm{O}_{2}(g) \rightarrow 2 \mathrm{Ga}_{2} \mathrm{O}_{3}(\mathrm{~s}) ; 2 \mathrm{Ga}(\mathrm{s})+3 \mathrm{~S}(\mathrm{~s}) \rightarrow \mathrm{Ga}_{2} \mathrm{~S}_{3}(\mathrm{~s}) ; 2 \mathrm{Ga}(\mathrm{s})+\) \(6 \mathrm{HCl}(a q) \rightarrow 2 \mathrm{GaCl}_{3}(a q)+3 \mathrm{H}_{2}(\mathrm{~g}) \quad\) 37. An amphoteric substance is one that can behave as either an acid or a base. \(\mathrm{Al}_{2} \mathrm{O}_{3}\) dissolves in both acidic and basic solutions. The reactions are \(\mathrm{Al}_{2} \mathrm{O}_{3}(s)+6 \mathrm{H}^{+}(a q) \rightarrow 2 \mathrm{Al}^{3+}(a q)+\) \(3 \mathrm{H}_{2} \mathrm{O}(l)\) and \(\mathrm{Al}_{2} \mathrm{O}_{3}(s)+2 \mathrm{OH}^{-}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) \rightarrow 2 \mathrm{Al}(\mathrm{OH})_{4}{ }^{-}(a q)\). 39. Compounds containing \(\mathrm{Si}-\mathrm{Si}\) single and multiple bonds are rare, unlike compounds of carbon. The bond strengths of the \(\mathrm{Si}-\mathrm{Si}\) and \(\mathrm{C}-\mathrm{C}\) single bonds are similar. The difference in bonding properties must be for other reasons. One reason is that silicon does not form strong pi bonds, unlike carbon. Another reason is that silicon forms particularly strong sigma bonds to oxygen, resulting in compounds with \(\mathrm{Si}-\mathrm{O}\) bonds instead of \(\mathrm{Si}-\mathrm{Si}\) bonds. 41. \(\ddot{\mathrm{O}}=\mathrm{C}=\ddot{\mathrm{O}}\) The darker green orbitals about carbon are \(s p\) hybrid orbitals. The lighter green orbitals about each oxygen are \(s p^{2}\) hybrid orbitals, and the gold orbitals about all of the atoms are unhybridized \(p\) atomic orbitals. In each double bond in \(\mathrm{CO}_{2}\), one \(\sigma\) bond and one \(\pi\) bond exist. The two carbon-oxygen \(\sigma\) bonds are formed from overlap of \(s p\) hybrid orbitals from carbon with an \(s p^{2}\) hybrid orbital from each oxygen. The two carbon-oxygen \(\pi\) bonds are formed from side-to-side overlap of the unhybridized \(p\) atomic orbitals from carbon with an unhybridized \(p\) atomic orbital from each oxygen, as illustrated in the figure. 43. a. \(\mathrm{SiO}_{2}(s)+2 \mathrm{C}(s) \rightarrow\) \(\mathrm{Si}(s)+2 \mathrm{CO}(g) ;\) b. \(\mathrm{SiCl}_{4}(l)+2 \mathrm{Mg}(s) \rightarrow \mathrm{Si}(s)+2 \mathrm{MgCl}_{2}(s) ;\) c. \(\mathrm{Na}_{2} \mathrm{SiF}_{6}(s)+\) \(4 \mathrm{Na}(s) \rightarrow \mathrm{Si}(s)+6 \mathrm{NaF}(s)\) 45. \(2: 1\) 47. Nitrogen's small size does not provide room for all four oxygen atoms, making \(\mathrm{NO}_{4}{ }^{3-}\) unstable. Phosphorus is larger so \(\mathrm{PO}_{4}{ }^{3-}\) is more stable. To form \(\mathrm{NO}_{3}{ }^{-}\), a pi bond must form. Phosphorus doesn't form strong pi bonds as readily as nitrogen. 49. \(2 \mathrm{Bi}_{2} \mathrm{~S}_{3}(s)+\) \(9 \mathrm{O}_{2}(g) \rightarrow 2 \mathrm{Bi}_{2} \mathrm{O}_{3}(s)+6 \mathrm{SO}_{2}(g) ; 2 \mathrm{Bi}_{2} \mathrm{O}_{3}(s)+3 \mathrm{C}(s) \rightarrow 4 \mathrm{Bi}(s)+3 \mathrm{CO}_{2}(g) ;\) \(2 \mathrm{Sb}_{2} \mathrm{~S}_{3}(s)+9 \mathrm{O}_{2}(g) \rightarrow 2 \mathrm{Sb}_{2} \mathrm{O}_{3}(s)+6 \mathrm{SO}_{2}(g) ; 2 \mathrm{Sb}_{2} \mathrm{O}_{3}(s)+3 \mathrm{C}(s) \rightarrow 4 \mathrm{Sb}(s)+\) \(3 \mathrm{CO}_{2}(g)\)
51.

Trigonal pyramid; \(s p^{3}\)

Trigonal bipyramid; \(d s p^{3}\)

Octahedral; \(d^{2} s p^{3}\)
Nitrogen does not have low-energy \(d\) orbitals it can use to expand its octet. Both \(\mathrm{NF}_{5}\) and \(\mathrm{NCl}_{6}{ }^{-}\)would require nitrogen to have more than 8 valence electrons around it; this never happens. 53. \(\frac{1}{2} \mathrm{~N}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \rightarrow \mathrm{NO}(g)\); \(\Delta G^{\circ}=\Delta G_{f(\mathrm{NO})}^{\circ}\); NO (and some other oxides of nitrogen) have weaker bond's as compared with the triple bond of \(\mathrm{N}_{2}\) and the double bond of \(\mathrm{O}_{2}\). Because of this, NO (and some other oxides of nitrogen) has a higher (positive) standard free energy of formation as compared to the relatively stable \(\mathrm{N}_{2}\) and \(\mathrm{O}_{2}\) molecules. 55. The pollution provides nitrogen and phosphorus nutrients so the algae can grow. The algae consume dissolved oxygen, causing fish to die. 57. The acidic hydrogens in the oxyacids of phosphorus all are bonded to oxygen. The hydrogens bonded directly to phosphorus are not acidic. \(\mathrm{H}_{3} \mathrm{PO}_{4}\) has three oxygen-bonded hydrogens, and it is a triprotic acid. \(\mathrm{H}_{3} \mathrm{PO}_{3}\) has only two of the hydrogens bonded to oxygen, and it is a diprotic acid. The third oxyacid of phosphorus, \(\mathrm{H}_{3} \mathrm{PO}_{2}\), has only one of the hydrogens bonded to an oxygen; it is a monoprotic acid. 59. 821 nm 61. \(\mathrm{H}_{2} \mathrm{SeO}_{4}(a q)+\) \(3 \mathrm{SO}_{2}(g) \rightarrow \mathrm{Se}(s)+3 \mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l)\) 63. In the upper atmosphere, \(\mathrm{O}_{3}\) acts as a filter for ultraviolet (UV) radiation:
\[
\mathrm{O}_{3}(\mathrm{~g}) \xrightarrow{h \nu} \mathrm{O}_{2}(\mathrm{~g})+\mathrm{O}(\mathrm{~g})
\]
\(\mathrm{O}_{3}\) is also a powerful oxidizing agent. It irritates the lungs and eyes, and at high concentration, it is toxic. The smell of a "spring thunderstorm" is \(\mathrm{O}_{3}\) formed during lightning discharges. Toxic materials don't necessarily smell bad. For example, HCN smells like almonds. 65. The M.O. electron configuration of \(\mathrm{O}_{2}\) has two unpaired electrons in the degenerate pi antibonding \(\left(\pi_{2 p}^{*}\right)\) orbitals. A substance with unpaired electrons is paramagnetic. 67. From the following Lewis structure, each oxygen atom has a tetrahedral arrangement of electron pairs. Therefore, bond angles are \(\approx 109.5^{\circ}\), and each O is \(s p^{3}\) hybridized.
\[

\]

Oxidation states are more useful. We are forced to assign +1 as the oxidation state for oxygen. Oxygen is very electronegative, and +1 is not a stable oxidation state for this element.
69.

V-shaped; \(<109.5^{\circ}\)

See-saw; \(\approx 120^{\circ}, \approx 90^{\circ}\)
Octahedral; \(90^{\circ}\)
\(\mathrm{OF}_{4}\) would not form. This compound would require oxygen to have more than 8 valence electrons around it. This never occurs for oxygen; oxygen does not have low-energy \(d\) orbitals it can use to expand its octet. 71. The oxyacid strength increases as the number of oxygens in the formula increases. Therefore, the order of the oxyacids from weakest to strongest acid is \(\mathrm{HOCl}<\mathrm{HClO}_{2}\) \(<\mathrm{HClO}_{3}<\mathrm{HClO}_{4}\). 73. a. \(\mathrm{IO}_{4}^{-}\); b. \(\mathrm{IO}_{3}^{-}\); c. \(\mathrm{IF}_{2}^{-}\); d. \(\mathrm{IF}_{4}^{-}\); e. \(\mathrm{IF}_{6}^{-}\) 75. Helium is unreactive and doesn't combine with any other elements. It is a very light gas and would easily escape the earth's gravitational pull as the planet was formed. 77. One would expect \(\mathrm{RnF}_{2}, \mathrm{RnF}_{4}\), and maybe \(\mathrm{RnF}_{6}\) to form in fashion similar to \(\mathrm{XeF}_{2}, \mathrm{XeF}_{4}\), and \(\mathrm{XeF}_{6}\). 79. \(\mathrm{N}_{2} \mathrm{H}_{4}(l)+\mathrm{O}_{2}(g) \rightarrow \mathrm{N}_{2}(g)+\) \(2 \mathrm{H}_{2} \mathrm{O}(g) ; \Delta H=-590 . \mathrm{kJ} \quad\) 81. If the compound contained \(\mathrm{Ga}(\mathrm{II})\), it would be paramagnetic and if the compound contained \(\mathrm{Ga}(\mathrm{I})\) and \(\mathrm{Ga}(\mathrm{III})\), it would be diamagnetic. Paramagnetic compounds have an apparent greater mass in a magnetic field. 83. NaH is an ionic compound composed of \(\mathrm{Na}^{+}\)and \(\mathrm{H}^{-}\)ions. Acid-base: A proton is transferred from an acid, \(\mathrm{H}_{2} \mathrm{O}\), to a base, \(\mathrm{H}^{-}\), forming the conjugate base of water, \(\mathrm{OH}^{-}\), and the conjugate acid of \(\mathrm{H}^{-}, \mathrm{H}_{2}\). Oxidationreduction: The oxidation state of hydrogen is -1 in \(\mathrm{NaH},+1\) in \(\mathrm{H}_{2} \mathrm{O}\), and zero in \(\mathrm{H}_{2}\). Hydrogen is oxidized when it goes from NaH to \(\mathrm{H}_{2}(\) from \(-1 \rightarrow 0\) ) and hydrogen is reduced when it goes from \(\mathrm{H}_{2} \mathrm{O}\) to \(\mathrm{H}_{2}\) (from \(+1 \rightarrow 0\) ). In this reaction, an electron is transferred from the hydride ion to a hydrogen in water when forming \(\mathrm{H}_{2} . \quad \mathbf{8 5} . \mathbf{a} . \mathrm{AgCl}(s) \xrightarrow{h \nu} \mathrm{Ag}(s)+\mathrm{Cl}\); the reactive chlorine atom is trapped in the crystal. When light is removed, Cl reacts with silver atoms to re-form AgCl ; i.e., the reverse reaction occurs. In pure AgCl , the Cl atoms escape, making the reverse reaction impossible. b. Over time, chlorine is lost and the dark silver metal is permanent. 87. In solution, \(\mathrm{Tl}^{3+}\) can oxidize \(\mathrm{I}^{-}\)to \(\mathrm{I}_{3}{ }^{-}\left(\mathscr{E}^{\circ}\right.\) cell \(\left.>0\right)\). Thus we expect \(\mathrm{TII}_{3}\) to be thallium(I) triiodide. 89. Both \(\Delta H\) and \(\Delta S\) will be positive. Since \(\Delta S\) is positive for this process, the rhombic form of solid sulfur will have the more ordered form (smaller positional probability and smaller \(S\) ). 91. Strontium and calcium are both alkaline earth metals, so both have similar chemical properties. Since milk is a good source of calcium, strontium could replace some calcium in milk without much difficulty. 93. +6 oxidation state: \(\mathrm{SO}_{4}{ }^{2-}, \mathrm{SO}_{3}, \mathrm{SF}_{6} ;+4\) oxidation state: \(\mathrm{SO}_{3}{ }^{2-}, \mathrm{SO}_{2}, \mathrm{SF}_{4} ;+2\) oxidation state: \(\mathrm{SCl}_{2} ; 0\) oxidation state: \(\mathrm{S}_{8}\) and all other elemental forms of sulfur; - 2 oxidation state: \(\mathrm{H}_{2} \mathrm{~S}, \mathrm{Na}_{2} \mathrm{~S}\) 95. a. \(\Delta H^{\circ}=132 \mathrm{~kJ}\); \(\Delta S^{\circ}=134 \mathrm{~J} / \mathrm{K} ;\) b. At \(\mathrm{T}>985 \mathrm{~K}\) and standard pressures, the favorable \(\Delta S^{\circ}\) term dominates, and the reaction is spontaneous \(\left(\Delta G^{\circ}>0\right) . \quad 97.0 .013 \mathrm{~mol} / \mathrm{L}\) 99. a. \(s p\); b. \(s p^{2}\); c. \(s p^{2}\); d. \(s p\) 101. a. \(d^{2} s p^{3}\); b. \(d s p^{3}\); c. \(s p^{3}\); d. \(d^{2} s p^{3}\) 103. a. \(0.17 \mathrm{~g} ;\) b. \(5 \times 10^{15}\) atoms 105. Ca; 12.698 107.I 109. For the reaction

the activation energy must in some way involve the breaking of a nitrogennitrogen single bond. For the reaction

at some point nitrogen-oxygen bonds must be broken. \(\mathrm{N}-\mathrm{N}\) single bonds ( \(160 \mathrm{~kJ} / \mathrm{mol}\) ) are weaker than \(\mathrm{N}-\mathrm{O}\) single bonds ( \(201 \mathrm{~kJ} / \mathrm{mol}\) ). In addition, resonance structures indicate that there is more double-bond character in the \(\mathrm{N}-\mathrm{O}\) bonds than in the \(\mathrm{N}-\mathrm{N}\) bond. Thus \(\mathrm{NO}_{2}\) and NO are preferred by kinetics because of the lower activation energy. 111. 5.89 113. 20. g 115. \(6.5 \times 10^{27}\) atoms \(\quad \mathbf{1 1 7}\). a. \(7.1 \mathrm{~g} ;\) b. 979 nm ; this electromagnetic radiation is not visible to humans; it is in the infrared region of the electromagnetic radiation spectrum; \(\mathbf{c}\). n-type \(\mathbf{1 1 9 .}\) a. +6 ; b. 4.42

\section*{Chapter 21}
5. The lanthanide elements are located just before the \(5 d\) transition metals. The lanthanide contraction is the steady decrease in the atomic radii of the lanthanide elements when going from left to right across the periodic table. As a result of the lanthanide contraction, the sizes of the \(4 d\) and \(5 d\) elements are very similar. This leads to a greater similarity in the chemistry of the \(4 d\) and \(5 d\) elements in a given vertical group. 7. No; both the trans and the cis forms of \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}{ }^{+}\)have mirror images that are superimposable. For the cis form, the mirror image only needs a \(90^{\circ}\) rotation to produce the original structure. Hence, neither the trans nor the cis form is optically active.
9. \(\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+6 \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q) \rightarrow 2 \mathrm{Fe}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}{ }^{3-}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)+6 \mathrm{H}^{+}(a q)\); the oxalate anion forms a soluble complex ion with iron in rust \(\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)\), which allows rust stains to be removed.

13. From Table 21.16, the red octahedral \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}\) complex ion absorbs blue-green light \((\lambda \approx 490 \mathrm{~nm})\), whereas the blue tetrahedral \(\mathrm{CoCl}_{4}{ }^{2-}\) complex ion absorbs orange light ( \(\lambda \approx 600 \mathrm{~nm}\) ). Because tetrahedral complexes have a \(d\)-orbital splitting much less than octahedral complexes, one would expect the tetrahedral complex to have a smaller energy difference between split \(d\) orbitals. This translates into longer-wavelength light absorbed \((E=h c / \lambda)\) for tetrahedral complex ions compared to octahedral complex ions. Information from Table 21.16 confirms this. 15. \(\mathrm{SCN}^{-}, \mathrm{NO}_{2}^{-}\), and \(\mathrm{OCN}^{-}\)can form linkage isomers; all are able to bond to the metal ion in two different ways. 17. \(\mathrm{Sc}^{3+}\) has no electrons in \(d\) orbitals. \(\mathrm{Ti}^{3+}\) and \(\mathrm{V}^{3+}\) have \(d\) electrons present. The color of transition metal complexes results from electron transfer between split \(d\) orbitals. If no \(d\) electrons are present, no electron transfer can occur, and the compounds are not colored. 19. \(0 ; \mathrm{Ni}(\mathrm{CO})_{4} \quad\) 21. At high altitudes, the oxygen content of air is lower, so less oxyhemoglobin is formed which diminishes the transport of oxygen in the blood. A serious illness called high-altitude sickness can result from the decrease of \(\mathrm{O}_{2}\) in the blood. High-altitude acclimatization is the phenomenon that occurs in the human body in response to the lower amounts of oxyhemoglobin in the blood. This response is to produce more hemoglobin, and, hence, increase the oxyhemoglobin in the blood. High-altitude acclimatization takes several weeks to take hold for people moving from lower altitudes to higher altitudes. 23. a. Sc: \([\mathrm{Ar}] 4 s^{2} 3 d^{1}\); b. \(\mathrm{Ru}:[\mathrm{Kr}] 5 s^{2} 4 d^{6}\) (expected), \([\mathrm{Kr}] 5 s^{1} 4 d^{7}\) (actual); c. Ir: \([\mathrm{Xe}] 6 s^{2} 4 f^{14} 5 d^{7}\); d. Mn: \([\mathrm{Ar}] 4 s^{2} 3 d^{5}\) 25. Transition metal ions lose the \(s\) electrons before the \(d\) electrons. Also, Pt is an exception to the normal filling order of electrons (see Figure 7.29). a. \(\mathrm{Co}:[\mathrm{Ar}] 4 s^{2} 3 d^{7}, \mathrm{Co}^{2+}:[\mathrm{Ar}] 3 d^{7}, \mathrm{Co}^{3+}:[\mathrm{Ar}] 3 d^{6} ;\) b. \(\mathrm{Pt}:[\mathrm{Xe}] 6 s^{1} 4 f^{14} 5 d^{9}\), \(\mathrm{Pt}^{2+}:[\mathrm{Xe}] 4 f^{14} 5 \mathrm{~d}^{8}, \mathrm{Pt}^{4+}:[\mathrm{Xe}] 4 f^{14} 5 d^{6}\); c. \(\mathrm{Fe}:[\mathrm{Ar}] 4 s^{2} 3 d^{6}, \mathrm{Fe}^{2+}:[\mathrm{Ar}] 3 d^{6}\), \(\mathrm{Fe}^{3+}:[\mathrm{Ar}] 3 d^{5}\) 27. a. \(\mathrm{Fe}^{3+}:[\mathrm{Ar}] 3 d^{5} ;\) b. \(\mathrm{Ag}^{+}:[\mathrm{Kr}] 4 d^{10} ;\) c. \(\mathrm{Ni}^{2+}:[\mathrm{Ar}] 3 d^{8}\); d. \(\mathrm{Cr}^{3+}:[\mathrm{Ar}] 3 d^{3}\) 29. a. molybdenum(IV) sulfide, molybdenum(VI) oxide; b. \(\mathrm{MoS}_{2},+4 ; \mathrm{MoO}_{3},+6 ;\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Mo}_{2} \mathrm{O}_{7},+6 ;\left(\mathrm{NH}_{4}\right)_{6} \mathrm{Mo}_{7} \mathrm{O}_{24} \cdot 4 \mathrm{H}_{2} \mathrm{O},+6\) 31. \(\mathrm{NH}_{3}\) is a weak base that produces \(\mathrm{OH}^{-}\)ions in solution. The white precipitate is \(\mathrm{Cu}(\mathrm{OH})_{2}(s) . \mathrm{Cu}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \rightarrow \mathrm{Cu}(\mathrm{OH})_{2}(s)\); with excess \(\mathrm{NH}_{3}\) present, \(\mathrm{Cu}^{2+}\) forms a soluble complex ion, \(\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+} . \mathrm{Cu}(\mathrm{OH})_{2}(s)+\) \(4 \mathrm{NH}_{3}(a q) \rightarrow \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q)+2 \mathrm{OH}^{-}(a q)\) 33. Only \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}\) will form a precipitate since only this compound will have \(\mathrm{Cl}^{-}\)ions in solution. The \(\mathrm{Cl}^{-}\)ions in the other compounds are ligands and are bound to the central \(\mathrm{Cr}^{3+}\) ion. The \(\mathrm{Cl}^{-}\)ions in \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}\) are counterions needed to produce a neutral compound; the \(\mathrm{NH}_{3}\) molecules are the ligands bound to \(\mathrm{Cr}^{3+}\). 35. a. hexacyanomanganate(II) ion; b. cis-tetraamminedichlorocobalt(III) ion; c. pentaamminechlorocobalt(II) ion 37. a. hexaamminecobalt(II) chloride; b. hexaaquacobalt(III) iodide; c. potassium tetrachloroplatinate(II); d. potassium hexachloroplatinate(II); e. pentaamminechlorocobalt(III) chloride; f. triamminetrinitrocobalt(III) 39. a. \(\mathrm{K}_{2}\left[\mathrm{CoCl}_{4}\right]\); b. \(\left[\mathrm{Pt}\left(\mathrm{H}_{2} \mathrm{O}\right)(\mathrm{CO})_{3}\right] \mathrm{Br}_{2}\); c. \(\mathrm{Na}_{3}\left[\mathrm{Fe}(\mathrm{CN})_{2}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}\right]\); d. \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}\left(\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)\right] \mathrm{I}_{2}\)
41. a.

47.

49. \(\mathrm{Cr}(\mathrm{acac})_{3}\) and cis- \(\mathrm{Cr}(\mathrm{acac})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\) are optically active. 51. With five electrons each in a different orbital, diagram (a) is for the weak-field \(\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) complex ion. With three electrons, diagram (b) is for the \(\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}^{2+}\) complex ion. With six electrons all paired up, diagram (c) is for the strong-field \(\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Br}_{2}{ }^{+}\)complex ion.
53. a. \(\mathrm{Fe}^{2+} \xrightarrow{\uparrow \downarrow} \stackrel{\uparrow}{\text { High spin }} \stackrel{\uparrow}{\uparrow}\)

55. weak field 57. a. 0; b. 2; c. 2 59. \(\mathrm{Co}(\mathrm{CN})_{6}{ }^{3-}<\mathrm{Co}(\mathrm{en})_{3}{ }^{3+}<\) \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}<\mathrm{CoI}_{6}{ }^{3-} \quad\) 61. The violet complex ion absorbs yellow-green light ( \(\lambda \approx 570 \mathrm{~nm}\) ), the yellow complex ion absorbs blue light ( \(\lambda \approx 450 \mathrm{~nm}\) ), and the green complex ion absorbs red light ( \(\lambda \approx 650 \mathrm{~nm}\) ). The violet complex ion is \(\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\), the yellow complex ion is \(\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}\), and the green complex ion is \(\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Cl}_{2}{ }^{+}\). 63. \(\mathrm{CoBr}_{4}{ }^{2-}\) is a tetrahedral complex ion, while \(\mathrm{CoBr}_{6}{ }^{4-}\) is an octahedral complex ion. Since tetrahedral \(d\)-orbital splitting is less than one-half the octahedral \(d\)-orbital splitting, the octahedral complex ion \(\left(\mathrm{CoBr}_{6}{ }^{4-}\right)\) will absorb higher-energy light, which will have a shorter wavelength than \(3.4 \times 10^{-6} \mathrm{~m}(E=h c / \lambda)\). 65. \(5 \quad\) 67. a. -11 kJ ; b. \(\Delta H^{\circ}=172.5 \mathrm{~kJ} ; \Delta S^{\circ}=176 \mathrm{~J} / \mathrm{K} ; T>980 . \mathrm{K}\) 69. \(\mathrm{Fe}_{2} \mathrm{O}_{3}\) : iron has a +3 oxidation state; \(\mathrm{Fe}_{3} \mathrm{O}_{4}\) : iron has a \(+8 / 3\) oxidation state. The three iron ions in \(\mathrm{Fe}_{3} \mathrm{O}_{4}\) must have a total charge of +8 . The only combination that works is to have two \(\mathrm{Fe}^{3+}\) ions and one \(\mathrm{Fe}^{2+}\) ion per formula unit. This makes sense from the other formula for magnetite, \(\mathrm{FeO} \cdot \mathrm{Fe}_{2} \mathrm{O}_{3}\). FeO has an \(\mathrm{Fe}^{2+}\) ion and \(\mathrm{Fe}_{2} \mathrm{O}_{3}\) has two \(\mathrm{Fe}^{3+}\) ions. 71. \(8 \mathrm{CN}^{-}(a q)+4 \mathrm{Ag}(s)+\mathrm{O}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \rightarrow\) \(4 \mathrm{Ag}(\mathrm{CN})_{2}{ }^{-}(a q)+4 \mathrm{OH}^{-}(a q) \quad\) 73. \(\mathrm{Hg}^{2+}(a q)+2 \mathrm{I}^{-}(a q) \rightarrow \mathrm{HgI}_{2}(s)\), orange
precipitate; \(\mathrm{HgI}_{2}(s)+2 \mathrm{I}^{-}(a q) \rightarrow \mathrm{HgI}_{4}{ }^{2-}(a q)\), soluble complex ion; \(\mathrm{Hg}^{2+}\) is a \(d^{10}\) ion. Color is the result of electron transfer between split \(d\) orbitals. This cannot occur for the filled \(d\) orbitals in \(\mathrm{Hg}^{2+}\). Therefore, we would not expect \(\mathrm{Hg}^{2+}\) complex ions to form colored solutions. 75. The molecular formula is \(\mathrm{EuC}_{15} \mathrm{H}_{21} \mathrm{O}_{6}\). Because each acac \({ }^{-}\)is \(\mathrm{C}_{5} \mathrm{H}_{7} \mathrm{O}_{2}^{-}\), an abbreviated molecular formula is \(\mathrm{Eu}(\mathrm{acac})_{3}\). \(\quad 77.0 .66 \mathrm{~V} ;-130 \mathrm{~kJ} ; 2.2 \times 10^{22} \quad\) 79. There are four geometrical isomers (labeled i-iv). Isomers iii and iv are optically active, and the nonsuperimposable mirror images are shown.

81. Octahedral \(\mathrm{Cr}^{2+}\) complexes should be used. \(\mathrm{Cr}^{2+}\) : [ Ar\(] 3 d^{4}\); highspin (weak-field) \(\mathrm{Cr}^{2+}\) complexes have four unpaired electrons and lowspin (strong-field) \(\mathrm{Cr}^{2+}\) complexes have two unpaired electrons. \(\mathrm{Ni}^{2+}\) : [ Ar\(] 3 d^{8}\); octahedral \(\mathrm{Ni}^{2+}\) complexes will always have two unpaired electrons, whether high or low spin. Therefore, \(\mathrm{Ni}^{2+}\) complexes cannot be used to distinguish weak- from strong-field ligands by examining magnetic properties. Alternatively, the ligand field strengths can be measured using visible spectra. Either \(\mathrm{Cr}^{2+}\) or \(\mathrm{Ni}^{2+}\) complexes can be used for this method. 83. a. \(\left[\mathrm{Co}\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)_{6}\right] \mathrm{Cl}_{3}\); b. \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{I}\right] \mathrm{I}_{2}\); c. \(\left[\mathrm{Ni}\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)_{3}\right] \mathrm{Br}_{2}\); d. \(\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]\); e. \(\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]\left[\mathrm{PtCl}_{4}\right] \quad\) 85. \(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{I}_{3}: 3\) moles of AgI ; \(\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{I}_{2}\right] \mathrm{I}_{2}: 2\) moles of \(\mathrm{AgI} ; \mathrm{Na}_{2}\left[\mathrm{PtI}_{6}\right]: 0\) moles of \(\mathrm{AgI} ;\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{I}_{2}\right] \mathrm{I}\) : 1 mole of \(\mathrm{AgI} \quad\) 87. 60 89. a. \([\mathrm{Ar}] 4 s^{1} 3 d^{10}\) is correct for Cu ; b. correct; c. correct; d. \([\mathrm{Xe}] 6 s^{2} 5 d^{1}\) is correct for La ; e. correct 91. \(\mathrm{Zn}^{2+}:[\mathrm{Ar}] 3 d^{10}\); \(\mathrm{Cu}^{2+}:[\mathrm{Ar}] 3 d^{9} ; \mathrm{Mn}^{3+}:[\mathrm{Ar}] 3 d^{4} ; \mathrm{Ti}^{4+}:[\mathrm{Ne}] 3 s^{2} 3 p^{6} ;\) color is a result of the electron transfer between split \(d\) orbitals. This cannot occur for the filled \(d\) orbitals in \(\mathrm{Zn}^{2+}\). This also cannot occur for \(\mathrm{Ti}^{4+}\), which has no \(d\) electrons. So \(\mathrm{Zn}^{2+}\) and \(\mathrm{Ti}^{4+}\) compounds/ions will not be colored. \(\mathrm{Cu}^{2+}\) and \(\mathrm{Mn}^{3+}\) do have \(d\) orbitals that are partially filled, so we would expect compounds/ions of \(\mathrm{Cu}^{2+}\) and \(\mathrm{Mn}^{3+}\) to be colored. 93. a. \(\mathrm{Zn}^{2+}\) has a \(3 d^{10}\) electron configuration. This diagram is for a \(d^{10}\) octahedral complex ion, not a \(d^{10}\) tetrahedral complex as is given. So this diagram is incorrect. b. This diagram is correct. In this complex ion, Mn has \(\mathrm{a}+3\) oxidation state and an \([\mathrm{Ar}] 3 d^{4}\) electron configuration. This strong field diagram for a \(d^{4}\) ion is shown. c. This diagram is correct. In this complex ion, \(\mathrm{Ni}^{2+}\) is present, which has a \(3 d^{8}\) electron configuration. The diagram shown is correct for a diamagnetic square planar complex. 95. \(\mathrm{Ni}^{2+}=d^{8}\); if ligands A and B produced very similar crystal fields, the cis- \(\left[\mathrm{NiA}_{2} \mathrm{~B}_{4}\right]^{2+}\) complex ion would give the following octahedral crystal field diagram for a \(d^{8}\) ion:

This is paramagnetic.
Because it is given that the complex ion is diamagnetic, the A and B ligands must produce different crystal fields, giving a unique \(d\)-orbital splitting dia-
gram that would result in a diamagnetic species. 97. a. -0.26 V ; b. From standard reduction potentials, \(\mathrm{Co}^{3+}\left(\mathscr{E}^{\circ}=1.82 \mathrm{~V}\right)\) is a much stronger oxidizing agent than \(\mathrm{Co}(\mathrm{en})_{3}{ }^{3+}\left(\mathscr{C}^{\circ}=-0.26 \mathrm{~V}\right)\); c. In aqueous solution, \(\mathrm{Co}^{3+}\) forms the hydrated transition metal complex, \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\). In both complexes, \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) and \(\mathrm{Co}(\mathrm{en})_{3}{ }^{3+}\), cobalt exists as \(\mathrm{Co}^{3+}\), which has \(6 d\) electrons. If we assume a strong-field case for each complex ion, then the \(d\)-orbital splitting diagram for each has the six electrons paired in the lower-energy \(t_{2 g}\) orbitals. When each complex ion gains an electron, the electron enters the higher-energy \(e_{g}\) orbitals. Since en is a stronger-field ligand than \(\mathrm{H}_{2} \mathrm{O}\), then the \(d\)-orbital splitting is larger for \(\mathrm{Co}(\mathrm{en})_{3}{ }^{3+}\), and it takes more energy to add an electron to \(\mathrm{Co}(\mathrm{en})_{3}{ }^{3+}\) than to \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\). Therefore, it is more favorable for \(\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\) to gain an electron than for \(\mathrm{Co}(\mathrm{en})_{3}{ }^{3+}\) to gain an electron. 99. No, in all three cases six bonds are formed between \(\mathrm{Ni}^{2+}\) and nitrogen. So \(\Delta H\) values should be similar. \(\Delta S^{\circ}\) for formation of the complex ion is most negative for \(6 \mathrm{NH}_{3}\) molecules reacting with a metal ion (7 independent species become 1). For penten reacting with a metal ion, 2 independent species become 1 , so \(\Delta S^{\circ}\) is the least negative. Thus the chelate effect occurs because the more bonds a chelating agent can form to the metal, the less unfavorable \(\Delta S^{\circ}\) becomes for the formation of the complex ion, and the larger the formation constant.
\[
\text { 101. } \begin{aligned}
& -\begin{array}{l}
d_{z^{2}} \\
- \\
- \\
d_{x^{2}-y^{2}}, d_{x y} \\
d_{x z}, d_{y z}
\end{array}
\end{aligned}
\]
103. The coordinate system for the complex ion is shown below. From the coordinate system, the \(\mathrm{CN}^{-}\)ligands are in a square planar arrangement. Since \(\mathrm{CN}^{-}\)produces a much stronger crystal field, the diagram will most resemble that of a square planar complex:
\begin{tabular}{|c|c|}
\hline \multicolumn{2}{|l|}{} \\
\hline \multicolumn{2}{|l|}{\multirow{2}{*}{NC}} \\
\hline & \\
\hline \(d_{x^{2}-y^{2}}\) & - \\
\hline \(d_{z^{2}}\) & 4 \\
\hline \(d_{x y}\) & 4 \\
\hline \(d_{x z}\) & 414 \(41 d_{y z}\) \\
\hline
\end{tabular}

With the \(\mathrm{NH}_{3}\) ligands on the \(z\) axis, we will assume that the \(d_{z^{2}}\) orbital is destabilized more than the \(d_{x y}\) orbital. This may or may not be the case.
105. No; if 0.10 mol of AgBr could dissolve, \(Q\) would be greater than the \(K_{\text {sp }}\) value, and a precipitate of \(\operatorname{AgBr}(s)\) would have to re-form. 107. \(\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5} I\right]_{2}\); octahedral

\section*{Chapter 22}
1. Carbon has the unusual ability to form bonds to itself, whether they are single, double, or triple bonds, as well as the ability to form long chains or rings of carbon atoms. Carbon also forms strong bonds to other nonmetals such as hydrogen, oxygen, phosphorus, sulfur, and the halogens. Because of this bonding ability, carbon can form millions of compounds, including biomolecules, which are the basis for the existence of life.
3. a. 1-sec-butylpropane
b. 4-methylhexane
\[
\underset{\substack{\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3} \\ \mathrm{CH}_{3} \\ \mathrm{CHCH} \\ 2}}{\mathrm{CH}_{3}}
\]

3-methylhexane is correct.
c. 2-ethylpentane

3-methylhexane is correct.

3-methylhexane is correct.
d. 1-ethyl-1-methylbutane

3-methylhexane is correct.

e. 3-methylhexane

f. 4-ethylpentane

3-methylhexane is correct.
All six of these are the same compound. They only differ from each other by rotations about one or more carbon-carbon single bonds. Only one isomer of \(\mathrm{C}_{7} \mathrm{H}_{16}\) is present in all of these names: 3-methylhexane.
5. Hydrocarbons are nonpolar substances exhibiting only London dispersion forces. Size and shape are the two most important structural features relating to the strength of London dispersion forces. For size, the bigger the molecule (the larger the molar mass), the stronger the London dispersion forces and the higher the boiling point. For shape, the more branching present in a compound, the weaker the London dispersion forces and the lower the boiling point. 7. The amide functional group is:

When the amine end of one amino acid reacts with the carboxylic acid end of another amino acid, the two amino acids link together by forming an amide functional group. A polypeptide has many amino acids linked together, with each linkage made by the formation of an amide functional group. Because all linkages result in the presence of the amide functional group, the resulting polymer is called a polyamide. For nylon, the monomers also link together by forming the amide functional group (the amine end of one monomer reacts with a carboxylic acid end of another monomer to give the amide functional group linkage). Hence nylon is also a polyamide. The correct order of strength is polyhydrocarbon \(<\) polyester \(<\) polyamide. The difference in strength is related to the types of intermolecular forces present. All of these polymers have London dispersion forces. However, polyhydrocarbons only have London dispersion forces. The polar ester group in polyesters and the polar amide group in polyamides give rise to additional dipole forces. The polyamide has the ability to form relatively strong hydrogen bonding interactions, hence why it would form the strongest fibers.
9. a.

b.

c.

e.

or

ester
11. a. A polyester forms when an alcohol functional group reacts with a carboxylic acid functional group. The monomer for a homopolymer polyester must have an alcohol functional group and a carboxylic acid functional group present in the structure. b. A polyamide forms when an amine functional group reacts with a carboxylic acid functional group. For a copolymer polyamide, one monomer would have at least two amine functional groups present and the other monomer would have at least two carboxylic acid functional groups present. For polymerization to occur, each monomer must have two reactive functional groups present. c. To form an addition polymer, a carbon-carbon double bond must be present. To form a polyester, the monomer would need the alcohol and carboxylic acid functional groups present. To form a polyamide, the monomer would need the amine and carboxylic acid functional groups present. The two possibilities are for the monomer to have a carbon-carbon double bond, an alcohol functional group, and a carboxylic acid functional group all present, or to have a carbon-carbon double bond, an amine functional group, and a carboxylic acid functional group present.
13. Denaturation is the breakdown of the three-dimensional structure of protein. Both the secondary and the tertiary structures of the protein are disrupted in denaturation. The primary structure (the order in which the amino acids link to each other) is not affected by denaturation.
15. \(\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{CH}_{3}\)

c. \(\quad \mathrm{CH}_{2} \mathrm{CH}_{3}\)

d.

33. a. 1,3-dichlorobutane; b. 1,1,1-trichlorobutane; c. 2,3-dichloro-2, 4-dimethylhexane; d. 1,2-difluoroethane 35. \(\mathrm{CH}_{2} \mathrm{Cl}-\mathrm{CH}_{2} \mathrm{Cl}, 1,2\) dichloroethane: There is free rotation about the \(\mathrm{C}-\mathrm{C}\) single bond that doesn't lead to different compounds. \(\mathrm{CHCl}=\mathrm{CHCl}, 1,2\)-dichloroethene: There is no rotation about the \(\mathrm{C}=\mathrm{C}\) double bond. This creates the cis and trans isomers, which are different compounds. 37. [27], compounds b and c; [29], all compounds
39. \(\mathrm{CH}_{2}=\mathrm{CHCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3} \quad \mathrm{CH}_{3} \mathrm{CH}=\mathrm{CHCH}_{2} \mathrm{CH}_{3}\)

41.

43.

45

b.

c.

47. There are many possible structural isomers for the formula \(\mathrm{C}_{6} \mathrm{H}_{12}\). Two structural isomers are:

Cyclohexane
\(\mathrm{CH}_{2}=\mathrm{CHCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\)

1-hexene
The structural isomer 2-hexene (plus others) exhibits geometrical isomerism.

The structural isomer 3-methyl-1-pentene exhibits optical isomerism (the asterisk marks the chiral carbon).

For this compound, the chiral carbon has four different groups bonded to it; the mirror image of this compound will be nonsuperimposable. Optical isomerism is also possible with some of the cyclobutane and cyclopropane structural isomers.
49. a. 3 monochloro isomers of n-pentane; b. 4 monochloro isomers of 2methylbutane; c. 3 monochloro isomers of 2,4-dimethylpentane; d. 4 monochloro isomers of methylcyclobutane 51. a. ketone; b. aldehyde; c. carboxylic acid; d. amine
53. a.

b. 5 carbons in ring and the carbon in \(-\mathrm{CO}_{2} \mathrm{H}: s p^{2}\); the other two carbons: \(s p^{3}\); c. 24 sigma bonds, 4 pi bonds 55. a. 3-chloro-1-butanol, primary; b. 3-methyl-3-hexanol, tertiary; c. 2-methylcyclopentanol, secondary 57. 1-butanol, 2-butanol, 2-methyl-1-propanol, and 2-methyl-2-propanol are the possible alcohols having the \(\mathrm{C}_{4} \mathrm{H}_{10} \mathrm{O}\) formula. There are three possible ethers with the formula \(\mathrm{C}_{4} \mathrm{H}_{10} \mathrm{O}\). 59. Butanal and 2-methylpropanal are the possible aldehydes, and 2-butanone is the only ketone having the \(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\) formula. 61. a. 4,5-dichloro-3-hexanone; b. 2,3-dimethylpentanal; c. 3methylbenzaldehyde or \(m\)-methylbenzaldehyde 63. a. 4-chlorobenzoic acid or \(p\)-chlorobenzoic acid; b. 3-ethyl-2-methylhexanoic acid; c. methanoic acid \((\) common name \(=\) formic acid) 65. Only statement \(d\) is false.
\(\stackrel{\stackrel{\mathrm{O}}{\|}}{\text { 2-butenal: }} \mathrm{HCCH}=\mathrm{CHCH}_{3}\).
The formula of 2-butenal is \(\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}\), while the alcohol has a formula of \(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\).
67. a. \(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\)

Cl
d. \(\mathrm{C}_{4} \mathrm{H}_{8}(g)+6 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(g)\)
69. For the iron-catalyzed reaction, one of the ortho or para hydrogens in benzene is replaced by chlorine. When an iron catalyst is not present, the benzene hydrogens are unreactive. To substitute for an alkane hydrogen, light must be present. For toluene, the light-catalyzed reaction substitutes a chlorine for a hydrogen in the methyl group attached to the benzene ring.
71. a.

77. \(\mathrm{CFCl}=\mathrm{CF}_{2}\)
79.

81.

83.

and

85. Divinylbenzene has two reactive double bonds that are used during formation of the polymer. The key is for the double bonds to insert themselves into two different polymer chains. When this occurs, the two chains are bonded together (are crosslinked). The chains cannot move past each other because of the crosslinks making the polymer more rigid. 87. a. The polymer from 1,2-diaminoethane and terephthalic acid is stronger because of the possibility of hydrogen bonding between chains. \(\mathbf{b}\). The polymer of

is more rigid because the chains are stiffer due to the rigid benzene rings in the chains. c. Polyacetylene is \(n \mathrm{HC} \equiv \mathrm{CH} \rightarrow(\mathrm{CH}=\mathrm{CH})_{n}\). Polyacetylene is more rigid because the double bonds in the chains make the chains stiffer. 89. a. serine; tyrosine; threonine; b. aspartic acid; glutamic acid; c. histidine; lysine; arginine; tryptophan; d. glutamine; asparagine 91. a. aspartic acid and phenylalanine; \(\mathbf{b}\). Aspartame contains the methyl ester of phenylalanine. This ester can hydrolyze to form methanol, \(\mathrm{RCO}_{2} \mathrm{CH}_{3}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{RCO}_{2} \mathrm{H}\) \(+\mathrm{CH}_{3} \mathrm{OH}\).
93.

ser-ala

ala-ser
95. a. Six tetrapeptides are possible. From \(\mathrm{NH}_{2}\) to \(\mathrm{CO}_{2} \mathrm{H}\) end: phe-phe-glygly, gly-gly-phe-phe, gly-phe-phe-gly, phe-gly-gly-phe, phe-gly-phegly, gly-phe-gly-phe; b. Twelve tetrapeptides are possible. From \(\mathrm{NH}_{2}\) to \(\mathrm{CO}_{2} \mathrm{H}\) end: phe-phe-gly-ala, phe-phe-ala-gly, phe-gly-phe-ala, phe-gly-ala-phe, phe-ala-phe-gly, phe-ala-gly-phe, gly-phe-phe-ala, gly-phe-ala-phe, gly-ala-phe-phe, ala-phe-phe-gly, ala-phe-gly-phe, ala-gly-phe-phe 97 . The secondary structure of a protein describes the arrangement in space of the protein's polypeptide chain. The most common secondary structures are the \(\alpha\)-helix and the pleated sheet. The \(\alpha\)-helix secondary structure gives a protein elasticity; examples are wool, hair, and tendons. The pleated sheet secondary structure has hydrogen bonding interactions between protein chains. As several protein chains interact with each other through hydrogen bonding, fibers result that are very strong and are resistant to stretching. Examples of proteins having pleated sheet secondary structures are silk and muscle fibers. 99. Ionic: his, lys, or arg with asp or glu; hydrogen bonding: ser, glu, tyr, his, arg, asn, thr, asp, gln, or lys with any amino acid; covalent: cys with cys; London dispersion: all amino acids with nonpolar R groups (gly, ala, pro, phe, ile, trp, met, leu, val); dipole-dipole: tyr, thr, and ser with each other 101. Glutamic acid has a polar \(R\) group and valine has a nonpolar \(R\) group. The change in polarity of the R groups could affect the tertiary structure of hemoglobin and affect the ability of hemoglobin to bond to oxygen.

\section*{103.}

105. aldohexose: glucose, mannose, galactose; aldopentose: ribose, arabinose; ketohexose: fructose; ketopentose; ribulose 107. They differ in the orientation of a hydroxy group on a particular carbon. Starch is composed from \(\alpha\)-D-glucose, and cellulose is composed from \(\beta\)-D-glucose.
109. The chiral carbons are marked with asterisks.

Isoleucine

Threonine
111.

is optically active. The chiral carbon is marked with an asterisk.
113. Aspartame has two chiral carbon atoms.
115. \(\mathrm{C}-\mathrm{C}-\mathrm{A}-\mathrm{G}-\mathrm{A}-\mathrm{T}-\mathrm{A}-\mathrm{T}-\mathrm{G}\) 117. Uracil will H-bond to adenine.

Uracil
119. a. glu: CTT, CTC; val: CAA, CAG, CAT, CAC; met: TAC; trp: ACC; phe: AAA, AAG; asp: CTA, CTG; b. ACC-CTT-AAA-TAC or ACC-CTC-AAA-TAC or ACC-CTT-AAG-TAC or ACC-CTC-AAG-TAC; c. four (see answer to part b); d. met-asp-phe; e. TAC-CTA-AAG; TAC-CTAAAA; TAC-CTG-AAA 121. a. 2,3,5,6-tetramethyloctane; b. 2,2,3,5tetramethylheptane; c. 2,3,4-trimethylhexane; d. 3-methyl-1-pentyne
123.

There are many possibilities for isomers. Any structure with four chlorines replacing four hydrogens in any of the numbered positions would be an isomer; i.e., 1,2,3,4-tetrachloro-dibenzo-p-dioxin is a possible isomer.
125.

n-hexane

2-methylpentane

2,2-dimethylbutane
127. \(-23^{\circ} \mathrm{C}: \mathrm{CH}_{3}-\mathrm{O}-\mathrm{CH}_{3} ; 78.5^{\circ} \mathrm{C}: \mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{OH}\) 129. Alcohols consist of two parts, the polar OH group and the nonpolar hydrocarbon chain attached to the OH group. As the length of the nonpolar hydrocarbon chain increases, the solubility of the alcohol decreases. In methyl alcohol (methanol), the polar OH group can override the effect of the nonpolar \(\mathrm{CH}_{3}\) group, and methyl alcohol is soluble in water. In stearyl alcohol, the molecule consists mostly of the long nonpolar hydrocarbon chain, so it is insoluble in water. 131. \(n\)-hexane, \(69^{\circ} \mathrm{C}\); pentanal, \(103^{\circ} \mathrm{C}\); 1-pentanol, \(137^{\circ} \mathrm{C}\); butanoic acid, \(164^{\circ} \mathrm{C}\). 133. 2-propanone; propanoic acid 135 . In nylon, hydrogenbonding interactions occur due to the presence of \(\mathrm{N}-\mathrm{H}\) bonds in the polymer. For a given polymer chain length, there are more \(\mathrm{N}-\mathrm{H}\) groups in nylon-46 as compared to nylon-6. Hence, nylon-46 forms a stronger polymer compared to nylon-6 due to the increased hydrogen-bonding interactions.
137. a.

b. Repeating unit:

The two polymers differ in the substitution pattern on the benzene rings. The Kevlar chain is straighter, and there is more efficient hydrogen bonding between Kevlar chains than between Nomex chains. 139. a. The bond angles in the ring are about \(60^{\circ}\). VSEPR predicts bond angles close to \(109^{\circ}\). The bonding electrons are much closer together than they prefer, resulting in strong electron-electron repulsions. Thus ethylene oxide is unstable (reactive). b. The ring opens up during polymerization and the monomers link together through the formation of \(\mathrm{O}-\mathrm{C}\) bonds.
\(+\mathrm{O}-\mathrm{CH}_{2} \mathrm{CH}_{2}-\mathrm{O}-\mathrm{CH}_{2} \mathrm{CH}_{2}-\mathrm{O}-\mathrm{CH}_{2} \mathrm{CH}_{2}-_{n}\)
141. \(\mathrm{H}_{2} \mathrm{~N}-\underset{\mid}{\mathrm{CH}} \mathrm{CH}-\mathrm{CH}_{2} \mathrm{CO}_{2}{ }^{-} \mathrm{Na}^{+}\)
or \(\mathrm{H}_{2} \mathrm{~N}-\underset{\mid}{\mathrm{CH}} \mathrm{CH}-\mathrm{CO}_{2}{ }^{-} \mathrm{Na}^{+}\)
The first structure is MSG, which is impossible for you to predict. 143. \(\Delta G=\) \(\Delta H-T \Delta S\); for the reaction, we break a \(\mathrm{P}-\mathrm{O}\) and \(\mathrm{O}-\mathrm{H}\) bond and form a \(\mathrm{P}-\mathrm{O}\) and \(\mathrm{O}-\mathrm{H}\) bond, so \(\Delta H \approx 0\) based on bond dissociation energies. \(\Delta S\) for this process is negative (unfavorable) because positional probability decreases. Thus, \(\Delta G>0\) due to the unfavorable \(\Delta S\) term, and the reaction is not expected to be spontaneous.
145.

147. Both \(\Delta H\) and \(\Delta S\) are positive values. 149. a. pentane or \(n\)-pentane; b. 3-ethyl-2,5-dimethylhexane; c. 4-ethyl-5-isopropyloctane 151. a. iodocyclopropane; b. 2-chloro-1,3,5-trimethylcyclohexane; c. 1-chloro-2-ethylcyclopentane; d. 1-ethyl-2-methylcyclopentene 153. a. 1-pentanol, 2-methyl-2,4-pentadiol; b. trans-1,2-cyclohexadiol, 4-methyl-1-penten-3-ol (does not exhibit cis-trans isomerism) 155. The necessary carboxylic acid is 2-chloropropanoic acid.
157.

159. 6.07 161. a. No; the mirror image is superimposable.

165. a. \(\mathrm{CH}_{3} \mathrm{CHCH}_{2} \mathrm{CH}_{3}\)

c.

d. \(\mathrm{CH}_{2}=\mathrm{CHCH}_{3}\)

167.

169. a. The temperature of the rubber band increases when it is stretched; b. exothermic (heat is released); c. As the chains are stretched, they line up more closely resulting in stronger London dispersion forces between the chains. Heat is released as the strength of the intermolecular forces increases. d. \(\Delta G\) is positive and \(\Delta S\) is negative; e. The structure of the stretched polymer chains is more ordered (has a smaller positional probability) than in unstretched rubber. Therefore, entropy decreases as the rubber band is stretched. 171. \(0.11 \%\) 173. a. \(37.50 \%\); b. The hybridization changes from \(s p^{2}\) to \(s p^{3}\); c. 3,4-dimethyl-3-hexanol

as proton donor, 140
in solutions containing common ion, 600-602
strength, 552-557
strong, 552, 560-561, 610-613, 615-617, 627-629
as strong electrolytes, 120-121
water as, 555-557
weak, 123, 552, 562-570
Acid catalysis, 503-506

Acid dissociation constant \(\left(K_{a}\right)\) the equilibrium constant for a reaction in which a proton is removed from an acid by \(\mathrm{H}_{2} \mathrm{O}\) to form the conjugate base and \(\mathrm{H}_{3} \mathrm{O}^{+}\). (14.1), 551
Acid rain a result of air pollution by sulfur dioxide. (5.10), 204
from coal burning, 239
Acid-base equilibrium, 600
acid-base indicators and, 629-632, 633-634
buffered solutions, 602-611
buffering capacity and, 611-614
polyprotic acid titrations, 634-635
in solutions of acids or bases containing a common ion, 600-602
titrations and pH curves, 615-628, 629
Acid-base indicator a substance that marks the end point of an acid-base titration by changing color. (15.5), 629-632, 633-634
Acid-base properties
effect of structure on, 587-588
of oxides, 589
of salts, 582-586, 587
Acid-base reactions, 130, 140-147
composition of solutions in, 436
performing calculations for, 141 titrations, 144-147
Acidic oxide a covalent oxide that dissolves in water to give an acidic solution. (14.10), 589
Acidimeter, 559
Acrylonitrile-butadiene-styrene (ABS), 881
Actinide series a group of 14 elements following actinium in the periodic table, in which the \(5 f\) orbitals are being filled. (7.11; 20.1), 282, 773
Activated complex (transition state) the arrangement of atoms found at the top of the potential energy barrier as a reaction proceeds from reactants to products. (12.6), 495
Activation energy the threshold energy that must be overcome to produce a chemical reaction. (12.6), 495-500 catalysis and, 500-506
Addition polymerization a type of polymerization in which the monomers simply add together to form the polymer, with no other products. (22.5), 877

Addition reaction a reaction in which atoms add to a carbon-carbon multiple bond. (22.2), 865
Adenosine diphosphate (ADP), 688
Adenosine triphosphate (ATP), 688
Adipic acid, 878
Adsorption the collection of one substance on the surface of another. (12.7), 501
Affinity, electron, 288-289
Air, 28. See also Atmosphere
liquefaction of, 777
pollution, 203, 471, 501
Air bags, automobile, 186
Air pollution contamination of the atmosphere, mainly by the gaseous products of transportation and production of electricity. (5.10)
Alanine, 882-883
Alarm pheromones, 347
Alchemy, 36
Alcohol an organic compound in which the hydroxyl group is a substituent on a hydrocarbon. (22.4), 868-871
concentration of, 127-128
Aldehyde an organic compound containing the carbonyl group bonded to at least one hydrogen atom. (22.4), 871-872
Alexandrite, 835
Alkali metal a Group 1A metal. (2.7; 20.2), 52, 778-779
periodic table information, 291-292
qualitative analysis of mixtures containing, 654-655
Alkaline earth metal a Group 2A metal. (2.7; 20.4), 52, 781-782, 783

Alkane a saturated hydrocarbon with the general formula \(\mathrm{C}_{n} \mathrm{H}_{2 n+2}\). (22.1), 855-863
cyclic, 862-863
isomerism in, 857
nomenclature, 858-861
reactions of, 861-862
Alkene an unsaturated hydrocarbon containing a carbon-carbon double bond. The general formula is \(\mathrm{C}_{n} \mathrm{H}_{2 n}\). (22.2), 863-866
reactions of, 865-866
Alkyne an unsaturated hydrocarbon containing a triple carbon- carbon bond.
The general formula is \(\mathrm{C}_{n} \mathrm{H}_{2 n-2}\). (22.2), 863-866
reactions of, 865-866

\section*{Allomones, 346}

Alloy a substance that contains a mixture of elements and has metallic properties. (10.4), 401-403

Alloy steel a form of steel containing carbon plus other metals such as chromium, cobalt, manganese, and molybdenum. (21.8), 403, 848

Alloying, 727
Alpha helix, 884-886
Alpha ( \(\alpha\) ) particle a helium nucleus. (19.1), 746

Alpha-particle production a common mode of decay for radioactive nuclides in which the mass number changes. (19.1), 746

Altitude sickness, 842
Aluminum, 784
Aufbau principle and, 279
Lewis acid-base model, 590-591
moles and number of atoms in sample of, 75
production, 733-734
in thermite reaction, 234
Aluminum chloride, 585-586
Aluminum oxide, 835
standard entropy for reduction of, 682
Americium, 74-75
Amine an organic base derived from ammonia in which one or more of the hydrogen atoms are replaced by organic groups. (14.6; 22.4), 575, 873
\(\boldsymbol{\alpha}\)-Amino acid an organic acid in which an amino group and an R group are attached to the carbon atom next to the carboxyl group. (22.6)
Amino acids, 504-505, 882-883
primary structure, 883
sequences, 882-883
tertiary structure, 886
Ammonia
amines, 575, 873
bond angles, 341
Boyle's law and, 170
in complex ion solutions, 656-660, 661
entropy changes in synthesis of, 679-680
gas, balancing chemical equations involving, 94-95
Haber process for synthesis of, 515-516
ideal gas law and, 175-176
Lewis acid-base model, 590
limiting reactant in formation of, 105-106
localized electron model, 357
passed over solid copper to prepare nitrogen gas, 107-109
pH of buffered solution of, 609-610
reaction quotient and synthesis of, 524-525
standard enthalpies of formation, 233-234
standard free energy change in synthesis of, 683
structural formula for, 49
synthesis reaction free energy, 695
as weak base, 123, 572-574
Ammonium acetate, 586
Ammonium chloride, 584-585
pH of buffered solution of, 609-610
Ammonium ions, 654-655
Ammonium nitrate, 51
Amorphous solid a solid with considerable disorder in its structure. (10.3), 393
Ampere the unit of electric current equal to one coulomb of charge per second. (18.7), 728

Amphoteric substance a substance that can behave either as an acid or as a base. (14.2)
water as, 555
Amylopectin, 891
Amylose, 891
Angular momentum quantum number
\((\ell)\) the quantum number relating to the shape of an atomic orbital, which can assume any integral value from 0 to \(n-1\) for each value of \(n\). (7.6), 269
Anion a negative ion. (2.6)
Anode the electrode in a galvanic cell at which oxidation occurs. (18.1), 705, 707. See also Electrolysis; Galvanic cells
Antibiotics, 346
Antibonding molecular orbital an orbital higher in energy than the atomic orbitals of which it is composed. (9.2), 368
Anticodons, 895
Antifreeze, 27, 453-454
Antimony, 674, 787
Aqueous solution a solution in which water is the dissolving medium or solvent. (4), 28, 117-119
acid-base reactions, 130, 140-147
base strength in, 584
boiling-point elevation, 451-452
composition of, 123-130
describing reactions in, 136-138
dilution of, 128-130
electrical conductivity of, 119,120
electrolysis of, 730-731
entropy changes in, 678-679
freezing-point depression, 452-454
molarity of, 123-130
nature of, 119-123
nonelectrolytes in, 119, 123
oxidation-reduction reactions, 130 , 147-152, 147-159
precipitation reactions, 130, 131-136, 138-140
Raoult's law and, 446-450
reaction between bromate ions and bromide ions in, 477-478
stock, 128
stoichiometry of precipitation reactions, 138-140
strong electrolytes in, 119, 120-121
temperature effects on solubility in, 444-445
titrations, 144-147, 158-159
types of reactions, 130
vapor pressures of, 445-450
weak electrolytes in, 119, 121-123
Argon, 178
as atomic solid, 396-397
Aufbau principle and, 280
nuclear equations, 748
Aromatic hydrocarbon one of a special class of cyclic unsaturated hydrocarbons, the simplest of which is benzene. (22.3), 866-867

Arrhenius, Svante, 119, 120-121, 122, 495, 549-550
Arrhenius concept a concept postulating that acids produce hydrogen ions in aqueous solution, while bases produce hydroxide ions. (14.1), 550, 571
Arrhenius equation the equation repre-
senting the rate constant as \(k=A e^{-E_{\mathrm{a}} / R T}\), where \(A\) represents the product of the collision frequency and the steric factor, and \(e^{-E_{\mathrm{a}} / R T}\) is the fraction of collisions
with sufficient energy to produce a reaction. (12.6), 496-497
Arsenic, 538
Aspartame, 828
Aspirin, 221, 873
Atactic chain a polymer chain in which the substituent groups such as \(\mathrm{CH}_{3}\) are randomly distributed along the chain. (22.5), 880

Atmosphere the mixture of gases that sur-
rounds the earth's surface. (5.10)
chemistry in the, 202-204
gases, 165, 202-204
greenhouse effect, 239-240
infrared radiation in, 239
nitrogen oxide production and, 502
oxygen in, 798
photochemical smog in the, 203
pressure, 166
water in, 239
Atomic mass, 40, 70-72
average, 71
writing symbols for, 48
Atomic number the number of protons in the nucleus of an atom. \((2.5 ; 18), 47,52,744\)
Atomic radius half the distance between the nuclei in a molecule consisting of identical atoms. (7.12), 289-291
Atomic solid a solid that contains atoms at the lattice points. (10.3), 396-397

Atomic structure
alkali metals, 291-295
atomic spectrum of hydrogen and, 260-262
Bohr model, 262-265
effect on acid-base properties, 587-588
effects on solubility, 441-442
electromagnetic radiation and, 252-254
electron spin and the Pauli principle, 273
history of periodic table and, 276-277
nature of matter and, 254-260
orbital shapes and energies, 270-273
periodic trends in atomic properties and, 284-291
polyelectronic atoms, 274-275
quantum mechanical model of the atom, 266-269
quantum numbers, 269-270
Atomic theory, Dalton's, 40-43
Atomic weights, 40
Atoms, 30
calculating numbers of, 76
determining moles of, 75
early experiments to characterize, 42-46
formal charge of, 334-337
modern view of structure of, 46-48
nuclear, 45-46
photoelectron spectroscopy (PES), 287-288
polyelectronic, 274-275
radii, 289-291
variety of substances from only 100 different, 4
visible using scanning tunneling microscope, 3
whole-number ratio of, 85
writing symbols for, 48
Aufbau principle the principle stating that as protons are added one by one to the nucleus to build up the elements, electrons are similarly added to hydrogenlike orbitals. (7.11), 278-284
Austentite, 849
Autoionization the transfer of a proton from one molecule to another of the same substance. (14.2) of water, 555-557
Automobiles. See also Fuel; Gasoline
antifreeze, 27, 453-454
fuel cells, 724-725
lead storage batteries, 436-437, 722-723
magneto-rheological fluid in, 392
tires, 875-876
Average atomic mass, 71
Avogadro, Amadeo, 41
Avogadro's hypothesis, 41-43

Avogadro's law equal volumes of gases at the same temperature and pressure contain the same number of particles. (2.3; 5.2), 172-173
kinetic molecular theory of gases and, 192
Avogadro's number the number of atoms in exactly 12 grams of pure \({ }^{12} \mathrm{C}\), equal to \(6.022 \times 10^{23}\). (3.3), 73, 760

Baekeland, Leo H., 874
Bakelite, 874
Baking soda, 99-100
Balancing of chemical equations, \(90-91\), 92, 92-95
oxidation-reduction equations, 152-158
Ball-and-stick model a molecular model that distorts the sizes of atoms but shows bond relationships clearly. (2.6), 49
Band model a molecular model for metals in which the electrons are assumed to travel around the metal crystal in molecular orbitals formed from the valence atomic orbitals of the metal atoms. (10.4), 401

Barium, 781, 782
Barium nitrate, constant-pressure calorimetry, 222-223
Barometer a device for measuring atmospheric pressure. (5.1), 166
Base a substance that produces hydroxide ions in aqueous solution; a proton acceptor. (4.2)
balancing oxidation-reduction reactions with, 157-159
Brønsted-Lowry model, 550
effect of structure on properties of, 587-588
Lewis, 589-591
nature of, 549-552
pH scale and, 557-560
properties of salts, 582-586, 587
as proton acceptor, 140
in solutions containing common ion, 600-602
strength, relative, 554
strength in aqueous solutions, 584
strong, 121, 571, 615-617
water as, 555-557
weak, 123, 572-575, 627-629
Basic oxide an ionic oxide that dissolves in water to produce a basic solution. (14.10)
Basic oxygen process a process for producing steel by oxidizing and removing the impurities in iron using a high-pressure blast of oxygen. (21.8), 849
Battery a group of galvanic cells connected in series. (18.5), 698
dry cell, 723
fuel cell, 724-725
lead storage, 436-437, 722-723
lithium-ion, 724

Bauer, Georg, 36
Beckman, Arnold, 559
Becquerel, Henri, 44
Bees, 346-347
Benzene, 866-867
bonding in, 378-379
freezing-point depression and, 454
Benzoic acid, 614
neutralization analysis, 146-147
Beryllium, 773, 782
Aufbau principle and, 278
molecular bonding, 370
Beryllium chloride, 338
Beryllium oxide, 781
Berzelius, Jöns Jakob, 41-43
Beta ( \(\boldsymbol{\beta}\) ) particle an electron produced in radioactive decay. (19.1), 745
Beta-particle production a decay process for radioactive nuclides in which the mass number remains constant and the atomic number changes. The net effect is to change a neutron to a proton.
(19.1), 746

Bicarbonate, 444-445
Bidentate ligand a ligand that can form two bonds to a metal ion. (21.3), 822
Bimolecular step a reaction involving the collision of two molecules. (12.5), 490
Binary compound a two-element compound. (2.8), 53
Binary covalent compounds (type III), 59-62
Binary ionic compounds
energy effects in, 314-317
type I, 54-55
type II, 55-57
Binding energy (nuclear) the energy required to decompose a nucleus into its component nucleons. (19.5) 759-761
Biologically important molecules. See Natural polymers
Biomolecule a molecule responsible for maintaining and/or reproducing life. (22), 855

Bismuth, 748, 787
Bismuth sulfide, 644
Black mamba snake, 293
Black phosphorus, 795
Blast furnace a furnace in which iron oxide is reduced to iron metal by using a very strong blast of hot air to produce carbon monoxide from coke, and then using this gas as a reducing agent for the iron. (21.8), 847-848

Blood
heme, 839-840
hemoglobin, 841-842
iron in, 839-840
isotonic solution with sodium chloride, 457, 458
myoglobin, 840-841
pH of, 559-560

Bohr, Niels, 262, 263
Bohr model, 262-265, 268
Boiler scale, 444
Boiling
chips, 422
physical changes with, 28, 389
water, 425
Boiling point, 419-420
elevation, 451-452, 459-460
normal, 421
van't Hoff factor and, 459-460
Bond energy the energy required to break a given chemical bond. (8.1)
Bond length the distance between the nuclei of the two atoms connected by a bond; the distance where the total energy of a diatomic molecule is minimal. (8.1)
Bond order the difference between the number of bonding electrons and the number of antibonding electrons, divided by two. It is an index of bond strength. (9.2)
Bonding molecular orbital an orbital lower in energy than the atomic orbitals of which it is composed. (9.2), 368
Bonding pair an electron pair found in the space between two atoms. (8.9), 325, 341
Bonds, 48, 301
in complex ions, 830-831
covalent, 48-49, 304, 318, 319-325
delocalized pi, 379
duet rule, 326
electronegativity, 305-306, 307
energy, 301
energy effects in binary ionic compounds, 314-317
in heteronuclear diatomic molecules, 376-377
in homonuclear diatomic molecules, 369-376
intramolecular, 385
ionic, 50-51, 310-318
length of, 304
Lewis structures, 325-329
localized electron (LE) model, 325
in metals, 400-401
octet rule, 326, 327, 329-332
order, 369, 375-376
partial ionic character of covalent, 318
pi, 359, 378, 379, 774-775
polar covalent, 304
polarity and dipole moments, 307-310
relative polarities, 306, 307
resonance and, 333-337
sigma, 358-359, 378
single, double, and triple, 322
types of chemical, 301-305
VSEPR model, 337-350
VSEPR model and multiple, 346-348

Borane a covalent hydride of boron. (20.5), 783-784
Boron, 773-774, 783
Aufbau principle and, 278
molecular bonding, 370-371
octet rule, 330
Boron trifluoride, 330
Lewis acid-base model, 590
Boyle, Robert, 8, 36
Boyle's law the volume of a given sample of gas at constant temperature varies inversely with the pressure. (5.2), 167-170, 191
Bragg equation, 395-396
Brass, 28
Breeder reactor a nuclear reactor in which fissionable fuel is produced while the reactor runs. (19.6), 765
Brittle tin, 785
Bromate ions, 477-478
Bromide ions, 477-478
Bromine, atomic radius, 290
Bromine nitrogen oxide, 495-496
Bromthymol blue, 630, 631-632
Brønsted, Johannes, 550
Brønsted-Lowry model a model proposing that an acid is a proton donor, and a base is a proton acceptor. (14.1), 550-555, 571, 587, 589-590
Buffered solution a solution that resists a change in its pH when either hydroxide ions or protons are added. (15.2),
602-611
adding strong acids to, 610-611, 612-613
buffering capacity, 611-614
mechanism of, 605-608
pH changes in, 604-605
pH of, 603, 608-610
preparing buffers for, 614
Buffering capacity the ability of a buffered solution to absorb protons or hydroxide ions without a significant change in pH ; determined by the magnitudes of [HA] and \(\left[\mathrm{A}^{-}\right]\)in the solution. (15.3), 611-614
Burets, 14
Butadiene, 484-485, 881
Butyraldehyde, 872
Cadaverine, 873
Cadmium, electron configuration, 283
Caffeine, molecular formula for, 89-90
Calcium, 781-782
Aufbau principle and, 280
Calcium carbonate molar mass of, 78-79
quicklime from decomposition of, 180, 520-521
Calcium fluoride, 641-642
solubility, 648

Calcium hydride, 780
Calcium hydroxide, 571
Calcium sulfite, 204
Calculations
significant figures and, 14-17
stoichiometric, 95-100
Calorimetry the science of measuring heat flow. (6.2), 220-225
Cancer cells, 828
Capacity
buffering, 611-614
heat, 220
Capillary action the spontaneous rising of a liquid in a narrow tube. (10.2), 390
Capsaicin, 378
Captive zeros, 14
Carbohydrate a polyhydroxyl ketone, a polyhydroxyl aldehyde, or a polymer
composed of these. (22.6), 887-892
chiral carbons in, 888,890
complex, 890-892
Carbon, 784, 785
atomic mass of, 71-72
as atomic solid, 396
Aufbau principle and, 278-279
in carbohydrates, chiral, 888, 890
as diamond, 227, 228, 230
as graphite, 227, 228, 230, 303
mass percent in ethanol, 82
as network atomic solid, 403-410
nuclear equations, 748
pi bonds, 774
steel, 848,849
Carbonated beverages, 442, 443-444
Carbonate ion, 444-445
Carbonates, insoluble, 654-655
Carbon-14 dating, 755-757
Carbon dioxide
in carbonated beverages, 442, 443-444
conversion to glucose, 688
dissolved in water, 444-445
effects on climate, 239-240
in Lake Nyos, Cameroon, 446
Lewis structure, 327-328
oxidation state, 149
phase diagram, 425, 427
polar bonds, 307
produced by mixing methane and oxygen, 180-182
\(s p\) hybridization, 360-361
Carbonic acid, 576-577
Carbon monoxide
reaction with nitrogen dioxide, 489, 491
reaction with steam, 512-513, 528-529
Carbon steel an alloy of iron containing up to about \(1.5 \%\) carbon. (21.8)
Carbon tetrachloride
decomposition of dinitrogen pentoxide in, 475
neutralization analysis, 146-147
Carbonyl group, 871

Carboxyhemoglobin a stable complex of hemoglobin and carbon monoxide that prevents normal oxygen uptake in the blood. (21.7), 842
Carboxyl group the - COOH group in an organic acid. (14.2; 22.4), 553, 872
Carboxylic acid an organic compound containing the carboxyl group; an acid with the general formula RCOOH. (22.4), 872-873
Carboxypeptidase-A, 504
Carothers, Wallace H., 874-875
Carvone, 82-83
Catalina Island, California, 458, 459
Catalysis, 500
acid, 503-506
heterogeneous, 500, 501-502
homogeneous, 500, 502-503
Catalyst a substance that speeds up a reaction without being consumed. (12.7)
Cathode the electrode in a galvanic cell at which reduction occurs. (18.1), 705. See also Electrolysis; Galvanic cells protection, 728
Cathode rays the "rays" emanating from the negative electrode (cathode) in a partially evacuated tube; a stream of electrons. (2.4)
Cathode-ray tubes, 43-44
Cathodic protection a method in which an active metal, such as magnesium, is connected to steel to protect it from corrosion. (18.6)
Cation a positive ion. (2.6), 56 binary ionic compounds (type I), 54-55 binary ionic compounds (type II), 55-57
Cell potential (electromotive force) the driving force in a galvanic cell that pulls electrons from the reducing agent in one compartment to the oxidizing agent in the other. (18.1), 705-706, 714-716 calculation of equilibrium constants for redox reactions and, 721-722 dependence on concentration, 717-722 ion-selective electrodes and, 721
Cells, concentration, 717-718
Cellulose, 892
Celsius scale, 22-26, 171
Cementite, 849-850
Ceramic a nonmetallic material made from clay and hardened by firing at high temperature; it contains minute silicate crystals suspended in a glassy cement. (10.5), 408

Cerium, 152
Cerium hydrogen sulfate, 158
Cerium nitrate, 650
Certain digits, 12
Chain reaction (nuclear) a self-sustaining fission process caused by the production of neutrons that proceed to split other nuclei. (19.6), 762-763

Changes, distinguishing between physical and chemical, 388-389
Changes of state, 419-422
Charles' law the volume of a given sample of gas at constant pressure is directly proportional to the temperature in kelvins. (5.2), 170-172
kinetic molecular theory of gases and, 191-192
Chelates, 822
Chelating ligand (chelate) a ligand having more than one atom with a lone pair that can be used to bond to a metal ion. (21.3), 822

Chemical bond the force or, more accurately, the energy that holds two atoms together in a compound. (2.6). See Bonds
Chemical change the change of substances into other substances through a reorganization of the atoms; a chemical reaction. (1.10), 30

Chemical energy, 214-218
Chemical equation a representation of a chemical reaction showing the relative numbers of reactant and product molecules. (3.8). See Equations, chemical
Chemical equilibrium a dynamic reaction system in which the concentrations of all reactants and products remain constant as a function of time. (13)
Chemical formula the representation of a molecule in which the symbols for the elements are used to indicate the types of atoms present and subscripts are used to show the relative numbers of atoms. (2.6)
Chemical kinetics the area of chemistry that concerns reaction rates. (12) Chemical reactions. See Reactions, chemical
Chemical stoichiometry the calculation of the quantities of material consumed and produced in chemical reactions. (3). See Stoichiometry
Chemistry
in the atmosphere, 202-204
early history of, 36-37
fundamental chemical laws in, 37-40
importance of, 2-3
learning to solve problems systematically in, 18
overview, 3-5
scientific method in, 5-8
units of measurement in, 8-11
Chili peppers, 378
Chiral carbons in carbohydrates, 888, 890
Chiral images, 827
Chirality the quality of having nonsuperimposable mirror images. (21.4)
Chlor-alkali process the process for producing chlorine and sodium hydroxide by electrolyzing brine in a mercury cell. (18.8)
Chlorate salts, 804

Chlorine, 776
in complex ion solutions, 659-660, 661
in formation of Freon-12, 324-325
gas from phosphorus pentachloride decomposition, 522
ionic bonds, 50-51
lack of bond polarity, 309
reaction with chloroform, 493-494
Chloroacetic acid, 614
Chlorofluorocarbons, 861
Chloroform, 450
reaction with chlorine, 493-494
Chromatography the general name for a series of methods for separating mixtures by using a system with a mobile phase and a stationary phase. (1.10), 29, 441
Chromium, 812, 818-819
Aufbau principle and, 280
balancing chemical equations involving, 93-94
Chrysoberyl, 835
Cinnamaldehyde, 872
Cis-trans isomerism, 826-830, 864
Classification of matter, 27-30
Clay, 408
Climate effects of carbon dioxide, 239-240
Closest packing, 397-398
calculating density of, 399-400
M\&Ms candies and, 402
Coagulation the destruction of a colloid by causing particles to aggregate and settle out. (11.8), 462-463
Coal, 238-239
conversion, 240-241
gasification, 240-241
slurries, 241
Coatings, titanium oxide, 818
Cobalt, 812, 819-820
calculating number of moles and mass of sample of, 76-77
Codeine, 575
Codons organic bases in sets of three that form the genetic code. (22.6), 894
Colligative properties properties of a solution that depend only on the number, and not on the identity, of the solute particles. (11.5)
of electrolyte solutions, 459-461
Collision model a model based on the idea that molecules must collide to react; used to account for the observed characteristics of reaction rates. (12.6), 495-496
Colloid (colloidal dispersion) a suspension of particles in a dispersing medium. (11.8), 461-463

Combustion, 37
distinguishing between physical and chemical changes with, 388-389 enthalpies of, 244-246
methane, 214-215, 388-389
reactions of alkanes, 861

Combustion reaction the vigorous and exothermic reaction that takes place between certain substances, particularly organic compounds, and oxygen. (22.1)
Commercial electrolytic processes, 733-737
Common ions, 600-602 effect, 601, 647-648
Common ion effect the shift in an equilibrium position caused by the addition or presence of an ion involved in the equilibrium reaction. (15.1)
Complete ionic equation an equation that shows all substances that are strong electrolytes as ions. (4.6), 137
Complex carbohydrates, 890-892
Complex ion a charged species consisting of a metal ion surrounded by ligands. (16.3; 21.1)
bonding in, 830-831
crystal field model, 832-838
equilibria involving, 656-660, 661
transition metals, 812
Composition of solutions, 123-130, 434-437
Compound a substance with constant composition that can be broken down into elements by chemical processes. (1.10), 30. See also Ionic compounds/salts binary, 53
coordination, 821-825
determining formula of, 83-90
electron configuration of, 310-314
naming simple, 53-63
percent composition, 81-83
standard states, 230
Concentration
calculating equilibrium pressures and, 526-531
cells, 717-718
dependence of cell potential on, 717-722 equilibrium effect of change in, 537-538
Concentration cell a galvanic cell in which both compartments contain the same components, but at different concentrations. (18.4)
Conceptual problem solving, 80-81
Condensation the process by which vapor molecules re-form a liquid. (10.8), 415-416
Condensation polymerization a type of polymerization in which the formation of a small molecule, such as water, accompanies the extension of the polymer chain. (22.5), 878
Condensed states of matter liquids and solids. (10.1), 385
Conductivity, electrical, 119, 120 semiconductors, 408-410
Conjugate acid the species formed when a proton is added to a base. (14.1), 550

Conjugate acid-base pair two species related to each other by the donating and accepting of a single proton. (14.1), 550
Conjugate base what remains of an acid molecule after a proton is lost. (14.1), 550
Constant-pressure calorimetry, 222-224
Constant-volume calorimetry, 223-225
Continuous spectrum a spectrum that exhibits all the wavelengths of visible light. (7.3), 261
Control rods rods in a nuclear reactor composed of substances that absorb neutrons. These rods regulate the power level of the reactor. (19.6), 764
Conversion, coal, 240-241
Conversions, unit, 18-22 pressure, 167
temperature, 24-26
Cooking, 378, 780
Coordinate covalent bond a metal-ligand bond resulting from the interaction of a Lewis base (the ligand) and a Lewis acid (the metal ion). (21.3), 822
Coordination compound a compound composed of a complex ion and counter ions sufficient to give no net charge. (21.3), 821-825
biological importance of, 838-842
nomenclature, 823-825
other geometries, 836-838
Coordination isomerism isomerism in a coordination compound in which the composition of the coordination sphere of the metal ion varies. (21.4), 825-826
Coordination number the number of bonds formed between the metal ion and the ligands in a complex ion. (21.3), 821
Copernicium, 279
Copolymer a polymer formed from the polymerization of more than one type of monomer. (22.5), 878, 881
Copper, 820
as atomic solid, 397
Aufbau principle and, 281
average mass, 72
cathodes, 707-708
electrolysis, 728-730
electrorefining, 734
nitrogen gas prepared by passing
gaseous ammonia over, 107-109
in precipitation reactions, 652-653
Copper bromide, 642-643
Copper chloride in fireworks, 255
Copper iodate, 644-645
Core electron an inner electron in an atom; one not in the outermost (valence) principal quantum level. (7.11), 280
Corrosion the process by which metals are oxidized in the atmosphere. (18.6), 726-728, 732
equilibrium constant, 696

Corundum, 835
Coulomb's law \(E=2.31 \times 10^{-19}\left(\frac{Q_{1} Q_{2}}{r}\right)\), action between a pair of ions, expressed in joules; \(r\) is the distance between the
ion centers in nm ; and \(Q_{1}\) and \(Q_{2}\) are the numerical ion charges. (8.1), 302
Counterions anions or cations that balance the charge on the complex ion in a coordination compound. (21.3), 821
Counting by weighing, 69-70
Covalent atomic radii, 290
Covalent bonds, 48, 304
combining the localized electron model and molecular orbital models, 377-379, 380
energies and chemical reactions, 322-325
in heteronuclear diatomic molecules, 376-377
in homonuclear diatomic molecules, 369-376
hybridization and localized electron model, 355-366
model of, 319-321
molecular orbital model, 366-369
partial ionic character of, 318
polar, 304
Covalent bonding a type of bonding in which electrons are shared by atoms. (2.6; 8.1)

Covalent compounds, binary (type III), 59-62
Covalent hydrides, 780
Critical mass the mass of fissionable material required to produce a self-sustaining chain reaction. (19.6), 763
Critical point the point on a phase diagram at which the temperature and pressure have their critical values; the endpoint of the liquid-vapor line. (10.9), 424
Critical pressure the minimum pressure required to produce liquefaction of a substance at the critical temperature. (10.9), 424

Critical reaction (nuclear) a reaction in which exactly one neutron from each fission event causes another fission event, thus sustaining the chain reaction. (19.6)
Critical temperature the temperature above which vapor cannot be liquefied no matter what pressure is applied. (10.9), 424

Crosslinking the existence of bonds between adjacent chains in a polymer, thus adding strength to the material. (22.5), 875

Crystal field model a model used to explain the magnetism and colors of coordination complexes through the splitting of the \(d\) orbital energies. (21.6), 832-838

Crystalline solid a solid with a regular arrangement of its components. (10.3), 393
types of, 396-397
Cubic closest packed (ccp) structure a solid modeled by the closest packing of spheres with an \(a b c a b c\) arrangement of layers; the unit cell is face-centered cubic. (10.4), 398-399
Cyanidation a process in which crushed gold ore is treated with an aqueous cyanide solution in the presence of air to dissolve the gold. Pure gold is recovered by reduction of the ion to the metal. (21.8), 845

Cyanide, 157-158
basic properties of, 584
Lewis structure, 328
pH of weak acid mixtures containing, 566-567
Cyclamate, 828
Cyclic alkanes, 862-863
Cyclohexane, 862
Cyclotron a type of particle accelerator in which an ion introduced at the center is accelerated in an expanding spiral path by the use of alternating electrical fields in the presence of a magnetic field. (19.3), 752

Cysteine, 886
Cytochromes a series of iron-containing species composed of heme and a protein. Cytochromes are the principal electron-transfer molecules in the respiratory chain. (21.7), 839

D-block transition metals, 811
\(4 d\) and \(5 d\) transition series, 816
Dacron, 878-879
Dalton, John, 38, 40-43
Dalton's law of partial pressures for a mixture of gases in a container, the total pressure exerted is the sum of the pressures that each gas would exert if it were alone. (5.5), 183-187 gas collection over water and, 187-189 kinetic molecular theory of gases and, 192
Dating by radioactivity, 755-757
DDT (pesticide), 437
De Broglie, Louis, 260, 266
Decay, radioactive, 744-748, 749
kinetics of, 749-751
types of, 746-747
Decay series, 748
Decomposition
determining formula by, 83-90
dinitrogen pentoxide, 475, 480-481
nitrogen dioxide, 468-472
nitrosyl chloride, 534-536
nitrous oxide, 486, 487
quicklime from calcium carbonate, 180, 520-521
radioactive decay, 744-748, 749
stepwise methane, 322
Degenerate orbitals a group of orbitals with the same energy. (7.7), 272
Dehydrogenation reaction a reaction in which two hydrogen atoms are removed from adjacent carbons of a saturated hydrocarbon, giving an unsaturated hydrocarbon. (22.1), 862
Delocalized pi bonding, 379
Demineralization of tooth enamel, 645
Demokritos of Abdera, 36
Denaturation the breaking down of the three-dimensional structure of a protein resulting in the loss of its function. (22.6), 886,887

Denitrification the return of nitrogen from decomposed matter to the atmosphere by bacteria that change nitrates to nitrogen gas. (20.8)
Density a property of matter representing the mass per unit volume. (1.9), 26-27 of closest packed solids, 399-400 gas, 182-183
Deoxyribonucleic acid (DNA) a huge nucleotide polymer having a doublehelical structure with complementary bases on the two strands. Its major functions are protein synthesis and the storage and transport of genetic information. (22.6), 892-895, 896
Desalination the removal of dissolved salts from an aqueous solution. (11.6), 458, 459
Determinate errors, 13
Diagrams, phase, 422-427, 428
Dialysis a phenomenon in which a semipermeable membrane allows transfer of both solvent molecules and small solute molecules and ions. (11.6), 456-457
Diamagnetism a type of magnetism, associated with paired electrons, that causes a substance to be repelled from the inducing magnetic field. (9.3), 372-374
Diamond, 227, 228, 230
as atomic solid, 397
bonding compared to graphite, 404-405
laboratory-made, 426
Diatomic molecules
bonding in heteronuclear, 376-377
bonding in homonuclear, 369-376
Diborane, 783
gas, 177
Hess's law and synthesis of, 228-229
Diethyl ether enthalpy of vaporization, 418
Differential rate law an expression that gives the rate of a reaction as a function of concentrations; often called the rate law. (12.2)

Diffraction the scattering of light from a regular array of points or lines, producing constructive and destructive interference. (7.2), 259
pattern, 259-260
x-ray, 393-396
Diffusion the mixing of gases. (5.7)
Diffusion and effusion, 196-198
Dihydroxyacetone (DHA), 889
Dilution the process of adding solvent to lower the concentration of solute in a solution. (4.3), 128-130
Dimensional analysis an equivalence statement between units used for converting from one unit to another. (1.7), 18-22
Dimer a molecule formed by the joining of two identical monomers. (22.5), 878 butadiene, 484-485
Dinitrogen monoxide. See Nitrous oxide
Dinitrogen pentoxide, 475, 480-481 activation energy, 497-498
Dinitrogen tetroxide, 526
Dipeptides, 882
Dipole-dipole attraction the attractive force resulting when polar molecules line up so that the positive and negative ends are close to each other. (10.1)
Dipole-dipole forces, 385-386, 388
Dipole moment a property of a molecule whose charge distribution can be represented by a center of positive charge and a center of negative charge. (8.3),
307-310, 344-345
in molecular solids, 411
Diprotic acid, 553, 576
Direct reduction furnace a furnace in which iron oxide is reduced to iron metal using milder reaction conditions than in a blast furnace. (21.8), 848
Disaccharide a sugar formed from two monosaccharides joined by a glycoside linkage. (22.6), 891
Dispersion, colloidal, 461-462
Disproportionation reaction a reaction in which a given element is both oxidized and reduced. (20.13), 804
Dissociation constant, 555
Distillation a method for separating the components of a liquid mixture that depends on differences in the ease of vaporization of the components. (1.10), 28-29
Disulfide linkage an S—S bond that stabilizes the tertiary structure of many proteins. (22.6), 886
Dobereiner, Johann, 276
Double bond a bond in which two pairs of electrons are shared by two atoms. (8.8), 322

Downs cell a cell used for electrolyzing molten sodium chloride. (18.8), 736-737
Dry cell battery a common battery used in calculators, watches, radios, and portable audio players. (18.5), 723
Dry ice, 410, 411
\(D s p^{2}\) hybridization, 831
Dsp \({ }^{3}\) hybridization, 362-363, 787
\(D^{2} \mathrm{sp}^{3}\) hybridization, 363, 831
Dual nature of light the statement that light exhibits both wave and particulate properties. (7.2), 258
Duet rule, 326
Effusion the passage of a gas through a tiny orifice into an evacuated chamber. (5.7)
Effusion and diffusion, 196-198
Einstein, Albert, 255, 258, 759
Electrical conductivity the ability to conduct an electric current. (4.2), 119, 120
Electric arc method, 849
Electrical work, 714-716
Electrochemistry the study of the interchange of chemical and electrical energy. (18)
calculation of equilibrium constants for redox reactions in, 721-722
cell potential, electrical work, and free energy, 705-706, 714-716
commercial electrolytic processes, 733-737
corrosion, 726-728, 732
defined, 704
dependence of cell potential on concentration in, 717-722
electrolysis, 728-732
galvanic cells, 704-706
ion-selective electrodes, 721
Nernst equation, 718-720
standard reduction potentials, 706-713
Electrodes, ion-selective, 721
Electrolysis a process that involves forcing a current through a cell to cause a nonspontaneous chemical reaction to occur. (18.7), 728-730, 777
commercial processes, 733-737
of mixtures of ions, 731
of sodium chloride, 736-737
of water, 730, 779
Electrolytes
solutions, colligative properties of, 459-461
strong, 119, 120-121
from water versus sports drinks, 461
weak, 119, 121-123
Electrolytic cell a cell that uses electrical energy to produce a chemical change that would otherwise not occur spontaneously. (18.7), 728

Electromagnetic radiation radiant energy that exhibits wavelike behavior and travels through space at the speed of light in a vacuum. (7.1), 252-254 diffraction patterns, 259-260 dual nature of light and, 258
Electromotive force, 705
Electron a negatively charged particle that moves around the nucleus of an atom. (2.4), 43-44. See also Lewis structures affinity, 288-289
Aufbau principle and, 278-284
capture, 747

vapor pressure, 416
solubility, 641-649
involving complex ions, 656-660, 661
precipitation and qualitative analysis, 649-654, 655
Equilibrium constant the value obtained when equilibrium concentrations of the chemical species are substituted in the equilibrium expression. (13.2), 514-517 applications of, 522-531
calculation for redox reactions in electrochemical cells, 721-722
temperature dependence of, 696-697
treating systems that have small, 534-536
Equilibrium expression the expression (from the law of mass action) obtained by multiplying the product concentrations and dividing by the multiplied reactant concentrations, with each concentration raised to a power represented by the coefficient in the balanced equation. (13.2)
Equilibrium point (thermodynamic definition) the position where the free energy of a reaction system has its lowest possible value. (17.9), 692
Equilibrium position a particular set of equilibrium concentrations. (13.2)
Equivalence point (stoichiometric point) the point in a titration when enough titrant has been added to react exactly with the substance in solution being titrated. (4.8; 15.4), 144
Errors
random, 13
systematic, 13
Ester an organic compound produced by the reaction between a carboxylic acid and an alcohol. (22.4), 872-873
Ethane, 856, 869
Ethanol, 869
carbon mass percent in, 82
density of, 27
as fuel, 246
half-reaction with potassium dichro-
mate, 154-156
mass percent, 435
molality, 435
molarity in solution, 435
mole fraction, 435
oxidization to acetic acid, 872
production by acid catalysis, 503
solubility in water, 118, 123
spontaneous reactions and formation of, 687
Ethene, 863
Ethylene, 687
polymers based on, 879-881
\(s p^{2}\) hybridization in, 358
Ethylene glycol, 27, 453-454
Ethylenediaminetetraacetate (EDTA), 822-823
Evaporation, 415
Exact numbers, 15
Exothermic refers to a reaction where energy (as heat) flows out of the system. (6.1)

Exothermic reactions, 214
coal gasification, 240-241
Exponential notation expresses a number as \(N \times 10^{M}\), a convenient method for representing a very large or very small number and for easily indicating the number of significant figures. (1.5), 15
Extent of reaction, 524
Fahrenheit scale, 22-26
Families, elements, 52
Faraday a constant representing the charge on one mole of electrons; 96,485 coulombs. (18.3), 715
Fats
hydrogenation of, 501
molecules, solubility of, 118-119
Fat-soluble vitamins, 441-442
Feldspar, 408
Femtometer, 0.035, 265
Ferrochrome, 818
Fertilizers, 796
Fibrous proteins, 882
Filtration a method for separating the components of a mixture containing a solid and a liquid. (1.10), 29
Fire extinguishers, 427
Fireworks, 255, 256-257
First ionization energy, 285-286
First law of thermodynamics the energy of the universe is constant; same as the law of conservation of energy. (6.1), 215, 665
First-order rate laws, 479-481
half-life of first-order reaction, 481-483 pseudo-, 488
First-row transition metals, 813, 816-820
Fish in ocean ice, 462
Fission, nuclear the process of using a neutron to split a heavy nucleus into two nuclei with smaller mass numbers.
(19.6), 762-766

Flex-fuel, 246

Flotation process a method of separating the mineral particles in an ore from the gangue that depends on the greater wettability of the mineral pieces. (21.8), 844
Fluorine, 48, 776, 801
atomic number, 48
Aufbau principle and, 279
in formation of Freon-12, 324-325
Lewis structure, 326
octet rule and, 326
precipitation reactions with, 651-652
reaction with nitrogen dioxide, 491-492
Formal charge the charge assigned to an atom in a molecule or polyatomic ion derived from a specific set of rules. (8.12), 334-337

Formaldehyde, 871
Formation constant (stability constant) the equilibrium constant for each step of the formation of a complex ion by the addition of an individual ligand to a metal ion or complex ion in aqueous solution. (16.3), 656
Formula equation an equation representing a reaction in solution showing the reactants and products in undissociated form, whether they are strong or weak electrolytes. (4.6)
Formulas, chemical equations, 136-137 of ionic compounds, predicting, 311-312
Forward reactions, 472-474
mechanisms with fast, 492-494
Fossil fuel coal, petroleum, or natural gas; consists of carbon-based molecules derived from decomposition of once-living organisms. (6.5), 211
coal, 238-239
formation of, 237
petroleum and natural gas, 237-238
Fracking, 237
Frasch process the recovery of sulfur from underground deposits by melting it with hot water and forcing it to the surface by air pressure. (20.12), 777, 799
Free energy a thermodynamic function equal to the enthalpy \((H)\) minus the product of the entropy \((S)\) and the Kelvin temperature ( \(T\) ); \(G=H-T S\). Under certain conditions the change in free energy for a process is equal to the maximum useful work. (17.4), 675-678 chemical reactions and, 683-689 dependence on pressure, 689-692 in electrochemical cells, 714-716 equilibrium and, 692-697 work and, 697-698
Free radical a species with an unpaired electron. (22.5), 877-878

Freezing
effects on animals and plants, 462
physical changes with, 28
water, 424-425
Freezing point
depression, 452-454, 459
London dispersion forces and, 387
van't Hoff factor an, 459-460
Freon-12, 324-325
Freons, 324-325, 503, 861
Frequency the number of waves (cycles)
per second that pass a given point in space. (7.1), 252
electromagnetic radiation, 253-254
Frequency factor, 496
Fructose, 887, 888
Fry, Art, 7
Fuel. See also Gasoline
ethanol, 246
fossil, 211, 237-239
hydrogen as, 241-246
methanol as, 247
Fuel cell a galvanic cell for which the reactants are continuously supplied. (18.5), 724-725
Functional group an atom or group of atoms in hydrocarbon derivatives that contains elements in addition to carbon and hydrogen. (22.4), 868
Fundamental chemical laws, 37-40
Fusion the process of combining two light nuclei to form a heavier, more stable nucleus. (19.6)
heat of, 419
nuclear, 765-766
Galena, 151, 785
Galileo, 7
Gallium, 281, 784
Galvanic cell a device in which chemical energy from a spontaneous redox reaction is changed to electrical energy that can be used to do work. (18.1), 704-706 batteries as, 722-725
cell potential, 705-706
complete description of, 712-713
line notation, 711-712
standard reduction potentials, 706-713
Galvanizing a process in which steel is coated with zinc to prevent corrosion. (18.6), 727

Gamma ( \(\gamma\) ) rays a high-energy photon. (19.1), 747

Gangue the impurities (such as clay or sand) in an ore. (21.8), 843
Gas(es), 165
atmospheric, 165, 202-204
Avogadro's law, 172-173, 192
Boyle's law, 167-170, 191
Charles' law, 170-172, 191-192
collected over water, 187-189

Dalton's law of partial pressures, 183187, 192
effusion and diffusion, 196-198
equilibrium expressions, 518-520
greenhouse, 239-240
Henry's law, 443-444, 446
ideal gas law, 173-178
kinetic molecular theory of, 189-196, 199
laws, 167-173
molar mass of, 182-183
noble, 52, 805, 806
pressure, 165-167
real, 198-202
root mean square velocity, 194-196
separation of, 185
solutions, 434
state of matter, 27-30
stoichiometry, 179-183
synthesis, 240-241
van der Waals curves, 427, 428
Gasification, coal, 240-241
Gasoline, 238
enthalpy of combustion, 245-246
hydrogen as by-product of production of, 779
methanol as replacement for, 109-110
octane ratings, 96
standard enthalpies of formation, 234-235
tetraethyl lead in, 238
Gatorade, 461
Gay-Lussac, Joseph, 40-43
Geiger-Müller counter (Geiger counter)
an instrument that measures the rate of
radioactive decay based on the ions and electrons produced as a radioactive particle passes through a gas-filled chamber. (19.4), 754-755
Gems, 835
Gene a given segment of the DNA molecule that contains the code for a specific protein. (22.6), 894
Genetic damage due to radiation, 766
Genetic information in DNA and RNA, 894-895, 896
Geometrical (cis-trans) isomerism isomerism in which atoms or groups of atoms can assume different positions around a rigid ring or bond. (21.4), 826-830
Germanium, 785
Glass an amorphous solid obtained when silica is mixed with other compounds, heated above its melting point, and then cooled rapidly. (10.5), 406-407
Glass electrode an electrode for measuring
pH from the potential difference that develops when it is dipped into an aqueous solution containing \(\mathrm{H}^{+}\)ions. (18.4), 721

Globular proteins, 882
Glucose
boiling-point elevation, 452
freezing-point depression, 459
solubility of, 444
starch, 891-892
vapor pressure of solution of, 447-448
Glyceraldehyde, 888
Glycogen, 892
Glycoside linkage a \(\mathrm{C}-\mathrm{O}-\mathrm{C}\) bond
formed between the rings of two cyclic monosaccharides by the elimination of water. (22.6), 891
Gold, 748, 812
Goodyear, Charles, 875-876
Graduated cylinders, 14
Grafting, 881
Graham's law of effusion the rate of effusion of a gas is inversely proportional to the square root of the mass of its parti-
cles. (5.7), 197-198
Graphene, 405
Graphite, 227, 228, 230, 303
bonding compared to diamond, 404-405
Gray tin, 785
Grease, 440
Greenhouse effect a warming effect exerted by the earth's atmosphere (particularly \(\mathrm{CO}_{2}\) and \(\mathrm{H}_{2} \mathrm{O}\) ) due to thermal energy retained by absorption of infrared radiation. (6.5), 239-240
Ground state the lowest possible energy state of an atom or molecule. (7.4), 262-263
Group (of the periodic table) a vertical column of elements having the same valence electron configuration and showing similar properties. (2.7), 52
Group 1A elements, 778-779
Group 2A elements, 781-782, 783
Group 3A elements, 783-784
Group 4A elements, 784-787
Group 5A elements, 787-788
Group 6A elements, 797
Group 7A elements, 801-804
Group 8A elements, 52, 805, 806
Guldberg, Cato Maximilian, 514

\section*{Haber, Fritz, 536}

Haber process the manufacture of ammonia from nitrogen and hydrogen, carried out at high pressure and high temperature with the aid of a catalyst.
(20.2), 515

Hafnium, 284
Half-life
of first-order reactions, 481-483
molybdenum-99, 751
of radioactive samples, 750
of second-order reactions, 483-486
technetium-99m, 750

Half-life (of a radioactive sample) the time required for the number of nuclides in a radioactive sample to reach half of the original value. (19.2)
Half-life (of a reactant) the time required for a reactant to reach half of its original concentration. (12.4)
Half-reactions the two parts of an oxidationreduction reaction, one representing oxidation, the other reduction. (4.10) galvanic cells, 707-714
method for balancing oxidationreduction reactions, 152-158
transition metals, 815
Halides, hydrogen, 802-803
Halogen a Group 7A element. (2.7; 20.13), 52, 801-804
Halogenation the addition of halogen atoms to unsaturated hydrocarbons. (22.2), 866

Hard water water from natural sources that contains relatively large concentrations of calcium and magnesium ions. (20.4), 782
Hassium, 53
Heart attack, 758
Heat energy transferred between two objects due to a temperature difference between them. (6.1). See also
Temperature
capacity, 220
defined, 212
as extensive property, 222
of fusion, 419
of hydration, 439
process of, 213
radiation, 239
of solution, 438
treatment of steel, 849-850
of vaporization, 415, 419
Heat capacity the amount of energy required to raise the temperature of an object by one degree Celsius. (6.2)
Heat of hydration the enthalpy change associated with placing gaseous molecules or ions in water; the sum of the energy needed to expand the solvent and the energy released from the solventsolute interactions. (11.2)
Heat of solution the enthalpy change associated with dissolving a solute in a solvent; the sum of the energies needed to expand both solvent and solute in a solution and the energy released from the solvent-solute interactions. (11.2)
Heat of vaporization the energy required to vaporize one mole of a liquid at a pressure of one atmosphere. (10.8)
Heating curve a plot of temperature versus time for a substance where energy is added at a constant rate. (10.8), 419, 420
Heisenberg, Werner, 266

Heisenberg uncertainty principle a principle stating that there is a fundamental limitation to how precisely both the position and momentum of a particle can be known at a given time. (7.5), 267
Helium, 805, 806
Aufbau principle and, 278
Dalton's law of partial pressures and, 184-185
Lewis structure, 326
nuclear binding energy, 761
nuclear fusion to form, 765
photoelectron spectroscopy (PES), 288
polyelectronic atom, 274
Heme an iron complex. (21.7), 839
Hemoglobin a biomolecule composed of four myoglobin-like units (proteins plus heme) that can bind and transport four oxygen molecules in the blood. (21.7), 841-842

\section*{Henderson-Hasselbalch equation an} equation giving the relationship between the pH of an acid-base system and the concentrations of base and acid:
\(\mathrm{pH}=\mathrm{pK}_{\mathrm{a}}+\log \left(\frac{[\text { base }]}{[\text { acid }]}\right)\). (15.2), 607, 631
Henry's law the amount of a gas dissolved in a solution is directly proportional to the pressure of the gas above the solution. (11.3), 443-444, 446
Hess's law in going from a particular set of reactants to a particular set of products, the enthalpy change is the same whether the reaction takes place in one step or in a series of steps; in summary, enthalpy is a state function. (6.3), 225-229
Heterogeneous catalysis, 500, 501-502
Heterogeneous equilibrium an equilibrium involving reactants and/or products in more than one phase. (13.4), 520-522
Heterogeneous mixtures a mixture having visibly distinguishable parts. (1.10), 28
Heteronuclear diatomic molecules, bonding in, 376-377
Hexagonal closest packed (hcp) structure a structure composed of closest packed spheres with an \(a b a b a b\) arrangement of layers; the unit cell is hexagonal. (10.4), 398, 401
Hexamethylenediamine, 878
Hexane, liquid, 440
Hexoses, 887
High-altitude acclimatization, 842
High-carbon steels, 403
High-density polyethylene (HDPE), 879-881
High-spin case, 833
Homogeneous catalysis, 500, 502-503
Homogeneous equilibrium an equilibrium system where all reactants and products are in the same phase. (13.4), 520

Homogeneous mixtures a mixture having visibly indistinguishable parts. (1.10), 28
Homonuclear diatomic molecules, bonding in, 369-376
Homopolymer a polymer formed from the polymerization of only one type of monomer. (22.5), 878
Honeybees, 346-347
Hormones, 454
Hund's rule the lowest energy configuration for an atom is the one having the maximum number of unpaired electrons allowed by the Pauli exclusion principle in a particular set of degenerate orbitals, with all unpaired electrons having parallel spins. (7.11), 278
Hybrid orbitals a set of atomic orbitals adopted by an atom in a molecule different from those of the atom in the free state. (9.1)
Hybridization a mixing of the native orbitals on a given atom to form special atomic orbitals for bonding. (9.1). See also Lewis structures
\(d s p^{2}, 831\)
\(d s p^{3}, 362-363\)
\(d^{2} \mathrm{sp}^{3}, 363,831\)
sp, 360-361, 831
\(s p^{2}, 358-359\)
\(s p^{3}, 355-357,831\)
Hydration the interaction between solute particles and water molecules. (4.1), 118
enthalpy of, 439
using water versus sports drinks, 461
Hydraulic fracturing, 237
Hydride a binary compound containing hydrogen. The hydride ion, H 2 , exists in ionic hydrides. The three classes of hydrides are covalent, interstitial, and ionic. (20.3), 780
Hydrocarbon a compound composed of carbon and hydrogen. (22.1), 855. See also Organic chemistry alcohols, 868-871 aldehydes and ketones, 871-872
alkanes, 855-863
alkenes and alkynes, 863-866
amines, 575, 873
aromatic, 866-867
carboxylic acids and esters, 872-873 derivatives, 868-873
Hydrocarbon derivative an organic molecule that contains one or more elements in addition to carbon and hydrogen. (22.4)

Hydrochloric acid, 803
added to buffered solution, 610-611, 612-613
baking soda and, 99-100
chemical reaction with solid sodium hydrogen carbonate, 91
dipole moment, 309
hydronium ion from, 550
molarity of, 124-125
neutralization of sodium hydroxide, 142
solubility in water, 121
as strong acid, 553
in weak base-strong acid titrations, 627-629
Hydrocyanic acid, 584
Hydrofluoric acid, 562-563
acid-base equilibria, 600-601
Hydrogen
in acidic solutions containing common ions, 601-602
atomic spectrum of, 260-262
bonding, 385-386
chemistry of, 779-781
duet rule and, 326
effusion rate, 197
energy quantization in, 264
enthalpy of combustion, 245-246
as fuel, 241-246
ground state, 262-263
halides, 802-803
ideal gas law and, 174
Lewis structure, 326
line spectrum of, 261
molecular orbital model, 366-369
orbital shapes and energies, 270-273
quantum number, 269
in water molecule, 4-5
Hydrogen bonding unusually strong dipole-dipole attractions that occur among molecules in which hydrogen is bonded to a highly electronegative atom. (10.1)

Hydrogen chloride, 141
Hydrogen cyanide gas, 623-625
Hydrogen fluoride
dipole moment, 307
equilibrium concentrations in formation of, 530-531
polar covalent bonds in, 304-305
Hydrogen halides, 587
Hydrogen iodide, 533-534
Hydrogen sulfide, 310, 446
Hydrogenation, 501
Hydrogenation reaction a reaction in which hydrogen is added, with a catalyst present, to a carbon-carbon multiple bond. (22.2), 865
Hydrohalic acid an aqueous solution of a hydrogen halide. (20.13), 803
Hydrometallurgy a process for extracting metals from ores by use of aqueous chemical solutions. Two steps are involved: selective leaching and selective precipitation. (21.8), 845-846

Hydronium ion the \(\mathrm{H}_{3} \mathrm{O}^{+}\)ion; a hydrated proton. (14.1), 550
Hydrophilic substances, 442
Hydrophobic substances, 442
Hydroxide ion, 121
Hydroxyapatite, 641, 645
Hydroxyl radical, 877
Hypervitaminosis, 442
Hypochlorite ion, 564-565
Hypochlorous acid, 553, 614
Hypofluorous acid, 804
Hypophosphorous acid, 796
Hypothesis one or more assumptions put forth to explain the observed behavior of nature. (1.2)

Ice, 424-425
fish in ocean, 462
Ideal gas a hypothetical gas that strictly obeys the ideal gas law. (5.2)
Ideal gas law an equation of state for a gas, where the state of the gas is its condition at a given time; expressed by \(P V=n R T\), where \(P=\) pressure, \(V=\) volume, \(n=\) moles of the gas, \(R=\) the universal gas constant, and \(T=\) absolute temperature. This equation expresses behavior approached by real gases at high \(T\) and low P. (5.3), 173-178
kinetic molecular theory of gases and, 190-191, 193-194 van der Waals curves and, 427, 428
Ideal solution a solution whose vapor pressure is directly proportional to the mole fraction of solvent present. (11.4)
Indeterminate errors, 13
Indicator a chemical that changes color and is used to mark the end point of a titration. (4.8), 144
acid-base, 629-632, 633-634
Infrared radiation, 239
Initial rates, method of, 475-477
Insects, 876
semiochemicals, 346-347
Insoluble carbonates, 654-655
Insoluble chlorides, 654-655
Instantaneous dipole, 387
Instantaneous rate, 471
Integers, nonzero, 14
Integrated first-order rate law, 479-481
Integrated rate law an expression that shows the concentration of a reactant as a function of time. (12.2), 474, 478-489 first-order rate laws, 479-481
for reactions with more than one reactant, 487-489
second-order rate laws, 483-486
zero-order, 486-487
Integrated rate law for zero-order reaction, 486-487
Integrated second-order rate law, 483-486

Intermediate a species that is neither a reactant nor a product but that is formed and consumed in the reaction sequence. (12.5), 489

Intermolecular forces relatively weak interactions that occur between molecules. (10.1), 385
dipole-dipole forces, 385-386, 388 and distinguishing between chemical and physical change at molecular level, 388-389
London dispersion forces, 387-388
Internal energy a property of a system that can be changed by a flow of work, heat, or both; \(\Delta E=q+w\), where \(\Delta E\) is the change in the internal energy of the system, \(q\) is heat, and \(w\) is work. (6.1), 215-217
calculations, 217-218
enthalpy and, 218-220
International System (SI), 8, 10
Interpretation, theory as, 6
Interstitial alloys, 403
Interstitial hydrides, 780
Intramolecular bonding, 385
Iodine-131, 758
Ion an atom or a group of atoms that has a net positive or negative charge. (2.6)
Ion exchange (water softening) the process in which an ion-exchange resin removes unwanted ions (for example, \(\mathrm{Ca}^{2+}\) and \(\mathrm{Mg}^{2+}\) ) and replaces them with \(\mathrm{Na}^{+}\)ions, which do not interfere with soap and detergent action. (20.4), 782
Ion-exchange resin, 782
Ion pairing a phenomenon occurring in solution when oppositely charged ions aggregate and behave as a single particle. (11.7)
Ion product, 649
Ion-product constant, 555
Ion-product (dissociation) constant ( \(K_{w}\) ) the equilibrium constant for the autoionization of water; \(K_{\mathrm{w}}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]\). At \(258 \mathrm{C}, K_{\mathrm{w}}=1.0 \times 10^{-14}\). (14.2)
Ion-selective electrode an electrode sensitive to the concentration of a particular ion in solution. (18.4)
Ionic bonding the electrostatic attraction between oppositely charged ions. (2.6; 8.1), 50-51, 302

Ionic compound (binary) a compound that results when a metal reacts with a nonmetal to form a cation and an anion. (8.1)
Ionic compounds/salts acid-base properties of, 582-586, 587 binary type I, 54-55
binary type II, 55-57
bonds in, 302
desalination from seawater, 458,459 electron configuration of, 310
energy effects in binary, 314-317
hydration of, 118
with polyatomic ions, 57-59
precipitation reactions, 131-136
predicting formulas of, 311-312
relative solubilities of, 646
simple rules for solubility in water, 134 solubility, 118
as strong electrolytes, 120
that produce acidic solutions, 584
as weak bases, 583
Ionic hydrides, 780
Ionic solid a solid containing cations and anions that dissolves in water to give a solution containing the separated ions, which are mobile and thus free to conduct an electric current. ( \(2.6 ; 10.3\) ), 51, 396, 412-415
Ionization energy, 284-287
photoelectron spectroscopy (PES), 287-288
transition metals, 815
Ionization of acids, 121
Ions, 48-51, 49
complex, 656-660, 661
concentration of, 125-126
electrolysis of mixtures of, 731
electron configurations and sizes, 310-314
isoelectronic, 312-313
polyatomic, 51
sizes of, 312-314
spectator, 137
in unit cell, determining, 413-414
Ion-selective electrodes, 721
Iron, 819
in the body, 839-840
corrosion of, 696, 726-727
electrorefining, 734
half-reaction with permanganate, 153-154
metallurgy of, 846-848
open hearth process, 848-849
oxidation-reduction titration, 158-159
pig, 847-848, 849
scrap, 849
Iron nitrate, writing reaction equations for, 137-138
Iron oxide in thermite reaction, 234
Irreversible process any real process.
When a system undergoes the changes
State \(1 \rightarrow\) State \(2 \rightarrow\) State 1 by any real pathway, the universe is different than
before the cyclic process took place in the system. (17.10), 698
Isoelectronic ions, ions containing the same number of electrons. (8.4), 312-313
Isomerism, 825-830
in alkanes, 857
cis-trans, 826-830, 864
linkage, 826
stereo-, 826-830
structural, 825-826, 857

Isomers species with the same formula but different properties. (21.4)
Isopentyl acetate, 79
Isopropyl alcohol, density of, 27
Isotactic chain a polymer chain in which the substituent groups such as CH 3 are all arranged on the same side of the chain. (22.5), 880
Isotonic solutions, 457
Isotopes, 47, 744
Juglone, 77-78, 346
Joule the SI unit for energy, defined as \(\mathrm{kg} * \mathrm{~m}^{2} / \mathrm{s}^{2}\). (5.6)
K. See Equilibrium constant

Kairomones, 346-347
Kaolinite, 408
Kelvin scale, 22-26, 171, 194
Kerogen, 246
Ketone an organic compound containing the carbonyl group

bonded to two carbon atoms. (22.4), 871-872
Kinetic energy \(\left(\frac{1}{2} m v^{2}\right)\) energy due to the motion of an object; dependent on the mass of the object and the square of its velocity. (6.1), 211-212, 258
Kinetic molecular theory (KMT) a model
that assumes that an ideal gas is composed of tiny particles (molecules) in constant motion. (5.6), 189-196, 199 deriving ideal gas law from, 193-194
Kinetics, chemical, 468
activation energy in, 495-500, 500-506
catalysis, 500-506
determining form of rate law in, 474-478 goals of, 468
integrated rate law, 474, 478-489
introduction to rate laws in, 472-474
model for, 494-500
reaction mechanisms, 489-494
reaction rates, 468-472
Kinetic stability, 744
Krypton, 281, 805
\(K_{s p}\). See Solubility, product
Lactic acid
percent dissociation of, 569-570
pH of, 608
Lake Nyos, Cameroon, 446
Lamp oil, 237-238
Lanthanide contraction the decrease in the atomic radii of the lanthanide series elements, going from left to right in the periodic table. (21.1)

Lanthanide series a group of 14 elements following lanthanum in the periodic table, in which the \(4 f\) orbitals are being filled. (7.11; 20.1; 21.1), 282, 773, 816
Lattice a three-dimensional system of points designating the positions of the centers of the components of a solid (atoms, ions, or molecules). (10.3)
Lattice, crystalline solid, 393, 410
Lattice energy the energy change occurring when separated gaseous ions are packed together to form an ionic solid. (8.5), 314 calculations, 316-317
"Laughing gas," 794
Lavoisier, Antoine, 8, 37-38
Law of conservation of energy energy can be converted from one form to another but can be neither created nor destroyed. (6.1), 211, 665

Law of conservation of mass mass is neither created nor destroyed. (1.2;2.2), 6, 38
Law of definite proportion a given compound always contains exactly the same proportion of elements by mass. (2.2), 38
Law of mass action a general description of the equilibrium condition; it defines the equilibrium constant expression.
(13.2), 514-516
equilibrium positions and, 517
Law of multiple proportions a law stating that when two elements form a series of compounds, the ratios of the masses of the second element that combine with one gram of the first element can always be reduced to small whole numbers. (2.2), 38-40

Leaching the extraction of metals from ores using aqueous chemical solutions. (21.8), 845

Lead, 785
decay series, 748,749
poisoning, 785-787
precipitation reactions with, 650-651, 652-653
storage batteries, 436-437, 722-723
Leading zeros, 14
Lead nitrate, 139-140
Lead storage battery a battery (used in cars) in which the anode is lead, the cathode is lead coated with lead dioxide, and the electrolyte is a sulfuric acid solution. (18.5)
Lead sulfide, 151
Le Châtelier, Henri Louis, 536
effect of change in concentration, 537-538
effect of change in pressure, 539-541 effect of change in temperature, 541-542

Le Châtelier's principle if a change is imposed on a system at equilibrium, the position of the equilibrium will shift in a direction that tends to reduce the effect of that change. (13.7), 536-542
acid-base equilibria and, 600 autoionization of water and, 556-557
heat treatment of steel and, 849-850
Length, bond, 304
Leucine, 882-883
Leucippos, 36
Lewis acid an electron-pair acceptor. (14.11)
Lewis acid-base model, 589-591
Lewis base an electron-pair donor. (14.11)
Lewis structure a diagram of a molecule showing how the valence electrons are arranged among the atoms in the molecule. (8.10), 325-329. See also Hybridization; VSEPR (valence shell electronpair repulsion) model
formal charge, 334-337
octet rule exceptions and, 329-332
odd-electron molecules, 334 resonance and, 333-337
Ligand a neutral molecule or ion having a lone pair of electrons that can be used to form a bond to a metal ion; a Lewis base. (21.3), 822-823
Light
dual nature of, 258
optical isomerism and, 826-830
Lime in steel production, 848-849
Lime-soda process a water-softening method in which lime and soda ash are added to water to remove calcium and magnesium ions by precipitation. (14.6), 571
Limestone
caves, 649
scrubbing using, 204
slag, 847
Limiting reactant (limiting reagent) the reactant that is completely consumed when a reaction is run to completion. (3.11), 100-110 determined using quantities of products formed, 106-107
determined using reactant quantities, 105-106
Line notation in electrochemical cells, 711-712
Line spectrum a spectrum showing only certain discrete wavelengths. (7.3), 261
Linear accelerator a type of particle accelerator in which a changing electrical field is used to accelerate a positive ion along a linear path. (19.3), 752
Linkage isomerism isomerism involving a complex ion where the ligands are all the same but the point of attachment of at least one of the ligands differs. (21.4), 826

Liquefaction the transformation of a gas into a liquid. (20.1), 777
Liquids, 384. See also Aqueous solutions changes of state, 419-422
condensation of, 415-416
density measurement of, 26-27
intermolecular forces, 385-390
smart, 392
solutions, 434
state of matter, 27-30, 390-392
structural model for, 391-392
superheated, 421-422
vapor pressure and, 415-419
Lithium, 778-779
Aufbau principle and, 278
ion batteries, 724
Lithium fluoride, 314-316
Lithium hydride, 780
Lithium hydroxide, 98-99
Localized electron (LE) model a model that assumes that a molecule is composed of atoms that are bound together by sharing pairs of electrons using the atomic orbitals of the bound atoms. (8.9), 325, 364-366 combined with molecular orbital
models, 377-379, 380
in complex ions, 830-831
\(d s p^{3}, 362-363\)
\(d^{2} \mathrm{sp}^{3}, 363\)
octet rule and, 329-331
sp, 360-361
\(s p^{2}, 358-359\)
\(s p^{3}, 355-357\)
\(s p^{3}\) hybridization, 355-357
London dispersion forces the forces, existing among noble gas atoms and nonpolar molecules, that involve an accidental dipole that induces a momentary dipole in a neighbor. (10.1), 387-388
Lone pair an electron pair that is localized on a given atom; an electron pair not involved in bonding. (8.9), 325, 341
Low-density polyethylene (LDPE), 879-881
Lowry, Thomas, 550
Low-spin case, 833
Lysine, 882-883

Magnesium hydroxide, 648
Magnetic quantum number ( \(\boldsymbol{m}_{\ell}\) ) the quantum number relating to the orientation of an orbital in space relative to the other orbitals with the same \(\ell\) quantum number. It can have integral values between \(\ell\) and \(-\ell\), including zero. (7.6), 269

Magnetism, 372-374, 375-376
Magneto-rheological (MR) fluid, 392
Main-group (representative) elements elements in the groups labeled \(1 \mathrm{~A}, 2 \mathrm{~A}\), \(3 \mathrm{~A}, 4 \mathrm{~A}, 5 \mathrm{~A}, 6 \mathrm{~A}, 7 \mathrm{~A}\), and 8 A in the periodic table. The group number gives the sum of the valence \(s\) and \(p\) electrons. (7.11), 283

Major species the components present in relatively large amounts in a solution. (14.3)

Manganese, 819
Aufbau principle and, 280
Manhattan Project, 764
Manometer a device for measuring the pressure of a gas in a container. (5.1), 166-167
Mars Climate Orbiter, 10
Mass the quantity of matter in an object. (1.3), 10-11
atomic, 40, 70-72
calculating number of moles and, 76-77
counting by weighing, 69-70
critical, 763
in density measurement, 26-27
law of conservation of, 6,38
law of definite proportion and, 38
law of multiple proportions and, 38-40
measurement uncertainty and, 12
molar, 77-79, 182-183
number, 47
of product formed, 138-140
Mass defect the change in mass occurring when a nucleus is formed from its component nucleons. (19.5)
Mass number the total number of protons and neutrons in the atomic nucleus of an atom. \((2.5 ; 18), 744\)
Mass percent the percent by mass of a component of a mixture (11.1) or of a given element in a compound. (3.5), 82, 85-90, 434
ethanol, 435
Mass spectrometer an instrument used to determine the relative masses of atoms by the deflection of their ions on a magnetic field. (3.2), 70, 72, 73
Mathematics rounding, 16 significant figures, 14-17
Matter the material of the universe. (1.10) classification of, 27-30 nature of, 254-260
Measurement a quantitative observation. (1.2) density, 26-27
dimensional analysis, 18-22
precision and accuracy, 13-14
significant figures and calculations, 14-17
temperature, 22-26
uncertainty in, 11-14

of weak acids, pH of, 565-567
mm Hg unit. See Millimeters of mercury
M\&Ms candies, 402

Models (theory) a set of assumptions put forth to explain the observed behavior of matter. The models of chemistry usually involve assumptions about the behavior of individual atoms or molecules. (1.2), 6-8
Moderator a substance used in a nuclear reactor to slow down the neutrons. (19.6)

Molal boiling-point elevation constant a constant characteristic of a particular solvent that gives the change in boiling point as a function of solution molality; used in molecular weight determinations. (11.5), 451
Molal freezing-point depression constant a constant characteristic of a particular solvent that gives the change in freezing point as a function of the solution molality; used in molecular weight determinations (11.5), 453
Molality the number of moles of solute per kilogram of solvent in a solution. (11.1), 434
Molar heat capacity the energy required to raise the temperature of one mole of a substance by one degree Celsius. (6.2), 220
Molar mass the mass in grams of one mole of molecules or formula units of a substance; also called molecular weight. (3.4), 77-79
calculated by boiling-point elevation, 452
calculated by freezing-point depression, 454
determined from osmotic pressure, 456-457
determining empirical and molecular formulas using, 85-90
of gases, 182-183
Molar volume the volume of one mole of an ideal gas; equal to 22.42 liters at STP. (5.4), 179

Molarity moles of solute per volume of solution in liters. (4.3; 11.1), 123-130, 434, 435
concentration and volume, 126-127 concentration of ions and, 125-126 solution composition calculated from, 436-437
Mole the number equal to the number of carbon atoms in exactly 12 grams of pure \({ }^{12} \mathrm{C}\) : Avogadro's number. One mole represents \(6.022 \times 10^{23}\) units. (3.3), 72-77
calculating mass and number of, 76-77 calculating numbers of atoms using, 76 determining number of atoms and, 75 ideal gas law and calculation of, 174 milli-, 615
in molarity, 123-130
ratio in stoichiometric calculations, 97 used to determine mass of sample of atoms, 74-75
Mole fraction the ratio of the number of moles of a given component in a mixture to the total number of moles in the mixture. \((5.5 ; 11.1), 185-186,434\) ethanol, 435
Mole ratio (stoichiometry) the ratio of moles of one substance to moles of another substance in a balanced chemical equation. (3.10)
Molecular formula the exact formula of a molecule, giving the types of atoms and the number of each type. (3.7), 85-90
Molecular orbital (MO) model a model that regards a molecule as a collection of nuclei and electrons, where the electrons are assumed to occupy orbitals much as they do in atoms, but having the orbitals extend over the entire molecule. In this model the electrons are assumed to be delocalized rather than always located between a given pair of atoms. (9.2; 10.4), 366-369
in homonuclear diatomic molecules, 369-376
localized electron model combined with, 377-379, 380
for metals, 401
paramagnetism in, 372-374
Molecular orientations (kinetics) orientations of molecules during collisions, some of which can lead to reaction while others cannot. (12.6), 496
Molecular solid a solid composed of neutral molecules at the lattice points. (10.3), 396, 410-411, 412

Molecular structure the three-dimensional arrangement of atoms in a molecule. (8.13)

Molecularity the number of species that must collide to produce the reaction represented by an elementary step in a reaction mechanism. (12.5), 490
Molecule a bonded collection of two or more atoms of the same or different elements. (2.6), 48-51
biologically important (See Natural polymers)
diatomic homonuclear, 369-376
distinguishing between physical and chemical changes in, 388-389
intermolecular forces, 385-390
Lewis structures, 325-329
molar mass and number of, 79
odd-electron, 334
photoelectron spectroscopy, 374
VSEPR model, 337-350
water as polar, 117

Molybdenum, 751, 816
Monodentate (unidentate) ligand a ligand that can form one bond to a metal ion. (21.3)

Monomers, 874 of nucleic acids, 893
Monoprotic acid an acid with one acidic proton. (14.2), 553, 626-627
Monosaccharide (simple sugar) a polyhydroxy ketone or aldehyde containing from three to nine carbon atoms. (22.6), 887-890
Myer, Julius Lothar, 276
Myoglobin an oxygen-storing biomolecule consisting of a heme complex and a proton. (21.7), 840-841

Naming of compounds. See Nomenclature
N -amyl acetate, 872
National Aeronautics and Space Administration (NASA), 9
Natural gas, 237-238
Natural law a statement that expresses generally observed behavior. (1.2), 6
Natural polymers, 881-895, 896
carbohydrates, 887-892
nucleic acids, 892-895, 896
proteins as, 881-886, 887
Neon, 805
Neoprene, 875
Neptunium, 748
Nernst equation an equation relating the potential of an electrochemical cell to the concentrations of the cell components: \(\mathscr{E}=\mathscr{E}^{\circ}-\frac{0.0591}{n} \log (Q)\) at \(25^{\circ} \mathrm{C}\) (18.4), 718-720
Net ionic equation an equation for a reaction in solution, where strong electrolytes are written as ions, showing only those components that are directly involved in the chemical change. (4.6), 137
Network solid an atomic solid containing strong directional covalent bonds. (10.5) carbon and silicon as, 403-410
Neutralization reaction an acid-base reaction. (4.8), 141-143. See also Acid-base reactions titration, 144-146
Neutron a particle in the atomic nucleus with mass virtually equal to the proton's but with no charge. \((2.5 ; 19), 46-47\), 744-745, 746
binding energy, 759
Newlands, John, 276
New System of Chemical Philosophy, A, 40
Nickel, 812, 820
Niobium, 816
Nitrate, 149

Nitric acid, 794
neutralization with potassium hydroxide, 143
solubility in water, 121
as strong acid, 553
Nitric oxide
in the atmosphere, 502-503
bonding in, 376-377
Nitrogen
Aufbau principle and, 279
chemistry of, 788-794
electron affinity, 289
formation with oxygen into nitrogen dioxide, 472-474

gas stoichiometry, 179
under high pressure, 329
law of multiple proportions and, 39-40
liquid, 777
localized electron model, 361, 362
mole fraction in air, 187
nuclear transformations, 752
separation from methane, 185
Nitrogen cycle the conversion of N 2 to nitrogen-containing compounds, followed by the return of nitrogen gas to the atmosphere by natural decay processes. (20.8)
Nitrogen dioxide decomposition, 468-472
reaction mechanism with carbon monoxide, 489,491
reaction with fluorine, 491-492
standard enthalpies of formation, 233-234
Nitrogen fixation the process of transforming \(\mathrm{N}_{2}\) to nitrogen-containing compounds useful to plants. (20.8)
Nitrogen-fixing bacteria bacteria in the root nodules of plants that can convert atmospheric nitrogen to ammonia and other nitrogen-containing compounds useful to plants. (20.8)
Nitrosyl chloride, 534-536
Nitrous acid, 553, 794
Noble gas a Group 8A element. (2.7; 0.14), 52, 805, 806
\(N\)-octyl acetate, 872
Nodal surfaces, 270
Nodes an area of an orbital having zero
electron probability. (7.7), 270-271
Nomenclature
acids, 62-63
alcohols, 870-871
aldehydes, 871
alkanes, 858-861
alkenes, 863
alkynes, 864
amines, 873

binary covalent compounds (type III), 59-62
binary ionic compounds (type I), 54-55
binary ionic compounds (type II), 55-57
coordination compounds, 823-825
esters, 873
ionic compounds with polyatomic ions, 57-59
simple compounds, 53-63
Nonelectrolyte a substance that, when dissolved in water, gives a nonconducting solution. (4.2), 119, 123
Nonideal solutions, 448-450
Nonmetal an element not exhibiting metallic characteristics. Chemically, a typical nonmetal accepts electrons from a metal. (2.7), 52
binary covalent compounds (type III), 59-62
Nonspontaneous reactions, 688-689
Nonzero integers, 14
Normal boiling point the temperature at which the vapor pressure of a liquid is exactly one atmosphere. (10.8)
Normal melting point the temperature at which the solid and liquid states have the same vapor pressure under conditions where the total pressure on the system is one atmosphere. (10.8), 421
Normal, straight-chain hydrocarbons, 856
Normality the number of equivalents of a substance dissolved in a liter of solution. (11.1), 436

N-type semiconductors, 409
Nuclear atom an atom having a dense center of positive charge (the nucleus) with electrons moving around the outside. (2.4), 45-46
Nuclear fission, 762-766
Nuclear fusion, 762-766
Nuclear reactors, 764-765
Nuclear transformation the change of one element into another. (19.3)
Nucleic acids, 892-895, 896
Nucleon a particle in an atomic nucleus, either a neutron or a proton. (19), 744
Nucleotide a monomer of the nucleic acids composed of a five-carbon sugar, a nitrogen-containing base, and phosphoric acid. (22.6), 893
Nucleus the small, dense center of positive
charge in an atom. (2.4), 744
binding energy, 759-761
fission and fusion, 762-766
kinetics of radioactive decay and, 749-751
stability and radioactive decay, 744-748, 749
thermodynamic stability of, 758-761
transformations, 752-754

Nuclide the general term applied to each unique atom; represented by \({ }_{Z}^{A} \mathrm{X}\), where X is the symbol for a particular element.
(19) 744-745, 746, 747
radioactive, 757-758
radiotracer, 757
Nylon, 874-875, 878-879
Octahedral complexes, 832-836
Octahedral holes in ionic solids, 412
Octahedral structure, 342
Octane ratings, gasoline, 96
standard enthalpies of formation, 234-235
Octet rule the observation that atoms of nonmetals tend to form the most stable molecules when they are surrounded by eight electrons (to fill their valence orbitals). (8.10), 326, 327
exceptions, 329-332
Odd-electron molecules, 334
Oil shale, 246
Open hearth process a process for producing steel by oxidizing and removing the impurities in molten iron using external heat and a blast of air or oxygen. (21.8), 848-849
Optical isomerism isomerism in which the isomers have opposite effects on planepolarized light. (21.4), 826-830
Orbital a specific wave function for an electron in an atom. The square of this function gives the probability distribution for the electron. (7.5)
Aufbau principle and, 278-284
bonding in heteronuclear diatomic molecules, 376-377
bonding in homonuclear diatomic molecules, 369-376
in complex ions, 830-831
\(d^{2} \mathrm{sp}^{3}\) hybridization, 363
\(d s p^{3}\) hybridization, 362-363
first-row transition metals, 813-814
hybrid, 357
molecular orbital model, 366-369
polyelectronic atoms, 274-275
quantum numbers of, 269-270
shapes and energies, 270-273
\(s p\) hybridization, 360-361
\(s p^{2}\) hybridization, 358-359
\(s p^{3}\) hybridization, 355-357
\(\boldsymbol{d}\)-Orbital splitting a splitting of the \(d\) orbitals of the metal ion in a complex such that the orbitals pointing at the ligands have higher energies than those pointing between the ligands. (21.6)
Order (of reactant) the positive or negative exponent, determined by experiment, of the reactant concentration in a rate law. (12.2)
Order, bond, 369, 375-376

Organic acid an acid with a carbon-atom backbone; often contains the carboxyl group. (14.2), 553
Organic chemistry the study of carboncontaining compounds (typically chains of carbon atoms) and their properties. (22), 855
alcohols, 868-871
aldehydes and ketones, 871-872
alkanes, 855-863
alkenes and alkynes, 863-866
amines, 575, 873
aromatic hydrocarbons, 866-867
carboxylic acids and esters, 872-873
hydrocarbon derivatives, 868-873
polymers, 874-881
Orientation, molecular, 496
Orthophosphoric acid, 796
Osmosis the flow of solvent into a solution through a semipermeable membrane. (11.6), 455
reverse, 458, 459
Osmotic pressure ( \(\pi\) ) the pressure that must be applied to a solution to stop osmosis; \(\pi=M R T\). (11.6), 454-458, 459
Ostwald process a commercial process for producing nitric acid by the oxidation of ammonia. (20.8)
Overall reaction order, 477
Oxidation an increase in oxidation state (a loss of electrons). (4.9)
Oxidation-reduction (redox) reaction a reaction in which one or more electrons are transferred. (4.9), 130
balancing, 152-158
calculation of equilibrium constants for, 721-722
characteristics of, 150-152
composition of solutions in, 436
galvanic cells and, 704-706
oxidation states in, 147-150
in production of steel, 848
standard reduction potentials, 706-713 titrations, 158-159
Oxidation states a concept that provides a way to keep track of electrons in oxida-tion-reduction reactions according to certain rules. (4.9; 21.3), 147-150 transition metals, 815, 821
Oxides
acid-base properties of, 589
phosphorus, 795-796
sulfur, 800
Oxidizing agent (electron acceptor) a reactant that accepts electrons from another reactant. (4.9), 151
Oxyacid an acid in which the acidic proton is attached to an oxygen atom. (14.2), 553, 587-588, 803 phosphorus, 795-796 sulfur, 800-801

Oxyanions, 58, 803
Oxygen
Aufbau principle and, 279
chemistry of, 797-798
Dalton's law of partial pressures and mixture of helium with, 184-185
electron affinity, 289
formation with nitrogen into nitrogen dioxide, 472-474
gas stoichiometry of mixing methane with, 180-182
law of multiple proportions and, 39-40
liquid, 777
molecular orbital model, 375
nomenclature of anion-containing, 62-63
nuclear stability, 758-760
as ozone, 203, 502-503, 798
partial pressure in air, 187
reaction with propane, 95-97
in sand, 3
in water molecule, 4-5
Oxygen difluoride, 804
Ozone \(\mathrm{O}_{3}\), the form of elemental oxygen in addition to the much more common \(\mathrm{O}_{2}\).
(20.11), 203, 502-503, 798

Ozonolysis, 798
Packing, closest, 397-398
Palladium, 780, 812
Paper chromatography, 29
Paracelsus, 36
Paramagnetism a type of induced magnetism, associated with unpaired electrons, that causes a substance to be attracted into the inducing magnetic field. (9.3), 372-374, 798
Partial pressures the independent pressures exerted by different gases in a mixture. (5.5), 183-187
gas collection over water and, 187-189
kinetic molecular theory of gases and, 192
Particle accelerator a device used to accelerate nuclear particles to very high speeds. (19.3), 752
Pascal the SI unit of pressure; equal to newtons per meter squared. (5.1), 167
Pathway, energy, 212, 232
Pauli, Wolfgang, 273
Pauli exclusion principle in a given atom no two electrons can have the same set of four quantum numbers. (7.8), 273
Pauling, Linus, 305
Pencils, 303
Penetration effect, 275
Penicillin, 828
Pentane, 857-858
Pentoses, 887

Peptide linkage the bond resulting from the condensation reaction between amino acids; represented by:

(22.6), 882

Percent composition of compounds, 81-83
Percent dissociation the ratio of the amount of a substance that is dissociated at equilibrium to the initial concentration of the substance in a solution, multiplied by 100. (14.5), 567-570
Percent yield the actual yield of a product as a percentage of the theoretical yield. (3.11), 109-110

Perchloric acid, 553, 804
Period a horizontal row of elements in the periodic table. (2.7), 53
Periodic table a chart showing all the elements arranged in columns with similar chemical properties. (2.7), 51-53
alkali metals in, 291-292
Aufbau principle and, 278-284
element 117, 753
history of, 276-277
trends in atomic properties, 284-291
PerkinElmer, Inc., 135
Permanganate
half-reaction between iron and,
153-154
titration, 158
Petroleum, 237-238
pH, 557-560
buffered solutions, 603, 608-610
changes in buffered solutions, 604-605
in mixture of weak acids, 565-567
percent dissociation and, 567-570
polyprotic acids, 578-581
solubility and, 648-649
strong acid solutions, 560-561
strong bases, 572
titrations and, 615-629
weak acid solutions, 562-570
when adding strong acid to buffered solution, 610-611
pH curve (titration curve) a plot showing the pH of a solution being analyzed as a function of the amount of titrant added. (15.4)
pH scale a \(\log\) scale based on 10 and equal to \(-\log \left[\mathrm{H}^{+}\right]\); a convenient way to represent solution acidity. (14.3)
Phase diagram a convenient way of representing the phases of a substance in a
closed system as a function of temperature and pressure. (10.9), 422-427, 428 for carbon dioxide, 425, 427
for water, 424-425
Phenol, 870
Phenolphthalein, 629

Phenyl group the benzene molecule minus
one hydrogen atom. (22.3), 867
Pheromones, 2-3, 347
Phosphoric acid, 796
as polyprotic acid, 576, 577-579
as triprotic acid, 577
as weak acid, 553
Phosphorus
black, 795
chemistry of, 795-796
in fertilizers, 796
first ionization energy, 287
oxides and oxyacids, 795-796
red, 795
white, 795
Phosphorus pentachloride, 331-332, 343-344
decomposition to liquid phosphorus trichloride and chlorine gas, 522
\(d s p^{3}\) hybridization, 362
equilibrium pressure, 526-527
Phosphorus trichloride, 522
Photochemical smog air pollution produced by the action of light on oxygen, nitrogen oxides, and unburned fuel from auto exhaust to form ozone and other pollutants. (5.10), 203
Photoelectric effect, 255-259
Photoelectron spectroscopy (PES)
for atoms, 287-288
for molecules, 374
Photon a quantum of electromagnetic radiation. (7.2)
Photon, energy of, 255
Photons, gamma rays, 747
Photosynthesis, 236, 688, 840
Physical change a change in the form of a substance, but not in its chemical composition; chemical bonds are not broken in a physical change. (1.10), 28
\(\operatorname{Pi}(\boldsymbol{\pi})\) bond a covalent bond in which parallel \(p\) orbitals share an electron pair occupying the space above and below the line joining the atoms. (9.1), 359, 378, 774-775
delocalized, 379
Pi molecular orbitals, 371
Pig iron, 847, 848-849
Pipets, 129
Planck, Max, 254, 258
Planck's constant the constant relating the change in energy for a system to the frequency of the electromagnetic radiation absorbed or emitted; equal to \(6.626 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s} .(7.2), 254,255,267\)
Plants
allomones, 346
coal from, 238-239
enzymes as catalysts, 504
ice effects on, 462
slippery pitcher, 876
thermogenic, 221

Plating
electro-, 730
metal, 735
Platinum, 748, 812, 816
Pleated sheet, 884-885
P-n junction, 409-410
Poisoning, lead, 785-787
Polar and nonpolar molecules, forces between, 390
Polar covalent bond a covalent bond in which the electrons are not shared equally because one atom attracts them more strongly than the other. (8.1), 304
Polar fish, 462
Polarity, bond, 307-310
Polarizability, 387
Polar molecule a molecule that has a permanent dipole moment. (4.1) water as, 117, 391
Pollution
air, 203, 471, 501
thermal, 444
Polonium, 797
Polyatomic ion an ion containing a number of atoms. (2.6), 51
ionic compounds with, 55-57
Polyatomic molecules, dipolar behavior in, 307
Polydentate ligands, 822
Polyelectronic atom an atom with more than one electron. (7.9), 274-275 ionization energy, 285
Polyesters, 879
Polyethylene, 876
Polymer a large, usually chainlike molecule built from many small molecules (monomers). (22.5), 874-881
based on ethylene, 879-881
development and properties of,
874-876
natural, 881-895, 896
proteins, 881-886, 887
types of, 876-879
Polymerization a process in which many small molecules (monomers) are joined together to form a large molecule.
(22.2), 866
addition, 877
condensation, 878
Polypeptide a polymer formed from amino acids joined together by peptide linkages. (22.6), 882,884
Polyprotic acid an acid with more than one acidic proton. It dissociates in a stepwise manner, one proton at a time. (14.7), 576-581
common ion effect and, 601
pH of, 578-579
titrations, 634-635
Polystyrene, 881
Polyvinyl chloride (PVC), 881

Porous disk a disk in a tube connecting two different solutions in a galvanic cell that allows ion flow without extensive mixing of the solutions. (18.1), 705
Porphyrin a planar ligand with a central ring structure and various substituent groups at the edges of the ring. (21.7), 840
Positional probability a type of probability that depends on the number of arrangements in space that yield a particular state. (17.1), 669-670
Positron production a mode of nuclear decay in which a particle is formed having the same mass as an electron but opposite charge. The net effect is to change a proton to a neutron. (19.1), 747
Post-it Notes, 7
Potassium, 889
Aufbau principle and, 280
blockage by black mamba snake venom, 293
nuclear equations, 748
Potassium chlorate collection over water, 188-189
Potassium chloride precipitation reactions, 133-134
writing reaction equations for, 137-138
Potassium chromate, precipitation reactions, 131-133
Potassium dichromate half-reaction between ethanol and, 154-156
titration, 158
Potassium hydroxide as base, 571
neutralization with nitric acid, 143
reaction with acetic acid, 141
writing reaction equations for, 137-138
Potassium iodate, 650
Potassium iodide, 440
Potential energy energy due to position or composition. (6.1), 211-212
Potentiometers, 559, 706
Precipitates, 131
Precipitation reaction a reaction in which an insoluble substance forms and separates from the solution. (4.5), 130, 131-136
predicting reaction products of, 136 selective, 652-653
solubility and, 649-653
stoichiometry of, 138-140
Precision the degree of agreement among several measurements of the same quantity; the reproducibility of a measurement. (1.4), 13-14
Pressure, 165-167
calculating equilibrium concentrations and, 526-531
constant-pressure calorimetry, 222-224

Pressure (continued)
conversions, 167
critical, 424
Dalton's law of partial pressures, 183189, 192
dependence of free energy on, 689-692
effect on ice, 424
effect on solubility, 442-444
enthalpy and, 218-220
equilibrium effect of change in, 539-541
equilibrium expressions involving, 518-520
ideal gas law and, 173-178
kinetic molecular theory of gases and, 191
nitrogen under high, 329
osmotic, 454-458, 459, 460
phase diagrams, 422-427, 428
PV work, 217
real gases and, 198-201
units of, 166-167
vapor, 415-419
Priestley, Joseph, 37
Primary structure (of a protein) the order (sequence) of amino acids in the protein chain. (22.6), 882
Primer pheromones, 347
Principal quantum number ( \(n\) ) the
quantum number relating to the size and energy of an orbital; it can have any positive integer value. (7.6), 269
Probability, positional, 669-670
Probability distribution the square of the
wave function indicating the probability of finding an electron at a particular point in space. (7.5), 268
Problem solving
acid-base problems, 560, 570
applying the VSEPR model, 339
balancing chemical equations, 93
calculating masses of reactants and products in chemical reactions, 98
conceptual, 80-81
dimensional analysis and, 18-22
empirical formula determination, 86
enthalpy calculations, 233
equilibrium, 531-536
half-reaction method, 152-153, 156
Hess's Law, 229
performing calculations for acid-base reactions, 141
pH curve for weak acid-strong base titration, 618
stoichiometry problem involving masses of reactants and products, 111
stoichiometry problems for reactions in solution, 139
systematic, 18
using the localized electron model, 364
weak acid equilibrium problems, 564
writing Lewis structures, 326
Product a substance resulting from a chemical reaction. It is shown to the right of the arrow in a chemical equation. (3.8) defined, 90
formed, determining mass of, 138-140 ion, 649
limiting reactant determined using quantities of formed, 106-107
physical states of, 91
solubility equilibria and solubility, 641-649
stoichiometric calculations, 95-100
Propane, 856
reaction with oxygen, 95-97
Propanoic acid, 614
Propene, 863
Protein a natural high-molecular-weight polymer formed by condensation reactions between amino acids. (22.6), 504-
505, 881-886, 887
denaturation, 886,887
molecular structure, 884-886
synthesis by DNA, 894
Proton a positively charged particle in an atomic nucleus. (2.5; 19), 46-47, 744745, 746
Aufbau principle, 278
binding energy, 759
nuclear fusion of, 765
radius of, 265
Proust, Joseph, 38
Pseudo-first-order rate law, 488
P-type semiconductors, 409
Pure substance a substance with constant composition. (1.10), 28, 30
Putrescine, 873
Pyrometallurgy recovery of a metal from its ore by treatment at high temperatures. (21.8), 845

Qualitative analysis, 654-655, 655
Quantization the concept that energy can occur only in discrete units called quanta. (7.2)
Quantized energy, 254
Quantum (wave) mechanical model, 267
Quantum mechanical model of the atom, 266-269
Quantum model, 262
Quantum numbers, 269-270
electron spin, 273
Quarks, 30
Quicklime
calcium carbonate decomposition into, 180, 520-521
gas stoichiometry and, 180
Quinine, 575
Quotient, reaction, 524-525

Racemic mixtures, 829
Rad a unit of radiation dosage corresponding to 1022 J of energy deposited per kilogram of tissue (from radiation absorbed dose). (19.7), 766
Radial probability distribution, 268
Radiation
denaturation of proteins, 886
effects of, 766-768
electromagnetic, 252-254
infrared, 239
linear model, 767-768
ozone and, 798
threshold exposure, 768
threshold model, 767-768
Radii, atomic, 289-291
Radioactive decay (radioactivity) the
spontaneous decomposition of a nucleus
to form a different nucleus. ( \(2.4 ; 19.1\) ),
744-748, 749
kinetics of, 749-751
types of, 746-747
Radioactivity, 44-45
dating by, 755-757
denaturation of proteins, 886
detection and uses of, 754-758
medical applications of, 757-758
Radiocarbon dating (carbon-14 dating) a method for dating ancient wood or cloth based on the rate of radioactive decay of the nuclide \({ }_{6}^{14} \mathrm{C}\). (19.4), 755-757
Radiotracer a radioactive nuclide, introduced into an organism for diagnostic purposes, whose pathway can be traced by monitoring its radioactivity. (19.4), 757-758
Radium, 284, 782
Rain, acid, 204
from coal burning, 239
Random-coil arrangement, 886
Random error an error that has an equal probability of being high or low. (1.4), 13
Raoult's law the vapor pressure of a solution is directly proportional to the mole fraction of solvent present. (11.4), 446-448
nonideal solutions and, 448-449
solutions containing two liquids and, 450
Rate constant the proportionality constant in the relationship between reaction rate and reactant concentrations. (12.2)
Rate-determining step the slowest step in a reaction mechanism, the one determining the overall rate. (12.5)
Rate law an expression that shows how the rate of reaction depends on the concentration of reactants. (12.2)
determining form of, 474-478
first-order, 479-481
integrated, 474, 478-489
introduction to, 472-474
method of initial rates, 475-477
pseudo-first-order, 488
for reactions with more than one reactant, 487-489
second-order, 483-486
types of, 473-474
zero-order, 486-487
Rate of decay the change in the number of radioactive nuclides in a sample per unit time. (19.2), 749
Rates, reaction, 468-472
constants, 473
order, 473
Reactant a starting substance in a chemical reaction. It appears to the left of the arrow in a chemical equation. (3.8)
defined, 90
half-life of first-order reactions and, 481-483
limiting, 100-110
physical states of, 91
stoichiometric calculations, 95-100
Reactions, chemical, 90-91. See also Com-
bustion; Enthalpy
acid-base, 130, 140-147
activation energy, 495-500, 500-506
of alkanes, 861-862
of alkenes and alkynes, 865-866

molecularity in, 490
with more than one reactant, integrated rate law for, 487-489
nonspontaneous, 688-689
oxidation-reduction, 130, 147-159
precipitation, 130, 131-136, 138-140
quotient, 524-525
rate laws, 472-489
rates, 468-472
second-order, 483-486
standard enthalpies of formation, 229-236
subcritical, 763
substitution, 861, 867
supercritical, 763
types of solution, 130
writing equations for, 137-138
zero-order, 486-487
Reaction mechanism the series of elementary steps involved in a chemical reaction. (12.5)
Reaction quotient, \(\boldsymbol{Q}\) a quotient obtained by applying the law of mass action to initial concentrations rather than to equilibrium concentrations. (13.5)
Reaction rate the change in concentration of a reactant or product per unit time. (12.1)

Reactor core the part of a nuclear reactor where the fission reaction takes place. (19.6), 764

Reactors
breeder, 765
nuclear, 764-765
Real gases, 198-201
characteristics of, 201-202
van der Waals curves, 427, 428
Red phosphorus, 795
Redox reactions. See Oxidation-reduction reactions
Reducing agent (electron donor) a reactant that donates electrons to another substance to reduce the oxidation state of one of its atoms. (4.9), 151
Reduction a decrease in oxidation state (a gain of electrons). (4.9)
Relative solubilities, 646
Rem a unit of radiation dosage that accounts for both the energy of the dose and its effectiveness in causing biological damage (from roentgen equivalent for man). (19.7), 767
Representative elements, 283, 773. See also Elements

group 8A, 52, 805, 806
survey of, 773-777
Repulsion, electrostatic, 462
Residual oil, 241

Resonance a condition occurring when more than one valid Lewis structure can be written for a particular molecule. The actual electronic structure is not represented by any one of the Lewis structures but by the average of all of them. (8.12), 333-337

Reverse osmosis the process occurring when the external pressure on a solution causes a net flow of solvent through a semipermeable membrane from the solution to the solvent. (11.6), 458, 459
Reverse reactions, 472-474
mechanisms with fast, 492-494
Reversible process a cyclic process carried out by a hypothetical pathway, which leaves the universe exactly the same as it was before the process. No real process is reversible. (17.10), 698
Rhombic sulfur, 799
Ribonucleic acid (RNA) a nucleotide polymer that transmits the genetic information stored in DNA to the ribosomes for protein synthesis. (22.6), 892-895, 896
messenger, 895,896
transfer, 895
Roasting a process of converting sulfide minerals to oxides by heating in air at temperatures below their melting points. (21.8), 151, 844

Rocks, 408
Root mean square velocity the square root of the average of the squares of the individual velocities of gas particles. (5.6), 194-196
Rounding, 16
Rubies, 835
Rutherford, Ernest, 45-46

\section*{S. See Entropy}

Salicylic acid, 221, 873
Salt an ionic compound. (14.8). See Ionic compounds/salts
Salt, table, 49
crystalline solid structure of, 396
physical change upon dissolving in water, 389
Salt bridge a U-tube containing an electrolyte that connects the two compartments of a galvanic cell, allowing ion flow without extensive mixing of the different solutions. (18.1), 705
Sapphire, 835
Saturated hydrocarbons. See Alkanes
Scandium, 816-817
Aufbau principle and, 280
Scanning tunneling microscope (STM), 3
Schoenbein, Christian, 874
Schrödinger, Erwin, 266

Scientific method the process of studying natural phenomena, involving observations, forming laws and theories, and testing of theories by experimentation. (1.2), 5-8

Scientific models, 6-8
Scintillation counter an instrument that measures radioactive decay by sensing the flashes of light produced in a substance by the radiation. (19.4), 755
Scrap iron, 849
Scrubbing, 204
Scuba diving tanks, 184-185
Scurvy, 442
Seawater, 28
Second ionization energy, 285
Second law of thermodynamics in any spontaneous process, there is always an increase in the entropy of the universe. (17.2), 671-672

Second-order rate laws, 483-486
half-life of second-order reactions, 483-486
Secondary structure (of a protein) the three-dimensional structure of the protein chain (for example, \(\alpha\)-helix, random coil, or pleated sheet). (22.6), 884
Selective precipitation a method of separating metal ions from an aqueous mixture by using a reagent whose anion forms a precipitate with only one or a few of the ions in the mixture. (16.2), 652-653
Selenium, 41-42, 797
Self-tanners, 889
Semiconductor a substance conducting only a slight electric current at room temperature, but showing increased conductivity at higher temperatures. (10.5), 408-410
Semimetals, 292
Semiochemicals, 346-347
Semipermeable membrane a membrane that allows solvent but not solute molecules to pass through. (11.6), 454-457
Shale, oil, 246
SI System International System of units based on the metric system and units derived from the metric system. (1.3), 8 , 10
Side chain (of amino acid) the hydrocarbon group on an amino acid represented by \(\mathrm{H}, \mathrm{CH} 3\), or a more complex substituent. (22.6), 882
Sigma ( \(\boldsymbol{\sigma}\) ) bond a covalent bond in which the electron pair is shared in an area centered on a line running between the atoms. (9.1), 358-359, 378
Sigma molecular orbitals, 367
Significant figures the certain digits and the first uncertain digit of a measurement. (1.4)
Significant figures and calculations, 14-17

Silica the fundamental silicon-oxygen compound, which has the empirical formula \(\mathrm{SiO}_{2}\), and forms the basis of quartz and certain types of sand. (10.5), 406, 774-775
Silicates salts that contain metal cations and polyatomic silicon-oxygen anions that are usually polymeric. (10.5), 406 ceramics from, 408
glass from, 406-407
Silicon, 42-43, 785
as network atomic solid, 403-410
number of atoms in microcomputer chip, 76
pi bonds, 774
in sand, 3
semiconductors, 408-410
Silver, 812
in complex ion solutions, 656-660, 661
corrosion, 732
density of solid, 399-400
half-reaction with cyanide ion, 157-158 plating, 735
Silver, Spencer F., 7
Silver chloride, 649
Silver chromate, 647
Silver nitrate
mass of product formed with sodium chloride, 138-139
precipitation reactions, 133-134
writing reaction equations for, 137-138
Silver phosphate, 649
Simple sugars, 887
Single bond a bond in which one pair of electrons is shared by two atoms. (8.8), 322
Sizes of ions, 312-314
Skeptical Chymist, The, 36
Slag, 847
Slaked lime, 571
Slippery pitcher plant, 876
Smart fluids, 392
Smelting a metallurgical process that involves reducing metal ions to the free metal. (21.8), 844
Smog, photochemical, 203
Sodium, 47
atoms, 47, 274
Aufbau principle and, 279
Sodium acetate, 603
Sodium azide, 186
Sodium chloride, 49
as binary ionic solid, 412-413
bonds, 301
concentration and volume, 126-127
electrolysis of, 736-737
formation, 294
freezing-point depression, 459-460
in isotonic solution with blood, 457, 458
mass of product formed with silver nitrate, 138-139
as strong electrolyte, 120
unit cell, number of ions in, 413-414

Sodium fluoride, 583
Sodium hydroxide
as base, 571
molarity of, 123-124
neutralization titration, 144-146
neutralization with hydrochloric acid, 142
pH of, 572, 604-605
reaction with hydrogen chloride, 141
in strong acid-strong base titration,
\[
615-617,618
\]
in weak acid-strong base titration, 618-623
Sodium lactate, 608
Sodium sulfate
constant-pressure calorimetry, 222-223
solution reactions, 139-140
vapor pressure of solution of, 448
Solar energy, 239
Solids, 384
amorphous, 393
changes of state, 419-422
crystalline, 393, 396-397
intermolecular forces, 385-390
ionic, 51, 396, 412-415
molecular, 396, 410-411, 412
network, 403-410
solubility product for, 642-643
solutions, 434
state of matter, 27-30
structure and bonding in metallic, 397-403
structures and types of, 393-397
types of, 414-415
unit cells, 393, 394
x-ray analysis of, 393-396
Solubility the amount of a substance that dissolves in a given volume of solvent at a given temperature. (4.1), 118
common ion effect and, 647-648
complex ions and, 658-660, 661
equilibria and solubility product, 641-649
factors affecting, 441-445
pH and, 648-649
precipitation and, 649-653
pressure effects on, 442-444
product, 642
product constant, 642
Raoult's law and, 446-449
relative, 646
structure effects on, 441-442
temperature effects on, 444-445
Solubility equilibrium, 641-649
involving complex ions, 656-660, 661
precipitation and qualitative analysis, 649-654, 655
Solubility product constant the constant for the equilibrium expression representing the dissolving of an ionic solid in water. (16.1)
Solute a substance dissolved in a liquid to form a solution. (4.2; 11.1), 119

Solution a homogeneous mixture. (1.10), 28, 117-119
acid-base reactions, 130, 140-147
of acids or bases containing common ion, 600-602
aqueous, 28, 117-119, 444-445, 445-450, 584, 678-679
boiling-point elevation, 451-452
buffered, 602-611
buffering capacity and, 611-614
colligative properties of electrolyte, 459-461
colloid, 461-463
composition of, 123-130, 434-437
describing reactions in, 136-138
dilution of, 128-130
electrical conductivity of, 119,120
electrolysis of, 730-731
energies of formation, 437-441
freezing-point depression, 452-454
isotonic, 457
molarity of, 123-130
nature of, 119-123
nonelectrolytes in, 119, 123
nonideal, 448-450
osmotic pressure and, 454-458, 459
oxidation-reduction reactions, 130, 147-159
pH of strong acid, 560-561
pH of weak acid, 562-570
pH scale for, 557-570
precipitation reactions, 130, 131-136, 138-140
qualitative analysis of, 654-655, 655
relative oxidizing abilities of, 731
salts that produce acidic, 584
salts that produce basic, 582-583, 582-584
salts that produce neutral, 582
stock, 128
stoichiometry of precipitation reactions, 138-140
strong electrolytes in, 119, 120-121
titrations, 144-147, 158-159
types of, 434
types of reactions, 130
van't Hoff factor, 459-460
vapor pressure of, 445-450
weak electrolytes in, 119, 121-123
Solvent the dissolving medium in a solu-
tion. (4.2), 119
properties, 440
water as common, 117-119
Somatic damage radioactive damage to an organism resulting in its sickness or death. (19.7), 766
Space-filling model a model of a molecule showing the relative sizes of the atoms and their relative orientations. (2.6), 49
Special theory of relativity, 258
Specific heat capacity the energy required to raise the temperature of one gram of a substance by one degree Celsius. (6.2), 220

Spectator ions ions present in solution that do not participate directly in a reaction. (4.6), 137

Spectrochemical series a listing of ligands in order based on their ability to produce \(d\)-orbital splitting. (21.6)
Spectroscopy, 392
photoelectron, 287-288
\(S p\) hybridization, 360-361, 831
\(S p^{2}\) hybridization, 358-359
\(S p^{3}\) hybridization, 355-357
Spin, electron, 273
Spinneret, 875
Splitting of the \(3 d\) orbital energies, 832-833
Spontaneity, 468, 716
entropy and, 665-671
free energy and, 675-678, 687
second law of thermodynamics and, 671-672
temperature effects on, 672-675
Spontaneous fission the spontaneous splitting of a heavy nuclide into two lighter nuclides. (19.1), 746
Spontaneous process a process that occurs without outside intervention. (17.1)
Sports drinks, 461
Square planar structure, 345
Stability, nuclear, 744-748, 749, 758-761
Stability constants, 656
Stahl, Georg, 37
Stainless steel, 727
Standard atmosphere a unit of pressure equal to 760 mm Hg . (5.1), 167
Standard enthalpy of formation the enthalpy change that accompanies the formation of one mole of a compound at 258C from its elements, with all substances in their standard states at that temperature. (6.4), 229-236
Standard free energy change the change in free energy that will occur for one unit of reaction if the reactants in their standard states are converted to products in their standard states. (17.7), 683-689
Standard free energy of formation the change in free energy that accompanies the formation of one mole of a substance from its constituent elements with all reactants and products in their standard states. (17.7), 686
Standard hydrogen electrode a platinum conductor in contact with \(1 M \mathrm{H}^{+}\)ions and bathed by hydrogen gas at one atmosphere. (18.2), 707
Standard reduction potential the potential of a half-reaction under standard state conditions, as measured against the potential of the standard hydrogen electrode. (18.2), 706-713 transition metals, 815
Standard solution a solution whose concentration is accurately known. (4.3)

Standard state a reference state for a specific substance defined according to a set of conventional definitions. (6.4), 230
Standard temperature and pressure (STP) the condition \(0^{\circ} \mathrm{C}\) and 1 atmosphere of pressure. (5.4), 179-180
Standing wave a stationary wave as on a string of a musical instrument; in the wave mechanical model, the electron in the hydrogen atom is considered to be a standing wave. (7.5), 266
Starch, 891-892
State
changes of, 419-422
function, 212
property, 212
standard, 230
State function (property) a property that is independent of the pathway. (6.1)
States (of matter) the three different forms in which matter can exist; solid, liquid, and gas. (1.10), 27-30
phase diagrams, 422-427, 428
Stationary phase, 29
Steam, reaction of carbon monoxide with, 512-513, 528-529
Steel
alloy, 403, 848
carbon, 848,849
cobalt in, 76-77
corrosion of, 726-727
heat treatment of, 849-850
high-carbon, 403
medium, 403
mild, 403
production, 848-849
stainless, 727
tempering, 850
vanadium, 817
zinc galvanizing, 727
Stereoisomerism isomerism in which all the bonds in the isomers are the same but the spatial arrangements of the atoms are different. (21.4), 826-830
Steric factor the factor (always less than 1) that reflects the fraction of collisions with orientations that can produce a chemical reaction. (12.6), 496
Stock solutions, 128
Stoichiometric mixtures, 102
Stoichiometric point, 144
Stoichiometric quantities quantities of reactants mixed in exactly the correct amounts so that all are used up at the same time. (3.10)
Stoichiometry
calculations, 95-100
chemical reactions, 90-91
conceptual problem solving, 80-81
counting by weighing, 69-70

Stoichiometry (continued)
determining formula of compound, 83-90
gas, 179-183
limiting reactants and, 100-110
meaning of chemical equation, 91,92
molar mass, 77-79
mole, 72-77
percent composition of compounds, 81-83
percent yield, 109-110
of precipitation reactions, 138-140
Strength, acid, 552-557
Strong acid an acid that completely dissociates to produce an \(\mathrm{H}^{+}\)ion and the conjugate base. (4.2; 14.2), 552
added to buffered solutions, 610-611, 612-613
pH of, 560-561
titrations with strong base, 615-617
titrations with weak bases, 627-629
Strong base a metal hydroxide salt that completely dissociates into its ions in water. (4.2; 14.6), 121, 571
titrations with strong acids, 615-617 titrations with weak acids, 618-627
Strong electrolyte a material that, when dissolved in water, gives a solution that conducts an electric current very efficiently. (4.2), 119, 120-121
Strong-field case, 833
Strontium, 781, 782
Structural formula the representation of a molecule in which the relative positions of the atoms are shown and the bonds are indicated by lines. (2.6), 48
Structural isomerism isomerism in which the isomers contain the same atoms but one or more bonds differ. (21.4; 22.1), 825-826
in alkanes, 857
Structure, atomic
alkali metals, 291-295
atomic spectrum of hydrogen and, 260-262
Bohr model, 262-265
effect on acid-base properties, 587-588
effects on solubility, 441-442
electromagnetic radiation and, 252-254
electron spin and the Pauli principle, 273
history of periodic table and, 276-277
nature of matter and, 254-260
orbital shapes and energies, 270-273
periodic trends in atomic properties and, 284-291
polyelectronic atoms, 274-275
quantum mechanical model of the atom, 266-269
quantum numbers, 269-270

Styrene, 881
Subcritical reaction (nuclear) a reaction in which less than one neutron causes another fission event and the process dies out. (19.6), 763
Sublimation the process by which a substance goes directly from the solid to the gaseous state without passing through the liquid state. (10.8)
Subshell a set of orbitals with a given azimuthal quantum number. (7.6), 269, 270
Substitutional alloys, 401
Substitution reaction (hydrocarbons) a reaction in which an atom, usually a halogen, replaces a hydrogen atom in a hydrocarbon. (22.1), 861, 867
Sucrose, 396, 891
Sugar. See Glucose
Sulfides
insoluble in basic solution, 654-655
insoluble in acid solution, 654-655
Sulfur
chemistry of, 799-801
electron configuration, 283
first ionization energy, 287
gas-phase reaction between methane and
diatomic, 499-500
oxides, 800
oxyacids, 800-801
rhombic, 799
Sulfur dioxide, 800
Boyle's law and, 169-170
from coal burning, 238-239
pollution and, 203-204, 501
VSEPR model, 346
Sulfur hexafluoride, 149
\(d^{2} \mathrm{sp}^{3}\) hybridization, 363
octet rule and, 330
Sulfuric acid, 801
dilution of, 129-130
dipole moment, 309
in pollution, 204, 501
as polyprotic acid, 576, 579-581
solubility in water, 121
as strong acid, 553
Sulfurous acid, 800
Sulfur trioxide, 501, 800, 801
Supercooled liquids, 421
Supercooling the process of cooling a liquid below its freezing point without its changing to a solid. (10.8)
Supercritical reaction (nuclear) a reaction in which more than one neutron from each fission event causes another fission event. The process rapidly escalates to a violent explosion. (19.6), 763
Superheated liquids, 421-422
Superheating the process of heating a liquid above its boiling point without its boiling. (10.8)

Surface tension the resistance of a liquid to an increase in its surface area. (10.2), 390
Surroundings everything in the universe surrounding a thermodynamic system. (6.1), 214

Suspensions, colloid, 461-462
Syndiotactic chain a polymer chain in which the substituent groups such as CH 3 are arranged on alternate sides of the chain. (22.5), 880
Syngas synthetic gas, a mixture of carbon monoxide and hydrogen, obtained by coal gasification. (6.6), 240-241
Synthesis gas, 240-241
System (thermodynamic) that part of the universe on which attention is to be focused. (6.1), 214
Systematic error an error that always occurs in the same direction. (1.4), 13

Table salt, 49
Tantalum, 816
Technetium-99m, 750, 758
Teeth, 645
Teflon, 828, 876
Temperature, 22-26. See also Heat
catalysis and, 500-506
celsius scale, 22-26, 171
changes of state due to, 419-422
critical, 424
dependence of equilibrium constant, 696-697
earth's surface, 239-240
effects on solubility, 444-445
effects on spontaneity, 672-675
equilibrium effect of change in, 541-542
in free energy and spontaneity, 675-678
heating curve, 419-420
ideal gas law and, 173-178
as intensive property, 222
Kelvin scale, 22-26, 171, 194
kinetic molecular theory of gases and, 191, 194
phase diagrams, 422-427, 428
real gases and, 198-201
Tempering a process in steel production that fine-tunes the proportions of carbon crystals and cementite by heating to intermediate temperatures followed by rapid cooling. (21.8), 850
Tension, surface, 390
Termolecular step a reaction involving the simultaneous collision of three molecules. (12.5), 490
Tertiary structure (of a protein) the overall shape of a protein, long and narrow or globular, maintained by different types of intramolecular interactions. (22.6), 886

Tetraethyl lead, 238
Tetrahedral holes in ionic solids, 412
Tetrahedral structure, 339
Tetraphosphorus decoxide, 796
Thallium-201, 758
Theoretical yield the maximum amount of a given product that can be formed when the limiting reactant is completely consumed. (3.11), 108-109
Theory a set of assumptions put forth to explain some aspect of the observed behavior of matter. (1.2), 6
Theory of relativity, 255, 759
Thermal pollution the oxygen-depleting
effect on lakes and rivers of using water for industrial cooling and returning it to its natural source at a higher temperature. (11.3), 444
Thermite reaction, 235
Thermochemistry
calorimetry, 220-225
enthalpy, 218-220
Hess's law, 225-229
nature of energy, 211-218
new energy sources and, 240-247
present sources of energy, 236-240
standard enthalpies of formation, 229-236
Thermodynamic stability (nuclear) the potential energy of a particular nucleus as compared to the sum of the potential energies of its component protons and neutrons. (19.1), 744
Thermodynamics the study of energy and its interconversions. (6.1), 215
first law of, 215, 665
second law of, 671-672
spontaneity and entropy in, 665-671
stability of the nucleus, 758-761
Thermogenic plants, 221
Thermoplastic polymer a substance that when molded to a certain shape under appropriate conditions can later be remelted. (22.5), 874
Thermoset polymer a substance that when molded to a certain shape under pressure and high temperatures cannot be softened again or dissolved. (22.5), 874
Thin layer chromatography (TLC), 441
Third law of thermodynamics the entropy of a perfect crystal at 0 K is zero. (17.6), 680
Thomson, J. J., 43-44, 45
3M Corporation, 7
Threshold exposure, 768
Thyroid gland, 758
Tin, 785
brittle, 785
disease, 785
gray, 785
half-reaction with cerium, 152
white, 785
Tires, rubber, 875-876
Titanium, 817
Aufbau principle and, 280
Titanium oxide, 817, 818
Titration a technique in which one solution is used to analyze another. (4.8)
acid-base, 144-147
oxidation-reduction, 158-159
pH curves and, 615-629
polyprotic acid, 634-635
strong acid-strong base, 615-617, 618
weak acids with strong bases, 618-627
weak bases with strong acids, 627-629
Torr another name for millimeter of mercury ( mm Hg ). (5.1), 167
Trailing zeros, 14
Transfer RNA (tRNA) a small RNA fragment that finds specific amino acids and attaches them to the protein chain as dictated by the codons in mRNA. (22.6), 895
Transformations, nuclear, 752-754
Transition metals several series of elements in which inner orbitals ( \(d\) or \(f\) orbitals) are being filled. (7.11; 20.1), 280, 773, 811. See also Metals
coordination compounds, 821-825
coordination numbers, 821
d-block, 811
\(4 d\) and \(5 d\) transition series, 816
electron configurations, 813-814, 815
first-row, 813, 816-820
gem colors and, 835
general properties, 811-813
isomerism, 825-830
ligands, 822-823
oxidation states and ionization energies, 815, 821
standard reduction potentials, 815
Transition state, 495
Transuranium elements the elements beyond uranium that are made artificially by particle bombardment. (19.3), 754
Triads, 276
Trigonal bipyramid structure, 342
Trigonal holes in ionic solids, 412
Trigonal planar structure, 338
Triiodide ion, 363
Tripeptides, 884
Triple bond a bond in which three pairs of electrons are shared by two atoms. (8.8), 322
Triple point the point on a phase diagram at which all three states of a substance are present. (10.9), 423-424, 425
Triprotic acids, 577
Tungsten, 812
Tyndall effect the scattering of light by particles in a suspension. (11.8), 461

Unbranched hydrocarbons, 856
Uncertain digits, 12
Uncertainty (in measurement) the characteristic that any measurement involves estimates and cannot be exactly reproduced. (1.4), 11-14
Uncertainty principle, 267
Unidentate ligands, 822
Unimolecular step a reaction step involving only one molecule. (12.5), 490
Unit cell the smallest repeating unit of a lattice. (10.3)
Unit cells of solids, 393, 394
Unit(s)
conversions, 18-22, 24-26, 167
dimensional analysis, 18-22
factor method, 18-22
of measurement, 8-11
of pressure, 166-167
Universal gas constant the combined proportionality constant in the ideal gas law; \(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}\) or \(8.3145 \mathrm{~J} / \mathrm{K} \cdot\) mol. (5.3), 174
Unsaturated hydrocarbons, 855
Uranium, 748, 749
breeder reactors, 765
nuclear fission, 762-764
Uranium hexafluoride, 197
Urea, 855
Valence electrons the electrons in the outermost principal quantum level of an atom. (7.11), 280-282
in alkali metals, 294
formal charge, 334-337
Valence shell electron-pair repulsion (VSEPR) model a model whose main postulate is that the structure around a given atom in a molecule is determined principally by minimizing electron-pair repulsions. (8.13)
Vanadium, 817
Aufbau principle and, 280
Van der Waals curves, 427, 428
Van der Waals equation a mathematical expression for describing the behavior of real gases. (5.8)
Van der Waals forces, 199-201
Vanillin, 872
van't Hoff factor the ratio of moles of particles in solution to moles of solute dissolved. (11.7), 459-460
Vaporization, 415
enthalpy of, 415, 418
heat of, 415,419
Vapor pressure the pressure of the vapor over a liquid at equilibrium. (10.8), 415-419 calculation of, 419 changes of state and, 419-422

Vapor pressure (continued)
of nonideal solutions, 448-450
phase diagrams, 422-427, 428
Raoult's law and, 446-450
sodium sulfate, 448
of solution containing two liquids, 450
of solutions, 445-450
sugar solution, 447-448
triple point, 423-424
Vaporization (evaporization) the change
in state that occurs when a liquid evapo-
rates to form a gas. (10.8)
Vegetable oils, 780
Venom, snake, 293
Vinegar, 121-122
Viscosity the resistance of a liquid to flow. (10.2), 391

Vitamins, 441-442
Volatile liquids, 416
Volt the unit of electrical potential defined as one joule of work per coulomb of charge transferred. (18.1), 705
Voltmeter an instrument that measures cell potential by drawing electric current through a known resistance. (18.1)
Voltmeters, 706
Volume, 9-10
concentration and, 126-127
constant-volume calorimetry, 223-225
in density measurement, 26-27
ideal gas law and, 173-178
kinetic molecular theory of gases and, 191, 192
real gases and, 198-201
Volumetric analysis a process involving titration of one solution with another. (4.8), 144

Volumetric flasks, 129
Von Beethoven, Ludwig, 786
Voodoo lily, 221
VSEPR (valence shell electron-pair repulsion) model, 337-350
complex ions and, 830-831
in molecules containing no single central atom, 349
multiple bonds and, 346-348
phosphorus pentachloride, 343-344
water, 340-342
xenon tetrafluoride, 344-345
Vulcanization a process in which sulfur is added to rubber and the mixture is heated, causing crosslinking of the polymer chains and thus adding strength to the rubber. (22.5), 876

Waage, Peter, 514
Water. See also Aqueous solutions ammonia combustion and standard enthalpies of formation of, 233-234 as amphoteric substance, 555
as an acid and a base, 555-557
in the atmosphere, 239
autoionization of, 555-557
boiling point, 425
bond angles, 341
calculating vapor pressure of, 419
as common solvent, 117-119
compared to sports drinks, 461
desalination of seawater into drinking, 458, 459
dissolving carbon dioxide in, 444-445
electrolysis of, 730, 779
enthalpy of vaporization, 418
gas collection over, 187-189
hard, 782
heating curve, 419,420
heat of vaporization of, 419
Lewis structure, 327, 340
molecule, 4-5
phase diagram for, 424-425
physical changes with boiling of, 389
as polar molecule, 117, 391
reaction with carbon monoxide, 512-513
supercooled, 421
uncertainty in measurement of, 12
valence electrons, 327
VSEPR model, 340-342
Water-soluble vitamins, 441-442
Wave function a function of the coordinates of an electron's position in threedimensional space that describes the properties of the electron. (7.5), 266-267
physical meaning of, 267-269
quantum numbers, 269-270
Wave mechanical model a model for the hydrogen atom in which the electron is assumed to behave as a standing wave. (7.5)

Wavelength the distance between two consecutive peaks or troughs in a wave.
(7.1), 252

Bragg equation, 395-396
calculations of, 259
x-ray diffraction, 393-396
Waves, electromagnetic, 252-254
diffraction pattern, 259-260
standing waves, 266
Weak acid an acid that dissociates only slightly in aqueous solution. \((4.2 ; 14.2)\), 123, 552
percent dissociation, 567-570
pH of, 562-570
pH of mixture of, 565-567
salts as, 584-586
titrations with strong bases, 618-627
Weak base a base that reacts with water to produce hydroxide ions to only a slight extent in aqueous solution. (4.2; 14.6), 123 ammonia as, 123, 572-574
methylamine as, 576
salts as, 583
titrations with strong acids, 627-629
Weak electrolyte a material that, when dis-
solved in water, gives a solution that
conducts only a small electric current.
(4.2), 119, 121-123

Weak-field case, 833
Weight the force exerted on an object by gravity. (1.3), 11
atomic, 40
counting by, 69-70
percent, 82
White phosphorus, 795
White tin, 785
Whole-number ratio of atoms, 85
Wind power, 242
Wine, 28
Wood alcohol, 869. See also Methanol
Work force acting over a distance. (6.1)
definition of, 212
free energy and, 697-698
gas expansion, 217
internal energy and, 216-217
Xenon, 805
Xenon tetrafluoride, 344-345
Lewis structure, 363
Xenon trioxide, 337
X-ray analysis of solids, 393-396
X-ray diffraction a technique for establishing the structure of crystalline solids by directing \(X\) rays of a single wavelength at a crystal and obtaining a diffraction pattern from which interatomic spaces can be determined. (10.3)

Yellow topaz, 835

Zero-order rate laws, 486-487
Zeros, 14-15
Zinc, 820
anodes, 707-708
Aufbau principle and, 281
electrorefining, 734
galvanizing, 727
Zirconium, 816
Zirconium oxide, 816
Zone of nuclear stability the area encompassing the stable nuclides on a plot of their positions as a function of the number of protons and the number of neutrons in the nucleus. (19.1), 745, 747
Zone refining a metallurgical process for obtaining a highly pure metal that depends on continuously melting the impure material and recrystallizing the pure metal. (21.8), 844-845

\section*{Page Numbers of Some Important Tables}
\begin{tabular}{|ll|}
\hline Bond Energies & 323 \\
Electron Configurations of the Elements & 281 \\
lonization Constants of Acids and Bases & \(554,573,577\), A24 \\
Reduction Potentials & 709, A26 \\
Solubility Products & 643, A25 \\

[^0]:    GURE 13.1 A molecular reperesentation of the reaction 2NOOX $(9) \rightarrow$ N:O.( $(9)$

[^1]:    __ New ChemWork end-of-chapter problems are now included, with many additional problems available to assign online for more practice.

[^2]:    *Democritus is an alternate spelling.

[^3]:     something about the stable ions formed by many atoms. For example, the atoms in column 1 always form 1+ ions. The transition metals, however, can form more than one type of stable ion. What if each transition metal ion had only one possible charge? How would the naming of compounds be different?

[^4]:    Polyatomic ion formulas must be memorized.

[^5]:    4.10 Balancing Oxidation-Reduction Equations
    The Half-Reaction Method of Balancing Oxidation-Reduction Reactions in Aqueous Solutions
    4.11 Simple Oxidation-Reduction
    Titrations

[^6]:    To begin, focus on the ions in solution before any reaction occurs.

[^7]:    *This reaction is very slow unless solid particles are present. See Chapter 12 for a discussion.

[^8]:    Energy is a state function; work and heat are not.

[^9]:    If two reactants at the same temperature are mixed and the resulting solution gets warmer, this means the reaction taking place is exothermic. An endothermic reaction cools the solution.

[^10]:    Coal has variable composition depending on both its age and location.

[^11]:    Wavelength, $\lambda$, and frequency, $\nu$, are inversely related.
    $c=$ speed of light
    $=2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}$

[^12]:    *After this example we will no longer show cancellation marks. However, the same process for canceling units applies throughout this text.

[^13]:    The sign convention for electron affinity values follows the convention for energy changes used in Chapter 6.

[^14]:    *In a sense this approach corrects for the fact that the localized electron model overemphasizes that a molecule is simply a sum of its parts-that is, that the atoms retain their individual identities in the molecule.

[^15]:    *We will assume that minimizing electron repulsions also is important for the peripheral atoms in a molecule and apply the VSEPR model to these atoms as well.

[^16]:    Malleable: can be pounded into thin sheets.

[^17]:    The bonding in the $\mathrm{CO}_{2}$ molecule was described in Section 9.1.

[^18]:    Printed circuits are discussed in the Chemical Connections feature on the student website.

[^19]:    Closest packed structures contain twice as many tetrahedral holes as packed spheres. Closest packed structures contain the same number of octahedral holes as packed spheres.

[^20]:    Ionic solids such as NaCl and NaF have very high melting points and enthalpies of fusion because of the strong ionic forces in these solids. At the other extreme is $\mathrm{O}_{2}(s)$, a molecular solid containing nonpolar molecules with weak intermolecular forces. (See Table 10.10.)

[^21]:    *The physics of ice skating is quite complex, and there is disagreement about whether the pressure or the frictional heating of the ice skate is most important. See "Letter to the Editor," by R. Silberman, J. Chem. Educ. 65 (1988): 186.

[^22]:    *In Morocco, a 50-km-long slab called Beni Bousera contains chunks of graphite that were probably once diamonds formed in the deposit when it was buried 150 km underground. As this slab slowly rose to the surface over millions of years, the very slow reaction changing diamond to graphite had time to occur. On the other hand, in the diamond-rich kimberlite deposits in South Africa, which rise to the surface much faster, the diamonds have not had sufficient time to revert to graphite.

[^23]:    *For more information see R. S. Treptow, "Le Châtelier's Principle Applied to the Temperature Dependence of Solubility," J. Chem. Educ. 61 (1984): 499.
    ${ }^{\dagger}$ The opposite behavior is observed for most nonaqueous solvents.

[^24]:    *Lattice energy was defined in Chapter 8 as the energy change for the process $\mathrm{M}^{+}(\mathrm{g})+\mathrm{X}^{-}(\mathrm{g}) \rightarrow \mathrm{MX}(s)$.

[^25]:    The value of the initial rate is determined for each experiment at the same value of $t$ as close to $t=0$ as possible.

[^26]:    *In the Questions and the Exercises, the term rate law always refers to the differential rate law.

[^27]:    A double arrow $(\rightleftharpoons)$ is used to show that a reaction can occur in either direction.

[^28]:    Molecules with strong bonds produce large activation energies and tend to react slowly at $25^{\circ} \mathrm{C}$.

[^29]:    *Each experiment was begun with a 3:1 mixture of $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$.

[^30]:    *The hydronium ion is actually a more complicated species than $\mathrm{H}_{3} \mathrm{O}^{+}$. See "The Solvated Proton Is NOT $\mathrm{H}_{3} \mathrm{O}^{+}$!" (J. Chem. Educ., 2011, 88(7), p 875).

[^31]:    A table of $K_{b}$ values for bases is also given in Appendix 5.3.

[^32]:    *The $K_{\mathrm{a}_{2}}$ value for $\mathrm{H}_{2} \mathrm{~S}$ is very uncertain. Because it is so small, the $K_{\mathrm{a}_{2}}$ value is very difficult to measure accurately.
